The ability of the central nervous system (CNS) to maintain immune privilege is well known, but poorly understood. Data from multiple sclerosis (MS) and its animal model, experimental autoimmune encephalomyelitis (EAE), suggests that the cervical lymph nodes (CxLNs) may participate in this process by receiving direct input from the CNS. We therefore wished to ascertain whether there was significant immune cellular traffic from the CNS to the CxLNs. Using dual label IHC, dendritic cells (DCs) were more numerous throughout the rostral migratory stream (RMS), a pathway of neural stem cell migration. Further, DCs migrated from the RMS to the CxLNs in a Fingolimod sensitive manner. Fingolimod.treatment led to selective accumulation of DCs in the RMS and more severe MOG induced EAE. The same treatment of 2D2, MOG T-cell transgenic, but EAE resistant mice, triggered spontaneous EAE with accumulation of CNS antigen specific T-cells in the spinal cord. In these 2D2 mice, spinal cord T-cell infiltration was proportional to the ratio of anti-inflammatory T-regulatory to pro-inflammatory T-effector cells in their CxLNs. Further, RMS Fingolimod treatment compromised CxLN-T-regulatory function suggesting DCs mediated this change. Using a delayed type hypersensitivity model, we demonstrated that the same treatment leads to fewer regulatory DCs in CxLNs. Finally, we show that a CNS DC subset significantly reduce anti-CNS immune responses in the CxLN by modulating T-regulatory activity. Combined, these data suggest that DCs migrate from the CNS to the CxLNs and regulate anti-CNS immunity representing a novel target for the treatment of CNS autoinflammatory disease.

P5.09.51
Immunomodulatory effects of Interleukin-27 on active experimental autoimmune encephalomyelitis

***M. S. Mojadadi Mehrabadi**[1], M. Ebtekar[2], M. Golkar[3], H. Khan Ahmad[4];*
[1]Department of Microbiology and Immunology, faculty of Medicine, Sabzevar University of Medical Sciences, Sabzevar, Iran, [2]Immunology, Faculty of Medical Sciences, Tarbiat Modares University, Tehran, Iran, [3]Molecular Parasitology Laboratory, Department of Parasitology, Pasteur Institute of Iran, Tehran, Iran, [4]of Anatomical Science and Genetics, Faculty of Medicine, Isfahan University of Medical Science, Isfahan, Iran.

Interleukin-27 (IL-27), a member of IL-12 cytokine family, has a pleiotropic role in immune responses. IL-27 is known as an inducer of Th1 responses. Several recent studies, however, have reported that this cytokine also has immunosuppressive properties. On the basis of these reports, this study was designed to investigate the immunomodulatory effects of IL-27 on active experimental autoimmune encephalomyelitis (EAE), a murine model of inflammatory demyelinating disease of human multiple sclerosis. 100 microgram of IL-27 coding plasmid (P240-mIL27) or vehicle was injected two times to experimental and control mice at days 15 and 22 post EAE induction, respectively. The results showed that P240-mIL27 markedly suppressed the disease severity and demyelination in association with decreased levels of both IFN-γ and IL-17 in the MOG35-55-induced EAE mice. In contrast, the level of IL-4 and IL-10 increased in experimental group; when compared with control EAE mice. Also the number of both CD4+Foxp3+ and CD4+IL-10+ regulatory T cells significantly increased in EAE mice treated with IL-27. Collectively, these results suggest that IL-27 may be considered as a suitable candidate for the treatment of inflammatory diseases such as MS.

Synaptic deficits in sepsis: Role of glial cells

C. A. Moraes[1], *G. Santos*[2], *J. D'Avila*[1], *P. Perdigao*[1], *C. Benjamin*[2], *F. Bozza*[3], *F. Gomes*[2];
[1]*Instituto Oswaldo Cruz, Rio de Janeiro, Brazil,* [2]*Universidade Federal Rio de Janiero, Rio de Janeiro, Brazil,* [3]*Instituto de Pesquisa Clinica Evandro Chagas IPEC, Rio de Janeiro, Brazil.*

Recent clinical studies have shown that sepsis survivors can develop long-term cognitive impairment. The cellular and molecular mechanisms involved in these events are not yet completely understood. In this study, we investigate the synaptic deficits in sepsis and the involvement of glial cells in this process. Using a clinically relevant model of sepsis (Cecal ligation and puncture/CLP), we observed a memory deficit in the septic animals 9 days after sepsis induction. At the same time, we observed a reduction in structural synapses in hippocampus and cerebral cortex, identified by synaptophysin and PSD-95 co-localization. To define the molecular mechanisms accountable for synaptic loss in sepsis, we used an in vitro approach treating neuronal cultures with conditioned medium from astrocyte (ACM) and microglial (MCM) cultures stimulated with LPS. We observed that the MCM reduced the synapse number and the ACM increased the number of synapsis. Analysis of conditioned medium composition, showed that MCM had increased levels of IL-1β while the ACM had increased levels of TGF-β1, as compared to medium from the non LPS-stimulated cultures. The addition of soluble IL-1β receptor (IL-1 Ra) to the neuronal culture prevented the MCM-induced synapsis loss. Patch-clamp recordings in the MCM- treated neurons showed a reduction in postsynaptic current frequency, while an increase in current amplitudes, suggests a functional synaptic deficit. These findings show, for the first time, a correlation between synaptic deficits and memory dysfunction, suggesting a possible mechanism for cognitive impairment after sepsis as well as a glial-derived molecule mediating synapse reduction.

P5.09.53
Day and Night Alterations of serum melatonin, MIP-1α, MCP-1 and IL-17A levels in multiple sclerosis

U. Musabak*, G. Genc, S. Demirkaya, R. S. Ilikci, O. Kartal, M. Gulec, O. Sener;*
Gulhane Military Medical Academy, Etlik, Turkey.

Backround and aims: Multiple sclerosis (MS) is a T cell-mediated autoimmune disease of the human central nervous system (CNS). The pineal hormone melatonin plays a crucial role in immunomodulation, mainly by effecting T cells. The aim of this study was to determine whether serum melatonin concentrations are associated with MS and serum macrophage inflammatory protein 1 alpha (MIP-1), monocyte chemoattractant protein-1 (MCP-1) and interleukin-17A levels.
Materials and methods: Seven patients (4 male, 3 female) newly diagnosed with MS were enrolled into the study. Venous blood samples were drawn from the patients with MS at 03.30 am and 10.00 am for determining the levels of melatonin, MIP-1, MCP-1 and interleukin-17A. Enzyme-linked immunosorbent assay (ELISA) method was used for this purpose.
Results: Serum melatonin and MIP-1 levels at 03.30 am in patients with MS were significantly higher than those serum levels measured at 10.00 am in same patients. In addition, there was a positive correlation between serum MIP-1 and IL-17A levels at 10.00 am.
Conclusion: Although no correlation was found between serum melatonin and MIP-1 levels in patients with MS, simultaneous decline or increase in their serum levels supports their possible role in the pathogenesis of MS through common mechanism.

P5.09.54
Identifying Biomarkers Associated with Pain in Swine using an In Vitro Inflammation Model

C. M. Deaver, E. Kenyon, S. M. Peters, M. Prescott, H. L. Swaim, K. Tanke, H. F. Yancy, ***M. J. Myers****;*
US Food and Drug Administration, Laurel, MD, United States.

This study sought to determine if biomarkers associated with pain could be measured in an *in vitro* model of inflammation. Success would constitute the first step towards using these biomarkers as surrogate endpoints to help support effectiveness indications for investigational new animal drugs to control pain in swine. Porcine whole blood samples were cultured *in vitro* with *E. coli* lipopolysaccharide (LPS) or without LPS for up to 48 hr. Supernatant from these cultures was collected to determine protein levels. Messenger RNA was also obtained from these cells and quantitative reverse transcription-PCR was used to determine if mRNA levels of genes associated with pain were altered in response to LPS-induced inflammation. Bradykinin protein levels steadily increased over time due to LPS stimulation and returned to 0 hr levels after 6 hr of culture. Corticotrophin-releasing factor protein levels were not affect by LPS. Substance-P protein levels steadily increased over time and returned to 0 hr levels after 4 hr LPS stimulation. Genomically, Chemokine Receptor 4 and Bradykinin Receptor 1 had a 3-fold fold increase at 6 hr after LPS stimulation. Cyclin-Dependent Kinase Inhibitor 1A showed a 4 fold increase at 6 hr and 24 hr after LPS stimulation. An additional 17 genes associated with pain showed no alteration in mRNA levels in this model. These results suggest that 5 biomarkers (2 protein and 3 genomic) may be useful as surrogate endpoints for evaluation of pain. These need to be evaluated *in vivo* to support their usefulness as biomarkers of pain in swine.

P5.09.55
Dopamine receptor D3 expressed on CD4+ T-cells favours neurodegeneration of dopaminergic neurons during Parkinson's disease

R. Pacheco[1,2], *H. González*[1,3], *F. Contreras*[1,3], *C. Prado*[1,3], *D. Elgueta*[1], *D. Franz*[1];
[1]*Fundación Ciencia y Vida, Santiago, Chile,* [2]*Universidad San Sebastián, Santiago, Chile,* [3]*Universidad Andrés Bello, Santiago, Chile.*

Emerging evidence has demonstrated that CD4+ T-cells infiltrate into the substantia nigra (SN) in Parkinson's disease (PD) patients and in animal models of PD. SN-infiltrated CD4+ T-cells bearing inflammatory phenotypes promote microglial activation and strongly contribute to neurodegeneration of dopaminergic neurons. Importantly, altered expression of dopamine receptor D3 (D3R) in peripheral blood lymphocytes from PD patients has been correlated with disease severity. Moreover, pharmacological evidence has suggested that D3R is involved in IFN-gamma production by human CD4+ T-cells. Here, we studied the role of D3R expressed on CD4+ T-cells in neurodegeneration of dopaminergic neurons in the SN using a mouse-model of PD. Our results show that D3R-deficient mice are strongly protected against loss of dopaminergic neurons and microglial activation during 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP)-induced PD. Notably, D3R-deficient mice become susceptible to MPTP-induced neurodegeneration and microglial activation upon transfer of wild-type (WT) CD4+ T-cells. Furthermore, RAG1 knockout mice, which are devoid of T-cells and are resistant to MPTP-induced neurodegeneration, become susceptible to MPTP-induced loss of dopaminergic neurons when reconstituted with WT CD4+ T-cells but not when transferred with D3R-deficient CD4+ T-cells. In agreement, experiments analyzing activation and differentiation of CD4+ T-cells revealed that D3R favours both T-cell activation and acquisition of the Th1 inflammatory phenotype. These findings indicate that D3R expressed on CD4+ T-cells plays a fundamental role in the physiopathology of MPTP-induced PD in a mouse model.

P5.09.56
Clinical cases of immune-mediated partial epilepsy

***T. Pertseva**;*
State Institute of Neurology, Psychiatry and Narcology, Kharkiv, Ukraine.

Antibody-mediated pathogenicity has been implicated as immune pathophysiological mechanisms in some epilepsy. The aim of work was to identify best means of immune-mediated seizures by clinical and immunological methods.
Results: 12 patients with partial epilepsy, PE (24-38 ears; mean epilepsy duration: 11.45±8.64 years) and 16 controls were investigated. The etiology was neuron-infection (8 cases) and history of immunization had 4 women. Analysis of immune status showed IgG - 14.65±3.41 mg/ml; IgM - 1.29±0.30 mg/ml; circulating immune complexes < 0.085; and in 8 women the presence of serum specific IgE and lymphocytotoxic autoantibodies, % - 19.3±5.4. All patients have long-standing intractable epilepsy with chronic pharmaco-resistant course, high seizure frequency associated with cognitive decline and behavioral and psychiatric problems and in anamnesis of group the first manifestation of PE was occurred as convulsive status epilepticus - 5 patients (41.6%). Four women (33.3%) were highlighted; their epilepsy was associated with being given diphtheria pertussis tetanus (DPT) vaccine. Now they have intractable PE with onset in early childhood, chronic pharmaco-resistant course, normal CT brain scans and epileptic abnormalities on EEG, predominantly left sided focus mainly at occipital, temporal and central lobes.
Conclusion: The results presented showed women with a subtype of encephalitis who might have had their condition precipitated by DPT-vaccination. Further studies are needed to determine exactly which kinds of seizures are immune-mediated, and whether immune system can guide clinical treatment, or play a direct role in epileptogenesis.

P5.09.57
NMR Metabolomics: a Diagnostic Tool for Multiple Sclerosis

*T. Gebregiworgis[1], C. Massilamany[1], A. Gangaplara[1], H. Nielssen[2], M. Werth[1,3], D. Steffen[1], R. Zabad[4], Z. Illes[5,2], R. Powers[1], **J. Reddy**[1];*
[1]University of Nebraska-Lincoln, Lincoln, NE, United States, [2]University of Southern Denmark, Odense, Denmark, [3]Nebraska Wesleyan University, Lincoln, NE, United States, [4]University of Nebraska Medical Center, Omaha, NE, United States, [5]University of Pecs, Pecs, Hungary.

A definitive diagnostic test for multiple sclerosis (MS) does not exist; instead physicians use a combination of medical history, magnetic resonance imaging, and cerebrospinal fluid analysis (CSF). Significant effort has been employed to identify biomarkers from CSF to facilitate MS diagnosis; however none of the proposed biomarkers have been successful to date. Urine is a proven source of metabolite biomarkers and has the potential to be a rapid, non-invasive, inexpensive, and efficient diagnostic tool for various human diseases. Nevertheless, urinary metabolites have not been extensively explored as a source of biomarkers for MS. Instead, we demonstrate that urinary metabolites have significant promise for monitoring disease-progression, and response to treatment in MS patients. NMR analysis of urine permitted the identification of metabolites that differentiate experimental autoimmune encephalomyelitis (EAE)-mice (disease model for MS), and healthy and EAE-mice treated with fingolimod, a drug recently approved for MS therapy. The potential metabolites include hippurate, fructose, citrate, oxoglutaric acid, taurine and urea. MS is the most common neurological disorder among young adults; and is also a complex disease with multiple manifestations and heterogeneity in its phenotypic expression. Correspondingly, properly diagnosing the disease is challenging and fraught with error. Thus, our proposed development of a non-invasive, rapid, and simple diagnostic tool based on the NMR analysis of urine metabolites has an extraordinary potential to benefit the health and well-being of MS patients.

P5.09.58
Influence of LRRK2 G2019 mutation on peripheral B cells from Parkinson's disease patients

***G. R. Rossi**[1,2], M. Kubo[3], M. Gonçalves[2], P. Rodrigues-Santos[2], C. Januário[2,4], F. Obata[3], R. de Carvalho[2,5], M. Souto-Carneiro[2];*
[1]Universidade Federal do Paraná, Curitiba, Brazil, [2]Center for Neuroscience and Cell Biology, University of Coimbra, Coimbra, Portugal, [3]Department of Immunology, School Health Sciences, Kitasato University, Sagamihara, Japan, [4]Department of Neurology, Coimbra University Hospital, Coimbra, Portugal, [5]Faculty of Sciences, University of Coimbra, Coimbra, Portugal.

Mutations in the Leucine Rich Repeat Kinase 2 (LRRK2) gene are associated with the risk of developing Parkinson´s disease (PD). Existing studies show that metabolism of leucocytes of PD and LRRK2-mutant PD patients are different than controls (PMID:19847307), and that B cells on PD patient's blood are decreased (PMID:22910543). However, little is known about how PD and LRRK2-mutations impact on B cells function. Therefore, we collected venous blood from age-matched controls, PD and LRRK2-mutant PD patients. Functional FACS-phenotyping of blood B cells was carried out. Total B cells were isolated by magnetic-beads, and B cell subsets were obtained by cell-sorting. The expression levels of MAPK6 and p38 proteins were evaluated by western-blot for total B cells, and LRRK2 in the B cell subsets. The supernatant of cultured B cells in U13C-glucose-rich medium was analyzed by nuclear magnetic resonance. LRRK2-mutant PD patients had significantly ($p<0.05$) more CD19+BAFF-R+, CD19+CD95+ and CD19+IgD-IgM-CD27+, less CD19+CD40+ cells than controls. Comparing to other PD patients, LRRK2-mutants had significantly ($p<0.05$) less CD19+CD69+ and CD19+CCR1+, and more CD19+BAFF-R+ cells. LRRK2-protein expression was observed in the CD19+IgD+CD27- and CD19+IgD-CD27+ subsets. MAPK6 and p38 expression was significantly decreased in all PD patients, no difference was found regarding B cell lactate production. These data suggest that neurodegeneration in PD is accompanied by functional changes in peripheral B cells, impacting on the MAPK pathway, BAFF-R and CD95 expression, contributing to defective B cell differentiation and proliferation. The G2019S mutation in LRRK2 seems to further increase B cell dysfunction. (Funding: MJFox Foundation, CNPq-Brazil)

P5.09.59
Anti-ganglioside antibodies in Pandemrix®-induced narcolepsy

***A. Saariaho**[1], O. Vaarala[2], M. Partinen[3], S. Meri[1];*
[1]Haartman Institute, Helsinki, Finland, [2]National Public Health Institute, Helsinki, Finland, [3]Helsinki Sleep Clinic, Vitalmed Research Center, Helsinki, Finland.

Narcolepsy with cataplexy (NC) is a chronic, neurological disease with an unknown etiology. It is caused by a selective loss of hypocretin-producing neurons in hypothalamus. This causes the typical symptoms of the disease: various sleep and metabolic disorders, cataplexy and hallucinations. NC is considered as an autoimmune disease, where genetic and environmental risk factors contribute to its development. NC has a strong association with HLA-DQB1*0602 (DQ6), and recent reports from several European countries have confirmed an association between the adjuvanted H1N1 Pandemrix® vaccine and NC in genetically susceptible children and adolescents. However, the triggering role of the vaccine components and the mechanisms behind the disease remain unsolved. We studied the role of humoral immunity in the pathogenesis of Pandemrix-narcolepsy by screening anti-neuronal antibodies from patients' sera. No antibodies were detected against the neuronal antigens (Hu, Ri, Yo, Tr, MAG, myelin, Ma/Ta, GAD, amphiphysin, aquaporin-4, NMDAR, AMPA-type glutamate receptor, glycine receptor, CASPR2 and LGI1) in patient sera (n=5). However, when sera of Pandemrix-narcolepsy patients (n=20) were screened for 12 anti-ganglioside antibodies (AGA) by line immunoassay a high frequency of (>30%) of AGA (IgG or/and IgM) were found. No AGA were detected in the control sera of healthy unvaccinated children (n=6). The majority of the found AGAs (IgG) were against gangliosides GM4, GM3 and GD3. Our results suggest that humoral immune response against gangliosides is a feature of Pandemrix-associated narcolepsy. AGA could cause at least part of the neuronal damage of the disease.

P5.09.60
Effects of vagotomy during inflammation and cytokine production in hamster amebic liver abscess

***E. Sánchez Alemán**, A. Quintanar-Stephano, M. Campos-Esparza, J. Ventura-Juarez;*
Universidad Autonoma de Aguascalientes, Aguascalientes, Ags., Mexico.

The inflammatory response is modulated by its interactions with the nervous system. The vagus nerve and its neurotransmitter acetylcholine is the major parasympathetic innervation to chest and abdominopelvic viscera, Thus, through the alpha 7 nicotinic receptor on macrophages and other cells, inhibits NF-kB pathway reducing the secretion of pro-inflammatory cytokines. *Entamoeba histolytica* (Eh) in humans causes several diseases including amebic liver abscess (ALA) that is characterized by formation of inflammatory granulomatous lesions. In this context, we studied the role of vagotomy during induction of ALA in hamster, this was done by cutting the ventral vagal branches that innervate the liver and after 30 days was inoculated 350.000 Eh trophozoites (H1-IMSS strain) by intrahepatic via. Animals were sacrificed at 6, 12, 24h, 2, 4 and 7d post-inoculation, then, was analyzed NFKB activation in neutrophils and macrophages, and the presence of pro and anti-inflammatory cytokines+ cells by Immunohistochemical and immunofluorescence techniques. During ALA kinetics in parasimpatectomized hamsters was observed significant NFKB activation in neutrophils (10.43 ± 0.93) and macrophages (7.77 ± 0.15) and an increase of IL-1β+ (8.1 ± 1.0) and TNF-α+ cells (17.02 ± 1.77) compared to Sham and control groups. However, only IL8+ cells significantly increased at 24h post-inoculation in vagotomized animal. No changes were observed in IL10+ cells. Our results demonstrate that vagotomy in ALA model induces a pro-inflammatory response more durable due to increased activation of NFKB and therefore higher release of IL-1β and TNF-α cytokines. The vagus nerve is important in regulation of inflammatory process during ALA.

P5.09.61
Steroids hormones on neurofibromas development

***A. Santos**[1], M. Geller[1], S. G. Mezitis[2], M. Ribeiro[3], L. Oliveira[4], K. Cunha[5], A. Fonseca[4], R. S. Batista[6], A. P. Gomes[6], G. Darrigo[7];*
[1]Instituto Carlos Chagas, Rio de Janeiro, Brazil, [2]New York University, New York, NY, United States, [3]Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil, [4]UNIFESO, Rio de Janeiro, Brazil, [5]Universidade Federal Fluminense, Rio de Janeiro, Brazil, [6]Universidade Federal de Viçosa, Viçosa, Brazil, [7]USP - Ribeirão Preto, São Paulo, Brazil.

A descriptive case study was performed on 75 patients with NF1 (neurofibromatosis type 1) from the CNNF (Brazil) database. Serum IgE levels were determined using the IgE radioimmunosorbent test, with the reference values of 75-502 IU mL-1. The patients were divided into groups, with 25 patients presenting plexiform neurofibromas, 25 presenting neurofibromas and 25 presenting no neurofibromas. The purposes of this study were to determine the serum IgE levels of patients with NF1 presenting plexiform neurofibromas, neurofibromas and no neurofibromas, as well as to determine possible correlations between serum IgE levels and the size of plexiform neurofibromas and neurofibromas presented by these patients. Elevated serum IgE levels were observed in all the patient groups. We did not observed a correlation between IgE levels and age in these patients; however, we did observe correlations between IgE levels and neurofibroma and plexiform neurofibroma size. We suggest further studies to confirm these results and to investigate in greater depth the possible role of IgE in the development and growth of neurofibromas and plexiform neurofibromas in NF1.

P5.09.62
Cocaine exposure, abstinence and relapse differentially affect dopaminergic, mu-opioid and CB2 receptors expression on immune cells

***R. Santos-Toscano**[1], A. Higuera-Matas[1], M. Ucha[1], D. Roura-Martínez[1], J. Fernández-Ruiz[2], M. Miguéns[1], E. Ambrosio[1], M. A. Assis[1];*
[1]Shool of Psychology, UNED, Madrid, Spain, [2]Shool of Medical Sciences, UCM, Madrid, Spain.

Immune cells express proteins from dopaminergic, opioidergic and endocannabinoid systems, which are key neurobiological targets of cocaine exposure. Therefore, cocaine may also modulate these systems at the immune level. We tested this hypothesis by analyzing the expression of D5 and D3 dopaminergic receptors (DARs), mu-opioid receptors (MOR) and CB2 receptors in splenic T-cells (CD3-FITC+), B-cells (CD45RA-PECy5+) and monocytes/macrophages (CD11b/c-PE+) from male Lewis rats using flow cytometry (FCM). Receptor expression was measured after: 1) cocaine self-administration (1 mg/kg/infusion, i.v.; 21 d); 2) extinction of cocaine self-administration (21 d); and 3) cocaine-induced (10 mg/kg, i.p.) reinstatement of drug-seeking behavior. Cocaine self-administration augmented DARs, MOR and CB2 receptor expression distinctly in T-cells, B-cells and monocytes/macrophages, effects that were not fully reversed during extinction. Reinstatement of cocaine seeking was associated with altered D5 expression in monocytes/macrophages, modifications in MOR+ T-cells percentage and increased T-cell/B-cell ratio compared to animals that did not relapse. Remarkable alterations in relative spleen weight, cellularity, relative and absolute numbers of splenic subpopulations as well as increased CD3 and CD11b/c expression levels were observed following cocaine self-administration, effects that were modulated distinctly by extinction and subsequent re-exposure to cocaine. These findings may help better understand the mechanisms involved in cocaine-mediated immune modulation and aid the development of novel therapeutic strategies to address the behavioral-immunological imbalances associated with cocaine addiction. As FCM allows clinicians to rapidly measure multiple parameters in a single sample, the Ab panel used here may facilitate the peripheral assessment of biological markers modulated by cocaine use.

P5.09.63
Prenatal immunological stress affects the development of reproductive system

***V. Sharova**[1], M. Izvolskaia[1], Y. Tillet[2], L. Zakharova[1];*
[1]Kol'tzov Institute of Developmental Biology, Russian Academy of Sciences, Moscow, Russian Federation, [2]Centre INRA de Tours à Nouzilly, Tours, France.

Immune and reproductive systems closely interact in critical periods of early ontogeny. The leading role in programming of reproductive and immune system development and functioning belongs to hypothalamic neuropeptide gonadotropin-releasing hormone (GnRH). GnRH neurons originate in olfactory epithelium and migrate to the forebrain on the surface of olfactory/vomeronasal nerves in prenatal life. Immunomediators are involved in regulatory and morphogenetic processes of GnRH system development during perinatal period. Rats were injected intraperitoneally with lipopolysaccharide (LPS) (18 µg/kg) on the 12th day of pregnancy and GnRH-immunoreactive neuron fractions were count along the migration route on 17th and 19th embryonic days (E). Body weights, the day of vaginal opening was recorded in prenatally LPS-treated and control offspring. Hypothalamic GnRH content was detected by radioimmunoassay on 5th, 14th and 30th postnatal days (P). The receptors to proinflammatory cytokines (IL-6, MCP-1, LIF) in GnRH-neurons were detected in untreated fetuses using double immunohistochemistry. The rate of GnRH neuron migration was decreased in nasal area on E17 after maternal LPS treatment, GnRH neuron distribution wasn't changed on E19. The body weight of postnatal LPS-treated animals was decreased and vaginal opening was also delayed. GnRH content was diminished on 25% in both sexes on P60. GnRH neurons were positive to IL-6R, LIFR and MCP-1 (CCR) in different areas of migration route. Thus, maternal infection on early stages of pregnancy affects GnRH neuron migration in fetuses and as a result GnRH synthesis is suppressed in postpubertal animals. Possible regulators of GnRH neuron migration might be the proinflammatory cytokines.

P5.09.64
Immune response in dorsal root ganglion of mice infected with Herpes Simplex-1 (HSV-1) leads to the development of hyperalgesic behaviour

***J. R. Silva**, A. H. P. Lopes, J. Talbot, R. F. O. França, B. A. L. Fonseca, T. M. Cunha, F. Q. Cunha;*
Ribeirão Preto School of Medicine, University of São Paulo, Ribeirão Preto, Brazil.

Herpes Zoster (HZ) is a disease caused by reactivation of latent herpesvirus Varicella Zoster in the sensory ganglion, characterized by dermal rash and pain. A murine model of HSV-1 infection on the hind paw skin has been used to study HZ, since mice develop HZ-like skin lesions and pain-related responses. There are no data available about the immune response in dorsal root ganglion (DRG) of these mice. Thus, the aim of this study was to evaluate cells and inflammatory mediators present in DRGs and its relationship with hiperalgesia during HSV-1 cutaneous infection. Mice developed hyperalgesia from 3 to 21 days post infection (dpi) only in the ipsilateral (ips) paws. At 12 dpi, all mice recovered from skin lesions. Approximately 50% of mice showed persistent hyperalgesic behavior until 45dpi. A higher viral load was detected in DRGs L4, L5 and L6 of infected mice at 7 dpi. We observed an intense inflammatory infiltrate composed by neutrophils and macrophages in ips DRGs at 7dpi. T lymphocytes (CD4+ and CD8+) infiltration was detected at 15 and 21dpi in ips DRGs. We also observed the activation of satellite cells in ips DRGs (GFAP expression). A higher mRNA expression of COX-2 and TNF-α was detected in ips DRGs of infected mice. Moreover, blockage of TNF-α reduced the development of hyperalgesia. Our results show the presence of an inflammatory infiltrate in DRGs of infected mice, and the early expression of inflammatory mediators that contribute for the induction of herpetic hyperalgesia. Financial support: FAPESP (2010/12309-8), TIMER (HEALTH-F4-2011-281608).

P5.09.65
IFN-ɣ is protective in EAE by activating CNS-resident microglia to phagocytose neurotoxic myelin debris

***R. A. Sosa**, A. E. Cardona, T. G. Forsthuber;*
University of Texas at San Antonio, San Antonio, TX, United States.

The central role of the Th1 cell-derived cytokine IFN-γ as a primary mediator of CNS pathology during EAE has been challenged by the recent characterization of "Th17" cells producing IL-17 and GM-CSF. Additionally, mice deficient in IFN-γ develop more severe disease, implicating its role in EAE and MS is protective. Using a novel quantitative immunofluorescence (qIF) technique to analyze confocal images of antigen-presenting cells (APCs) in the CNS of wild-type (Wt) and IFN-$\gamma^{-/-}$ or IFN-$\gamma R^{-/-}$ C57BL/6 mice, we found that this higher disease severity corresponded to decreased myelin Ag uptake by CNS APCs. qIF further showed that the lack of antigen uptake corresponded to a lack of myelin debris cleanup at CNS lesions. Surprisingly, IFN-$\gamma R^{-/-}$ APCs from EAE mice or *in vitro* cultures with exogenous myelin Ag and 2D2 tg T cells produced more IL-17 and GM-CSF in cytokine ELISPOT assays. Flow cytometry for phagocytosis and antigen presentation markers revealed that $CD11b^{+}CD45^{lo}$ microglia were affected most by the absence of IFN-γ signaling with a dramatic reduction in activation markers, while $CD11b^{+}CD45^{hi}$ infiltrating macrophages were also less activated. However, $CD11c^{+}$ dendritic cells (DCs) only experienced a slight decrease in activation markers. These results illuminate IFN-γ's primary protective role via activation of CNS-resident microglia to promote removal of myelin debris, thus facilitating remyelination. Importantly, the activation of DCs to present myelin Ag to encephalitogenic T cells appeared independent of IFN-γ signaling and thus represents a potential therapeutic target slowing MS progression.

P5.09.66
Influenza split vaccine in regulation of autoimmune processes in experimental autoimmune encephalomyelitis

***A. Stojkovic**, D. Kosanovic, N. Vukov, K. Jovanova-Nesic;*
Biomedical Center of the Institute Torlak, Belgrade, Serbia.

Activation of autoantibodies and MHC class I and class II proteins expression represent the main characteristics of experimental autoimmune encephalomyelitis (EAE). Therefore, effects of influenza vaccine on antibody titers, expression of MHC I and II classes in brain tissue and clinical signs were examined. In this study 24 female 8 week-old C57BL/6 mice were divided in four groups: first EAE-influenza vaccinated; second EAE-induced; third influenza vaccinated and fourth non-treated (intact control). Mice were vaccinated intramuscularly with influenza split vaccine (Vaxigrip, Sanofi-Pasteur). EAE groups were immunized subcutaneously with MOG35-55 in complete Freund's adjuvants and pertussis vaccine intraperitoneally injected. The serum antibody titer to MOG35-55 was detected by ELISA test. Significant increase of anti-MOG antibodies ($p<0.01$) was detected in EAE-influenza vaccinated and mice with EAE mice in comparison to both controls (influenza vaccinated and intact). Mild but not significant increase in anti-MOG antibody titer was detected in EAE-influenza vaccinated compared to mice with EAE. There were no differences between both control groups (influenza vaccinated and intact). Strong expression of MHC-II and mild expression MHC-I were detected in EAE-influenza vaccinated and mice with EAE, while no expression was found in both controls. No differences were observed between EAE-influenza vaccinated and mice with EAE in both MHC I and MHC II expression. Results obtained show that influenza vaccine has no significant influence on autoimmune processes and induction of EAE.

P5.09.67
Evaluation of Tumor necrosis factor (TNF-α) cascade in the brain of rat model of collagen-induced arthritis (CIA)

***R. M. Talaat**, A. S. Abo-Elatta;*
Genetic Engineering and Biotechnology Research Institute (GEBRI), Menoufiya University, Egypt, Sadat city, Egypt.

Tumor necrosis factor α (TNF-α) is an inflammatory cytokine that contributes to the cytokine cascade in collagen-induced arthritis (CIA) and it can cross blood brain barrier via carrier mediated transport. The aim of our work was to study the production of TNF α and its receptors 1 (TNFR-1) and 2 (TNFR-2) and transcription factor NF-kB (nuclear factor kappa B) in brain of CIA rat model with and without methotrexate (MTX) treatment. CIA was induced in Wistar rats by intradermal injection of bovine type II collagen. The rats were divided into normal, CIA and MTX treated groups. Treatment was received the day after the onset of arthritis (day 12) until the day 35^{th}. TNF-α, TNFR-1, TNFR-2, and NF-kB were quantified by enzyme-linked immunosorbent assay (ELISA) in brain homogenates. Our results showed significant increase in CIA rats ($p<0.001$; $p<0.001$ and $p<0.05$ for TNF-α, TNFR-1 and TNFR-2; respectively) compared to normal ones. Remarkable reduction was reported in various mediators (TNF-α, TNFR-1, TNFR-2, and NF-kB)after treatment with MTX ($p<0.001$; $p<0.01$ and $p<0.001$ and $p<0.01$ for TNF-α,TNFR-1, TNF-R2 and NF-kB; respectively). In conclusion,our study revealed a causal link between CIA model and increased expression of cellular TNF-α and its receptors (TNFR-1 and TNF-R2). MTX therapy influences brain immunity in CIA rats, leading to overall amelioration of TNF-α cascade (TNF-α and both receptors 1 and 2 and NF-kB transcription factor), suggesting that anti-rheumatic potential of MTX may extend to affect on brain tissues leading to impairment of TNF-α.

P5.09.68
Microglia induced Foxp3+CD4+Treg through PD-L1 in experimental autoimmune encephalomyelitis

*J. Hu[1], H. He[1], G. Zhu[1], W. Song[1], B. Bai[2], **H. Tang**[1];*
[1]Taishan Medical University, Taian, China, [2]Jining Medical University, Jining, China.

During experimental autoimmune encephalomyelitis (EAE), microglia has been considered as potential antigen-presenting cells (APC) and had the capability to present antigen. CD4+ Foxp3+ regulatory T cells play a central role in the control of autoimmune responses. However, the role of microglia in CD4+Foxp3+ Treg induction during EAE remains largely unknown. Here, we observed that the number of microglia gradually increased after induction of EAE, and followed by the subsequent reduction during recovery phase. This was closely associated with the change of CD4+Foxp3+ Treg cells. By using real-time PCR and FACS analysis, we found that, at the peak stage of EAE, the expression of MHC II and PD-L1on microglia was significantly up regulated when compared with microglia in control mice. In *ex vivo* co-culture systems, microglia from EAE mice has been found to inhibit the proliferation of antigen-specific CD4+T cell triggered by splenic dendritic cells. Furthermore, microglia from EAE displayed the capacity of induction of Treg, which was diminished by administration of anti-PD-L1 antibody. The suppressive effects of microglia were also inhibited by neutralizing PD-L1 antibody in *ex vivo* co-culture system. Collectively, these data suggest a scenario in which microglia might control of the recovery of CNS autoimmune disease through upregulation of PD-L1 expression and expansion of CD4+ Foxp3+ Treg.

P5.09.69
Gene expression upregulation of TNF superfamily members in temporal lobe epilepsy-associated hippocampal sclerosis

***M. A. Teocchi**, L. D'Souza-Li;*
University of Campinas, Campinas, Brazil.

Temporal lobe epilepsy (TLE) is the most treatment resistant (refractory) form of partial epilepsy. In TLE associated with hippocampal sclerosis (HS) [TLE(HS)], only 10% of patients become seizure free after taking antiepileptic drugs. Recent evidence strongly suggests that inflammation plays a pivotal role in TLE(HS) physiopathology. Neuronal apoptosis in HS can be triggered by excitotoxic damage and specific cytokines. Several TNF superfamily members might be involved in the hippocampal damage caused by seizure precipitation and recurrence. Our goal is to identify critical targets to clarify the molecular physiopathology in TLE-associated HS. We evaluated the relative mRNA expression of fifteen genes, all TNF superfamily receptors or ligands: *FAS, FASLG, NGF, NGFR, TNF*, *TNFRSF10A*, *TNFRSF10B*, *TNFRSF10C*, *TNFRSF10D*, *TNFRSF1A, TNFRSF1B*, *TNFRSF21*, *TNFRSF25*, *TNFRSF6B* and *TNFSF10*. Experiments were carried out in resected hippocampal tissue samples from 12 TLE(HS) patients and compared to four *post mortem* controls. Moreover, immunohistochemistry for TNFRSF1A and TNFRSF1B was performed in patient and control tissues. All target genes were augmented in TLE(HS) patients ($P<0.05$), except *NGF* and *TNFRSF21*. *TNF* showed a marked upregulation ($P<0.01$). Both TNF receptors were clearly activated in patient's tissues. We conclude that the TNF signaling plays a crucial role in TLE hippocampal apoptosis through death receptors. However, TNFRSF1B activation is controversial: it could be related to a survival mechanism or, as it has already been demonstrated, TNFRSF1B may reinforce the TNFRSF1A deleterious action. Our evidence indicates the TNF pathway as an important field for pharmacological studies regarding the benefits of an anti-inflammatory therapy in these patients.

P5.09.70
Prognostic value of autoimmune response in post-stroke hypertensive patients

***I. M. Voloshyna**, V. A. Vizir, M. A. Voloshyn;*
Zaporoshye State Medical University, Zaporozhye, Ukraine.

Purpose: To define the serum levels of IL-17, NR2-antibody quantity and their prognostic values in post-stroke hypertensives during one-year follow-up.
Methods: 105 patients aged 59±1,5 yrs were prospectively included in this study. Thirty normothensive subjects of equal age were included in control group. Serum levels of IL-17 were detected by immunoassay using eBioscience kits. NR2-antibody quantity were revealed using Gold Dot NR2 Antibody Test, Biotech, INC. Follow-up period was up to 360±20 days. All cases of deaths from any cause and nonfatal stroke and myocardial infarction had been considered as primary clinical end-points.
Results: The mean serum level of IL-17 was up to 32% ($p<0,05$) higher and NR2-antibody quantity was up to 162% ($p<0,05$) higher than in the control group. Patients with multiple brain infarctions had greater amount of NR2-antibodies on 44% ($p<0,05$) compared with subjects with one stroke event in anamnesis. The risk of recurrent stroke and cardiovascular complication was definitely increased in patients with quantity of NR2-antibodies more than 3,97 ng/ml (HR=1,21; 95% CI 1,06-1,37). Autoimmune response was also related to hypertension progression.
Conclusion: Post-stroke bran lesions should be considered as an object of auto-immune activation which has been strongly related to hypertension progression and could increase recurrent stroke risk and risk of adverse cardiovascular events.

P5.09.71
The effect of exogenously administered charged microparticles on the acute phase response

***S. Wang**[1], Y. Couch[1], G. Bort[2], B. Davis[2], D. Anthony[1];*
[1]Department of Pharmacology, Oxford University, Oxfordshire, United Kingdom, [2]Department of Chemistry, Oxford University, Oxfordshire, United Kingdom.

Circulating microvesicles in the blood are small membrane bound particles of between 50 and 1,000 nanometers (nm). In disease or after injury they are released into the circulation and our taken up in target organs such as the liver where they modify cytokine and chemokine production. We have discovered that the administration of micron sized suspensions of less than 1um reduces basal TNF production by the naïve liver. Here, we sought to discover whether we could manipulate the pathogenesis of the focal cytokine-induced inflammatory lesion in the CNS. We injected 50ng of IL-1b intracerebrally into the brain parenchyma in the presence or absence of intravenously injected positively (NH2) or negatively (COOH) charged particles. The liver, brain, and spleen were collected for cytokine expression profiling. In animals injected with IL-1b in the brain, the presence of circulating microparticles reduced the hepatic expression of cytokines and altered neutrophil recruitment to the brain and liver. This was most marked during the injection of positively charged particles, in which the level of TNF, CXCL10, and CCL2 has been down-regulated in the liver and spleen, while the level of CXCL1 and SAA2 is not changed dramatically. This pilot research supplies charged microparticles as a potential tool for the treatment of neuroinflammation.

P5.09.72
The interaction of polymorphisms of IL-1β and MnSOD was associated with tardive dyskinesia in Chinese Han schizophrenic patients

F. Wang*[1], H. Fan*[1], H. Sun*[1], Q. Yan[2], F. Yang[1], L. Lu[3], X. Zhang**[4,1];
[1]Beijing Hui-Long-Guan Hospital, Beijing, China, [2]Inner Mongolia Medical University, Hohhot, China, [3]National Institute on Drug Dependence, Peking University, Beijing, China, [4]Menninger Department of Psychiatry and Behavioral Sciences, Baylor College of Medicine, Houston, TX, United States.

Objective: Previous studies have indicated that the immune and antioxidant molecules may be related to the pathogenesis of tardive dyskinesia (TD). Some polymorphisms in immune genes and the Val/9Ala in manganese superoxide dismutase (MnSOD) genes have been associated with TD. The genetic association between the interleukin-1β (IL-1β) -511A/G and TD is unclear. The interaction of two polymorphisms with severity and symptoms of TD has not been reported. This study was to investigate whether these variations and their interaction were associated with clinical phenotypes and TD. Methods: We genotyped the -511A/G and Val/9Ala in schizophrenic patients with TD (n=383) and without TD (NTD; n=430) in a genetically homogeneous northern Chinese Han population. The Abnormal Involuntary Movement Scale (AIMS) and Positive and Negative Syndrome Scale (PANSS) were used to assess the severity of TD and psychopathology of schizophrenia, respectively. Results: The allele and genotype frequencies of -511A/G did not significantly differ between TD and NTD ($p>0.05$), but the genotype frequencies of Val/9Ala showed a significant difference between two groups ($p=0.026$). Interestingly, a significant association was found between -511A/G and total AIMS score in TD patients ($p=0.011$), and the interaction of -511A/G and Val/9Ala showed a trend toward the significant association with the AIMS total score ($p=0.055$). Additionally, the PANSS negative symptom subscore was associated with risk for TD ($p<0.0001$). Conclusion: These findings suggest the role of the Val/9Ala variant in susceptibility to TD. However, the -511A/G and its interaction with Val/9Ala may play a role in the TD severity.

P5.09.73
The function of TREM2 mutants

Y. Yamanishi*, M. Colonna;*
Department of Pathology and Immunology, Washington University School of Medicine, St. Louis, MO, United States.

TREM2 is a DAP12-coupled immune receptor predominantly expressed in macrophages including microglia. Homozygous inactivating mutations in TREM2 are associated with presenile dementia called Nasu-Hakola disease (NHD) which is a rare autosomal recessive disorder characterized by progressive demyelination in brain. It is hypothesized that the pathogenesis of NHD is due to the inability of TREM2-deficient microglia to remove apoptotic cells and neuronal debris from brain without excess inflammation. Recent studies have demonstrated that TREM2 heterozygous mutations are associated with late onset dementia especially Alzheimer's disease (AD), suggesting an important role of microglial TREM2 in the pathogenesis of AD as well as NHD. In this study, we cloned TREM2 mutants and tested a) their abilities to bind anionic ligands; b) their abilities to activate reporter cell lines. We found that at least one TREM2 mutation impaired binding to anionic ligands and activation of reporter cell lines. We envision that TREM2 enables microglia to clear anionic ligands, such as apoptotic cells in brain, and that impairment of this function results in dysfunction of microglia leading to neurodegeneration.

P5.09.74
Induction of upregulated expression of histamine receptors and increased release of inflammatory mediators from microglia by histamine

S. Zhang*, X. Zeng, S. He;*
Clinical Research Center, the First Affiliated Hospital of Nanjing Medical University, Nanjing, China.

Histamine is a potent mediator of inflammation and a regulator of innate and adaptive immune responses. However, the influence of histamine on microglia, the resident immune cells in the brain, remains uninvestigated. In the present study, we found that microglia can constitutively express all four histamine receptors (H_1R, H_2R, H_3R and H_4R), and the expression of H_1R and H_4R can be selectively upregulated in primary cultured microglia in a dose dependent manner. Histamine can also dose dependently stimulate microglia activation and subsequently production of pro-inflammatory factors TNF-α and IL-6. The antagonists of H_1R and H_4R but not H_2R and H_3R reduced histamine-induced TNF-α and IL-6 production and p38/JNK MAPK pathway activation, and mitochondrial membrane potential loss in microglia, suggesting that the actions of histamine are via H_1R and H_4R. On the other hand, inhibitors of JNK or p38 inhibited histamine-induced TNF-α and IL-6 release from microglia, suggesting that the actions of histamine are through JNK/p38 signaling pathway. In summary, the present study identifies the expression of histamine receptors on microglia. We also demonstrate that histamine induced TNF-α and IL-6 release from microglia are via H_1R and H_4R-JNK/p38 signaling pathway, which will contribute to the development of microglia-mediated inflammation in brain.

P5.10.01
The prokineticin system in experimental autoimmune encephalomyelitis: possible novel targets for immune intervention

M. Abou-Hamdan*[1], M. Costanza[1], E. Fontana[2], M. Di Dario[3], S. Musio[1], L. Negri[4], P. Poliani[2], C. Farina[3], G. Balboni[5], R. Pedotti[1];
[1]IRCCS Neurological Institute Carlo Besta, Milan, Italy, [2]University of Brescia, Brescia, Italy, [3]Institute of Experimental Neurology (INSpe), San Raffaele Scientific Institute, Milan, Italy, [4]University of Roma "La Sapienza", Rome, Italy, [5]University of Cagliari, Cagliari, Italy.

Prokineticins (PK)s are small secreted proteins (8-11kDa), widely expressed in different tissues and involved in a wide spectrum of biological functions. They comprise two proteins, PK-1 and PK-2, signalling through two cognate G-protein-coupled receptors (PK-R1 and PK-R2). Prokineticins and their receptors were reported to modulate immune response. In particular PK-2, highly expressed in inflamed tissues, promotes macrophage activation and migration, and can promote Th1 polarization. However, their role has never been investigated in multiple sclerosis or in its animal model, experimental autoimmune encephalomyelitis (EAE).
During chronic MOG35-55 induced EAE in C57BL/6 mice, we observed a significant increase of mRNA expression of PK-2 in lymph node cells and purified CD4+ T cells. PK-2 protein serum levels were also increased during EAE.
Blocking PK-Rs with the non-peptide-antagonist PC7 reduced the severity of both chronic and relapsing-remitting EAE, when PC7 was used either as a preventive or as a therapeutic treatment. In vitro results showed a dramatic reduction of Th1 cytokines and of IL-17 in antigen-stimulated T cells obtained from PC-7 treated mice, and an increase of the suppressor cytokine IL-10. In vitro treatment with PK-2 reduced IL-4 and IL-10 levels in splenocytes from 2D2 transgenic TCR mice.
These results suggest that PK-2 and its receptors can play an important role in the development of EAE, and might help revealing novel targets of therapy in autoimmune demyelination of the CNS.

P5.10.02
Immunopathological patterns in relapsing-remitting and chronic models of experimental autoimmune enchephalomyelitis and the therapeitc effect of glatiramer acetate

***R. Aharoni**, R. Eilam, R. Arnon;*
The Weizmann Institute od Science, Rehovot, Israel.

Multiple sclerosis (MS) and its animal model experimental autoimmune encephalomyelitis (EAE) are immune mediated diseases, but the role of inflammatory versus degenerative processes in their pathology is controversial. We analyzed the *in situ* pathological manifestations in relapsing-remitting and chronic EAE models, induced by peptides of the myelin proteins PLP and MOG, respectively, using immunohistochemistry, transmission electron microscopy (TEM) and magnetic resonance imaging. Brain and spinal cord analysis revealed in both models multiple T-cell infiltrations. In particular, Th17-cells were found in sites of myelin damage. Extensive activation of resident immune cells, namely microglia, was also characteristic in all the EAE-induced mice. Notably, different patterns of CNS tissue damages were detected in the two EAE models. Thus, demyelination and remyelination were characteristic to relapsing-remitting EAE, whereas in the chronic model axonal degeneration and neuronal loss was the main manifestation. The effect of glatiramer acetate (GA, Copaxone) was evident by drastic reduction in the prevalence of inflammatory cells such as Th17 and by the elevation of Foxp3-expressing regulatory T-cells. Quantitative TEM analysis provided for the first time evidence for significant augmentation of remyelination as a consequence of GA treatment. In the chronic model, axonal deterioration and motor neurons loss were reduced following GA-treatment. Furthermore, GA augmented the three processes characteristic of neurogenesis - neuronal proliferation, migration and differentiation. All these effects were obtained when GA-treatment was applied by a therapeutic regimen, after disease exacerbation. These results support the notion that immunomodulation can lead to effective neuroprotection and repair consequences in the CNS.

P5.10.03
Association of SNP rs6897932 in CD127 gene in Relapsing Remitting Multiple Sclerosis (RRMS) patients compared to control group

***F. Alesahebfosoul**[1], R. Salehi[2], A. Zavaran Hosseini[1], M. Etemadifar[2], M. Kazemi[2], M. Tajedin[2], B. Zarkeshfard[3];*
[1]Tarbiat Modares University, Tehran, Iran, [2]Isfahan University Of Medical Sciences, Isfahan, Iran, [3]Isfahan University Of Medical Sciences, Isfahan, Iran.

MS is an inflammatory, demyelination disorder of the CNS. Isfahan is considered as an area with high risk of MS. Recent GWAS have identified a number of SNPs associated with susceptibility to MS. we decided to study the polymorphism of the CD127 gene in RRMS patients.
Materials & Methods: After written consent, blood samples from 200 patients with RRMS (180 females and 20 male; mean age=31.65±8.3) with clinically and MRI definited RRMS who had recuited to Isfahan MS research center , and 203 age and sex matched healthy subjects of blood donors (163 females and 40 male; mean age=31.74±7.75) with no history of neurological disorders were included in the study.DNA was extracted from whole blood using a commercially available kit and stored at -20°C until used for genotyping. SNP analysis was performed using HRM Real Time PCR.Differences in genotype frequencies among the respective groups were evaluated by chi square calculation.
Result: Decreased heterozygosis rate of the genomic C allele was detected in patients with RRMS (p= 0.56) while the CC genotypes were decreased in control (OR: 0.88, confidence interval (0.57–1.36).
Once the effect of the associated *CD127* protective allele is accounted for, as estimated by rs6897932^c, there is no residual evidence of association to MS susceptibility within the *CD127* locus in our region. This result suggests that rs6897932^c is not correlated to MS susceptibility.
Conclusion: The results for the frequency of rs6897932 SNP in CD127 locus was identified no differential allelic expression among patients with RRMS and healthy controls

P5.10.04
Frequency of null allele of HLA-G Locus in East Azarbayjan patients with recurrent miscarriage

***N. Alizadeh Gharamaleki**;*
Tabriz University of Medical Science, Tabriz, Iran.

Human leukocyte antigen-G (HLA-G) is a non-classical class I molecule highly expressed by extra villous cytotrophoblast cells . The HLA-G gene contains 15 alleles, including the HLA-G* 0105 N null allele. HLA-G* 0105 N presents a single base pair deletion, which rules out translation of both membrane bound (HLA-G1) and full length soluble isoform (HLA-G5), but other isoforms such as HLA-G2 can compensate their roles. The aim of this study was to demonstrate the frequency of HLA-G* 0105 N null alle le in East Azarbayjan patients with recurrent miscarriage. To investigate the frequency of HLA-G*0105 N null allele in recurrent miscarriage patients, the PCR-RFLP method was used. Genomic DNA was extracted from whole blood of 60 randomly selected patients using the salting-out technique. Then, PCR amplification of the exon 3 of HLA-G gene was performed. The work was continued with the digestion of PCR products with PpuM-I enzyme. Afterwards, the analysis of resulting fragments was carried out using the gel electerophoresis technique. To determine the accuracy of the RFLP method, six samples were selected and sent for sequencing. In this study, digestion of the restriction enzyme showed heterozygous HLA-G*0105 N null allele in 6/6% of the patient population. Data analysis demonstrated that the frequency of heterozygous HLA-G* 0105 N null allele was relatively high in patients with recurrent miscarriage.

P5.10.05
Th1/Th17 imbalance in clinical subtypes of Multiple Sclerosis: association with disability and unresponsiveness to IFN-β therapy in relapsing-remitting disease

***G. Arellano**[1], E. Acuña[1], L. Reyes[2], F. Vergara[1], R. Uribe[1], E. Ciampi[1], C. Cárcamo[1], R. Naves[1];*
[1]Department of Neurology, School of Medicine, Pontificia Universidad Católica de Chile, Marcoleta 391, Santiago, Chile, [2]Depto. Cs. Biológicas y Químicas, Facultad de Ciencia, Universidad San Sebastián, Campus Los Leones de Providencia, Santiago, Chile.

There is an enormous need to understand the immunological processes associated with the different clinical subtypes of Multiple Sclerosis (MS) as well as the identification of immunological parameters associated with disease activity and treatment responsiveness. In this study, ninety-four MS patients diagnosed with Clinical Isolated Syndrome (CIS, n=22), relapsing-remitting (RR) MS (n=44), secondary progressive MS (n=10) and primary progressive MS (n= 18) without treatment and 18 healthy controls (HC) were tested for the plasmatic expression of Th1 (IFN-γ) and Th17 (IL-17A and IL-17F) cytokines by ELISA. We defined the IFN-γ/IL-17F ratio reflecting the Th1/Th17 balance. Th1 and Th17 cell response was determined in PBMC upon CD3/CD28 stimulation by flow cytometry. A group of responders (n=9) and nonresponders (13) RRMS patients to IFN-β therapy was also analyzed. Patients with different MS subtypes exhibited a disturbed and distinctive Th1/Th17 balance skewed towards a Th1 or Th17 disease. Furthermore, a predisposition to develop a Th1 or Th17 cell response was observed in these patients. Remarkably, the Th1/Th17 balance and high levels of IFN-γ and IL-17F were associated with disability (EDSS) in RRMS patients. Most strikingly, the Th1/Th17 balance and high levels of IL-17F distinguished between responder and nonresponder patients to IFN-β therapy. In conclusion, our results provide new evidence to the understanding of immunopathological mechanisms underlying MS subtypes and suggest that the Th1/Th17 balance and plasmatic levels of IFN-γ and IL-17F might have prognostic implications and putative value in monitoring therapy effectiveness. Supported by Fondecyt 1110523.

P5.10.06
The role of STI-571 in the treatment of EAE

G. Azizi[1], *A. Mirshafiey*[2];
[1]*Alborz University of Medical Sciences, karaj, Iran,* [2]*Department of Immunology, School of Public Health, Tehran University of Medical Sciences, Tehran, Iran.*

Background: Multiple sclerosis (MS) is an autoimmune disease of the central nervous system (CNS) that leads to an inflammatory demyelination, axonal damage and progressive neurologic disability. STI-571 is a selective protein tyrosine kinase inhibitor that abrogates multiple signal transduction pathways implicated in auto immune diseases.
Method: EAE induction was performed by Hooke Kit. The kit consists of antigen (MOG_{35-55}) in CFA emulsion, and pertussis toxin (PTX) in PBS. The mice were injected subcutaneously on upper back and lower back with 0.1 ml of emulsion respectively. Within 2 hours of injection of the emulsion, the first dose of PTX (0.1 ml per mouse) was injected intraperitoneally. 22-26 hours after injection of the emulsion, the intraperitoneally injection of second dose of PTX into the mice (0.1 ml) were done. The mice were administered orally with STI-571 at the specified dose (60 mg/kg) from day 7 after immunization on six consecutive d per wk for 2 wk. The mice were sacrificed on day 35 post-immunization. Brains, cerebellums and lumbar spinal cords were removed, post-fixed in formalin, embedded in paraffin, sectioned and then stained with Luxol fast blue (LFB) and with eosin and hematoxylin.
Results: Our findings showed that treatment with STI-571 caused a significant delay in the time of onset and a significant reduction in severity of the EAE in treated animals compared with normal groups.
Conclusion: Our results suggest that FDA-approved drug STI-571 has potential therapeutic effects on EAE as an autoimmune demyelinating disease.

Interleukin-17A and Interleukin-17F mRNA Expressions in Peripheral Blood Mononuclear Cells of Patients with Multiple Sclerosis

F. Babaei[1], *Z. Babaloo*[1], *M. Farhoodi*[2];
[1]*Tabriz University of Medical Sciences, Tabriz, Iran,* [2]*Neuroscience Research Center, Tabriz University of Medical Sciences, Tabriz, Iran.*

Multiple sclerosis (MS) is a CD4+ T cell-mediated autoimmune disease affecting the central nervous system (CNS). It was previously believed that Th1 cells were pathogenic T cells in experimental autoimmune encephalomyelitis (EAE). How- ever, the functional role of Th1 cells in EAE has been reconsidered upon the discovery of IL-17-producing T cells which are considered as dominant effectors for inducing autoimmune tissue inflammation. Objective: The objective of this study was to assess the role of IL-17A and IL-17F in MS pathogenesis. Methods: We evaluated mRNA expres- sion of IL-17A and IL-17F in thirty-five Iranian patients with relapsing-remitting MS (RRMS) and twenty-five healthy controls by Quantitative Real Time PCR. Results: The results of this study showed a twenty-fold increase in the expression of IL-17A mRNA in MS patients compared to the control group ($p < 0.0001$). IL-17F mRNA expression in MS patients was thirty three-times greater than the control group ($p = 0.0008$). IL-17A mRNA expression in the periphery was positively correlated with the expression of IL-17F transcripts in MS patients and controls ($p < 0.01$ and $p < 0.05$, respectively). Conclusion: These results indicate the critical role of Th17- mediated cytokines in the development of MS which was classically considered as a Th1-mediated disorder. The results of this study showed, for the first time, the importance of IL-17F in MS immunopathogenesis.

Inflammatory stimuli and oxidative stress alter mitochondrial transport in neurons

E. Bros[1,2,3], *R. Niesner*[4], *F. Paul*[2,3], *C. Infante Duarte*[1,2];
[1]*Institute for Medical Immunology, Charité-Universitätmedizin Berlin, Berlin, Germany,* [2]*Experimental and Clinical Research Center, Berlin, Germany,* [3]*NeuroCure Clinical Research Center, Berlin, Germany,* [4]*Deutsches Rheuma-Forschungszentrum, Berlin, Germany.*

In multiple sclerosis (MS), autoimmune inflammatory processes may lead to neuronal damage. Numerous studies link mitochondrial dysfunction to the pathogenesis of neurodegenerative diseases, and recent reports suggest this may also be the case for MS. Mitochondria are crucial to cell survival: They produce ATP, maintain ion homeostasis and regulate apoptosis. Within the axon, they are delivered to, and remain in areas where metabolic demand is highest. The health of neurons depends critically on their distribution, which raises the possibility that inflammation-induced alteration of mitochondrial dynamics could promote neuropathology. To investigate whether inflammatory stimuli and oxidative stress can directly influence mitochondrial behavior, we used an *ex-vivo* model of peripheral nerves explanted from the murine spinal cord. Axonal tracts and mitochondrial dynamics are preserved for several hours after explantation and can therefore be targeted experimentally. The application of bacterial endotoxin (lipopolysaccharide), a prototypic inflammatory stimulus, induced a significant increase in the number of motile mitochondria. This increase was directional, augmenting the proportion of mitochondria moving towards the cell body. In contrast, incubation with an oxidative stress inducer, buthionine sulfoximine (BSO), produced a substantial decrease in mitochondrial motility. This reduction could be partially prevented by pre-incubating the nerves with the antioxidant (-)-epigallocatechin-3-gallate before BSO addition. Using an *ex-vivo* model we were able to monitor different alteration patterns of mitochondrial trafficking. These results are consistent with a role of inflammation and oxidative stress-induced alterations of mitochondrial dynamics in neurodegeneration, and highlight the utility of simplified models to examine mitochondrial response to pathological stimuli.

P5.10.09
A systems biology approach to identify biomarkers and therapeutic targets in peripheral monocytes of multiple sclerosis patients

I. Burba[1,2], *S. Baldassarri*[1], *A. Torri*[1], *S. Fumagalli*[1,2], *C. Ripamonti*[1], *D. Caputo*[3], *M. Rovaris*[3], *M. Foti*[1,2];
[1]*Università Milano Bicocca, Milano, Italy,* [2]*Genopolis Consortium - Università Milano Bicocca, Milano, Italy,* [3]*Multiple Sclerosis Unit IRCCS Santa Maria Nascente, Fondazione Don Gnocchi, Milano, Italy.*

Multiple Sclerosis (MS) lesions are characterized by perivascular infiltration of inflammatory mononuclear cells accompanied by demyelination and axonal injury. Peripheral monocytes serve as a source of the infiltrate and it is assumed that they acquire a unique transcriptional signature after repeated passages through the vascular bed. Because of the unpredictable clinical course, biological surrogate markers are much needed in the field of MS.
This project is aimed to identify gene markers that best discriminate between patients with different disease activity, to achieve an improvement in disease monitoring and in treatment efficacy.
We performed a gene expression and microRNA (miRs) profiling in monocytes from female MS patients in the relapsing remitting (RR; n=13) and primary progressive (PP; n=5) phenotypes, compared to healthy volunteers (Ctr; n=10). We were able to identify significantly regulated miRs in monocytes of MS patients compared to Ctr and between the two different disease phenotypes. Seven down-regulated miRs were validated by Q-PCR, confirming that the miR-130a is down-regulated in RR compared to Ctr while the miR-125a is specifically decreased in RR compared to both Ctr and PP subjects. Current experiments in the laboratory are investigating the role of these molecules in regulating monocytes functions and MS phenotypes. We are also validating our findings on an extended number of MS patients and controls to increase the power of the analysis. In conclusion, our preliminary data suggest that a Systems Biology approach based on gene expression and miRNA profiling is feasible and promising to identify reliable biomarkers in MS

P5.10.10
Micro/nanoparticles platforms for "inverse vaccination" in Experimental Autoimmune Encephalomyelitis (EAE)

G. Cappellano[1], *A. Demeke Woldetsadik*[1], *Y. Shivakumar*[1], *M. Rizzi*[2], *F. Carniato*[3], *E. Orilieri*[1], *A. Chiocchetti*[1], *F. Renò*[2], *U. Dianzani*[1]; [1]*IRCAD and Department of Health Sciences, University of Eastern Piedmont A.Avogadro, Novara, Novara, Italy,* [2]*Laboratorio di Ricerca Innovativa per il Wound Healing Department of Health Sciences, University of Eastern Piedmont A. Avogadro, Novara, Novara, Italy,* [3]*Department of Science and Technology, University of Eastern Piedmont A. Avogadro, Alessandria, Novara, Italy.*

"Inverse vaccination" uses autoantigens in combination with appropriate "adjuvants" to trigger "regulatory" cells specifically inhibiting an autoimmune response. Recently, an inverse DNA vaccine showed a therapeutic effect in patients with multiple sclerosis (MS), but DNA vaccination has potential risks limiting its use in humans. An alternative approach could be use of protein vaccines released from polymeric biodegradable lactic-glycolic acid (PLGA) particles (PLGA-NP), approved by FDA, to sustain release of antigens and regulatory adjuvants for extended periods. Aim of this work was to develop protein-based tolerogenic PLGA-NP vaccines containing myelin autoantingen (MOG35-55) and adjuvants to inverse vaccinate EAE (Experimental Autoimmune Encephalomyelitis) mice. We produced PLGA-NP loaded with either MOG35-55 or rIL-10 used as an adjuvant for regulatory cells. The morphology of these particles was evaluated by Scanning Electron Microscope and showed a mean diameter of 591.7 nm. PLGA-NP were not toxic to cells and did not induce secretion of proinflammatory cytokines (IL-1β and TNF-a) on monocytes. The encapsulated proteins were released in vitro for up to 2 months and the released rIL-10 maintained the ability to inhibit LPS-induced secretion of TNF-α on monocytes. Preliminary experiments showed that subcutaneous treatment with MOG35-55- and rIL-10-loaded PLGA-NP significantly inhibited development of EAE in C57/B6 mice without detectable toxic effects. These data suggest that PLGA-NP-based inverse vaccination may be an effective tool to treat autoimmune diseases.

P5.10.11
In-vitro up-regulation of Regulatory T cells markers with IFN-beta and c-Phycocyanin: pertinence of a combined treatment for Multiple Sclerosis

M. Cervantes-Llanos[1], *R. Alonso-Ramírez*[2], *G. Martínez-Sánchez*[3], *J. Cabrera-Gómez*[4], *C. Valenzuela-Silva*[1], *A. Llópiz-Arzuaga*[1], *A. Milian-Jordan*[1], *E. De Armas*[5], *P. López-Saura*[1], *G. Pentón-Rol*[1]; [1]*Center of Genetic Engineering and Biotechnology, La Habana, Cuba,* [2]*Center of Molecular Immunology, La Habana, Cuba,* [3]*Center for Research and Biological Evaluations, Institute of Pharmacy and Food Sciences, University of Havana, Cuba, La Habana, Cuba,* [4]*Center of Neurological Restoration, La Habana, Cuba,* [5]*GENIX, La Habana, Cuba.*

Nowadays there is a growing knowledge of the pathogenic process that takes place in Multiple Sclerosis (MS) characterized either by signs of autoimmunity, inflammation and demyelination or primary oligodendrocyte loss. Reactive oxygen species (ROS), have been implicated as mediators of demyelination and axonal damage in MS.
Interferon-beta is an approved therapy for MS, due to the immunomodulatory, antiviral and stimulation of neurotrophic substances and endogenous opioids properties.
C-Phycocyanin is the principal phycobiliprotein of the Spirulina platensis, a blue - green alga, with several reports documenting its pharmacological properties as strongly antioxidant and anti-inflammatory.
After performing the molecular characterization of cellular immune response (TNF-α, IFN-γ, IL-10, MMP-9, TIMP-1) and oxidative stress parameters (MDA, AOPP, Peroxidation Potential, SOD, Catalase, Total Hydroperoxides) we found a profound oxidative stress state and a significant down-regulation in serum levels of the regulatory cytokine, IL-10, in MS patients when compared to controls.
Furthermore, in-vitro stimulation of peripheral blood mononuclear cells from MS patients with IFN-beta or c-Phycocyanin, significantly up-regulated mRNA as well as surface markers of Regulatory T cells.
Most MS approved therapies point only toward the inflammatory and immunological components. Still, there is an increasing need of approaches in response to the more complex physiopathological phenomenon of the disease.
Antioxidant and anti-inflammatory properties of c-Phycocyanin suggest it might be used in the treatment of neurodegenerative diseases like Alzheimer, Parkinson and also MS. Moreover, in MS, our results support the combination of IFN-beta and c-Phycocyanin for a wider spectrum and likely more effective treatment for the disease.

P5.10.12
Complex changes in invariant natural killer T (iNKT) cells in patients with different clinical forms and treatments of multiple sclerosis

S. De Biasi[1], *M. Nasi*[1], *A. Simone*[2], *D. Ferraro*[2], *F. Vitetta*[2], *L. Gibellini*[1], *M. Pinti*[3], *C. Del Giovane*[4], *P. Sola*[2], *A. Cossarizza*[1]; [1]*Department of Surgery, Medicine, Dentistry and Morphological Sciences, University of Modena and Reggio Emilia, Modena, Italy,* [2]*MS Center, Neurology Clinic, Nuovo Ospedale Civile Sant'Agostino Estense (NOCSAE), Modena, Italy,* [3]*Department of Life Sciences, University of Modena and Reggio Emilia, Modena, Italy, Modena, Italy,* [4]*Department of Diagnostic and Clinical Medicine and Public Health, University of Modena and Reggio Emilia, Modena, Italy, Modena, Italy.*

Although associations between Multiple Sclerosis (MS) and defects in invariant natural killer T (iNKT) or in proinflammatory CD8+CD161+ T cells have been reported, a more detailed characterization of these cells is needed to clarify their role in different form of MS.
We analyzed iNKTs subsets and CD8+CD161+ T cells in 66 patients: 52 with a Relapsing Remitting (RR), 9 with a Primary Progressive (PP) and 5 with a Secondary Progressive (SP) MS and 16 healthy controls (CTR).CD3+ T cells were counted with CyFlow Counter (Partec, Germany). PBMCs were stained with different mAbs for the analysis on a 6-color cytometer (Attune, Life Technologies, USA): anti-Va24Ja18 TCR, -CD4, -CD8, -CD161, -CD3, -CD19 and -CD14.
MS RR patients displayed a statistically significant lower number of iNKT cells, compared to CTR. Patients with other MS forms showed a similar trend. Among iNKT cells the CD8+ subset was diminished. The CD4-CD8- subset was significantly lower in the RR form compared to CTR. Among iNKT cells, the population of CD8+CD161+ cells was lower in all MS patients. When compared to CTR, PP and SP patients had a lower number and percentage of CD8+ T cells; CD8+,CD161+ T cells were lower in all SP patients vs. CTR. RR patients taking Fingolimod had a lower number of CD3+ T cells and a lower percentage of iNKT expressing CD4.
Changes in iNKT cell subpopulations we observed in RR patients, along with the trends present in the other patients, suggest a role for these cells in the pathogenesis of MS.

P5.10.13
MBP85-99 specific TCR repertoire in DRB1*15 patients affected by Multiple Sclerosis

G. Di Sante[1], *S. Rolla*[2], *A. Patanella*[3], *G. Migliara*[1], *A. Piermattei*[1], *M. Valentini*[1], *A. Batocchi*[1], *M. Mirabella*[1], *F. Novelli*[2], *F. Ria*[1]; [1]*Università Cattolica del Sacro Cuore, Rome, Italy,* [2]*Università di Torino, Turin, Italy,* [3]*Fondazione Don Carlo Gnocchi, Rome, Italy.*

Multiple Sclerosis (MS) is an inflammatory, chronic, disease of the CNS whose main genetic contribution is HLA DRB1*15 (DR2). We used Immunoscope analysis (TRBV-TRBJ spectratyping) to investigate the repertoire of T cells specific for MBP85-99 and MBP111-129 in 18 untreated DR2+ patients and 6 healthy DR2+ subjects. We identified specific MBP85-99TCR repertoire shared among the 18 MS patients that are characteristic of MS disease as they were not founded in HS: one was shared by 90% of MS DR2+ patients at the onset of disease and one present in 50% of CIS and MS patients. Moreover, the TCR repertoire specific for MBP85-99 is apparently broader in CIS than in MS patients. The MBP111-129-specific response used a distinct TCR repertoire with no significant variation in the number of expansions, suggesting that the response to this sub-dominant epitope doesn't play an active role in the disease. Twentyfive % of the investigated TCR rearrangements were used by Th1 cells, whereas one was exclusively used by Th17 cells;

its presence was downregulated following IFNβ therapy that also reduced the overall circulating MBP specific TCR repertoire. Intriguingly, before the relapse the Th17 specific-MBP85-99 TCR repertoire reappeared. Our observations may allow to focus future treatment on these MS-related antigen specific T cells.

P5.10.14
Frequency of Myelin Oligodendrocyte Glycoprotein (MOG) specific B cells in the blood and the CSF of patients with Multiple Sclerosis (MS)

A. Elong Ngono[1], *F. Guillot*[1], *A. Garcia*[1], *A. Genty*[1], *M. Salou*[1], *N. Degauque*[1], *A. Nicot*[1], *S. Brouard*[1], *D. Laplaud*[1,2], *J. Soulillou*[1];
[1]*INSERM UMR 1064, Nantes, France,* [2]*Service de Neurologie, CHU, Nantes, France.*

Multiple Sclerosis is a chronic inflammatory demyelinating disease of the Central Nervous System (CNS) where B cells play a key role. Indeed, recent advances with anti-CD20 therapy underscored involvement of B cells in MS outside their capacity to mature in plasmocytes.
Objectives: We measured the frequency and characterized circulating and intrathecal MOG-specific B cells in MS.
Methods: We used a bead-based method using fluorescent beads coupled to MOG. We first analyzed the frequency of MOG-specific B cells in 30 MS patients and 39 Healthy Volunteers (HV). Then, the anti-MOG B cell phenotype was characterized with CD19, CD27 and IgD staining.
Results: First, we obtained a substantial fraction of B cells binding to MOG coated beads in the blood of both HV and MS patients. We also observed a significant lower frequency of MOG-specific B cells in patients as compared to HV, which was not the case when using negative (albumin) or positive (tetanus toxin) control antigens. No significant difference was observed between MS and HV frequencies of memory and class switched cells in the MOG-specific B cells. Interestingly, preliminary results showed a trend for an increased frequency of MOG-specific B cells in the cerebrospinal Fluid (CSF) of MS patients.
Discussion and perspectives: A decreased frequency of circulating MOG-specific B cells may suggest apoptosis, modified homing and/or migration to CNS, although an increased frequency in CSF may promote a migration to the CNS. Further experiments will compare the transmigration of B cells from MS and HV across a Blood-Brain Barrier model.

P5.10.15
Effector T cell depolarization after glucocorticoid treatment impairs migration and APC conjugate formation

H. J. Fischer[1], *N. Müller*[2], *H. M. Reichardt*[1];
[1]*University of Göttingen Medical School, Institute for Cellular and Molecular Immunology, Göttingen, Germany,* [2]*University of Würzburg, Institute for Virology and Immunobiology, Würzburg, Germany.*

Glucocorticoids (GCs) are in widespread use for the treatment of acute relapses of multiple sclerosis (MS) patients. Currently, the beneficial effects of GCs are believed to primarily depend on transcriptional repression of T lymphocytes. In this study we investigated modulation of antigen-specific effector T cells within the first few hours after GC application. By use of polarized effector T cells in vitro we identified a novel mechanism by which GCs impact T cell function. Briefly after addition of GCs effector T cells started to depolarize, which impaired their migratory capacity and their ability to interact with APCs. The observed morphological changes were mediated by activation of the cytoskeleton associated ERM-proteins and correlated with an increased rigidity of the cells. The rapid GC effects were dependent on Phospholipase C activity, since its inhibition prevented effector T cell depolarization and ERM activation. In contrast, they were independent of altered gene expression, because inhibition of translation did not affect the observed cytoskeleton rearrangement. Furthermore, we could show that the morphological alterations of effector T cells also occured in vivo. Collectively, we have identified a novel mechanism through which GCs rapidly modulate effector T cell function.

P5.10.16
The atypical antipsychotic agents, clozapine and risperidone, reduce disease severity in the animal model of multiple sclerosis

L. K. Green[1], *M. Kharkrang*[1], *D. O'Sullivan*[1], *B. Conner*[2], *A. C. La Flamme*[1,3];
[1]*Victoria University of Wellington, Wellington, New Zealand,* [2]*University of Auckland, Auckland, New Zealand,* [3]*Malaghan Institute of Medical Research, Wellington, New Zealand.*

Multiple sclerosis (MS) is an immune-mediated disease of the central nervous system (CNS) whereby immune cells target the myelin sheath surrounding the nerve often leading to severe life-long disability. Current disease modifying medications available are only effective for one of the four MS disease forms and are further limited by treatment efficacy, toxicity, cost, and means of administration; thus, there is much interest in identifying alternative and more effective MS therapies. Recent work with atypical antipsychotic agents (AAPs) has shown that AAPs not only antagonize the dopamine D2 and serotonin 5-HT2α receptors but also have immunomodulatory properties capable of acting within the CNS in schizophrenic patients. We examined ability of the AAPs, clozapine and risperidone, to modify the immune response in MS and found that chronic oral administration reduces disease severity in the animal model, experimental autoimmune encephalomyelitis (EAE). Additionally, treatment with clozapine or risperidone reduces pro-inflammatory cytokine production by LPS-stimulated splenocytes while maintaining the antigen-specific IFN-ɣ response. Furthermore, we have identified synergy with clozapine and the commonly prescribed MS-treatment, glatiramer acetate whereby using suboptimal doses of each reduces the incidence of disease in EAE-immunised mice. Clozapine also demonstrates moderate MS disease protection at human equivalent doses below that prescribed for the treatment of schizophrenia thus circumventing the unwelcome side-effect of weight gain. Together these studies indicate that AAPs are effective immunomodulatory agents with the potential to treat immune-mediated diseases such as MS.

P5.10.17
Development and assessment of multifunctional gold nanoparticle system for dendritic cell targeting in the treatment of EAE

D. Haghmorad[1], *M. B. Mahmoudi*[1], *M. Hosseini*[2], *N. Tabasi*[1], *S. Zamani*[1], *M. Rastin*[1], *M. Mahmoudi*[1];
[1]*Immunology Research Center, Mashhad University of Medical Sciences, Mashhad, Iran,* [2]*Neuroscience Research Center, Department of Physiology, School of Medicine, Mashhad, Iran.*

Experimental autoimmune encephalomyelitis (EAE) is used as an animal model of Multiple sclerosis. Nanocarriers have provided a novel platform for target-specific delivery of therapeutic agents. Gold nanoparticles have recently emerged as an attractive candidate for delivery of various payloads into their targets. Delivering antigen to quiescent DC via DC-205 results antigen specific T cells is deleted and the mice became unresponsive to re-challenge even with adjuvant. Multifunctional gold nanoparticles were prepared by the reduction of aqueous chloroaurate ions with trisodium citrate and conjugate with MOG and Anti-DEC 205. EAE was induced in C57/BL6 mice by subcutaneous injection of MOG and CFA and intraperitoneal injection of pertussis toxin. Treatment group received a daily subcutaneous injection of multi functional MOG-Anti DEC-nanogold for 1 week. Clinical assessment, histological studies, flowcytometry, Brdu assay and Real-time PCR were performed for determine the profile of immune response. Our results showed significant Clinical score decrease in treatment group. Histological studies revealed lower lymphocytic infiltration and demyelination. The percentages of spleen $Foxp3^+$ cell and IL-4 positive cells induced and the percentages of spleen IL-17 and IFN-γ positive cells reduced in treatment group. Expression of transcription factor and cytokines related to Treg and Th2 showed increase in treatment group. It seems that produced multifunctional nanoparticles alleviate disease condition in EAE through reducing inflammatory immune responses. Significant increase in spleen Treg cells might be a sign for suppressed immune responses. Moreover, a significant decrease in Th17 demonstrates reducing inflammatory responses. Consequently, the balance between Treg and Th17 is deviated to Treg.

P5.10.18

1, 25-dihydroxyvitamin D3 ameliorates experimental autoimmune encephalomyelitis in C57BL/6 mice

D. Haghmorad[1], *M. B. Mahmoudi*[1], *A. Amini*[2], *N. Tabasi*[1], *S. Zamani*[1], *M. Rastin*[1], *M. Mahmoudi*[1];
[1]*Immunology Research Center, Mashhad University of Medical Sciences, Mashhad, Iran,* [2]*Department of Immunology, School of Medicine, Mashhad, Iran.*

Background: The experimental autoimmune encephalomyelitis (EAE) is an animal model for human multiple sclerosis. Vitamin D has several reported immunomodulatory properties including the reduced generation of pro-inflammatory $CD4^+$ Th1 cells and the increase in levels of the anti-inflammatory Th2 subset.
Method: 24 C57BL/6 male mice were divided into 3 groups: 1-Control, 2-EAE without treatment and 3- 1,25-dihydroxyvitamin D3 (Vitamin D3) treated EAE. EAE was induced in Groups2 and 3 by subcutaneous injection of MOG and CFA and intraperitoneal injection of pertussis toxin. Mice in group3 received intraperitoneal injection of 40 ng/kg vitamin D3 daily for 10 days. Clinical and weight assessments were performed daily. On day 25 animals were sacrificed. The brain tissues were stained for histological studies. Spleen cells were analyzed using flowcytometer and Real-time PCR. Brdu assay was used for splenocyte proliferation.
Results: Our results showed significant mean weight increase and Clinical score decrease in group3 comparing with group2. Histological studies revealed lower lymphocytic infiltration and demyelination in group3 compared to group2. Splenocytes proliferation showed significant reduction in group3 in comparison to group2. The percentages of spleen $Foxp3^+$ cell population in $CD4^+$ cells reduced in groups3 compared group2. Expression of transcription factor and cytokines related to Treg and Th2 showed significant increase in group3 in comparison to group2.
Conclusion: It seems that 1,25-dihydroxyvitamin D3 may alleviate disease condition in EAE mice through reducing inflammatory immune responses. Moreover it seems 1,25-dihydroxyvitamin D3 drives the polarization of Th2 and Treg subsets.

P5.10.19

miR-132 suppresses autoimmune encephalomyelitis by inducing cholinergic anti-inflammation: a novel Ahr-based exploration

H. Hanieh[1,2], *A. Alzahrani*[1];
[1]*King Faisal University, Alhasa, Saudi Arabia,* [2]*Immunology Frontier Research Center, Osaka University, Japan.*

MicroRNAs (miRNAs) are a small group of RNAs that is emerging as new pathway able to modulate autoimmune diseases. MiRNAs are involved in pathogenesis of multiple sclerosis (MS). However, the interaction of miRNAs with environmental-responsive transcription factors that play prominent roles in MS is still unexplored. Therefore, identification of novel mechanisms linking these two players in MS development could enable earlier treatment. Activation of aryl hydrocarbon receptor (Ahr) by 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) alleviates inflammation in Experimental Autoimmune Encephalomyelitis (EAE), the best MS model available; therefore, we predicted that TCDD ameliorates EAE by inducing miRNA(s) targeting inflammatory mediators. Here, we provide evidence about a novel miRNA-based mechanism through which TCDD induces a cholinergic anti-inflammatory response in EAE mice via upregulation of acetylcholiesterase (AChE)-targeting miR-132. $CD4^+CD62L^+$ cells purified from spleens of wild type or $Ahr^{-/-}$ C57BL/6 mice were stimulated with TGF-β alone or combined with IL-6 in the presence of TCDD. EAE was induced by MOG_{35-55} with/without i.p. injection of TCDD or antisense (as)-miR-132. MiR-132 was overexpressed or silenced by oligonucleotide transfection. AChE was quantified by qPCR and immunoblotting. We found that activation of Ahr by TCDD in T cells *in vitro* and *in vivo* induced miR-132 and its cluster partner miR-212,. Treating EAE mice with TCDD alleviated EAE symptoms, manifested by the reciprocal relationship between miR-132, AChE and pro-inflammatory cytokines. In conclusion, TCDD-activated Ahr mitigates autoimmune inflammation by miR-132-mediated cholinergic anti-inflammation. Therefore, our findings may represent a base for future application of miR-132 mimics in the treatment of MS.

P5.10.20

Study of the frequency of different CD8+ T cell subsets in patients with Multiple Sclerosis

M. Izad[1], *Z. Salehi*[1], *M. Sahraian*[2], *E. Janzamin*[3], *R. Doosti*[4], *P. Khosravani*[3];
[1]*Medical Faculty,Tehran University of Medical Sciences, Tehran, Iran,* [2]*Iranian Neurological Research Center, Sina Hospital, Tehran University of Medical Sciences, Tehran, Iran,* [3]*Flow Cytometrylaboratory, Department of Stem Cell and Developmental Biology, Royan Institute, Tehran, Iran,* [4]*2Iranian Neurological Research Center, Sina Hospital, Tehran University of Medical Sciences, Tehran, Iran.*

Multiple sclerosis (MS) is an inflammatory autoimmune disease of the central nervous system (CNS) that affects several million people worldwide and more than 50000 individuals in Iran which is now increasing at an alarming rate. Most prior reports have focused on the role of $CD4^+$ T cells and their subsets in the pathogenesis of the disease, but recent evidence points to an important role of CD8+ T cells comes from their dominance in white matter lesions in the CNS. In addition, like $CD4^+$ T cells, $CD8^+$ T cell subsets with distinct cytokine patterns: Tc1, Tc2 and Tc17, were described in mice and humans. However, the role of these T cell subsets in the pathogenesis of MS has been less investigated.
In this study we analyzed the frequency of CD8+ T cell subsets in Multiple sclerosis patients with different clinical patterns, RRMS (n=18), SPMS (n=10) and PPMS (n=4) using a Multi color flowcytometric assay in comparison with healthy age- and gender-match controls (n=10).
We found that Tc1 cells significantly increased in SPMS patients in comparison to patients in relapse phase, remission phase, PPMS and controls (p=0.04, p=.000, p=0.01 and p=.000 respectively). Our finding also indicated higher frequency of Tc1 cells in relapse patients than healthy controls (p=0.04). Moreover, our data showed significantly increased frequency of Tc17 cells in relapse patients as compared with remission (p=0.04) and healthy controls (p=0.05). These data demonstrate the contribution of different CD8+ T cell subsets in active MS phases.

P5.10.21

Biased Treg/Th17 balance away from regulatory toward inflammatory phenotype in relapsed multiple sclerosis and its correlation with severity of symptoms

A. Jamshidian[1], *M. Gharagozloo*[1,2], *V. Shayganneja*[1], *A. Pourazar*[1], *S. Zarkesh*[1];
[1]*Isfahan University of Medical Sciences, Isfahan, Iran,* [2]*University of Waterloo, Kitchener-Waterloo, ON, Canada.*

The opposing immune functions of Treg and Th17 lymphocytes despite their common developmental pathway, alongside Treg-Th17 plasticity, has led to a paradigm shift of each subset prevalence and function to their counterbalance and interaction duties in immune homeostasis. We have concomitantly evaluated the frequency of two subsets through surface and intracellular staining and flow-cytometry detection of peripheral blood mononuclear cells obtained from 23 definitively diagnosed relapsing-remitting multiple sclerosis (RR-MS) and 11 clinically isolated syndrome (CIS) patients in documented relapse of disease, and 23 healthy subjects. This study demonstrated a decreased Treg frequency versus an increased Th17 cells frequency and a several fold reduction in Treg/Th17 ratio in relapsed MS (both RR-MS and CIS) against health (all P Values<0.001). Also a reverse correlation between these two lymphocyte subsets was observed in controls but this correlation was lost in patients. Treg frequency and Treg/Th17 ratio were both negatively correlated with severity of symptoms, and Treg frequency had been increased with disease enduring (all P Values<0.05). Our results suggests an important role for Treg/Th17 imbalance in MS relapses which remains to be more studied in details of Treg functionality and Th17 sensitivity to their suppressive effect, also Treg-Th17 conversion and relative rates of IL-17 production by $FOXP3^+$Tcells in this disease. In addition to these clues for basic studies, our data confirms the changes of Treg/TH17 balance as an informative efficacy marker for evaluating or comparing the effectiveness of MS therapies, and highlights Treg-Th17 interaction as a target for new therapeutic approaches.

P5.10.22
Vav1 influences susceptibility to central nervous system autoimmunity

S. Kassem[1], *C. Colacios*[1], *A. Dejean*[1], *G. J Fournié*[1], *B. Malissen*[2], *A. Saoudi*[1];
[1]*Centre de Physiopathologie Toulouse Purpan, INSERM U1043, CNRS UMR5282, Toulouse, France, Toulouse, France,* [2]*Centre d'Immunologie de Marseille-Luminy, Marseille, Toulouse, France.*

Genetic studies performed by our group using congenic rats lead us to identify a locus on rat chromosome 9 that controls the size of the Foxp3 regulatory lymphocytes (Treg) and susceptibility to central nervous system inflammation (CNS). Fine mapping of this locus identified a non-synonymous SNP in the Vav1 gene that leads to the substitution of an arginine by a tryptophan. To provide the definitive proof that these Vav1 variants are involved and to understand their mechanisms of action, we generated a knock-in (KI) mouse characterized by an arginine (R) to a tryptophan (W) substitution in the Vav1 protein (Vav1W63 KI). Using this model, we provided the definite demonstration that this Vav1W63 mutation is responsible for the increased proportion of Treg and decreased susceptibility to CNS inflammation. In addition, we showed that autoreactive CD4 T cells from KI mice produce reduced amount of effector cytokines, IFN-γ, IL-17 and GM-CSF. Together, these results demonstrate that alterations in Vav1 signaling are involved in CNS inflammation and this may be related to the effect of Vav1 variants on both regulatory and effectors T cells.

P5.10.23
Microglia are potent producers of IFNβ in the context of autoimmunity and microbial stimulation

M. Kocur[1], *R. Schneider*[2], *A. Pulm*[1], *J. Bauer*[1], *S. Kropp*[1], *J. Alferink*[3], *T. Prozorovski*[2], *O. Aktas*[2], *S. Scheu*[1];
[1]*Institute of Medical Microbiology and Hospital Hygiene, Duesseldorf, Germany,* [2]*Department of Neurology, Duesseldorf, Germany,*
[3]*Department of Psychiatry and Psychotherapy, Muenster, Germany.*

Multiple sclerosis (MS), the most common neurological disease in western countries, is a chronic autoimmune disorder of the CNS. The standard medication of relapsing remitting MS is recombinant IFNβ decreasing frequency of relapses and severity of disease. Genetic deletion of IFNβ in mice also leads to aggravation of disease symptoms in the MS mouse model of MOG35-55 induced experimental autoimmune encephalomyelitis (EAE). The cell type responsible for the endogenous IFNβ production and their protective functions remain unknown.
Time course studies showed that IFNβ mRNA was expressed in the early phase of EAE in secondary lymphoid organs, while in the effector phase highest IFNβ levels were detected in the CNS, especially in the spinal cord. Using an YFP knock-in reporter mouse model for IFNβ we identified resident microglia in the CNS as main producers of IFNβ at the peak of EAE. FACS sorting of intracerebral cell populations according to the expression of CD45 versus CD11b and the analysis of the respective IFNβ mRNA levels confirmed these findings. An adult microglia culture system allowed for further functional analysis of IFNβ/YFP-producing microglia in vitro. Here poly(I:C) stimulation confirmed their high ability to produce IFNβ. In organotypic slice cultures IFNβ/YFP-producing cells showed the morphology of activated microglia and were stained co-positive for Iba-1 in situ.
Taken together, we show for the first time that activated microglia are the major endogenous producers of the protective IFNβ at the peak of EAE with analyses defining the specific functional properties of the IFNβ producers being currently performed.

P5.10.24
Features of Sema4D/CD72 expression in immune system in multiple sclerosis

E. M. Kuklina[1], *T. V. Baidina*[2], *I. Y. Danchenko*[2], *I. V. Nekrasova*[1];
[1]*Institute of Ecology and Genetics of Microorganisms, Russian Academy of Science, Ural Department, Perm, Russian Federation,* [2]*Perm State Medical Academy, Perm, Russian Federation.*

Sema4D is a semaphorin family member, mainly of lymphocyte origin, that is exist in membrane-bound or soluble forms and involved both in nerve and immune system regulation. A series of last findings suggests the involving of Sema4D in pathogenesis of multiple sclerosis (MS), namely, the resistance of Sema4D$^{-/-}$ mice to the development of experimental autoimmune encephalomyelitis, the animal MS model, as well as Sema4D-induced apoptosis in oligodendrocytes, the key factors of demyelination. Here, the features of the expression of Sema4D, as well as of their receptor, CD72, by lymphocytes of MS patients have been studied. MS was shown to be associated with the increasing of Sema4D level on the intact T lymphocytes, as well as with more intensive semaphorin shedding from cell membrane in case of lymphocyte activation. Taking into account a negative Sema4D role in nerve fibers myelination, the data obtained suggest its possible involving in MS pathogenesis. Additionally, the decreasing of the expression of Sema4D receptor, CD72, on B lymphocytes has been revealed in MS patients. Since CD72 is a negative B cell regulator, the decreasing of its level in MS may be responsible for hyperactivation of B lymphocytes, a key players in MS, and along with the increasing of Sema4D expression may represent a new mechanism of MS induction and/or progression.

P5.10.25
NK cells are functionally defective in multiple sclerosis

A. Laroni[1], *R. Gandhi*[2], *E. Armentani*[1], *I. Gandoglia*[1], *F. Ivaldi*[1], *G. L. Mancardi*[1], *H. L. Weiner*[2], *A. Uccelli*[1];
[1]*University of Genoa, Genova, Italy,* [2]*Harvard University, Boston, MA, United States.*

Multiple Sclerosis (MS) pathogenesis might be linked to impaired function of regulatory subsets of immune cells. In vitro, activation of NK cells with IL-27 or the anti-CD25 monoclonal antibody can induce suppressor function of CD56bright NK (NKbr) cells with mechanisms involving lytic enzymes such as perforin and granzyme K. The pro-inflammatory cytokines, IL-12 and IL-15, activate NK cells and are upregulated in MS patients. Our hypothesis is that under inflammatory conditions, NKbr cells acquire T-cell suppressor function to regulate T-cell activation. We further postulate that such a feedback mechanism is impaired in MS.
Methods: NKbr and CD56dim NK cells (NKdim) isolated from healthy subjects (HS) and MS patients were cultured with activation with IL-12 and IL-15. NK Cells were then co-cultured with autologous CD4+ T cells and T cell proliferation was tested. Cytotoxicity of NK cells towards T cells in co-culture was assessed. Results. Activated NKbr cells from HC, but not MS patients, suppressed autologous T cell proliferation. We found evidence of cytotoxicity of NKbr cells towards T cells in HS. Expression of cytotoxic enzymes was similar in MS patients and HS. In conclusion, we provide evidence that the suppressor function of NKbr cells is induced by inflammatory stimuli in HS. While we found a normal number of circulating NKbr cells in MS patients at early disease stage, their suppressor function appears to be defective. Functional studies are needed in order to dissect the mechanism of such NK immunoregulatory function in HC and the altered response observed in MS.

P5.10.26
Multiple sclerosis mesenchymal stromal cells exhibit a distinct gene profile and decreased immunosuppressive properties in relation to healthy control cells

***G. Lelis Vilela de Oliveirra**, K. C. R. Malmegrim, K. W. A. Lima, D. G. Ribeiro, A. Colombini, D. T. Covas, J. C. Voltarelli, E. A. Donadi; National Institute of Science and Technology in Stem Cells and Cell Therapy, Ribeirão Preto, Brazil.*

Mesenchymal stromal cells (MSCs) have immunosuppressive effects and have been used for the treatment of autoimmune diseases. We evaluated the gene expression profiles and the in vitro immunomodulatory properties of MSCs obtained from multiple sclerosis patients and controls. Bone-marrow MSCs were isolated by plastic adherence. Gene expression profile was evaluated by microarrays using an Agilent platform. For coculture assays, PBMCs were labeled with CFSE, added to patient or control MSCs, and stimulated with PHA. After 5 days, T-cell proliferation was assessed by flow cytometry. IL-10 and TGF-β were measured in supernatants by CBA flex. The results were analyzed by the Limma-T and Mann-Whitney tests. The study was approved by the local Ethics Committee. Compared to controls, 641 differentially expressed genes in patient MSCs ($p<0.01$; fold change≥2), comprising 262 repressed genes, including TGFB1 and HGF and, 379 induced, among them, IL10 and IL6. The inhibitory effect of patients MSCs (52,1 ± 5,6%) on T-cell proliferation was significantly reduced ($p=0.024$) compared with controls (69.4 ± 7.2%). There were no differences in the percentages of CD4+CD25hiFoxp3+ cells in both MSCs cocultures. IL-10 and TGF-β secretion were significantly diminished ($p<0.05$) in supernatants from cocultures with patient MSCs (IL-10: 53.8 ± 49.4; TGF-β: 59.4 ± 24.6 pg/mL) compared with controls (IL-10: 109.9 ± 64.6; TGF-β: 226.6 ± 153.2 pg/mL). Concluding, patient and control MSCs exhibited distinct transcription profiles and patient MSCs secreted low amounts of IL-10 and TGF-β and exhibited decreased ability to inhibit T lymphocyte proliferation. Financial support: FAPESP.

P5.10.27
The regulation synthesis and hydrolysis of cGMP in brain cortex rats during the course of experimental autoimmune encephalomyelitis (EAE)

***N. Lubina-Dąbrowska**[1], G. Sulkowski[2], K. Turska[3], J. Langfort[2], A. Stępień[1], M. Chalimoniuk[3];*
[1]Millitary Institute of Medicine, Warsaw, Poland, [2]Mossakowski Medical Research Center, of Polish Academy of Sciences, Warsaw, Poland, [3]Faculty of Biology and Environmental Sciences Cardinal Stefan Wyszynski University in Warsaw, Warsaw, Poland.

cGMP has important functions in the central nervous system. Have a protective effect on oligodendrocytes and microglia modulates macrophage response to inflammatory agents. Mizrachi et al. (2010) observed changes in the levels of phosphodiesterase (PDEs) in multiple sclerosis (MS), which suggests that PDEs may be a potential target for the treatment of MS. The aim of this study was to evaluate the regulation of cGMP concentration in the cerebral cortex of the rat EAE Levis depending on the stage of the disease. To induce EAE, rats were immunized with inoculums containing guinea pig spinal cord in PBS and homogenized emulsion in complete Freund's adjuvant containing 110 mg per 100 ml of the appropriate antigen into the emulsion and the addition of 4 mg / ml Mycobacterium tuberculosis (H37Ra). In the group of rats were sacrificed 5 animals respectively at 0, 4, 8, 12 and 20 days of the experiment. EAE induced a dramatic reduction in the concentration of cGMP in the brain, which corresponded closely to the course of neurological symptoms and weight loss. These changes are accompanied by decreasing soluble guanlylate cyclase, PDE 9 and increase expression of PDE 2. No change was observed PDE5. The greatest changes were observed in 12 and 20 day experiment. Match the severity of the disease in MS relapse. These results suggest that the lower cGMP level by PDE2 might play important role in pathological changes and neuronal dysfunction in EAE.

P5.10.28
Natural killer cells in early multiple sclerosis

***H. Mareckova**[1], L. Skacikova[1], Z. Hruskova[1], D. Horakova[2], E. Havrdova[2];*
[1]Inst. Immunology and Microbiology, Medical faculty, Charles University, Prague, Prague 2, Czech Republic, [2]Neurology Clinic, Medical faculty, Charles University, Prague, Prague 2, Czech Republic.

In 85% of young adults with multiple sclerosis (MS), onset is a subacute clinically isolated syndrome (CIS). However, only 30-70% of patients with a CIS develop MS. There are some potential candidates for markers to predict the development of MS in patients with CIS, for example an increase of CD5 positive subset of B lymphocytes in peripheral blood.
The aim of our study was to evaluate other immunological predictors of CIS conversion into MS.
Method: 148 patients with CIS treated with interferon beta have been followed for 3 years. Lymphocyte subsets were analyzed by flow cytometry at baseline and after 6, 12, 24 and 36 months of therapy. 101 patients
remained on the assigned therapy throughout the 3 year follow up(respondents), whereas 47 patients converted to MS (non-respondents).
Results: Higher numbers (16,7%) of natural killer (NK) cells in patients with CIS, compared to patients with MS, were found. A permanent statistically significant very slow reduction of NK cells subpopulation was found in the respondent group after 6,12,24 and 36 months of interferon therapy
(17% to 10% in 3 years). Very significant reduction was found in the non-respondent group (15,7 % to 12% within 6 month) followed by nonsignificant reduction to 11,5% by the end of the study.
As in other autoimmune diseases, NK cells of MS patients naïve to treatment are present in reduced numbers. A relatively high numbers of NK cells and especially their slow reduction in CIS could be good prognostic factor.

P5.10.29
Microvesicles derived from mesenchymal stem cells: potent organelles for induction of tolerogenic signaling

***A. Mokarizadeh**;*
Kurdistan University of Medical Sciences, Sanandaj, Iran.

Generation and maintenance of immunological tolerance is pivotal in autoimmunity. Regulatory molecules of Programmed Death Ligand-1 (PD-L1), galectin-1 and TGF-β are described as key mediators of peripheral tolerance, that actively suppress auto-reactive cells and inhibit their induction of tissue damage. Accordingly, biological intervention in host immune system for induction of peripheral tolerance is pivot to many recent studies. Mesenchymal stem cell-derived microvesicles (MVs) are viewed as potential mediators in peripheral tolerance toward auto-reactive cells via bearing of tolerogenic molecules. Here, MVs were isolated from mesenchymal stem cell (MSC) cultures' conditioned medium. They were explored for the expression of PD-L1, galectin-1 and membrane bound TGF-β by flow cytometery. The immunoregulatory effects of MVs on splenic mononuclear cells (MNCs) derived from experimental autoimmune encephalomyelitis (EAE) affected mice were investigated using MTT assay, ELISA and flow cytometry. MVs derived from MSCs expressed PD-L1, galecin-1 and membrane-bound TGF-β. MVs exhibited the potential to inhibit auto-reactive lymphocyte proliferation and also the potency to promote them to secret anti-inflammatory cytokines of IL-10 and TGF-β. Interestingly, inducing inflammatory setting on MSCs, revealed the enhancing regulatory effects of MVs via increased expression of some regulatory molecules, specifically PD-L1 and TGF-β. Induction of tolerogenic signaling, promotion of CD4+ CD25+ Foxp3+ regulatory T cells generation and apoptotic activity towards activated T cells are shown to be possible mechanisms involved in MV-mediated regulation. A recent study suggests MSC-derived MVs as potent organelles for induction of peripheral tolerance and modulation of immune responses.

The association of Epstein-Barr virus infection with multiple sclerosis

A. Najafipoor[1]*, R. Roghanian*[2]*;*
[1]*Univercity of Isfahan, Isfahan, Iran,* [2]*University of Isfahan, Isfahan, Iran.*

Background: Multiple sclerosis (MS) is a chronic inflammatory and demyelinating disease of the CNS with as yet unknown cause. Epstein-Barr virus (EBV) infection is widely considered to be a risk factor for multiple sclerosis. Individuals with high levels of antibodies to the EBV viral capsid antigen (VCA) have an increased risk of developing MS.
Objective: The aim of this study was to find out if there is any relationship between the elevated titer of antibody against EBV and the onset of MS.
Method: Sera were collected from fifty patients with primary clinical MS manifestation (10 male subjects, 40 female subjects, mean age 30 years). Samples were prepared from the MS Clinic in Alzahra and Kashani Hospitals in Isfahan. The level of Immunoglobulin G (IgG) against EBV capsid antigen (EBV-CA) was assessed by using commercially available quantitative ELISA.
Results: Our results indicated that in all MS patients' sera higher titer of IgG to EBV-CA with mean of 178.2 IU/ml comparing to individuals normal range ≤ 16 IU/ml were seen in the onset of MS disease.
Conclusion: These finding suggest that this virus plays an important role in the pathogenesis of MS.

P5.10.31
Monomethyl fumarate induces a switch of activated microglia from a pro-inflammatory to a neuroprotective phenotype

B. Parodi[1]*, C. Cordano*[1]*, D. Giunti*[1]*, C. Usai*[2]*, N. Kerlero De Rosbo*[1]*, R. H. Scannevin*[3]*, A. Uccelli*[1]*;*
[1]*Department of Neuroscience, Ophthalmology and Genetics. University of Genoa, Genoa, Italy,* [2]*National Research Council, University of Genoa, Genoa, Italy,* [3]*Biogen Idec, Cambridge, MA, United States.*

BG-12, a fumaric acid ester with immunomodulatory and neuroprotective potential, is under investigation as treatment for multiple sclerosis. We hypothesize that its beneficial effects are mediated, at least in part, through its action on microglia. This possibility was investigated in vitro using activated microglial line and primary cell cultures in the absence or presence of its bioactive metabolite, monomethyl fumarate (MMF). MMF inhibited microglia activation by lipopolysaccharide (LPS), significantly reducing the production and expression of pro-inflammatory molecules, TNFα, IL1β, and iNOS, as well as inhibiting the expression of PU.1, a transcription factor that is considered a marker of activation phenotype of microglia. MMF also inhibited the proliferation of LPS-activated primary microglia. Conversely, MMF significantly increased the expression of receptors typical of "steady-state microglia", NURR1, CD200R, and CX3CR1. MMF induced functional changes in activated microglia increasing calcium concentration and phagocytosis, itself associated with an increased expression of TREM2, through which signaling in microglia facilitates debris clearance, creating a pro-regenerative environment. These findings suggest that upon exposure to MMF, microglia revert from a pro-inflammatory to a neuroprotective phenotype.
We have postulated that the effects of MMF are mediated, at least in part, through binding to the nicotinic acid receptor HCA2, for which it is an agonist. We have now shown that HCA2 is expressed on microglia and will present results of experiments designed to ascertain if signaling through HCA2 pathway is involved in the mode of action of MMF in microglia, and how this leads to downregulation of the inflammatory phenotype.

P5.10.32
Deficiency of CD8 effector memory T cells impairs response to Epstein-Barr virus in multiple sclerosis

M. P. Pender[1]*, P. A. Csurhes*[1]*, C. M. M. Pfluger*[1]*, S. R. Burrows*[2]*;*
[1]*The University of Queensland, Brisbane, Australia,* [2]*Queensland Institute of Medical Research, Brisbane, Australia.*

A large body of evidence indicates that infection with Epstein-Barr virus (EBV) has a role in the pathogenesis of multiple sclerosis (MS) and the other human chronic autoimmune diseases. We have hypothesized that a genetically determined defect in the elimination of EBV-infected B cells by cytotoxic CD8 T cells predisposes to the development of chronic autoimmune diseases by allowing EBV-infected autoreactive B cells to accumulate in the target organ (Pender MP, 2003, Trends Immunol 24:584-588). Using interferon-γ (IFN-γ) enzyme-linked immunospot assays we recently demonstrated that MS patients have a decreased frequency of CD8 T cells reactive to their own EBV-infected B cells (Pender MP et al, 2009, J Neurol Neurosurg Psychiatry 80:498-505). In the present study we used 9-colour flow cytometry and intracellular IFN-γ staining to analyze further the T cell response to EBV-infected autologous lymphoblastoid cell lines and synthetic EBV peptides in EBV-seropositive patients with MS and EBV-seropositive healthy subjects. Our results demonstrate that the decreased CD8 T cell response to EBV in MS is due to a deficiency of effector memory (EM) ($CD45RA^-$ $CCR7^-$) CD8 T cells. We propose that this decreased memory CD8 T cell response allows EBV-infected autoreactive B cells to accumulate in the central nervous system, which leads to the development of MS. These findings have implications for the prevention and treatment of MS and the other human chronic autoimmune diseases by controlling EBV infection.

P5.10.33
Investigating the causes of A20 down-regulation in Multiple Sclerosis: genetic mechanisms and hormonal modulations

S. Perga[1]*, S. Martire*[1]*, N. D. Navone*[1]*, F. Montarolo*[1]*, P. Berchialla*[2]*, A. Bertolotto*[3]*;*
[1]*Neuroscience Institute Cavalieri Ottolenghi (NICO), Orbassano, Italy,* [2]*University of Turin Biological and Clinical Science Department, Turin, Italy,* [3]*AOU San Luigi Gonzaga and Neuroscience Institute Cavalieri Ottolenghi (NICO), Orbassano, Italy.*

A20 enzyme (codified by TNFAIP3 gene) is a key player in the negative regulation of inflammation and immunity. Recently we demonstrated a significant decrease of A20 expression in peripheral blood of Multiple Sclerosis (MS) patients, with a reversion to normal level during pregnancy.
To investigate the causes underlying A20 expression deregulation in MS, we assessed possible genetic mechanisms and pregnancy-related hormonal factors.
To evaluate a correlation between A20 genotype and gene expression, we performed a haplotype tagging SNPs analysis in A20 coding and regulatory regions. We identified and genotyped 28 tagSNPs in 50 treatment-naïve MS patients and 50 healthy controls (HC). A20 expression resulted significantly lower in MS patients compared to HC. However, no single SNP or haplotype combinations were significantly associated to A20 expression.
In parallel, we evaluated the effects of beta-estradiol, progesterone, hydrocortisone and prolactin, followed or not by LPS/PHA stimulation, on whole blood A20 expression in 10 MS patients and 20 HC. We demonstrated that all hormones are able to modulated A20 expression in both HC and MS patients, but in the latter with a lower magnitude. However, while in HC all hormones increased A20 level, in MS patients progesterone decreases it. This was rescued by LPS/PHA addition but at lower levels compared to HC.
A20 down-regulation in MS patients seems not to depend on genetic mechanisms, but it is partially influenced by sex-hormones. Moreover, we can hypothesize that other mechanisms such as epigenetic ones could have a role in the decreased gene level observed in MS.

P5.10.34
Increased CD8+ T Cell Response to Epstein-Barr Virus Lytic Antigens in the Active Phase of Multiple Sclerosis

E. Piras[1], *B. Serafini*[2], *C. Gasperini*[3], *R. Mechelli*[4], *M. Salvetti*[4], *D. Centonze*[5], *G. Borsellino*[1], *F. Aloisi*[2], *L. Battistini*[1], *D. Angelini*[1];
[1]*Santa Lucia Foundation Scientific Institute, Rome, Italy,* [2]*Department of Cell Biology and Neuroscience, Istituto Superiore di Sanita', Rome, Italy,* [3]*Department of Neurosciences, S Camillo Forlanini Hospital, Rome, Italy,* [4]*Centre for Experimental Neurological Therapies, S Andrea Hospital, Faculty of Medicine and Psychology, Sapienza University, Rome, Italy,* [5]*Department of Neurosciences, Tor Vergata University, Rome, Italy.*

Several evidence support a role for Epstein-Barr virus (EBV) in the aetiology of multiple sclerosis (MS) although the mechanisms are debated. This study was designed to assess the prevalence and magnitude of CD8+ T-cell responses to EBV latent (EBNA-3A, LMP2-A) and lytic (BZLF-1, BMLF-1) antigens in relapsing-remitting MS patients (n=113) and healthy donors (HD) (n=43) and to investigate whether the EBV-specific CD8+ T cell response correlates with disease activity. Using flow cytometry and HLA class I pentamers in MS patients and HD we observed that a significantly lower fraction of inactive MS patients had a detectable CD8+ T cell response to peptides from EBV latent (EBNA-3A, LMP2-A,) and lytic (BZLF-1, BMFL-1) proteins compared to HD and active MS patients. The lower response to EBV in these patients was associated with higher expression of the inhibitory molecule Programmed Death-1 receptor on viral-specific CD8+ T cells. Marked differences in the prevalence of EBV-specific CD8+ T cell responses were observed in patients treated with interferon-β and natalizumab. Most importantly, the frequency of CD8+ T cells specific for EBV lytic antigens was significantly higher in active MS patients compared to HD, and longitudinal monitoring of two patients revealed expansion of CD8+ T cells specific for EBV lytic antigens during active MS. Analysis of post-mortem MS brain samples showed expression of the EBV lytic protein BZLF-1 in inflammatory white matter lesions. We therefore propose that lowered control of EBV infection during inactive MS could set the stage for intracerebral viral reactivation and disease relapse.

P5.10.35
Dysfunction of gene expression in B cells from patients with multiple sclerosis

C. Policano*, V. Annibali, R. Umeton, A. Annese, A. Palermo, R. Mechelli, M. Buscarinu, G. Mattei, G. Ristori, M. Salvetti;*
Centre for Experimental Neurological Therapies, S. Andrea Hospital-site, Department of Neuroscience, Mental Health and Sensory Organs (NESMOS), Faculty of Medicine and Psychology, Sapienza University, Roma, Italy.

Over the past two decades B cells have increasingly moved into the spotlight in multiple sclerosis (MS) research. The primary aim of this project was to analyze the whole B cell-transcriptome (coding and non-coding RNA) in MS context.
We studied peripheral CD19+ B cell subsets obtained from 10 MS patients, 10 healthy donors (HD), and 2 monozygotic twins discordant for MS. All affected individuals were treatment-naïve and all the investigations were performed at least three months after the last steroid therapy. Microarray data was performed using two Affymetrix's GeneChip: Human Exon and miRNA. The statistical analysis was performed by means of two different software packages, whose output results have been compared: Partek Genomic Suite (version 6.6) and our own analysis pipe-line based on EasyExon tools. Ingenuity Pathway Analysis (IPA). The miR Analysis was performed by IPA microRNA Target Filter.
We focused on EasyExon (less permissive) results and we selected 26 genes differentially expressed in MS compared HD ($p<0.03$ and $|\text{fold change}|>=1.5$). The list was then submitted to IPA and performed a pathway analysis that led us to choose seven, among the original 26 genes that were among those differentially expressed MS patients and HD. Performing the miR analysis with IPA, it has emerged that 6 genes from our list are targeted by 9 miR differentially expressed in MS/HD groups. Peripheral B cell compartment seems to be promising for the identification of mRNA and miR signature. We have identified an MS-related pattern, in terms of miR and/or genes.

P5.10.36
The role of Chlamydia pneumonia in Multiple Sclerosis

M. Rahimi*, R. Roghanian;*
Isfahan University, Isfahan, Iran.

Background: Multiple sclerosis (MS) is a chronic inflammatory and relatively common demyelinating disease of central nervous system white matter in humans with as yet unknown cause. *Chlamydia pneumonia* (Cpn) is an obligate intracellular bacterium that infects the respiratory tract of humans. Cpn has been proposed as a possible etiologic agent in multiple sclerosis (MS). Some support for this hypothesis is provided by the detection of higher serum anti-Cpn immunoglobulin G (IgG) titers among Patients with MS compared to controls.
Objective: The aim of this research was to find out the role of *Chlamydia pneumonia* in multiple sclerosis by detecting the level of IgG and IgM in patients with MS.
Method: Sera were collected from fifty patients with primary clinical MS manifestation (10 male subjects, 40 female subjects, mean age 30 years). Samples were prepared from the MS Clinic in Alzahra and Kashani Hospitals in Isfahan. The level IgG and IgM against *Chlamydia pneumoniae* was assessed by using commercially available quantitative and semi quantitative ELISA.
Results: Our results revealed higher titer of IgG in 21out of 50 MS patients' with mean of 87.12 IU/ml comparing to individuals normal range ≥ 22 IU/ml. Detection of IgM showed only one elevated titer in all the patients.
Conclusion: These findings suggest that *Chlamydia pneumonia* plays an important role in the pathogenesis of MS.

T cell repertoire analyses and comparison between blood, CSF and CNS lesions in patients with Multiple Sclerosis

M. Salou[1], *A. Gainche-Salmon*[1], *L. Michel*[1,2], *D. Loussouarn*[3], *A. Garcia*[1], *S. Wiertlewski*[2], *J. Soulillou*[1], *S. Brouard*[1], *N. Degauque*[1], *D. Laplaud*[1,2,4];
[1]*INSERM UMR 1064 - ITUN, Nantes, France,* [2]*Department of Neurology, University Hospital, Nantes, France,* [3]*Anatomo-pathology department, University hospital, Nantes, France,* [4]*CIC INSERM 004, university hospital, Nantes, France.*

Background. Multiple Sclerosis (MS) is an inflammatory autoimmune demyelinating disease of the central nervous system (CNS). Although assumed in several studies, the concordance between the T-cell repertoires in the periphery and in the CNS has never been studied. If proved, T cells implicated in the disease process could be studied directly from the periphery.
Methods. Lesions from the brain and the spinal cord were classified according to their inflammatory and demyelinating status. The TCR Vb repertoire was analyzed by CDR3 spectratyping in 15 lesions, in the CSF and in the blood (purified CD8+ and CD4+ T cells) from three deceased patients with MS. Sequencing was then used to assess clonality.
Results. While some concordance between the blood CD8+ T cell repertoire and the CNS lesions was observed (50% +/- 14%), the TCR Vb repertoire in the CSF was closer to the one in the CNS (80% +/- 7%). Interestingly, several monoclonal Vb families were found in the lesions while appearing polyclonal in the periphery.
Conclusion. Taken together, these results strongly suggest that the CSF is a window on the T cell clones infiltrating the CNS lesions. The presence of monoclonal Vb families exclusively in the CNS lesions may hypothesize a local proliferation of the T cell clones. Additional experiments using laser-capture microdissection on the CNS will be undertaken on the infiltrating CD8+ T cells. This may allow a better understanding of the functional role of these cells, relative to their monoclonal/polyclonal status in the CNS and/or the periphery.

P5.10.38
Expression of Th1/Th17-related genes in IFN-β-treated relapsing-remitting multiple sclerosis patients

E. Savic[1], *M. Markovic*[1], *J. Drulovic*[2], *I. Dujmovic Basuroski*[2], *S. Mesaros*[2], *V. Pravica*[1], *D. Popadic*[1], *M. Mostarica Stojkovic*[1];
[1]*Institute of Microbiology and Immunology, School of Medicine, University of Belgrade, Belgrade, Serbia,* [2]*Institute of Neurology, Clinical Centre of Serbia, School of Medicine, University of Belgrade, Belgrade, Serbia.*

In multiple sclerosis (MS), T helper cells (Th) 1 and Th17 are considered the orchestrators of the myelin destruction. Recently, in animal studies, IFN-γ and IL-17A double-knockout cells were proven enchephalitogenic via GM-CSF production. It is yet unknown how IFN-β treatment, first-line therapy in relapsing-remitting (RR) MS, affects GM-CSF mRNA levels.
RRMS patients (n=45) starting IFN-β1b therapy were considered responders (R, n=20), if without relapses or progression on EDSS during 2 year follow-up and the rest as non-responders (NR, n=25). Gene expression relative to GAPDH was determined by TaqMan qPCR for marker of IFN-β biological response (MX1), Th1/17 polarizing cytokines (IL-12/23p40, IL-12p35, IL-23p19), respective receptors (IL-12Rβ1, IL-12Rβ2, IL-23), transcription factors (Tbet, RoRγt) and effector cytokines (IFN-γ, IL-17A, IL-17F, GM-CSF) in peripheral blood mononuclear cells before start and at 6, 12 and 24 months of IFN-β therapy.
R and NR had similar MX1 mRNA levels. In both groups, IL-12/23p40, IL-12p35, IL-23p19 and GM-CSF mRNA expression decreased, while IL-23R, RoRγt and IFN-γ statistically significantly increased at 6 months. Other mediators did not change statistically significantly during follow-up. However, all altered mRNA levels reverted to baseline at 24 months, except IL-23R, which had statistically significantly higher expression in NR at 24 months. Similarly, GM-CSF had a tendency of higher expression in NR than in R at 24 months.
R and NR did not differ in IFN-β biological response, according to MX1 mRNA levels. The trend towards higher GM-CSF and IL-23R mRNA levels in NR during IFN-β therapy warrants further investigation.

The vitamin D and expression of IL-10 and NF-KB genes in Iranian multiple sclerosis patients

Z. Shirvani Farsani[1], *M. Behmanesh*[1], *M. Sahraian*[2,3], *R. Doosti*[3];
[1]*Tarbiat modares university, Tehran, Iran,* [2]*Department of Neurology, Tehran University of Medical Sciences, Tehran, Iran,* [3]*Multiple Sclerosis Research Center, Tehran, Iran.*

Background: Multiple sclerosis (MS) is a complex autoimmune disease of the central nervous system characterized by chronic inflammation, demyelination, and axonal damage. Despite decades of research, the etiology and pathogenesis of MS is still unknown, though both genetic and environmental components of the disease seem evident. One potential environmental factor affecting the development of MS may be vitamin D [1,25-(OH)2D3]. A protective effect of Vitamin D on multiple sclerosis is supported by the reduced risk associated with sun exposure and use of Vitamin D supplements. Moreover, high circulating levels of Vitamin D have been associated with lower risk of multiple sclerosis. We hypothesize that 1,25 dihydroxyvitamin D3 may regulate gene expression patterns in a manner that would resolve inflammation.
Methods: To test this hypothesis, Multiple sclerosis patients placed into a vitamin D supplemented group. Blood samples from 10 patients with MS before and 2 months after vitamin D therapy and 10 age and sex-matched controls obtained. Level of the IL-10 mRNA measured using Real Time PCR and the results compared.
Results: We observed expression changes of the IL-10 gene in MS patients after vitamin D therapy.
Conclusion: In summary, this is the first study to report the expression of the IL-10 in MS patients supplemented vitamin D. This study further implicates vitamin D as a strong environmental candidate in MS by demonstrating functional interaction with the effecting genes in MS.

P5.10.40
Alpha-melanocyte-stimulating hormone (α-MSH) inhibits the development and progression of autoimmune encephalomyelitis by generating functional regulatory T cells

N. Sucker*, L. Klenner, S. Laggies, C. Bürger, T. Luger, K. Loser; Department of Dermatology, Universitiy of Münster, 48149 Münster, Germany.*

The neuropeptide α-MSH is a potent immunomodulator capable of inducing immunosuppression and tolerance. Using the mouse model of experimental autoimmune encephalomyelitis (EAE) we systemically treated MOG-immunized mice with α-MSH before and after the onset of hind limb paralysis. Whereas control mice showed a significant weight loss and developed severe ascending paralysis, mice preemptively injected with α-MSH were resistant to EAE development. Notably, therapeutic treatment attenuated EAE progression and prevented mice from weight loss. Flow cytometry, immunofluorescence staining and gene expression analyses revealed the absence of pathogenic Th17 and Th1 cells from brain tissue of α-MSH-treated animals. This effect was mediated by up-regulated numbers of $Foxp3^+$ regulatory T cells (Treg) in α-MSH-injected mice versus controls. Since α-MSH has been shown to expand Treg by the induction of tolerogenic dendritic cells (DC) we analyzed the DC phenotype at different stages of disease. DC from α-MSH-treated mice expressed increased levels of PD-L1 or IL-10 and down-regulated maturation markers pointing to the induction of a tolerogenic DC phenotype. Since signaling via melanocortin-1-receptor (MC-1R) mediates the immunomodulatory effects of α-MSH we induced EAE in MC-1R-deficient mice. Interestingly, upon α-MSH injection these mice developed hind limb paralysis similar to PBS treated controls demonstrating that binding to MC-1R is essential for the α-MSH-mediated prevention of EAE. Together, these data indicate that α-MSH induces tolerogenic DC and expands functional Treg *in vivo.* These Treg suppress pathogenic Th1 and Th17 cells during EAE development, suggesting α-MSH as potential therapeutic option for the treatment of patients with moderate multiple sclerosis.

Regulatory T-cells in relapsing-remitting multiple sclerosis patients: Effect of disease activity and treatment regimens

N. Dimisianos[1], *M. Rodi*[2], *D. Kalavrizioti*[2], *A. Lastic*[2], *P. Sakellaraki*[2], ***A. Tapeinou***[3], *T. Tselios*[3], *J. Matsoukas*[3], *P. Papathanasopoulos*[1], *A. Mouzaki*[2];
[1]*Neurology Clinic, Medical School & University Hospital, Patras, Greece,* [2]*Division of Hematology, Departmant of Internal Medicine, University of Patras, Patras, Greece,* [3]*Department of Chemistry, University of Patras, Patras, Greece.*

Multiple sclerosis (MS) is an inflammatory, demyelinating disease of the central nervous system (CNS), resulting from an imbalance between CNS-specific CD4+ autoreactive T-cells and peripheral suppressive mechanisms, mediated mainly by regulatory T-cells (Tregs). In this study, we collected peripheral blood samples from 83 patients with relapsing-remitting MS (RRMS) and 45 healthy controls (HC), to determine the sizes of their Treg populations, and the effects of disease activity and treatment regimens (methylprednizolone, interferon, natalizumab) thereof. Treg populations studied included CD4+CD25highFoxp3 Tregs (nTregs), CD3+CD4+HLA-G+, CD3+CD56+ (NKT), CD8+CD28- (CD8+ Tregs), and CD56bright. We also cultured isolated PBMC±different peptides, mapping to myelin oligodendrocyte glycoprotein or myelin basic protein epitopes, to determine the responsiveness of Tregs to autoantigens. The results showed decreased levels of nTregs in RRMS patients in the acute phase±methylprednizolone, but HC levels in acute phase patients+interferon; patients in remission(-treatment) had near-to-HC levels, but +natalizumab treatment their nTregs were downregulated to treatment-naive acute phase levels. Patients+interferon had the highest levels of CD3+CD4+HLA-G+ and NKT, and patients in the acute phase±methylprednizolone the lowest. Patients in remission had the highest levels of NKT, and patients in remission+natalizumab, the highest levels of CD56bright cells. nTregs remained functional regardless of disease activity and treatment regimen, and the relevant effector/suppressor ratio changes during culture+autoantigens showed variable degrees of tolerogenicity. In conclusion, in RRMS nTregs are downregulated but

functional during the acute phase, and are restored to normal levels in patients in remission or treated with interferon.

P5.10.42
Plasma biomarkers can discriminate among multiple sclerosis clinical forms

M. Tejera-Alhambra[1], *A. Casrouge*[2], *C. de Andrés*[1], *A. Seyfferth*[3], *R. Ramos-Medina*[1], *B. Alonso*[1], *J. Vega*[4], *M. Albert*[2], *S. Sánchez-Ramón*[1];

Multiple sclerosis (MS), the most common cause of neurological disability in young population after trauma, lacks of biomarkers that enable to define which patients are going to evolve to recurrent-remittent (RR-MS) form and to progressive forms (primary and secondary progressive MS: PP-MS and SP-MS), for which there is no effective treatment. These biomarkers are of outmost clinical relevance for the individual patient.
Objective: To carry out a multifaceted evaluation of circulating cytokines, chemokines, soluble receptors, growth/angiogenic factors to identify specific biomarkers and their combinations which might serve as effective tools to differentiate among the different clinical forms in 165 subjects (129 MS patients and 53 healthy controls, HC) in two independent cohorts.
Patients & Methods: The first cohort consisted of 65 MS patients and 16 HC; the second cohort consisted of 64 MS patients and 37 HC. Plasma samples were analyzed by the Human cytokine 30-Plex panel (Invitrogen) with Luminex xMAP technology platform.
Results: A multivariate logistic regression model was obtained (accuracy 82.6%) with combination biomarkers panels, where HGF and Eotaxin were risk factors (positive predictive value, (PPV: 82.5%,) and EGF and MIP-1β were protective factors for developing a progressive MS. FGFb discriminated well the PP-MS form (p=0.01 vs Relapses and vs SP-MS); while VEGF the SP-MS form (p=0.0004 vs RR-MS).
Conclusions: Our findings suggest that specific chemokines and growth/angiogenic factors may differentially account for divergent MS clinical course. Our proposed biomarkers might be useful in the clinical setting.

P5.10.43
Low DPP4 expression and activity in multiple sclerosis patients

M. Tejera-Alhambra[1], *A. Casrouge*[2], *C. de Andrés*[1], *R. Ramos-Medina*[1], *B. Alonso*[1], *J. Vega*[3], *M. Albert*[2], *S. Sánchez-Ramón*[1];
[1]*Hospital General Universitario Gregorio Marañón, Madrid, Spain,* [2]*Institut Pasteur, Paris, France,* [3]*Centro de Esclerosis Múltiple Alicia Koplowitz, Madrid, Spain.*

Multiple sclerosis (MS) is a chronic autoimmune disease of the central nervous system. Dipeptidylpeptidase 4 (DPP4) is a multifunctional enzyme with a key immunoregulatory activity. Substrates for DPP4 include several chemokines important in MS pathophysiology.
Objective: To analyze the plasma levels of soluble (s)DPP4, DPP activity and DPP4 surface expression on $CD4^+$ and $CD8^+$ T-cells in 129 MS patients with different clinical forms and 53 healthy controls (HC) in two independent cohorts.
Patients and Methods: The first cohort consisted of 65 MS patients and 16 HC and the second of 64 MS patients and 37 HC. Levels of sDPP4 were measured by ELISA (human DPPIV/CD26 ELISA;R&D Systems) and DPP activity present in plasma was measured using a luciferase-based assay (DPP4-Glo™ protease Assay; Promega). Peripheral blood samples were analyzed by multiparametric flow-cytometry.
Results: sDPP4 levels and DPP activity were significantly diminished in MS patients as compared to controls ($p<0.0001$ and $p<0.01$, respectively). These data were validated in the two independent cohorts. Moreover, DPP activity inversely correlated with clinical disease activity score in MS (EDSS) ($r= -0.315$, $p=0.01$).The lowest DPP activity was found in secondary-progressive MS. The frequency of circulating $CD8^+DPP4^{hi}$ T-cells was significantly increased in MS patients with respect to controls ($p=0.02$).
Conclusions/Discussion: We provide new evidence that sDPP4 levels and DPP activity are significantly diminished in MS patients as compared to controls, which might account in part for the immunoregulatory defect in MS. We hypothesize that DPP4 regulatory activity of chemokines antagonism may be central for MS.

P5.10.44
Andrographolide suppresses chronic and relapsing-remitting experimental autoimmune encephalomyelitis

J. E. Tichauer[1], *E. Molina*[1], *E. Acuña*[1], *R. Burgos*[2], *J. Hancke*[2], *C. Cárcamo*[1], *R. Naves*[1];
[1]*Departamento de Neurología, Facultad de Medicina, Pontificia Universidad Catolica de Chile, Santiago, Chile,* [2]*Instituto de Farmacologia y Morfofisiologia, Facultad de Ciencias veterinarias, Universidad Austral de Chile, Valdivia, Chile.*

Multiple sclerosis (MS) is an autoimmune and demyelinating disease of the CNS. Despite the several drugs available for MS treatment, a significant percentage of patients do not respond or develop exacerbations to these therapies. Andrographolide is a bicyclic diterpenoid lactone derived from Andrographis paniculata, a plant indigenous to South Asian countries that has been used as an official herbal medicine in China and India. Andrographolide has anti-inflammatory and immunomodulatory action blocking T cell activation and modulating transcriptional activity. We have previously shown that prophylactic andrographolide administration ameliorated experimental autoimmune encephalomyelitis (EAE), an animal model of MS. In this study, we tested the therapeutic effect of andrographolide on the development of chronic and relapsing-remitting (RR) EAE. Control mice were treated with either vehicle or 1 µg/ml of IFN-β1a (Rebif®). Clinical score was recorded daily and spinal cords were collected and fixed for histological analysis. We found that andrographolide (1 to 4 mg/kg) administered intraperitoneally either daily or every other day significantly improved the symptoms of chronic EAE induced by myelin oligodendrocyte glycoprotein in C57BL/6 mice whereas IFN-β1a showed a moderate effect. Remarkably, andrographolide provided long-lasting protection after treatment cessation. Spinal cords from andrographolide treated mice exhibited less cell infiltration, demyelination and microglia activation as compared with vehicle-treated mice. Furthermore, andrographolide prevented relapses in RR-EAE (SJL mice). Our results suggest that andrographolide is more efficacious in mouse EAE as compared with IFN-β and that it might have therapeutic benefits for MS treatment.

CD28 individual signals amplify pro-inflammatory cytokine production in relapse-remitting multiple sclerosis T lymphocytes

L. Tuosto[1], *C. Camperio*[1], *M. Muscolini*[1], *E. Volpe*[2], *R. Mechelli*[3], *S. Ruggieri*[4,1], *E. Piccolella*[1], *M. Salvetti*[3,1], *C. Gasperini*[4], *L. Battistini*[2];
[1]*Sapienza University, Rome, Italy,* [2]*Santa Lucia Foundation, IRCCS, Rome, Italy,* [3]*S. Andrea Hospital, Rome, Italy,* [4]*San Camillo Forlanini Hospital, Rome, Italy.*

CD28 is a crucial costimulatory reseptor that following engagement by its natural ligands, B7.1/CD80 or B7.2/CD86, expressed on the surface of professional APC, lowers TCR activation threshold, thus leading to the enhancement of early signaling events necessary for efficient cytokine production, cell cycle progression, survival and regulation of T cells effector responses. The role of CD28 in multiple sclerosis (MS) has been evaluated as the source of costimulatory signals integrating those delivered by TCR. However, CD28 is also able to act as a unique signaling receptor and to deliver TCR-independent autonomous signals, which account for its critical role in the regulation of pro-inflammatory cytokine/chemokine production. In the present work, we compared the cytokine profiles of CD4+ T cells from relapse-remitting (RRMS) patients and healthy donors (HD) following CD28 individual stimulation. We found that CD28 engagement strongly up-regulates IL-8 transcription and production in

RRMS compared to HD. More interestingly, in RRMS but not in HDs, CD28 stimulation selectively induces the transcription and secretion of IL-6, IL-21 and IL-17A, all cytokines involved in Th17 differentiation. By using specific inhibitory drugs, we also demonstrate that the up-regulation of all pro-inflammatory cytokines tested was dependent on CD28-mediated phosphatydilinositol 3 kinase (PI3K) activation. Our data identify CD28 as a critical regulator of the inflammatory response in MS and suggest the PI3K signaling pathway as a potential therapeutic target.

P5.10.46
Antigen-presenting cells in the central nervous system in EAE

***A. Wlodarczyk**, M. Løbner, O. Cédile, T. Owens;*
Institute of Molecular Medicine, University of Southern Denmark, Odense, Denmark.

Experimental autoimmune encephalomyelitis (EAE) is a mouse model for the inflammatory demyelinating disease multiple sclerosis (MS). MS is considered to be mediated by autoreactive myelin-specific T cells. Crucial events in generating autoimmune responses in the central nervous system (CNS) are presentation of self-antigen to naïve T cells in lymph nodes and their subsequent reactivation in the brain by infiltrating or resident antigen-presenting cells (APC). The major APCs in the periphery are dendritic cells (DC). In the steady state they are rarely observed in the CNS parenchyma. However, during CNS inflammation they cross the blood-brain barrier where together with microglia (CNS-resident APC) they can present antigen to infiltrating T cells.
The goal of this study was to compare two subpopulations of microglia: CD11c- and CD11c+ with brain DC in terms of promoting different T cell responses.
Two subpopulations of microglia: (CD11c- CD45dim CD11b+) and (CD11c+ CD45dim CD11b+) as well as (CD11c+ CD45hi) bDC have been sorted from the CNS of C57BL/6 mice subjected to EAE. Sorted cells were used either for ex vivo proliferation and cytokine assays or for qRT-PCR.
Our results show that bDC and CD11c+ microglia are similar with regard to ability to induce proliferative T cell response from both primed and naïve T cells. Nevertheless, they differ in their cytokine profile and ability to promote cytokine release by T cells.
Our findings suggest that different subtypes of APC in the CNS promote different immune responses.

P5.10.47
Transforming growth factor beta and interleukin-10 in multiple sclerosis patients after intravenous infusion of autologous mesenchymal stem cells

***M. Zafranskaya**[1], H. Ivanchik[1], D. Nizheharodava[1], M. Yurkevich[1], Y. Motuzova[2], E. Selezneva[3], A. Borisov[2];*
[1]Belarusian Medical Academy of Post-Graduate Education, Minsk, Belarus, [2]Belarusian State Medical University, Minsk, Belarus, [3]Minsk City Hospital № 9, Minsk, Belarus.

Introduction. Mesenchymal stem cells (MSC) based therapy of multiple sclerosis (MS) is a promising alternative approach. One of the ways via MSC mediate immunosuppression is the production of anti-inflammatory cytokines.
Objective. To investigate in vivo and in vitro dynamics of transforming growth factor beta (TGFβ) and interleukin-10 (IL-10) in serum and cell culture supernatants of MS patients before and after MSC infusion.
Materials and methods. Serum and peripheral blood mononuclear cells (PBMC) were obtained from relapsing-remitting MS patients (n=7) at baseline, 10 days, 1, 3 and 6 months after autologous bone marrow-derived MSC administration. PBMC were stimulated by mitogen or myelin antigen in the presence/absence of MSC. Cytokines concentrations were determined using ELISA kits.
Results. TGFβ, but not IL-10, was detected in serum of MS patients before MSC infusion inversely correlating with EDSS (R=-0,5, p<0,05). In vitro study revealed increased TGFβ and IL-10 under mitogen- but not myelin- stimulation (p<0,05). The addition of MSC to PBMC resulted in significantly elevated TGFβ and IL-10 in all co-cultures irrespectively of antigenic stimuli. After MSC transplantation TGFβ and IL-10 dynamics differed. TGFβ production decreased on day 10 in serum as well as in cell culture in response to mitogen followed by elevation after 3 months of treatment (p<0.05). IL-10 production significantly increased on day 10 in mitogen and myelin stimulated antigen PBMC' supernatants and correlated with the number of transplanted MSC.
Conclusion. MSC transplantation restores insufficient IL-10 production in myelin-specific conditions and promotes TGFβ secretion after a 3-month treatment.

P5.10.48
Characterization of immune cell infiltrates in the lesions of multiple sclerosis patients

***S. E. J. Zandee**, M. D. Leech, A. Williams, S. M. Anderton;*
University of Edinburgh, Edinburgh, United Kingdom.

It is generally believed that the onset of multiple sclerosis (MS) is caused by autoreactive pathogenic T cells accessing the central nervous system (CNS). Pathogenic T cells are re-activated by exposure to autoantigen presented by CNS-resident antigen presenting cells (APC). Following reactivation, the pathogenic T cells activate macrophages and microglia (CNS resident macrophages). Subsequently, inflammatory lesions develop, leading to impairment in nerve function.
It is thought that $Foxp3^+$ Regulatory T cells (Treg) play an important role in the control of autoimmune disease. Studies investigating the role of Treg in MS have demonstrated that although the frequency of Treg isolated from the peripheral blood of MS patients is not altered, their function appears to be impaired. Despite these findings, our studies in experimental autoimmune encephalomyelitis (EAE) have shown that the function of Treg in controlling CNS inflammation is most important within the CNS itself. This suggests a potential role for Treg within the human inflamed CNS.
Currently, the presence and location of Treg within the CNS of MS patients is a matter of debate. Using immunohistochemistry we have been able to detect and quantify the number of $CD4^+Foxp3^+$ Treg within different types of MS lesions. Furthermore, the presence of $CD4^+$ T cells, $CD8^+$ T cells and $CD11b^+$ APC were also documented. In order to measure the functionality of CNS Treg, *In situ* hybridization was used to detect the presence of pro- and anti-inflammatory cytokines in close proximity to Treg. Subsequently immunofluorescence was applied to confirm cytokine production on a protein level.

P5.10.49
Activated natural killer T cells recruit myeloid-derived suppressor cells to the central nervous system to suppress multiple sclerosis-like disease

***D. F. Zegarra Ruiz**[1], V. V. Parekh[2], L. Van Kaer[2];*
[1]Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Vanderbilt University, Nashville, TN, United States.

Background: Invariant Natural Killer T (iNKT) cells are a particular T lymphocyte population that behaves as immunomodulatory cells of the immune system. In a multiple sclerosis (MS) murine model it has been demonstrated that after iNKT activation there is an increase in the myeloid derived suppressor cells (MDSC) percentage in the central nervous system (CNS) and decreases the pathogenic T lymphocytes percentage.
Objectives: 1. Induce an MS-like model in mice. 2. Isolate MDSCs, obtain RNA and cDNA. 3. Evaluate the chemokine receptors expression necessary for MDSC migration to the CNS.
Methodology: C57BL/6 mice were induced with experimental autoimmune encephalomyelitis, a MS-like model. The experimental group was treated with αGalCer; the control group was treated with vehicle. Monocytic and granulocytic MDSCs (CD11b+ Ly6C+ and CD11b+ Ly6G+) from the experimental and the control groups were isolated by FACS. RNA was extracted with Trizol and cDNA was acquired. Real time PCR was performed with 14 pairs of primers for chemokine and integrin receptors. The data obtained was analyzed with Bio-Rad CFX Manager 2.1.
Results: Different chemokine and integrin receptors expression patterns were found in MDSCs after iNKT activation with αGalCer. Chemokine receptor CXCR3 was overexpressed in Ly6C+ MDSCs

whereas chemokine receptor 6 (CCR6) was overexpressed in both MDSCs subpopulations.
Conclusions: iNKT activation induced chemokine receptors CXCR3 and CCR6 overexpression in MDSCs. These chemokine receptors could be responsible for MDSCs migration towards the CNS providing protection against a MS-like model.

P5.10.50
Month of Birth,Vitamin D and Risk of Immune Mediated Disease

***E. Zare**;*
private, Tehran, Iran.

BACKGROUND: A season of birth effect in immune-mediated diseases (ID) such as multiple sclerosis and type 1 diabetes has been consistently reported. We aimed to investigate whether season of birth influences the risk of rheumatoid artritis and immune disease, and to explore the correlation between the risk of ID and vitamin D status during gestation.METHODS: The monthly distribution of births of patients with ID from the Iran (n = 120,172) was compared to that of the general population by Cosinor test. vitamin D status during pregnancy were calculated for each month of birth and correlated with risk of ID using the Spearman's correlation coefficient.RESULTS: The distributions of ID births significantly differed from that of the general population (P = 5e-12) with a peak in April (odds ratio = 1.045) and a trough in October (odds ratio = 0.945). Stratification by disease subtype showed seasonality in all ID but Crohn's disease. The risk of ID was inversely correlated with third trimester vitamin D status (Spearman's rho = -0.54, P = 0.0003).CONCLUSIONS: The risk of different ID in the Iran is significantly influenced by the season of birth, suggesting the presence of a shared seasonal risk factor or factors predisposing to ID. Gestational vitamin D exposure may be implicated in the aetiology of ID.

The investigation of Anti Centromer Antibodies in Autoimmune Diseases

*B. Karaayak Uzun, A. Sener, E. Tarhan, **I. Afsar**, S. Kaya;*
Izmir Katip Celebi University IAEH, Department Of Microbiology, Izmir, Turkey.

Objective: Anti-centromere antibodies (ACA) have been determined to be positive in many autoimmune diseases. The purpose of the study was to investigate the relationship of antibody positivity in respect to autoimmune diseases.
Methods: The sera of 10.778 patients with suspected autoimmune diseases sent from different clinics were reviewed retrospectively between January 2012- June2013. ACA was studied by indirect immunofluorescence method (Euroimmun, Lübeck, Germany). Those found positive were evaluated qualitatively.
Results: Female/male ratio of patients was 78/3 and between 16 to 85 years old (average: 58). Of 10.778 patients, 81 (0,76%) were determined to be positive for ACA. ACA positivity was borderline in 12 patients, 1/1000 titer in 12 patients, and 1/320 titer in 53 patients. The autoantibody pattern was found mixed, with 1/1000 titer in two patients and 1/320 titer in two patients. While 19 (23.5%) of ACA positive patients had diseases not associated with autoimmunity, 22 (27%) of patients had CREST Syndrome, 19 (23,5%) had undifferentiated connective tissue disease, 12 (15%) had Sjögren Syndrome, 6 (7,4%) had rheumatoid arthritis, 1 (1,2%) had poliartritis nodosa, 1(1,2%) had iridocyclitis, 1(1,2%) had CREST plus Sjögren Syndrome, respectively.
Conclusions: ACA positivity was found quite often in CREST syndrome, a subtype of systemic sclerosis, as reported in the literature. Although ACA positivity was found rarely in Sjögren's syndrome, it was highly positive in this study. ACA thus represents a valuable laboratory test for the diagnosis and monitoring of many autoimmune diseases.

P5.12.02
Oxidative stress or NK cells: The combination is getting deadlier for rheumatoid arthritis

***A. Aggarwal**[1], A. Sharma[2], A. Bhatnagar[1];*
[1]Panjab University Chandigarh, Chandigarh, India, [2]Postgraduate Institute of Medical Education and Research, Chandigarh, Chandigarh, India.

Innate immunity has been widely accepted as one of the major cause for the progression of Rheumatoid Arthritis (RA). The supplementation of ROS and altered NK cell immunobiology might be crucial in the disease severity of RA. Hence, the role of oxidative stress and cytolytic impairments of NK cells in the pathogenesis of RA was investigated. The state of oxidative stress in plasma, RBC and PBMC, percentage NK cell and their altered apoptotic signalling pathways involving mitochondrial membrane potential, FAS associated death domain (FADD) mediated pathways, DNA damage and cytolytic impairments were analyzed. Results indicated a state of profound oxidative stress in the peripheral blood of RA patients where percentage of NK and NKT cell diminished. Surprisingly, the balance of NK and NKT cell populations remained unaffected in the disease state. The depolarized mitochondrial membrane potential, FAS, FASL and active caspase-3, perforin and granzyme positive NK and NKT cell subsets were considerably elevated in patients. The DNA damage, assessed as percentage of DNA in comet tail, was significantly elevated. Findings of the present work indicate increased apoptosis of peripheral NK and NKT cells in the diseased condition. PBMC and RBC are the major sites of enhanced oxidative stress. The state of oxidative stress and altered immunobiology of NK and NKT cells strongly correlated with Disease activity score. The present study points towards futuristic therapeutic targets that can be crucial in the treatment strategy of RA patients, especially the balance of NK and NKT cells need to be explored.

P5.12.03
B-cell activating factor versus biopsy in lupus nephritis among Egyptians systemic lupus patients

***S. Algergawy**[1], E. Abd Algwad[2], r. zakaria[3];*
[1]Benha University Faculty of Medicine Rheumatology and Rehabilitation Department, Benha, Egypt, [2]Benha University Faculty of Medicine Clinical Pathology, Benha, Egypt, [3]benha university faculty of medicine pathology department, Benha, Egypt.

Aim: To study the importance of BAFF in lupus nephritis in comparison to renal biopsy in Systemic Lupus Erythematosus patients.
Patients and methods: BAFF levels were measured in 55 lupus patients and 20 healthy volunteers, renal biopsy was obtained from all patients. SLE patients were divided into 2 groups: Group (A) without lupus nephritis (LN) and Group (B) with LN. Disease activity in SLE patients was assessed by SLEDAI score.
Results: Patients with SLE had elevated BAFF as compared to controls and correlated with disease activity ($P<0.001$). Levels of BAFF were higher in patients with LN than those without LN ($P<0.001$). In patients with LN, serum levels of BAFF were significantly correlated with the SLEDAI renal score. BAFF levels varied significantly and there was a significant positive correlation with the activity and chronicity scores of renal biopsies.
Conclusions:BAFF plays an important role in the pathogenesis of LN and its levels parallel the renal involvement assessed by biopsy. The BAFF level could thus be used as a surrogate marker of renal biopsy.

P5.12.04
Carotid intima media thickness, plaques , IL-6 and disease activity in rheumatoid arthritis patients among Egyptians

***S. Algergawy**[1], A. Shamsaldeen[1], M. Rifat[2], K. Belal[3];*
[1]Benha university faculty of medicine rheumatology department, Benha, Egypt, [2]Benha university faculty of medicine clinical pathology department, Benha, Egypt, [3]Benha university faculty of medicineclinical pathology department, Benha, Egypt.

Aim: To study the extent of the carotid intima-media thickness (IMT), plaques and the most predicting subclinical atherosclerotic variables (IL-6) in different grades of disease activity in rheumatoid patients .

Patients and methods: 120 RA patients, sex and age matched controls were recruited at rheumatology department Benha university Egypt. They were 98 females and 22 males. Their ages ranged between 25 and 66 years and disease duration from 1 to 26 years with a mean of 9.7± 6.04 .Cardiovascular (CV) risk factors, RA characteristics were recorded. cartoid (IMT) and plaques were assessed in RA patients and controls with high resolution B-mode ultrasound ultrasound (US).
Results: The mean value of IMT in the patients was 1.18± 0.98 mm while in the controls was 0.63± 0.18 mm which show highly statistically significant between two groups(p<0.001). The incidence of carotid plaques in our patients were significantly higher compared to controls. There were statistically significant correlations (P<0.05) between IMT of the CCA ,plaques in RA and disease related variables; articular index, CRP, ESR, BMI,T cholesterol, HDL, TG, hemoglobin leve l,and highly significant correlations (P<0.001) were found in relation to IL-6, LDL, disease duration, Larsen score, and pain severity.
Conclusion: These results support that RA patient have an ultrasonic marker (plaques and intima media thickness) of early atherosclerosis and these findings correlate significantly with disease activity and IL-6 levels, IL-6 being one of the most predictive marker of these findings.

P5.12.05
Anti-Interleukin-6 and anti-TNF-alpha treatment do not have a negative impact on the immune response against CMV, but disease status influences the balance and the cytokine profile in juvenile idiopathic arthritis patients (JIA)

***G. Almanzar**, R. Trippen, K. Sustal, K. Höfner, M. Prelog;*
Department of Pediatrics, University of Würzburg, Würzburg, Germany.

Th17 cells have been identified as pro-inflammatory cells in several autoimmune conditions, such JIA. This study evaluated the phenotype and the cytokine-production profile of T-cells in JIA showing active disease (group-1,n=17), remission on-medication (group-2,n=39), remission off-medication (group-3,n=10), disease flare after remission (group-4,n=16) compared to healthy donors (HD,n=28) and the CMV-specific immune response using in vitro blockade of Interleukin-6(IL-6) and tumour-necrosis-factor-alpha(TNFalpha) to simulate therapy.
The phenotype characterization and the intracellular production of IFNgamma, TNFalpha, and IL-17 on naïve:CD28+CD45RO-, memory:CD28+CD45RO+, effector:CD28-CD45RO+, terminally differentiated:CD28-CD45RO- and regulatory:Tregs:CD25+CD127-FoxP3+ CD4+ T-cells were investigated by flow cytometry. CMV-specific IFNgamma-production was determined by ELISPOT following stimulation with CMV-antigens:CMVpp65,CMV-IE in combination with monoclonal antibodies against IL-6 and TNFalpha. Results were expressed in spot forming units (SFU)/1,000,000 cells.
IFNgamma-producing CD4+ T-cells(4.9%vs6.9%) and Tregs(2.9%vs3.8%) were significantly lower in JIA than HD. Memory CD4+ T-cells produced lower amounts of IFNgamma in group-4:6.3%, group-1:6.3% and group-2:7.6% compared to HD:11.3%. . However, disease flare group showed higher proportions of IL-17-producing memory-effector T-cells:1.3% than patients in group-3:0.6%. CMV-seropositive JIA patients showed a significant higher number of IFNgamma-producing T-cells:39.03% than CMV-seronegative:16.55%. No differences were found in the IFNgamma-production by CMV-specific T-cells between HD and JIA in the presence of anti-TNFalpha(JIA:27.8%vsHD:27.3%), but a trend to lower IFNgamma-production by anti-IL-6(JIA:13.3%vsHD:35.0%). Memory and effector T-cells in JIA patients have an imbalance in the cytokine production profile. Although the CMV-specific response was not altered, long-term aspects of T-cells chronic stimulation by CMV as known from healthy elderly persons resulting in exhaustion of CD28- T-cells may follow in older age

P5.12.06
IL-1β membrane-bound receptors in health and in rheumatoid arthritis

***A. Alshevskaya**, F. Vasiliev, J. Lopatnikova, N. Shkaruba, O. Chumasova, A. Sizikov, S. Sennikov;*
Institute for Clinical Immunology, Siberian Branch of Russian Academy of Medical Sciences, Novosibirsk, Russian Federation.

Background: IL-1β is involved in the induction and maintenance of chronic inflammation in rheumatoid arthritis (RA). Its activity is regulated by soluble and membrane-bound receptors; herewith the effectiveness of the cytokine depends largely on the number of expressed receptors.
Objective: to investigate the expression of IL-1β membrane-bound receptors (IL-1R1 and IL-1R2): the percentage of cells with receptors and the number of receptors themselves in different subsets of immune cells in RA patients and in healthy donors.
Methods: to determine membrane-bound receptors on T-, B-lymphocytes and monocytes flow cytometry method was used. To determine receptors number on the cells Quantibrite PE Beads(BD) were used.
Results: Among the studied subpopulations the largest percentage of IL-1R1+ cells was estimated for monocytes, besides the percentage in healthy donors was significantly higher than in RA patients. The least number of IL-1R1 was found on healthy donors monocytes, and the number of IL-1R1 on RA patients monocytes was significantly higher in compare with other subsets. The percentage of IL-1R2+ cells in all subsets was higher in RA, and the highest number of receptors was defined on monocytes in the acute stage of RA. At the same time, the number of both types receptors on T-and B-lymphocytes was significantly higher in control group.
Conclusions: Thus, identified changes indicate the active involvement of IL-1R1 high-expressing monocytes in RA inflammation and their participation in the cytokine imbalance development. Decreasing numbers of IL-1R2 on lymphocytes are associated with active shedding of receptors from them in this pathology.

P5.12.07
Anti-C1q antibodies and systemic lupus erythematosus in the Tunisian population

***H. Ben Hassine**[1], B. Trad[1], M. Khalifa[2], N. Idriss[1], F. Slama[1], J. Boukadida[2], R. Sghiri[1];*
[1]Faculty of Medicine of Sousse, Sousse, Tunisia, [2]Farhat Hached Hospital, Sousse, Tunisia.

Objectives. The presence of a wide variety of autoantibodies is a characteristic feature of systemic lupus erythematosus (SLE). Although non-specific, anti-complement C1q (anti-C1q) were shown to correlate with the occurrence of active nephritis. The present study aimed to investigate the prevalence of anti-C1q in Tunisian SLE patients and their association with clinical manifestations, especially renal involvement.
Patients and methods. IgG anti-C1q antibodies were assessed by Elisa in 98 SLE patients, 55 patients with rheumatoid arthritis (RA) and 65 healthy individuals (HI).
Results. Anti-C1q antibodies were found in 53 (54.1%) patients with SLE, three (5%) patients with RA and six (9.3%) HI. Among the 65 patients with renal involvement, anti-C1q antibodies were present in 35 (53.8%) patients. There was no significant association between anti-C1q and renal or extrarenal manifestations. In addition, there was no correlation between anti-C1q titer and SLEDAI index. Anti-C1q were significantly associated with anti-nucleosome (P = 0.001), anti-Sm (P = 0.01) and a low C4 level (P = 0.046). Concomitant presence of anti-C1q and anti-dsDNA antibodies was not associated with renal manifestations.
Conclusion. Our study shows that prevalence of anti-C1q antibodies was comparable with that previously reported in Caucasian populations. These antibodies were associated with a low C4 level. However, there was no association between anti-C1q antibodies and renal involvement or severity of nephritis.

P5.12.08
Performance of anti-CCP3 IgG/IgA (CCP3.1) test compared to anti-CCP2 IgG test

***M. Benidir**, H. Amroun, S. S. Salah, G. Hamadi, O. Rendja, N. Attal, M. C. Abbadi;*
Immunology Department, Pasteur Institute of Algeria, Algiers, Algeria.

Introduction: Diagnostic contribution of ACPA and RF finds its place in RA. Improvements have been made in measurement of ACPA (modified citrullinated peptides, simultaneous search of specific IgG and IgA auto-antibodies).
Objective: The aim of this work is to evaluate performance of anti-CCP3 IgG/IgA (CCP 3.1) test compared to anti-CCP2 IgG test.
Methods: Detection and measurement of anti-CCP3 IgG/IgA auto-antibodies were compared to the anti-CCP2 IgG ones using ELISA in sera of 82 patients; RF was measured by nephelometry.
Results: Results are shown in 4 subgroups:
42 patients anti-CCP2 IgG(-) RF(-) : 2/42 (5%) are anti-CCP3 IgG/IgA(+);
15 patients anti-CCP2 IgG(+), RF(-) : 1/15 (6%) are anti-CCP3 IgG/IgA(-);
14 patients anti-CCP2 IgG(-), RF(+) : 8/14 (57%) are anti-CCP3 IgG/IgA(+);
11 patients anti-CCP2 IgG (+), RF (+): 11/11 (100%) are anti-CCP3 IgG/IgA (+).
Discussion: We observe that every patient CCP2 IgG (+) is anti-CCP3 IgG/IgA (+) except one subject (1/26 = 4%) presents RA during 2 years. On the other side, 10 out of 56 subjects (18%) are anti-CCP3 IgG/IgA (+) and anti-CCP2 IgG (-). 8 of these 10 patients RF (+), 5 have known RA. Among the remaining 5 patients with suspected RA disease duration was 1 to 2 years, showing that anti-CCP3 IgG/IgA are the first to become positive, followed by RF, then the other ACPA which was confirmed by Nicoloudi A. in 2007 and Szabo Z. in 2008.
Conclusion: Anti-CCP3IgG/IgA is more sensitive than its competitors in early and proven RA.

P5.12.09
Rheumatoid arthritis: early thymic involution or increased proliferation rate?

***E. A. Blinova**, V. S. Kozhevnikov, A. E. Sizikov, V. A. Kozlov;*
Research Institute of Clinical Immunology, Novosibirsk, Russian Federation.

It is often observed impaired thymic function in adults with immunopathology, particularly with rheumatoid arthritis (RA). We determined 2 markers of thymic functional activity (T cell receptor excision circles or TREC number and amount of CD31+ T cells) to establish the mechanisms for replenishment of the peripheral T cell pool in RA.
Absolute and relative TREC number in CD4+ and CD8+ cells was measured in 30 patients with RA (mean age 50±8,2)and 15 healthy age-matched controls using Real-time PCR. Proportion of CD4+CD31+ and CD8+CD31+ cells was quantified in 11 patients with RA (mean age 43±14,3) and 5 healthy donors (mean age 43±5,5).
Relative TREC number was reduced about 2 times in RA compared with control, both in CD4+ and CD8+ cells. Absolute TREC number in CD4+ population did not differ in patients with RA from donors, whereas it was decreased in CD8+ population in RA. To determine whether the reduction of TREC number in RA due to insufficient thymic function or increased proliferation rate, it was quantified proportion of CD31+ T cells. There were no significant differences in the amount of thymic naïve T cells between patients with RA and healthy donors. CD4+31+ value in RA group was 26 (range 21,6-32,2) vs 27,8 (range 24,9-40,1) in control group, and CD8+CD31+ - 62 (49,7-70,8) vs 53,8 (50,8-66,5) respectively.
Obtained data suggest that replenishment of the peripheral T cell pool in adults with RA occurs more due to the cell proliferation, thymic function is maintained within the normal limits.

P5.12.10
TNF receptor function is dispensable for generation of CD23+ CD21-high B cells in inflamed nodes

*I. Kuzin[1], E. Schwarz[1], **A. Bottaro**[2];*
[1]University of Rochester School of Medicine, Rochester, NY, United States, [2]Cooper Medical School of Rowan University, Camden, NJ, United States.

We have previously shown that total B cells expand, and a population of CD23+, CD21-high, CD1d-high B cells (B cells in inflamed nodes, or Bin) selectively accumulate in the lymph nodes that drain arthritic joints in the human TNF-alpha transgenic (hTNF) mouse model of inflammatory erosive arthritis. These changes are associated with altered lymph node architecture, lymphatic drainage dysfunction and disease flare in the knee, and can be reversed by B cell depletion therapy. Bin cells also appear in normal lymph nodes in response to other inflammatory stimuli including immunization and antigen-free adjuvants, and display increased antigen capture and processing, and T cell costimulation potential compared to conventional follicular B cells.
Bin cells can rapidly (24-72 hrs) differentiate from adoptively transferred sort-purified normal mature follicular B cells within the milieu of hTNF-transgenic inflamed lymph nodes, raising the question whether their differentiation is directly dependent on TNF-alpha-mediated inflammatory signals. Here we will show: 1) that TNF receptor (TNFR) 1/TNFR2 double deficient B cells give rise to Bin cells when adoptively transferred into hTNF-transgenic mice, and 2) that footpad immunization of TNFR1/TNFR2 double deficient animals also gives rise to total B cell and Bin cell accumulation, as in normal mice. We conclude therefore that TNF receptor function is not required for either the dramatic changes in lymph node B cell composition that accompany lymph node inflammation, or for the specific differentiation of Bin cells in normal and hTNF-transgenic lymph nodes.

P5.12.11
Biomarker of inflammation in juvenile idiopathic Arthritis (JIA)

***J. Brunner**, T. Giner, G. Weiss, D. Fuchs;*
Medical University Innsbruck, Innsbruck, Austria.

Background: Juvenile idiopathic arthritis (JIA) is a relevant autoimmune disease in children. T cells, B cells, and damage-associated molecular patterns (DAMPS) are involved in the pathogenesis of the disease. Biomarkers for JIA and its subtypes are not established. Pro-inflammatory pathways activate enzyme indoleamine 2,3-dioxygenase (IDO) which enhances tryptophan (Trp) conversion to kynurenine (Kyn). Thus, in conditions of chronic immune activation reduced Trp availability and production of Kyn and its down-stream metabolites may inhibit cell proliferation. [1-3].
Methods: In this study, Trp and Kyn metabolism was investigated in children with JIA and compared to serum neopterin concentrations. Fifty-four sera of 25 JIA patients and 10 samples of synovial fluid were examined with HPLC (Trp and Kyn) and Elisa (Neopterin, BRAHMS, Hennigsdorf, Germany). Eighteen sera from 18 children with non-inflammatory diseases were used as controls.
Results: Trp in the sera of patients was mean 57.2 + SD 19.0 µmol/L and Kyn was mean 2.40 + SD 0.81 µmol/L). Serum neopterin was 5.69 + SD 1.72 nmol/L. In the synovial fluid, neopterin was mean 10.5 + SD 7.41 nmol/L), Trp was 36.7 + SD 17.4 µmol/L and Kyn was 2.13 + SD 0.75 µmol/L). In control patients, neopterin was 6.93 + SD 3.10), Trp was 57.6 + SD 14.8) and Kyn was 2.60 + SD 1.60 µmol/L.
Conclusion: Serum Trp concentrations showed no relevant difference in JIA patients vs. controls. IDO activity reduces Trp primarily in the synovial fluid in JIA patients.
.

P5.12.12
APRIL, a TNF family member, can be a predictor of resistance to antigen-induced arthritis in mice

A. Carvalho[1]*, R. Vasconcellos*[2]*, C. E. C. Pinto*[2]*, M. Hahne*[3]*, W. Savino*[1]*, D. M. S. Villa-Verde*[1]*;*
[1]*Oswaldo Cruz Institute, Fiocruz, Rio de Janero, Brazil,* [2]*Federal Fluminense University, Niterói, Brazil,* [3]*Institut de Génétique Moléculaire de Montpellier, Montpellier, France.*

APRIL (A Proliferation-Inducing Ligand) acts as a secreted factor and plays important roles in B cell biology. The reported capacity of APRIL to stimulate B cells *in vitro* raised the hypothesis that APRIL may be a disease promoter in autoimmune diseases such as rheumatoid arthritis. This study was undertaken to examine the ability of APRIL to regulate the B cell-mediated inflammatory response in a model of antigen-induced arthritis (AIA) in mice and to influence cell migration in synovial tissue. AIA was induced by administration of antigen (mBSA) into the knee joints of previously immunized APRIL-transgenic (APRIL-Tg) mice and their littermates. In the acute stage of disease APRIL-Tg mice displayed a decrease in inflammatory response parameters, i.e., joint swelling, disease score and inflammatory infiltrate in articular tissues, as compared with their littermates. In addition, we observed a decrease of cellularity in draining lymph nodes of APRIL-Tg mice. These results were correlated with a milder chronic disease. FACS analysis revealed an increase of IgM+CD5+ cell population in draining lymph nodes in APRIL-Tg mice and increased IL-10 production *in vitro* at the acute phase of the disease. Our results suggest that APRIL and IL-10 producing B cells could reach the inflamed synovia and build an anti-inflammatory environment in arthritis. However, this issue remains to be further elucidated. Our data show that the ectopic APRIL expression can be correlated with higher resistance to arthritis and suggest that this regulatory axis should be investigated in human rheumatoid arthritis.

P5.12.13
Optimization of "in vitro" culture conditions for human arthritis rheumatoid synovial fibroblasts

C. Casnici*, D. Lattuada, K. Crotta, O. Marelli;*
University of Milan, Milan, Italy.

In this study we evaluated the use of synovial fluid, obtained from patients with arthritis rheumatoid, as optimal culture condition to perform "in vitro" studies on arthritis rheumatoid synovial fibroblasts. Actually "in vitro" studies are performed on unstimulated fibroblasts or cells cultured in the presence of recombinant cytokines, such as alpha-TNF, but these conditions are not faithful to the real ones, therefore the results obtained might be not corrected. We used a pool of six different arthritis rheumatoid synovial fluids in our "in vitro" study performed with arthritis rheumatoid synovial fibroblasts. Our observations in proliferation studies demonstrate that the synovial fluid was more effective to induce DNA synthesis and proliferation of synovial fibroblasts with respect to alpha-TNF, used at the optimal dose. The morphological aspect of the cells was also modified with synovial fluid. We also evaluated the modulation of expression of some cytokines known to be involved in the pathological process of RA. The cytokines expression was greater in the cells cultured in the presence of synovial fluid than those cultured in the presence of alpha-TNF or in the culture medium. These results emphasize the importance of using the synovial fluid in "in vitro" studies to ensure culture conditions as similar as possible to those of physiopathological environmental characteristic of the rheumatoid arthritis joints. This should ensure the possibility to have more accurate information both to clarify the pathogenesis of rheumatoid arthritis that to evaluate the therapeutic efficacy of new molecules.

P5.12.14
S100A8 plays an anti-inflammatory role in collagen-induced arthritis

A. Cesaro[1]*, N. Pagé*[1]*, M. R. Tardif*[1]*, A. Al-Shami*[2]*, T. Oravecz*[2]*, P. A. Tessier*[1]*;*
[1]*Axe des maladies infectieuses et immunitaires, Centre de recherche du Centre Hospitalier Universitaire de Quebec, Université Laval, Quebec, QC, Canada,* [2]*Lexicon Pharmaceuticals inc, The Woodlands, TX, United States.*

S100A8 and S100A9, cytoplasmic proteins expressed by neutrophils and monocytes, are found in the extracellular milieu during inflammatory episodes. While the pro-inflammatory activity of S100A9 has been clearly established, the functions of S100A8 remain controversial. S100A8 is a chemotactic factor for neutrophils and monocytes and induces a potent inflammatory response in vivo. However, it is easily oxidized and its oxidized form has been shown to inhibit mast cell activation and to suppress eosinophil functions. In this study, S100A8-/- mice were generated to investigate its role in acute and chronic inflammation like rheumatoid arthritis. Leukocytes subpopulations were similar in bone marrow, blood, spleen and thymus between S100A8-/- and WT mice. Interestingly, deletion of S100A8 gene resulted in absence of S100A9 protein in naïve mice, although mRNA for S100A9 was detected, suggesting that S100A8 is necessary to stabilize S100A9 protein. No differences between S100A8-/- and WT mice were detected in the number and subtypes of leukocytes migrating to the air pouch in response to LPS. However, striking differences were observed in the collagen-induced arthritis model of chronic inflammation. S100A8-/- mice showed increased disease incidence, edema, leukocyte infiltration and bone destruction in the LPS-synchronized collagen-induced arthritis model. In conclusion, these data suggest that S100A8 acts as an anti-inflammatory molecule during experimental arthritis and thus contains the disease development.

P5.12.15
ERAP1 gene polymorphisms influence the risk of Spondyloarthritis in HLA-B27 positive Romanians

M. Cherciu[1]*, L. O. Popa*[2]*, M. Bojinca*[3]*, M. I. Dutescu*[4]*, V. Bojinca*[5]*, R. Caisan*[4]*, C. Bara*[1]*,* ***O. M. Popa***[1]*;*
[1]*Department of Immunology and Pathophysiology, Faculty of Medicine, University "Carol Davila", Bucharest, Romania,* [2]*Molecular Biology Department, GrigoreAntipa National Museum of Natural History, Bucharest, Romania,* [3]*Department of Rheumatology, Faculty of Medicine, University "Carol Davila", "I.C. Cantacuzino" Hospital, Bucharest, Romania,* [4]*"Prof. Dr. C. T. Nicolau" National Institute of Blood Transfusion, Bucharest, Romania,* [5]*Department of Rheumatology, Faculty of Medicine, University "Carol Davila", "St. Maria" Hospital, Bucharest, Romania.*

Spondyloarthritis (SpA) is a family of rheumatic diseases with common clinical features (inflammatory back pain, asymmetrical oligoarthritis, enthesitis), but also with genetic similarities - such as HLA-B27. ERAP1 gene encodes an endoplasmic reticulum aminopeptidase involved in peptide precursor trimming before loading into HLA class I molecules. Recent studies found associations of ERAP1 variants with the susceptibility to SpA and with ankylosing spondylitis (AS) which is the most common form of SpA. The association of ERAP1 variants with the risk of spondyloarthritis in HLA-B27+ individuals has not been yet investigated.
Our aim was to explore the influence of two coding single nucleotide polymorphisms (SNPs) of ERAP1 gene - rs30187 (Lys528Arg) and rs27044 (Gln730Glu) - on the risk of SpA in HLA-B27+ Romanians.
We genotyped 150 HLA-B27+ SpA patients (105 AS, 31 undifferentiated spondyloarthritis, 14 psoriatic arthritis) and 108 HLA-B27+ healthy controls using TaqMan assays. Statistical analyses were performed with PLINK software.
Both SNPs were associated with the risk of spondyloarthritis (OR 1.80, 95%CI 1.24-2.62, p=0.001 for rs30187, OR 1.58, 95%CI 1.07-2.34, p=0.02 for rs27044). The haplotypic combination of the major alleles of the two SNPs (CC) had protective value for developing SpA (57% in patients versus 70% in controls, p=0.002), while the TG haplotype was a risk factor (33% in patients versus 23% in controls, p=0.01).

Our results show that ERAP1 functional variants influence the risk of spondyloarthritis in HLA-B27+ individuals suggesting that the common pathological pathway of spondyloarthritides implicates not only HLA-B27, but also the ERAP1 molecule.

P5.12.16
TWEAK Promotes Osteoclastogenesis in Rheumatoid Arthritis

***M. Cho**, J. Park, M. Lim, S. Kwok, J. Jhun, S. Park;*
The Rheumatism Research Center, Catholic Research Institute of Medical Science, The Catholic University of Korea, Seoul, Republic of Korea.

Bone destruction is critical in the functional disability of patients with rheumatoid arthritis (RA). Osteoclasts, specialized bone-resorbing cells regulated by cytokines such as receptor activator of NF-κB ligand (RANKL), are primarily implicated in bone destruction in RA. The aim of the study was to examine whether tumor necrosis factor (TNF)-like weak inducer of apoptosis (TWEAK), a member of the TNF superfamily, has osteoclastogenic activity in RA patients and in animal models including mice with collagen-induced arthritis (CIA mice) and IL-1 receptor antagonist knockout (IL-1RaKO) mice. TWEAK was increased in the synovium, synovial fluid and serum of RA patients and in the synovium of CIA mice and IL-1RaKO mice. TWEAK induced RANKL expression in mixed joint cells and splenocytes from CIA mice, IL-1RaKO mice and in fibroblast-like synoviocytes (FLSs) from RA patients. Both osteoclast precursor cells and osteoclasts express TWEAK receptor fibroblast growth factor-inducible 14 (Fn14). In addition, TWEAK enhanced in vitro osteoclastogenesis without the presence of RANKL-providing cells and by inducing RANKL expression in FLSs. Moreover, treatment with Fn14-Fc inhibited RANKL-induced osteoclastogenesis, indicating endogenous TWEAK also has osteoclastogenic activity. Our data demonstrated that TWEAK promotes osteoclastogenesis in RA, suggesting that therapeutic strategies targeting TWEAK could be effective for treatment of patients with RA, especially in preventing bone destruction.

P5.12.17
CD8+ T cell reactivity against apoptotic self-epitopes in rheumatoid arthritis patients treated with etanercept

***A. Citro**[1], R. Scrivo[2], H. Martini[1], S. Piconese[1], F. Miranda[2], V. Barnaba[1], G. Valesini[2];*
[1]Immunology Unit, Dipartimento di Medicina Interna e Specialità Mediche, Sapienza, Università di Roma, Rome, Italy, [2]Rheumatology Unit, Dipartimento di Medicina Interna e Specialità Mediche, Sapienza, Università di Roma, Rome, Italy.

Apoptotic cells play an important role in autoimmune disorders since they represent an important source of self-antigens. We have shown that T cell apoptosis generates a wide array of caspase-cleaved proteins, which can be cross-presented by dendritic cells to a broad repertoire of autoreactive CD8+T cells. This process is involved in establishing chronic immune activation (CIA) in HIV and HCV infections. Here, we evaluated the role of self-apoptotic-specific CD8+T cells in the maintenance of CIA in rheumatoid arthritis (RA) and the clinical impact of these cells on the response to immunosuppressive therapy. Our study has been conducted on RA patients treated with Etanercept at different times. Frequency and function of self-specific CD8+ T cells were analysed by staining with dextramers of HLA-A*0201 molecules complexed to apoptotic epitopes and IFNγ-ELISPOT assay. Our data showed increased frequencies of autoreactive CD8+T cells in patients compared to healthy donors, related to increased frequency of circulating apoptotic T cells. In addition, a large apoptotic epitope repertoire recognized by IFN-γ+CD8+ TEM cells was found in all patients. Interestingly, at baseline a significant difference in autoreactive responses was found in responders compared to non responders. After starting therapy, an early dramatic decrease of self-reactive CD8+T cells was observed only in the group of responders. Altogether these data suggest that chronic inflammation in RA may be sustained by an autoimmune reaction towards apoptotic T cells. The presence of self-reactive T cells, markedly increased in responders patients already at baseline, may be useful to predict the response to therapy.

P5.12.18
The effect of the *Slc11a1* gene on pristane-induced arthritis chronic phase

***M. A. Correa**[1,2], T. Canhamero[1,2], J. L. Guerra[3], A. Borrego[1], J. R. Jensen[1], W. H. Cabrera[1], N. Starobinas[1], O. G. Ribeiro[1], O. C. Ibanez[1], M. De Franco[1];*
[1]Instituto Butantan, São Paulo, Brazil, [2]Instituto de Ciências Biomédicas -USP, São Paulo, Brazil, [3]Universidade Anhembi Morumbi, São Paulo, Brazil.

Genetic and environmental factors contribute to the development and establishment of rheumatoid arthritis. The *Solute carrier family 11a member 1* (*Slc11a1*) gene is involved in the ion transport at the endosomes in macrophages and neutrophils, interfering in their activation. Mice homozygous for *Slc11a1 S* allele (AIRmax^{SS}) selected from the high inflammatory response AIRmax line are more susceptible than AIRmax^{RR} to pristane-induced arthritis (PIA). In order to study the chronic phase of PIA, AIRmax^{RR} and AIRmax^{SS} mice received two i.p. injections of 0.5 mL pristane at a 60-day interval, and arthritis development of arthritis was assessed for 180 days. Multiplex analysis of serum and peritoneal macrophage culture supernatants showed higher production of IL1β, IL-6, TNFα, IL-10 and MIP-2 by AIRmax^{SS}. We also identified increased H_2O_2 and NO release by AIRMax^{SS} macrophages. Significant differences ($p<0.001$) were found in expression, by AIRMax^{SS} macrophages, of metalloproteinase genes (*Mmp-2* and *Mmp-9)* and their inhibitors (*Timp-1* and *Timp-3)*. Histological analysis of paws of AIRMax^{SS} mice after PIA showed a moderate inflammatory process, characterized by mononuclear cells. These results suggest that *Slc11a1* alleles modulate cytokines profile and proteases contributing for arthritis severity.

P5.12.19
Role of the expression CCR7+CCR5+ CX3CR1+ CD95 +/- in the peripheral blood lymphocytes in systemic lupus erythematous patients

***L. A. Damiati**, A. M. Al-Dahlawi, M. F. El-Shal, S. M. Bahlas;*
King Abdulaziz University, Jeddah, Saudi Arabia.

SLE is one of the autoimmune diseases characterized by the loss of immune tolerance. Cytokines and chemokines are proteins that play an important role in the pathogenesis of SLE. Previous studies indicated that the expression of CD95 is the determinant for the induction of apoptosis in T-helper lymphocytes, and abnormalities in their expression may lead to ADs. We investigated the expression of CD95 and CCR7, CCR5 and CX3CR1 on freshly isolated lymphocytes from SLE patients. The CD95 and CCR7, CCR5 and CX3CR1 expression on $CD4^+$ lymphocytes were analyzed in 44 SLE patients and 20 controls using multi-parameter flow cytometry. Concentrations of plasma IL-6, IL-12, IL-17, TNF-α and IL-10 were also quantified using ELISA. The percentage of $CD4^+CCR7^+CD95^+$ cells was statistically significant in SLE patients compared with controls ($P<0.001$) the percentage of $CD4^+CCR5^+CD95^-$ cells was statistically significant in SLE patients compared with controls ($P<0.002$); the percentage of $CD4^+CX3CR1^+CD95^-$ cells was statistically significant in SLE patients compared with controls ($P<0.018$). Altered apoptosis is a common finding in autoimmune diseases including SLE. We found in our study that the expression of chemokine receptors on viable T-helper cells significantly different in the secretion of cytokines when compared to the cells resistant to apoptosis as evidenced by the increased expression of death-receptor CD95. These expanded $CD95^+$ primed T-helper cells most likely reflect the presence of activated lymphocytes as a consequence of abnormalities in the peripheral deletion of activated lymphocytes. These persistently activated lymphocytes might play a role in the induction of autoimmunity in SLE.

Rheumatoid Arthritis (RA) is an autoimmune-mediated disease characterized by chronic inflammation and leukocyte recruitment into the inflamed joints. Chemokines and chemokine receptor activation are known to represent a major component of the effector molecules involved in the onset of RA.
CCRL2 [Chemokine (CC motif) receptor-like 2], also known as L-CCR, is a seven transmembrane protein that shows a high homology degree with many members of the CC chemokine receptor family. CCRL2 possesses a non-canonical DRYLIVE motif in the second intracellular loop that makes it to resemble like a nonsignaling chemotactic receptor (e.g. D6, DARC, CCX-CKR). CCRL2 is expressed by LPS-stimulated murine macrophages, neutrophils, mast cells, dendritic cells, glial cells, astrocytes and microglia and is up-regulated in human RA synovial neutrophils.
In order to elucidate the role of CCRL2 in RA, CCRL2 KO mice were tested in the model of collagen-induced arthritis. Only few CCRL2 KO mice displayed the pathological signs characteristic of arthritis with reduced leukocyte infiltration, synovial hyperplasia and joint erosions and with a significant reduction in visual scoring and paw thickness. Moreover, CCRL2 KO mice showed a marked delay (about ten days) in the onset of the disease and histological features reminiscent of recent joint damage. Conversely, the level of specific anti-collagen II IgG in the serum was similar in CCRL2 KO and control mice. The mechanisms underling the protection of CCRL2 mice in RA models are currently under investigation and will help to define whether CCRL2 may represent a new therapeutic target for RA.

Collagen-specific TCR Repertoire usage in RA and cytokine secretion

G. Di Sante[1], *A. Fedele*[2], *B. Tolusso*[2], *C. Nicolò*[1], *A. Carbonella*[2], *S. Bosello*[2], *E. Gremese*[2], *S. Canestri*[2], *F. Ria*[1], *G. Ferraccioli*[2];
[1]*Università Cattolica del Sacro Cuore, Rome, Italy,* [2]*Complesso Integrato Columbus, Rome, Italy.*

Rheumatoid arthritis (RA) is an autoimmune disease characterized by chronic joint inflammation, associated with HLA-DR4. Collagen II specific T cells repertoire in DR4+ patients is characterized by a limited number of TCR-beta chain during the acute phase, in part enriched in Synovial fluid. The two more used TCR-beta chains are BV11 and BV13. PBMC from 85 RA patients (47 acute presentations and 38 remissions), cultured with or without collagen peptide, were examined by immunoscope. We also studied IL-17 and IL-13 secretion of collagen-specific individual T cells of 3 DR4+ patients after in vitro stimulation with the peptide and with or without bacteria-derived products. At acute presentation 6/15 patients showed BV11+ T cells and 7/15 showed BV13+ T cell, while after remission the number falls to 1/11 and 2/10, respectively. Some DR7+ patients displayed T cells using similar BV11 and BV13 chains. In this latter case, frequency of positive BV13 samples did not decrease with remission. We observed that 1/17 T cell clonotypes secreted IL-17 or IL-13 after stimulation with peptide. However, after stimulation with peptide in the presence of bacterial products, 3 more individual T cells became able to secrete IL-17. Thus, BV11+ and BV13+ cells are bystander of RA at acute presentation in DR4+ patients. The relative high frequency of these TCRs also in DR1+ and DR7+ patients is possibly due to similarities in peptide selection. In RA patients, secretion of the pro-inflammatory cytokine IL- 17 is modulated by exogenous (or endogenous) factors, possibly interacting with PRRs.

Rheumatoid arthritis (RA) is an autoimmune disorder, systemic and inflammatory. Understanding of the immuno-molecular pathology of this entity has been considerable progress in recent years that have to revisit the diagnosis and care of patients. In Africa, few studies are available. The aim of our study was to investigate some immunological markers for diagnostic purposes. We conducted a prospective study of 78 patients received outpatient RA between June 2012 and January 2013. RA was diagnosed according to the criteria of the ACR (American College of Rheumatology) 1987. A questionnaire on sociodemographic data of the patient, disease activity at the time of the study, the Rapid Assessment score 3 and 5 RADAI was administered to each patient after informed consent. A blood sample for determination of parameters immunoserological was performed. The patients were aged between 19 and 83 old, with a disease duration of 6.2 years with a range from 2 months to 32 years. Clinical features, scores and RAPID3 RADAI 5 and immunological profile of patients were analyzed. Preliminary results have improved knowledge of Senegalese patients with RA.

P5.12.23
T676G polymorphims of the TNF receptor type II is associated with ankylosing spondylitis

M. D. J. Durán-Avelar[1], *J. Gutiérrez-Franco*[1], *N. Vibanco-Pérez*[1], *F. D. Trejo-Ramírez*[1], *S. Peña-Virgen*[2], *J. F. Zambrano-Zaragoza*[1];
[1]*U.A. Ciencias Químico Biológicas y Farmacéuticas-Universidad Autonoma de Nayarit, Tepic, Mexico,* [2]*Clínica de Reumatologia, Depto. Medicina Interna-Instituto Mexicano del Seguro Social, HGZ #1, Tepic, Mexico.*

Tumor necrosis factor-alpha plays a central role in the pathogenesis s ankylosing spondylitis (AS), participating in the genesis of the inflammatory process. Both TNF-a mRNA and its protein have been identified in sacroiliac joints of patients with active disease. TNF-a is a pro-inflammatory cytokine exerting its actions through a link with two cellular surface receptors: TNFR1 and TNFR2. The TNFR2 could play a role in the promotion of the inflammatory process, and in the new bone formation, a characteristic of the AS. The M196R polymorphism of the TNFR2 has been associated with an impaired NF-KB signaling, and then it is associated with the inflammatory process. AS is a chronic inflammatory disorder of the axial skeleton involving mainly sacroiliac joints and lumbar spine, in which genetic factors play an important role. In this study we analyze the T676G polymorphism of TNFR2, which resulted in a non-conservative amino acid substitution (methionine-arginine) at position 196. Thirty three consecutive patients with AS, diagnosed according to the current criteria, and 52 healthy controls were included. DNA was extracted from each subject, and the T676G genotype was determined by PCR-SSCP according to the methods previously described. Our results showed that the 676-G/G genotype could have a protective role (OR 0.2778; 95%CI= 0 0.1112-0.6941), but the 676-T allele represents a risk factor (OR =4; 95%CI = 1.9054-8.3972). However, this conclusion requires further investigation, because of the limitation of a small sample size.

P5.12.24
Cytokines in relation to autoantibodies before onset of symptoms in systemic lupus erythematosus (SLE)

C. Eriksson[1]*, S. Rantapää Dahlqvist*[2]*;*
[1]Clinical immunology/clinical microbiology, Umeå university, Umeå, Sweden, [2]Dpt of public health and clinical medicine/rheumatology Umeå university, Umeå, Sweden.

Background. This study was performed in order to analyse cytokines in blood, and their relationship to autoantibodies in individuals who later developed SLE
Methods. Thirty-five patients with SLE (ACR criteria) who had donated blood to the Medical Biobank, Umeå, Sweden, before onset of symptoms, and 140 age- and sex-matched controls from the same biobank.were analysed for interferon (IFN)-α, interleukin (IL)-4, IL-9, IL-10, interferon inducible protein 10 (CXCL10/IP-10) and monocyte chemotactic protein-1 (CCL2/MCP-1), using a multiplex method. The associations of these cytokines to autoantibodies (ANA, ENA, anti-dsDNA and anti-histones) from the same blood samples (analysed earlier) were evaluated.
Results. The IP-10 levels were higher in the presymptomatic individuals than in controls, p=0.02, and had the most obvious association to autoantibodies, significantly correlated with ANA, SSA, Jo-1 and to autoantibody positivity over all (p=0.03, 0.01, 0.03 and <0.001 respectively). MCP-1 correlated with SSA, SSB and antibody positivity over all (p=0.009, 0.047 and 0.015 respectively), IFN-α with anti-SSB and antibody positivity over all (p=0.027 and 0.025). The levels of IFN-α, IP-10 and MCP-1 correlated with the number of autoantibodies in presymptomatic individuals (p= 0.066, <0.01 and 0.015 respectively). IL-10, IP-10 and MCP-1 increased between the presymptomatic sample and after SLE diagnose, (p=0.026, <0.0001 and <0.0001 respectively).
Conclusions. IP-10, MCP-1 and IFN-α had the clearest correlation with autoantibody formation before disease onset of SLE. Since secretion of IP-10 and MCP-1 are mediated by IFN- α, these findings support previous theories that the IFN-system is important in the early SLE pathogenesis and autoantibody formation.

P5.12.25
Identification of myeloid dendritic cells and plasmacytoid dendritic cells in the peripheral blood of rheumatoid arthritis

S. A. Falaleeva*, V. Kurilin, N. Shkaruba, O. Chumasova, A. Sizikov, S. Sennikov;*
Institute for Clinical Immunology, Siberian Branch of Russian Academy of Medical Sciences, Novosibirsk, Russian Federation.

Background: The study of peripheral blood dendritic cells (PBDCs) is increasingly reaching clinical relevance in a wide range of pathologies, including infectious, neoplastic and autoimmune diseases, because DCs are key antigen presenting cells that prime, polarize and regulate adaptive immune responses.
Objectives: To estimate quantitative and qualitative characteristics of dendritic cells subtypes in peripheral blood in patients with rheumatoid arthritis (RA).
Methods: Phenotypic characterization of immature mDC and pDC in the whole blood was estimated by the negative selection and the positive expression of HLA-DR, CD11c, CD123. To determine the ability of dendritic cells to mature stimulants R848 and lipopolysaccharide were used.
Results It was showed a significant quantitative imbalance of DC in peripheral blood in patients with RA, a significant decrease the pDC. In patients with RA mDC and pDC were characterized by a low expression of CD80, CD83 with high amount of CCR7-positive pDC in compare to the healthy donors. After stimulation percentage of CD80, CD83 and CCR7 positive cells was significantly increased in compare to the samples without stimulation in both groups.
Conclusions: The change in the ratio of subtypes of DC and low expression of CD83, CD80 on them, as well as high expression of CCR7 on peripheral blood pDCs in patients with RA may be explained by the mechanisms of general inflammation. Results of the assessment of maturation of dendritic cells in RA patients in response to TLR agonists indicate the ability of initially less mature mDCs and pDC respond adequately to the maturation.

Extended characterization of human chondrocytes for establishment of co-culture systems with synovial fibroblasts under different culture conditions in the context of Rheumatoid Arthritis

S. Möller[1]*, P. Kern*[2]*, H. Joos*[1]*, R. Brenner*[1]*, **J. A. A. Fischer***[2]*;*
[1]University of Ulm, Ulm, Germany, [2]Roche Large Molecule Research, pRED Penzberg, Penzberg, Germany.

Rheumatoid Arthritis is the most common form of polyarthritis leading to massive joint destruction and increased morbidity of affected patients. Besides conventional treatment, biologic reagents are successfully used to efficiently slow down RA progression- although still some patients fail to respond and are highly dependent on alternative treatment options. Several different cell types are known to be involved in the development, progression and maintenance of RA. Different immune cells contribute to inflammatory processes, which activate synovial fibroblasts resulting in the development of a highly aggressive pannus tissue and finally cartilage/bone destruction. FLS and chondrocytes are important downstream effector cells and co-culture systems between both cell populations might represent a suitable way of modeling RA *in vitro*. In this study, different *in vitro* co-culture formats between human chondrocytes and RA-derived FLS were assessed on the basis of immortalized and primary-derived chondrocytes. In order to characterize these cells in terms of their chondrogenic phenotype, de-/re-differentiation potential and inflammatory state, extended gene and protein expression analyses have been performed by using qRT-PCR, FACS and immunofluorescence analysis. In addition, several co-culture formats (indirect/direct co-culture, e.g. RA-FLS conditioned medium, alginate beads or transwell system) were compared and also the impact of pro-inflammatory cytokines and anti-rheumatic drugs was assessed. All co-culture models resulted in the induction of an inflammatory chondrocyte phenotype represented by up-regulated gene expression of pro-inflammatory cytokines and MMPs reflecting the RA-diseased background. These *in vitro* co-cultures might serve as promising systems for testing potential anti-rheumatic drugs and studying intercellular mechanisms in RA.

P5.12.27
Interplay of myeloid cells and synovial fibroblast boosts the inflammatory response

P. Kern[1]*, B. Schwarz*[1]*, M. Galm*[2]*, L. Pradel*[2]*, **J. A. A. Fischer***[1]*;*
[1]Roche Large Molecule Research, pRED Penzberg, Penzberg, Germany, [2]Roche Discovery Oncology, pRED Penzberg, Penzberg, Germany.

The interaction between synovial fibroblasts (FLS) and different myeloid subpopulations (monocytes and polarized macrophages) might be a contributor of the induction/aggravation of inflammatory processes in rheumatoid arthritis (RA) and other autoimmune diseases. In this study the interplay between monocytes layered over confluent fibroblasts was tested in a co-culture system analyzing several parameters: there was a massive increase in pro-inflammatory cytokine production (IL-6 or-8) and also matrix-metalloproteases (MMP1 and MMP3) in co-cultures compared to single cultured cells. Furthermore, expression of the adhesion marker ICAM-1 was also tremendously elevated on co-cultured fibroblasts in addition to the overall proliferation. Interestingly, the production of other cytokines/MMPs was only slightly elevated or even reduced in co-cultures. And there were no differences detectable between FLS from healthy donors or RA patients. To study whether the phenotype of the myeloid cells was essential for this boosted immune response, monocytes were compared with M1 and M2c polarized macrophages from the same donor: the response of M1 macrophages was in the range of freshly isolated monocytes or even higher, demonstrating a massively increased cytokine production in co-cultures. However, although there was a clear amplification in M2c co-cultures, the cytokine levels reached only about half of those from monocyte co-cultures and this was also true for the ICAM-1 upregulation. Similar effects were observed regarding the MMP production. Application of neutralizing antibodies to both adhesion molecules (such as e.g. ICAM-1) and different cytokines might help to disclose the interplay between these cell types and the signaling cascades involved in inflammatory processes.

P5.12.28
The candidate rheumatoid arthritis autoantigen aggrecan enhance IL-9 response in peripheral blood of Rheumatoid Arthritis' patients

G. Giardina*;*
Research Fellow, Palermo, Italy.

Rheumatoid arthritis (RA) is a chronic autoimmune disorder, characterized by sinovitis, leading to both cartilage and bone erosion. Recently, a citrullinated arthritogenic aggrecan peptide was identified in peripheral blood of RA patients and it has been demonstrated to activate Th17-mediated responses highlights the potential value of citrullinated aggrecan peptide specific responses as biomarkers of RA. In this study we evaluated CD4 T cell subsets percentage in RA patients and controls in response to citrullinated and non citrullinated aggrecan peptide and we investigated a possible role of IL-9, that wasn't studied in RA immune response. Peripheral blood mononuclear cells (PBMCs) were isolated from patients and controls and were stimulated with citrullinated e non citrullinated aggrecan peptide. After incubation cells were collected and stained with the following monoclonal antibodies: anti-CD4, anti-IFN-γ, anti-IL-17, anti-IL-9, anti-PU.1, anti-CD25, anti-FoxP3; flow cytometry analysis then was performed. The specific stimulation with the citrullinated peptide is characterized by production of proinflammatory cytokines and particularly IFN-γ and IL-17 that are actively involved in the articular damage in RA patients. Our results demonstrate an increase of CD4 T effector subsets after *in vitro* stimulation with citrullinated aggrecan, and provide the first evidence of a Th9 response in RA patients.

Certolizumab Pegol in Rheumatoid Arthritis. Follow-up in latinoamerican experience

R. Guzman Moreno*[1], G. Roa Montes[1], J. Cordoba[1], W. Rodriguez[1], W. Otero[2];*
[1]IDEARG, Bogota, Colombia, [2]Servimed, Bucaramanga, Colombia.

Certolizumab pegol (CZP) is a TNF inhibitor, with efficacy in RA, (Rheumatoid Arthritis) clinical trials. Many clinical trials recruited patients from USA and Europe and therefore clinical experience in countries like Latin America is limited. This is the experience with CZP in daily clinical practice inColombia . We describe the characteristics of the first Latin-American patients receiving CZP in clinical practice. 150 clinical records of patients with RA were reviewed; . We used 400 mg in weeks 0,2,4 followed by 400mg every 4 weeks. DAS28 score was recorded before treatment initiation with follow-ups at weeks 12 and 24. Mean change in DAS28 score, EULAR response and change in disease activity according to DAS28 score were calculated. 150 patients were included. 125 were women, aged 21 to 80 years old (mean ±SD 54.8 ±13.2). Patients had used 2 Synthetic DMARDs Drugs, 35 patients had received one biological agents previously (23.3.%). Mean baseline DAS28 score was 5.50±0.64; after 12 and 24 weeks the DAS28 was 2.9±0.99 and 2.64±1.24, with a mean change of -2.5±0.96 and -2.6±1.25 respectively. In 110 patients (86.32%) the decrease (>/=1.2 points) was clinically significant at week 24. At the end of the follow up period 108 participants (72.63%) showed a good EULAR treatment response, 25 patients (17.79%) showed a moderate response and 17 were non-responders (11.33%).. Fifteen adverse events were reported which included a serious one. This experience suggest an adequate effectiveness and safety profile in latinamerican patients treated with CZP.

P5.12.30
Chondrocytes as mediators of citrullination and humoral immunity to citrullinated type II collagen in Rheumatoid Arthritis

S. Haag*[1], N. Schneider[2], D. E. Mason[3], J. Tuncel[1], I. E. Andersson[1], E. C. Peters[3], H. Burkhardt[2], R. Holmdahl[1];*
[1]Karolinska Institutet, Stockholm, Sweden, [2]Johann Wolfgang Goethe University, Frankfurt am Main, Germany, [3]Genomics Institute of the Novartis Research Foundation, San Diego, CA, United States.

Collagen type II (CII) is the major component of articular cartilage targeted by the autoimmune response in RA. CII is arthritogenic in animal models, and anti-CII antibodies alone can induce arthritis in mice. The aim of this study was to investigate CII as a joint-specific target of the anti-citrulline response in RA. We identified potential citrullinated neoepitopes by high-resolution tandem mass spectrometry (MS) of CII treated in vitro with peptidyl arginine deiminase (PAD) 2, and showed that CII could be citrullinated in its native triple helical conformation. Based on the MS analyses, synthetic peptides were designed and analyzed for serum IgG reactivity in 356 RA patients. We identified two new citrulline-specific B-cell epitopes on CII that are recognized by autoantibodies in 40% of RA patients. We further affinity-purified citrulline-specific anti-CII antibodies from RA sera and proved the presence of post translationally-modified CII in arthritic cartilage. Finally, we provide evidence for PAD expression in chondrocytes as well as its localization in the pericellular matrix in RA cartilage, suggesting chondrocytes as local mediators of CII citrullination. We therefore propose the involvement of chondrocytes in provoking cartilage-directed anti-citrulline immunity contributing to the initiation and perpetuation of joint inflammation in RA.

P5.12.31
TNF-alpha and IL1-beta contribute to the increased severity of serum-induced arthritis in NOX2 deficient mice

Y. Huang*[1], P. A. Nigrovic[2], C. Shieh[1];*
[1]Institute of Clinical Medicine, National Cheng-Kung University, Tainan, Taiwan, [2]Department of Medicine, Division of Rheumatology, Immunology, and Allergy, Brigham and Women's Hospital; Department of Medicine, Division of Immunology, Children's Hospital Boston, Harvard Medical School, Boston, MA, United States.

Oxidant stress has been implicated in the immune-mediated tissue damage in arthritis. To elucidate the role of reactive oxygen species (ROS) in modulating tissue inflammation, we established an arthritis model by intraperitoneally injecting the K/BxN serum into wild type and *ncf1*$^{-/-}$ CGD mice, which have deficiency in p47phox of NOX2. By comparing the joint inflammation index, we found that the serum-induced arthritis were more severe in CGD mice than in wild type mice. Neutrophil-dominant joint inflammation was marked in both strains of mice. By depleting neutrophils with anti-Ly6G antibodies, we found that serum-induced arthritis was abrogated in both *ncf1*$^{-/-}$ and wild type mice, which confirms previous reports that neutrophils play an important role in the induction and progression of serum-induced arthritis. We further analyzed the pro-inflammatory cytokines and chemokines to elucidate the possible mechanisms involved in ROS-mediated innate immunity in regulating the joint inflammation. We found that IL1β, IL6 and TNFα levels are higher in *ncf1*$^{-/-}$ than in WT control. Furthermore, we found that the blockade of either IL1β or TNFα may suppress the arthritic inflammation in both strains of mice while IL17-depletion suppressed the arthritic severity in WT, but not in *ncf1*$^{-/-}$ mice. In conclusion, IL17-type inflammation mediates the joint inflammation in mice with wild type NOX2 while IL1β and TNFα contribute to the increased severity of serum-induced arthritis in ROS deficient mice. These results indicate that ROS play an important role in modulating immune-mediated tissue damage in arthritis.

P5.12.32
TNFα-induced adipose-related protein (TIARP) functions as a negative regulator of inflammatory process in arthritis

A. INOUE*[1], I. Matsumoto[1], N. Umeda[1], Y. Tanaka[1], C. Takai[1], S. Takahashi[2], T. Sumida[1];*
[1]Division of Rheumatology, Department of Internal Medicine, Faculty of Medicine, University of Tsukuba, Tsukuba, Ibaraki, Japan, [2]Department of Anatomy and Embryology, Doctoral Program in Biomedical Sciences, Graduate School of Comprehensive Human Sciences, University of Tsukuba, Tsukuba, Ibaraki, Japan.

Objective
TIARP is a six-transmembrane protein induced by TNFα and IL-6. We found that TIARP is dominantly expressed in macrophages and synoviocytes of two arthritic mouse models (collagen induced arthritis; CIA and GPI-induced arthritis; GIA), although the pathogenic mechanisms of arthritis remain unclear. To elucidate the role of

TIARP in the development of arthritis, we have generated TIARP-deficient (TIARP-/-) mice.
Methods
We investigated several organs in TIARP-/- mice. To assess the role of TIARP in macrophages, peritoneal macrophages were cultured with TNFα. The levels of IL-6 production, apoptotic cell numbers, and NF-κB signaling were measured. We also examined the susceptibility of TIARP-/- to CIA and GIA. In addition, to examine the effects of IL-6 on the development of arthritis, mice were injected with anti-IL-6R mAb (MR16-1) after CII immunization. Moreover, the expression of STAT3, phosphorylated-STAT3 (P-STAT3) and SOCS3 in TIARP-/- macrophages after IL-6 stimulation were detected by Western blotting.
Results
We found 80% of TIARP-/- spontaneously developed weak synovitis with high concentration of IL-6 in serum. TIARP-/- macrophages with TNFα stimulation produced high amount of IL-6, and sustained degradation of IκBα. TNFα-induced apoptotic cells were significantly increased in WT but unchanged in TIARP-/-. TIARP-/- showed exacerbated inflammatory response in both CIA and GIA. Administration of MR16-1 significantly suppressed the progression of arthritis in TIARP-/- CIA. P-STAT3 was enhanced in TIARP-/-, whereas SOCS3 was comparable.
Conclusion
TIARP might be a negative regulator in autoimmune arthritis through the suppression of IL-6 production, NF-κB, STAT3 signaling, and the induction of apoptosis.

P5.12.33
Increase of PADI4 in the joints and anti-CCP antibody in the sera of a murine model for rheumatoid arthritis before the clinical onset of arthritis

***K. Ishihara**, A. Yahagi, T. Saika, H. Igarashi;*
Department of Immunology and Molecular Genetics, Kawasaki Medical School, Kurashiki, Japan.

A knock-in mouse gp130F759 has a point mutation Y759F in gp130, a common receptor subunit for IL-6 family cytokines, and spontaneously develops arthritis like rheumatoid arthritis (RA) around 8 months old (MO). Due to interruption of the negative regulatory pathway mediated through Y759, tyrosine-phosphorylation of STAT3 is prolonged by the stimulation with physiological ligands. To find the earliest pathophysiological changes, we quantitatively analyzed the expression of genes for inflammatory cytokines and proteases in the joint before the onset of clinical arthritis. At 5 MO, when no obvious symptom of arthritis was detectable, the expression of MMP8 and IL-6, but not TNFα or IL-1β increased. Flowcytometric analyses of the cells from the synovium revealed presence of neutrophils, macrophages, eosinophils, erythroid and B cells, but not T cells, indicating that the increase of inflammatory cells at the synovium starts as early as 5 MO.
Furthermore, increased expression of peptidyl arginine deiminase type IV(padi4), whose SNPs have been reported as risk factor for RA in certain ethnic groups, was also found in the joints of gp130F759. Western blot analysis revealed the increases of PADI4 protein as well as phosphorylated-STAT3 in extracts from the joints of gp130F759 compared with control C57BL/6. Interestingly, the serum levels of anti-CCP antibody also increased in gp130F759 at 5 MO.
These data have suggested that the molecular mechanisms similar to RA are operating at the earliest phase of arthritis in gp130F759. Thus, the analysis of the relationships between these events will facilitate understanding of the pathophysiology of early RA.

P5.12.34
Promoter polymorphisms of the TNFα (-308 G/A) and IL-6 (-174G/C) genes predict therapeutic response to etanercept

***I. R. Jančić**[1], N. Arsenović-Ranin[1], M. Đefik-Bukilica[2], S. Đivojinović[2], N. Damjanov[3], V. Spasovski[4], S. Srzentić[4], B. Stanković[4], S. Pavlović[4];*
[1]Departmant of Microbiology and immunology, University of Belgrade-Faculty of Pharmacy, Belgrade, Serbia, [2]Institute of Rheumatology, Faculty of Medicine,University of Belgrade, Belgrade, Serbia, [3]Institute of Rheumatology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia, [4]Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Belgrade, Serbia.

The aim of the study was to explore putative influence of - 308 G/A TNFα and -174 G/C IL-6 promoter polymorphisms (releated to TNFα and IL-6 level) on the therapeutic response to etanercept, a TNF-α blocker, in patients with rheumathoid arthritis (RA).
73 patients suffering from active RA were examined at the begining of etanercept treatment and 6- and 12-months following the begining of the treatment. The therapeutic response was estimated according to the European League Against Rheumatism response criteria. Patients were genotyped for -308 G/A TNFα and -174 G/C IL-6 gene polymorphisms by the PCR-RFLP method, and influence of the genotype to clinical response to etanercept was assessed.
Association between -308 G/A TNFα polymorphism and a response to etanercept after 6 and 12 months of therapy was not found. After 12 months the percentage of responders (patients who had DAS28 improvement > 1.2) was significantly increased in patients with the -174 GG IL-6 genotype (95.7 %) compared with those with the -174 GC IL-6 (75.6 %) and -174 CC IL-6 (44.4 %) genotype ($p = 0.006$). The best responders after 12 months were patients with -308 GG TNFα/-174 GG IL-6 genotype combination compared to the other genotype combinations ($p = 0.022$).
The patients with RA exhibiting -308 GG TNFα/-174 GG IL-6 genotype respond better to etanercept than patients with other genotypes examined. This finding suggests that this polymorphism combination should be considered as a genetic marker of responsiveness to TNF-α blockers in RA.

P5.12.35
Accumulation of CD4+CD28-PD-1lowOX40+ T cells and its clinical significance in rheumatoid and collagen-induced arthritis

***J. Jiang**[1], C. Liu[1], Y. Chen[2], J. Jiang[1], R. Zhu[2], T. Wang[2], M. Wu[3], X. Zhang[1];*
[1]The First Affiliated Hospital of Soochow University, Suzhou, China, [2]Soochow University, Suzhou, China, [3]The Third Affiliated Hospital of Soochow University, Changzhou, China.

$CD4^+CD28^-$ T cells play a key role in the immunopathogenesis of Rheumatoid arthritis (RA). Co-inhibitory molecule of PD-1 has a crucial role in suppression of T cell responses. However, presence of PD-1 and absence of CD28 do not induce $CD4^+$ T cells into apoptosis in RA. In this study, we characterized a novel $CD4^+CD28^-PD\text{-}1^{low}OX40^+$ T cells subset and investigated its clinical significance in rheumatoid and collagen-induced arthritis (CIA). Peripheral blood samples were collected from RA, osteoarthritis and healthy subjects. CIA was induced in DBA/1 mice. After separation of mononuclear cells from peripheral blood of the patients or spleen of CIA mice, $CD4^+CD28^-PD\text{-}1^{low}OX40^+$ T cells were examined by flow cytometry. In RA patients and CIA mice, there were increased expressions of PD-1 and OX40 on $CD4^+$ T cells, with PD-L1 and OX40L expressions augmented on monocytes and B cells. Analyses showed that $CD4^+CD28^-PD\text{-}1^{low}OX40^+$ T cells were accumulated and closely correlated with clinicopathological features of RA patients and CIA mice. Moreover, immunosuppressive therapy significantly reduced the percentage of $CD4^+CD28^-PD\text{-}1^{low}OX40^+$ T cells. Additionally, $CD4^+CD28^-PD\text{-}1^{low}$ T cells displayed a phenotype of $CD45RA^{low}CD45RO^{high}CD25^{low}$. In summary, low PD-1 and enhanced OX40 expression implied longevity and persistent activation of these T cells both in RA patients and CIA mice. A phenotype of memory T cells and fine correlations with clinicopathological features suggested that these T cells may be involved in the immunopathogenesis of RA and CIA. Interventions with pathological functions of this T cells subset may provide a new therapeutic interesting in RA.

P5.12.36
Dendritic Cell ImmunoReceptor (DCIR) is a negative regulator in balancing bone metabolism

T. Kaifu[1,2], *T. Maruhashi*[3], *G. Ma*[4], *R. Yabe*[1], *A. Seno*[3], *Y. Iwakura*[1,2];
[1]*Tokyo University of Science, Noda, Japan,* [2]*Core Research for Evolutional Science and Technology (CREST), Tokyo, Japan,* [3]*The University of Tokyo, Tokyo, Japan,* [4]*Hebei Medical University Fourth Hospital, Heibei, China.*

C-type lectin receptors (CLRs) are important pathogen recognition receptors, which are capable of inducing a wide array of cytokine expression and are responsible for host defense against virus and bacteria. Dendritic cell immunoreceptor (DCIR) is a CLR that possesses immunoreceptor tyrosine-based inhibitory motifs (ITIM) docking site for tyrosine phosphatases, suggesting a functional involvement of DCIR in the regulation of the immune system. In line with the structural nature, Dcir−/− mice spontaneously developed autoimmune diseases with age, showing that DCIR maintains immune homeostasis in a negative manner. Here, we demonstrate that DCIR is a key negative regulator in osteoclastogenesis and bone metabolism. Osteoclasts (OC) expressed DCIR at the mRNA and protein levels and DCIR deficiency remarkably elicited OC formation in in vitro culture. As retroviral reconstitution of DCIR into Dcir−/− preOCs reduced OC formation at the comparable level with wild type, ITIM-mediated signal is required for proper osteoclastogenesis. We observed higher responsiveness to M-CSF in Dcir−/− preOCs, suggesting that DCIR may modulate signaling pathways downstream of c-Fms during OC formation. Interestingly, histomorphometric analysis revealed that Dcir−/− mice had the increased femoral bone volume accompanied with higher number of osteoclasts and osteoblasts. Moreover, calcein double-labeling showed a marked increase in bone formation rate in Dcir−/− mice, despise no expression of DCIR in osteoblasts. We will discuss DCIR-mediated regulation of bone metabolism that is regulated by a dynamic balance between osteoclasts and osteoblasts.

P5.12.37
Immunomodulatory role of Fasiola gigantica derived somatic antigens

Y. A. Khan[1,2], *S. Umar*[3,4], *M. A. H. Khan*[1,2], *P. A. A. Shareef*[1,2], *R. Ullah*[1,2], *A. Rehman*[1,2], *S. M. A. Abidi*[1,2];
[1]*Section of Parasitology, Department of Zoology, Aligarh Muslim University, Aligarh, India,* [2]*Aligarh Muslim University, Aligarh, India,* [3]*Clinical toxicology Lab., Department of Toxicology, Jamia Hamdard, New Delhi, New Delhi, India,* [4]*Jamia Hamdard University, New Delhi, India.*

Helminth infections of live stock and humans in tropical and subtropical countries are known to polarize host immune responses toward anti-inflammatory Th2 type, which characteristically suppresses inflammatory mediators (like IFN gamma and TNF alpha) while promoting secretion of anti-inflammatory cytokines (like IL-4, IL-5, IL-10, IL-13). This shift in immune responses could be beneficial in autoimmune disorders where host immune environment is pro-Th1 type. In this context nothing is known about the effect of tropical liver fluke, Fasciola gigantica (Fg), derived products (in human or animals) on the rheumatoid arthritis (RA) which also affects a large population in Indian subcontinent. In this study we evaluated immunosuppressive and therapeutic effects of Fg somatic antigen on the collagen induced arthritis (CIA) in Wistar rats. The animals were primed with somatic antigen, one day prior to induction of CIA. Subsequently rats were separately immunized with collagen type II and different doses of parasite antigen. Controls were simultaneously run to avoid animal stock variations. Successful induction of CIA was evident in scoring of paw diameter and histopathological examinations. The results on the level of antioxidant enzyme SOD, level of NO (Nitric oxide), expression of MMP8 and the transcription factor NF kappa B, levels of TNF alpha and IL10 revealed pronounced immunomodulatory effect of Fg antigen. Taken together, it is concluded that Fg-derived products could be immunoprotective in this autoimmune model.

P5.12.38
Fibrinogen induced inhibition of osteoclastogenesis is reversed by citrullination of fibrinogen by peptidylarginine deiminase

J. S. Kim[1], *M. K. Choi*[2], *J. Y. Choi*[1], *J. Y. Kim*[1], *J. S. Song*[2], *H. J. Kim*[2], *K. H. Park-Min*[3], *L. B. Ivashkiv*[3], *Y. W. Song*[1], *E. Y. Lee*[1];
[1]*Division of Rheumatology, Department of Internal Medicine, Seoul National University College of Medi, Seoul, Korea, Republic of Korea,* [2]*Department of Chemistry, Seoul National University, Seoul, Korea, Republic of Korea,* [3]*Hospital for Special Surgery, New York, New York, United States of America, NY, United States.*

Background: There are increasing evidences that autoantibodies and immune complexes containing citrullinated fibrinogen are present in RA patients' sera and contribute to synovitis. We have in vitro data that fibrinogen can inhibit osteoclastogenesis from precursor cells. In this experiment, we investigated the effect of citrullinated fibrinogen, which are abundant in RA, on the in vitro osteoclastogenesis.
Method: Fibrinogen was citrullinated in vitro by reacting with rmPAD2. Fibrinogen, citrullinated or non-citrullinated, were applied with increasing doses to CD14+ cells, and osteoclastogenesis was induced in the presence of M-CSF and RANKL. To confirm a migration shift due to citrullination, western blotting was performed. The citrullinated sites of fibrinogen were analyzed using mass spectrometry.
Result: Fibrinogen inhibited osteoclastogenesis in a dose-dependent manner. In contrast, citrullinated fibrinogen via rmPAD2 did not show inhibition of osteoclastogenesis, which were evident with non-citrullinated fibrinogen. Several osteoclastogenesis related genes, especially DC-STAMP, were suppressed by fibrinogen during osteoclastogenesis, but restored by citrullinated fibrinogen. Citrullination of fibrinogen was confirmed by western blot analysis and mass spectrometry, showing peak changes between citrullinated and non-citrullinated fibrinogen at five sites in the α-chain, two in the β-chain, and one in the γ-chain. Western blot with anti-citrullinated antibody showed that proteins from RA synovial fluid were more citrullinated than those from OA synovial fluid.
Conclusion: Fibrinogen was citrullinated by PAD and confirmed by western blot and mass spectrometry. In contrast to fibrinogen, citrullinated fibrinogen did not show inhibition of osteoclastogenesis. These results may suggest that citrullinated fibrinogen can contribute to osteoclastogenesis in RA patients.

P5.12.39
Caspase-5 inhibition suppresses inflammatory responses in fibroblast-like synoviocytes with rheumatoid arthritis

Y. Kwon, *J. Song, Y. Park, S. Lee, M. Park;*
Yonsei University College of Medicine, Seoul, Republic of Korea.

Background: Caspases form an conserved family of cytosolic, aspartate-specific, cysteine proteases. Beyond its role in apoptosis, certain caspases exert non-apoptotic functions, including cytokine maturation, cell proliferation, and NF-κB activation. This study investigated the effect of a selective caspase-5 inhibitor (Z-WEHD-fmk) on inflammatory response in fibroblast-like synoviocytes (FLS) in patients with rheumatoid arthritis (RA).
Methods: Caspase-5 expression in rheumatoid FLS were measured after stimulation either without or with pro-inflammatory agents, IL-1β (2 ng/mL), TNF-α (20 ng/mL) and lipopolysaccharide (1000 ng/mL) by real-time quantitative RT-PCR. The involvement of caspase-5 in inflammation and cellular proliferation was examined. The mRNA expressions of proinflammatory mediators after caspase-5 inhibitor treatment were determined by real-time quantitative RT-PCR, and FLS proliferation in response to caspase-5 inhibitor was measured by MTT assay. The levels of phosphorylated JNK, c-jun, ATF-2 and p-38 proteins were evaluated using western blot analysis and the DNA binding activity of NF-κB was measured using EMSA.
Results: Caspase-5 mRNA expression in rheumatoid FLS was increased by IL-1β, TNF-α and lipopolysaccharide stimulation. Caspase-5 inhibitor treatment induced significant reductions of proinflammatory mediators (IL-1β, IL-6, IL-18, COX-2, MMP-9 and CCL-2) from RA FLS. But, cellular proliferation of rheumatoid FLS was not suppressed by caspase-5 inhibitor. The phosphorylated JNK, c-jun, ATF-2 and p-38 were down-regulated and DNA binding activity of NF-κB was decreased following caspase-5 inhibitor treatment.

Conclusions: Caspase-5 inhibition suppresses various proinflammatory responses via modulation of NF-κB in RA FLS. These results suggest that inhibition of caspase-5 may represent a novel therapeutic approach in RA.

P5.12.40
Significant reduction of the Cia25/Pia42 interval, a new arthritis severity and joint damage locus that regulates the invasive properties of synovial fibroblasts. Cia25/Pia42

*M. Brenner, **T. Laragione**, P. S. Gulko;*
The Feinstein Institute for Medical Research, Manhasset, NY, United States.

Rheumatoid arthritis (RA) is a chronic and commonly disabling disease with a prevalence of 1% world-wide. Disease remission is rarely achieved with current treatments and little is known about the genes that control disease severity and joint damage. We have identified the arthritis severity and joint damage regulatory quantitative trait locus, *Cia25/Pia42* on rat chromosome 12, in an intercross between MHC-identical arthritis-susceptible DA and arthritis-resistant ACI rats. *Cia25/Pia42* regulates collagen-induced arthritis (CIA) and pristane-induced arthritis (PIA), two established models of RA. *Cia25/Pia42* regulates the synovial expression of IL-6, IL-1β, MMP-3 and other key mediators of arthritis pathogenesis. Here we report the genotype-guided breeding of twelve different DA.ACI(Cia25/Pia42) subcongenic strains. These new strains were studied in the homozygous state in PIA, and based on the subcongenic effect on arthritis severity we were able to reduce the gene-containing interval from 23Mb to 1.7Mb. The new and reduced interval contains 34 genes. We also studied the invasive properties of synovial fibroblasts from DA.ACI(*Cia25/Pia42*) congenics in an *in vitro* model of through Matrigel, a phenotype known to correlate with radiographic and histologic damage in arthritis. Synovial fibroblasts from congenics had an 80% reduction in invasion, compared with DA (p=0.02). Therefore, we have significantly reduced the *Cia25/Pia42* interval towards positional cloning, and identified evidence suggesting that at least part of its effect is mediated via synovial cell function and invasion. The discovery of the *Cia25-Pia42* gene has the potential to generate a new target for therapy in arthritis, and a new prognostic biomarker for RA.

P5.12.41
The arthritis severity locus Cia4 is an early regulator of IL-6, IL-1b and genes implicated in NFkB activation in synovial tissues of rats with pristane-induced arthritis

*M. Brenner, **T. Laragione**, P. S. Gulko;*
The Feinstein Institute for Medical Research, Manhasset, NY, United States.

Cia4 is a quantitative trait locus that regulates disease severity and joint damage in rats with pristane-induced arthritis (PIA). To identify cellular and molecular processes regulated by *Cia4,* synovial tissues from DA (severe erosive disease) and DA.F344(Cia4) congenic (mild non-erosive disease) rats were collected before and after onset of PIA and analyzed for gene expression. Before onset of arthritis, *Il6* levels were 135-fold higher in DA compared with congenics, and remained significantly increased. The *Il6* increase preceded a modest increase in *Il1b* (4.2-fold) suggesting that *Il6* could be driving cytokine expression and early histologic inflammatory infiltration. 187 genes had significantly different expression and included inflammatory mediators expressed in increased levels in DA such *Slpi* (10.94-fold) and its receptor *Plscr1* (2.31-fold), *Cd163* (5.85-fold), *Ccl7* (5.17-fold), and *Litaf* (2.09-fold). *Syk* or NFκB pathway activating and interacting genes were increased in DA synovial tissues. 59 genes implicated in cancer-related phenotypes were increased in DA, while genes involved in cell metabolism, transport across membranes and tissue protection such as *Acat1, Dgat1, Dhcr7, Slc25a29*, and *Slc1a1* were increased in *Cia4* congenics. 21 genes differentially expressed, or expressed in only one of the two strains were located within the *Cia4* interval, and could be the gene accounting for the arthritis effect. In conclusion, the *Cia4* interval contains a new arthritis gene that regulates the expression *of Il6*, *Il1b*, other inflammatory molecules known to mediate arthritis, and genes involved in cancer that may be implicated in synovial hyperplasia, invasion, and cartilage and bone destruction.

P5.12.42
The nuclear receptor NR1D1 suppresses the invasive properties of synovial fibroblasts from rheumatoid arthritis

***T. Laragione**, M. Brenner, P. S. Gulko;*
The Feinstein Institute for Medical Research, Manhasset, NY, United States.

Rheumatoid arthritis (RA) is a common and chronic autoimmune disease. Arthritis severity and joint damage predict clinical outcome and the risk for disability in RA. Yet, little is known about disease severity and joint damage regulatory genes. We have identified a new nuclear receptor (NR) expression signature in synovial tissues that correlates with arthritis protection and development of mild and non-erosive disease. NR1D1 was the NR with the most significant difference in expression in synovial tissues, with an 8.75-fold increase in the protected rats, suggesting that increased levels and activity of NRs have a suppressive effect on disease severity and joint damage. We hypothesized that NR1D1 mediates arthritis protection at least in part via inhibition of the invasiveness of fibroblast-like synoviocytes (FLS) derived from RA patients and arthritic rats, an *in vitro* phenotype known to correlate with histologic and radiographic joint damage. FLS obtained from arthritic DA rats and RA patients treated with the NR1D1 agonist GSK4112 had a significant 70% and 60% reduction on their invasiveness through Matrigel ($p \leq 0.002$), respectively, compared with vehicle. GSK4112 treatment reduced numbers of thick actin filaments, numbers of elongated cells and the polarized formation of lamellipodia, all actin cytoskeleton and FLS morphologic changes required for invasion. GSK4112 did not significantly affect the IL-1β-induced expression of MMP-1, MMP-2 and MMP-3 in FLS. In conclusion, we have identified an association between increased synovial expression of NR1D1 and arthritis protection, and a new role for this gene in the regulation of FLS properties.

P5.12.43
TRPV2 is new suppressor of arthritis severity and joint damage

***T. Laragione**[1], C. Beeton[2], P. S. Gulko[1];*
[1]The Feinstein Institute for Medical Research, Manhasset, NY, United States, [2]Baylor College of Medicine, Houston, TX, United States.

Rheumatoid arthritis (RA) is a common and chronic disease associated with increased risk of developing disability. Disease remission is still rarely achieved and better treatments are needed. The fibroblast-like synoviocyte (FLS) has a central role in the formation of synovial hyperplasia and in articular damage. The FLS *in vitro* invasive properties correlate with disease severity and joint damage in rodents and patients with RA, yet, little is known about the genes regulating RA severity, FLS invasion and joint damage. We have identified significantly increased levels of the non-selective cation channel Trpv2 (transient receptor potential vanilloid subfamily, type 2 channel) in highly invasive FLS obtained from arthritis-susceptible DA rats. Knock-down of Trpv2 with siRNA unexpectedly further increased FLS invasion by nearly 4-fold suggesting that this gene is a suppressor of invasion. We next used the Trpv2-specific agonist O-1821 to treat FLS from DA rats and RA patients. O-1821 significantly reduced invasion by as much as 90% ($p<0.01$). O-1821 was then used to treat KRN serum-induced arthritis in C57BL/6 mice and it significantly reduced arthritis severity scores and preserved a nearly normal joint histology. In conclusion, we have identified a new regulator of arthritis severity and joint damage *in vivo*, and show that at least part of that effect involves suppression of the invasive properties of FLS both in rodents and patients with RA. These new discoveries should provide the basis for the development of new drugs targeting Trpv2 to better preserve joint architecture and improve outcome in RA.

P5.12.44
Decreased heart rate variability in patients with Behcet's disease

***J. Lee**;*
Busan st. Mary's hospital, Busan, Republic of Korea.

The aim of this study was to investigate autonomous functions by means of heart rate variability (HRV), influence of conventional cardiovascular risk factors, and relationship with the disease activity in patients with Behcet's disease (BD).
30 patients with BD and 30 age- and sex-matched healthy controls were included in this study. All the participants were screened for basic cardiovascular risk factors. BD activity was studied with Behcet's disease current activity form (BDCAF) and acute phase indices. HRV was analyzed by 5-min-at rest ECG. Time and frequency domain parameters of HRV were calculated.
Patients with BD had decreased HRV in comparison to healthy controls as reflected by decrease of the standard deviation of normal R-R intervals (34.0±17.5 vs. 56.2±32.3 ms, respectively, p< 0.011) and of the HF power (120.0±79.9 vs. 343.5± 134.2 ms2, respectively, p< 0.006). A significant negative correlation of HRV parameters with BDCAF and CRP in BD was found.
Patients with BD had impaired autonomous cardiac regulation which is related to the presence of systemic inflammation and which could contribute to the increased cardiovascular risk in these patients.

P5.12.45
Upregulation of circulating soluble programmed death-1 is associated with genetic variants in patients with rheumatoid arthritis

***C. Liu**[1], J. Jiang[1], L. Gao[2], Y. Chen[2], T. Wang[2], R. Zhu[2], M. Wu[3], G. Gu[1], X. Zhang[1];*
[1]The First Affiliated Hospital of Soochow University, Suzhou, China, [2]Soochow University, Suzhou, China, [3]The Third Affiliated Hospital of Soochow University, Changzhou, China.

The Programmed death 1 (PD-1) gene is a critical regulator of T-cell activation and is also an important therapeutic target for autoimmune diseases. It had been showed that the human PD-1 gene has 5 splice variants, one of which is a soluble form lacking transmembrane domains. However, little is known about the regulation and the functional properties of soluble PD-1(sPD-1) variants. To better understand how sPD-1 could be involved in autoimmunity, we set out to characterize biochemical and functional properties of sPD-1. We first developed a specific, quantitative ELISA and then used it to detect the presence sPD-1 in serum and joint fluids from patients with rheumatoid arthritis (RA) and osteoarthritis (OA). The levels of sPD-1 occurred at high concentrations in sera and synovial fluid of RA patients and correlated with titers of rheumatoid factor, swollen joint counts and DAS 28 score in RA patients. Further characterization of soluble PD-1 revealed that it could functionally block the regulatory effect of membrane-bound PD-1 on T cell activation. Next, in correlation with their inflammatory status, we identified IFN-γ, TNF-α and IL-17 as inducers of sPD-1. Finally, the PDCD1+ 6370 single polymorphisms was found as a regulator of sPD-1 levels, serum sPD-1 levels in RA patients with GG genotype were significantly higher than those in AA genotype. Takentogether, the mechanism of antagonism of the function of PD-1 by soluble PD-1 may have important clinical relevance in the understanding of RA pathology.

P5.12.46
Antibodies against TIF1gamma in cancer associated myositis precede cancer symptoms and persist after cancer removal

***I. E. Lundberg**[1], L. Dani[1], M. Dastmalchi[1], N. Martínez[2], M. Labrador-Horrillo[3], A. Selva O'Callaghan[3];*
[1]Rheumatology Unit, Stockholm, Sweden, [2]Sant Pau Hospital, Barcelona, Spain, [3]Vall d'Hebron General Hospital, Barcelona, Spain.

Objectives: To analyse levels of TIF1gamma antibodies in longitudinally collected sera taken before cancer diagnosis and after treatment of the malignancy in patients with Cancer Associated Myositis (CAM).
Methods: Serum samples and clinical data were available from 54 patients with CAM. Serum levels of anti-TIF1gamma antibody were tested by ELISA using a commercially available purified recombinant protein (OriGene, Rockville, MD).
Results: Sera from 16 (29.6%) patients (13 females and 3 males) were positive for anti-TIF1gamma antibodies in at least one serum sample. Serum samples taken before cancer diagnosis were available from 15 patients and 4 were positive for anti-TIF1gamma. One of these patients had detectable anti-TIF1gamma antibodies up to 5 years before cancer diagnosis. Of the 16 patients positive for anti-TIF1 gamma, 12 patients had died at time of our study, 7 within 1 year from cancer diagnosis. The 7 patients who died within one year had a mean antibody level of 1976 +/- 304 au, the 5 patients who died after more than 1 year had a mean antibody level of 1036 +/- 555 au (p=0.003). Four patients were still alive at time of the investigation, between 2-13 years after cancer treatment. Two of these became negative for anti-TIF1gamma antibodies.
Conclusions: Anti-TIF1gamma antibodies can be detected before clinical symptoms of cancer and may thus become a helpful marker to alert for cancer in patients with myositis. Levels of anti-TIF1gamma antibodies may be a prognostic marker for survival in CAM.

P5.12.47
Anti-Saccharomyces cerevisiae antibodies in rheumatoid arthritis patients

*W. Sakly[1,2], A. Mankai[3,2], W. Manoubi[2], **I. Ghedira**[2,4];*
[1]Faculty of Sciences, University of Gabes, Tunisia, [2]Research unit (03UR/07-02), Faculty of Pharmacy, Monastir, Tunisia, [3]High School of sciences and techniques of health, Tunis el Manar University, Tunis, Tunisia, [4]Laboratory of Immunology, Farhat Hached Hospital, Sousse, Tunisia.

Aim. To evaluated, retrospectively, the frequency of anti-Saccharomyces cerevisiae antibodies (ASCA) in patients with Rheumatoid Arthritis (RA). Patients and Methods. ASCA, IgG and IgA were determined by ELISA in sera of 131 patients with RA and 160 healthy subjects. Results. The frequency of ASCA (IgG and/or IgA) was significantly higher in RA patients than in the control group (12.8% vs. 3.7%, p = 0.003). ASCA IgG were significantly more frequent in RA patients than in healthy subjects (8.4% vs. 3.1%, p = 0.049). The same observation was found with ASCA IgA (6.1 % vs. 0.6%, p = 0.008). In RA patients, no significant difference between the frequency of ASCA-IgG and ASCA-IgA were found (8.4% vs. 6.1%). The mean level of ASCA-IgG was significantly higher in RA patients than in the control group (4.5±9.4 vs.2.2±2.8, p= 0.005). There was no significant difference of ASCA-IgA levels between RA patients and control group (4.7±10.3 vs. 3.5±1.7). In RA patients, mean ASCA-IgA level was similar to that of ASCA-IgG (4.7±10.3 vs. 4.5±9.4).
Conclusion. Patients with RA had a high frequency of ASCA compared to the control group.

P5.12.48
Anti-Saccharomyces cerevisiae antibodies in patients with systemic lupus erythematosus.

*A. Mankai[1,2], W. Sakly[3,2], Y. Thabet[2], A. Achour[2], W. Manoubi[2], **I. Ghedira**[2,4];*
[1]3- High School of sciences and techniques of health, Tunis el Manar University, Tunis, Tunisia, [2]Research unit (03UR/07-02), Faculty of Pharmacy, Monastir, Tunisia, [3]Faculty of Sciences, University of Gabes, Tunisia, [4]Laboratory of Immunology, Farhat Hached Hospital, Sousse, Tunisia.

Anti-Saccharomyces cerevisiae antibodies (ASCA) had been known to be specific for Crohn's disease but it has been found in many other autoimmune diseases like systemic lupus erythematosus (SLE). Furthermore, cross-reactive epitopes on β2-glycoprotein I (β2GPI) and Saccharomyces cerevisiae were found in SLE patients. The aims of this study were to evaluate the frequency of ASCA in patients with SLE and to compare it with that of anti-β2GPI antibodies (aβ2GPI). Sera of 116 patients with SLE were analyzed in this retrospective study. Sera of 160 blood donors were included as normal controls. ASCA IgA and IgG and aβ2GPI antibodies were determined by

ELISA. The frequency of ASCA (IgG and/or IgA) was significantly higher in SLE patients than in control group (31.9 vs. 3.7 %, $p < 10^{-6}$). ASCA IgG and ASCA IgA were more frequent in SLE patients than in control group (29.3 vs. 3.1 %, $p < 10^{-6}$ and 12.1 vs. 0.6 %, $p = 10^{-4}$, respectively). The mean level of ASCA IgG was higher than that of ASCA IgA (9.5 vs. 6.4 U/ml) but the difference was not statistically significant. The frequencies of aβ2GPI (IgG and/or IgA) and aβ2GPI IgA were significantly higher than those of ASCA (IgG and/or IgA) and ASCA IgA (54.3 vs. 31.9 %, $p = 5 \times 10^{-4}$ and 50.9 vs. 12.1 %, $p < 10^{-6}$, respectively). Increased ASCA IgG was observed in patients with SLE, suggesting a role of environmental stimuli in its pathogenesis.

P5.12.49
MiRNA expression profile of peripheral blood mononuclear cells from RA patients and their relationship with anti-TNF therapy

P. Meroni[1], *M. Raimondo*[1], *M. Borghi*[1,2], *M. Mirolo*[1,3], *F. Pregnolato*[4], *F. Ambrogi*[1], *E. Biganzoli*[1], *M. Locati*[1,3];
[1]*University of Milan, Milan, Italy,* [2]*Ist Auxologico Italiano, Milan, Italy,* [3]*Humanitas Clinical and Research Center, Milan, Italy,* [4]*Istituto Auxologico Italiano, Milan, Italy.*

Inhibition of inflammatory cytokines, including TNFalpha, can ameliorate Rheumatoid Arthritis (RA). Nevertheless, a significant proportion of patients are refractory to anti-TNF treatment and no reliable biomarkers are available to predict therapeutic response. The immune system is under complex genetic and epigenetic mechanisms, i.e. miRNA. Aim of this study was to investigate miRNA expressed in RA PBMCs and the effect of anti-TNFa treatment, with the final goal to identify novel disease biomarkers and potential therapeutic targets.
The miRNA profile was evaluated by TaqMan® Human miRNA Array in PBMCs from 4 active RA patients, before (T0) and 6 months after anti-TNFalpha therapy (T6) and from age-matched healthy controls (ND). All patients were responsive to therapy (mean DAS28 T0=5.63, T6=2.40). We identified 9 miRNA associated with the disease activity as differentially expressed between T0 and ND ($p \leq 0.05$), including miR-92a-1-5p (FC: -5.4), miR-639 (FC: 5.2), miR-801 (FC: 7.6), miR-124-3p (FC: 9.8), miR-572 (FC: 5.6), miR-630 (FC: 3.9), miR-922 (FC: 4.4), miR-7-1-3p (FC: -2.8), and miR-30d-5p (FC: -2.5). Interestingly, among these disease-associated miRNA, miR-124 has been previously associated with RA pathogenesis and it is involved in regulation of macrophage activation. The expression analysis identified 62 miRNA associated with response to treatment as differentially expressed between T0 and T6 ($p \leq 0.05$). These also include the disease-associated miR-7-1-3p and miR-30d-5p, which are significantly reduced in T0 as compared to both ND and T6.
MiRNA may be helpful biomarkers RA management and may offer further insights on the mechanism of action of TNFalpha-inhibitors.

Podoplanin is upregulated at the Th17-mediated inflammation in SKG arthritic mice

Y. Miyamoto*, H. Uga, M. Kadowaki, M. Ikeda, H. Kurata;*
Sysmex Corporation, Kobe, Japan.

Recent advances in biomodifiers with early intervention strategy have dramatically improved the disease courses of rheumatoid arthritis (RA). In contrast, the diagnostics of RA is still lacking for objective and quantitative parameters. Recently, interleukin 17-producing helper T cell lineage (Th17) has been proven to be critical in the pathogenesis of chronic inflammation and autoimmune diseases. Therefore, we searched for Th17-specific biomarkers, useful for monitoring the pathophysiology of RA.
To identify the Th17-specific markers, (1) we improved culturing conditions of four murine helper T cell subsets, including Th17 cells, (2) identified more than one hundred Th17-specific candidate genes by comparative microarray analysis, and (3) validated the candidate markers in three autoimmune disease models (SKG arthritis, SCID colitis and experimental autoimmune encephalomyelitis (EAE)). Among them, twenty-five Th17-specific marker candidates, including IL17A and CCL20, were up-regulated in accordance with disease activities of all the three models. Gene ontology analysis revealed candidate markers, including twenty-nine cell-surface molecules. We focused podplanin, one of the Th17-specific cell-surface molecules, was highly expressed on SKG arthritic joint tissues by qRT-PCR. Moreover, we confirmed that podoplanin-positive Th17 cells significantly upregulated in the inflamed joint tissues of SKG arthritic mice by flow cytometrical (FCM) and immunohistochemical analyses.These results indicate that podoplanin would be a useful Th17 cell marker for diagnosing pathological conditions of Th17-related diseases, including RA.

Allelic expression of 89G/A, 90T/C and 92G/C PADI4 polymorphisms in rheumatoid arthritis

S. Muñoz-Barrios[1], *L. I. Angel-Chávez*[1], *C. A. Palafox-Sánchez*[1], *E. Oregón-Romero*[1], *I. Parra-Rojas*[2], *Z. Reyes-Castillo*[1], *M. Vázquez-Villamar*[1], *J. F. Muñoz-Valle*[1];
[1]*Grupo de Inmunogenética Funcional, Departamento de de Biología Molecular y Genómica, Centro Universitario de Ciencias de la Salud, Universidad de Guadalajara, Guadalajara, Jalisco, Mexico,*
[2]*Laboratorio de Investigación en Obesidad y Diabetes, Unidad Académica de Ciencias Químico Biológicas, Universidad Autónoma de Guerrero, Chilpancingo, Guerrero, Mexico.*

Introduction: Rheumatoid Arthritis (RA) is an inflammatory joint disease of unknown etiology where genetic factors have been associated with the onset and progression of the disease. Polymorphisms *89G/A, 90T/C* and *92G/C*, including the haplotype (GTG) of *PADI4* gene, have been associated with RA susceptibility in several populations. However, the allelic expression of these polymorphisms has not been reported. **Aim:** To assess the allelic expression of *89G/A*, *90T/C* and *92G/C PADI4* polymorphisms in RA. **Methods:** RA patients classified according to the 1987 ACR criteria and control subjects (CS), adjusted by age and sex, were included. The allelic expression was determined by ASTQ method in heterozygotes of *89G>A, 90T>C* and *92G>C PADI4* polymorphisms and mRNA expression of the *PADI4* gene was determined with qPCR in samples classified as homozygotes for the ACC and GTG haplotypes. The data was analyzed with STATA v 9.2 software and *p<0.05* was reported as statistically significant. **Results:** We found a high expression of 89A, 90C and 92C alleles in CS compared with RA patients (62.3% *vs* 46.7%, 55.6% *vs* 27.7% and 84.7% *vs* 43.9%, respectively) and a high expression of 89G, 90T and 92G alleles in RA patients compared with CS (53.3% *vs* 37.7%, 72.3% *vs* 44.4% and 56.1% *vs* 15.3%, respectively). Also, we observed in RA patients that GTG haplotype carriers has 3.29-fold more expression that ACC haplotype carriers (*p<0.001*). **Conclusion:** This study revealed that the 89G, 90T and 92G alleles and the GTG susceptibility haplotype was associated with increased gene expression in RA.

P5.12.52
Evaluation of anti-PADI4 antibodies in rheumatoid arthritis: Association with clinical parameters

S. Muñoz-Barrios[1], *Z. Reyes-Castillo*[1], *M. Vázquez-Villamar*[1], *C. A. Palafox-Sánchez*[1], *E. Oregón-Romero*[1], *I. Parra-Rojas*[2], *L. I. Angel-Chávez*[1], *M. O. Guzmán-Ornelas*[1], *R. E. Navarro-Hernández*[1], *J. F. Muñoz-Valle*[1];
[1]*Grupo de Inmunogenética Funcional, Departamento de de Biología Molecular y Genómica, Centro Universitario de Ciencias de la Salud, Universidad de Guadalajara, Guadalajara, Jalisco, Mexico,*
[2]*Laboratorio de Investigación en Obesidad y Diabetes, Unidad Académica de Ciencias Químico Biológicas, Universidad Autónoma de Guerrero, Chilpancingo, Guerrero, Mexico.*

Introduction: Rheumatoid Arthritis (RA) is an inflammatory joint disease of unknown etiology where the antibody production has been associated with the onset and progression of the disease. PADI4 autoantibodies (anti-PADI4) been described, suggesting relevance in the clinical course of RA. Aim: To assess the association of the anti-PADI4 levels with clinical parameters in RA. Methods: RA patients classified according to the 1987 ACR criteria and control subjects (CS), adjusted by age and sex, were included. Serum levels of anti-PADI4 and anti-CCP antibodies were determined by ELISA method and rheumatoid factor (RF) was determined by turbidimetry. The data was analyzed with STATA v 9.2 and GraphPad v 5.04 software and p<0.05 was reported as statistically significant. Results: Levels of anti-PADI4 in the RA group were higher than CS (2660.7 U/mL vs

210.3 U/mL; p<0.001) and 41.7% of RA patients were positive to anti-PADI4 compared to 4.2% of CS (*p<0.001*). Moreover, we found a positive correlation between anti-PADI4 antibodies and disease evolution, ESR, hsCRP, RF and anti-CCP antibodies (*p=0.032*, *p<0.001, p<0.001, p<0.001* y *p<0.001*, respectively). Finally, we found that 30% of RA patients anti-CCP negative were anti-PADI4 positive and 50% of RA patients RF negative were anti-PADI4 positive. Conclusion: This study revealed that RA patients have high levels of anti-PADI4 and more positive for anti-PADI4 regarding CS and a high percent of RA patients anti-CPP or FR negative were anti-PADI4 positive. These suggest that anti-PADI4 antibodies could be used as a new serological marker of diagnostic and progression in RA.

P5.12.53
Study of IGA1 O-Glycosylation in a multi-ethnic population of IGA Nephropathy patients in Kwazulu Natal, South Africa

*P. Nansook, **A. G. Assounga**;*
University of KwaZulu-Natal, Durban, South Africa.

Background - IgAN is a leading cause of chronic disease and end-stage renal disease worldwide. The pathogenesis is poorly understood. Immune complexes mask the ligand for the hepatic asialoglycoprotein receptor, preventing clearance, promoting selective mesangial deposition which show higher levels of degalactosylation.
Objectives - To study the O-glycosylation of serum IgA1 molecules in a multi-ethnic population of IgAN patients in KwaZulu Natal, South Africa.
Materials and Methods - An ELISA based lectin binding assay was used to measure and compare the level of IgA1 degalactoslyation between IgAN patients and controls. Participants included individuals of African, Caucasian, Coloured, Indian (predominantly) and mixed-race descent. 19 IgAN patients were recruited between 2005 and 2011; 53% were terminal. The mean A value corresponding to the degree of degalactosylation, for the IgAN group was compared to that of the normal control group for each test. Wilcoxom matched pairs test was used. The two-tailed p value was used to assess for statistical significance between the groups.
Results - When all the means of the tests were compared, the average means of the tests of the IgAN patients was 0.3678+- 0.0790 SEM which is statistically significantly greater than the normal controls which was 0.2969=-0.0586 SEM (p = 0.0076). IgAN patients exhibited abnormal IgA1 O-glycosylation with a greater level of terminal degalactosylation of IgA1 in comparison to normal controls.
Discussion - This finding is consistent with that of other populations globally; supporting a universal strategy for therapeutic or curative agents that target this aberrancy

P5.12.54
The mesenchymal stem cell supernatant therapy improves symptoms of collagen-induced arthritis in rats

***M. Nezafat Firizi**, T. Mousavi, E. Entezami;*
Tehran University of Medical Sciences, Tehran, Iran.

The Mesenchymal stem cells (MSCs)-mediated immunosuppression mainly acts through the secretion of soluble molecules. The immunosuppressive activity of MSC supernatants in prevention of rat collagen-induced arthritis (CIA) were examined in this study.
The model of Wistar rats with CIA was created using chicken type II collagen and Complete Freund's Adjuvant. Following this immunization, Rats treated with rat bone marrow derived MSC supernatants via tail vein.
Results this study showed that MSC supernatants suppresse paw swelling significantly (P<0.05) compared with the model group. This treatment also improved pathological changes, MSC supernatants - treated rats showed a significant improvement in synovial hyperplasia, inflammatory infiltration, cartilage and bone destruction and other symptoms. The levels of Anti-type II collagen antibodies and TNF-α significantly decreased in MSC supernatant treated rats compared to control group. The results of MTT assay showed that proliferative ability of splenocytes from MSC supernatant treated rats following exposure with chicken type II collagen significantly decreased compared with splenocytes from control group (P<0.01).
Taken together, we found that a single i.v. injection of MSC supernatants was able to improve symptoms of CIA.

P5.12.55
A monoclonal CCP-antibody derived from RA patients binds to several citrullinated antigens in the human cellular components

***T. Ozawa**[1], R. Tuda[2], E. Kobayashi[1], H. Hounoki[2], K. Shinoda[2], H. Taki[2], K. Tobe[2], H. Kishi[1], A. Muraguchi[1];*
[1]Dept. Immunol., Univ. of Toyama, Toyama, Japan, [2]1st Dept. Int. Med., Univ. of Toyama, Toyama, Japan.

Appearance of antibodies that bind to cyclic citrullinated peptides (CCP) (CCP-Abs) has been reported in the serum of rheumatoid arthritis (RA) patients. However, the physiological role of CCP-antibodies during the progression of RA are unclear. In this study, we tried to obtain monoclonal RA-derived CCP-antibody (RA-CCPAb) to identify the antigens in the cellular components to which the RA-CCPAb binds. To obtain the monoclonal RA-CCPAbs, we used an immunospot-array assay on a chip (ISAAC) technology in which we can detect antigen-specific antibody-secreting cells (ASCs) in human peripheral blood lymphocytes and can produce antigen-specific human monoclonal antibodies. We obtained two monoclonal RA-CCPAbs (IgG4) with the same amino acid sequence from RA patients. Western-blot analysis revealed many proteins to which the RA-CCPAb bound in the peptidyl-arginine- deiminase (PAD)-treated HEK293 cell lysate, but not in the PAD-non-treated lysate. Subsequently, we identified these proteins using immunoprecipitation with the RA-CCPAb followed by the mass technology. Several candidate proteins were identified using the nanoLC-MS/MS. To confirm the binding of the RA-CCPAb to the candidate proteins, we immunoprecipitated PAD-treated HEL293 lysate using RA-CCPAb and then examined whether the antibodies to candidate proteins can bind to the proteins. As a result, some antibodies bound to the candidate proteins under discussion. These data suggest that the RA-CCPAb recognizes several citrullinated proteins in the human cellular components. The analysis of antigens using the monoclonal RA-CCPAb should greatly contribute to the elucidation of the physiological roles of CCP-antibodies during the onset and progression of RA.

P5.12.56
Complement Regulatory Protein MCP; CD46 in Rheumatoid Arthritis

***R. Pahwa**, U. Kumar, N. Das;*
All India Institue of Medical Sciences, New Delhi, India.

Introduction: Rheumatoid Arthritis (RA) is a chronic inflammatory disease characterized by pain, swelling and progressive destruction of multiple joints, affecting approximately 1% of the adult human population. The growing importance of Membrane cofactor protein (MCP; CD46) not only as central membrane bound complement inhibitor but also as critical regulator of T-cell immunity, suggests that regulation of its expression may have significant effects on health and disease.
Objectives: Studies on animal models suggest disease modulating activity of Leukocyte CD 46 (L-CD46) in autoimmune disorders. We conducted a case-control study to explore the role of L-CD 46 in human RA.
Methodology: The L-CD46 expression in 40 healthy controls and 40 RA patients on different leukocyte subpopulations was observed by Flow cytometry and expression at mRNA level was monitored using Real-Time PCR. The clinical parameters Circulating Immune Complexes (CIC), Disease activity scores (DAS28), swollen and tender joint counts (SJC and TJC) were determined and correlated with L-CD46 expression in patients.
Results: In patients, the L-CD46 expression reduced significantly on lymphocytes followed by monocytes. Further L-CD46 transcripts declined significantly in patients. Significant inverse correlations of L-CD 46 expression on lymphocyte and monocyte surface and transcript level with DAS28, SJC and CIC were observed in patients.

Conclusions: Decline in the L-CD46 levels suggests failure in protective role of L-CD46 against complement mediated damage in RA patients. The negative correlations of L-CD46 with disease activity indices suggest its significant association with the disease state. Follow-up study confirming L-CD46 role as pivotal biomarker is warranted.

P5.12.57
Halofuginone ameliorates autoimmune arthritis by regulation the balance between Th17 and Tregs and the inhibition of osteoclastogenesis

***S. Park**, M. Park, E. Park, D. Lee, S. Baek, E. Yang, J. Woo, S. Kwok, H. Kim, M. Cho;*
The Catholic University of Korea, Seoul, Republic of Korea.

Objective: The small molecule halofuginone (HF) has been shown to inhibit fibrosis, angiogenesis, and tumor progression. The objective of this study was to evaluate the effects of HF in preventing autoimmune arthritis in mice.
Methods: The effects of HF on joint diseases were assessed by clinical scoring and histological analysis. Protein expressions were confirmed by immunohistochemistry, ELISA, flow cytometry, and/or western blotting. The mRNA expression levels of various molecules were determined by realtime-PCR. Proliferation of osteoclast precursors was assessed by bromodeoxyuridine (BrdU) uptake. Osteoclast differentiation and activity were determined by quantifying tartrate-resistant acid phosphatase (TRAP)+ multinucleated cells and area of resorbed bone.
Results: Treatment with HF suppressed the development of autoimmune arthritis and reciprocally regulated Th17 cell and Foxp3+ regulatory T (Treg) cells. These effects of HF on Th17 differentiation involved increased signaling of extracellular signal-regulated kinase (ERK), and reduction of signal transducer and activator of transcription 3 (Stat3) and nuclear factor of activated T cells cytoplasmic 1 (NFATc1) expression. Furthermore, HF induced expression of indoleamine 2, 3-dioxygenase (IDO) in dendritic cells (DCs), leading to reduced the production of Th17 cells. In addition, HF prevented the formation and activity of osteoclasts through suppression of transcription factors, such as activator protein-1 (AP-1) and NFATc1, and inhibition of cell cycle arrest of the committed osteoclast precursors via expression of ccnd1 encoding cyclin D1.
Conclusion: Taken together, our results suggested that HF is a promising therapeutic agent for the treatment of Th17 cells-mediated inflammatory diseases and bone diseases.

P5.12.58
Number of activated cytotoxic T-lymphocytes and natural killers in children with juvenile arthritis.

***I. A. Pashnina**;*
Institute of Immunology and Physiology, Ekaterinburg, Russian Federation.

Now participation of cytotoxic T-lymphocytes and natural killers (NK) in pathogenesis of various autoimmune diseases is actively discussed. One of markers of cytotoxic cells activation is CD38, participating in regulation of endocellular calcium concentration. The estimation of expression CD38 on T-lymphocytes and NK in children with juvenile arthritis was the purpose of our work.
Children of 7-17 years old are surveyed: 12 children with oligo- and 16 with polyarticulare juvenile arthritis, 6 children with system onset of juvenile arthritis, 12 children with juvenile spondiloarthopathy, 10 healthy children. Quantity of CD3+CD8+, CD3-CD16+/56+, CD3+CD8+CD38+, CD3-CD16+/56+CD38+, CD3-CD16+/56+CD8+CD38+ was estimated by flow cytometry with staining by monoclonal antibodies (Beckman Coulter, USA).
The number of T-cells (CD3+) and NK-cells (CD3-CD16+/56+) in all groups were the similar. Amount of T-cytotoxic cells (CD3+CD8+) was above in children with polyarticulary juvenile arthritis in comparison with the control group (p<0,05). The number of T-lymphocytes and NK with activation marker CD38 in children with arthritis in all cases was above control values (p<0,05). Amount of natural killers, simultaneously expressed CD8+ and CD38+, has been raised at juvenile spondiloarthopathy (p<0,05). It is considered that these cells possess the greatest cytotoxic activity and are capable to multiple killing of target cells. Thus, increase of the number of activated T-lymphocytes and natural killers in children with an autoimmune pathology testifies involving of these cells in pathogenesis of this diseases.

P5.12.59
Antibodies to citrullinated peptide in children with juvenile arthritis.

***I. A. Pashnina**, I. M. Krivolapova;*
Institute of Immunology and Physiology, Ekaterinburg, Russian Federation.

Detection of antibodies to citrullinated peptides is widely used for diagnostics of rheumatoid arthritis in adults and demonstrates high sensitivity and specificity. Using of these tests is much less common in the diagnostics of juvenile arthritis (JA). The aim of our work was to investigate the frequency of anti-mutated citrullinated vimentin (anti-MCV) and anti-cyclic citrullinated peptide (anti-CCP) antibodies in children with juvenile arthritis.
The levels anti-MCV (Orgentec, Germany) and anti-CCP (Euroimmun, Germany) antibodies were determined by ELISA in 219 children with juvenile arthritis and in 25 healthy children.
Anti-MCV antibodies were found in 12% of children with oligoarticular JA (n = 114), 19% with polyarticular JA (n = 79), and 23% with systemic onset of disease (n = 26). The total frequency of anti-MCV antibodies was 18%, thus, the test sensitivity is low for the diagnostics of juvenile arthritis. High levels of anti-MCV antibodies were detected in 2 of 25 healthy children.
A simultaneous determination anti-MCV and anti-CCP antibody was held in 124 children with juvenile arthritis. Using the manufacturer's cut-off threshold 20U/ml for anti-MCV antibodies 19 children had concentrations of anti-MCV antibodies above normal, high levels of anti-CCP antibodies were observed in 11 ones. Increasing cut-off for anti-MCV antibodies up to 30U/ml the positive results were only in 11 patients, which shows the specificity of laboratory tests became equal. The concentration of anti-MCV antibodies was below 30U/ml in all healthy children. Thus, the cut-off for anti-MCV antibodies should be specified for the diagnostics of juvenile arthritis.

P5.12.60
The number of B-cells subpopulations and level of autoantibodies in children with juvenile arthritis

***I. A. Pashnina**, I. M. Krivolapova;*
Institute of Immunology and Physiology, Ekaterinburg, Russian Federation.

It is known that increasing of the autoantibody level could have interconnection with the expansion of B1-cells (CD19+CD5+). The amount of B-memory cells (CD19+CD27+) could be also increased in autoimmune diseases. The aim of our work was to investigate the number of B-cells and their subpopulations and autoantibody level in children with juvenile arthritis (JA).
Children of 7-17 years old are surveyed: 33 children with oligo- and 32 with polyarticular JA, 23 children with juvenile spondiloarthopathy, 23 healthy children. Quantity of CD19+, CD19+CD5+, CD19+CD27+ was estimated by flow cytometry with staining by monoclonal antibodies (Beckman Coulter, USA). The level of antinuclear factor was investigated by indirect immunofluorescence (Euroimmun, Germany).
The levels of antinuclear factor were higher in all children with arthritis than in healthy children (p<0,05). But the number of B-cells (CD19+) in patients with oligoarticular onset and with juvenile spondiloarthopathy were less in comparison with the control group (p<0.05). The amounts of CD19+CD5+ and CD19+CD27+ in children with oligoarticular JA were more than in healthy children (p<0,05). Thus, the most considerable changing of B-cells subpopulations was observed in children with oligoarticular JA. It could be connected with level of antinuclear factor which was the biggest in this group. And we found correlation (p<0.05) between antibody level and CD19+ and CD19+CD27+ in these children but not with CD19+CD5+. In patients

with polyarticular JA we also observed correlation of the level of antinuclear factor (p<0.05) with the amount of CD19+CD27+, and in patients with juvenile spondiloarthopathy with the amount of CD19+.

IL12B gene haplotype influences the risk of ankylosing spondylitis in Romanians

O. Popa[1], *E. Kriegova*[2], *L. Popa*[3], *M. Cherciu*[1], *M. I. Dutescu*[4], *M. Bojinca*[1], *V. Bojinca*[1], *P. Schneiderova*[2], *C. Bara*[1], *M. Petrek*[2];
[1]*Faculty of Medicine, University 'Carol Davila', Bucharest, Romania,* [2]*Faculty of Medicine and Dentistry, Palacky University, Olomouc, Czech Republic,* [3]*Molecular Biology Department, Grigore Antipa National Museum of Natural History, Bucharest, Romania,* [4]*National Institute of Blood Transfusion, Bucharest, Romania.*

Ankylosing spondylitis (AS) is a chronic inflammatory disease with predominant involvement of the spine. Recent findings showed that variations of the genes coding for members of the Th17 axis influence the risk of AS. Among these genes, IL12B that encodes the common subunit p40 of the heterodimeric cytokines IL12 and IL23 was less studied. Our aim was to investigate the possible influence of IL12B gene single nucleotide polymorphisms (SNPs) on the risk of AS in Romanian population.
Four SNPs mapping to IL12B gene were genotyped in 168 consecutive AS patients and 161 healthy controls of Romanian ethnicity using the Sequenom MassARRAY platform (Sequenom, San Diego, CA). Statistical analyses were performed with PLINK software. The intronic SNP rs1363670 was associated with a lower risk of AS (OR 0.59, 95%CI 0.358-0.998, p=0.04). The other polymorphisms were not associated with AS at individual level. The SNPs were not in linkage disequilibrium in the studied population (D'<0.22). Four haplotypic combinations (AAAC, CAAC, ACAC, ACGG) of the investigated SNPs (rs32132227/rs2853694/rs1433048/rs1363670) had frequencies over 5% in either controls or patients. Of these, the haplotype AAAC was significantly overrepresented in patients compared with controls (35.5% versus 26.8%, p=0.01). In conclusion, our results suggest that a particular haplotype of IL12B gene may increase the risk of AS in Romanian population.

Decrypting the genomic signatures associated with Rheumatoid Arthritis: A systems immunological approach

P. N. Pushparaj[1], *L. A. Damiati*[2], *S. M. Bahlas*[3], *J. Manikandan*[1], *K. Gauthaman*[1], *M. H. Al-Qahtani*[1];
[1]*Center of Excellence in Genomic Medicine Research, King Abdulaziz University, Jeddah, Saudi Arabia,* [2]*Biology Department, King Abdulaziz University, Jeddah, Saudi Arabia,* [3]*Department of Internal Medicine, Faculty of Medicine, King Abdulaziz University, Jeddah, Saudi Arabia.*

Rheumatoid Arthritis (RA) is a chronic autoimmune inflammatory disease characterized by synovitis, articular damage, and other associated problems in brain, lungs and vasculature. The inflammatory synovitis in RA patients is characterized by a rapid influx and proliferation of immune cells resulting in the excessive cytokine production, tissue damage and other co-morbidities. In the present study, we have identified various genomic signatures and biological pathways associated with RA using systems immunological approaches. Raw microarray expression (Affymetrix CEL) files in the public domain derived from studies on RA patients were downloaded from the Gene Expression Omnibus (GEO) and analysed by Genespring GX 12.5 software (Agilent, USA). The significantly expressed genes were selected by a standard cut-off at 2-fold increased expression compared with the normal controls. These differentially expressed genes were then classified based on Gene Ontology (GO) such as the expression of immune cell receptors, regulation of inflammatory response, cytokines and chemokines etc., Additionally, the differentially expressed genes were analysed by Ingenuity Pathway Analysis (IPA) software for the identification of canonical and novel pathways implicated in RA. The genomic signatures identified clearly showed the disparity of proinflammatory and anti-inflammatory cytokines and chemokines in RA synovia that augment the destruction of adjacent cartilages and sub-chondral bone erosions, ligaments and the laxity of tendons in RA. Hence, systems immunological dissection of high throughput data is necessary to understand various disease promoting gene signatures in RA patients and help to efficiently devise therapeutic strategies to control the disease and successfully prevent relapse and attain remission.

Angiogenic T cell depletion in Rheumatoid Arthritis patients

J. Rodriguez-Carrio[1], *M. Alperi-López*[2], *P. López*[1], *S. Alonso-Castro*[2], *F. J. Ballina-García*[2], *A. Suárez*[1];
[1]*University of Oviedo, Oviedo, Spain,* [2]*Hospital Universitario Central de Asturias, Oviedo, Spain.*

Since Angiogenic T cells (Tang) could have a role in endothelial repair through cooperating with Endothelial Progenitor Cells (EPC), we analyzed both populations in Rheumatoid Arthritis (RA) patients and their associations with disease specific parameters and traditional cardiovascular (CV) risk factors. Thus, Tang ($CD3^+CD31^+CD184^+$) and EPC ($CD34^+VEGFR2^+CD133^+$) populations were quantified by flow cytometry in peripheral blood samples from 81 patients with long-standing RA and 18 matched-healthy controls (HC). Clinical features and traditional CV risk factors were obtained from case records and IFNα serum levels were assessed by immunoassays.
Results showed a strong depletion of Tang (p<0.001) and EPC (p<0.0001) in RA patients. In HC, but not in patients, both populations were positively correlated (r=0.886, p<0.0001) and inversely related to LDL- and total-cholesterol levels. Moreover, gender, presence of diabetes, dyslipidemia, hypertension or obesity in patients did not influence significantly Tang, although a higher depletion was detected in smokers (p=0.013). However, Tang depletion was strongly correlated with disease activity (DAS28: r=-0.562, p=0.001) and IFNα serum levels (r=-0.329, p=0.003). Multiple regression analysis adjusted for traditional CV risk factors confirmed that only disease activity (β[95% CI]: -0.413[-1.008, -0.339], p=0.0001), age at diagnosis (-0.310[-0.088,-0.018], p=0.003), ANA positivity (-0.247[-1.959,-0.184], p=0.019) and smoking habit (-2.826[-2.189,-0.374], p=0.006) could predict Tang frequency. Finally, patients who had suffered CV events from their RA diagnosis (n=16) presented stronger Tang depletion (p=0.007) and increased IFNα levels (p=0.019) than those CV events-free. All these data indicate that disease-specific parameters, rather than traditional CV risk factors, are implicated in Tang depletion in RA patients.

Hospital Civil de Guadalajara "Fray Antonio Alcalde", Guadalajara, Jalisco, Mexico.*

INTRODUCTION: Rheumatoid arthritis (RA) is an autoimmune disease, characterized by inflammation of the synovial membrane and destruction of cartilage and bone. T lymphocytes trigger an abnormal response against self-antigens, which leads to the activation of autoreactive B cells and autoantibody production. A large number of genes have been proposed as candidates for the development of RA, like PTPN22, which encodes a lymphoid protein phosphatase (LYP), a potent inhibitor of T and B cell activation. The -1123G>C and the +1858C>T PTPN22 gene polymorphisms have been reported in association with RA susceptibility. Both polymorphisms have been found in strong linkage disequilibrium and CT haplotype, consisting of both risk alleles, was reported as susceptibility haplotype to autoimmune diseases. OBJECTIVE: To

study the +1858C>T/-1123G>C PTPN22 haplotypes and linkage disequilibrium in rheumatoid arthritis patients from the Western Mexico. METHODS: Genotypes for -1123G>C and +1858C>T PTPN22 polymorphisms were identified by PCR-RFLP. Statistical analysis was performed using the Arlequin program v3.0, following the Expectation-Maximization algorithm. RESULTS: The inference of haplotypes for polymorphisms -1123G>C and +1858C>T PTPN22 gene, showed a strong linkage disequilibrium of 98% in CS (X2 = 6.87, p = 0.008). The distribution of frequencies of haplotypes inferred and their association with RA, showed that CT haplotype was significantly associated with the disease (p = 0.040, OR 3.4, 95% CI 1.09-10.69). CONCLUSIONS: Polymorphisms -1123G>C and +1858C>T are in linkage disequilibrium, with a magnitude of D' = 0.98 in CS. The CT haplotype is associated with RA susceptibility in patients from Western Mexico.

P5.12.65
Anti-TNF treatment limits the prothrombotic features of platelets and neutrophils in rheumatoid arthritis

*M. Baldini, N. Maugeri, P. Rovere-Querini, E. Baldissera, G. Peretti, **M. G. Sabbadini**, A. A. Manfredi;*
Ospedale San Raffaele and Università Vita-Salute San Raffaele, Milan, Italy.

Systemic inflammation contributes to the increased cardiovascular risk in rheumatoid arthritis (RA), in which ischemic heart disease is the leading cause of mortality and is not fully explained by traditional risk factors. Immuno-suppressive treatments, in particular anti-TNF agents, have been suggested to reduce the disease-related cardiovascular risk. Platelet activation and pro-inflammatory platelet-leukocyte heterotypic aggregates have been observed in both acute coronary syndromes and RA. The expression of Tissue Factor (TF), the initiator signal of the extrinsic pathway of the coagulation cascade, is regulated by TNF-alpha in neutrophils. Platelets also express functional TF upon activation.
The aim of our study was to analyze the *in vivo* effect of anti-TNF treatment in RA patients on platelet/leukocyte activation and TF expression. Platelets and neutrophils from RA patients (n = 42) were activated compared to those from control groups (osteoarthritis, n = 12; chronic stable angina, n = 37; age- and sex-matched healthy controls, n = 70), as demonstrated by expression of activation markers (platelet P-selectin expression and vWF content, neutrophil CD40L expression and MPO content) and by circulating heterotypic aggregates. Neutrophil and platelet TF expression was also significantly increased. Platelet P-selectin and TF expression were particularly high in untreated patients. Anti-TNF treatments resulted in a significantly lower expression of activation markers and TF by platelet and neutrophils and quenched heterotypic aggregates formation.
In conclusion, circulating platelets and leukocytes from RA patients are activated and express TF. Anti-TNF treatment partially rescues these phenomena, suggesting a role of endogenous TNF-alpha in the patients' prothrombotic phenotype.

P5.12.66
Comparative significance of YKL-40 in different types of arthritis

*M. Kazakova[1], A. Batalov[1], N. Mateva[1], Z. Kolarov[2], **V. Sarafian**[1];*
[1]Medical University - Plovdiv, Plovdiv, Bulgaria, [2]Medical University - Sofia, Sofia, Bulgaria.

Background: The high concentrations of YKL-40 is a potential novel biomarker of disease activity and poor prognosis in patients with disorders characterized by inflammation and tissue remodeling. Little information has been obtained about serum and synovial YKL-40 levels in rheumatoid, psoriatic and gout arthritis. The aim of the study is to evaluate YKL-40 levels in these diseases and its association with proinflammatory cytokines TNF-α and IL-6.
Methods: The investigation involved 101 patients: 39 with RA (aged 53.18 ± 2.29), 14 with psoriatic arthritis (aged 49.36 ± 4.67), 8 patients with gout (aged 54.50 ± 5.32) and a control group of 40 age-matched healthy people. The concentrations of YKL-40, TNF-α and IL-6 were determined by ELISA.
Results: In all patients with arthritis, the concentration of serum YKL-40 was remarkably elevated compared to the serum level in the control group (P≤0.01). A strong association between serum and synovial levels of YKL-40 and serum TNF-α in patients with RA (P≤0.01) was detected. In this group of patients, a significant relationship between serum and synovial levels of TNF-α and IL-6 was also determined (P=0.001). In patients with psoriatic and gout arthritis, no evidence of correlation between levels of YKL-40 and proinflammatory cytokines was observed.
Conclusion**:** In conclusion, the results suggest that YKL-40 could be involved in disease activity and pathogenesis of rheumatoid arthritis but not in the other types of arthritis studied. The levels of the glycoprotein might reflect different pathogenetic routes in inflammatory joint diseases.

P5.12.67
A positive feedback mechanism of IL-6 through phosphorylated and unphosphorylated STAT3 in inflammatory arthritis

***M. A. K. Sedhom**[1], A. G. Pratt[2], A. Anderson[2], C. Routledge[2], J. Chay[1], J. Isaacs[2], R. Thomas[1];*
[1]The University of Queensland Diamantina Institute, Woolloongabba, QLD, Australia, [2]Institute of Cellular Medicine (Musculoskeletal Research Group), Newcastle University, Newcastle upon Tyne, UK, United Kingdom.

In rheumatoid arthritis (RA), autoimmune joint inflammation is driven by pro-inflammatory cytokines, including TNF and IL-6. However, the molecular mechanisms linking these cytokines with disease activity are unknown. STAT3 is phosphorylated (P-STAT3) upon IL-6 signalling, leading to gene transcription of STAT3 target genes including STAT3 itself. Unphosphorylated (U)-STAT3 complexes with NF-κB to activate κB-dependent genes, including IL-6. We showed previously that CD4+ T-cells of early RA were distinguished by an expression signature of STAT3-inducible genes, which correlated with serum IL-6 levels. In the current work, we used flow cytometry to determine basal and IL-6-stimulated induction of P-STAT3 in whole blood of 11 healthy controls (HC), 40 recent-onset RA, 22 non-RA inflammatory arthritis and 35 non-inflammatory arthritis patients. Serum cytokine levels were measured by chemiluminescence. Constitutive P-STAT3 and total (P-STAT3 and U-STAT3) levels were significantly higher in T cells of RA patients compared to HC, and P-STAT3 and total-STAT3 levels were positively associated. Constitutive T cell P-STAT3 was positively associated with measures of disease activity and with serum IL-6 and TNF. Consistent with the high unstimulated P-STAT3, IL-6-stimulated P-STAT3 was negatively associated with serum IL-6 and TNF. Hence P-STAT3 appears to reflect inflammatory burden across a range of inflammatory arthropathies. In longitudinal analyses of RA, constitutive P-STAT3 correlated with response to treatment. The associations between systemic IL-6, constitutive P-STAT3 and U-STAT3 are consistent with a positive feedback mechanism for IL-6 through both forms of STAT3 in inflammatory arthritis, which may underlie the potent therapeutic effect of IL-6 inhibitors.

P5.12.68
Anti-mutated citrullinated vimentin antibodies of IgA isotype during rheumatoid arthritis

*H. Ben Hassine[1], O. Khalifa[2], H. Ben Fraj[2], H. Zaglaoui[2], E. Bouajina[2], **R. Sghiri**[2];*
[1]Faculty of Medicine of Sousse, Sousse, Tunisia, [2]Farhat Hached Hospital, Sousse, Tunisia.

Objectives. We seeked the presence of anti-mutated citrullinated vimentin antibodies of IgA isotype (IgA anti-MCV) during rheumatoid arthritis (RA) and compared their diagnostic value with those of anti-mutated citrullinated vimentin antibodies of IgG isotype (IgG anti-MCV), anti-cyclic citrullinated peptide antibodies of IgA isotype (IgA anti-CCP), anti-cyclic citrullinated peptide antibodies of IgG isotype (IgG anti-CCP), IgA, IgM, and IgG rheumatoid factors for RA.
Methods. 82 RA patients with early and established RA and 191 controls were tested. Twenty five patients with recent onset disease

were evaluated 1 year after diagnosis to assess the predictive value of these antibodies for radiological damage.
Results. IgA anti-MCV were present in 42 (52.4%) patients and IgA anti-CCP in 45 (54.9%) patients. Specificity of IgA anti-MCV and IgA anti-CCP were 94.8 % and 86.4% respectively.
Out of 12 RA patients who had neither IgG anti-MCV nor IgG anti-CCP, 6 patients have IgA anti-MCV and 3 patients have IgA anti-CCP. There was no association between IgA anti-MCV or IgA anti-CCP and disease duration or radiological damage. Anti-MCV IgA gave the highest combined sensitivity when they were combined with IgG anti-CCP (91.5%).
Their sensitivity reached 89% when they were combined with IgG anti-MCV.
Conclusion. IgA anti-MCV are very specific of RA. Given the relatively low cost of anti-MCV kits, the high specificity of IgA anti-MCV and the high combined sensitivity of IgA anti-MCV/ IgG anti-MCV, it could be interesting to combine anti-MCV IgA and anti-MCV IgG tests.

P5.12.69
Genetic susceptibility to rheumatoid arthritis in the Tunisian population: case of PADI4 and REL genes

*H. Ben Hassine[1], R. Zemni[2], O. Khalifa[1], H. Zaglaoui[3], E. Bouajina[3], F. slama[1], J. Boukadida[3], **R. Sghiri**[3];*
[1]Faculty of Medicine of Sousse, Sousse, Tunisia, [2]Faculty of Medicine, Sousse, Tunisia, [3]Farhat Hached Hospital, Sousse, Tunisia.

To study genetic susceptibility in rheumatoid arthritis we assessed two single nucleotide polymorphisms (SNPs) located in the REL locus: rs13031237 rs6727504 and two SNPs located in PADI4 locus, padi4 94 (rs2240340) and padi4 96 (rs1748032).
Two hundred and nineteen RA patients were genotyped by PCR-RFLP and MS-PCR.
For REL locus, SNP rs6727504 was not polymorphic. Regarding SNP rs13031237, G allele was the most frequent and was detected in 66.4% of RA patients and 73% of controls and among all genotypes GT was the most frequent in RA patients (46.1%) and GG (55.7%) was the most common in controls. SNPrs13031237 was significantly associated with RA. The minor allele T was not associated with the disease. However, GT genotype was significantly associated with the disease with an OR = 1.71 (IC95%: 1.26-2.32), P = 0.018. Besides, no evident association with anti-CCP or erosion was found. For PADI4, the most frequent haplotypic combinations found in our series were (CT/TC) and (CT/CT). No single-point association between genotype and allele with susceptibility for RA was detected. Haplotype analysis revealed no evident association with RA even after stratification of patients by sex, presence of erosion, and of anti-CCP.
Our study is the first to examine the potential role of REL and PADI4 polymorphism in the Tunisian and the North African population. Taken together our results indicate that PADI4 polymorphisms and SNP rs13031237 lacks association with RA in the Tunisian population and genotype seems to be in linkage disequilibrium with another polymorphism of susceptibility to be determined.

P5.12.70
The development of antibodies specific for carbamylated protein precedes disease onset in mice with collagen induced arthritis

***J. N. Stoop**, B. Liu, J. Shi, D. T. S. L. Jansen, T. W. J. Huizinga, L. A. Trouw, R. E. M. Toes;*
Leiden University Medical Center, Leiden, Netherlands.

Introduction: Antibodies against citrullinated proteins (ACPA) are a characteristic of rheumatoid arthritis. Recently, we described antibodies recognizing another type of post-translationally modified proteins, i.e. homocitrulline containing proteins. Because homocitrulline is post-translationally formed by a process called carbamylation, we named these novel auto-antibodies Anti-Carbamylated Protein Antibodies (anti-CarP antibodies). As no information is present on the mechanisms underlying the break of tolerance and hence the induction of anti-CarP-responses, we now analyzed their appearance in collagen induced arthritis (CIA).
Methods: CIA was induced in DBA/1 and C57Bl/6 mice by immunization with type II collagen in CFA. Arthritis severity was monitored and Anti-CarP levels were determined by ELISA. The specificity of the ELISA was validated using inhibition assays.
Results: Anti-CarP antibodies were not detected in non-immunized mice. However, unlike ACPA, they were readily detectable in mice suffering from arthritis. The onset of clinical symptoms was preceded by an increase in serum anti-CarP IgG2a levels. Although all immunized C56Bl/6 mice had anti-CII antibodies, only 60% developed arthritis. Anti-CarP IgG2c could only be detected in arthritic mice, but not in the non-arthritic immunized mice. Inhibition assays confirmed the ELISA results regarding the specificity of the antibodies for carbamylated proteins.
Conclusion: DBA/1 mice with CIA develop anti-CarP antibodies before disease onset and in C57Bl/6 mice the presence of these antibodies is associated with disease development. These results indicate a break of B-cell tolerance to carbamylated proteins which appears to be associated with the induction of chronic inflammation.

P5.12.71
Aryl hydrocarbon receptor genetic polymorphisms are associated with Rheumatoid Arthritis

***J. Talbot**[1], R. S. Peres[1], R. D. R. Oliveira[1], J. R. Silva[1], B. Ryffel[2], T. M. Cunha[1], J. C. Alves-Filho[1], E. Y. Liew[3], P. Louzada-Junior[1], F. Q. Cunha[1];*
[1]School of Medicine of Ribeirao Preto - Universidade de Sao Paulo, Ribeirao Preto, Brazil, [2]CNRS Orleans, Orleans, France, [3]University of Glasgow, Glasgow, United Kingdom.

Rheumatoid Arthritis (RA) is a chronic inflammatory arthropaty with unknown etiology. RA development is associated with the pathogenic CD4+ lymphocyte T helper 17 (Th17). Then, the knowledge of the mechanisms related to Th17 generation and function is essential to disease control. For instance, it was described that Th17 express the aryl hydrocarbon receptor (AhR) which acts as Th17 function regulator. AhR is a ligand-dependent transcription factor that is activated by organic compounds as halogenated aromatic hydrocarbons present in smoking. The aim of this study was to evaluate the role of AhR in RA development. We evaluated the distribution of two AhR single nucleotide polymorphisms (SNPs) in sex/smoking pared samples of healthy individuals (104) and RA patients (104). Experimental arthritis was accessed by mBSA-induced arthritis (AIA) in C57BL/6 or AhrKO mice, and by collagen-induced arthritis in DBA1/J mice (CIA). Mice were treated i.p. with Vehicle, FICZ (AhR agonist) or CH223191 (AhR antagonist). To access experimental arthritis we evaluated: articular hiperalgesia, articular histopathology and Th17 frequencies. This study was approved by Human and Animal Ethics Committees from HCFMRP/USP. We found an AhR haplotype overrepresented in RA patients. This haplotype contains a SNP that enhanced AHR transactivation function and was related to higher Th17 frequencies in RA patients. In experimental arthritis, FICZ exacerbated AIA and CIA, whereas CH223191-treated or AhrKO mice developed a less severe form of AIA and Th17 frequencies. Our data suggest that AhR could be associated with RA development by enhancement of Th17/IL-17 signalling. Financial Support: FAPESP (2011/02505-7); TIMER (HEALTH-F4-2011-281608)

P5.12.72
Premolis semirufa caterpillar-bristles toxic components induce intense cellular and humoral immune responses

*I. M. Villas-Boas, R. M. Gonçalves de Andrade, C. C. Squaiella-Baptistão, O. A. Sant'Anna, **D. V. Tambourgi**;*
Butantan Institute, São Paulo, Brazil.

The caterpillar of the moth *Premolis semirufa*, commonly named *Pararama*, is endemic of the Amazon basin. Accidental contact with these caterpillar bristles causes local symptoms such as heat, pain, edema and itching which last for three to seven days; however, after multiples contacts, it may induce to a chronic inflammatory reaction with immobilization of the affected joints. Specific treatment for this disease does not exist. Despite public health hazard of *pararama* caterpillar poisoning, little is known about the immune response

induced by this envenomation and its potential contribution to the development of the chronic disease.
Here we have evaluated the immune response against caterpillar-bristles toxic components, after intraplantar injection of the toxins into the mice hind footpads, for seven times, every two weeks. Data obtained showed a significant edematogenic response and an intense infiltration of inflammatory cells to the envenomation site. Immunohistochemical and immunofluorescence analyses showed the presence of a large number of neutrophils and macrophages in the paw tissues of the envenomated animals. The bristle extract was able to induce high specific antibody titers, but not autoantibodies (anti-DNA or anti-collagen type II), and proliferation/migration and activation of T and B lymphocytes in the lymph nodes. Evaluation of the cytokines production demonstrated elevated levels of IL-6, IL-10, IL-12, IL-17 and IL-23 after the 7th bristle extract inoculation. These data show that the intense cellular and humoral immune responses, induced by bristles toxic components, may play an important role in the establishment of the disease associated to the pararama envenomation.

P5.12.73
Association of the 22 genotype of enhancer HS1,2A of the Ig heavy 3′ regulatory region (IgH3′RR-1) with non response to DMARDS and response to Rituximab in rheumatoid arthritis patients.

B. Tolusso[1], *E. Gremese*[1], *A. Fedele*[1], *E. Serone*[2], *D. Frezza*[2], *M. Gigante*[1], *M. Nowik*[1], *S. Canestri*[1], *C. Di Mario*[1], *G. Ferraccioli*[1];
[1]*Division of Rheumatology, Catholic University of the Sacred Heart, Rome, Italy,* [2]*Laboratory of Genetics, Department of Biology Enrico Calef, University of Rome, Tor Vergata, Rome, Italy.*

The aim of the study was to evaluate a possible association between the polymorphism in the enhancer HS1,2A of the IgH3′RR-1 (Giambra V., Genes 2005) and the response to therapy in 535 RA patients at different phases of RA (326 with an early RA (ERA), treated according to a tight control strategy; 89 TNF-treated patients with a long-standing RA (TNF-treated-LSRA) and 120 seropositive LSRA patients treated with Rituximab (RTX-treated-LSRA), not responsive to previous DMARDs and/or TNF-blockers).
The frequency of the 2/2 genotype was similar in ERA patients (28%) and in RTX-treated LSRA (22%, *p=0.17*), but lower than in TNF-treated LSRA (40%, *p=0.03* vs ERA). In ERA patients carrying the 2/2 genotype of HS1,2A enhancer, the percentage of sustained-EULAR-remission at 6-month FU (13%) was lower compared with subjects without the 2/2 genotype (26%, OR(95%CIs):0.40(0.18-0.91). ERA patients carrying the 22 genotype showed a more severe disease at baseline and a higher percentage of subjects treated with TNF-blockers at 6 months FU compared to patients without the 22 genotype. There was no association between the HS1,2A enhancer polymorphism and the response to therapy over time, in TNF-treated-LSRA patients. On the contrary, the percentage of good-EULAR response was more prevalent in RTX-treated-LSRA patients carrying the 2/2 genotype compared to subjects without the 22 genotype (42% vs 20%, OR:2.90(1.15-7.32)). The demonstration of the presence of a binding site for NF-kB in the allele*2 of HS12A enhancer (Frezza D., Ann Rheum Dis 2012), could explain the more aggressive phenotype in ERA patients poorly responsive to DMARDs.

P5.12.74
TRAF-6 dependent signaling pathway is essential for TNF-related apoptosis-inducing ligand (TRAIL) induces osteoclast differentiation

H. Tsai[1], *H. Liao*[2], *P. Hsu*[2];
[1]*Graduate Intitute of Clinical Medicine, Taipei Medical University, Taipei, Taiwan,* [2]*Graduate Intitute of Immunology, National Taiwan University, Taipei, Taiwan.*

Human osteoclast formation from mononuclear phagocyte precursors involves interactions between tumor necrosis factor (TNF) ligand superfamily members and their receptors. Recent evidence indicates that in addition to triggering apoptosis, the TNF-related apoptosis-inducing ligand (TRAIL) induces osteoclast differentiation. To understand TRAIL-mediated signal transduction mechanism in osteoclastogenesis, we demonstrated that TRAIL induces osteoclast differentiation via a Tumor necrosis factor receptor-associated factor 6 (TRAF-6)-dependent signaling pathway. TRAIL-induced osteoclast differentiation was significantly inhibited by treatment with TRAF-6 siRNA and TRAF6 decoy peptides in both human monocytes and murine RAW264.7 macrophage cell lines, as evaluated in terms of tartrate-resistant acid phosphatase (TRAP)-positive multinucleated cells and bone resorption activity. Moreover, TRAIL-induced osteoclast differentiation was also abolished in TRAF6 knockout bone marrow macrophages. In addition to induction of NFATc1, treatment of TRAIL also induced ubiquitination of TRAF6 in osteoclast differentiation. Thus, our data demonstrate that TRAIL induces osteoclastic differentiation via a TRAF-6 dependent signaling pathway. This study suggests TRAF6-dependent signaling may be a central pathway in osteoclast differentiation, and that TNF superfamily molecules other than RANKL may modify RANK signaling by interaction with TRAF6-associated signaling.

P5.12.75
Prevalence of hyperprolactinaemia in antiphospholipid syndrome

C. Tsigalou[1], *T. G. Konstantinidis*[1], *E. Konstantinidou*[1], *T. Gioka*[1], *N. Galanopoulos*[2], *A. Tsirogianni*[1], *G. Kampouromiti*[1];
[1]*Immunology Department of Microbiology Laboratory, University General Hospital of Alexandroupolis, Alexandroupolis, Greece,* [2]*Rheumatology Unit, University General Hospital of Alexandroupolis, Alexandroupolis, Greece.*

Aim: The aim of our study was to measure PRL level in patients with systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA) with or without secondary antiphospholipid syndrome (APS) and correlation between PRL levels and antiphospholipid antibodies presenting.
Materials and methods: The study included 31 patients with autoimmune diseases like SLE (16) and rheumatoid arthritis (15) age: 41-68 years old and 20 age matched subjects as control group. All patients were females, Serum PRL concentration was determined by electrochemeluminescent method, anti nuclear antibodies (ANA) were determined by IIF, anti-dsDNA by ELISA and IIF kits and antiphospholipid antinodes were determined by ELISA. Patients with end-stage renal disease and patients who take medications that might cause HPRL, such as antidepressants were excluding from this study.
Results: Hyperprolactinemia -HPRL (> 20 ng/ml) was found in 8 patients (25,8%). The mean PRL level was higher in SLE than in patients with RA and control group (24,2±12 ng/ml, 14.5 ng/ml and 10,5±7 ng/ml). Only 5 patients (3 with SEL and 2 with RA) fulfilled the Sapporo APS classification criteria. HPRL was more common among patients who had b2GPI type G ($p<0.05$), but was not related to the presence of anticardiolipin antibodies both types G and M.
Conclusions: Hyperprolactinemia may be a marker of some APS. More research is required to elucidate the mechanisms involved in PRL immune effects in patients with APS.

P5.12.76
Deficiency of prostaglandin D2 receptor CRTH2 deteriorates adjuvant-induced arthritis

Y. Tsubosaka[1], *S. Matsumoto*[1], *H. Hirai*[2], *M. Hori*[1], *M. Nakamura*[3], *H. Ozaki*[1], *T. Murata*[1];
[1]*Department of Veterinary Pharmacology, Graduate School of Agriculture and Life Sciences, The University of Tokyo, Bunkyo-ku, Tokyo, Japan,* [2]*Department of Advanced Medicine and Development, BML, Inc., Kawagoe-shi, Saitama, Japan,* [3]*Human Gene Sciences Center, Tokyo Medical and Dental University, Bunkyo-ku, Tokyo, Japan.*

Cyclooxgenase-metabolites, prostaglandins are known to be involved in the development of arthritis. However, the role of prostaglandin D2 (PGD2) in arthritis remains unknown. In this study, we investigated the contribution of one PGD receptor, chemoattractant receptor-homologous molecule expressed on Th2 cells (CRTH2) to the progression of adjuvant induced-arthritis (AIA). CRTH2 naïve (WT) or deficient mice (CRTH2-/-) were injected into the ankle joint with complete Freund's adjuvant (CFA, 150 microg). In both WT and

CRTH2-/-, CFA injection induced paw swelling. CRTH2-/- represented much more severe features than WT throughout the test period (~ day 11). RT-PCR analysis revealed that the mRNA expression levels of pro-inflammatory cytokines as well as Th1/Th17-producing cytokines in the paw of CRTH2-/- were higher than that of WT. Morphological studies showed that gene deficiency of CRTH2-/- accelerated infiltration of CD68-positive macrophage into the paw in the early phase of AIA (day 3), and infiltration of CD4- or CD8-positive T cell in the late phase (day 11). Treatment with a macrophage inactivator, gadolinium chloride, improved all the exacerbated symptoms of AIA observed in CRTH2-/-. These results indicated the protective roles for CRTH2-mediated signaling in arthritis by attenuating macrophage activation and Th1/Th17 responses.

P5.12.77
Association of PD1.1 and PD1.6 polymorphisms with ankylosing spondylitis

N. Vibanco-Pérez[1], *J. Gutiérrez-Franco*[1], *M. D. J. Durán-Avelar*[1], *J. M. Agraz-Cirbian*[1], *M. A. Jiménez-Alvarez*[1], *S. Peña-Virgen*[2], *J. F. Zambrano-Zaragoza*[1];
[1]*U.A. Ciencias Químico Biológicas y Farmacéuticas-Universidad Autonoma de Nayarit, Tepic, Mexico,* [2]*Clínica de Reumatologia, Depto. Medicina Interna-Instituto Mexicano del Seguro Social, HGZ #1, Tepic, Mexico.*

Ankylosing spondylitis is a chronic inflammatory disease included in the spondyloarthritis group. It is considered as autoimmune disease, in which environmental and genetic factors are involved. Among the genes associated with autoimmune diseases, PD1 has been considered as a candidate because of their role in regulation for the immune homeostasis and in the maintenance of the peripheral tolerance through secondary co-stimulatory signaling in T cells. PD1.1 and PD1.6 are two single nucleotide polymorphisms, at -600 G/A (rs36084323), and +8669 G/A (rs10204225) respectively, that have been associated with others autoimmune diseases such as rheumatoid arthritis, type I diabetes mellitus, and systemic lupus erythematosus. In this work, we have determined and compared the frequencies of PD1.1 and PD1.6 polymorphisms in a group of 31 patients with AS diagnosed at HGZ No. 1 from IMSS according to the current criteria, and 90 healthy subjects as a control group. DNA was extracted form each subject and genotypification of PD1.1 and PD1.6 was carried out by using specific primers by bidirectional PCR amplification of specific alleles. Frequencies were determined, and odds ratio and CI95% were calculated. Our results showed no differences in the frequencies of neither PD1.1 (genotype AG or GG) nor PD1.6 between groups were found. However, the genotype PD1.1-AA showed statistically differences between groups (OR = 9.4286, 95%CI= 1.3648-65.1380), suggesting that it could be a risk factor, but it is necessary to increase the sample size in order to validate these association.

P5.12.78
IL-6R blockade enhances CD39+ efficient regulatory T cells in Rheumatoid Arthritis Patients

R. Vicente[1], *Y. Pers*[2], *P. Portales*[3], *J. Quentin*[1], *J. Eliaou*[3], *C. Jorgensen*[1,3], *P. Louis-Plence*[1];
[1]*Inserm U844, Montpellier, France,* [2]*Unité Clinique d'Immuno-Rheumatologie, CHU Lapeyronie, Montpellier, France,* [3]*Laboratoire d'Immunologie, Hôpital Saint-Eloi, Montpellier, France.*

Introduction: Tocilizumab is a humanized anti-IL-6 receptor monoclonal antibody, which binds to circulating soluble and membrane-expressed IL-6 receptor, inhibiting IL-6 binding. Tocilizumab is an efficient therapy for adults with Rheumatoid Arthritis (RA) in whom the most common treatments like DMARDs or TNF inhibitor have failed.
However, the consequences of anti-IL-6R treatment on cells and particularly on Treg and Th17 phenotype and activation remain unclear.
Patients and methods: 15 patients with severe and active RA were treated with Tocilizumab monthly. Peripheral blood was recovered for each patient at day 0, as well as 1 and 3 month after treatment. Peripheral blood mononuclear cells (PBMC) were purified for intracellular staining of FoxP3 and IL-17.
Results: Frequencies of IL-17 secreting cells were not significantly modified by Tocilizumab therapy, and no difference was observed between responders and non-responders (0.53%±0.22% and 0.23%±0.09%, respectively). Concerning the Tregs cells, CD39 is constitutively expressed on 50% of human CD25+FoxP3+Tregs cells in healthy controls. The percentage of CD39+cells among CD4+CD25+FoxP3+Tregs was significantly higher in the responders than in the non-responders after 3 months of therapy (72%±4% versus 44%± 8%, $p<0.05$). Comparison of the suppression capacity of both CD39- versus CD39+ Treg showed that both populations presented an equivalent capacity to supress the activation of effector cells in vitro.
In conclusion, the present study establishes that IL-6 pathway inhibition by anti-IL-6R antibody therapy in arthritis involves Treg cells. The induction of a CD39+ FoxP3+ Treg population was found to be associated with an attenuation of disease severity in RA.

P5.12.79
Prediction rheumatoid arthritis outcome in patients with unclassified arthritis considering enzymatic serum activity

M. Volkava[1], *A. Kundzer*[2];
[1]*Vitebsk state medical university, Vitebsk, Belarus,* [2]*Belarusian Medical Academy of Post-graduate Education, Minsk, Belarus.*

The aim of our preliminary study was to develop new method for predicting the outcome of unclassified arthritis (UA) in rheumatoid arthritis RA evaluating the influence of clinical, laboratory data, autoantibodies presence, enzymatic properties of serum.
36 patients with UA were examined prospectively at 6 and 12 months after first visit. DNAse and hyaluronidase serum activity was determined by rivanol clot prevention test.
In 30.56% patients with UA was developed RA, in 11.11% - not RA, in 30.56% - UA, 27.78% patients were recovered. Median of serum hualuronidase activity in RA outcome patients was 4.50 (95%CI 3.00-5.00), in other outcomes patients - 2.00 (95%CI 2.00-3.00), p=0.0007. Median of serum DNAse activity in patients with RA outcome was 4.75 (95%CI 2.89-5.00), in other outcomes - 2.75 (95%CI 2.00-3.61), p=0.0059. 63.64% RA outcome patients and 8.33% other outcomes patients were anti-CCP positive, $p<0.01$. Predictive model that included all three variables had the highest rates of sensitivity (90.00%), specificity (92.31%) and the area under the ROC-curve (0.96), and meets the criteria of excellence quality for expert scale. The model was tested in a control group (retrospective analysis), the agreement between the predicted results and held outcomes were noted in 89% of patients.
We evaluated influence of different factors on UA outcomes. According our study DNAse and hyaluronidase serum activity play a certain role in development of RA. The use of detection of serum DNase and hyaluronidase activity may serve an additional way for the prediction outcome of UA in RA.

P5.12.80
Nuclease IgG activity toward different DNA substrates in patients with rheumatoid arthritis

M. Volkava[1], *A. Kundzer*[2], *I. Generalov*[1];
[1]*Vitebsk state medical university, Vitebsk, Belarus,* [2]*Belarusian Medical Academy of Post-graduate Education, Minsk, Belarus.*

Autoimmune mechanisms of rheumatoid arthritis (RA) are regarded as a certain immune regulation disbalance with high production of autoantibodies. The main goal of our study was to assess putative nuclease activity of RA IgG toward different DNA substrates.
IgG samples of 3 patients with RA (1 male and 2 female with disease duration 8, 6 and 16 weeks respectively) and two healthy person were examined. All patients were fulfilled 2010 RA Classification Criteria.
IgG were purified from the sera by combined method of protein A column affinity chromatography. The methods for activity assessment were developed and tested. For the assessment of nuclease IgG activity it has been used thymus bovine DNA, plasmid dsDNA and Cl. trachomatis DNA as reaction substrates. DNAse activity was registered with agarose gel electrophoresis.
It has been shown that RA IgG samples gydrolysed all DNA substrates and demonstrated different patterns of DNA degradation.

Healthy control IgG had not DNAse properties. All ERA samples gydrolysed low and high polymeric fraction thymus bovine DNA and changed down the mobility of Cl. trachomatis DNA due to nick cuts. One sample rendered full dsDNA hydrolysis, whereas two others displayed multiple nick cuts of super-coiled plasmid dsDNA fraction.
For the first time we confirmed the presence abzyme IgG activity against different DNA substrate in patients with RA. The different patterns of DNA degradation upon abzyme action were confirmed. Futher it seems worthy to study other DNA substrates to assign various kinds of DNAse IgG activity to certain subsets of RA.

P5.12.81
Reactive arthritis of Yersinia etiology: diagnostics and immunological analysis

O. P. Vostrikova[1]*, O. Portnyagina*[1]*, A. Dubikov*[2]*, O. D. Novikova*[1]*;*
[1]G.B. Elyakov Pacific Institute of Bioorganic Chemistry, Vladivostok, Russian Federation, [2]Regional state budget Facility Health Hospital №2, Vladivostok, Russian Federation.

Autoimmune manifestations of yersiniosis can be associated with the defeat of the functions of almost all organs and systems. There are limited data on the diagnostics of autoimmune diseases (secondary immunodeficiencies) of *Yersinia* etiology in literature. This study is devoted to the improvement of verification methods of rheumatoid arthritis, caused by Yersinia. First for this purpose ELISA test-system with pore-forming protein F, species-specific protein of the outer membrane of *Y. pseudotuberculosis* and *Y. enterocolitica,* as antigen was used. The presence of specific anti-porin antibodies (Abs) was determined by ELISA in sera of almost half patients (44 women and 12 men) with rheumatoid arthritis. Immunological analysis showed the high level of IgG and low level of IgM anti-porin Abs. This observation is consistent with the capacity of *Yersinia* to give a prolonged antibody response that is a central issue in the pathogenesis of *Yersinia*-induced reactive arthritis. It is also shown that level of Abs against some auto-Ags, components of host's own cells, in the sera of the patients differs from the normal physiological level. It may be due to significant pathological changes in the host. The reason of higher level of auto-Abs in 57.1% of patients is the active pathological process increasing its intensity and/or duration, i.e. the polyclonal activation of the immune system. A decrease in overall immunological reactivity (immune suppression) in 42.9% of patients is accompanied by infringement clearance process leading to chronic self-poisonings with exchange products.

P5.12.82
The protective role of intracellular reactive oxygen species in autoimmune arthritis

S. Winter[1]*, F. Laulund*[1]*, M. Hultqvist*[2]*, R. Holmdahl*[1]*;*
[1]Karolinska Institute, Stockholm, Sweden, [2]Redoxis, Lund Life Science Incubator, Lund, Sweden.

Rheumatoid arthritis (RA) is a polygenic systemic autoimmune disease characterized by chronic inflammation in the joints. Recently, a SNP in the human *NCF4* gene was found to be associated with RA, yet functional studies are missing to determine conclusively whether *NCF4* is a RA susceptibility gene. This gene encodes the $p40^{phox}$ regulatory subunit of the NOX2 complex, which is responsible for the production of reactive oxygen species (ROS) generated by phagocytes as a defense mechanism against invading microbial pathogens. Whereas the role of the NOX2 complex during the innate immune defense is well established, its function in the adaptive immune system remains less well understood. The identification of the *NCF1* gene, encoding the $p47^{phox}$ organizer subunit of NOX2, as a RA susceptibility gene in rats has shown that ROS can regulate autoimmune responses. Recent data suggest now that $p40^{phox}$ takes stage in regulating specifically the intracellular levels of ROS by retaining the NOX2 complex at the phagosomal membrane via binding of its PX domain to phosphatidylinositol-3-phosphate ($PtdInsP_3$). We hypothesize that polymorphisms in the *NCF4* gene that reduce the intracellular production of ROS could modify antigen processing in antigen presenting cells and directly or indirectly regulate the activation status of arthritogenic T cells. Functional studies in mice carrying a mutation in $p40^{phox}$ that prevents its binding to $PtdInsP_3$ point towards the concept that intra- rather than extracellularly produced ROS regulate the development of chronic inflammation in autoimmune arthritis.

P5.12.83
Anti-inflammatory effect of palm tocotrienol fractions in arthritis

Z. Zainal*, Z. Shahrim, S. Abdul Hafid;*
Malaysian Palm Oil Board, Bandar Baru Bangi, Kajang, Malaysia.

Arthritis is an inflammatory joint disease that results in destruction of the articular cartilage. In the present study, palm tocotrienol fractions from palm oil have shown to possess anti-inflammatory effect and provided a powerful new nutrient for reducing arthritis. Well-characterized models systems derived from bovine joint tissue were used in order to examine the proposed link between palm tocotrienol fractions and anti-inflammatory effects in arthritis. Interleukin-1 (IL-1α) used not only to stimulate chondrocytes and to synthesize cartilage matrix-degrading proteinases, but they also regulate matrix protein synthesis, inflammatory markers and cell proliferation. Chondrocytes isolated from the knee articular cartilages of bovine were treated with or without tocotrienol fractions. The actions of palm tocotrienol fractions were monitored by examining mRNA and protein levels of cytokines (COX-2, IL-B, IL-6), metalloproteinase enzymes (MMPs) and tissue inhibitor metalloproteinase enzyme (TIMPs) by qPCR, ELISA, GAG and Western blot analysis. Results demonstrated that palm-tocotrienols strongly inhibited the inflammatory response with gamma-tocotrienol being the most effective to treat osteoarthritis. The results of this study revealed that the use of palm tocotrienols significantly down regulated the production of COX-2, IL-β, IL-6 and MMP-3 in arthritis. On the other hands, palm tocotrienol fractions induced TIMPs that produces an anti-inflammatory effect to block inflammation directly in arthritis. These findings show that palm tocotrienol fractions may be of potential therapeutic value in regulating the joint destruction in arthritis.

P5.12.84
Association of the +49-A/G polymorphism of CTLA-4 in mexican patients with ankylosing spondylitis

J. F. Zambrano-Zaragoza[1]*, J. Gutiérrez-Franco*[1]*, M. D. J. Durán-Avelar*[1]*, B. V. de León-Amaral*[1]*, S. Peña-Virgen*[2]*, N. Vibanco-Pérez*[1]*;*
[1]U.A. Ciencias Químico Biológicas y Farmacéuticas-Universidad Autonoma de Nayarit, Tepic, Mexico, [2]Clínica de Reumatologia, Depto. Medicina Interna-Instituto Mexicano del Seguro Social, HGZ #1, Tepic, Mexico.

Ankylosing spondylitis (AS) is the prototype of an interrelated group of rheumatic diseases now known as spondyloarthritides, in which environmental and genetic factors are involved. CTLA-4 is a costimulatory molecule involved in the regulation of T cell activation. Theoretically, polymorphism within CTLA4 that lead to reduction of CTLA-4 expression may cause autoimmune T cell clonal proliferation and therefore contribute to the pathogenesis of autoimmune diseases. The +49-A/G polymorphism (rs231775) has been associated with autoimmune diseases such as Grave's disease, type II diabetes mellitus, and multiple sclerosis. Taking into account that genetic factors have been involved in the pathogenesis of AS, and that T cells could play an important role because of their implication in peripheral tolerance, we analyze the possible association of the +49-A/G polymorphism with AS. Thirty one consecutive patients with AS, diagnosed according to the New York criteria, and 67 healthy controls were included. DNA was extracted from a peripheral blood sample, and the +46-A/G genotype was determined by allele-specific PCR, by using previously reported primers. Frequencies for each genotype were obtained, and add ratio, 95% CI were determined. No statistically differences in the frequencies of GG, and AG genotypes were found between groups. However, the frequencies of the AA genotype could be considered as a risk factor (OR = 3.3102, 95%CI = 1.3068-8.3849). Although these data should be considered as preliminary, because of the small sample size, it is a strong candidate gene to be associated with AS.

P5.12.85
Implication for the detection of the joint lesion associated factors and EBV infection in patients with rheumatoid arthritis

D. Q. Zhang[1]*, X. Chen*[2]*, R. Xu*[3]*;*
[1]*Shanghai jiaotong University School of Medicine, Shanghai, China,* [2]*Department of Surgery,Shanghai Institute of Digestive Surgery ,Ruijin Hospital, Shanghai, China,* [3]*GuangHua Hospital of Traditional and Western Medicine,Changning District, Shanghai, China.*

To analyze the implication for the detection of joint lesion associated factors and EBV infection in RA so as to explore the relationship between the pathogenesis of RA, joint lesions associated MMP-3 and TIMP-1 were detected by ELISA, while clonal expansion of RA self-reactive T cells induced by synthesized EBV peptides was analyzed by [^{3}H]-TdR incorporation anlysis. The results showed that the anti-collagen II Ab were found both in serum and SF of RA, while in SF, the level of IgG Abs. in RA was significantly higher than that in the OA. The levels of joint lesion associated MMP-3 and TIMP-1 in the SF of RA were both higher than those in serum of RA. Moreover, the anti-EBV gp110 Abs. were detected in most of RA SF and peripheral blood of RA, The self reactive T cells from RA were found to have marked auto-reactivity to synthesized EBV gp110 peptide. From these results, it is concluded that the EBV infection has some relationship with abnormal expansion of T/B cells in RA, especially the abonormal high levels of MMP-3,TIMP-1 and anti-CII Abs. Possibly, these abnormality may be caused by the mechanism of “molecular mimicry”, the self-reactive cells in RA may cross-react with EBV and peptides during the course of viral infection, and lead to the self-tissue destruction and finally cause activation and development of RA. The results suggest that the anti-virus therapy and immune-regulation may be one of the new idea for the prevention and treatment of RA.

P5.12.86
A CD19/CD3 bispecific TandAb, AFM11, facilitates safe and potent killing of CD19$^+$ cells mediated by T-cells

E. Zhukovsky*, U. Reusch, C. Burkhardt, S. Knackmuss, M. Eser, I. Fucek, K. Ellwanger, F. McAleese, M. Little;*
Affimed Therapeutics AG, Heidelberg, Germany.

CD19, due to broader expression on B-cell subtypes, is an attractive alternative to CD20 as a target for treatment of B-cell malignancies. T-cells are tumor-killing effectors that cannot be recruited by full-length antibodies. The CD3 RECRUIT TandAb AFM11, a bispecific tetravalent antibody with two binding sites for both CD3 and CD19, enables T-cells to potently and specifically kill CD19+ tumors and possesses advantageous PK properties. *In vitro* assays demonstrate higher AFM11 target cytotoxicity relative to a bispecific tandem-scFv. CD8+ T-cells dominate early cytotoxicity (4 hrs) while after 24 hrs both CD4$^+$ and CD8$^+$ T-cells equally contribute to tumor lysis with EC_{50} of 0.5-5 pM. AFM11 exhibits similar cytotoxicity at Effector:Target ratios from 5:1 to 1:5 and facilitates T-cell serial target killing. AFM11 activates T-cells only in the presence of CD19+ cells. In PBMC cultures AFM11 induces CD69 and CD25 expression, T-cell proliferation, production of IFN-γ, TNF-α, IL-2, IL-6, and IL-10. Depletion of CD19$^+$ cells from PBMC abrogates these effects indicating strict CD19$^+$ target-dependent T-cell activation. Thus, AFM11 should not elicit the devastating cytokine release observed when full-length antibodies bind CD3. One week co-incubation with AFM11 does not inhibit T-cell cytotoxicity and thus it does not induce anergy. In a NOD/scid xenograft model reconstituted with human PBMC AFM11 exhibits a dose-dependent growth inhibition of Raji tumors; a single dose of AFM11 exhibits similar efficacy as five daily injections. AFM11 is an efficacious drug candidate for the treatment of CD19+ malignancies with an advantageous safety profile and anticipated dosing regimen.

Genome-wide linkage scan for psoriasis susceptibility loci in multiplex Tunisian families

M. Ammar[1]*, C. Bouchlaka*[1]*, I. Zaraa*[2]*, C. Helms*[3]*, C. Jordan*[4]*, N. Doss*[5]*, R. Marrakchi*[1]*, A. El Gaied*[6]*, M. Mokni*[7]*, A. Bowcock*[3]*;*
[1]*Faculty of Sciences of Tunisia, Tunis, Tunisia,* [2]*Hopital La Rabta de Tunis, Tunis, Tunisia,* [3]*Washington University, Saint Louis, MO, United States,* [4]*Washington university, Saint Louis, MO, United States,* [5]*Hopital militaire, Tunis, Tunisia,* [6]*Faculty of Sciences, Tunis, Tunisia,* [7]*La rabta hospital, Tunis, Tunisia.*

Psoriasis is a relapsing chronic inflammatory skin disease affecting all populations groups with a peak prevalence of 3% in northern European and Scandinavian Caucasians. Epidemiologic studies have implicated a genetic component to psoriasis. In the last 12 years multiple genomewide linkage analyses have identified putative susceptibility loci on several chromosomes, with a major locus in the MHC region. In order to investigate the genetic basis of familial psoriasis in Tunisian population we undertook a genome-wide linkage scan in seven multiplex psoriatic families from Tunisia. Following SNP genotyping on the Affymetrix 10K SNP array, we performed non-parametric linkage (NPL) multipoint analyses to identify genotypes and obtain evidence for linkage with psoriasis across the genome. No chromosomal region gave consistent evidence for linkage, providing evidence for genetic heterogeneity in Tunisian psoriasis families. Significant evidence for linkage of psoriasis to chromosome 2p12 was seen in one family. We also identified several regions of tentative psoriasis linkage on chromosomes 2q, 4q, 6p, 11q, 12q, 9q and 13q. One family exhibiting suggestive evidence for linkage to 17q25 (PSORS2) was identified and all affected members were shown to harbor a p.Gly117Ser mutation in *CARD14* (caspase recruitment domain family, member 14), recently described to lead to psoriasis in a large family from the U.S. Our results support the genetic heterogeneity of psoriasis in the Tunisian population, provide confirmatory evidence for a novel psoriasis locus at chromosome 2p12 and identify a psoriasis family with a mutation within PSORS2.

P5.14.02
Absence of functional or quantitative defects of peripheral regulatory T lymphocytes in patients with Alopecia areata

A. Ben Hmid[1]*, N. Belhaj Hmida*[1]*, M. Mokni*[2,3]*, H. Louzir*[1,3]*, I. Zaraa*[2,3]*, M. Ben Ahmed*[1,3]*;*
[1]*Laboratory of Clinical immunology, Institut Pasteur de Tunis,, Tunis, Tunisia,* [2]*Departement of Dermatology La Rabta Hospital, Tunis, Tunisia,* [3]*Faculté de Médecine de Tunis, Université Tunis El Manar, Tunis, Tunisia.*

Alopecia areata (AA) is characterized by a reversible form of patchy or complete hair loss associated with T-cell infiltration of hair follicles. It has been hypothesized that AA is a cell-mediated autoimmune disease but the mechanism underlying the loss of self-tolerance is unknown. A deregulation of regulatory T cell biology could be a possible hypothesis. We analyzed the percentage as well as the suppressive effects of peripheral regulatory T cells in 25 patients with AA and 20 sex- and age-matched healthy controls. The percentage of CD4+CD25bright T cells within the peripheral compartment was analyzed by flow cytometry. The suppressive effects of peripheral Tregs on proliferation and interferon (IFN)-γ production of conventional CD4+CD25- T cells were tested in our patients and controls after stimulation with an anti-CD3 antibody. We did not find any intrinsic functional or quantitative defect in peripheral regulatory T cells of patients with AA. Our data did not support the involvement of a peripheral regulatory T cell deregulation in the pathogenesis of Alopecia areata.

P5.14.03
Atypical pemphigus

***E. Berti**, L. Venegoni, D. Fanoni, L. Lunardon, R. Fiorani, S. Muratori; Dept. of Dermatology - Fondazione IRCCS Cà Granda - Ospedale Maggiore Policlinico, Milan, Italy.*

We diagnosed 300 cases of pemphigus vulgaris (PV) and foliaceus (PF), collecting clinical data, skin and blood serum. Methods used were: direct immunofluorescence (DIF); indirect IF (IIF) on normal human skin (NHS); ELISA for Desmoglein (DSG) 1-3 and bullous pemphigoid (BP) antigens 180-230; transfected cells for DSG1-3. Atypical clinical presentations were observed in case of herpetiform pemphigus (HP). HP demonstrated IgA intercellular (IC) deposits, anti DSG3 or IC staining in absence of DSG1-3 reactivity (Desmocollin+). Concurrent neoplasia were detected in 2 HP patients. Localized oral pemphigus vulgaris (OPV) were also observed, IgA and IgG mucosal deposits were demonstrated in 2 cases (1 case associated with thyroid neoplasia). In 2 exceptional cases OPV and PF firstly occurred during pregnancy. Patients affected by chronic lymphatic leukemia showed aggressive paraneoplastic pemphigus or a common OPV. In children PV, PF and a case of IgA pemphigus were observed. Typical cases of subcorneal pustolosis like IgA pemphigus were also observed in adults. Looking at serology anti DSG1-3 and anti BP180-230 were simultaneously detected by ELISA in some patients (aggressive cases?). Complete clinical remission was observed in patients with persistent high titre of antibodies. IIF on NHS stained lower part of epidermis (DSG3+) or upper part of epidermis (DSG1+). The specificity of cells transfected by DSG1-3 and BP230 was also confirmed in all cases analyzed. In conclusion the majority of atypical pemphigus cases should be identify and classify by old and new technologies, while antibody titre by ELISA not always was in correlation with clinical evolution.

P5.14.04
Neutrophil depletion by two different antibodies in a hapten-induced inflammation model in mice

***A. Christensen**[1,2], S. Skov[1], C. Haase[2];*
[1]University of Copenhagen, Copenhagen, Denmark, [2]Novo Nordisk A/S, Copenhagen, Denmark.

Neutrophils are thought to play a role in contact hypersensitivity (CHS) model which is a T-cell mediated immune reaction in response to epicutaneous application of a hapten. For depletion of neutrophils a rat anti-mouse antibody (clone RB6.8C5) has previously been used. However this antibody has recently been shown to deplete not only neutrophils but also a population of $CD11b^{+}LyC^{+}$ cells which are most likely monocytes. The impact of neutrophil-depletion may therefore have been overstated. The objective of this study was to evaluate the consequences of specific neutrophil-depletion by comparing administration of the RB6.8C5-antibody with a neutrophil-specific depletion using monoclonal antibodies in the dinitrofluorobenzene (DNFB)-induced CHS model.
For induction of CHS, mice were sensitized on day 0 by application of 0.5% DNFB on the abdominal skin and five days later mice were challenged by applying 0.3% DNFB on the ear. Ear thickness was measured on day 1-3 post-challenge. Antibodies and their isotype-controls were administered intraperitoneally a day prior to challenge and level of depletion was confirmed by flow cytometry.
Flow cytometry confirmed that RB6.8C5 depletes both neutrophils and a $CD11b^{+}LyC^{+}$ monocyte-population whereas neutrophil-specific depletion only targets neutrophils. Furthermore, administration of both antibodies results in significantly reduced inflammation however the RB6.8C5-antibody mediates the highest suppression. Thus, it can be concluded that treatment with the RB6.8C5-antibody in the CHS model results in a non-neutrophil specific depletion and therefore most likely overstates the relative importance of neutrophils in this model; specific depletion of neutrophils confirmed a role for these cells in contact hypersensitivity.

P5.14.05
Secretory leukocyte protease inhibitor (SLPI) controls the immunogenicity of DNA deposits in psoriasis

***J. Cichy**[1], J. Skrzeczynska-Moncznik[1], A. Wlodarczyk[1], K. Zabieglo[1], M. Banas[1], M. Kapinska-Mrowiecka[2], A. Dubin[1];*
[1]Fac. of Biochem. Biophys. & Biotech., Krakow, Poland, [2]Zeromski Hospital, Krakow, Poland.

Plasmacytoid dendritic cells (pDCs) emerged as a pivotal cell type in autoimmune and chronic autoinflammatory conditions such as SLE and psoriasis. The contribution of pDCs to these disorders is largely attributed to the production of IFNI by these cells following activation of TLR9 by endogenous DNA. The delivery of self-DNA to endosomal TLR9 was reported to require coupling of the DNA to several proteins/peptides primarily of neutrophil origin, including; LL37 and HMGB. A candidate source of these molecules are neutrophil extracellular traps (NETs), which release nucleic acids into the extracellular environment, generating a weblike structure composed of DNA as well as nuclear, granular and cytoplasmic proteins. In these studies we validated the concept that inhibitor of serine proteases-Secretory Leukocyte Protease Inhibitor (SLPI), produced by keratinocytes in injured skin or released along with DNA and serine proteases after neutrophil activation, contribute to psoriasis by inducing pDCs to secrete IFNI. Here we demonstrate that circulating neutrophils of psoriasis patients express more SLPI and its target enzymes (neutrophil elastase and cathepsin G) compared to healthy individuals. We also show that neutrophils infiltrating lesional skin of psoriasis patients were further enriched in elastase, released NETs and localized in the vicinity of pDCs. Whereas DNA deposits in psoriatic skin stained for neutrophil elastase, cathepsin G and SLPI, a mixture of SLPI with neutrophil DNA and elastase or cathepsin G, strongly stimulated production of IFNI in pDCs in TLR9-dependent manner. Thus, our data define a novel role for SLPI as pDC-regulating molecule in psoriasis.

P5.14.06
Skin inflammation is induced by weathered marine crude oil exposure

*J. M. Kemp, L. R. Luckett-Chastain, W. M. McShan, **R. M. Gallucci**; OUHSC College of Pharmacy, Oklahoma City, OK, United States.*

The 2010 BP oil spill in the Gulf of Mexico is undoubtedly the worst marine oil spill in US history. Oil spill clean up workers tend to suffer a myriad of health effects, including contact dermatitis. Since nothing is known concerning the effects of exposure to weathered crude oil, a mouse model was used to investigate this pathology. Denuded skin of C57 and Balb/c mice was exposed to weathered oil or acetone (control) for 7 days. Histopathology showed inflammation, primarily characterized by epidermal thickening and neutrophil infiltration which was most pronounced in Balb/c mice. Analysis of skin inflammatory cytokine expression showed that oil exposure increased IL-6, CXCL1, CCL2, and CCL4 protein levels, the extent of which varied based on mouse strain. M1 macrophage marker (CD86) mRNA expression was increased in oil exposed skin, but not the M2 marker CD206. Since the source of irritancy of weathered oil is not known, but may be associated with bacterial content, microbial populations analyzed. Most were unclassified (42%), but identified species included environmental and hydrocarbon degrading bacteria, as well as several *Pseudomonas* species which are opportunistic human pathogens. Thus, it appears that weathered oil is indeed a skin irritant, and characteristic inflammation may depend on genetic background. Further, the contribution of bacterial load on irritancy is not known, but pathogenic bacteria appear to reside in weathered oil.

P5.14.07
The Ying & Yang of p40 in psoriatic plaque formation in mice

S. Haak[1], *P. Kulig*[2], *S. Pantelyushin*[2], *G. Gyülvészi*[3], *F. Sallusto*[3], *B. Reizis*[1], *B. Becher*[2];
[1]*Columbia University, Dept. Microbiology & Immunology, New York, NY, United States,* [2]*University of Zurich, Institute of Experimental Immunology, Zurich, Switzerland,* [3]*Institute for Research in Biomedicine, Cellular Immunology Division, Bellinzona, Switzerland.*

Cytokines are mediators as well as regulators of inflammatory immune responses. The myeloid cell derived cytokine IL-23 is a critical player in psoriatic pathogenesis. Monoclonal antibodies (mAbs) directed against the common subunit p40, targeting both IL-12 and IL-23, is currently used therapeutically with impressive efficacy in treating psoriasis.
Recently, it was shown that AldaraTM cream, a drug used in the treatment of basal cell carcinoma, is a potent inducer of psoriatic plaque formation in mice and (inadvertently) human patients. Its mode of action in mice implicates TLR7 dependent induction of the proinflammatory cytokines IL-17A, -17F and -22.
Although in accordance to the successful therapeutic regime in human patients, anti-p40 mAbs treatment dramatically reduced psoriatic plaque formation in this mouse model, a mild degree of lesion formation persists. Since anti-p40 mAbs blocks pathogenic IL-23 as well as IL-12, we hypothesised a conflicting role of the two sister cytokines in psoriatic plaque formation.
While IL-23p19 mutant mice are resistant to induction of disease, we found that skin inflammation was highly increased in mice defective in IL-12 signalling (IL-12null or IL-12Rb2null). These more severe lesions exhibit an even more prominent IL-17 cytokine signature and a change in the composition of infiltrating innate lymphocytes. The effect was IL-12 specific as local injection of recombinant IL-12 during disease development reverted the alterations in IL-12null mice.
Taken together, our findings suggest a protective role of IL-12 in psoriatic inflammation and stress the need of specificity, when targeting the IL-23/IL-17 axis therapeutically.

P5.14.08
Essential role of ITAM-Syk-IL-1 axis in skin dendritic cells for the sensitization of allergic contact dermatitis

H. Hara[1], *S. Yasukawa*[2], *H. Yoshida*[1], *M. Furue*[2];
[1]*Department of Biomolecular Sciences, Saga Medical School, Saga, Japan,* [2]*Department of Dermatology, Kyushu University School of Medicine, Fukuoka, Japan.*

Allergic contact dermatitis (ACD) is a skin inflammation caused by T cells reactive to environmental and industrial allergens. Optimal T cell priming requires co-stimulatory signals from DCs that are activated through innate immune sensors. However, the innate immune pathways through which various contact allergens activate skin DCs are obscure. We show that stimulation of DCs with chemical contact sensitizers (haptens) but not irritants induces activation of the tyrosine kinase Syk. This not only induces the synthesis of pro-IL-1α/β but also engages the NLRP3 inflammasome, resulting in DC release of bioactive IL-1α/β, which is essential for the sensitization of pathogenic T cells. We found both CARD9 and MyD88-deficient mice failed to induce contact hypersensitivity (CHS) to a hapten, TNCB. DAP12, Syk and CARD9 but not MyD88 were essential for TNCB-induced IL-1 secretion by DCs, whereas the IL-1R1-MyD88 signaling but not CARD9 was required for T cells to differentiate into effector T cells producing IL-17 and IFN-γ. The hapten-induced inflammasome activation in DCs was dependent on ROS generation, which was dependent on DAP12-mediated Syk activation but not on the CARD9/BCL10 complex. The CARD9/BCL10–mediated signaling selectively controlled pro-IL-1 synthesis after hapten stimulation by regulating NF-κB activation. Finally, DC-specific deletion of CARD9, DAP12, Syk or NLRP3 but not MyD88 in mice by our newly-developed MixC-Treck system resulted in impaired CHS sensitization. Thus, our results identified an essential molecular axis of innate immunity required for the sensitization of ACD.

P5.14.09
αE integrin augments Arthus reaction by modulating the function of CD8+ T cells

T. Kadono, *D. Yamada, Y. Masui, Y. Asano, Y. Tada, M. Sugaya, S. Sato;*
Department of Dermatology, University of Tokyo, Tokyo, Japan.

Arthus reaction is induced by the deposition of immune complexes, which leads to acute inflammatory responses mimicking vasculitis. This inflammatory process is mediated by cell adhesion molecules that recruit various leukocytes to a site of inflammation. αE integrin is present in the form of αEβ7 integrin heterodimer. Whereas the expression of αE integrin is limited to subpopulation of lymphocytes and dendritic cells, β7 integrin is expressed on most leukocytes and is essential for their migration to gut-associated lymphoid tissues. Although αEβ7 integrin-positive dendritic cells are well known to play important roles in intestinal immunity, the role of αEβ7 integrin in Arthus reaction is not known. In this study, we investigated the role of αE and β7 integrin in peritoneal and cutaneous reverse passive Arthus reaction. The reaction was significantly attenuated in β7 integrin deficient mice and, surprisingly, also in αE integrin deficient mice. Infiltration of neutrophils was decreased in both mouse strains with reduced Il-6 levels, whereas the number of infiltrating mast cells was decreased only in β7 integrin deficient mice. The decrease of Arthus reaction in β7 integrin deficiency could be explained by defective recruitment of mast cells that express β7 integrin, however, mast cells did not express αE integrin. Instead, we found that the number of CD8+ T cells was decreased by αE integrin deficiency after peritoneal Arthus reaction, and the adoptive transfer of αE integrin-expressing CD8+ T cells rescue the reaction. Overall, these results indicate an important role of αE integrin in peritoneal and cutaneous Arthus reaction.

P5.14.10
IRF-2 haploinsufficiency and a TLR 7/8 stimulator synergize in the development of psoriasis-like skin inflammation

M. Kawaguchi, *S. Makoto, K. Takayuki, M. Sohshi, S. Hiraku, K. Takafumi, S. Shinichi;*
The University of Tokyo, Bunkyo-ku, Japan.

Psoriasis is a T-cell-mediated immunological skin disease with a complex pathogenesis where both genetic and environmental factors are involved. Interferon (IFN) regulatory factor (IRF)-2 is one of the potential susceptibility genes for psoriasis. IRFs are a family of transcription factors regulating expression of pro- and anti-inflammatory genes. IRF-2 binds the same regulatory sequences as IRF-1, suppressing transcription of IFN-inducible genes. It was previously reported that IRF-$2^{-/-}$ mice spontaneously developed an inflammatory skin disease resembling human psoriasis. In this study, we applied TLR 7/8 ligand imiquimod (IMQ), which induces a psoriasis-like skin inflammation critically dependent on the IL-23/IL-17 axis, on the backs of IRF-$2^{+/-}$ and wild-type (WT) mice to know whether combination of IRF-2 gene status and environmental stimulus (IMQ) would cause severer skin lesions. IRF-$2^{+/-}$ mice showed a larger cumulative skin score (erythema, scaling, and skin thickness) than WT mice after daily application of IMQ (day 0-5). Increased mRNA levels of TNF-α, IL-12/23 p40, IL-23p19, and inducible nitric oxide synthase (iNOS) were detected on day 2, while TNF-α, IL-12 p35, IL-17A, and iNOS mRNA levels were increased on day 5 in IRF-$2^{+/-}$ mice compared to WT mice. Peritoneal macrophage stimulated with 5.0 μg/ml IMQ for 24 hours expressed significantly higher mRNA levels of TNF-α and IFN-α than non-stimulated macrophages. Interestingly, macrophages from IRF-$2^{+/-}$ mice expressed a higher levels of these cytokines. Our results suggest that IRF-2 haploinsufficiency and a TLR 7/8 stimulator synergize in the development of Th17-associated skin inflammation, which may serve as a good model of human psoriasis.

P5.14.11
High B-cell-activating factor (BAFF) levels in Tunisian pemphigus patients

L. Laadhar[1], *K. Mejri*[1], *M. Kallel Sellami*[1], *I. Zarraa*[2], *H. Lahmar*[1], *M. Mokni*[2], *I. Mokhtar*[3], *B. Fazaa*[4], *M. Zitouni*[1], *S. Makni*[1];
[1]*Immunology Department, La Rabta Hospital, Tunis, Tunisia,*
[2]*Dermatology Department, La Rabta Hospital, Tunis, Tunisia,*
[3]*Dermatology Department, Habib thameur Hospital, Tunis, Tunisia,*
[4]*Dermatology Department, Charles Nicolle Hospital, Tunis, Tunisia.*

Background: High serum BAFF (B cell activating factor belonging to the TNF family) (sBAFF) level was observed in several autoimmune diseases such as lupus, Sjögren syndrome and rheumatoid arthritis. Its expression in autoimmune blistering diseases is controversial. The aim of our study was to determine sBAFF levels in pemphigus vulgaris (PV) and foliaceus (PF) patients.
Patients and methods: sBAFF levels were analysed in 50 PF patients, 36 PV patients and 38 healthy controls using an enzyme linked immunosorbent assay.
Results: The mean value of sBAFF in healthy subjects was 759 pg/ml. SBAFF levels were significantly increased in pemphigus patients (means 982 pg/ml in PV and 875 pg/ml in PF $p<0.0001$). High levels of sBAFF were observed in 14 (28%) PF patients and 11 (30,5%) PV patients ($p=0,004$ and $p=0,003$ respectively). Mean sBAFF levels were significantly higher in PF patients who did not receive yet corticosteroid treatments and in PF and PV patients with severe lesions. There was a significant correlation of sBAFF levels with anti-Dsg1 antibodies titres in PV ($p=0,007$) patients and a correlation, with a p value near the significance threshold, in PF patients ($p=0,079$).
Conclusion: High sBAFF levels were observed in pemphigus patients, suggesting a role in disease pathogenesis.

P5.14.12
IgE levels and immune response in bullous pemphigoid and mucous membrane pemphigoid

L. Lunardon*, D. Fanoni, M. Riboldi, F. Vaira, S. Muratori, E. Berti; Dept. of Dermatology - Fondazione IRCCS Cà Granda - Ospedale Maggiore Policlinico, Milan, Italy.*

Bullous pemphigoid (BP) and mucous membrane pemphigoid (MMP) are autoimmune blistering diseases characterized by subepidermal blisters, linear deposit of immunoglobulins and/or C3 and circulating autoantibody directed against the basal membrane zone (BP180 and BP230).
The growing interest regarding the potential pathogenic role of IgE class autoantibodies in the pemphigoid group is supported by presence of elevated blood IgE levels.
We conducted a retrospective study on patients affected by BP (n=90) and MMP (n=36). BP sera were examined for the presence of IgE, IgG and/or C3c by indirect immunofluorescence (IIF) and correlated to blood IgE levels. A perilesional skin biopsy was performed in order to test the deposition of IgE, IgG, IgA, IgM and/or C3c along the dermo-epidermal junction.
We therefore studied the specificity of serum anti-BP IgE testing BP (n=24) sera on commercial slides with biochips (BP180) or transfected cells (BP230).
In BP circulating IgE level resulted higher than 160 U/ml in 65 out of 90 patients (72%) (median value 672). In BP and MMP direct immunofluorescence (DIF) showed IgE deposits in 67%-75% and Indirect IF on salt skin split in 77%-16% of the patients respectively. Specificity of serum anti-BP IgE was confirmed on 18/24 sera (75%) by using biochip-slides and transfected cells.
Our findings indicate that specific IgE autoantibodies provide an additional criterion for diagnosis of pemphigoid, both BP and MMP, suggesting an important pathogenetic role of IgE-mediated immune response in these diseases.
Demonstration of IgE pathogenicity should be useful for new biological and immunomodulating strategies.

P5.14.13
Keratinocyte-restricted Rabgef1 gene deletion results in the development of lesions resembling atopic dermatitis, as well as systemic inflammation, in vivo

T. Marichal[1,2], *L. L. Reber*[1], *P. Starkl*[1], *S. Tam*[1], *M. Tsai*[1], *S. J. Galli*[1];
[1]*Stanford University, Stanford, CA, United States,* [2]*University of Liege, Liege, Belgium.*

RabGEF1, a guanine nucleotide-exchange factor for Rab5 GTPase, has been shown to negatively regulate mast cell activation *in vitro*. In addition, RabGEF1-deficient mice develop morbidity and severe skin inflammation associated with marked increases in skin mast cell numbers. These findings suggest that over-reactive skin mast cells may contribute to the observed skin pathology *in vivo*. In order to identify the cell type(s) which contribute to skin inflammation when RabGEF1 is absent, we attempted to delete *Rabgef1* gene specifically in three major skin cell types, namely mast cells, myeloid cells and keratinocytes; thus, *Rabgef1* floxed ($^{fl/fl}$) mice were crossed with mice expressing the Cre-recombinase under the influence of the promoter of Mcpt5, LysZ or K14, respectively, and the efficiency and specificity of Cre-mediated *Rabgef1* gene deletion were assessed by single-cell genomic PCR. Unexpectedly, Mcpt5-Cre;*Rabgef1*$^{fl/fl}$ and Lysz-Cre;*Rabgef1*$^{fl/fl}$ mice appeared normal without phenotypic abnormalities. However, K14-Cre;*Rabgef1*$^{fl/fl}$ mice were normal at birth but developed morbidity and skin inflammation after 2-3 days, and died between 1 and 8 weeks of age. Skin pathology was characterized by epidermal hyperplasia, keratinocyte differentiation defects, and death of keratinocytes, followed by dermal infiltration of eosinophilic granulocytes, increases in mast cell numbers, and increased pro-inflammatory cytokine expression. Mice surviving 6-8 weeks also displayed signs of systemic inflammation, such as lymphadenopathy and splenomegaly, blood eosinophilia and neutrophilia, and elevated levels of serum IgE. Further experiments will attempt to determine the mechanism by which keratinocyte-restricted RabGEF1 expression plays an essential role in maintaining skin immune homeostasis *in vivo*.

P5.14.14
Evidence for vitamin D deficiency and increased prevalence of fractures in autoimmune bullous skin diseases

A. V. Marzano[1], *V. Trevisan*[1], *C. Eller-Vainicher*[2], *P. Beck-Peccoz*[2], *C. Crosti*[1], *I. Chiodini*[2], ***E. Berti***[3];
[1]*Dept. of Dermatology - Fondazione IRCCS Cà Granda - Ospedale Maggiore Policlinico, Milan, Italy,* [2]*Dept. of Endocrinology - Fondazione IRCCS Cà Granda - Ospedale Maggiore Policlinico, Milan, Italy,* [3]*Dept. of Dermatology - Fondazione IRCCS Cà Granda - Ospedale Maggiore Policlinico, Emilio.berti@unimib.it, Italy.*

Vitamin D deficiency plays a role in autoimmune diseases and risk of fractures. No data are available on vitamin D levels and vertebral fractures in autoimmune bullous skin diseases.We studied 13 consecutive inpatients with untreated PV (age 53·5 ± 14·3 years), 15 with BP (age 76·9 ± 12·4 years) and 28 age-, body mass index- and sex-matched controls. The 25-hydroxyvitamin D (25-OHD) levels and presence of vertebral fractures on spinal X-ray were assessed in all subjects. In patients with PV, 25-OHD levels were lower (mean ± SD 12 ± 4·4 ng mL(-1)) and prevalence of severe hypovitaminosis D higher (62%) than in controls (mean ± SD 22·2 ± 11·7 ng mL(-1) , P = 0·012; 23%, P = 0·0047, respectively). The prevalence of fractures was 54% and 31% in patients with PV and controls, respectively. Patients with BP showed lower 25-OHD levels (mean ± SD 9·6 ± 7·2 ng mL(-1)) and higher prevalence of severe hypovitaminosis D (73%) than controls (mean ± SD 22·6 ± 18·7 ng mL(-1) , P = 0·022; 27%, P = 0·01, respectively). The prevalence of fractures was higher in patients with BP than in controls (67% vs. 33%, respectively, P = 0·068). The low 25-OHD levels found in PV and BP suggest a role for this agent in their pathogenesis. The increased prevalence of fractures should be taken into consideration in patients who must be given corticosteroids.

P5.14.15
Expression of pemphigus vulgaris antigen desmoglein 3 on pancreatic cells

E. V. Matushevskaya[1], *A. V. Prokhorov*[2], *E. V. Svirshchevskaya*[2];
[1]*Institute of Post Diploma Education, Moscow, Russian Federation,* [2]*Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry RAS, Moscow, Russian Federation.*

Pemphigus vulgaris (PV) is autoimmune disease mediated by the formation of IgG4 antibodies to desmoglein 3 (DSG3). Autoanibodies target desmosomes in skin epidermis and mucosa inducing intraepithelial splitting. Other organs and tissues are not affected in PV. Recently we have identified DSG3 expression in pancreatic adenocarcinoma cell lines BxPC-3, AsPC-1, M3T4, Colo357, Su86.86. Earlier it was thought that the major desmosomal protein in the epithelium of internal organs is DSG2. The aim of this work was to study DSG3 expression in pancreatic biopsy and in the epithelial cells of different origin. Cryosections of pancreas from a patient with chronic pancreatitis or various cell lines grown on cover glasses were stained with anti-DSG3 antibody and analyzed by confocal microscopy. Human pancreas expressed DSG3 as well as DSG2. Cell lines from kidney (HEK293) and liver (HepG2) did not express DSG3; some breast cancer cells (HBL-100) but not others (BT474) expressed DSG3; melanoma A375 and Mewo did not express DSG3. These data show for the first time expression of pemphigus antigen in internal organs and rise the question of IgG4 traffic to various tissues not affected in PV.
This work was facilitated by funding from the European Union Framework Program 7 (SaveMe) project.

Most squamous cell carcinoma (SCC) of the skin develops after ultraviolet (UV) light-induced DNA damage and repair errors. However, significant portion of SCC appears to occur independently from UV light because SCC often occur in light-protected areas such as chronic ulcers and burn scars underneath clothing, and oropharyngeal mucosa. Such UV-independent SCC is speculated to have a causal link with chronic inflammation. However, how chronic inflammation leads to cancer is unclear. We propose here that activation-induced cytidine deaminase (AID) is a mechanistic link between chronic inflammation and SCC. AID is an enzyme essential for DNA cleavage involved in immunoglobulin class switch and somatic hypermutation. We found that tumor frequencies were elevated by transgenic expression of AID from keratin14 promoter, and decreased by genetic deletion of AID in a mouse skin cancer model using 7,12-dimethylbenz[a]anthracene (DMBA) and 12-O-tetradecanoylphorbol 13-acetate (TPA). Significant numbers of mutations were observed in the Trp53 gene of SCC developed spontaneously in AID transgenic mice. Human primary cultured keratinocytes and SCC cell line expresses AID after stimulation with LPS, TPA, poly(I:C), or inflammatory cytokines such as TGF-β and TNF-α. Overexpression of AID in human keratinocyte cell line caused point mutations in TP53 gene. These results suggest that AID is a DNA damaging factor involved in inflammation-associated SCC.

P5.14.17
Role of Interleukin-1 processing and signaling in imiquimod-induced psoriasis-like skin inflammation

H. Rabeony[1], *P. Vasseur*[1,2], *I. Paris*[1,2], *J. Jégou*[1], *B. Ryffel*[3], *F. Bernard*[4,1], *J. Lecron*[1,2], *F. Morel*[1];

The pathogenesis of inflammatory skin diseases such as psoriasis involves the release of numerous proinflammatory cytokines, including IL-1. To highlight the potential role of IL-1 α and β in the induction and maintenance of psoriasis-like skin inflammation in mice, we assessed the expression of IL-1 family members after topical application of the TLR7/8 agonist imiquimod (IMQ) in C57BL/6 mice. Daily skin application of IMQ in wild type (wt) mice induced overexpression of IL-1α and IL-1β mRNA, followed by induction of IL-1 receptor antagonist expression. IMQ-treated IL-1α- or IL-1β-deficient mice display inflamed, red and scaly skin lesions, and epidermal hyperplasia, similar to IMQ-treated wt mice. Furthermore, IMQ induced expression of IL-23, IL-17 and IL-22, antimicrobial peptides b-defensin3 and S100A9, and chemokine CXCL3 is similar in mice deficient for IL-1α or IL-1β and wt mice. The absence of NALP3 or ASC in knock-out mice does not affect the inflammatory response to IMQ, demonstrating a modest role of NALP3/ASC inflammasome and downstream IL-1b processing in IMQ model. However, IMQ-induced dermatitis was partially reduced in mice deficient for IL-1RI. Finally, we showed that IMQ-induced skin inflammation was totally abolished in MyD88-deficient mice (the adaptator molecule shared by IL-1 and TLR signaling pathways) which indicate that, as expected, IMQ stimulation is largely TLR-dependent. Our data show that in IMQ model, IL-1α and IL-1β have a functional redundancy as demonstrated by the decreased development of skin inflammation in the absence of IL-1RI signaling.

P5.14.18
TSLP and CD40-ligand promote IL-23 production in human psoriasis

E. Volpe[1], *C. Martinez-Cingolani*[2], *L. Pattarini*[2], *M. Touzot*[2], *S. Meller*[3], *B. Homey*[3], ***V. Soumelis***[2];
[1]*Fondazione Santa Lucia, Rome, Italy,* [2]*Institut Curie, Paris, France,* [3]*Heinrich Heine University, Dusseldorf, Germany.*

Thymic stromal lymphopoietin (TSLP) is a keratinocyte-derived dendritic cell (DC)-activating cytokine expressed in atopic dermatitis (AD). TSLP plays a central role in the pathophysiology of allergy by initiating and sustaining pathogenic T helper (Th) 2 responses. Here, we report the unexpected finding that TSLP is involved in the physiopathology of human psoriasis, an auto-immune skin disease. In situ, TSLP was strongly expressed by keratinocytes of untreated psoriasis lesions, but not in normal skin. TSLP synergized with CD40-ligand (CD40L) to promote DC activation, and pathogenic IL-23 production by blood and skin DCs. Although CD40L was equally expressed in psoriasis and AD, we could demonstrate that IL-4, an important component of the Th2 inflammation in AD, inhibited IL-23 production induced by TSLP and CD40L. Our results identify TSLP as a novel player within the complex psoriasis cytokine network, and a potential early inducer of IL-23 production. We propose that inhibiting TSLP in psoriasis patients may contribute to decreasing DC activation and shutting down the production of pathogenic IL-23.

P5.14.19
Role and mechanisms of action of fibroblast growth factors in epidermal barrier function: Implications for inflammatory skin disease

J. Sulcova[1]*, E. Guiducci*[1]*, M. Meyer*[1]*, M. Kopf*[1]*, H. Rodewald*[2]*, S. Werner*[1]*;*
[1]*Institute for Molecular Health Sciences, Zurich, Switzerland,* [2]*Division for Cellular Immunology, Deutsches Krebsforschungszentrum (DKFZ), Heidelberg, Germany.*

A large percentage of the population suffers from inflammatory skin diseases such as psoriasis and atopic dermatitis, but the molecular and cellular mechanisms underlying the pathogenesis of these diseases are not fully understood yet. Recently, our laboratory identified a novel and unexpected function of fibroblast growth factors (FGFs) in the control of epidermal barrier function and cutaneous homeostasis. Mice lacking FGF receptors (FGFR) 1 and 2 in keratinocytes have a severe phenotype with features resembling atopic dermatitis that results from impairments in tight junction formation. To identify the cellular mechanisms underlying these abnormalities, we mated the double knockout mice with mice lacking either T cells or mast cells (Cre-Master mice), since the number of these immune cells is strongly increased in the absence of FGFR1 and FGFR2 in keratinocytes. The phenotypes of the triple mutant mice suggest that both types of immune cells functionally contribute to the abnormalities caused by FGFR deficiency. To characterize the skin of these mice by flow cytometry, we have established a procedure to efficiently isolate immune cells from the dermis and epidermis. This allows us to obtain a fairly complete picture of the cutaneous immune cell composition of the triple mutant mice and to determine if and how the loss of T cells or mast cells affects other immune cells in the skin, the epidermal and dermal structure, as well as proliferation and differentiation of epidermal keratinocytes.

P5.14.20
Di methyl fumarate (DMF), is there a possibility for broader use in psoriasis treatment?

S. Tahvili*, B. Zandieh, Z. Amirghofran, F. Hanjani;*
Shiraz University of Medical Sciences, Shiraz, Iran.

Background: Fumaric acid esters were introduced for treatment of Psoriasis, a chronic inflammatory disease of the skin, more than fifty years ago. The oral preparation that is now used mainly contains DMF. This compound involves in suppressing the expression of proinflammatory cytokines, and also deviation of Th1-driven immune responses toward Th2 subset.
Objective: As DMF involvement in suppression of Th1 cells has been figured out, we decided to investigate its probable same effect on Th17 subset activity. Methods: We isolated lymphocytes from peripheral blood of 35 psoriatic patients with no immunosuppressive medication history, and also 35 normal controls. Lymphocytes were cultured in the presence or absence of DMF. mRNA expression of IFN-γ as a marker for Th1 activity, IL-4 for Th2 activity, and IL-17, IL-22 and GM-CSF as markers for Th17 development and function were determined by Real time PCR.
Results: As showed by previous studies, after DMF treatment, we detected a decrease in IFN-γ expression and also an increase in IL-4 expression. A decrease in IL-17, IL-22 and GM-CSF after DMF treatment was also detected.
Conclusion: An increase in IL-4 mRNA expression and a decrease in mRNA expression of IL-17, IL-22 and GM-CSF besides IFN-γ show the DMF ability in suppressing Th17 in addition to Th1 activity . Therefore, DMF may have promising effects for the treatment of autoimmune diseases in which Th1 and Th17 subsets have a dominant role.

P5.14.21
An orally bioavailable CCR6 antagonist confers protection against IL17-mediated inflammation

J. B. Tan*, Z. Miao, R. Berahovich, K. Ebsworth, J. Powers, M. Leleti, T. Schall, J. Jaen, M. Walters;*
Chemocentryx, Mountain View, CA, United States.

The contribution of dysregulated IL17 expression to the pathology of various immune-related diseases is well documented. The clinical benefit derived from blocking IL17 signaling, provides support for targeting IL17 as a therapeutic approach in alleviating certain immunological disorders. Several reports indicate that the majority of IL17-secreting cells in human and mice co-express the chemokine receptor CCR6, thereby making it an attractive drug target. We have generated a potent orally bioavailable CCR6 antagonist, CCX9664, that inhibits CCL20-mediated chemotaxis of both human and mouse CCR6+ cells. The utility of CCR6 inhibition was tested in preclinical models of psoriasis, whereby CCX9664-treated cohorts were completely protected against imiquimod (IMQ) induced skin thickening (1.26 ± 0.05 mm for IMQ + Veh vs.1.03 ± 0.02 mm for IMQ + CCX9664 group; non-IMQ treated mice 1.06 ± 0.02 mm). Histological analysis of the skin confirmed the protective effect of CCX9664 compared to vehicle. CCX9664 also significantly reduced ear-thickening induced by intradermal injections of IL-23 (0.26 ± 0.0008 mm in IL-23 injection + vehicle vs. 0.20 ± 0.0004 mm in IL-23 + CCX9664; p=0.0001 vs.0.2 mm in PBS injection group). The mechanism of action for CCX9664 is unique from other therapeutics targeting IL17 such that inhibition of CCR6 disrupted the positioning of infiltrating leukocytes into the epidermis upon skin-damage, thereby protecting against epidermal hyperplasia. Thus pharmacological inhibition of CCR6 with an orally bioavailable small molecule antagonist inhibits IL17-driven inflammation in psoriasis models and may have therapeutic utility in other IL17-dependent indications.

P5.14.22
The inhibitory effects of yuzu seed oil to atopic dermatitis model mice by oral administration

K. Terashita[1]*, Y. Watanabe*[1]*, K. Asano*[2]*, K. Yamawaki*[1]*, S. Aoki*[1]*, E. Takahashi*[1]*, M. Toutani*[2]*, S. Mizobuchi*[1]*;*
[1]*Kochi University, Nankoku, Japan,* [2]*Umajimura agricultural cooperative, Umaji-mura, Japan.*

In this study, we examined the effects of yuzu seed oil to anti-atopic dermatitis (AD) using NC/Nga mice, a model animal of human AD. Yuzu (*Citrus junos Sieb.* ex Tanaka) is a typical Japanese citrus fruit with a desirable smell. Yuzu was brought via Korea from China to Japan more than 1,000 years ago. We have established an AD model in NC/Nga mice by repeated local exposure of mite-antigen for analyzing anti-AD effect. Two kinds of yuzu seed oil (crude oil and distilled oil) were used. We administered yuzu seed oil (1 ml/kg) for 4 weeks into tick-antigen treated NC/Nga mice. Surprisingly, these mice inhibited the development of AD-like skin lesions in these mice as exemplified by the significant decrease in the total skin severity scores and the decrease in hypertrophy and hyperkeratosis. Furthermore, the oral administration of yuzu seed oil to NC/Nga mice depressed the elevation of serum IgE levels. The serum IgE levels in the yuzu seed oil oral administrated NC/Nga mice with control (water), the crude oil and the distilled oil, were 1.89±0.475 (mean±SE; n=5) μg/ml, 0.57±0.092 and 0.78±0.204, respectively. Significant differences were found in the crude oil group (p=0.0004) and the distilled oil group (p=0.0007) between control group.
In conclusion, yuzu seed oil is a good candidate to be used as an alternative medicine against AD. Now, we are doing histological analysis of NC/Nga mice after yuzu seed oil oral administration and are confirming the depletion of mast cells and/or eosinophils.

P5.14.23
IL-17A-producing CD8$^+$ T cells in psoriasis: correlation with psoriasis severity and relationship with MAIT cell lineage

***M. B. M. Teunissen**, N. Yeremenko, D. Baeten, S. Chielie, P. I. Spuls, M. A. de Rie, P. C. M. Res;*
Academic Medical Center, Amsterdam, Netherlands.

Our observation that IL-17A-producing CD8$^+$ T cells are overrepresented in psoriatic lesions is in line with the general consensus that T cells and IL-17A are critically involved in psoriasis. Here we provide further proof that CD8$^+$ T cells are involved in the pathogenesis and analyzed T cells derived from peripheral blood and lesional dermis and epidermis by flow cytometry. The frequency of IL-17A-producing CD8$^+$ T cells in blood correlated with psoriasis severity. Such correlation was not found for IL-22-producing CD8$^+$ and CD4$^+$ T cells. Of note, a remarkable higher frequency of skin-homing molecule CLA was found in IL-17A and/or IL-22 producing CD8$^+$ blood T cells of psoriasis patients. However, this feature was also observed in healthy individuals. IL-17A-producing CD8$^+$ T cells in blood have been described to belong to the mucosa-associated invariant T (MAIT) cell lineage, expressing the invariant T cell receptor Vα7.2-Jα33 chain, CD161 (high) and IL-18Rα. We unequivocally show the presence of MAIT cells in psoriatic as well as healthy skin. IL-17A-producing CD8$^+$ MAIT cells were only present in psoriatic lesional skin, suggesting contribution to psoriasis development. IL-17A was also expressed by a considerable proportion of CD8$^+$ T cells without MAIT cell characteristics, likely containing MHC class I-restricted psoriasis-associated autoreactive T cells. In conclusion, we provide supporting evidence that implicates conventional CD8$^+$ T cells in the pathogenesis of psoriasis and describe the presence of innate MAIT cells in psoriatic lesions as an additional source of IL-17, a feature that was not appreciated before.

P5.14.24
Skin involvement in cutaneous and systemic vasculitis

***P. Vezzoli**[1], A. V. Marzano[2], E. Berti[2];*
[1]Dept. of Dermatology - Ospedale Papa Giovanni XXIII, Bergamo, Italy, [2]Dept. of Dermatology - Fondazione IRCCS Cà Granda - Ospedale Maggiore Policlinico, Milan, Italy.

Cutaneous vasculitides are a heterogeneous group of inflammatory disorders affecting skin blood vessels. They may be triggered by several factors, such as infection or drug, or may be related to underlying disease, notably connective tissue or malignancies. However, vasculitis occurs without any demonstrable triggering agents in a relevant number of patients. On the other hand, vasculitic skin lesions may manifest as a component of vasculitis affecting also internal organs; in someone of these patients, skin involvement occurs initially as the sole sign of disease, leading to consider cutaneous vasculitis a diagnosis of exclusion. In this review, we have focused on the most common variants of cutaneous vasculitis, including cutaneous small vessel vasculitis and urticarial vasculitis as well as Henoch-Schönlein purpura, a systemic form in which however skin involvement often predominates. We have also argued on livedoid vasculopathy, a cutaneous entity which, although nonfrankly vasculitic in origin, is frequently associated with connective tissue disease. Finally, we have analyzed the variety of cutaneous manifestations that may develop during the course of the main systemic vasculitides, such as Wegener's granulomatosis, Churg-Strauss syndrome and polyarteritis nodosa.

P5.14.25
Topical application of the yuzu seed oil inhibits mite-antigen induced atopic dermatitis in NC/Nga mice

***K. Yamawaki**[1], Y. Watanabe[1], K. Asano[2], S. Aoki[1], K. Terasita[1], E. Takahashi[1], M. Toutani[2], S. Mizobuchi[1];*
[1]Kochi University, Nankoku, Japan, [2]Umajimura agricultural cooperative, Umaji-mura, Japan.

The yuzu (*Citrus junos Sieb.* ex Tanaka) is a citrus fruit and this fruit was brought to Japan from China about a thousand years ago. The yuzu have been traditionally used as not only the food but also a folk remedy for a cold, gout, skin care and rheumatism in Japan. It is known that the yuzu contains a lot of material, such as limonene, hesperidine, auraptene and pinene, which contributes to health maintenance.
In this study, we show the effects of yuzu seed oil for topical application on the progress of atopic dermatitis (AD)-like skin lesions in NC/Nga mice induced by mite-antigen. We used two kinds of yuzu seed oil (crude oil and distilled oil). We evaluated skin dermatitis severity, ear thickness, serum IgE levels, histopathological examination and histamine level in AD-mice treated with the yuzu seed oil. The yuzu seed oil inhibited atopic dermatitis symptoms and signs in the antigen-treated Nc/Nga mice. Topical application of yuzu seed oil significantly inhibited the increase of the clinical skin severity score and the ear thickness in comparison with the negative control group (olive oil). Especially, the crude oil (1.24±0.11)μg/g (mean±SD.; n=5) and the distilled oil (1.00±0.07) strongly decreased the histamine levels in the skin lesions of the control group (1.84±0.13) at 4 weeks after antigen challenge compared to the negative control group, respectively.
In conclusion, yuzu seed oil is a good candidate to be used as an alternative medicine against atopic dermatitis.

Contribution of quanta-lite® M2 EP (MIT3) test in primary biliary cirrhosis immunological diagnosis

***M. Benidir**[1], S. S. Salah[1,2], A. Aït-Kaci[1], S. Kebbab[1], S. Semmane[1], M. C. Abbadi[1,2];*
[1]Immunology Department, Pasteur Institute of Algeria, Algiers, Algeria, [2]Immunogenetics and Immunopathology Laboratory (LIGIP), Pasteur Institute of Algeria – Algiers University, Medicine Faculty, Algiers, Algeria.

Introduction: PBC is a chronic auto-immune hepatopathy, characterized by an inflammatory destruction of the small intra-hepatic common bile ducts. In 90-95% of cases, PBC is accompanied by production of M2 AMA. These AMA, usually, are sought by IFA on LKS. However, they can be specifically detected by ELISA (MIT3) using as antigen the Pyruvate Dehydrogenase Complex (PDC).
Objective: The aim of this study is to compare results obtained using ELISA Quanta-Lite® M2 EP (MIT3) for detection and semi-quantitative measurement of AMA (M2) with those obtained using IFA in PBC immunological diagnosis.
Methods: Our study related to 217 sera of patients with suspected PBC. Among these sera : 174 (80%) are AMA (-) using IFA and 43 sea (20%) are AMA (+). All the sera were also tested using ELISA Quanta-Lite® M2 EP (MIT3) as well as sear of 100 healthy controls.
Results: Concordance rate between IFA and ELISA Quanta-Lite® M2 EP (MIT3) for AMA detection were 81%. Among 174 sera IFA (-) (LKS): 140 (81%) were MIT3 (-), on the other hand 34 sera (19%) showed a positivity of MIT3 test; while on 43 sera IFA (+): 36 (84%) were MIT3 (+) and 7 (16%) MIT3 (-). Quanta-Lite® M2 EP (MIT3) has a specificity of 98%: on the 100 healthy controls tested by ELISA: only 2 showed positivity, whereas 98 were MIT3 (-).
Conclusion: A good concordance rate exists between IFA and ELISA (MIT3) for AMA (M2) detection, with, however, a better sensitivity of ELISA compared to IFA.

P5.16.02
Interleukin-6 and C-reactive protein are overexpressed in the liver of perinatal deaths diagnosed with fetal inflammatory response syndrome

*L. H. M. Pereira[1], J. R. Machado[1], J. G. P. Olegário[1], L. P. Rocha[1], M. V. Silva[2], C. S. O. Guimarães[1], M. A. Reis[1], **L. R. Castellano**[3], F. S. Ramalho[4], R. R. M. Corrêa[1];*
[1]Biological Sciences Department, General Pathology Division, Universidade Federal do Triangulo Mineiro, Uberaba Minas Gerais, Brazil, [2]Biological Sciences Department, General Immunology Division, Universidade Federal do Triangulo Mineiro, Uberaba Minas Gerais, Brazil, [3]Escola Técnica de Saúde, Universidade Federal da Paraíba, João Pessoa Paraíba, Brazil, [4]Pathology and Forensic Medicine Department, Ribeirão Preto Faculty of Medicine of São Paulo University, Ribeirao Preto São Paulo, Brazil.

Anatomopathologic studies have failed to define the Fetal Inflammatory Response Syndrome (FIRS) as cause of fetal death. Here, liver fragments of perinatal autopsies were collected at a University Hospital from 1990 to 2009 and classified according to cause of death, perinatal stress and gestational age (GA) of the fetus. The IL-6, TNF-alpha and C-Reactive Protein (CRP) expression were immunostained respectively with primary antibody. Cases with Congenital Malformation, Ascending Infection and Perinatal Anoxia showed increase respectively of IL-6, CRP and TNF-alpha. Prematures presented higher expression of IL-6 whereas term births showed higher expression of CRP. Cases classified as acute stress presented higher expression of IL-6 and TNF-α and cases with chronic stress presented higher expression of CRP. GA correlated negatively with IL-6 and positively with CRP and TNF-alpha. Body weight correlated negatively with IL-6 and positively with CRP and TNF-alpha. Despite the diagnosis of FIRS being clinical and based on serum parameters, the findings in the current study allow the inference of FIRS diagnosis in the autopsied infants, based on an in situ liver analysis of these markers

P5.16.03
Critical role of invariant natural killer T cells in xenobiotic induced murine model of primary biliary cirrhosis

*C. Chang, H. Jen, Y. Chen, **Y. Chuang**;*
National Taiwan University, Taipei, Taiwan.

Primary biliary cirrhosis (PBC) is an organ-specific autoimmune liver disease characterized by the presence of anti-mitochondrial antibodies (AMAs) and the destruction of small intrahepatic bile ducts with portal inflammation. The major autoantigen is the E2 subunits of the pyruvate dehydrogenase complex (PDC-E2). We have developed a murine model of PBC based upon immunization with 2-OA-BSA. To define the role of iNKT cells in PBC, we examined PBC disease progress of α-GalCer, an iNKT cell activator, and 2-OA-BSA co-immunized wild type mice and 2-OA-BSA immunized iNKT cell deficient $CD1d^{-/-}$ mice. We found that simultaneously activation of iNKT cells by α-GalCer leads to a profound exacerbation of portal disease in 2-OA-BSA immunized mice, including increased production of AMAs, a significant increase in both $CD4^+$ and $CD8^+$ T cells, portal inflammation, bile duct damage, and fibrosis after 12 weeks. In addition, significant increases of IFN-γ and IL-17 production of recombinant mouse PDC-E2 (rmPDC-E2) stimulated T cells as well as supernatant anti-PDC-E2 antibodies of rmPDC-E2 stimulated B cells in 2-OA-BSA/α-GalCer immunized mice were noted. In 2-OA-BSA immunized $CD1d^{-/-}$ mice, decreased $CD4^+$ T cells and B cells in the liver were observed. In addition, IFN-γ production of liver mononuclear cells in 2-OA-BSA immunized $CD1d^{-/-}$ mice were also decreased. These results suggest that iNKT cells are critical in the early pathogenesis of PBC. With activation, iNKT cells secrete amounts of cytokines to recruit immune cells to the liver and then accelerate bile duct damage.
This work was supported by NHRI, Taiwan (NHRI-EX102-10027SC).

P5.16.04
Deranged neutrophil phagocytic capacity on cirrhosis and hyperammonemia is recovered by the blue agave inulin effect on cirrhotic patient gut microbiota

*A. J. Tovar-Cuevas[1], J. E. Segura-Ortega[2], G. E. Hernandez-González[1], J. Ríos-Bojorquez[1], V. Delgado-Rizo[1], **M. Fafutis-Morris**[1];*
[1]Universidad de Guadalajara, Guadalajara, Mexico, [2]Antiguo Hospital Civl de Guadalajara, Guadalajara, Mexico.

Intestinal bacterial overgrowth and endotoxemia play an important role on the cirrhosis complications like spontaneous bacterial peritonitis and hyperammonemia. The increased susceptibility to infection of cirrhotic patients is by peripheral blood neutrophil deranged phagocytosis and increased proinflammatory cytokine production. The short chain fatty acids (lactic, acetic and butyric acid) are bacterial metabolic products which can unfold complex carbohydrates, blue agave inulin. Several papers have been considered that butyrate is the preferred energy source for colonocytes and it get stronger tight junctions between them. Finally, Butyrate inhibits inflammatory responses through NFκB inhibition. The aim of this research was to stablish the blue agave inulin effect on cirrhotic and hyperammonemia patients through reducing serum levels of ammonium and TNF-α, restoration of the phagocytic capacity of peripheral blood neutrophils and increasing colonization resistance against invading pathogens by gut microbiota modifications. The study included sixteen cirrhotic patients of whatever etiology but with hyperammonemia/Minimal hepatic encephalophaty. Two groups were formed by 8 patients randomised. One group was treated with inulin, and the second with lactulose. Ammonium levels was measured by spectrophotometric method, phagocytic index and phagocytic rate were for modified Cunningham assay, microbiota was assessed by RT-PCR. Finally, TNF-α was mesured by ELISA kit. Inulin or lactulose don´t decrease ammonium arterial levels (P=0.125 y 0.344 respectively) same as TNF.alpha (P=0.268 and P=0.422). However, just inulin increased phagocytic index and phagocytic rate (P=0.016 and 0.031). The Inulin effect of 5 days of treatment doesn't decrease arterial ammonium but restore neutrophil phagocytic capacity.

P5.16.05
Disruption of chemokine-glycosaminoglycan interactions protects the liver in the murine Concanavalin A-induced acute hepatits model

***R. Fernandez-Botran**, Q. Xie, L. Gobejishvili, Z. Zhang, S. Joshi-Barve, C. McClain, S. Barve;*
University of Louisville, Louisville, KY, United States.

Autoimmune-mediated liver injury is responsible for the pathogenesis of immune-, viral- and drug-associated liver diseases, conditions that constitute a significant health problem worldwide. The purpose of this research was to investigate the therapeutic potential, in liver disease, of inhibitors that target chemokine interactions with glycosaminoglycans (GAGs). Because of the key role played by GAG-attached chemokines in the migration of leukocytes into inflamed tissues, we predicted that interference with the binding of chemokines to GAGs, would lead to reduced leukocyte infiltration and decreased liver damage in a Concanavalin-A (ConA)-induced model of acute hepatitis in mice. Administration of a synthetic peptide that interferes with the binding of chemokines to GAGs into ConA-treated mice resulted in significant protection against liver damage. Peptide-treated mice showed a substantial reduction in areas of hepatocyte necrosis upon histological examination, and had significantly lower serum levels of liver enzymes (ALT and AST) as well as hepatocyte apoptosis compared to mice that received only ConA. Immunofluorescent staining of liver slices showed that this protection was correlated with reduced hepatic levels of IFNγ, IL-17 and TNFα as well as with significant reductions in the numbers of infiltrating T leukocytes and myeloid cells (both granulocytes and monocytes). Moreover, among the infiltrating T cells, peptide-treated animals showed reduced percentages of $IFN\gamma^+$-$CD4^+$ and $IFN\gamma^+$-$CD8^+$ cells. These results suggest that targeting chemokine/GAG interactions in vivo decreases the recruitment and activation of leukocytes and has potential as anti-inflammatory therapy in liver diseases.

P5.16.06

Development of a new murine model for autoimmune hepatitis useful for pathogenic studies and preclinical trials

I. Gil Fariña[1], *M. di Scala*[1], *N. Zabaleta*[1], *E. López-Franco*[1], *C. Olagüe*[1], *Á. Vales*[1], *L. Guembe*[2], *J. Prieto*[1,3], *G. González-Aseguinolaza*[1];
[1]*Division of Gene Therapy and Hepatology; Centre for Applied Medical Research, Pamplona, Spain,* [2]*Morphology core facility; Centre for Applied Medical Research, Pamplona, Spain,* [3]*Unit of Hepatology (CIBERehd); Clínica Universidad de Navarra, Pamplona, Spain.*

Background and aims: Autoimmune hepatitis (AIH) consists of an immune-mediated destruction of hepatocytes due to the loss of the immunologic tolerance against self-antigens. Understanding the molecular mechanism underlying AIH is critical to improve current therapies. Animal models resembling human AIH are essential. In the present work a murine model of AIH was developed.
Methods: Adenoassociated viruses expressing constitutively and hepatospecifically murine IL-12 or luciferase (AAVIL-12/AAVLuc) were intravenously injected in C57BL/6 mice at a very low dose. At different time points after treatment, transaminases, cytokines and presence of auto-antibodies were analyzed. Animals were sacrificed 30 and 60 days post-treatment for histopathological analysis of the liver and study of the intrahepatic lymphocytic populations. To determine the role of CD4+ and CD8+T cells they were depleted using specific antibodies.
Results: Mice treated with AAVIL-12, but no AAVLuc, developed anti-nuclear (ANA) and anti-smooth muscle actin (ASMA) antibodies, but no anti-mitochondrial or anti-LKM. Livers showed an initial portal hepatitis that, 60 days post-treatment, progressed into an erosive necrosis with a concomitant rise in serum transaminases. We observed an increase in $CD8^+$ and $CD4^+$ cells and depletion experiments showed that both were essential for the development of AIH.
Conclusions: AAV-mediated expression of low levels of IL-12 in the liver leads to the break of immunological tolerance to self-antigens giving rise to ANA and ASMA and to an erosive necrosis in the liver with significant lymphocytic infiltration. This scenario mimics human type I AIH and constitutes the first reported model without the use of transgenic animals.

P5.16.07

High frequency of antiphospholipid antibodies in primary biliary cirrhosis

A. Mankai[1,2], *W. Manoubi*[2], *W. Sakly*[2,3], *A. Achour*[2], *Y. Thabet*[2], ***I. Ghedira***[2,4];
[1]*High School of sciences and techniques of health, Tunis el Manar University, Tunis, Tunisia,* [2]*Department of Immunology, Research Unit (03/UR/07-02), Faculty of Pharmacy, Monastir, Tunisia,* [3]*Faculty of Sciences, University of Gabes, Tunisia,* [4]*Department of Immunology, Farhat Hached Hospital, Sousse, Tunisia.*

Background: The aim of our study was to evaluate, retrospectively, the frequency of serum autoantibodies of antiphospholipid syndrome (APLS) in Tunisian patients with primary biliary cirrhosis (PBC).
Materials and methods. We analyzed 80 PBC sera (all positive in anti-mitochondrial antibodies) and 80 sera from blood donors. ELISA was used to determine antibodies against cardiolipin and beta2 glycoprotein I.
Results: The frequency of antiphospholipid antibodies was significantly higher in PBC patients than in controls (70% vs 5%, $p<10^{-6}$). The frequency of aCL (IgG or IgA or IgM) was significantly higher in PBC patients than in the control group (23.7% vs 3.7%, p=0.0005). The frequencies of aCL IgA and aCL IgM in PBC patients sera were significantly higher in patients than in the control group (10% vs 0%; p=0.003 and 20% vs 2.5%; p=0.001 respectively). Two patients out of 80 (2.5%) had aCL IgG, aCL IgA and aCL IgM and none of the control group had this three isotypes. The frequency of aβ2GPI (IgG or IgA or IgM) was significantly higher in PBC patients than in the control group (70% vs 1.25%; $p < 10^{-6}$). The frequencies of aβ2GPI IgG, aβ2GPI IgA and aβ2GPI IgM in PBC patients sera were significantly higher in patients than in the control group (12.5% vs 0%, p=0.003; 62.5% vs 1.2%, $p<10^{-6}$ and 21.2% vs 0%, $p<10^{-4}$ respectively).
Conclusion: Autoantibodies related to APLS were present in the majority of patients with PBC, reflecting the ability of these antibodies to engage mediators of damage.

P5.16.08

CD8 T cell responses to T cell apoptosis-derived antigens as a marker of chronic immune activation and liver inflammation in chronic HCV infection

H. Martini[1], *A. Citro*[1], *S. Piconese*[1], *G. Labbadia*[1], *G. D'Ettorre*[2], *V. Vullo*[2], *V. Barnaba*[1];
[1]*Dipartimento di Medicina Interna e Specialità Mediche, Sapienza Università di Roma, Rome, Italy,* [2]*Infectious Diseases Department, Sapienza Università di Roma, Rome, Italy.*

The mechanisms responsible for chronic liver inflammation and fibrosis observed in several patients with chronic hepatitis C are not completely elucidated. Current opinion is that liver damage is caused by HCV-specific T cells attacking HCV-infected hepatocytes. However, they represent only a minority of the about 10-20 billions lymphocytes that generally infiltrate an infected liver. We have previously shown that T cell apoptosis creates a wide assortment of caspase-cleaved peptides, which can be cross-presented by dendritic cells to a broad repertoire of autoreactive CD8+ T cells specific for apoptotic antigens. This event takes part to the chronic immune activation (CIA) observed in chronic infections. We show here increased T cell apoptosis and high frequencies of CD8 T cells specific for self-apoptotic and HCV antigens (as detected by dextramers of class I molecules complexed with the relevant paptides or by IFN-γ-ELISPOT assay) in the periphery of chronically-HCV infected patients. This phenomenon is even more represented in inflamed livers. Importantly, a significant reduction of HCV-CD8 T cell frequencies since the first month of therapy (Peg-IFNα/ribavirin) and a decrease of self-reactive CD8 T cells since the third month are seen. Interestingly, we observe a linear correlation between the self-apoptotic (but not the virus-specific) CD8 T cell frequencies and the Ishak score (liver inflammation/fibrosis scoring system) on the liver biopsies. Altogether, these data suggest a possible involvement of self-apoptotic CD8 T cells in liver inflammation/fibrosis in chronic hepatitis C.

P5.16.09

Activation of $CD11b^+$ Kupffer cells/macrophages as a common cause for exacerbation of TNF/ Fas-ligand-dependent hepatitis in hypercholesterolemic mice

H. Nakashima, *Y. Ogawa, S. Shono, M. Kinoshita, M. Nakashima, A. Sato, M. Ikarashi, S. Seki;*
Department of Immunology and Microbiology, National Defense Medical College, Saitama, Japan.

We have reported that the mouse hepatic injury induced by either α-galactosylceramide (α-GalCer) or bacterial DNA motifs (CpG-ODN) is mediated by the TNF/NKT cell/ Fas-ligand (FasL) pathway. $F4/80^+$ Kupffer cells can be subclassified into $CD68^+$ subset with a phagocytosing capacity and $CD11b^+$ subset with a TNF-producing capacity. $CD11b^+$ subset increase if mice are fed high-fat and cholesterol diet (HFCD). The present study examined how a HFCD affects the function of NKT cells and $F4/80^+$ $CD11b^+$ subset and these hepatitis models. After the C57BL/6 mice received a HFCD, high-cholesterol diet (HCD), high-fat diet (HFD) and control diet (CD) for four weeks, the HFCD mice increased surface CD1d and intracellular TLR-9 expression by the $CD11b^+$ population compared to CD mice. Hepatic injury induced either by α-GalCer or CpG-ODN was more severe in HCD and HFCD mice compared to CD mice, which was in proportion to the serum TNF levels. In addition, liver cholesterol levels but not serum cholesterol levels nor liver triglyceride levels were involved in the aggravation of hepatitis. The FasL expression of NKT cells induced by both reagents was upregulated in HFCD mice. Furthermore, the liver
mononuclear cells and purified $F4/80^+$ $CD11b^+$ subset from HFCD mice stimulated with either reagent *in vitro* produced a larger amount of
TNF than did those from CD mice. Intracellular TNF production in $F4/80^+$ $CD11b^+$ cells was confirmed**.** The increased number of $F4/80^+$

CD11b$^+$ Kupffer cells/macrophages by HFCD and their enhanced TNF production thus play a pivotal role in TNF/NKT cell/FasL dependent hepatic injury.

Hepatitis C virus (HCV) infection is characterized by a high risk of chronicity, which may progress to cirrhosis and hepato-cellularcarcinoma. We have shown that natural regulatory T cell (Treg) play an important role in this disease progression and are associated with the severity of the HCV recurrence after liver transplantation. In this context, one essential question remains to know whether HCV infection could alter Tregs function thus promoting liver pathogenesis.
Tregs were isolated from blood of healthy donors and infected with HCVcc/JFH-1. Internalization of HCV protein was confirmed by immunofluorescence and western-blotting. Expression of several cell markers associated to Treg phenotypic and function was analyzed using flow cytometry and Q-PCR. The Treg activity is evaluated by suppression tests (MLR) and correlated with cytokines secretion profile by ELISA.
We showed that infected Treg significantly increases the expression of virus receptors and that HCV proteins (Core, NS5A) are well internalized. We also showed that HCV infection promotes the Treg proliferation and probably the recruitment of infected Treg by infected liver cells. In addition, HCV infection potentiates the "suppressive phenotype" of Treg showing a significant increase of markers associated with their phenotype and immunosuppressive function. These results were correlated with increased suppression activity and increased secretion of immunosuppressive cytokines (IL-10, TGF-β).
This work showed for the first time that HCV is able to infect human Treg and promote their recruitment and suppressive activity, contributing to one mechanism by which HCV could escape the immune system thus leading to a worsening of the disease.

Disproportionate decline of liver infiltrating regulatory T cells under therapy for autoimmune hepatitis

R. Taubert[1], *M. Hardtke-Wolenski*[1], *F. Noyan*[1], *A. Wilms*[1], *A. Baumann*[1], *J. Schlue*[1], *S. Olek*[2], *M. Manns*[1], *E. Jaeckel*[1];
[1]*Hannover Medical School, Hannover, Germany,* [2]*Epiontis GmbH, Berlin, Germany.*

Background & Aims: Autoimmune hepatitis (AIH) is a chronic autoimmune inflammation of the liver usually requiring life-long immunosuppression. The mechanisms responsible for the disease initiation are largely unknown. A contribution of deficient regulatory T cells in the peripheral blood was controversially discussed recently. So far investigations in the target organ of the autoimmune attack have been limited to single parameter analysis in untreated AIH.
Methods: We analyzed the pattern of liver infiltrating T, B and regulatory T cells (Treg) semi-quantitatively with a simultaneous multicolour immunofluorescence before and under therapy in patients with AIH. Data was correlated with disease activity and clinical outcome.
Results: Intrahepatic CD4+ cells dominate over CD8+ at diagnosis, but with increasing disease activity the CD4+/CD8+ ratio approaches 1. Treg enrich in liver infiltrates in untreated AIH independent from disease activity but may not be sufficient to balance the overwhelming infiltration of effector T cells (Teff). But more important immunosupressive therapy with steroids and azathioprin caused a disproportional loss of intrahepatic Tregs and better treatment response seems be associated with higher intrahepatic Treg/Teff ratios. Intraportal B cells correlated with serum IgG suggesting an autochtonous intahepatic production. This might be regulated by Tregs as serum IgG negatively correlated with Treg/B cell ratio.
Conclusion: Intrahepatic Tregs are rather enriched than numerically deficient in untreated AIH. The disproportional decrease of Tregs during immunosuppressive therapy might explain the high relapse rate after discontinuation of therapy. Therapies increasing intrahepatic regulation might be better suited for long-term control of AIH.

P5.16.12
IFNγ/STAT1-mediated tissue factor expression contributes to T cell-mediated hepatitis via induction of hypercoagulation in mice

H. Tsutsui, *R. Uchiyama;*
Dept. Microbiol., Hyogo College of Medicine, Nishinomiya, Japan.

Concanavalin A (Con A) treatment induces severe hepatitis in mice in a manner dependent on T cells, IFN-γ and TNF. Treatment with the anticoagulant heparin protects against hepatitis despite normal production of IFNγ and TNF. Here, we investigated molecular and cellular mechanisms for hypercoagulation-mediated hepatitis. After Con A challenge liver of wild-type mice showed prompt induction of Ifnγ and Tnf, followed by mRNA expression of tissue factor (TF) and plasminogen activator inhibitor-1 (PAI-1), which initiate blood coagulation and inhibit clot lysis, respectively. The mice developed dense intrahepatic fibrin deposition and massive liver necrosis. In contrast, Ifnγ-/- mice and Ifnγ-/-Tnf-/- mice neither induced Pai1 or Tf, nor developed hepatitis. In wild-type mice TF blockade with an anti-TF mAb protected against Con A-induced hepatitis, whereas Pai1-/- mice were not protected. Both hepatic macrophages and sinusoidal endothelial cells expressed Tf after Con A challenge. Macrophage-depleted wild-type mice reconstituted with hematopoietic cells including macrophages deficient in STAT1 essential for IFNγ signaling, exhibited substantial reduction of hepatic Tf and of liver injuries. This was also true for macrophage-depleted Stat1-/- mice reconstituted with wild-type macrophages. Exogenous IFNγ and TNF rendered T cell-null, Con A-resistant mice deficient in recombination-activating gene 2, highly susceptible to Con A-induced liver injury involving TF. Collectively, these results strongly suggested that pro-inflammatory signals elicited by IFNγ, TNF and Con A in both hepatic macrophages and sinusoidal endothelial cells are necessary and sufficient for the development of hypercoagulation-mediated hepatitis.

The proliferative response to PHA and SEB stimulation of peripheral blood mononuclear cells from oral lichen planus patients

T. F. A. Almeida, *A. M. Mesquita, G. E. B. Alvim-Melo, E. Rocha-Vieira;*
Federal University of Jequitinhonha and Mucuri Valleys, Diamantina, Brazil.

Oral lichen planus (OLP) is a chronic inflammatory disorder of oral mucosa, which represents T-cell-mediated autoimmune disease. It has been suggested that clones bearing specific T cell receptor repertoires may be involved in the pathogenesis of OLP. This study assessed the *in vitro* proliferative response of lymphocytes from OLP patients to phytohemagglutinin (PHA) and to *Staphylococcus aureus* enterotoxin B (SEB) stimulation. Peripheral blood mononuclear cells (PBMC) were obtained from 8 women clinical and histopathological diagnose of OLP (45 ± 14 yrs old), and 8 healthy female blood donors (41±16 yrs old) (CTRL). At the time of blood collection patients had at least one of four clinical manifestations: atrophic, bullous, erosive or reticular OLP, and were not in corticoid therapy for at least 3 months. PBMC were stained with 5,6-carboxyfluorescein diacetate

succinimidyl ester (CFSE, 10mM) and then stimulated *in vitro* with PHA (5µg/mL) or SEB (100ng/mL) for 5 days (37°C, 5% CO_2). Cell proliferation (PI) was evaluated using flow cytometry. The proliferative response to PHA stimulation was increased (P = 0.04, Student's t test) in OLP (PI = 1.87 ± 0.95) compared to CTRL (PI = 1.15 ± 0.48). Also, in response to SEB stimulation we observed a tendency (P = 0.06 Student's t test) to increased proliferation in OLP (PI = 1.18 ± 0.58 OLP versus 0.72±0.29 CTRL). Our results show increased proliferative response of PBMC from OLP patients to PHA, a polyclonal mitogen, and SEB, a repertoire restricted mitogen, thus suggesting a general, repertoire unrestricted, lymphocyte activation in OLP.

P5.17.02
Posttranscriptional Gene Regulation of IL-17 by the RNA-binding Protein HuR

***U. Atasoy**, J. Chen, J. Cascio, J. Magee, P. Techasintana, M. Gubin, G. Dahm, R. Calaluce;*
University of Missouri-Columbia, Columbia, MO, United States.

Interleukin 17 (IL-17A) is a proinflammatory cytokine produced by activated CD4+ Th17. Th17 cells are major contributors to autoimmune diseases, including multiple sclerosis. Although the transcriptional control of IL-17 and Th17 differentiation have been well studied, posttranscriptional gene regulation is unclear. The RNA-binding protein (RBP) HuR regulates the stability of many target mRNAs via binding the AU-rich elements (ARE) present in the 3' untranslated region (UTR), of many pro-inflammatory cytokines such as IL-4, IL-13 and TNF. Since IL-17 mRNA also possesses HuR binding motifs, we investigated whether HuR can regulate Il-17 expression. We demonstrated that HuR directly binds IL-17 mRNA 3' UTR by using RNA immunoprecipitation methods as well as biotin pull down assays. Th17 cells from $HuR^{fl/fl}$ KO mice have decreased IL-17 steady-state mRNA and protein expression compared to wild type Th17 cells. IL-17 mRNA stability was decreased by 3-fold in HuR KO mice. We used the experimental autoimmune encephalitis (EAE) model of neuroinflammation to investigate whether HuR plays a role in CD4+ Th17 differentiation and disease initiation. Mice with adoptive transfer of HuR KO $CD4^+$ T cells had delayed onset, reduced severity of EAE symptoms, as well as reduced CNS inflammation and decreased IL-17 production by Th17-producing cells recovered from the CNS. Our results reveal HuR-controlled posttranscriptional regulatory mechanisms of Th17 differentiation and direct effects upon EAE initiation. These findings could provide novel therapeutic targets for treatment of IL-17- mediated autoimmune neuroinflammation and also potentially other diseases in which IL-17 plays a major role.

P5.17.03
Endogenous IFN-γ prevents escalation of normal immunity into a Th17-driven inflammation reminiscent of systemic juvenile idiopathic arthritis

***A. Avau**[1], T. Mitera[1], S. Put[1], K. Put[1], E. Brisse[1], A. Liston[2], G. Leclercq[3], A. D. Billiau[4], C. H. Wouters[5], P. Matthys[1];*
[1]Laboratory of Immunobiology, Rega Institute, University of Leuven, Leuven, Belgium, [2]VIB, Autoimmune Genetics Laboratory, University of Leuven, Leuven, Belgium, [3]Department of Clinical Chemistry, Microbiology and Immunology, Ghent University, Gent, Belgium, [4]Laboratory of Experimental Transplantation, University of Leuven, Leuven, Belgium, [5]Pediatric Rheumatology, University Hospital Gasthuisberg, Leuven, Belgium.

Whereas the mechanisms that initiate and maintain strong inflammatory reactions against endogenous and exogenous stimuli are well documented, regulatory circuits that prevent such reactions from escalating to harmful proportions are less well understood. Here we have studied endogenous IFN-γ as a proposed key player in such circuits. Mice were given heat-killed mycobacteria in Freund's adjuvant, an almost innocuous immunological challenge in wildtype mice. In the absence of IFN-γ, normal immunity escalated into a persistent systemic inflammatory syndrome. Elevated IL-6 production and cascading Th17 activation resulted in the development of arthritis, weight loss, anemia, neutrophilia, thrombocytosis, lymphadenopathy, splenomegaly, and abundant immature blood cells and hemophagocytes, all features reminiscent of systemic juvenile idiopathic arthritis (sJIA) in humans. The lack of a suitable animal model is a major drawback in the investigation of sJIA. The underlying pathogenic mechanism is not understood but prolonged stimulation of immune cells and excessive production of cytokines are considered to be important in the pathogenesis of the disease. Here we descibe an animal model of sJIA. The data point IFN-γ as an important counter-regulator of IL17, and suggest that a failure to produce sufficient IFN-γ during normal immunological events may be a primary driver of systemic juvenile idiopathic arthritis development.

P5.17.04
Risk factors of asthma in preschool children

*L. Aghebati Maleki, **B. Baradaran**, j. Majidi, A. Aghebati Maleki, F. Zare Shahneh, F. Zamani;*
Immunology Research Center, Tabriz, Iran.

Asthma is the leading cause of chronic inflammatory illness in children. Common symptoms include wheezing, coughing, chest tightness, and shortness of breath. Asthma is caused by a combination of environmental and genetic factors. The prevalence of asthma in children, for unknown reasons, has increased in many countries over recent years steadily. The International Study of Asthma and Allergies in Childhood (ISAAC), was founded to maximize the value of epidemiological research into asthma and allergic disease, by establishing a standardized methodology and facilitating international collaboration. To plan effective interventions to reverse this trend we need a better understanding of the risk factors for asthma in early life. Multiple factors were associated with asthma symptoms in preschool children. Factors which increased the risk of asthma were: atopy or presence of allergies, having a parent with a history of asthma or allergies, low birth weight, having had a serious respiratory infection in the first 2 years of life, male gender, lower air conditioning, using feather pillow and blanket bedding and exposure to tobacco smoke before or after birth. Breast feeding and consumption of polyunsaturated fats decreased the risk of asthma. Also, change in environmental factors and sedentary life style from first year of life may prevent the development of childhood asthma.

P5.17.05
Pertussis toxin- driven IL-1β production is required for highly encephalitogenic GM-CSF$^+$ T cell generation in EAE pathogenesis

***C. Basso**[1], F. Ronchi[2], S. Preite[1], A. Reboldi[3], A. Lanzavecchia[4], F. Sallusto[1];*
[1]Institute for Research in Biomedicine (IRB), Cellular Immunology, Bellinzona, Switzerland, [2]University of Bern , Mucosal Immunology, Bern, Switzerland, [3]UCSF, Microbiology & Immunology, San Francisco, CA, United States, [4]Institute for Research in Biomedicine (IRB), Immune Regulation, Bellinzona, Switzerland.

IL-1β is a pleiotropic cytokine and plays an important role in several inflammatory disorders in humans and in animal models. In our study we showed that mice deficient for IL-1β or for a component of the inflammasome (ASC), after immunization with myelin antigen (MOG) emulsified in complete Freund's adjuvant (CFA) and treated with a double injection of pertussis toxin (PTX), did not develop experimental autoimmune encephalomyelitis (EAE). Autoreactive T cells were primed in wild-type (WT), $IL\text{-}1\beta^{-/-}$ and $ASC^{-/-}$ mice. While in WT mice T cells proliferated extensively and acquired a multifunctional phenotype ($IL\text{-}17^+IL\text{-}22^+IFN\gamma^+GM\text{-}CSF^+$), in knockdown mice the cells expanded poorly and showed reduced capacity to produce inflammatory cytokines. The same defects were observed both in $Myd88^{-/-}$ and $CCR2^{-/-}$ animals, as well as by depleting Gr^+ myeloid cells. We found that the induction of multifunctional T cells in WT mice was dependent on the presence of PTX. After PTX injections, IL-1β secretion was induced by $CD11c^+$ and $Gr1^+$ myeloid cells which were highly recruited in secondary lymphoid organs. These data supported the notion that the disease-inducing effect of PTX was due to its ability to induce recruitment of $Gr1^+$ myeloid cells, production of IL-1β and differentiation of pathogenic multifunctional T cells.

P5.17.06
Expression of Suppressor of Cytokine Signalling (SOCS) 1 and 3 in Behçet's Disease

***L. A. Bergmeier**, M. Hamedi, E. Hagi-Pavli, G. Warnes, F. Fortune;*
Queen Mary's School of Medicine and Dentistry, University of London, London, United Kingdom.

Behçet's disease (BD) is an autoinflammatory disease of unknown aetiology where a pro-inflammatory cytokine profile is a key feature. Suppressor of Cytokine Signalling molecules (SOCS) 1 and 3 belong to a family of eight intracellular proteins which have been shown to negatively regulate cytokine signals through the JAK-STAT pathway and have profound effects on many immunological processes. SOCS 1 deficient mice develop severe skin and eye lesions, reminiscent of BD, through recruitment of TH1 and TH17 cells into these non-lymphoid tissues. We have investigated the expression of SOCS1, 2 and 3 in Neutrophils and PBMCs in BD and healthy controls (HC) along with TH1 and TH17 cytokines and the Stats and Transcription factors associated with these pathways. Proteins were examined using western blot and mRNA expression was quantified by RT-PCR. Cytokine profiles of serum were investigated using multiplex bead analysis and cytokine secreting cells were enumerated by ELISPOT. Stats 1, 3 and 5 and the transcription factors t-bet and ROR γt were assayed using PhosFlow FACS analysis.
Results: SOCS3 was down regulated in PBMCs but up regulated in Neutrophils in BD patients compared to healthy controls. SOCS 1 and 3 show inconsistent bands in western blot analysis in both Neutrophils and PBMC's. IL-6, IL-23 and IL-17 ELISPOTS were detected after stimulation with LPS and human heat shock protein. Transcription factors and Stats showed altered levels in BD compared HC and also between active and inactive disease episodes, consistent with a failure of SOCS function in BD.

P5.17.07
Analysis of neutrophil function in severe and moderately affected Chronic Fatigue Syndrome subjects

*S. L. Hardcastle[1], **E. W. Brenu**[1], D. Staines[2], S. Marshall-Gradisnik[1];*
[1]National Centre for Neuroimmunology and Emerging Diseases, Griffith Health Institute, Griffith University, Gold Coast, Australia,
[2]Queensland Health, Gold Coast Public Health Unit, Gold Coast, Australia.

Research has commonly shown that people with Chronic Fatigue Syndrome (CFS) have immune system abnormalities. Decreases have been found in neutrophil respiratory burst in a CFS cohort. Reduced ability of neutrophils to eliminate pathogens can contribute to the impaired immune function in CFS subjects. It is unknown whether neutrophil function is more impaired in patients severely affected by CFS. The purpose of this study was to examine neutrophil activity including phagocytosis and respiratory burst in patients with severe CFS in comparison to those with moderate symptoms and non-fatigued controls. CFS subjects were characterised using the CDC Case Definition and the International Consensus Criteria for CFS. CFS subjects were then grouped as either moderate or severely affected based on health and quality of life questionnaires. Blood samples were taken from age and sex matched non-fatigued controls, moderately affected and severely affected CFS subjects. Response to *E.coli* bacteria was measured in neutrophils by assessing phagocytic activity and respiratory burst, these were then analysed on the flow cytometer. Preliminary data from CFS subjects showed differences in neutrophil function based on respiratory burst and phagocytic activity when compared to the control group. These results suggest that differences in neutrophil function in CFS patients may contribute to CFS related immune dysfunction.

P5.17.08
To investigate the roles of IL-12 family cytokines on islet graft rejection and tolerance

***H. Chen**, F. Chou, H. Sytwu;*
Department and Graduate Institute of Microbiology and Immunology, National Defense Medical Center, Taipei, Taiwan.

IL-12 family cytokines are mainly produced by antigen presenting cells and have crucial roles in the control of T helper (Th) cell differentiation and function. It has been reported that Th1 and Th17 cells are linked to the graft rejection whereas Th2 and Treg cells are correlated to graft tolerance. In this study, we aim to investigate whether IL-12 family cytokines modulate the differentiation of Th cells and subsequently influence the survival of islet grafts in diabetic recipients. Bone marrow-derived dendritic cells (BMDCs) from IL-12 knockout, IL-23 or IL-27 knockdown mice displayed similar capacity to induce T cell proliferation. However, BMDCs from IL-12 knockout or IL-23 knockdown mice showed slightly reduced ability to promote Th1 and Th17 differentiation. In contrast, BMDCs from IL-27 knockdown mice enhanced Th1 and Th17 development. In transplantation experiments, the survival of islet grafts was prolonged in IL-12 knockout or IL-23 knockdown recipients and was reduced in IL-27 knockdown mice after diabetogenic T cell transfer, as compared with the control recipients. Histological examination of grafts from IL-12 knockout or IL-23 knockdown recipients displayed less severe infiltration than grafts from control group. Our findings suggest that IL-12 and IL-23 mediate the islet grafts rejection through promoting Th1 and Th17 differentiation, respectively. IL-27 acts as a regulatory cytokine to dampen immune responses and reduction of IL-27 leads to increased T cell activation and early graft rejection.

P5.17.09
Characterization of tonsil infiltration and gene expression profile of innate sensors in PFAPA Syndrome

***S. Chiesa**[1], R. Caorsi[1], F. Penco[1], A. Bertoni[1], S. Borghini[1], A. Omenetti[1], A. Sementa[1], F. Bellora[2], A. Martini[1], M. Gattorno[1];*
[1]Institute G.Gaslini, Genova, Italy, [2]Medicina Sperimentale, Università degli Studi di Genova, Genova, Italy.

The syndrome of periodic fever, aphthous stomatitis, pharyngitis, and cervical adenitis (PFAPA) is the most common periodic fever disease in young children. The etiology of this disorder is still unknown. Palatine tonsils are sites where innate immunity leads to onset of the adaptive immunity, mediated by B and T lymphocytes.
We aimed to investigate differences in leucocytes subpopulations and innate receptors gene expression of palatine tonsil cells from patients with PFAPA in order to understand the pathogenesis of this inflammatory condition. We have collected tonsil tissue from 2 groups of pediatric patients undergoing tonsillectomy: PFAPA patients (n=20), and patients who had indication of bacterial tonsillitis (control group, CG) (n=16) . We have performed staining of subpopulations on tonsil cells and tissues using flow cytometry and immunohistochemistry. We have analyzed NLRs, and RLRs gene expression by quantitative real-time RT-PCR.
FACS analysis demonstrated a higher number of naïve and a significantly lower percentage of effector memory $CD4^+$ and $CD8^+$ T cells in PFAPA patients compared to CG. Remarkably, we observed a considerably recruitment of NK cells in tonsils of PFAPA patients with respect to CG. In particular, we discovered a significant expansion of $CD56^+CD16^-$ and $CD56^+CD16^+$ NK cell subsets when compared to CG. Moreover, in PFAPA patients we demonstrated a significant increase in the gene expression of NALP1 and NALP3 when compared to CG. These results indicate a possible involvement of NK cells and of innate receptors in pathogenesis of PFAPA supporting the crucial role of the innate immunity.

P5.17.10
Autoantibodies characteristics of patients with autoimmune liver disease in Uygur people

***L. De Mei**, Z. Jian Mei, S. Gulinaer;*
Department of Medical Laboratory Diagnosis Center, First Affliated Hospital, Xinjiang Medical Univer, Urumqi, China.

Objective To study the clinical significance of immunological characteristics in patients with autoimmune liver disease in Uygur people. Methods A total of 51 patients with autoimmune liver disease in Uygur people were examined for anti-nuclear antibodies (ANA), anti-mitochondria antibodies (AMA), and anti-smooth muscle antibodies (SMA) using immunofluorescent assays. Soluble liver antigen (SLA)/liver-pancreas antigen (LP), anti-liver kidney microsomal antibody-1 (LKM-1), liver cytosolic-1 (LC-1), subtype of AMA (M2), as well as ANA profile were detected by an immune blotting assay and an enzyme-linked immune absorbent assay, respectively. Cytokines were tested by flow cytometry. Results Out of the 51 patients with autoimmune liver disease in Uygur people, 20 cases were diagnosed with autoimmune hepatitis (AIH). The AIH group could be divided into 3 subtypes according to the difference of the autoantibodies as I (65%), II (20 %), III (10 %). 31 cases were diagnosed with primary biliary cirrhosis (PBC), who were 97% AMA positive and 94% M2 positive. Conclusion Autoimmune liver disease is a progressive liver inflammation accompanied by production of characteristic antibodies. Detection of autoantibodies is useful clinically for identifying and classifying liver diseases.

P5.17.11
BAFF, κ and λ free light chains, C4d and IgG in serum and relations with peripheral blood lymphocyte populations in patients with primary Sjögren's syndrome

***I. Dumalakiene**[1], A. Siaurys[1], D. Mieliauskaite[2], I. Butrimiene[2], D. Characiejus[1], M. Mauricas[1], G. Sudzius[1];*
[1]State Research Institute Centre for Innovative Medicine Department of Immunology, Vilnius, Lithuania, [2]State Research Institute Centre for Innovative Medicine Department of Innovative diagnostic treatment and health monitoring technology, Vilnius, Lithuania.

Serum markers and their relations with peripheral blood lymphocyte populations` (absolute counts) of patients with primary Sjögren's syndrome (pSS) with (1pSS) or without (2pSS) extra-glandular manifestations were investigated.
Blood samples for flow cytometry and immunoassay were collected from 30 1pSS, 23 2pSS patients and 35 healthy controls.
Significantly increased levels of B-cell activating factor (BAFF) and IgG in patients with pSS were observed, results between pSS groups were comparable. Complement fragment C4d levels in all groups were similar. κ free light chains (FLC) levels were significantly increased in pSS patients likewise in 2pSS group in comparison to 1pSS group. λ FLC levels were significantly higher only in 2pSS group compared to control group. κ/λ FLC ratio in all groups were comparable. Correlations in 1pSS group were observed among κ, λ FLC and BAFF levels. Correlations were detected in 2pSS group between κ and λ FLC levels, κ/λ FLC ratio negative correlated with λ FLC and C4d levels. In 1pSS BAFF levels negative correlated with CD3+, CD4+, CD8+, CD8brightCD57-CD27+ and CD19+ cells. κ/λ FLC ratio correlated with CD3-CD16+56 and CD19+ cells. C4d levels correlated with CD8+, CD8brightCD57-CD27+ and CD3+CD16+56 cells. In 2pSS group only negative correlation between λ FLC levels and CD4+ cells was observed.
Despite the fact that between pSS groups only κ FLC levels differed, distinct linkage of investigated markers with peripheral blood lymphocyte populations` were observed. The distributions of markers investigated in 1pSS and 2pSS patients groups may indicate several ongoing mechanisms during the progression of the disease.

P5.17.12
Antinuclear antibodies without identified antigenic target: what is their diagnostic value?

***S. Feki**[1], F. Frikha[2], Y. Ben Haj Hmida[3], M. Ben Ayed[3], O. Abida[3], Z. Bahloul[4], H. Masmoudi[3];*
[1]immunology department, Habib Bourguiba Hospital of Sfax (Tunisia), Sfax, Tunisia, [2]Internal medicine Department, Hedi Chaker Hospital of Sfax (Tunisia), Sfax, Tunisia, [3]Immunology Department, Habib Bourguiba Hospital of Sfax (Tunisia), Sfax, Tunisia, [4]Internal Medicine Department, Hedi Chaker Hospital of Sfax (Tunisia), Sfax, Tunisia.

The objective of this study was to determine the clinical relevance and the diagnostic significance of positive ANA without identified antigenic target by the usual characterization technique.
It was a retrospective study conducted in our laboratory during 18 months. The inclusion criteria were the presence of an ANA titer ≥ 1/320 with negative characterization result. ANA screening was performed by indirect immunofluorescence (IIF) on Hep2 cells. Each positive serum was tested by IIF on Crithidia luciliae (anti-native DNA) and by immunodot (Euroimmun®, profile 3). Sera of systemic lupus erythematosus (SLE), myositis, and scleroderma patients were tested for antisynthetase antibodies.
Sera of 90 patients were studied: 18 men and 72 women. Drug-induced ANA was found in eight patients. The most frequent clinical symptoms were joint (56.7%), cutaneous (54.4%) and constitutional symptoms (45.6%). The diagnosis of an autoimmune disease was suspected in 49 patients (54.5%) and confirmed in 30 (33.3%) including 20 cases of connective tissue disease: myositis (n = 6), scleroderma (n = 5), Sjögren's syndrome (n = 3), SLE (n = 4), rheumatoid arthritis (n = 6) and antiphospholipid syndrome (n = 4). Other autoimmune diseases were less frequent. The anti-Ku antibody was detected in the majority of patients with connective tissue disease.
Our study demonstrated the diagnostic value of the presence of ANA even in the absence of known antigenic target, confirmed the role of the IIF as "gold standard" test for ANA screening, and suggested the usefulness of the addition of Ku antigen in the immunodot classic profile.

P5.17.13
Cyclophosfamide plus Rituximab treatment in a case of plurirefractory cutaneous sarcoidosis with large vessels vasculitis

***V. Ferri**, N. Compagno, R. Scarpa, M. Gazzola, P. Tartaro, C. Agostini;*
Allergology and Clinical Immunology, Department of Medicine, University of Padova, Padova, Italy.

Sarcoidosis is a multi-systemic disease; its clinical course ranges from an incidental finding to a life-threatening disease, sometimes associated with other immunological diseases. Cutaneous involvement is present in about 20% of patients. We report a case of atypical, aggressive and therapy-resistant cutaneous sarcoidosis. A 57-y old Caucasian male was referred to our attention with a diagnosis of cutaneous sarcoidosis; the patient reported joint pain in the hands, feet, ankles and shoulders and a transient Raynaud's phenomenon. Physical examination revealed papules and plaques on the limbs. Seriated skin biopsies showed granulomatous and giant-cellular inflammation consistent with sarcoidosis (quantiferon test and PCR for atypical mycobacteria were negative). Lymphocyte subpopulations in the BAL were normal. HRCT showed enlarged bilateral mediastinal lymph nodes. PET-CT scan was negative. Laboratory findings showed an increase of inflammatory indexes, sACE, 24-h calciuria and phosphaturia. Patient was unsuccessfully treated with several regimens of treatment: steroids, methotrexate plus hydroxychloroquine, anti-TNFα, pulse i.v. cyclophosphamide and PUVA therapy, but a disease progression was observed with recrudescence of the skin lesions, the onset of severe large vessels vasculitis (an angio-CT showed an extensive involvement of the major abdominal and lower limbs arteries) and ocular involvement confirmed by episcleral biopsy. A cyclophosphamide plus rituximab regimen was initiated followed by surgical revascularization, observing until today (6 months later) a complete remission on skin and vascular disease. Despite classically sarcoidosis well respond to first-line steroid therapy, a wide spectrum of classic

immunosuppressant and biologic drugs, including rituximab, should be used in resistant patients.

P5.17.14
CD8+ T cells in the pathogenesis of Systemic Sclerosis

P. Fuschiotti[1], *A. Larregina*[2], *J. Ho*[2], *C. Feghali-Bostwick*[3], *T. Medsger Jr.*[1];
[1]*Department of Immunology, University of Pittsburgh School of Medicine, Pittsburgh, PA, United States,* [2]*Department of Dermatology, University of Pittsburgh School of Medicine, Pittsburgh, PA, United States,* [3]*Division of Pulmonary, Allergy, and Critical Care Medicine, Department of Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA, United States.*

T lymphocytes play an important role in systemic sclerosis (SSc), a connective tissue disease characterized by inflammation, fibrosis and vascular damage. Its most characteristic feature is cutaneous fibrosis that is attributable to excessive deposition of collagen and other connective tissue components by activated dermal fibroblasts. Although the pathogenesis is still unclear, this fibroblast activation is believed to result from their interaction with immune mediators, such as T cell-derived cytokines, and other growth factors. We recently found that dysregulated production of the profibrotic cytokine IL-13 by peripheral blood effector CD8+ T cells correlates with more severe forms of cutaneous SSc and is associated with defects in the molecular control of IL-13 production, such as the aberrant expression of the transcription factor GATA-3. The following are our most recent results. Firstly, we found high numbers of IL-13+ and CD8+ T cells in the skin lesions of early SSc patients. Secondly, we established that increased numbers of CD8+ T cells expressing skin homing receptors and producing IL-13 are found in the peripheral blood of SSc patients compared to normal controls. Finally, we demonstrated that CD8+ T-cell supernatants from SSc patients induce collagen production by normal skin fibroblasts and that this is inhibited by the addition of an anti-IL-13 antibody. We conclude that IL-13-producing CD8+ T cells are directly involved in the initiation and maintenance of dermal fibrosis in SSc. These new insights into disease pathogenesis suggest novel therapeutic targets that may be exploited for the treatment of SSc.

P5.17.15
Anti-BPI (bactericidal permeability increasing) in autoimmune vasculitis

S. N. Gadiri[1], *H. Meriche*[1], *S. Brougui*[1], *A. Guermaz*[2], *M. Abbadi*[3];
[1]*departement of Immunology, CHU Annaba, Annaba, Algeria,* [2]*departement of internal medecine, Birtaria Hospital, Algiers, Algeria,* [3]*departement of Immunology, Pasteur institute of Algeria, Algiers, Algeria.*

Anti-neutrophil cytoplasmic antibodies are autoantibodies directed against neutrophil lysosomal enzymes, accompanying vasculitis. Indirect immunofluorescence distinguishes two aspects: cytoplasmic (C-ANCA) and perinuclear aspect (P-ANCA). These antibodies are respectively directed against the proteinase 3 (PR3) and the myeloperoxydase (MPO). Recent studies showed the existence of other types of antibodies in vascular involvement, among these, those directed against the BPI (bacterial permeability increasing), cytotoxic protein specific of Gram (-) bacteria.
This work aims to evaluate the frequency of anti-BPI in 40 subjects (32F/8M) aged between 12 and 40 years with vasculitis, as well as the sensitivity of the technique used for their detection. The determination of antigenic targets in case of positive ANCA is performed by ELISA. 30 sera from healthy subjects, with no autoimmune disease served as controls. All the studied sera are PR3 (-) and MPO (-). 52,5% of them are BPI (+), 35% have a c-ANCA fluorescence and 17,5% have a p-ANCA fluorescence. 17, 5% of the sera have no anti-BPI antibodies. Finally, 30% of these sera are ANCA (-).
We conclude that BPI is a major target antigen for ANCA with a clear predominance of the cytoplasmic aspect. The presence of anti-BPI in the control population reflects the high sensitivity of ELISA test used, which requires confirmatory tests such as Western Blot.

P5.17.16
Association of enhanced Tim-3 expression on monocytes with disease activity in systemic lupus erythematosus

B. Liu, X. Liang, C. Ma, ***L. Gao****;*
Institute of Immunology,Shandong University School of Medicine, Jinan, China.

Background: SLE is a typical chronic autoimmune disease. Considerable evidences support the notion that impaired clearance of apoptotic cells is respossible for the development of SLE. It is found that Tim-3 is also expressed on innate immune cells such as macrophage and dendritic cells, and it can mediate of the uptake, engulfment of apoptotic cells and plays a role in immune tolerance.
Aims: To investigate expression of Tim-3 in PBMC from SLE patients and healthy controls and analyze correlation between Tim-3 expression level and disease activity of SLE.
Methods: FITC-conjugated anti-human CD14 and PE-conjugated anti-human Tim-3 were used to detect Tim-3 expression by flow cytometric analysis. Annexin-V/PI cells were analyzed by flow cytometry.
Results: We found that expression of AnnexinV+ cells in peripheral blood from SLE patients was significant higher than that of healthy controls, and the expression of AnnexinV+ cells in peripheral blood positively correlated with SLEDAI scores and negatively correlated with C3. Expression of Tim-3 on CD14+ cells from active SLE patients with SLEDAI>5 increased compared with healthy controls, and the expression of Tim-3 on CD14+ cells in peripheral blood positively correlated with anti-dsDNA. Positive correlation between CD14+-Tim3+ cells and AnnexinV+ cells was found in peripheral blood from SLE patients.
Conclusions: Our results suggest that Tim-3 might participate in the pathogenesis of SLE by inducing CD14+ monocytes defects in eliminating apoptotic cells.
* Supported in part by grants from the National Nature Science Foundation of China (No. 30872298, 81172862, 81100203), Shandong Provincial Natural Science Foundation (No. ZR2010HM025).

Effects of Vitamin D on regulatory T cells in lupus patients

M. Ghoryani[1], *H. Reihani*[1], *M. Rastin*[1], *M. Mahmoudi*[1], *M. Sahebari*[2], *F. Lavi*[1], *F. Faraji*[1], *N. Tabasi*[1], *S. Zamani*[1], *M. Khazaee*[1];
[1]*Immunology Research Center, BuAli Research Institute, Faculty of Medicine, Mashhad University of Medical Sciencses, Mashhad, Iran,* [2]*Rheumatology Research Center, Ghaem Hospital,Mashhad University of Medical Sciencses, Mashhad, Iran.*

Introduction: Systemic lupus erythematosus (SLE) is a chronic, systemic, autoimmune disease with unknown aetiology, leading to an array of different clinical presentations. Regulatory cells are involved in the pathogenesis of SLE, and depletion of regulatory T cells has been shown to cause autoimmune diseases in animal models. Vitamin D as an environmental factor has anti-inflammatory and modulatory effects on the immune system, and Vitamin D deficiency was also suspected in the pathogenesis of SLE. In this research we studied the immunomedulatory effects of vitamin D on regulatory T cells (Tregs) by flow cytometry method, and on the expression level of its predominant cytokine genes in SLE patients by Real-Time PCR.
Materials and Methods: We enrolled 30 SLE patients (14 patients were new cases with active SLE and had received no therapeutic intervention). PBMCs isolated using Ficoll-Hypaque, and cultured in the presence of vitamin D. Then Regulatory T cells were analysed by flow cytomtry using a commercial Treg staining kit (eBioscience). RNA extracted using Tripure (Roche) , cDNA synthesized and the expression levels of FOXP3, and IL-6 analysed by Real Time-PCR.
Results: In the presence of Vitamin D the percentage of regulatory T cells and the expression level of FOXP3 increased significantly in PBMCs from SLE patients.

P5.17.18
Oral changes in Wegener granulomatosis(WG)

***J. Gruden Pokupec**;*
Policlinic of stomatology, Zagreb, Croatia.

Wegener granulomatosis (WG) is a rare multisystem autoimmune disease of unknown etiology. Its hallmark features include necrotizing granulomatous inflammation and pauci-immune vasculitis in small- and medium-sized blood vessels. The pathologic hallmarks of Wegener granulomatosis are vasculitis of the small- to medium-sized vessels, "geographic" necrosis, and granulomatous inflammation, particularly in the airways. The initial pathologic lesion is that of the granuloma believed to be caused by cellular immune processes. These criteria from the American College of Rheumatology are used for enrolling patients in studies and should not be considered as diagnostic criteria. These criteria were developed before antineutrophil cytoplasmic antibody (ANCA) testing was in widespread use as a diagnostic test for WG.They are: nasal or oral inflammation, abnormal chest radiography findings, urinary sediment, granulomatous inflammation on biopsy.
Case report:
The patient comes for gingival hyperplasia, and looseness of the teeth. From history of the patient is suffering from schizophrenia, high blood pressure, diabetes and asthma has long away. The patient was subjected to biochemical, hematological tests, immunologic, viral serology, HIV and hepatitis, and a biopsy was taken.
Results showed decreased hemoglobin and hematocrites, high elevated leukocytes, eosinophils, basophils, neurophils, lymphocytes and monocytes, very high CRP and elevated levels of protein and leukocytes in the urine, decreased albumin, alpha and beta globulins were increased, positive EBV, CMV IgG, IgM and c-ANCA. A gingival biopsy was made, conferming the diagnosis of WG. The patient was referred for further treatment.

P5.17.19
Epidemiology study of patients with suspected and diagnosed Celiac Disease

***L. Herráiz-Nicuesa**[1], L. Martín-Martín[1], S. Sánchez-Ramón[2], M. Rodriguez-Mahou[1];*
[1]Hospital General Universitario Gregorio Marañón, Madrid, Spain,
[2]Hospital Clínico San Carlos, Madrid, Spain.

Background: Celiac disease (CD) affects 0.5% of the population and is more prevalent in women than men (3:1). Regarding age, there are two peaks, 1-3 and 30-50 years, which is higher the number of cases diagnosed.
Mehods: 2590 patients (985 children and 1605 adults) with suspicions or diagnostic of CD were included in the study between January-May 2013. Prevalence of CD markers (anti-tissue transglutaminase (tTG) IgA and IgG and anti-deamidated gliadin peptide (PDG) IgG antibodies), clinical features and biopsy were evaluated.
Results: Prevalence of positive markers of CD in children was 15% (148/985): 148 PDG IgG, 39 tTG IgA and 15 tTG IgG; 73 were female and 75 male. Positive biopsies (Marsh classification) were 23/52 (12/23: 1-3 years-old and 11/23: 3-17 years-old children). Main Symptoms: anaemia, pondostatural delay, malabsorption syndrome, chronic diarrhea, abdominal pain and constipation. Prevalence of positive markers of CD in adults was 6,9% (111/1605): 111 PDG IgG and 12 tTG IgA, 74 were female and 37 male. Positive biopsies were 18/35 (7/18: 18-29 years-old, 9/18 in 30-50 years-old and 2/18: 51-87 years-old adults). In addition to the classic symptoms these patients had polyneuropathies, liver diseases, polyarthralgia, pruritus, irritability and recurrent miscarriage.
Conclusions: CD in children showed the same prevalent in both gender, affecting more between ages 1-3 years and predominantly gastrointestinal symptoms. However, in adults is more common in female, the diagnosis is made mainly before 50 years and the symptoms are more variable. Screening of CD should be performed only with antiDGP IgG antibody determination.

P5.17.20
Dense fine speckled patterned antinuclear antibody in patients with fibromyalgia

***H. Kim**;*
The Soonchunhyang Univ. Seoul Hospital, Seoul, Republic of Korea.

Fibromyalgia (FM) is characterized by chronic widespread pain and various manifestations. There has been reported high prevalence of psychologic distress, comorbidity, inflammatory autoimmune characteristics in patients with FM. Despite of its high prevalence, there is still no standardized laboratory test to suggest FMG or its severity. Anti-dense fine speckled antibody (anti-DFS Ab) Ab is found in 10% of healthy individuals, but only in a tiny population of with autoimmune rheumatic disease. It was initially identified as an atypical anti-nuclear antibody from a patient with interstitial cystitis. It has been studied in many specific rheumatic diseases. But there is no report in FM patients. FM patients (n=39) were recruited and 17 systemic lupus erythematosus patients and 19 healthy individuals were recruited as control groups. Especially for physical measurement, we evaluated weight, BMI, disease duration, tender point, Fibromyalgia Impact Questionnaire (FIQ), VAS (Visual Analogue Scale) and somatic symptoms. Anti-DFS Abs were measured with ELISA kit.
There is no statistically significant differences and relativity between anti-DFS Abs and age, BMI, disease duration, tender point, and FIQ. The level of anti-DFS Ab in FM patients did not differ from those in SLE patients and controls. However there was a significant correlation between the anti-DFS Ab level and VAS, fatigue. The prevalence of anti-DFS Ab in Korean FM patients was quite undetermined. In this study, the anti-DFS Ab level in FM patients was correlated with VAS and fatigue. In future, we should evaluate the autoimmune feature in FM.

P5.17.21
Expression and function of the NLRP3 inflammasome in Behçet's disease

***E. Kim**;*
Kwan Dong University Cheil general hospital, Seoul, Republic of Korea.

Behcet's disease (BD) is a systemic inflammatory disorder with diverse clinical manifestations. A new concept to BD is 'autoinflammation'. We explored the expression of the different components of the NLRP3 inflammasome in tissue and serum samples from patients with BD.
The expression of NLRP3, apoptosis-associated speck-like protein containing CARD domain (ASC) and caspase-1 in erythema nodosum lesions and serum of 25 BD and 25 non-BD patients were examined by immunohistochemistry and Western blot. The release of IL-1β, IL-18 from PBMCs and monocytes after stimulation with LPS, ATP and caspase-1 was evaluated in 20 BD patients and 10 healthy control (HC) by ELISA. The mRNA expressions of NALP3, ASC and caspase-1 were examined by Real time-PCR.The immunohistochemistry showed NLRP3 and ASC expression was higher in BD patients. When PBMCs from BD patients were stimulated with LPS, IL-1β secretion increased compared to control. With ATP, IL-1β release was more increased compared to LPS stimulation alone. NLRP3, ASC, caspase-1 mRNA was up-regulated in active BD compared to inactive BD and HC. When caspase-1 inhibitor, zYVAD-fmk, was treated on PBMCs, IL-1β secretion was decreased compared to LPS stimulation. When ATP was added to LPS primed PBMCs treated with zYVAD-fmk, IL-1β secretion was only slightly decreased. In conclusion NLRP3 inflammasome was upregulated both at the mRNA and protein levels in BD patients. Also in active BD, ATP stimulation in LPS primed PBMCs induced mRNA components of the NLRP3 inflammasome with increased IL-1 β production. However, caspase-1 inhibition was unsuccessful in decreasing IL-1β secretion.

P5.17.22
The cytokine production of peripheral blood mononuclear cells reflects the autoantibody profile of patients suffering from type 1 diabetes

***J. Labiková**, J. Včeláková, S. Kolou□ková, K. □techová;*
Dpt. of Paediatrics, Univ. Hosp. Motol and 2nd Faculty of Medicine, Charles University in Prague, Prague, Czech Republic.

Type 1 diabetes (T1D) is an autoimmune disease characterised by the destruction of pancreatic beta-cells. Proinflammatory Th1 response is considered as the most pathological. Specific autoantibodies can be detected a long time before the disease clinical onset. This study describes the influence of synthetic diabetogenic autoantigens GAD65 and IA2 on the cytokine response of peripheral blood mononuclear cells (PBMC) obtained from T1D patients with regards to their antibody profile.
The study has been carried out on T1D patients (n = 40) positive for anti-GAD65 and/or anti-IA2 autoantibodies. Using flow cytometry we measured the cell type ratio in PBMC samples. The cells have been stimulated by three different concentrations of mentioned antigens. Their IFN-gamma and IL-17 production has been detected by ELISPOT assay.
In the case of both cytokines we have found a significant interaction between the way of stimulation (type and antigen concentration) and the patient's antibody profile ($p = 0.003$ IFN-gamma; $p < 0.001$ IL-17). The IA2 autoantibodies level correlates positively with the proportion of Tc cells and negatively with the proportion of Th cells ($p = 0.004$; $p = 0.001$). The IFN-gamma production correlates positively with the proportion of T cells and negatively with the proportion of NK cells in PBMC ($p = 0.001$; $p = 0.001$).
Our results show that patient´s autoantibody profile reflects the type of his/her cellular responses too. This approach can be helpful in designing immunointervention strategies aimed at preventing T1D onset. Such an immunointevention should apparently be individualised.
Supported by IPL00064203, IPL699001 and IGA5240.

P5.17.23
Glucocorticoid cooperates with complement prevent the development of systemic lupus erythematosus via maintenance of homeostasis of plasmacytoid dendritic cell

***S. Liu**;*
Department of Immunology, Shanghai, China.

Controlling the accumulation of type I interferon-producing activated and mature pDC (ampDC) is important for impeding the progression of systemic lupus erythematosus (SLE). Complement and glucocorticoid have been considered protective and therapeutic for SLE, here we investigated the effect of complement, glucocorticoid, and their interplay on regulating ampDC accumulation. PDC exhibit decreased expression of complement regulatory proteins (CRP) and increased sensitivity to complement-mediated cytotoxicity (CMC) along with maturation and activation. Nuclear acid-containing immune complexes trigger and enhance CMC to ampDC by downregulating CRP, but reduced complement activity in SLE impairs the CMC to ampDC, leading to the accumulation of ampDC. Glucocorticoid-treated pDC alive are immature but highly resistant to CMC because of expressing high levels of CRP despite glucocorticoid induces a large number of pDC deaths. Downregulation of P53, as a target of hsa-let-7b/7i which expression is dependent on P38 pathway by TLR9 or CD40, is responsible for the decreased CD59 expression on ampDC, while glucocorticoid blocks the activation of P38 pathway. So, CMC contributes to immature pDC homeostasis via deleting ampDC, which is facilitated by glucocorticoid. Together, our study outlines novel mechanistic explanations for protective role by complement and the therapeutic role of gucocorticoid in SLE.

P5.17.24
Accelerated spontaneous apoptosis of neutrophils in patients with familial Mediterranean fever

***G. Manukyan**[1], A. Martirosyan[1], G. Hagobyan[2], R. Aminov[3], T. Davtyan[4];*
[1]Institute of Molecular Biology, Yerevan, Armenia, [2]Department of Internal Medicine, Yerevan State Medical University, Yerevan, Armenia, [3]Faculty of Medical Sciences, University of the West Indies, Mona, Kingston 7, Jamaica, [4]Analytical Laboratory Branch, Scientific Centre of Drug and Medical Technology Expertise JSC, Yerevan, Armenia.

The hallmark of acute inflammatory attacks in Familial Mediterranean fever (FMF) is inappropriate neutrophil activation and their influx to the serosal membranes. The mechanisms of neutrophil apoptosis in FMF are poorly understood. To investigate apoptotic behaviour of resting neutrophils and neutrophils cultured for 3 and 24 hours with TNF-α, LPS, MDP, CSK4 and colchicine, we measured apoptotic rate of circulating neutrophils in whole blood of 7 FMF patients in remission period and 7 healthy subjects using flow cytometry. FMF neutrophils displayed a higher rate of constitutive ($p<0.05$) and spontaneous ($p<0.01$) apoptosis of the cells cultured in media for 24 hours compared to healthy cells. Cultured healthy neutrophils were significantly more sensitive to TNF-α, LPS, MDP, and CSK4, while diseased neutrophils showed no differences in apoptotic rate after inducers exposure. Short cultivation (3h) of healthy cells resulted LPS- and TNF-α-induced inhibition of apoptosis ($p<0.05$). Thus, neutrophils of FMF patients undergo spontaneous apoptosis at an accelerated rate *ex vivo*. Our findings suggest that enhanced inducible apoptosis in FMF neutrophils is likely to be mediated by the intrinsic signaling pathways.

P5.17.25
Comparison between enzyme-linked immuno-sorbent assay and multiplex assay for serological markers of Celiac Disease detection

***L. Martín-Martín**[1], L. Herráiz-Nicuesa[1], Y. Oleo-Pérez[1], S. Sánchez-Ramón[2], M. Rodriguez-Mahou[1];*
[1]Hospital General Universitario Gregorio Marañón, Madrid, Spain, [2]Hospital Clínico San Carlos, Madrid, Spain.

Objective: To compare ELISA with multiplex assay for anti-deamidated gliadin peptide (anti-DGP) IgG and anti-tissue transglutaminase (anti-tTG) IgA antibodies detection in order to identify the best according to sensivity and specificity.
Methods: 101 patients with suspicion or diagnostic of celiac disease (CD) were selected. Each serum was tested by ELISA (Orgentec Diagnostika) and multiplex assay (Bioplex 2200, Bio-Rad) for the anti-DGP IgG and anti-tTG IgA autoantibodies quantification. The association with clinical features was examinated by systematical review of the clinical histories. Also previous CD markers determinations, biopsy and HLA features were studied.
Results: Compared to the clinical, biopsy and HLA features, the ELISA showed a sensitivity of 96.15% and a specificity of 38.09% (Positive predictive value (PPV): 79.36%; Negative predictive value (NPV): 80%), whereas multiplex assay had a sensitivity of 79.59% and a specificity of 100% (PPV: 100%; NPV: 68.75%) for anti-DGP IgG antibodies detection. Furthermore, the ELISA showed a sensitivity of 68.42% and a specificity of 100% (PPV: 100%; NPV: 93.18%), and multiplex assay had a sensitivity of 100% and a specificity of 96.34% (PPV: 86.36%; NPV: 100%) for anti-tTG IgA antibodies testing.
Conclusions: Taking into consideration the previous CD markers determination and clinical, biopsy and HLA features, ELISA showed a higher sensitivity for anti-DGP IgG antibodies, but specificity was better for multiplex assay. In addition, ELISA showed a higher specificity and multiplex had a better sensitivity for anti-tTG IgA antibodies detection.

The prevalence of wheezing and its relationship with some environmental factors in children aged 6-7 in Yazd

M. Mirzaei[1], *M. Mirzaei*[2];
[1]*Tehran University of Medical Sciences, Tehran, Iran,* [2]*Yazd University of Medical Sciences, Yazd, Iran.*

Backgrounds: Asthma is an inflammatory disease of conducting airways which affects quality of life of children, also posing a high level of burden on health care system. Avoiding exposure to environmental allergens is a well-known method for control of symptoms of asthma.
Objectives: To measure the prevalence of wheezing among children who were exposed to different environmental factors.
Methods: In this cross sectional study, parents of 2740 children aged 6-7 attending selected schools in Yazd, received the International Study of Asthma and Allergies in Childhood (ISAAC) written questionnaire. The children were classified according to exposure to cigarette smoking (mother vs. father vs. babysitter) and keeping cats and dogs (in first year of life vs. past 12 months) at home.
Results: Prevalence of wheezing was 10.9 (12.9% among boys and 8.4% among girls) ,and only 3.8% claimed physician assessed asthma diagnosis.
Prevalence of wheezing was significantly increased in those with the history of keeping cats at home for past 12 months.(12.2% vs. 8.5%. p value : 0.03) ,in addition having a smoker mother was associated with increased wheezing.(2.4% vs. 1%. P value: 0.04).
Other associations were not statistically significant.
Conclusion: A smoker mother and keeping cats at home in past 12 months were associated with increase of wheezing among children of our study

P5.17.27
Psychoneuroimmunologycal study in Cuban in patients with systemic lupus erythematosus

E. Noris- Garcia[1], *M. Lánigan*[2], *N. Diaz*[1], *I. Corrales*[1], *A. Brito*[1], *N. Fresneda*[1], *D. Barberia*[1], *R. Rodríguez*[1], *S. Arce*[1], ***G. Penton Rol***[3];
[1]*National Institute Nephrology, La Havana, Cuba,* [2]*HQC Joaquin Albarran, La Havana, Cuba,* [3]*Center for Genetic Engineering and Biotechnology, La Havana, Cuba.*

Systemic lupus erythematosus (SLE) is a chronic disabling disease with a complex clinical presentation and course. Patients and clinicians widely believe in the relationship between stress and this disease, but the evidence supporting this association is limited. This study aimed to assess the behavior of psychological stress and immunological marker in these patients. Sixty people participated in this study, thirty were patients with SLE from the Nephrology Institute in Cuba and equal number of control subjects with the following diagnoses: (rheumatoid arthritis, primary Sjogren's syndrome, fibromyalgia). To evaluate of stress, we used the stress vulnerability inventory (Miller and Smith), personality inventory (Eysenck), self-esteem (Coopersmith) and personal strength test (Bagés and Kobasa). The new Systemic Lupus International Collaborating Clinics (SLICC) and the 1997 American College of Rheumatology (ACR) systemic lupus erythematosus classification criteria were also evaluated. Eight patients were classified as LES and tree were excluded when the new SLICC classification was applied instead of 1997ACR criteria. The inclusion was due to the presence of biopsy proven lupus nephritis in the existence of antinuclear antibodies. The exclusion was because they had only clinical criterion. On the other hand, the mainly characteristic of personality in SLE patients were introverted (92.8%) obsessive (85.7%) and melancholic(64.2%). Both groups presented the same behavior according to personal strength and stress vulnerability. Nevertheless the SLE patients showed statistically significant reduction in self-esteem ($p<0.05$). The right characterization of SLE patients should be including both the new SLICC classification criteria as psychological study.

P5.17.28
CAPS monocytes are highly susceptible to oxidative stress: effects on cytokine secretion, reversal by antioxidants

P. Piccioli[1], *S. Carta*[1], *L. Delfino*[1], *F. Penco*[2], *A. Martini*[2,3], *M. Gattorno*[2,3], *A. Rubartelli*[1];
[1]*Cell Biology Unit, IRCCS-AOU San Martino - IST, Genoa, Italy,* [2]*Pediatrics II Unit, G Gaslini Institute, Genoa, Italy,* [3]*University of Genoa, Genoa, Italy.*

Cryopyrin associated periodic syndromes (CAPS) are autoinflammatory diseases where NLRP3 mutations result in increased IL-1β secretion upon TLR stimulation. We recently showed that monocytes from CAPS patients exhibit a dramatic suppression of IL-6 and of IL-1receptor antagonist (IL-1Ra) production. The deficient secretion of these cytokines coupled to increased IL-1β release may explain the severity of the IL-1-related clinical manifestations and the predominant implication of innate immunity in CAPS.
CAPS monocytes also display a mild level of stress at baseline. We then investigated the functional link between stress and altered cytokine production. Our results show that: i secretion of IL-1Ra and IL-6 is restored in CAPS monocytes by antioxidants that prevent oxidative stress but it is not induced in normal monocytes; ii. the mild stress level at baseline makes CAPS monocytes prone to be activated by low doses of TLR agonists, unable to stimulate healthy monocytes. iii. CAPS monocytes display autophagy defects due to the stress state. In agreement with the inverse correlation between autophagy and IL-1β secretion, these defects result in increased IL-1β secretion. In conclusion, CAPS monocytes display a higher susceptibility to TLR stimulation, due to the presence of stress at baseline. This condition: i. affects the response to TLR agonists, lowering the threshold required to activate CAPS monocytes; ii: impairs the normal autophagic process resulting in increased IL-1β secretion; iii. causes the rapid induction of oxidative stress upon exposure to full doses of TLR agonists, leading to defective production of cytokines downstream of IL-1β.

Loci associated with N-glycosylation of human IgG show pleiotropy with autoimmune diseases and haematological cancers

M. Pucic Bakovic[1], *G. Lauc*[2], *J. Huffman*[3], *J. Wilson*[4], *M. Wuhrer*[5], *A. Wright*[3], *P. Rudd*[6], *C. Hayward*[3], *H. Campbell*[7], *I. Rudan*[4];
[1]*Genos Ltd., Zagreb, Croatia,* [2]*Faculty of Pharmacy and Biochemistry, Zagreb, Croatia,* [3]*Institute of Genetics and Molecular Medicine, Edinburgh, United Kingdom,* [4]*Centre for Population Health Sciences, Edinburgh, United Kingdom,* [5]*Leiden University Medical Centre, Leiden, Netherlands,* [6]*National Institute for Bioprocessing Research and Training, Dublin, Ireland,* [7]*Centre for Population Health Sciences, Edinurgh, United Kingdom.*

After analysing glycans attached to human immunoglobulin G in 4095 individuals we performed the first genome-wide association study (GWAS) meta-analysis of the glycome of an individual protein. Nine genetic loci were found to associate with glycans with genome-wide significance. Of these, four were glycosyltransferases which participate in IgG glycosylation, thus the observed associations were biologically founded. The remaining five genetic loci were not previously implicated in protein glycosylation, but the most of them have been reported to be relevant for autoimmune and inflammatory conditions and/or haematological cancers. A particularly interesting gene, IKZF1 was found to be associated with multiple IgG N-glycan traits. This gene has been implicated in numerous diseases, including systemic lupus erythematosus (SLE). We explored biomarker potential of N-glycans in 101 cases with SLE and 183 matched controls and demonstrated substantial discriminative power. Our study shows that it is possible to identify new loci that control glycosylation of a single plasma protein using GWAS. The results may also provide an explanation for the reported pleiotropy and antagonistic effects of loci involved in autoimmune diseases and haematological cancer.

P5.17.30
B-cell depletion in neuropsychiatric disease in MRL/lpr mice

***C. Putterman**;*
Albert Einstein College of Medicine, Bronx, NY, United States.

Neuropsychiatric disease in one of the earliest clinical manifestations in systemic lupus erythematosus (SLE). However, the mechanisms leading to neuropsychiatric SLE (NPSLE) are not fully understood, and the optimal treatment yet to be defined. Since antibodies play an important role in lupus pathogenesis, B-cell depletion has been proposed as a directed treatment approach. In lupus, a compromised blood brain barrier may allow for the passage of circulating autoantibodies into the brain, where they then can induce neuropsychiatric abnormalities. To conclusively determine if indeed B-cells and/or autoantibodies are instrumental in the pathogenesis of murine NPSLE, we evaluated B-cell depleted (JhD/MRL/lpr) and wild type MRL/lpr lupus mice, the latter of which are known to develop several cardinal features of human neuropsychiatric disease. Comprehensive neurobehavioral assessment including forced swim, anhedonia, open field, object recognition, object placement, and social preference were employed to evaluate the neuropsychiatric manifestations in JhD/MRL/lpr as compared to MRL/lpr mice. We confirmed that peripheral B-cells were substantially depleted in JhD/MRL/lpr mice, and that autoantibody levels were very low in serum and cerebrospinal fluid. Nevertheless, B-cell depleted MRL/lpr mice surprisingly had no attenuation of key neuropsychiatric features, including depression-like behavior and cognitive dysfunction. Nevertheless, an increased number of rears were observed in JhD/MRL/lpr mice, indicating higher motor activity. Thus, constitutive depletion of B-cells was not sufficient to ameliorate lupus-associated neuropsychiatric disease, at least in the MRL/lpr strain. Whether conditional B-cell ablation later on in life will have the same effect remains under investigation.

P5.17.31
Induction of immunoglobulin G Fc-sialylation is associated with disease remission in CIDP

***I. Quast**[1], F. Cueni[1], M. A. Maurer[1], F. Nimmerjahn[2], M. Dalakas[3], J. D. Lünemann[1];*
[1]Universität Zürich, Zürich, Switzerland, [2]University of Erlangen-Nürnberg, Erlangen, Germany, [3]Thomas Jefferson University, Philadelphia, PA, United States.

Humoral immune responses mediate peripheral nerve damage and represent important pharmacological targets in chronic inflammatory demyelinating polyneuropathy (CIDP), the most common treatable acquired chronic polyneuropathy. IgG Fc-linked glycan structures determine antibody-mediated effector functions and were identified as a molecular switch shifting IgG activity from a pro-inflammatory to an anti-inflammatory pathway. Here, we demonstrate that patients with CIDP show higher levels of IgG-Fc N-glycans lacking terminal galactose and sialic acid residues as compared to demographically matched healthy individuals and that induction of Fc-sialylation is associated with clinical disease remission. Furthermore, CIDP patients show altered expression levels of both activating and inhibitory Fc-receptors. Treatment with intravenous immunoglobulins (IVIG) can partially restore normal expression levels and may therefore reset the threshold for immune-complex mediated cell activation. Our findings underline the importance of IgG Fc-linked glycan structures and Fc receptor expression in human autoimmune diseases and support the concept that the clinical response to antibody-mediated immunotherapies in CIDP can be improved by Fc-glycan modification.

Expression QTL analysis from primary immune cells of a multi-ethnic cohort identifies novel disease-causing regulatory effects

***T. Raj**[1,2], K. Rothamel[1], C. Ye[3], S. Mostafavi[4], M. Lee[3], J. Replogle[2], D. Koller[4], A. Regev[3], N. Hacohen[3], B. E. Stranger[5], P. L. De Jager[2], C. Benoist[1], .. Immunological Variation Consortium[1];*
[1]Harvard Medical School, Boston, MA, United States, [2]Department of Neurology, Brigham and Women's Hospital, Boston, MA, United States, [3]Broad Institute, Boston, MA, United States, [4]Department of Computer Science, Stanford University, Boston, MA, United States, [5]Section of Genetic Medicine, University of Chicago., Boston, MA, United States.

The extent to which human genetic variation drives inter-individual variation in immune function is critical to the systematic dissection of altered immune function in disease. We have performed an expression quantitative trait locus (eQTL) study of highly purified CD4+T cells and CD14+CD16- monocytes, representing adaptive and innate immunity, respectively, from a multiethnic cohort of 650 healthy individuals representing Caucasian, African American, and East Asian ancestry. Here, we report small differences in cis-eQTLs among populations, primarily due to population divergence in allele frequencies. We demonstrate that meta-analysis across populations facilitates fine mapping of putative causal regulatory variants. Using a joint-analysis for both cell types, we estimate that 63% of cis-eQTLs are shared between the two cell types, though effect sizes often vary. When exploring the functional impact of disease-associated genetic variation, we observe that susceptibility alleles for inflammatory diseases display a preponderance of regulatory effects in T cells, suggesting that altered T cell function may play a larger role in these diseases. In contrast, for Alzheimer's and Parkinson's disease (PD) susceptibility alleles, we observe a striking enrichment of regulatory effects in monocytes: suggesting the innate immune system appears to play an important role in these neurodegenerative diseases. Finally, we report of and replicate trans-eQTLs and highlight trans-regulatory effects in PD. Overall, this multiethnic exploration of both arms of the immune system identifies many novel eQTLs, highlights a remarkable level of cis-eQTL sharing and provides important new insights into the role of immune cell populations in neurodegenerative, inflammatory, and other diseases.

P5.17.33
Antibody profile and their relationship with clinical manifestations in patients with Systemic Lupus Erythematosus

***M. Rastin**, M. Mahmoudi, N. Tabasi, S. Zamani, M. Khazaee, M. Ghoriani, H. Reihani, F. Faraji, F. Lavi;*
Immunology Research Center, BuAli Research Institute, Faculty of Medicine, Mashhad University of Medical Sciencses, Mashhad, Iran.

The autoantibodies which are produced in systemic lupus erythematosus (SLE) patients have different clinical and pathological importance, and are used for diagnosis, activity evaluation, prediction of tissue involvement, and in the prediction of prognosis. Some of the autoantibodies are produced years before organ involvement and can be used as a tool for prediction of an organ involvement.
Methods & Materials: In this project the sera of 98 SLE patients were studied (76 female, 22 male). Autoantibody profile was performed on sera of all participants using a commercial kit (EUROIMMUN; Germany). By using this kit autoantibodies against nRNP/Sm, Sm, SSA, SSB, Ro-52, CDENP, Jo-1, Scl-70, Nucleosome, Histone, Rib.p-Protein were assessed.
Results: anti-SSA and anti-Ro-52 with prevalence of 44.6% and 39.3% were the most prevalent autoantibodies in all patients, but anti-Scl70 and anti-Jo-1 were not observed in any of the patients in our study. In patients with kidney involvement anti-nucleosome with prevalence of 43.4% was the most prevalent antibody. Anti-dsDNA, and anti histone autoantibodies were related to active phase of SLE disease. In female SLE patients the number of autoantibodies increased in comparison to male patients, and SSA, SSB, Ro-52 were more prevalent in females.

1,25 Dihydroxy vitamin D modulatory effects in patients with systemic lupus erythematosus

M. Rastin[1], *M. Mahmoudi*[1], *M. Sahebari*[2], *N. Tabasi*[1], *S. Zamani*[1], *D. Haghmorad*[1], *R. Nosratabadi*[1];
[1]*Immunology Research Center, BuAli Research Institute, Faculty of Medicine, Mashhad University of Medical Sciencses, Mashhad, Iran,* [2]*Rheumatology Research Center, Ghaem Hospital,Mashhad University of Medical Sciencses, Mashhad, Iran.*

Objectives: Systemic lupus erythematosus is an autoimmune disease that is complicated by autoantibody mediated organ involvements. In SLE immune tolerance breakdowns and some environmental and genetic factors are involved in the pathogenesis of SLE. In recent year's disorders in regulatory suppressive lymphocytes has been suspected. Vitamin D has been implicated as an environmental immunomodulatory factor which targets various immune cells and may play a role in immune regulation via increasing and activating regulatory cells and its related molecules.
Immunosuppressive effects of vitamin D have been investigated in various studies, however the mechanism by which it induces its modulatory effects is not well understood.
In this investigation we studied the mechanisms by which vitamin D may regulate the immune responses in SLE patients.
Materials & Methods: Study group comprised of 25 SLE patients, and 20 age and sex matched controls. lymphocytes cultured with 1,25 dihydroxyvitamin D3, and CD4+CD25+FOXP3+ cells were analyzed by flowcytometry methods before and after incubation. RNA was extracted and after cDNA synthesis the expression levels of FOXP3, IL-17, IL-6, IL-12, IFN-γ, TGF-β genes was studied by Real-Time PCR method.
Results: 1,25 dihydroxyvitamin D_3 increased CD4+CD25+FOXP3+ cells, and the expression levels of FOXP3, TGF-β, and IFN-γ genes increased, while IL-6, and IL-17 decreased significantly in SLE patients.
Conclusions: 1,25 dihydroxyvitamin D_3 modulates inflammatory immune resposes in lupus patients by increasing the regulatory T cells subsets.

P5.17.35
Effects of Vit D on Th17 cells and related cytokines in lupus erythematosus patients

H. Reihani[1], *M. ghoryani*[1], *M. Rastin*[1], *M. Mahmoudi*[1], *M. Sahebari*[2], *R. Nosratabadi*[1], *F. Faraji*[1], *F. Lavi*[1], *N. Tabasi*[1], *S. Zamani*[1];
[1]*Immunology Research Center, BuAli Research Institute, Faculty of Medicine, Mashhad University of Medical Sciencses, Mashhad, Iran,* [2]*Rheumatology Research Center, Ghaem Hospital,Mashhad University of Medical Sciencses, Mashhad, Iran.*

Introduction: Systemic lupus erythematosus is a multisystem inflammatory autoimmune disease characterized by autoreactive T cell activation against self-antigens and subsequent production of autoantibodies causing inflammation and tissue damage. Emerging data suggests that Th17 cells are the main pathogenic cells involved in SLE that secrete proinflamatory cytokines and increased frequency of these cells in peripheral blood is correlated with disease activity. Environmental and genetic factors are involved in the pathogenesis of SLE disease. Vitamin D deficiency has been proposed as a potential environmental factor triggering SLE. In the present study we investigated the effects of vitamin D on modulation of Th17 cells and related cytokines.
Materials and Methods: Blood samples were obtained from 30 patients with SLE. Lymphocytes were isolated using Ficoll-Hypaque. Isolated lymphocytes were cultured in the presence and in the absence of vitamin D. After incubation the IL-17 secreting cells were analyzed by flowcytometry. RNA was extracted using Trizol, cDNA synthesized, and the expression levels of IL-17, IL-6, IL-23 genes was analyzed by Real-time PCR.
Results: 1,25 dihydroxyvitamin D decreased IL-17 secreting cells, and the expression levels of IL-17, IL-23 genes in SLE patients.

P5.17.36
Disease modeling and drug discovery using induced pluripotent stem cells from CINCA syndrome patients

M. Saito;
Kyoto University, Kyoto, Japan.

Chronic infantile neurological cutaneous and articular (CINCA) syndrome is an IL-1-driven autoinflammatory disorder caused mainly by NLRP3 mutations. The pathogenesis of CINCA syndrome patients who carry NLRP3 mutations as somatic mosaicism has not been precisely described because of the difficulty in separating individual cells based on the presence or absence of the mutation. Here, we report the generation of NLRP3-mutant and non-mutant induced pluripotent stem cell (iPSC) lines from two CINCA syndrome patients with somatic mosaicism, and describe their differentiation into macrophages (iPS-MPs). We found that mutant cells are predominantly responsible for the pathogenesis in these mosaic patients because only mutant iPS-MPs showed the disease relevant phenotype of abnormal IL-1beta secretion. Next, after confirming that the existing anti-inflammatory compounds inhibited the abnormal IL-1beta secretion from iPS-MPs, we started candidate compound screening for treating CINCA syndrome and other NLRP3-related inflammatory conditions using a recently-established feeder-free differentiation protocol. Our results illustrate that patient-derived iPSCs are useful for dissecting somatic mosaicism, and that NLRP3-mutant iPSCs can provide a valuable platform for drug discovery for multiple NLRP3-related disorders.

P5.17.37
Distribution of peripheral blood lymphocyte populations in patients with primary Sjögren's syndrome

G. Sudzius[1], *D. Characiejus*[1], *D. Mieliauskaite*[2], *A. Siaurys*[1], *I. Butrimiene*[2], *I. Dumalakiene*[1];
[1]*State Research Institute Centre for Innovative Medicine Department of Immunology, Vilnius, Lithuania,* [2]*State Research Institute Centre for Innovative Medicine Department of Innovative diagnostic treatment and health monitoring technology, Vilnius, Lithuania.*

Distribution of lymphocyte populations' in peripheral blood mononuclear cells (PBMCs) of patients with primary Sjögren's syndrome (pSS) without (1pSS) or with (2pSS) extraglandular manifestations were investigated.
30 1pSS, 23 2pSS and 35 healthy controls were enrolled in the study. PBMCs were stimulated in whole blood with PMA and ionomycin, PBMCs labelled for CD3, CD4, CD8, CD19, CD16+56, CD25, CD27, CD57, Foxp3 and IL-17A and analyzed by flow cytometry.
Decline in CD3+ T cells in PBMCs of patients with pSS was detected. The reason for this was significantly decreased absolute counts of CD4+, CD8+ and CD3+CD16+56 cells in patients with pSS. Significant decrease in absolute counts of CD4+IL17A+ and CD8brightCD57-CD27+ cells in patients with pSS were observed as compared to control group. Absolute counts of CD4+25brightFoxp3 and CD19+ cells were similar in all three groups and CD3-CD16+56 cells was significantly decreased only in 1pSS group. All results between 1pSS and 2pSS groups were comparable. However, different correlations between lymphocyte populations in 1pSS and 2pSS groups were found. Only in 1pSS the correlation between CD3-CD16+56 and CD3+CD16+56, CD3-CD16+56 and CD4+25brightFoxp3, CD4+ and CD19+, CD4+ and CD8brightCD57-CD27+ cells was registered. Whereas, in 2pSS the correlation between CD4+ and CD4+IL-17A+, CD8+ and CD3+CD16+56, CD4+IL-17A+ and CD8brightCD57-CD27+ cells was revealed.
Declining and variations of T-lymphocyte subsets in pSS patients` could be the result of increased apoptosis and/or migration to inflamed tissues of CD4+IL-17A+, CD8brightCD57-CD27+, CD3+CD16+56 and
CD3-CD16+56 (only in 1pSS group) cells. We suppose that these cell populations play an important role in pSS pathogenesis.

P5.17.38
Protease activation receptors - A new link between IgE mediated and non-IgE mediated inflammatory reactions

S. Sun[1]*, G. Mackay*[2]*, A. Lopata*[1]*;*
[1]*Comparative genomics center, Faculty of medicine,health & molecular sciences, James cook university, townsville, Australia,* [2]*Department of pharmacology, University of melbourne, Melbourne, Australia.*

Background: Food derived proteases are known to have a central role in inflammatory reactions via activate protease activation receptors (PAR's) on various cells types. The interplay with IgE-mediated reactions however is not understood. We investigate in this study the effect of a novel crustacean protease on the up-regulation of PAR's in the presence of IgE-receptor activation.
Methods: Trypsin (PT) from black Tiger prawn (Penaeus monodon) was purified by HPLC/C18 chromatography and activity studied using zymography. The impact of PAR's (PAR-1, -2, -3, -4) on IgE mediated degranulation were analysed using a humanized rat basophilic leukemia (RBL-2H3) cells, while PT stimulation on the four PAR-receptors was evaluated using a human lung epithelial cell line (A549). The expression level of PAR-receptors and cytokines was quantified by qPCR and cell signaling pathways explored by western-blotting.
Results: A novel PT is highly resistant to autoproteolysis. Stimulated RBL cells demonstrated after IgE-Antigen stimulation or exposure to PT very strong up-regulation of IL4/IL13 mRNA level. In addition IgE stimulation enhanced the expression of PAR-2 but none of the other three receptors. In contrast PT stimulation of A549cells boosted both expressions of PAR2 and PAR4 and 9 different cytokines. Both cell types utilized the MAPK pathway.
Conclusions: This is first study to demonstrate the up-regulation of PAR-2 receptor via activation of IgE-receptors on RBL cells besides enhanced up-regulation of IL-4/IL-13 cytokines. These cytokines favor the production of more IgE antibody in a Th2 driven milieu, demonstrating the crucial link between IgE and non-IgE mediated pro-inflammatory reactions.

P5.17.39
Identification of a novel cold-associated autoantigen, heterogeneous nuclear RNP-K, in patients with secondary Raynaud's phenomenon by proteomic approach.

O. Tomoharu[1]*, L. Yang*[2]*, H. Honda*[1]*, S. Serada*[1]*, M. Fujimoto*[1]*, T. Naka*[1]*;*
[1]*Laboratory for Immune Signal, National Institute of Biomedical Innovation, Osaka, Japan,* [2]*Department of Dermatology Course of Integrated Medicine Graduate School of Medicine, Osaka University, Osaka, Japan.*

Objective: To identify cold-associated autoantibodies in patients with Raynaud Phenomenon (RP) secondary to connective tissue diseases (CTDs).
Method:Indirect immunfluorescence staining was performed on non-permeabilized cold-stimulated normal human dermal microvascular endothelial cells (dHMVECs), using patients' sera. Cold-induced alterations in cell surface proteome were analyzed by iTRAQ analysis. Serological proteome analysis was applied to screen cold-associated autoantigens. Prevalence of the candidate autoantibody was determined by ELISA in 231 patients with RP secondary to CTDs (systemic sclerosis, systemic lupus erythematosus or mixed connective tissue disease), 10 patients with primary RP and 27 healthy controls.
Results: Enhanced cell surface immunoreactivity was detected in cold-stimulated dHMVEC cells, when incubated with sera from patients with secondary RP. By iTRAQ analysis, many proteins including heterogeneous nuclear RNP-K (hnRNP-K) were found increased on the cell surface of dHMVECs after cold stimulation. By SERPA approach, hnRNP-K was identified as a candidate autoantigen in patients with secondary RP. Cold-induced translocation of hnRNP-K to cell surface was confirmed by immunoblotting and flow cytometry. By ELISA analysis, patients with secondary RP represented a significantly higher prevalence of anti-hnRNP-K autoantibody (28.4%, 52 of 183) than patients without RP (8.3%, 4 of 48, P = 0.0019), patients with primary RP (0%, 0 of 10, p = 0.0396) and healthy controls (0%, 0 of 27, P = 0.0003).
Conclusions: By comprehensive proteomics, we identified hnRNP-K as a novel cold-associated autoantigen in patients with secondary RP. Anti-hnRNP-K autoantibody may potentially serve as a biomarker for RP secondary to various CTDs.

P5.17.40
Increased levels of IL-17F but not IL-17A in patients with immunosuppressive therapy for autoimmune hepatitis (AIH).

P. Thomas-Dupont[1]*, L. A. Sanchez-Vargas*[1]*, I. Y. Izaguirre-Hernandez*[1]*, M. Maldonado-Renteria*[1]*, A. Torre-Delgadillo*[2]*, J. M. Remes-Troche*[1]*, E. Bravo-Sarmiento*[3]*,* ***H. Vivanco-Cid***[1]*;*
[1]*instituto de Investigaciones Medico-Biológicas. Universidad Veracruzana, Veracruz, Veracruz, Mexico,* [2]*Departamento de Gastroenterología, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán., Mexico City, Mexico,* [3]*Centro Estatal de Transfusión Sanguínea de Veracruz, Veracruz, Veracruz, Mexico.*

AIH is an inflammatory condition of the liver in which the mechanisms that operate in tissue destruction and/or tissue repair are still unknown. Corticosteroids are the mainstay of therapy and, either alone or in combination with azathioprine. This treatment has been shown to improve survival rates and quality of life. Patients on corticosteroid therapy evolve to remission but some of them experience an exacerbation after withdrawal of drug(s). Relapse is common and occurs in a significant percentage of the patients within 6 months. In this study, we analyzed the serum levels of Th17-associated cytokines in 55 Mexican patients with confirmed AIH diagnosis under different treatment regimens (prednisone, prednisone-azathioprine or azathioprine), comparing against healthy donors (HD). The results were analyzed by Mann-Whitney U or Kruskal-Wallis tests, using Sigma Plot statistics software. A value of $P<0.05$ was considered significant. Elevated levels of IL-17F (98.5 pg/ml), IL-21 (161.83 pg/ml) and IL-23 (39.49 pg/ml) were detected in patients under treatment. In contrast, very low or undetectable levels for these cytokines were measured in the HD group (IL-17F: undetected, IL-21: 12.46 pg/ml, IL-23: 8.52 pg/ml). There were not differences between the values for IL-17A in the AIH and HD groups (35 pg/ml vs. 23 pg/ml) and IL-22 (29 pg/ml vs. 18.46 pg/ml). Collectively, these results suggest a differential effect of the Immunosuppressive therapy on Th17 cytokine production. IL-17F could play an important role in the pathogenesis of AIH in patients under conventional immunosuppressive therapy.

P5.17.41
Amplification of T cell autoreactivity by OX40/OX40L functional complex on peripheral CD4+ T cells in Graves' disease and clinical significance

Q. Wang[1]*, X. Zhang*[1]*, Y. Ma*[1]*, X. Zhang*[2]*;*
[1]*Soochow University, Suzhou, China,* [2]*The First Affiliated Hospital of Soochow University, Suzhou, China.*

Persistent activation of autoreactive T cell is crucial in the development of Graves' disease (GD) since the prodution of autoantibody (TRAb) is T-cell dependent. It was reported that some costimulatory receptors and their ligands such as CD28 and CD80 coexpressed on activated T cells as well as T cells from some autoimmune diseases, could enhance T cell autocrine stimulation. Because OX40/OX40L pathway plays a very important role in the antigen priming T cells and effector T cells, in this study we address whether OX40/OX40L was expressed on T cells from 124 patients with GD. It was very interesting to find that OX40 and OX40L were abnormally coexpressed on $CD4^+$ T cells of peripheral blood in GD patients. Then we also evidenced these OX40, OX40L expression and coexpression levels on $CD4^+$ T cells were all notably higher in $TRAb^h$ group than that in $TRAb^n$ group and changed with TRAb alteration after therapy. This means that the expression levels were closely correlated with TRAb levels. In addition, blocking OX40/OX40L signal in vitro inhibited T cell proliferation, which suggested OX40 and OX40L coexpressed on $CD4^+$ T cells could enhance $CD4^+$ T cell proliferation in GD by self-enhancing loop of T cell activation independent of APCs. The data of confocal microscopy and coimmunoprecipitation further showed that OX40 and OX40L formed functional complex which may facilitate signal transduction

from OX40L to OX40 and contribute to the pathogenesis of GD. Our results indicated targeting OX40/OX40L signal could be a new therapeutic approach in patients with GD.

P5.17.42
Increased frequency of Th17 cells in patients with dermatomyositis

X. Tang, J. Tian, J. Chen, Y. Liu, ***S. Wang****;*
Department of Laboratory Medicine, The Affiliated People's Hospital, Jiangsu University, Zhenjiang, China.

DM (dermatomyositis) is a subtype of inflammatory myopathies,which is a rare autoimmune disease of skeletal muscle. Although the pathogenic mechanism of DM is still unclear, it was considered as a CD4+T cells driven disease. It was reported that IL-17, a key cytokine of Th17 cells, has been detected in the inflammatory patients. But there is no study focusing on the alteration of Th17 cells in the peripheral blood of patients with DM. In this study, we investigate the roles of Th17 cells in the pathogenesis of DM.
The percentage of Th17 cells was significant increased in PBMCs from patients with DM compared with healthy controls. qRT-PCR analysis displays an enhanced expression of IL-17mRNA in the PBMCs from DM patients, with lower expression in healthy controls. The expression of RORC mRNA in PBMCs from DM patients is significant higher than that from healthy controls. We found that there was a positive correlation between the percentages of Th17 cells and serum level of CK, but not with level of LDH. In addition, we found that DM patients have significant increased serum concentration of IL-6 and TGF-βin comparison with healthy controls. In addition, serum concentrations of IL-1βis higher in DM patients compared with healthy controls, but this difference did not reach statistical significant.
In summary, our data collectively suggest that there is an enhanced frequency of Th17 lymphocytes in DM patients, and these cells might participate in the pathogenesis of the inflammatory phenomenon observed in this condition.

P5.17.43
Plasma microparticles and LL-37 levels regulate Behcet's Disease severity

T. Kahraman[1], ***F. Yagci****[1], I. Gursel[1,2];*
[1]Biotherapeutic ODN Research Lab., Department of Molecular Biology and Genetics, Bilkent University, Ankara, Turkey, [2]Bilgen Research Center, Bilkent University, Ankara, Turkey.

Microparticles (MPs) are small vesicles secreted from immune and non-immune cells. The number of MPs was found to be elevated in rheumatic diseases such as rheumatoid arthritis, systemic sclerosis, and vasculitis. However, the relationship between Behçet's Disease (BD) and level of MPs has not been examined.
This study aimed to characterize the cell source, cell activation state and quantity of MPs in Behcet's patients with different clinical features. We also attempted to identify MP mediated immune activation of BD patients PBMCs. MPs isolated from peripheral blood plasma of 72 patients with BD and 22 healthy controls were stained with Annexin-V together with specific cell surface markers of CD3, CD14, CD31, CD42a, CD69, and CD105. Isolated MPs incubated with healthy PBMCs to assess IL-6 production. The concentration of LL-37 in subjects` plasma and MPs were determined by ELISA.
Data suggested that platelets are the major source of MPs. Furthermore, the number of MPs/ml plasma in active BD patients increased by 2 fold and by 5 fold with respect to inactive BD and healthy individuals, respectively. PBMCs efficiently took up syngeneic patients` MPs and MPs stimulation led to IL-6 secretion proportional to disease progression/severity. The plasma and MP-associated LL-37 levels were the highest for active BD patients and correlated with cytokine production.
This study suggested that MP levels and source along with persistence and cargo plays a pivotal role in regulating the disease activity and may contribute to the pathogenesis of BD.

Modulation of macrophage differentiation by crotoxin from *Crotalus durissus terrificus* in acute intestinal inflammation in mice

C. S. Almeida*[1], J. Jacysyn[2], E. L. Faquim-Mauro[1];*
[1]Instituto Butantan, São Paulo, Brazil, [2]Universidade de São paulo, São Paulo, Brazil.

Macrophages are important cells to maintain homeostasis between host and commensal microbiota and also play essential role mediating inflammatory reaction against pathogenic agents. Macrophages, including 'classical' (M1) and 'alternatively' activated (M2) have been studied as a target for the treatment of inflammatory bowel diseases such as Crohn's disease. Crotoxin (CTX) is the main component of the *Crotalus durissus terrificus* rattlesnake venom and has immunosuppressive effect. Here, we evaluated the induction of M1 and M2 macrophage populations by CTX on 2,4,6-trinitrobenzene sulfonic acid (TNBS)-induced colitis in mice. After 18 hs of the TNBS-colitis induction, the mice were treated with CTX or PBS. After 24 or 48h of the treatment the peritoneal lavage and mesenteric lymph node cells were collected for flow cytometry analysis. Clinical and histological scores showed that the CTX-treatment decreased the disease progression in TNBS-colitis induced mice. Higher percentage of $CD11b^{+}CD68^{+}$ (M1) cells was observed in peritoneal lavage at 24 and 48h as well as in the lymph nodes after 48h of PBS administration in TNBS-colitis mice compared with the CTX administered in TNBS-group. The highest percentage of $CD11b^{+}CD206^{+}$ (M2) cells was found in peritoneal lavage and mesenteric lymph nodes collected at 24 and 48h after the CTX treatment of TNBS-induced mice. As previously observed this macrophage population (M2) is able to produce IL-10 which can modulate the intestinal inflammatory response. Our preliminary results suggest a modulatory role of CTX in the macrophage differentiation in acute intestinal inflammation induced by TNBS in mice. Financial Support: FAPESP 2010/05701-9 and CNPq

The role of IFITM genes in the pathogenesis of the gastro-intestinal tract

Z. Alteber*, E. Tzehoval, L. Eisenbach;*
Weizmann Institute of Science, Rehovot, Israel.

The Interferon inducible transmembrane protein family (IFITM) includes several highly homologous family members. These genes are involved in multiple molecular and cellular processes, such as, early development, immune response to pathogens, viral restriction, inflammation, malignant transformation, cellular adhesion and cell cycle control. Several findings associate between IFITM genes and pathogenesis in the gastro-intestinal (GI) tract. IFITM2 and IFITM3 genes were shown to be over-expressed in colitis-associated cancers, and in severely inflamed mucosa. Moreover, polymorphisms of the IFITM3 gene were found to be associated with susceptibility to ulcerative colitis.
Our research aims at investigating the molecular pathways governing IFITM genes expression and their role in colon related diseases.
To study the role of IFITM genes in colitis, we induced acute colitis by administration of Dextran Sodium Sulfate (DSS). Colitis severity was monitored and assessed in IFITM3KO (knockout) mice. The severity of the disease was evaluated by daily weighting, endoscopic scoring, and histological analysis. We have shown that the absence of a single IFITM3 allele, results in a significantly severe acute colitis. Gene expression analysis in colons of healthy IFITM3KO mice revealed that these mice predominantly express pro-inflammatory genes, such as IL-beta and IL-6.
Further investigation of the mechanisms, by which IFITM genes are regulated, as wells as their role in GI pathogenicity, are of great importance in attributing to our understanding of the role that immunity plays in complex processes of inflammation and malignancy.

Profile of ANCA (Anti-Neutrophil Cytoplasmic Antibodies) and ASCA (Anti-Saccharomyces Cerevisiae mannan Antibodies) in patients with IBD (Inflammatory Bowel Diseases): Crohn's disease and Ulcerative Colitis

S. Aziz[1], *N. Tahiri Jouti*[1], *W. Badre*[2], *A. Naya*[3], *Z. Serhier*[4], *R. Alaoui*[2], *S. Zamiati*[1];
[1]*Laboratory of Pathology, Faculty of Medicine and Pharmacy, Casablanca, Morocco,* [2]*Gastroenterology Department, CHU Ibn Rochd, Casablanca, Morocco,* [3]*Laboratory of Molecular Physiology and Genetics, Faculty of Sciences Aïn Chock,, Casablanca, Morocco,* [4]*Laboratory of Medical Informatics, Faculty of Medicine and Pharmacy, Casablanca, Morocco.*

Introduction: ANCA (Anti-Neutrophil Cytoplasmic Antibodies), directed against the cytoplasmic granules of neutrophils. They are associated with various antigenic targets and found during a set of inflammatory pathologies. ASCA (Anti-Saccharomyces cerevisiae mannan Antibodies), react with yeast "Saccharomyces cerevisiae". They are directed against mannose residues of the cell wall of S. cerevisiae and found in patients with Crohn's disease (CD) and ulcerative colitis (UC). Objectif: To study the involvement of ANCA and ASCA in CD and UC Moroccan patients and establish ANCA/ASCA profile in these complementary pathologies. Materials and methods: We tested sera from 89 patients of Gastroenterology Department, Ibn Rochd University Hospital of Casablanca. The presence of ANCA was investigated by IIF on slides of neutrophils cytocentrifuged and fixed in ethanol or formalin-acetone and ELISA: ANCA-combi Kits. The presence of ASCA was investigated by ELISA: ASCA (IgG+IgA) Kits. Results: ASCA showed a significant association (p= 0.0000003) with CD and p-ANCA with UC (p= 0.00071). The combination of both tests ASCA/p-ANCA leads to higher association than tests alone. c-and a-ANCA pattern were also found and showed an association with these digestive diseases complicated with underlying infectious diseases. Beside PR3 and MPO, we identify other antigenic targets (Lactoferrin, Bactericidal Permeability Increasing Protein, Cathepsin G, Elastase) associated with different patterns in IIF. Conclusion: The application of both ANCA and ASCA tests may be helpful in our country for the differential diagnosis between CD and UC. It should however find a possible association with an infectious disease suggesting an infectious etiology underlying these inflammatory diseases.

P5.18.04

Glucocorticoid-induced leucine zipper (GILZ) regulates intestinal immune homeostasis and anti-inflammatory effects of glucocorticoids

O. Bereshchenko[1], *M. Coppo*[1], *M. Biagioli*[1,2], *T. Frammartino*[1], *M. Cimino*[1,2], *A. Venanzi*[1,3], *D. Sorcini*[1], *M. Di Sante*[1], *S. Bruscoli*[1], *C. Riccardi*[1];
[1]*University of Perugia, Perugia, Italy,* [2]*University of Messina, Messina, Italy,* [3]*University of Sassari, Sassari, Italy.*

Inflammatory bowel disease (IBD) comprises a group of diseases of the gastrointestinal tract. Glucocorticoids (GCs) are one of the most widely used drugs in IBD treatment. Glucocorticoid-induced leucine zipper gene (GILZ) is rapidly induced by GCs. We have recently generated a conditional knock out mice of gilz gene (gilz cKO). To determine whether deletion of gilz influences the susceptibility to chemichally-induced colitis, we compared the development of dinitrobenzene sulfonic acid (DNBS)-induced colitis in wild-type (wt) and gilz cKO mice. The severity of colitis was markedly more severe in gilz cKO mice compared to wt controls, as measured by increased mortality, body weight loss, diarrhea score and colon shorteining and increased post-injection recovery time. Levels of TNFα were significantly higher in mesentheric lymph nodes of DNBS-treated gilz cKO compared to wt mice. These results suggest that GILZ absence in T cells dampens a normal intestinal immune response.
The DNBS-induced colitis was not cured by dexamethasone (DEX) treatment in gilz cKO mice as occurs in wt mice, evidenced by lack of DEX effect on body weight loss and overall clinicall score in gilz cKO mice. Thus, lack of GILZ precludes efficient anti-inflammatory effects of GC.
Finally, the exacerbated inflammation of DNBS-induced colitis in gilz cKO mice was fully prevented by recombinant TAT-GILZ protein administration, suggesting that pharmacologic modulation of GILZ expression can represent a new strategy for the treatment of IBD.

P5.18.05

Polymorphisms of NOD2/CARD15 and PTPN22 in Algerian adult inflammatory bowel disease (IBD)

A. Boukercha[1], *A. Bouzidi*[1], *H. Saoula*[2], *F. Chemandji*[2], *M. Nakmouche*[2], *C. Touil-Boukoffa*[1], *H. Mesbah-Amroun*[1];
[1]*Team "Cytokines and NOSynthases", Laboratory of Cellular and Molecular Biology, Faculty of Biological Science, University of Sciences and Technology Houari Boumediene (USTHB), Algiers, Algeria,* [2]*Department of Gastroenterology, Maillot hospital, Algiers, Algeria.*

Background:
Susceptibility to IBD, a complex genetic disorder, is influenced by common variants at many loci. The aim of this preliminary work is to highlight the presence of allelic variants in NOD2, the first susceptibility gene described as being linked to IBD, and the allele of a minor gene, PTPN22 which has been unequivocally confirmed by GWAS as conferring susceptibility to IBD and many autoimmune diseases.
Methods:
The SNP-s for NOD2 (C2104T, G2722C, 3020insC) and PTPN22 (C1858T) were investigated by PCR-RFLP, in a case-control study. 37 Algerian IBD patients were genotyped and compared to 39 healthy controls and 19 DT1 Algerian patients. All participants provided written informed consent before participation.
Results:
The three risk alleles for NOD2 (C2104T, G2722C, 3020insC) are present in IBD patients (4, 06%, 5,40%, 1,35%) and are more frequent than in controls (3,84%, 1,92% , 0%). The frequencies of the three alleles were higher in CD compared to UC patients (16,22% vs 1,70%), and thus support the literature data. For PTPN22 gene, (C1858T) allelic variant frequencies are (1,25%, 5,27% and 0%) in IBD, T1D controls and healthy controls, respectively and appear to be much less frequent compared to the neighbor Tunisian population.
Conclusion:
In this preliminary study on Algerian population, we present for the first time, allelic variants frequencies of two susceptibility genes, NOD2 and PTPN22, which seem to be associated with IBD. It would be interesting to extend our sampling in order to better evaluate the impact of those two loci in IBD disorder.

P5.18.06

Autoimmune diseases association study with the KIAA1109-IL2-IL21region in a Tunisian population

D. Bouzid[1], *H. Fourati*[1], *A. Amouri*[2], *I. Marques*[3], ***O. Abida***[1], *N. Tahri*[2], *C. Penha-Gonçalves*[4], *H. Masmoudi*[1];
[1]*Immunology Department, Medicine school and Habib Bourguiba hospital, Sfax, Tunisia,* [2]*Gastroenterology Department, Hédi Chaker hospital, Sfax, Tunisia,* [3]*Instituto Gulbenkian de Ciência, Portugal, Oeras, Portugal,* [4]*Instituto Gulbenkian de Ciência, Oeras, Portugal.*

Autoimmune diseases share many genetic factors resulting in similarity of disease mechanisms. For instance polymorphisms from the KIAA1109-IL2-IL21 block in the 4q27 chromosome, has been associated with a number of autoimmune phenotypes. Here we performed a haplotype-based analysis of this autoimmune related region in Tunisian patients. Ten SNPs (rs6534347, rs11575812, rs2069778, rs2069763, rs2069762, rs6852535, rs12642902, rs6822844, rs2221903, rs17005931) of the block were investigated in a sample set consisting of 93 systemic lupus erythematosus (SLE), 67 ulcerative colitis (UC), 39 Crohn's disease (CD) patients and 162 healthy control subjects of Tunisian origin.
In SLE population, haplotypes AGCAGGGTC, AGAAGAGTC, AGAAGGGTC and AGCCGAGTC provided significant evidence to be associated with SLE risk (P = 0.013, 0.028, 0.008 and 0.021, respectively).
In the UC population, haplotypes AGCCGGGTC and AGCAGAGTT have a susceptibility effect for UC (p = 0.007and p= 0.028, respectively).
In the CD population, haplotype CAGGCC showed a protective effect against the development of CD (p = 0.038). Haplotypes GAGA, AAGGTT and CGGGCC provided significant evidence to be associated with CD risk (P = 0.048, 0.0004, 0.041, respectively).
Our results replicate and extend the association found in the *KIAA1109 /IL2/IL21* gene region with autoimmune diseases, implying

that this locus is a general risk factor for multiple autoimmune diseases.

P5.18.07
Frequency of NOD2/CARD15 and MDR1 gene polymorphisms in a cohort of Algerian pediatric Crohn's disease patients

A. Bouzidi[1], *A. Boukercha*[1], *F. Benhassine*[2], *W. Messadi*[3], *C. Touil-Boukoffa*[1], *H. Mesbah-Amroun*[1];
[1]*Team "Cytokines and NOSynthases", Laboratory of Cellular and Molecular Biology (BCM), Faculty of Biological Science (FSB), University of Sciences and Technology Houari Boumediene (USTHB), Algiers, Algeria,* [2]*CHU Beloghine, Algiers, Algeria,* [3]*CHU Beni Messous, Algiers, Algeria.*

Objective: The aim of this study is to describe for the first time, the allele frequency of most relevant SNPs in two candidate genes for inflammatory bowel disease, NOD2 which encodes an innate immune receptor and MDR1 which encodes a membrane transport protein, in Algerian Pediatric Crohn's disease patients.
Material and methods
15 unrelated pediatric CD patients and 39 healthy controls were studied. Clinical data and personal information were collected after obtaining informed consent from each participant. NOD2 (C2104T, G2722C, and 3020insC) and MDR1 (C3435T, C1236T, G2677T/A) polymorphisms were analyzed using PCR-RFLP method.
Results: The mean age of diagnosis is 10±3,5 years old with a sex ratio of 1,5 (M/F). 33,33% of parents are consanguineous and 36,36% of patients have family history of CD. The frequency of ileitis, Ileocolitis and colitis is 50%, 41,66% and 8,33% respectively. 45,45% had surgery and 33,33% extraintestinal manifestations. The 2104T allele of NOD2 gene is more frequent in CD patients than controls but neither G2722C nor 3020insC mutations are found in patients. Interestingly, only the 3435T and 1236T alleles of MDR1 gene are significantly more frequent in patients compared with controls (45,45% vs 31,25% and 46,66% vs 38,23%, respectively).
Conclusion: Our study shows that allelic variants of NOD2 and MDR1 are present in the Algerian population and their frequency varies between CD patients and controls. An increase of sampling is required to understand the impact of these genes in CD. Exploring MDR1 polymorphisms may contribute to explain inter-individual differences in pharmacokinetics of drugs.

P5.18.08
miR-132/212 cluster knockout ameliorated DSS-induced colitis

I. Chinen*, T. Nakahama, N. T. Nguyen, D. Millrine, S. Lee, T. Kishimoto;*
Osaka University, Suita, Japan.

MicroRNAs (miRNAs), a 20- to 25-base-pair single-stranded non-cording RNA fragments, are important post-transcriptional regulators. By modulating the expression of numerous target mRNAs mainly at the post-transcriptional level, these miRNAs have been involved in most, if not all, biological processes as well as in the pathogenesis of a number of diseases including human ulcerative colitis. Our previous work demonstrated that Aryl hydrocarbon receptor (Ahr) has important roles in differentiation or activation of immune cells and autoimmune disease. Subsequently, our group found mir-132/212 cluster was driven and participated in differentiation of immune cells such as Th17 cells and macrophages in condition of the Ahr activation. However, the role of mir-132/212 in autoimmune diseases remains unknown. To investigate the function of mir-132/212 in immune system, we produced DSS-induced colitis in Wild type (WT) mice and examined mir-132/212 expression by real time-PCR. Interestingly, expression of mir-132/212 was upregulated in DSS administrated mice colon. Furthermore, mir-132/212 KO mice showed mild symptoms of DSS-induced colitis compared to WT mice.These results suggest that mir-132/212 has anti- inflammatory function in DSS-induced colitis. We further examine the effect of mir-132/212 deficiency to pathological and biological alterations and its target genes.

P5.18.09
Overexpression of IL-9 and its receptor in Crohn's disease

M. T. Chiriac[1,2], *N. Nalleweg*[1], *G. Hundorfean*[1], *M. F. Neurath*[1], *J. Mudter*[1];
[1]*Department of Medicine 1, University of Erlangen-Nuremberg, Erlangen, Germany, Erlangen, Germany,* [2]*Department of Biology and the Molecular Biology Center, Interdisciplinary Research Institute on Bio-Nano-Sciences, Babes-Bolyai University Cluj-Napoca, Cluj-Napoca, Romania.*

Th9 cells have been recently defined as the main producers of IL-9. However, the role of this cytokine and its receptor in Crohn's disease, one of the two major forms of inflammatory bowel disease, has not been addressed so far. The capacity of cultured peripheral blood lymphocytes to produce IL-9 upon stimulation has been investigated by ELISA whereas the expression of the IL-9/IL-9R was monitored by flow cytometry and immunofluorescence. Spontaneous apoptosis in cultured granulocytes has been addressed by flow cytometry using annexin V and 7-AAD, and various concentrations of IL-9 were used to modulate this process. Stimulated Crohn's disease lymphocytes produced significantly more IL-9 compared to cells from healthy controls. Intracellular anti-cytokine staining demonstrated that IL-9-producing cells represent a subset of lymphocytes that is distinct from IL-17+ cells in Crohn's disease. Patients expressed significantly more IL-9R on their peripheral blood cells compared to controls. Functionally, IL-9 addition decreased the rate of spontaneous granulocyte apoptosis in a dose-dependent manner. Nevertheless, granulocytes from Crohn's disease biopsies stained positive for the IL-9R suggesting a possible pathogenic implication of these cells in situ. Our present results identify IL-9-producing cells as a distinct subpopulation of lymphocytes in Chron's disease patients. Moreover, the high levels of IL-9 production and/or IL-9R expression by peripheral blood cells in Crohn's disease might define therapy-resistant cases and thus IL9/IL-9R could become novel disease markers and/or future therapeutic targets.

P5.18.10
Integrity of the splenic nerve is required to mediate the vagal anti-inflammatory effect on colonic inflammation in a murine DSS-induced model of colitis

L. M. M. Costes[1], *B. J. Olivier*[1], *J. van der Vliet*[1], *W. J. de Jonge*[1], *G. E. Boeckxstaens*[2], *C. Cailotto*[1];
[1]*Academic Medical Center, Amsterdam, Netherlands,* [2]*University Hospital Leuven, Leuven, Belgium.*

Background: Subdiaphragmatic vagotomy enhances colonic inflammation in a Dextran Sodium Sulfate (DSS)-induced mouse model of colitis. In sepsis, vagal control of the splenic nerve was proposed to mediate the vagal anti-inflammatory effect. To which extent this neuronal circuitry is involved in modulating DSS-induced colonic inflammation remains unknown.
Aim: We therefore investigated the role of the spleen and splenic innervation in modulating the immune system during colonic inflammation.
Methods: A time-course preliminary study was performed to collect evidence supporting immune activation in the spleen during colonic inflammation. C57BL/6 mice were exposed to DSS (2%) for 5 days and sacrificed at day 1, 3, 12 and 21. Denervation of the spleen or Sham operation was performed prior to DSS treatment to evaluate the role of splenic innervation in modulating colonic inflammation.
Results: At day 12, enhanced expression of CD80 on splenic macrophages and increased percentages of splenic neutrophils and regulatory T cells (T regs) were observed in the spleen of DSS-treated mice compared to water-exposed animals. Spleen denervation did not affect the splenic response. However, an increased Disease Activity Index (i.e. inflammatory score, diarrhea score, visible fecal blood), suggesting a higher colonic inflammation, and enhanced expression of colonic CD45 mRNA, showing a higher cell infiltration, were observed in spleen-denervated DSS-treated mice. The colonic expression of FoxP3 mRNA, a Treg marker, was also increased in these mice.
Conclusion: Our study suggests that splenic denervation increases colonic inflammation. Further experiments are currently conducted to confirm the role of the spleen in DSS-induced colonic inflammation.

P5.18.11
Neutrophil gelatinase B-associated lipocalin - matrix metalloproteinase-9 (NGAL-MMP-9) complex as a surrogate serum marker for mucosal healing in ulcerative colitis

M. de Bruyn[1,2]*, I. Arijs*[2]*, W. Wollants*[2]*, K. Machiels*[2]*, K. Van Steen*[3]*, M. Ferrante*[2]*, S. Vermeire*[2]*, P. Rutgeerts*[2]*, G. Opdenakker*[1]*;*
[1]Rega Institute for Medical Research, Department of Microbiology and Immunology, KU Leuven, Leuven, Belgium, [2]Translational Research Center for Gastrointestinal Disorders (TARGID), Department of Clinical and Experimental Medicine, KU Leuven, Leuven, Belgium, [3]Montefiore Institute, Electrical Engineering and Computer Science, University of Liège, Liège, Belgium.

Objective. The current standard for assessing intestinal inflammation and mucosal healing after therapy in inflammatory bowel diseases (IBD) is endoscopy. However, a need exists for non-invasive, accurate serum markers. Several studies have shown that MMPs are predominant proteases in IBD. Serum NGAL-MMP-9 complex levels were studied as a surrogate marker for mucosal healing in ulcerative colitis (UC) patients.
Design. Serum NGAL-MMP-9 complex levels were determined from 66 infliximab (IFX)-naïve patients with active UC before and 4-6 weeks after first IFX infusion and from 40 healthy controls (HC), using zymography analysis and sandwich ELISA. The response to IFX was defined as complete mucosal healing at control endoscopy. Data were analyzed with the use of non-parametric tests in SPSS Statistics 20.0 software and p-values <0.05 were considered significant.
Results. At baseline, serum NGAL-MMP-9 complex levels were significantly increased in UC patients versus HC (103.8 vs 42.4 ng/ml; p<0.0001), whereas in more than 50% of the patients CRP levels were normal. NGAL-MMP-9 levels decreased after therapy in UC responders (median range: 116.3 to 32.0 ng/ml; p<0.0001) and non-responders (median range: 94.7 to 54.1 ng/ml; p= 0.0469). NGAL-MMP-9 complex levels correlated more (τ=0.317) with endoscopic activity as measured by the Mayo endoscopic subscore than CRP titers (τ=0.299). ROC analysis defined a NGAL-MMP-9 complex cut-off value of 97.7 ng/ml predicting complete mucosal healing with high specificity (93%).
Conclusion. NGAL-MMP-9 complex outperforms CRP in assessing mucosal healing after treatment with IFX in UC patients and is suggested as a new serum marker for UC.

P5.18.12
Rip-2 mediated control of pathogenic and protective T cell function during chronic colitis

N. K. Escalante*, M. Cruz Tleugabulova, D. Philpott, T. Mallevaey; University of Toronto, Toronto, ON, Canada.*

Inflammatory bowel diseases (IBD) are poorly understood conditions which are characterized by chronic inflammation of the gastrointestinal tract and deregulation of T cell homeostasis. Since mutations to Nod2 have been linked to an increased susceptibility to IBD in humans and mice, my hypothesis is that innate Nod1&2 signals, conducted through the signalling adaptor molecule Rip2, are important for regulating pathogenic and protective adaptive T cell function during chronic colitis.
The T cell transfer model of colitis and Rip2 deficient mice were used to investigate the role of innate Nod1&2 signals in T cell function during colitis. Pathogenic CD45RB^{hi} T cell were injected alone or with protective CD45RB^{low} T cells into Rag1$^{-/-}$ or Rip2$^{-/-}$Rag1$^{-/-}$ mice. The severity of colitis was quantified by measurement of weight loss; analysis of mesenteric lymph node, lamina propria and spleen lymphocyte numbers, intracellular cytokines and surface markers by flow cytometry; pathological scoring of colons; screening of colon explant supernatants via Luminex and ELISA; and analysis of inflammatory mediators via RT- qPCR.
Rip2$^{-/-}$Rag1$^{-/-}$ mice had an increased rate of disease onset as indicated by rapid weight loss, high pathological scores at week 4 and increased frequency of IFN-γ^{+} colon infiltrating lymphocytes. Furthermore, co-injection of protective CD45RB ^{low} T cells did not protect the Rip2$^{-/-}$Rag1$^{-/-}$ mice even though normal frequencies of FoxP3^{+} regulatory T cells were found in the colon. Further investigation of this novel finding will lead to a better understanding of the mechanisms controlling both pathogenic and regulatory T cell populations in the gut.

P5.18.13
Significance of IL-9 levels in inflammatory bowel disease

C. Defendenti[1]*,* ***A. Fabiola***[2]*, S. Saibeni*[3]*, S. Bollani*[3]*, S. Bruno*[3]*, P. Almasio*[4]*, P. Sarzi-Puttini*[2]*;*
[1]Laboratory Unit, Fatebenefratelli Hospital, Milan, Italy, [2]Rheumatology Unit, L.Sacco University Hospital, Milan, Italy, [3]Divisions of Pathology and Gastroenterology, Fatebenefratelli Hospital, Milan, Italy, [4]GI & Liver Unit, DI.BI.M.I.S, Policlinico University of Palermo, Palermo, Italy.

The primary aim of this study was to evaluate serum IL-9 levels in patients with inflammatory bowel disease (IBD); the secondary aim was to analyse the levels of interferon-γ (INF-γ), Th2 cytokines (IL-4, IL-5 and IL-13), and IL-6, and their relationships with the clinical features of the disease.
Methods: Venous blood samples of 43 IBD patients (20 with Crohn's disease [CD] and 23 with ulcerative colitis [UC]) were analysed by means of quantitative enzyme-linked immunosorbent assays using purified anti-human IL-4, IL-5, IL-13, INFγ, IL-9 and IL-6 antibodies, and the laboratory findings were statistically correlated with clinical expression.
Results: All of the patients were negative for IL-4, IL-5 and IL-13. Forty (93%) were positive for INFγ, thus confirming the presence of Th1 in both UC and CD; INF-γ also correlated with disease activity (p=0.045). Eighteen patients (41%) were clearly positive for IL-9, which was associated with a severe prognosis (p<0.001), and 72.2% of the IL-9-positive patients were also IL-6 positive, which suggests that pro-inflammatory cytokines play a role in the disease. There was a significant correlation between disease severity and IL-9 in the CD patients (p<0.001), but not in the UC patients (p = 0.1).Conclusion: Our findings confirm the presence of the common Th1 cytokines underlying both UC and CD. Regardless of the diagnosis, clinical severity seems to be associated with the detection of serum IL-9, which suggests the presence an alternative T cell population with inflammatory function that conditions the prognosis of patients with IBD

P5.18.14
The role of thymic stromal lymphopoietin (TSLP) in intestinal pathologies

G. Fornasa[1]*, K. Tsilingiri*[1]*, F. Caprioli*[2]*, A. Sonzogni*[1]*, G. Penna*[1]*, M. Rescigno*[1]*;*
[1]Istituto europeo di oncologia (IEO), Milan, Italy, [2]Fondazione IRCCS Cà Granada, Milan, Italy.

Thymic stromal lymphopoietin (TSLP) is an IL-7 like cytokine produced by epithelial, stromal cells and some hematopoietic cells. TSLP has been shown to play a major role in several homeostatic immune responses but also in the pathogenesis of allergic and autoimmune disorders. In the gut, it is expressed by intestinal epithelial cells and educates non-inflammatory DCs the have reduced ability to produce IL-12p70 and drive the differentiation of inducible Tregs. Conversely, overexpression of TSLP and TSLP-induced Th2 responses are often associated with strong allergic manifestations, like asthma and atopic dermatitis, and with the progression of breast, pancreatic and lung cancer.
In humans, two homologous isoforms of TSLP are expressed, the "long" isoform (159 AA) and the "short" isoform (63 AA). Even though the most well characterized form of TSLP so far is the long one, we found the putative promoter for the long isoform to be almost completely inactive in most of the cell lines present in the UCSC database. On the contrary, the promoter region for the short isoform seems to have a high capacity to bind a number of different transcription factors and the protein is readily expressed in various tissues. We found that the short isoform is the only one expressed by intestinal epithelial cells under steady-state conditions and it is downregulated in inflammatory bowel disease. The long isoform instead shows an opposite trend, in fact it is expressed by epithelial cells only in inflamed ulcerous tissue.

P5.18.15
Vanin-1 (VNN1), an epithelial pantetheinase that regulates intestinal inflammation

***T. Gensollen**, C. Bourges, F. Galland, P. Naquet;*
ciml, Marseille, France.

Vanin-1 molecules are epithelial pantetheinases and regulators of intestinal inflammation in mouse. Vanin-1 modulates PPARγ anti-inflammatory potential in gut mucosa and exerts pro inflammatory or cytoprotective properties depending of the tissue context. We showed that Vanin-1 is tightly regulated in the mouse gut in normal and colitis conditions and that PPARγ regulates its expression. We investigated the contribution of human VNN1 to IBD and showed the constant upregulation of VNN1 in the colon of IBD patients, establishing VNN1 as a new marker of IBD. The sequencing of VNN1 regulatory regions in a cohort of 480 IBD patients and healthy controls enabled the identification of 3 VNN1 SNPs statistically associated to the disease. These polymorphic positions in the VNN1 gene locus are direct targets for nuclear factors and include a PPARγ binding site. In addition, we described a rare VNN1 variant associated with very high VNN1 levels and severe colitis. We developed transgenic mice, lacking or overexpressing Vanin-1 and analyzed their response to DSS -induced colitis. Preliminary results show that Vanin-1 expression levels could be correlated to the severity of colitis.

P5.18.16
Assessment of loss of response to Infliximab therapy in inflammatory bowel diseases using antibodies to Infliximab and trough Levels

***L. Guidi**, M. Marzo, G. Andrisani, A. Papa, C. Felice, D. Pugliese, S. Canestri, B. Tolusso, E. Gremese, A. Armuzzi;*
Università Cattolica del Sacro Cuore, Roma, Italy.

Currently the management of inflammatory bowel disease (IBD) patients on infliximab therapy who lose response is mostly empirical: an increase of dose up to double or a decrease of treatment intervals is the common clinical practice, with a consequent increase of drug use and high costs. Measuring trough levels (TL) and antibodies to infliximab (ATI) may be of great benefit in optimizing therapy. We aimed to evaluate the relationship of TL and ATI assay with loss of response and infusion reactions in an Italian IBD unit.
Methods: Sera were obtained from 82 IBD patients on infliximab maintenance therapy from at least 6 months. Patients were classified as being or not in clinical response. The occurrence of acute reactions to infliximab infusions was recorded. ATI and TL were measured by a commercial ELISA (Immundiagnostik AG, Bernsheim, Germany).
Results: ATI were detected in 18 patients (22%), 50% of which were in clinical response as compared to 80% of patients without detectable serum ATI levels (p=0.0271 by χ2 test). 5/18 (28%) of ATI positive patients had infusion reactions as compared to 2/64 (3%) ATI negative (p=0.0047 by χ2 test). 60/82 patients had infliximab TL >0,1 µg/ml and 80% of them were in clinical response, as compared with 54% of patients with TL lower than 0,1 ug/ml (p=0.0043 by χ2 test). Median TL were not significantly different among clinical responders and non-responders.
Conclusion: The combination of ATI and infliximab TL assay could help in managing loss of clinical response in IBD.

P5.18.17
Mannose receptor contributes to intestinal inflammation

***S. E. M. Heinsbroek**[1], R. Schilderink[1], A. A. te Velde[1], S. Gordon[2], W. J. de Jonge[1];*
[1]Tytgat Institute, Amsterdam, Netherlands, [2]Sir William Dunn School of Pathology, Oxford, United Kingdom.

Macrophage mannose receptor (MR) plays a role in innate immune responses. It is a multifunctional pattern recognition receptor that recognises a large number of micro-organisms including various bacteria, fungi, and viruses. We describe a novel role for the MR in LPS mediated cytokine responses and show that this receptor contributes to intestinal inflammation.
We studied MR mediated cytokine production in human and mouse macrophages. LPS stimulation of MR deficient macrophages showed at least a 50% decrease in IL-6, IL-12 and TNF-α production. Furthermore, incubation with MR blocking antibody gave a similar reduction in IL-6 in human monocyte derived macrophages. Following induction of dextran sodium sulphate (DSS) mediated colonic injury in MR deficient mice and WT mice we found that MR deficient animals had significantly reduced inflammation. Colon weights, pathology scores and levels of pro-inflammatory cytokines in the colons showed that MR deficient mice hardly had any inflammation. Furthermore, colons of MR deficient animals had significantly reduced influx of macrophages, DCs and neutrophils during DSS induced colitis. Using fluorescent immunohistochemistry we show that both in human and mouse the number of MR expressing macrophages increases during colonic inflammation.
Our data is the first to show that MR plays a significant role in LPS mediated macrophage responses and suggests that this is the underlying cause of reduced intestinal inflammation after DSS induced colitis in MR deficient mice. Since we found an increase in MR positive cells in IBD patients it is likely that MR plays a role in the pathogenesis of IBD.

P5.18.18
Microscopic colitis patients demonstrate a mixed Th17/Tc17 and Th1/Tc1 mucosal cytokine profile

***A. K. Kumawat**[1], H. Strid[2], C. Tysk[3], J. Bohr[3], E. Hultgren Hörnquist[4];*
[1]School of Health and Medical Sciences, Örebro University, Orebro, Sweden, [2]School of Health and Medical Sciences, Örebro University and and Dept of Medicine, Division of Gastroenterology, Örebro University Hospital, Orebro, Sweden, [3]Dept of Medicine, Division of Gastroenterology, Örebro University Hospital, and School of Health and Medical Sciences, Örebro University, Orebro, Sweden, [4]School of Health and Medical Sciences, and School of Medicine, Örebro University, Orebro, Sweden.

Data on the local cytokine profile in collagenous colitis (CC) and lymphocytic colitis (LC) is limited. This study investigated the T helper (Th) cell and cytotoxic T lymphocyte (CTL) mucosal cytokine profile at messenger and protein levels in CC and LC patients. Mucosal biopsies from CC (n=10), LC (n=5), and CC or LC patients in histopathological remission, (CC-HR, n=4), (LC-HR, n=6), ulcerative colitis (UC, n=3) and controls (n=10) were analyzed by real time PCR and Luminex. Mucosal mRNA but not protein levels of IFN-γ and IL-12 were significantly up regulated in CC, LC and UC patients compared to controls. Transcription of the Th1 transcription factor T-bet was significantly enhanced in CC but not LC patients. mRNA levels for IL-17A, IL-21, IL-22 and IL-6 were significantly up regulated in CC and LC patients compared to controls, albeit less than in UC patients. Significantly enhanced IL-21 protein levels were noted in both CC and LC patients. IL-6 protein and IL-1β mRNA levels was increased in CC and UC but not LC patients.
Although at lower magnitude, IL-23A mRNA was upregulated in CC and LC, whereas TNF-α protein was increased in CC, LC and UC patients. Neither mRNA nor protein levels of IL-4, IL-5 or IL-10 were significantly changed in any of the colitis groups. LC-HR and especially CC-HR patients had normalized mRNA and protein levels of the above cytokines compared to LC and CC patients. In conclusion, LC and CC patients demonstrate a mixed Th17/Tc17 and Th1/Tc1 mucosal cytokine profile.

P5.18.19
Involvement of mast cells in the development of colitis-associated colon cancer

***Y. Lee**[1], M. Xin[1], D. Kim[2];*
[1]Department of Oriental Pharmacy, College of Pharmacy, Wonkwang University, Iksan, Republic of Korea, [2]Department of of Immunolgy and Institute of Medical Sciences, Medical School, Chonbuk National University, Jeonju, Republic of Korea.

The chronic inflammatory process contributes multi-step tumorigenesis of colorectal cancer in the inflammed colon. The aim of this study was to examine whether mast cells regulate colitis-associated colon cancer (CAC) in the mast-cell-deficient mice (W/W^{v})

and C57BL/6 wide-type (WT) mice. *W/W^v* and WT mice (each n=10) intraperitoneally given azoxymethane (AOM) were provided 2.5% dextran sodium sulfate (DSS) in drinking water, repeated for 3 cycles. Colon tissues were used to examine the development of colon cancer, various gene expression, and activation of MAPK signals. As a result, macroscopic and microscopic analysis showed that W/W^v mice were significantly attenuated in colon tissue injuries and the occurrence of colon cancer induced by AOM+DSS compared to WT mice. In particular, the expression of cancer proliferating proteins, including Ki-67 and β-catenin and the inflammatory makers, including COX-2 and iNOS, were dramatically decreased in in colon tissues of W/W$^{v(+)}$ mice. Moreover, W/W^v mice revealed the attenuation in MAPKs phosphorylation including JNK, ERK, and p38 in the colon tissues. Thus, these results suggest that mast cells could affect the generation of colitis-associated colorectal cancer through pathological multiple mechanisms

P5.18.20
Whey and Soy protein supplements improves body composition in patients with Crohn`s disease under azathioprine and anti-TNF- α therapy

***J. F. Machado**, V. Oya, C. S. R. Coy, A. M. Morcillo, M. M. S. Vilela;*
State University of Campinas Medical School - UNICAMP, Campinas, Brazil.

Introduction: Cohn's disease (CD) is a chronic inflammation of the gastrointestinal tract. Obesity is becoming common among CD patients and it is well known that adipose tissue produces pro-inflammatory cytokines creating a favorable environment for disease progression.
Objective: Evaluate the effects of two nutritional supplements on nutritional status and disease's activity of CD patients.
Methods: A double-blind, randomized clinical trial study was conducted with two groups of patients: one was supplemented with whey protein enriched with TGF-β (WP-TGF-β) and the other was supplemented with soy protein (SP). Bioimpedance analysis, anthropometric measurements, Crohn's Disease Activity Index (CDAI), and dosages albumin, prealbumin and C-reactive protein (CRP) were performed at the beginning of the intervention and after 8 and 16 weeks. Spearman's correlation, Student's t-test, Friedman test and Analysis of Variance were used to analyze data.
Results: Forty-one patients received WP-TGF-β or SP; 29% were overweight or obese. There were no significant differences between the groups before and during the study, but both supplements improved body composition. Triceps skin fold ($p< 0.001$) and body fat percentage ($p=0.001$) decreased, whereas mid-arm muscle circumference ($p=0.004$), corrected arm muscle area ($p=0.005$) and lean mass percentage ($p=0.001$) increased. CDAI was positively correlated to CRP levels, and both negatively correlated to albumin and pre-albumin.
Conclusion: These different sources of protein reduced body fat. Although the underlying mechanisms are still unknown, we suggest that these supplements contribute to a reduction the inflammatory cytokine secretion of the adipose tissue, preventing CD relapse.
Financial support: FAPESP (processes: 2007/57558-2 and 2011/04750-9), CNPQ.

P5.18.21
The role of FIBCD1 in intestinal homeostasis and inflammation

***J. B. Moeller**[1], A. Schlosser[1], T. Bak-Thomsen[1], M. Hammond[1], L. Dubey[1], O. Nielsen[2], G. L. Sorensen[1], U. Holmskov[1];*
[1]University of Southern Denmark, Odense C, Denmark, [2]Odense University Hospital, Odense C, Denmark.

We have recently identified and characterized FIBCD1 as a homotetrameric transmembrane protein expressed by epithelial cells in the gastrointestinal tract. Moreover, we have shown that FIBCD1 is an endocytic receptor that binds selectively and calcium-dependently to acetylated structures but not their non-acetylated counterparts.
We have produced fibcd1-/- mice and investigated the role of FIBCD1 in gut homeostasis and in a mouse model for inflammatory bowel disease (IBD). The unchallenged fibcd1-/- mice have an increased intestinal permeability and display a reduced intestinal mucosal layer compared to wild type littermates. When challenged in a chemically induced colitis model, fibcd1-/- mice exhibit significantly elevated weight loss, reduced colon length and increased cytokine levels compared to that of wild type littermates.
The observed phenotypes of fibcd1-/- combined with the binding affinity toward acetylated structures led us to investigate a potential interaction between FIBCD1 and mucosal components. Using in vitro assays we demonstrate that FIBCD1 binds solubilized mucus with high affinity in a calcium-dependent manner. Moreover, we identify the glycosaminoglycan (GAG) chondroitin sulphate A as a potential mucosal component through which FIBCD1 interact.
Taken together our results suggest that FIBCD1 play a role in the maintenance of intestinal homeostasis during steady state and inflammatory conditions, through interactions with mucosal components containing chondroitin sulphate A.

P5.18.22
Protective role of HLADRB1*04 allele against ulcerative colitis in Iran

***M. Mohammadi**[1,2], M. M. Hayatbakhsh[3], H. Abdoli Sereshki[2], M. J. Zahedi[3], H. Rafatpanah[4], M. Rastin[5], A. R. Nicpoor[2];*
[1]Physiology Research Centre, Kerman University of Medical Sciences, Kerman, Iran, [2]Medical school, Microbiology, Virology and Immunology department, Kerman University of Medical Sciences, Kerman, Iran, [3]Gastroentrology department, Afzalipour Hospital, Kerman University of medical sciences, Kerman, Iran, [4]Immunology Research Centre, Buali Institute, Mashhad University of Medical Sciences, Mashha, Iran, [5]Immunology Research Centre, Buali Institute, Mashhad University of Medical Sciences, Mashhad, Iran.

Crohn's disease (CD) and ulcerative colitis (UC) are two major clinical manifestation of inflammatory bowel disease (IBD) with uncertain etiology thought to be triggered by interactions between various environmental, genetic, and immunologic factors. Previous studies on the association of UC and human leukocyte antigen (HLA) class II genes suggested a role for HLA DRB1 gene polymorphisms with this disease. Several studies reported that HLADRB1*1502 and HLADRB1*0101 are in association with UC in the different populations such as Japanese. The aim of this study was investigation of association between UC and HLA-DRB1 gene polymorphisms using molecular technique. 95 healthy controls and 85 patients with ulcerative colitis disease were enrolled in our study. Molecular technique based on PCR-SSP was recruited to detect HLA-DRB1 gene polymorphisms. Allelic analysis showed that HLA-DRB1*01 and HLA- DR B1*15 are not in association with UC in our patients whereas the common HLA-DRB1*04 allele is significantly associated with the disease ($p<0.05$). According to the results of this study, HLADRB1*04 allele seemingly has protective role against the ulcerative colitis disease in our patients, in Iran. Genetic factors also vary from region to region due to differences in race, ethnicity and geographical conditions. Future research on genetic susceptibility to ulcerative colitis in different regions in Iran might be helpful to people who are prone to this disease.
Key word: HLA DR B1, ulcerative colitis, HLA DRB1*04 , Iran, PCR-SSP

P5.18.23
SHIP represses auto-inflammation and is required for intestinal immune homeostasis

***E. N. Ngoh**, S. B. Weisser, H. Brugger, R. Jen, A. Hirschfeld, S. Turvey, L. M. Sly;*
Child and family Research Institute, BC Children's Hospital, University of British Columbia, Vancouver, BC, Canada.

Crohn's Disease (CD) is an inflammatory bowel disease characterized by inflammation in the gastrointestinal tract. It has been suggested that CD may result from a primary immune dysfunction in macrophages. Macrophages contain multi-protein complexes, inflammasomes that mediate the production of IL-1β, a key driver of auto-inflammation. The SH2 domain-containing inositol 5´-phosphatase, SHIP, is a hematopoietic-restricted negative regulator of class I PI3-kinases (PI3K). We have reported that SHIP-/- mice develop spontaneous intestinal inflammation that shares key

pathological features with CD. Herein, we demonstrate that ileal homogenates from SHIP knockout mice contain high levels of IL-1β. Ex vivo SHIP-/- macrophages produced significantly more IL-1β than SHIP+/+ upon inflammasome activation and increased IL-1β production was dependent on TLR activation of the p110α subunit of class I PI3K. Intestinal pathology was dramatically reduced in SHIP-/- mice by depleting macrophages with clodronate-containing liposomes or by treating mice with the IL-1 receptor antagonist, anakinra. Furthermore, we show that SHIP protein levels are low in PBMCs and ileal biopsies in a subset of subjects with ileal CD. A single nucleotide polymorphism (SNP) in the autophagy-related gene, ATG16L1, is a susceptibility locus for CD and we have found that reduced SHIP expression correlated with expression of the ATG16L1 SNP. Importantly, PBMCs from subjects with low SHIP levels produced more IL-1β than PBMCs from subjects with high SHIP levels. Taken together, our data suggest that CD may be caused by auto-inflammation in some people and that these people may be amenable to treatment with anakinra or other IL-1/IL-1R antagonists.

Multispecific anti-neutrophil cytoplasmic antibodies in chronic inflammatory bowel diseases: what does that mean?

B. Nikolic[1]*, M. Nikolic*[2]*, S. Dobric*[1]*, D. Popovic*[3]*, S. Andrejevic*[1]*;*
[1]*University of Belgrade, Faculty of Medicine, Department of Allergy and Clinical Immunology, Belgrade, Serbia,* [2]*University of Belgrade, Faculty of Medicine, Department of Dermatology, Belgrade, Serbia,* [3]*University of Belgrade, Faculty of Medicine, Department of Gastroenterology, Belgrade, Serbia.*

Background: Neutrophilic proteases and cationic proteins have antimicrobial and immunomodulatory effects. Recent data suggest an association between gut inflammation and immune response to commensal or pathogenic bacteria in inflammatory bowel diseases (IBD). We analyzed specificity of anti-neutrophil cytoplasmic antibodies (ANCA) in IBD patients and its clinical significance.
Methods: Data from 52 ulcerative colitis (UC) patients with 32 Crohn's disease (CD) patients were compared. Primary sclerosing cholangitis (PSC) was present in 12/84 patients. ANCA, ANA and anti-smooth muscle antibodies (ASMA) were detected by IIF. ANCA were tested by ELISA for proteinase 3 (PR3), myeloperoxidase, bactericidal/permeability increasing protein (BPI), elastase, cathepsin G, lysozyme and lactoferrin.
Results: pANCA were more frequently present in UC than in CD patients ($p<0.001$). ANCA titer correlated with the disease activity only in UC patients ($p<0.05$). UC patients more frequently had two or more ANCA specificities compared to CD patients ($p<0.01$). Patients with UC more frequently had ANCA specific to BPI ($p<0.01$) and PR3 ($p<0.05$) compared to CD patients. 14/22 UC patients with multispecific ANCA concomitantly had ANA and ASMA. Multispecific ANCA in medium and/or high concentrations were associated with long-lasting ($p<0.05$) and left-sided UC ($p<0.001$). Multispecific ANCA with ANA and ASMA had sensitivity 67% for PSC.
Conclusion: Higher concentrations of multispecific ANCA in long-lasting, left-sided UC suggest an influence of bacterial stimulation on the break of tolerance. Multispecific ANCA with ANA and ASMA could be markers for PSC. ANCA specific to several antigens may worsen inflammation by reducing antimicrobial capacity of neutrophil proteases and cationic proteins.

P5.18.25
Phenotypic and functional characterization of intraepithelial and lamina propria inflammatory cell infiltrate in autoimmune enteropathy

M. Paroni[1]*, G. Nizzoli*[1]*, A. Magarotto*[2]*, U. Gianelli*[2]*, C. Ciafardini*[2]*, D. Conte*[3]*, S. Abrignani*[1]*, J. Geginat*[1]*, F. Caprioli*[2]*;*
[1]*INGM, Milano, Italy,* [2]*Dipartimento di Fisiopatologia Medico-Chirurgica e dei Trapianti, Università degli Studi di Milano, Milano, Italy,* [3]*Unità Operativa di Gastroenterologia 2, Fondazione IRCCS Cà Granda, Ospedale Policlinico di Milano, Milano, Italy.*

Autoimmune enteropathy (AE) is a rare syndrome characterized by severe villous atrophy, lamina propria (LP) infiltration by T lymphocytes and increased intraepithelial lymphocytes (IEL).
We characterized phenotype and function of inflammatory cells obtained from duodenal biopsies at disease onset and after steroid therapy.
Biopsies' analysis revealed an extensive infiltration of IEL mainly expressing CD4-CD8+CD103+. These cells produced high amounts of IFN-γ and a relevant amount of them coexpressed IL-17. Steroid treatment reduced the number of IEL CD4-CD8+CD103+ as well as the amount of IFN-γ and IL-17. Within LP CD4+ T cells, we found the same proportion of CXCR3+ and CCR6+ and a relevant number of CXCR3+CCR6+ cells. LP CD4+ T cells expressed high levels of IFN-γ, IL-17 and IL-22, while CD8+ cells expressed mainly IFN-γ.
After therapy we observed an increased number of CXCR3+ and a decreased number of CCR6+ and CXCR3+CCR6+ cells. Nevertheless, the levels of IFN-γ were dramatically reduced while IL-17 and IL-22 were increased. Steroid treatment was not affecting CD8+ cytokine production. In LP we found two population of dendritic cells (DCs), one expressing cell myeloid marker CD11c and CD103, the other being CD11c- CX3CR1+. Steroid treatment induced an increase of CX3CR1+ DC and a decrease of CD11c+ CD103+ DC.
Our data demonstrated that active AE leads to a massive infiltration by CXCR3+, CCR6+ cells and activated CD8+ T cells in LP, which is reduced after steroid therapy.
These results could be relevant for the identification of novel therapeutic targets in patients with AE.

Decrypting the role of S1P/SphK axis in the dextran sulphate sodium-mediated colitis in mice

P. N. Pushparaj[1]*, L. A. Damiati*[2]*, S. D. Kumar*[3]*, K. Gauthaman*[1]*, J. Manikandan*[1]*, M. H. Al-Qahtani*[1]*;*
[1]*Center of Excellence in Genomic Medicine Research, King Abdulaziz University, Jeddah, Saudi Arabia,* [2]*Biology Department, King Abdulaziz University, Jeddah, Saudi Arabia,* [3]*Lee Kong Chian School of Medicine, Nanyang Technological University, Singapore, Singapore.*

Ulcerative colitis (UC) is one of the common types of inflammatory bowel disease (IBD) in humans. The aetiology is still not well defined. Dextran sulphate sodium-mediated colitis in mice is a well-studied model for human UC. In the present study, we have specifically decrypted the role of sphingosine 1 phosphate (S1P) and sphingosine kinase (SphK) in the development of DSS-colitis in mice. For acute colitis induction, the wild-type (WT) C57BL/6j, SphK1-/- and SphK2-/- mice were given 3.5% (weight/volume) DSS (molecular weight 36-50 kDa; ICN Biomedicals, Aurora, Ohio, USA) in their drinking water from day 0 for consecutive 7 days. The control mice were given with normal drinking water. The body weight, stool consistency, and rectal bleeding were monitored daily using the modified method of Cooper and colleagues. Body weight loss was calculated as the difference between the predicted body weight and the actual body weight on a particular day. All the mice were sacrificed on day 7. The blood samples were collected for the isolation of serum for S1P and multiplex cytokine assays. The colons were dissected and properly cleaned for morphological, histological and molecular analyses. The serum S1P levels were significantly elevated in the WT mice administered with DSS compared with SphK1-/- and SphK2-/- mice. Furthermore, both SphK1-/- and SphK2-/- mice were protected from body weight loss, colon shortening, and other pathological changes. Our results vouch for the importance of designing specific therapeutic strategies to target S1P/SphK axis in human UC in the near future.

Systems immunological strategies to decipher the genomic expression patterns in dextran sulphate sodium-mediated acute colitis

P. N. Pushparaj[1]*, L. A. Damiati*[2]*, J. Manikandan*[1]*, K. Gauthaman*[1]*, M. H. Al-Qahtani*[1]*;*
[1]*Center of Excellence in Genomic Medicine Research, King Abdulaziz University, Jeddah, Saudi Arabia,* [2]*Biology Department, King Abdulaziz University, Jeddah, Saudi Arabia.*

Dextran Sulphate Sodium (DSS)-induced colitis in mice is a thoroughly studied model for human UC. In the present study, we

have deduced the genomic signatures and biological pathways associated with DSS-induced colitis in mice using systems immunological approaches. Raw microarray expression (Affymetrix CEL) files (GSE22307) in the public domain derived from mouse colon tissue in response to DSS induction at day 0, 2, 4 and 6 were downloaded from the Gene Expression Omnibus (GEO) and analysed by Genespring GX 12.5 software (Agilent, USA). The significantly expressed genes were selected by a standard cut-off at 2-fold increased expression compared with the values on day 0. These differentially expressed genes were then classified based on Gene Ontology (GO) such as the expression of receptors, endopeptidases, regulation of inflammatory response, cytokines and chemokines as well as chemotaxis in the colonic epithelium of DSS-induced colitis in mice. Furthermore, the differentially expressed genes were analysed by Ingenuity Pathway Analysis (IPA) software. The Genespring GX12.5 analysis coupled with IPA to delineate the effect of DSS on the colonic epithelial cells has shown that it could potentially induce the expression of proinflammatory cytokines and chemokines, immune receptors, as well as the adhesion molecule expression in the colonic epithelium. Besides, it has also significantly induced the expression of transcription factors such as NFkB as well as the tissue destructive enzymes such as MMPs. Henceforth, designing and assessing biological therapies against these disease causing genomic signatures would help in the improvement of current therapeutic modalities against human UC.

P5.18.28
Dissecting the effect of resveratrol in dextran sulphate sodium-mediated colitis in Balb/c mice

P. N. Pushparaj[1], *S. D. Kumar*[2], *L. A. Damiati*[3], *J. Manikandan*[1], *K. Gauthaman*[1], *M. H. Al-Qahtani*[1];
[1]*Center of Excellence in Genomic Medicine Research, King Abdulaziz University, Jeddah, Saudi Arabia,* [2]*Lee Kong Chian School of Medicine, Nanyang Technological University, Singapore, Singapore,* [3]*Biology Department, King Abdulaziz University, Jeddah, Saudi Arabia.*

Resveratrol (3,5,4'-trihydroxy stilbene) is a phytoalexin. In the present study, we have dissected the therapeutic effect of resveratrol in dextran sulphate sodium (DSS)-mediated colitis in mice. For colitis induction, the male & female Balb/c mice were given 3.5% (weight/volume) DSS (molecular weight 36-50 kDa; ICN Biomedicals, Aurora, Ohio, USA) in their drinking water from day 0 for consecutive 15 days. The control mice were given only normal drinking water. The two treatment groups received 10 mg/Kg and 15 mg/Kg of resveratrol i.p in 200 µL respectively and 3.5% DSS in the drinking water. On the other hand, the positive control group received only 200 µL PBS i.p and 3.5% DSS in the drinking water. The body weight, stool consistency, and rectal bleeding were monitored daily using the modified method of Cooper and colleagues. Body weight loss was calculated as the difference between the predicted body weight and the actual body weight on a particular day. All the mice were sacrificed on day 15. The resveratrol treated mice given with DSS had significantly less body weight loss, colon shortening compared with the positive control. The amelioration of DSS-induced colitis in both male and female Balb/c mice could be ascribed to the decrease in local and systemic inflammation. Besides, it would be valuable to explore the therapeutic targets of resveratrol for the development of de novo therapeutics for ulcerative colitis in humans.

P5.18.29
TL1A/DR3 interaction is associated with pathogenesis of inflammatory bowel disease in adults and children

T. J. Slebioda[1], *P. M. Wierzbicki*[1], *M. Stanislawowski*[1], *K. Celinski*[2], *P. Landowski*[3], *B. Kaminska*[3], *A. Bojarska-Junak*[4], *J. Rolinski*[4], *K. Adrych*[5], *Z. Kmiec*[6];
[1]*Department of Histology, Medical University of Gdansk, Gdansk, Poland,* [2]*Department of Gastroenterology with Endoscopic Unit, Medical University of Lublin, Lublin, Poland,* [3]*Department of Pediatrics, Pediatric Gastroenterology, Hepatology and Nutrition, Medical University of Gdansk, Gdansk, Poland,* [4]*Department of Clinical Immunology, Medical University of Lublin, Lublin, Poland,* [5]*Department of Gastroenterology and Hepatology, Medical University of Gdansk, Gdansk, Poland,* [6]*Department of Human Histology and Embryology, Faculty of Medicine, University of Warmia and Mazury, Olsztyn, Poland.*

TL1A is a proinflammatory cytokine and the ligand for death receptor 3 (DR3). These proteins are strongly up-regulated on activated cells of the immune system. TL1A/DR3 interaction costimulates T-cells and induces production of several proinflammatory cytokines (including IL-4, IL-13, IL-17A, IFN-γ) by these cells. TL1A and DR3 are linked to the development of Crohn's disease (CD) and ulcerative colitis (UC), although their exact pathological role remains unknown. In this study, we investigated the mRNA level of TL1A, IL-4, IL-13, IL-17A and IFN-γ in colon mucosal biopsies of paediatric and adult inflammatory bowel disease (IBD) patients. We found that expression of TL1A was significantly elevated in inflamed but not in non-inflamed colonic tissue of both CD and UC patients as compared to healthy individuals. Interestingly, we detected up-regulation of DR3 only in inflamed colonic tissue of paediatric but not adult patients. Up-regulation of TL1A mRNA was accompanied by elevated expression of proinflammatory cytokines and positively correlated with the expression level of IL-17A mRNA in inflamed and non-inflamed tissue of both paediatric and adult UC patients. Furthermore, TL1A and DR3 protein expression was localized by immunohistochemical technique not only to mucosa-infiltrating mononuclear cells but also to enterocytes. Our study also provides evidence for the first time that TL1A mRNA expression is significantly higher while DR3 mRNA expression is significantly lower in healthy adults compared to healthy children. These findings show that TL1A contributes to the development of IBD via induction of IL-17A expression and this observation may have therapeutic implications.

P5.18.30
Anti-TNF-alpha monoclonal antibody therapy of crohn's disease is associated with acute reduction of circulating classical and intermediate monocyte numbers

S. M. Slevin[1], *C. Dennedy*[1], *A. Ribeiro*[1], *R. Ceredig*[1], *M. D. Griffin*[1], *L. J. Egan*[2];
[1]*REMEDI, National University of Ireland, Galway, Galway, Ireland,* [2]*Discipline of Pharmacology and Therapeutics, National University of Ireland, Galway, Galway, Ireland.*

Monocytes, recently classified as $CD14^{++}/CD16^{-}$ (classical), $CD14^{++}/CD16^{+}$ (intermediate) and $CD14^{+}/CD16^{++}$ (non-classical), play an as-yet poorly characterised role in inflammatory bowel disease (IBD) pathogenesis. In this study, proportions and absolute numbers of circulating monocyte subsets were determined by flow cytometry of fresh PBMC samples from 3 groups: **A**. Healthy controls (n=16); **B**. Crohn's Disease (CD) not receiving infliximab (n=6); **C**.CD receiving infliximab (n=19). For Group C, samples were analysed before and after anti-TNF-[[Unsupported Character - Symbol Font α]] (infliximab) infusions.
Total monocyte numbers were higher in Group A compared to Groups B and C, (15.0±3.4; 10.0±3.0 and 4.5±5.8 $x10^4$ cells/ml respectively; $p<0.0001$, one-way ANOVA). Group C total monocytes were further reduced to 1.7±1.4 $x10^4$ cells/ml following infliximab ($p=0.05$, paired t-test). Subset analysis indicated that classical monocytes were reduced to the greatest degree in CD patients (Group A 10.4±3.1; Group B 5.2±2.5; Group C, 2.0±2.1 pre-infliximab and 0.6±0.6 $x10^4$ cells/ml post-infliximab, $p<0.0001$). Similar trends were present for intermediate monocytes (Group A 3.4±1.8; Group B 2.7±1.3; Group C, pre-infliximab 1.5±2.2; Group C, post-infliximab 0.6±0.6 $x10^4$ cells/ml, $p<0.0001$), although the magnitude of the differences were not as great resulting in a proportionate increase in

intermediate monocytes in CD patient groups. Non-classical monocyte numbers demonstrated no significant differences between the groups.
Thus, Crohn's Disease is associated with reduction in total monocytes in the circulation that predominantly affects the classical subset. Infliximab infusion leads to further reduction in the classical and, to a lesser extent, intermediate subset suggesting that anti-TNF therapy directly targets specific monocyte populations.

P5.18.31
A crude extract of hydatid laminated layer prevents Dextran Sulfate Sodium induced-colitis in mice by Nitric Oxide Synthase2 down-regulation

***I. Soufli**, H. Rafa, M. Amri, R. Toumi, K. Abdelouhab, C. Touil-Boukoffa;*
University of Sciences and Technology Houari Boumediene, Team cytokines and NOsynthases, Laboratory of Cellular and Molecular Biology., Algiers, Algeria.

Inflammatory bowel diseases (IBD) are immunologically mediated diseases, they are more prevalent in developed countries but less frequent in countries where exposure to helminthes is common. Several studies suggest strongly a beneficial role of helminthes in IBD experimental models. Recent work of our team showed that Nitric Oxide (NO) production is strongly implicated in human IBD pathogenesis as well as in experimental colitis. *Echinococcus granulosus* is helminth which causes cystic hydatid disease; cysts of *E.granulosus* are able to survive for several years in chronic infection. Previously, our team showed that laminated layer extracted from the cyst wall induces parasitic protection by down-regulating NO production. The aim of the current study is to investigate the immuno-modulatory effect of the hydatid laminated layer in Dextran Sulfate Sodium (DSS) induced colitis model. An acute colitis was induced in Swiss mice using 2.5% DSS and the prophylactic effect of the laminated layer was investigated. A crude extract of laminated layer was daily administered orally starting five days before colitis induction. Colonic damage was evaluated histologically and NOsynthase2 expression was assessed by immunofluorescence staining. The production of NO was concomitantly measured in the supernatants of peritoneal macrophages (pMϕ) cultures. Interestingly, our results showed significant NO decrease levels in supernatant of pMϕ cultures in correlation with an important inhibition of colonic NOsynthase2 expression and decrease of mucosal alterations when compared with non treated mice.
Collectively, our findings suggest a potential preventive effect of the laminated layer by local NOsynthase2 down regulation in this model of colitis.

P5.18.32
Transfer of Myeloid Derived Suppressor Cells from neonatal tolerized IL-10 gene-deficient mice protects from development of intestinal inflammation.

***B. C. Sydora**, E. J. Albert, R. R. Foshaug, B. S. Sydora, R. N. Fedorak;*
University of Alberta, Edmonton, AB, Canada.

Myeloid-derived suppressor cells (MDSCs) are a heterogeneous population characterized by the co-expression of CD11b and Gr-1 that exhibit potent immunosuppressive functions. We have previously shown that these cells greatly expand in IL-10 gene-deficient mice, tolerized as neonates to endogenous bacterial antigens, and are involved in the suppression of the bacterial antigen-stimulated T cell responses and, hence, reduced intestinal inflammation in these mice. To investigate whether MDSCs from tolerized mice can suppress colitis development in recipient IL-10 gene-deficient mice we isolated CD11b+ MDSCs by FACS from spleen cell cultures of 20 week old mice and transferred 106 cells per mouse by intra peritoneal injection into 8 week old IL-10 gene-deficient mice before the microscopic visible onset of colonic inflammation. Control littermates were injected with saline. Mice were analyzed 10 weeks later for macroscopic and histopathologic intestinal injury, pro-inflammatory cytokine and myeloperoxidase (MPO) release. Adopted transfer of CD11b+ MDSCs resulted in reduced incidence and severity of intestinal inflammation in IL-10 gene-deficient mice at age 18 weeks as judged by significantly reduced numbers in injury scores (0.8 ± 0.8 versus 4.4 ± 1.2 in controls) and colon weight/length ratio (49.3 ± 9.6 versus 76.7 ± 7.5 in control) as well as a decrease in intestinal MPO and IFNγ release compared to saline treated controls. Treatment with MDCS can protect IBD-prone IL-10 gene-deficient mice from developing disease. These results indicate that MDSCs play an immunoregulatory role in intestinal inflammation and that an enrichment of MDSCs may provide a therapeutic approach for IBD development.

P5.18.33
Infiximab Simultaneously Restore Foxp3$^+$Treg, Type 1-Like Treg and B cells in IBD

*Z. Li[1,2], S. Vermeire[3], D. Bullens[1], M. Ferrante[3], K. Van Steen[4,3], M. Noman[3], P. Rutgeerts[3], J. L. Ceuppens[1], **G. Van Assche**[3];*
[1]Catholic University of Leuven, Clinical Immunology Unit, Leuven, Belgium, [2]Tongji University, Tenth Hospital, Shanghai City, China, [3]Catholic University of Leuven,IBD group,Division of Gastroenterology, Leuven, Belgium, [4]Université de Liège,Dept of Bioinformatics -Statistical Genetics, Liège, Belgium.

Background: Infliximab (IFX) increases circulating Foxp3(+)T cells in patients(pts) with IBD. Co-expression of CD45RA & Foxp3 distinguishes resting & active Treg(rTreg&aTreg) from Foxp3(+)effector T cells(Teff). Subsets of B cells induce Tr1-like cells(Tr1L) and expand Foxp3+Treg.
We investigated these cells in IBD during IFX therapy.
Methods: Blood was taken from healthy controls(HC, N=37) and pts (N=99) and assessed by flow cytometry. Globe Assessment distinguished responders(RS, N=59) from non-responders (NRS, N=15).
Results: 1. Pts before therapy had low rTreg(0.43±0.080, p<0.001), aTreg(0.62±0.12, p<0.001), Foxp3Teff(2.38±0.27, p=0.002) , Tr1L(4.79±0.68,p<0.001) and B cells(0.17±0.02, p=0.002)(N=25), compared with HC(1.47±0.16),(2.40±0.17),(3.75±0.34),(16.82±1.7) and (0.27±0.02)(10e6/L blood mean±SEM for Tr1L, 10e9/L for others).
2. Compared with baseline, change was seen in rTreg(RS: 1.57±0.21, p<0.001; NRS: 1.14±0.24, p<0.001), aTreg(RS: 2.70±0.26 , p<0.001; NRS: 1.48±0.33,p=0.0057), Foxp3+Teff (RS: 3.19±0.24, p=0.09; NRS: 3.02±0.41,p= 0.25),Tr1L(RS: 26.09±2.21, p<0.001; NRS: 8.92±1.00, p=0.013) and B cells(RS: 0.25±0.03, p=0.035;NRS:0.14±0.01, p=0.31).
3. Significant differences between RS and NRS only for aTreg, Tr1L and B cells(p=0.0067, <0.001, <0.001).
4. CRP negatively correlated with rTreg, aTreg, Tr1L and B cells (p=0.0011, r=- 0.32),(p<0.001, r=- 0.40),(p<0.001, r=- 0.39) and(p=0.044, r=- 0.21).
5. B cells positively correlated with rTreg, aTreg and Tr1L(p=0.002, r=0.31), (p<0.001, r=0.49) and(p<0.001, r=0.37).
Conclusions: Foxp3T cells,Tr1L and B cells are decreased in active IBD and an increase in these cells (except for Foxp3Teff) correlates with biological response and/or with the clinical response. The positive correlation between B cells and others might suggest a cross talk between B cells and Tregs.

P5.18.34
BCG-specific lymphocyte proliferation and cytokine in patients with Crohn` s disease under anti-TNF- α and azathioprine therapy.

*V. Oya[1], T. Davanço[2], C. S. R. Coy[2], M. T. N. da Silva[2], T. N. Mazzola[2], A. M. Morcillo[2], E. L. C. Pinto[2], **M. M. S. Vilela**[2];*
[1]State University of Campinas Medical School- UNICAMP, Campinas São Paulo, Brazil, [2]State University of Campinas Medical School - UNICAMP, Campinas, São Paulo, Brazil.

Background: Anti-TNF-alpha, in combination with azathioprine, is used in patients with Crohn Disease (CD) and may result in an increased risk of infection and latent tuberculosis reactivation.
Objectives: To evaluate BCG-specific lymphocyte proliferation and cytokine production in cultures with peripheral blood mononuclear

cells (PBMC) from patients with Crohn's disease under anti-TNF- α and azathioprine therapy.
Methods: Thirty-two patients who were using anti-TNF-α and azathioprine (Group A) and 11 patients using only azathioprine (group B) were followed up at the Gastrocenter, UNICAMP, all of them with BCG scar. The comparison group consisted of 34 healthy individuals (group C) with BCG scar. BCG-specific lymphoproliferation and T-cell subsets CD4+, CD8+ and TCR γδ+ were analyzed by flow cytometry and cytokine concentration by ELISA. Data analysis was performed with Kruskal-Wallis test and nonparametric multiple comparison ($p < 0.05$).
Results: When compared to the healthy control group the patients from group A and group B showed significant reduction ($p < 0.001$) in the following parameters: BCG-specific lymphoproliferation, TCRγδ+ lymphoblasts and production of IFN-γ, TNF-α, IL-6 and TGF-β1. However, there was no statistical difference when the A and B patient groups were compared.
Conclusion: We conclude that BCG specific adaptive immune response in patients with CD treated with TNFα inhibitors and azathioprine is reduced and may contribute to an increase in the risk of infection and latent tuberculosis reactivation. Although BCG scar was present before starting therapy, the patients should be screened for possible latent infections.
Financial support: FAPESP process: 07/57558-2 and 2008/53902-3.

P5.18.35
Prevalence of IgA anti-zein antibodies in Mexican patients with celiac disease (CD) and irritable bowel syndrome (IBS)

*L. A. Sanchez-Vargas[1], J. M. Remes-Troche[1], G. Mellado-Sanchez[1], E. Bravo-Sarmiento[2], **H. Vivanco-Cid**[1];*
[1]Instituto de Investigaciones Medico-Biológicas. Universidad Veracruzana, Veracruz, Veracruz, Mexico, [2]Centro Estatal de Transfusión Sanguínea de Veracruz, Veracruz, Veracruz, Mexico.

Introduction: A high prevalence of CD is found among patients with a clinical diagnosis of IBS. CD is a gluten-sensitivity autoimmune disease of the small intestine affecting genetically susceptible individuals worldwide. The gluten-free diet is not enough to treat Celiac Disease patients, because some of them present high inflammation, poor vitamin status, and leaky gut which persist on a gluten-free diet, suggesting there are cross reactivity or specific immune responses against related-prolamines in other cereals. In this study we evaluated the prevalence of IgA anti-zein antibodies (IgA-AZA) in a group of Mexican patients diagnosed with CD and IBS. Corn has been the basis of the Mexican diet for thousands of years, however the humoral response against zein has not been studied before. Methods: 23 CD and 366 IBS patients were included in this study. All of the IBS subjects met the Rome III criteria and were negative for the following tests: IgA h-tTG, IgA and IgG Gliadin II (INOVA diagnostics, Inc). IgA-AZA were measured by ELISA. Results: 4 patients with CD (17.39%) were positive to IgA-AZA. The prevalence among women was 15.78% (3/19) and for men 25% (1/4). 13 patients with IBS (3.55%) were positive to IgA-AZA. The prevalence among women was 4.16% (13/312). Conclusion: There is a high prevalence of IgA-AZA (17.39%) in Mexican patients with CD and even in patients with IBS. These results open the possibility to explore more about the contribution of the humoral response to zein in the immunopathogenesis to CD and IBS.

P5.18.36
NDST4 deficiency enhances acute colitis and colitis-associated tumorigenesis in mice

*C. Y. Huang[1], M. H. Tsai[2,3], T. M. Jao[1], S. T. Tzeng[1], J. X. Lee[1], W. C. Lo[1], C. W. Chang[1], Y. L. Li[1], **Y. C. Yang**[1,4];*
[1]Department of Clinical Laboratory Sciences and Medical Biotechnology, College of Medicine, National Taiwan University, Taipei, Taiwan, [2]School of Medicine, Fu-Jen Catholic University, New Taipei City, Taiwan, [3]Department of Surgery, Cardinal Tien Hospital, New Taipei City, Taiwan, [4]Department of Laboratory Medicine, National Taiwan University Hospital, Taipei, Taiwan.

NDST4 is one member of N-deacetylase/N-sulfotransferase (heparan glucosaminyl) (NDST) family, which are responsible for heparan sulfate (HS) biosynthesis on a core protein to form heparan sulfate proteoglycans (HSPGs). The HS chains of HSPGs bind to and regulate their functions of various growth factors, cytokines and chemokines. HSPGs ubiquitously reside on cell surface, inside the cell, and in the extracellular matrix. Importantly, the content and distribution of HSPGs are altered during tumorigenesis. Here we show that 30 (57.7%) out of 52 human colorectal carcinomas exhibited a dramatic reduction in NDST4 RNA transcripts, and that genetic loss of NDST4 was significantly associated with poor survival of patients with colorectal cancer. In addition, we generated an NDST4-knockout mouse strain, which developed and reproduced normally, while showed a marked increase in the thickness of the colonic crypts and the number of goblet cells of the colonic mucosa. Using the dextran sodium sulfate model of acute colitis, homozygous NDST4 mutants showed a significantly higher disease activity index and obviously hyperemic appearance in the cecum. In a colitis-associated cancer model, the size of colonic tumors induced by azoxymethane/dextran sodium sulfate was significantly increased in NDST4-deficient mice compared with wild-type mice. These results suggest that NDST4 might limit tumor-promoting inflammation and tumorigenesis by regulating the modification of HS chains of specific HSPGs in colon.

P5.19.01
HLA antigens and anti-sperm antibody

***G. Azizi**[1], A. Mirshafiey[2], M. Eslami[2], S. Namaki[3];*
[1]Alborz University of Medical Sciences, karaj, Iran, [2]Department of Immunology, School of Public Health, Tehran University of Medical Sciences, Tehran, Iran, [3]Department of Pathobiology, Faculty of Paramedical Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran.

Background: Anti-sperm antibodies (ASAs) leading to autoimmune male infertility. It is suggested that HLA antigen play key roles in the autoimmune diseases and antibody production. Therefore in this study we evaluated the serum ASA in men after vasectomy and investigated the correlation of ASA production with HLA class I and II in vasectomized men.
Methods: 110 vasectomized and 130 healthy men were examined for ASAs by Gelatin Agglutination Test (Kibrick) and indirect mixed antiglobulin reaction (MAR) test. Also their HLA-A, B, C, DR and -DQ frequency were investigated using microlymphocytotoxicity method in T cells and B cells.
Results: The ASA was detected in 95% vasectomized men, regarding that 53% have an ASA titer of 1/32 or 1/64. Whereas, the levels of ASA only in 13.8% normal men were positive with maximum titer 1/8. No statistically significant correlation was found between the high responder group and frequency of HLA antigens, but a statistically significant correlation was observed in the low responder group and frequency of HLA-A2 and DQw2 antigens. **Conclusion:**
Predisposition to produce ASA seems correlate with HLA class I and II antigens, so that men expressing HLA-A2 and DQw2 produced lower ASA than other populations, although understanding the impact of these findings requires further study.

P5.19.02
Multiple immune accentuations predict implantation failure and mark target group among IVF patients for intravenous immunoglobulin therapy

***V. Chernyshov**[1], I. Sudoma[2,3], B. Dons'koi[1], Y. Goncharova[2];*
[1]Institute of Pediatrics, Obstetrics and Gynecology, Kiev, Ukraine, [2]Nadia Clinic for Reproductive Medicine, Kiev, Ukraine, [3]National Medical Academy for Post-graduate Education, Kiev, Ukraine.

Problem: Studies of immune markers that predict implantation failure and show indications for intravenous immunoglobulin therapy may be perspective for IVF results.
Method of study: Totally 244 women (≥3 IVF failures) in IVF program were investigated as two groups: 123 women not treated by IVIG and 121 women treated by IVIG. Flow-cytometry was used to study NK

cell cytotoxicity, lymphocyte subsets and expression of activating molecules on them.
Results: We selected some immune accentuations (IA) that predict implantation failure: elevated expression of CD56 and CD158 in T cells, decreased levels of T helper cells and increased levels of CD8 T cells, elevated expression of HLA-DR in CD8 T and NK cells, elevated NK cell count and NK cytotoxicity, decreased expression of CD158a and CD8 in NK cells. In women without or with isolated IA Pregnancy Rate (PR) and Birth Rate (BR) were 50.9% (27/53) and 33.9% (18/53). In contrast, patients with more than 2 IA had dramatically decreased PR and especially BR 21% (9/42) and 9.5% (4/42). Patients with more than 2 IA had not decrease of PR (43%, 20/46) and BR (30.4%, 14/46) if IVIG treatment was used. These indices were significantly higher in comparison to women not treated by IVIG. So IVIG treatment significantly increased PR and BR in women with multiple immune accentuations.
Conclusions: Multiple immune accentuations (more than 2) may serve as immune markers that predict implantation failure and at the same time mark target group for intravenous immunoglobulin therapy to improve results of IVF procedure.

P5.19.03
Features of the immune response and microbial colonization in children with extremely low birth weight

***G. Chistyakova**;*
Mother and Child Care Research Institute of Russian Public Health Ministry, Yekaterinburg, Russian Federation.

101 newborns with extremely low birth weight (ELBW) from birth until 38-40 weeks of adjusted age were examined: 60 children with a gestational age of 23-27 weeks, and 41 infants - 28-31 weeks. The control group included 18 full-term infants. Cytokines and acute-phase proteins were determined using kits made by Vector-Best (Russia). The immune system of premature infants with ELBW at birth was characterized by leukopenia, neutropenia, decreased levels of lactoferrin, ferritin, haptoglobin, IFN-γ and increased expression of the apoptosis-related molecule CD95 and C-reactive protein (CRP) concentrations. The ratio of INF-γ-and IL-4-producing T cells is biased towards the Th-1 path. The children with ELBW at term had increased B-lymphocyte and NK-cell numbers and preserved Th1-dependent immune responses while maintaining leukopenia and neutropenia and reduced content of lactoferrin, ferritin and CRP. Children born at 23-27 weeks of gestation had decreased neopterin concentration, children born at term (28-31 weeks) had a reduced level of haptoglobin. All the children with ELBW at 5-7 days of life had a colonization of the intestine by gram-positive cocci. Coccal flora of the intestine pushed by the opportunistic pathogens for the gestational age full-term children (to a greater degree in children, born with a lower gestational age), while receiving antibiotic therapy and passive immunization which was associated with a violation of the local (reduced sIgA in coprofiltrates) and system (reduction of neopterin in the blood) immunity.

P5.19.04
Maternal-fetal immunotolerance from mice with pregnancy loss induced by adoptively transferring exosomes from T lymphocytes

***C. Cui**[1], S. Hao[2], Y. Wang[2], M. Li[2], W. Lv[2];*
[1]Bethune Military Medical College, Shijiazhuang, China, [2]Fourth Hospital of Hebei Medical University, Shijiazhuang, China.

Objective: To explore the feasibility of exosomes from T lymphocyte as a non-cellular therapy that can replace the traditional cellular therapy on unexplained recurrent spontaneous abortion (URSA). Methods: Exosomes from splenocytes of BALB/c male mice were isolated by sucrose gradient ultracentrifugation and ultrafiltration. CBA/J (♀) without mating as non-pregnancy. CBA/J (♀) ×BALB/c (♂) as normal pregnancy, and CBA/J(♀) ×DBA/2 (♂) as URSA were randomly divided into groups of URSA, Cellular Therapy and Non-cellular Therapy. The rates of fetal absorption and pregnancy loss were calculated. A492 of induced proliferation were measured through MTT, the expressions of Th1-type (IFN-γ, IL-2) and Th2-type cytokines (IL-4, IL-10) were analyzed by flow cytometry. Through immunohistochemical staining, the expressions of immunosuppressors (TGF-β1, IL-10, COX-2) were analyze. Results: After both of cellular and non-cellular adoptive transferring, the rates of embryo adsorption and pregnancy loss, and the A492 of splenocytes decreased significantly (All $P<0.01$), in which the effects of non-cellular therapy exerted greatly more than cellular therapy ($P<0.05$). Conclusions: (1) Adoptive transfer of periphery lymphocytes or their non-cellular components can induce maternal-fetal immunotolerance, which should be helpful for normal pregnancy. (2) Adoptive transfer of non-cellular components from paternal lymphocytes can induce stronger maternal-fetal immunotolerance than T lymphocytes. (3) Peripheral lymphocytes or non-cellular components should initiate Th2 shift and local immunosuppressions in placenta, and induce efficient maternal-fetal immunotolerance. (4) Non-cellular components secreted by T lymphocytes from paternal individuals could become a biological product, which should replace traditional adoptive immunotherapy of lymphocytes.

P5.19.05
The predominance of Th17 lymphocytes and decreased number and function of Treg cells are present in preeclampsia

***D. A. Darmochwal-Kolarz**, M. Kludka-Sternik, B. Kolarz, J. Rolinski, J. Oleszczuk;*
Medical University of Lublin, Lublin, Poland.

Problem: The aim of the study was to estimate the prevalence of T lymphocytes producing IL-17, T regulatory cells and the immunosuppressive activity of Treg cells of patients with preeclampsia in comparison with healthy women in the third trimester of pregnancy. Material and methods: 34 patients with preeclampsia and 27 healthy women in third trimester of pregnancy were included to the study. The percentage of Treg cells and CD3+CD4+ T lymphocytes with intracellular expressions of cytokines were estimated using flow cytometry. The in vitro functional assays were performed with the use of Treg Cells Isolation Kit and 3H-thimidine. Results: The percentages of T lymphocytes producing IL-17A were significantly higher in preeclampsia when compared to healthy normotensive pregnant women in the third trimester of normal pregnancy. The population of Treg cells was significantly lower in the study when compared to the control group. There were no changes in the stimulation index of CD3+CD4+CD25- T lymphocytes of patients with preeclampsia during in vitro assay without Treg cells and after the addition of autologous Tregs. In normal pregnancy the stimulation index of CD3+CD4+CD25- T lymphocytes was significantly higher without Treg cells when compared to this response after addition of autologous Tregs. Conclusions: The results obtained suggest the up-regulation of Th17 immune response in preeclampsia. It seems that the decreased number and function of Treg cells may be responsible for the activation of inflammatory response in this disorder. In preeclampsia the predominance of Th17 immunity can act through the modulation of Th1/Th2 immune response.

P5.19.06
Effect of prenatal steroid treatment on the developing immune system

***I. Dipenbruck**[1], C. C. Much[2], A. Krumholz[3], R. Thieme[4], D. Thieme[3], M. Solano[4], P. C. Arck[4], E. Tolosa[1];*
[1]UKE - Dept. of Immunology, Hamburg, Germany, [2]UKE - Dept. of Radiology, Hamburg, Germany, [3]Institute of Doping Analysis and Sports Biochemistry, Dresden, Germany, [4]UKE - Laboratory for Experimental Feto-Maternal Medicine, Hamburg, Germany.

Prenatal steroids have an undisputed positive effect decreasing neonatal morbidity and mortality by improving fetal lung maturation. Some concerns have been raised on long term consequences on the HPA axis and cognition, but there are no studies addressing effects on the immune system. The thymus is an essential organ for the development and selection of T cells, and thymocytes are extremely sensitive to steroids. Using a mouse model for prenatal steroid administration, we show here that betamethasone treatment to the mother has a profound effect on the thymus of the offspring. We find the thymus volume reduced, affecting mostly the developing CD4+ CD8+ double positive thymocytes, and a compensatory accelerated

transition of the earlier stages to replenish the depleted compartment. This effect lasts for at least three days, which correspond to a very relevant period for the selection of the T cell repertoire. Moreover, we show that low doses of betamethasone have similar effects on human thymocytes. Therefore, further studies are needed to analyze possible long-term consequences of this treatment on the immune system of the offspring.

P5.19.07
HLA-G6 and reproductive immunology

***F. Farzad**, S. Abediankenari, I. Naghavian;*
Mazandaran University of Medical Sciences, Sari, Iran.

Background:The definite cause of several pathologies of pregnancy including reproductive failure is still unknown. HLA-G6, a nonclassical class Ib HLA, is novel molecule in the tolerance between fetus and mother. The purpose of this study was evaluation of HLA-G6 soluble isoforms and also difference in total expression of these antigens in threatened miscarriage pregnant women termination to reproductive failure in comparison with control group.
Materials & Methods: The study sample enrolled 101 threatened miscarriage pregnant women in age of 20-32Y in first trimester without any physiological or genetic disorders related to reproductive failure as cases and 101 women with normal pregnancy by history of term pregnancy and no miscarriage as controls. We evaluated expression of HLA-G6 soluble isoforms on PBMCs by Real-time PCR.
Results: The results showed the significant decrease in expression level of HLA-G6 isofrms in threatened miscarriage pregnant women in comparison with controls ($p< 0.05$).
Conclusion: The different concentration of HLA-G6 molecule is necessary for saving of pregnancy. Therefore, it is concludedthat HLA-G6 is an important molecule as predictive marker in early stages of reproductive failure for setting a clinical test.

P5.19.08
Automated clustering of flow cytometry data identifies a Th0 population induced by influenza vaccination in pregnant women

***D. Gilmandyar**, D. Roumanes, J. Rebhahn, L. Thornburg, T. R. Mosmann;*
University of Rochester, Rochester, NY, United States.

Pregnancy alters the immune system, causing increased susceptibility to pathogens such as Influenza virus, and/or increased disease severity. This may be related to the proposed feto-protective model of a shift in T effector cell responses away from Th1 (and possibly towards Th2) during the gestational period. We recently showed that Ki-67 is a sensitive marker of influenza vaccination responses in non-pregnant individuals. We investigated responses to influenza vaccination during pregnancy using Ki-67 expression to focus on vaccine-induced responses. Blood was collected from pregnant and non-pregnant subjects prior to vaccination, at 7 and 28 days post vaccination, and 12 weeks postpartum. We evaluated CD4 T cell cytokine secretion after in vitro stimulation with influenza vaccine and 16-color flow cytometry. Datasets were analyzed with SWIFT, our new, high resolution flow cytometry algorithm, that uses model-based clustering to objectively detect very small altered populations in large, high-dimensional datafiles. Assigning samples to cluster templates allows rigorous comparison between samples. Both pregnant and non-pregnant subjects responded to the vaccine, as we detected a transient influenza-specific Ki-67+ cytokine-secreting population at day 7 in both groups. We also discovered an unusual CD4 T cell population secreting high levels of IL-10, IL-4 and IFNgamma in response to influenza. These cells were present in pregnant day 7 samples, but not in pregnant day 0 samples, or day 0 or 7 samples of non-pregnant subjects. Thus pregnancy does not prevent the Ki-67 response to influenza vaccination, but does produce a distinctly altered cytokine pattern, consistent with a stronger Th0 phenotype.

P5.19.09
Inflammation as a cause of placental dysfunction in high-risk pregnancies

***S. Girard**, A. E. P. Heazell, H. Derricott, C. P. Sibley, S. M. Allan, R. L. Jones;*
University of Manchester, Manchester, United Kingdom.

Inflammation during pregnancy is associated with stillbirth and life-long diseases in surviving newborns. The mechanism underlying this association is mostly unknown. We hypothesize that cytokines induce placental dysfunction, resulting in fetal nutrient/oxygen deprivation. To test this hypothesis we determined the inflammatory profile in human placentas from high-risk pregnancy associated with reduced fetal movements (RFM) and investigated the effects of identified cytokines on placental function.
Methods: Term placentas were collected from women experiencing RFM and compared with uncomplicated pregnancies. ELISA and immunohistochemistry were used to determine cytokine levels in placental lysates and assess their localization respectively. Placental explants from normal pregnancies were treated with interleukin (IL)-1 and the effects on inflammation, hormone production and cell turnover were determined.
Results: Levels of IL-1β and IL-1 receptor antagonist (IL-1Ra) were increased in RFM pregnancies, while levels of IL-6 and TNF- remained unchanged. Placentas from pregnancies with RFM also showed a decreased expression of IL-10, suggesting a pro-inflammatory imbalance within the tissue. RFM placentas also had elevated numbers of CD45+ cells within placental parenchyma, which were highly positive for IL-1Ra. Treatment of placental explants with IL-1 led to decreased secretion of hormone (hCG) and immune activation.
Conclusion: This study identifies a pro-inflammatory profile in high-risk pregnancies associated with RFM, characterized by a predominant involvement of the IL-1 system and decreased anti-inflammatory IL-10. IL-1-treated placental explants showed altered function. These results emphasize the importance of inflammation-induced placental dysfunction in human high-risk pregnancies and subsequent fetal mortality and morbidity.

P5.19.10
Inhibition of TLR3 mediated direct natural killer cell activation by a macrolide antibiotic clarithromycin

*N. Hirohata, S. Komine-Aizawa, **S. Hayakawa**;*
Department of Microbiology, Nihon University School of Medicine, Tokyo, Japan.

Anti-inflammatory benefits of macrolide antibiotics s have long been reported in patients with chronic pulmonary inflammatory disorders. They are also prescribed for pregnant women with premature labour and threatened miscarriage. However, their effects on female reproductive immune responses are so far unknown. Human uterine mucosa especially decidual tissues contain a large number of Natural killer (NK) cells. They provide resistance to viral infections and play important roles in immune -surveillance and possible regulatory roles for maintenance of pregnancy. However over activation of uterine NK cells is considered to be involved in pregnancy failures including recurrent spontaneous abortion and premature labour.
In the present study we investigated inhibitory effects of a macrolide antibiotic clarithromycin (CAM) on TLR3 mediated interferon-γ (IFN-γ) production by human mucosal CD56+ NK cell line KHYG-1 using ELISA and flow cytometry.
We observed dose and time dependent suppression of the Poly(I:C) and IL-2 +IL-12 induced IFN-γ production in KHYG-1 cells. Of interest, CAM showed no remarkable suppression of other cytokine production including IL-22. Taken together, we propose decidual natural killer cells as novel targets of clarithromycin other than its antibacterial effects by inhibition of bacterial protein synthesis by binding to the bacterial 50S ribosomal subunit . As the safety of clarithromycin for early pregnant subjects has been reported recently on large cohort clinical studies, its use for prevention of miscarriage can be justified.

P5.19.11
The export of T helper cells from thymus during pregnancy

S. Hellberg[1], *R. B. Mehta*[1], *M. Edström*[1], *A. Forsberg*[1], *G. Berg*[2], *O. Winqvist*[3], *M. C. Jenmalm*[1], *J. Ernerudh*[1];
[1]*Division of Clinical Immunology, Unit for Autoimmunity and Immune Regulation, Department of Clinical and Experimental Medicine, Faculty of Health Sciences, Linköping University, Linköping, Sweden,* [2]*Division of Obstetrics and Gynecology, Department of Clinical and Experimental Medicine, Faculty of Health Sciences, Linköping University, Linköping, Sweden,* [3]*Translational Immunology Unit, Department of Medicine, Karolinska Institute, Stockholm, Sweden.*

Recent thymic emigrants (RTEs) comprise an essential population of T cells, connecting thymic output to the recirculating T cell pool, which can be a useful measure of thymic function. Little is known about the role of thymus in human pregnancy and pregnancy-associated tolerance. In this study we explore the role of thymus in human pregnancy by analyzing the output of T helper cells from the thymus. DNA from isolated CD4+ blood cells from healthy 2nd trimester pregnant and non-pregnant women were analyzed by RT-PCR for the content of T cell receptor excision circles (TRECs), which are enriched in newly synthesized T cells. Further, whole blood was analyzed for the frequency of RTE T helper subsets in pregnant and non-pregnant women by flow cytometry, utilizing CD31 as a marker of recent thymic exposure. Pregnant women had significantly reduced levels of TREC in the CD4+ population as compared to non-pregnant women, indicating a reduced output of the CD4+ population from thymus. Next, we attempted to determine if the decreased output during pregnancy also included regulatory T cells (Tregs). Preliminary results suggest that pregnant women rather have an increased frequency of RTE Tregs. In conclusion, we show that the TREC levels in CD4+ cells are reduced in pregnant women, likely as a result of reduced output of the entire T helper cell population from thymus. However, the output of Tregs may be differently regulated in pregnant women, contributing to the establishment and maintenance of the fetal-tolerant environment in pregnancy.

P5.19.12
Expression of LAG-3, but not PD-1, is enriched on double negative T cells at the female genital tract

J. Juno[1], *J. Lajoie*[1], *C. Wachihi*[2], *M. Kimani*[2], *J. Kimani*[2], *F. Plummer*[1], *K. Fowke*[1];
[1]*University of Manitoba, Winnipeg, MB, Canada,* [2]*University of Nairobi, Nairobi, Kenya.*

Background: LAG-3 is an inhibitory protein expressed on activated T, NK and NKT cells that is associated with immune exhaustion, but its expression at mucosal surfaces is unknown. Engagement of its ligand, MHC class II, initiates APC maturation and activation, and LAG-3 expression inhibits allo-responses, making it a candidate for the modulation of immune activation at the genital mucosa, an issue of importance during HIV exposure.
Methods: The expression of LAG-3, PD-1, CCR5, CD69 and CD40L were quantified on CD4+, CD8+ and double negative (DN) T cell populations in 11 matched PBMC and CMC samples from Kenyan women. Cytokine and chemokine concentrations in plasma and CVL samples were quantified by bead array.
Results: Expression of LAG-3 was significantly higher among CMC T cell subsets compared to PBMC ($p<0.01$), and was highest among the DN T cell subset. PD-1 expression was only significantly increased on CD4+ T cells derived from CMC ($p<0.05$). LAG-3+ T cells expressed CCR5 and CD69, indicating that LAG-3 expression may be associated with activated and HIV-susceptible CD4 T cell subsets. Double negative T cell activation correlated with soluble markers of mucosal inflammation ($p<0.05$).
Significance: The expression of LAG-3 at the genital mucosa suggests that a better understanding of its function in mucosal immunity is required. The enrichment of LAG-3 on mucosal DN T cells could be related to the immunoregulatory function of these cells in the periphery. The co-expression of LAG-3 with CCR5 and CD69 suggests the association between LAG-3 and HIV susceptibility should be further examined.

P5.19.13
Reduced inhibitory NK cell receptors expression in women with recurrent spontaneous abortions (RSA)

V. Kitsiou[1], *S. Dendrinos*[2], *K. Psarra*[1], *E. Konsta*[1], *E. Grigoriou*[1], *G. Kreatsas*[2], *C. Papasteriades*[1];
[1]*Evangelismos Hospital, Athens, Greece,* [2]*Aretaieio Hospital, Athens, Greece.*

It has long been suggested that NK cells and their allorecognition system based on inhibitory and activating NK cell receptors and their ligands play an important role in pregnancy as well as in miscarriages.
Aim of this study was to investigate the expression of NK cell receptors in couples with unexplained RSA.
Material and methods: 32 individuals who experienced RSA (16 women and their partners) were studied. Other probable genetic factors have been excluded. Expression of inhibitory (KIR2DL1, KIR2DL2/3, KIR3DL1) and activating (KIR2DS4, NKp46, NKp30, NKp40) receptors in NK cells were determined by flow cytometry using four color direct whole blood immunofluorenscence.
Results: Percentages of inhibitory CD158a (KIR2DL1) and CD158b (KIR2DL2/3) receptors expression in NK cells was found significantly decreased in women with RSA compared to their partners (19.2% (5.3-44.1) vs 30.2% (14.0-61.3) of NK cells, $p=0.012$ and 19.6% (0.0-41.2) vs 28.8% (6.2-49.0) of NK cells, $p=0.014$, respectively). Full repertoire of the three inhibitory KIRs tested was found in 18.75% of women in comparison to 31.25% of men. In addition, in 12.5% of women no inhibitory receptor was detected, a finding that was not observed in the respective partners. It should be noticed that 56.25% of women were lacking at least one inhibitory receptor expressed by their partner.
Conclusions: Our findings show that NK cells in women with RSA express low levels and a narrow repertoire of inhibitory receptors in comparison to their partners. This could possibly contribute to elevated NK cytotoxicity and may interfering with RSA pathogenesis.

P5.19.14
Lipid bodies in preimplantation embryo health

C. Kyvelidou[1], *G. J. Tserevelakis*[2,3], *G. Filippidis*[3], *C. Fotakis*[2,3], *I. Athanassakis*[1];
[1]*Department of Biology, University of Crete, Heraklion, Greece,* [2]*Department of Physics, University of Crete, Heraklion, Greece,* [3]*Institute of Electronic Structure and Laser, Foundation of Research and Technology, Heraklion, Greece.*

Lipid bodies (LBs) are dynamic cell organelles, present in virtually any cell type and are involved in a number of cellular procedures ranging from energy storage and generation to cell activation, antigen cross-presentation, oocyte maturation and early stage embryo development. Treatments, such as L-Carnitine administration, that affect LB function and survival where followed in order to investigate the role of lipid bodies in preimplantation embryo development and correlate embryo health to maternal physiology in BALB/c mice. LB number and distribution in the preimplantation embryos was evaluated using confocal microscopy and Third Harmonic Generation microscopy, a novel non-destructive imaging technique. Maternal physiology was examined through cytokine evaluation and MHC production/expression, parameters actively involved in embryo development, in blood serum and isolated spleen cells. Although a 7-day in vivo administration of L-Carnitine in mice has been shown to prevent pregnancy by inducing an inflammatory state associated with infertility, administration for 3 or 4 days was able to attain oocyte maturation and even preimplantation embryo development, reducing, however, the LB content of the cells. Correlating embryo health to maternal physiology, it was shown that L-Carnitine administration in addition to lipid body reduction also induced an increase in MHC II and anti-inflammatory cytokine production.

P5.19.15
Influence of THP-1 cells on endothelial cells tube formation in the presence of soluble placenta-derived factors

***T. Y. Lvova**, O. I. Stepanova, K. N. Furaeva, E. A. Potolicina, D. A. Korenkov, S. A. Selkov, D. I. Sokolov;*
The D.O.Ott Research Institute of Obstetrics and Gynecology, Saint-Petersburg, Russian Federation.

Angiogenesis plays an essential role in formation of placental vascular network. It is regulated by placental macrophages and other cells of placenta which secrete different cytokines. The aim of the research was investigation of THP-1 cells influence on capillary-like tube formation of endothelial cells EA.Hy926 at presence of soluble placental products obtained from healthy pregnant women on 38-39 weeks of gestation (n=20) and from pregnant women with an preeclampsia on 38-39 weeks of gestation (n=20). Endothelial cells were seeded on Matrigel-coated 24-well plates (BD, USA) at density of 150000 cells/well, also were added placental tissue supernatants and 2,5% fetal bovine serum. To part of wells THP-1 cells were added (250000 cells/well), to part of wells - the cultural medium without THP-1 cells. Capillary tube formation was assessed 24 hours later using microscope AxioObserverZ1(100x). It is established that tube length formed by endothelial cells was higher ($p<0.001$) and number of cellular aggregate was lower ($p<0.05$) in the presence of placental tissue supernatants from women with preeclampsia compared with physiological pregnancy. There were no differences between compared groups when THP-1 cells were added to the system. Our data suggest that in comparison with physiological pregnancy preeclamptic placenta tissue secretes factors that lead to reduced activity of angiogenic process and domination of non-branching angiogenesis, which suggests the violation of angiogenesis at this pathology. Addition of THP-1 cells led to compensation of the observed effects. Work is sustained by grants of the President of the Russian Federation №НШ-131.2012.7, СП-3492.2013.4 and МД-150.2011.7.

P5.19.17
Effect of high-dose dexamethasone in early pregnancy on pregnancy outcome

***H. Namdar Ahmadabad**, S. Moazzeni, M. Salehnia;*
Tarbiat Modares University, Tehran, Iran.

In the present study, we aimed to evaluate the anti-inflammatory effects of high-dose dexamethasone in the window of implantation on pregnancy outcome.
Pregnant BALB/c mice were treated daily with dexamethasone as experimental group or an equivalent volume of saline as control group on days 0.5-4.5 of pregnancy. On day 13.5 of pregnancy, the pregnant mice were sacrificed and placental, decidual and blood were collected. Serum levels of progesterone, 17-β estadiole and ferritin determined with ELISA. The effect of decidual and placenta cell supernatants (DS and PS, respectively) on PHA or LPS-induced lymphocyte proliferation was investigated by MTT assay.
Results of this study showed a statistically significant higher abortion rate in the experimental compared to the control group. Dexametasone treated BALB/c mice showed the increasing amounts of progesterone and decreasing amounts of 17-β estadiol, but we didn't see a significant difference in ferritin concentration between the two groups. MTT assay results showed that dexamethasone significantly decreased ($P < 0.05$) LPS and PHA-stimulated splenocyte proliferation in the experimental group compared to the control group. PS from experimental group compared to control group showed no significant effect on LPS and PHA-stimulated splenocyte proliferation.
The present results demonstrate that maternal high-dose dexamethasone application in early pregnancy has pronounced effects on hormone levels and the immune state of the decidua, and finally on fetus resorption.

P5.19.18
Genetic polymorphisms of KIR2DL4 and LILRB1 in spontaneous abortion and control women in Polish population

***I. Nowak**[1], E. Barcz[2], A. Malinowski[3], J. Wilczyński[3], M. Banasik[3], E. Majorczyk[1,4], P. Kuśnierczyk[1];*
[1]Institute of Immunology and Experimental Therapy, Polish Academy of Sciences, Wrocław, Poland, [2]Medical University of Warsaw, Warsaw, Poland, [3]Polish Mother's Memorial Hospital - Research Institute, Łódź, Poland, [4]The Opole University of Technology, Opole, Poland.

NK cells are the major leukocyte population in the decidua during the first few months of pregnancy. These cells express a variety of receptors, among them KIR2DL4 (killer cell immunoglobulin-like receptor) and LILRB1 (leukocyte immunoglobulin-like receptor subfamily B member 1), which are both capable of recognizing HLA-G expressed by placental trophoblast. Therefore, polymorphisms of KIR2DL4 (9A and 10A alleles) and LILRB1 (SNP G>A, rs 41308748) genes can affect susceptibility to spontaneous abortion.
We tested 152 women with recurrent spontaneous abortion (RSA, 3 or more abortions) and 77 with sporadic spontaneous abortion (SSA, 1 - 2 abortions) and 178 control women (with 2 or more healthy-born children). *KIR2DL4* 9A/10A alleles were distinguished in HRM (high resolution melting) method, and RFLP (restriction fragment length polymorphism) was used for *LILRB1* genotyping. Statistical odds ratios (OR), and significance (*p*) were generated from two-by-two tables using two-sided Fisher's exact test.
Frequencies of 9A and 10A alleles and genotypes of *KIR2DL4* in RSA women were similar to those in control women. Only in SSA women we observed increased frequency of 10A homozygotes (35%) of *KIR2DL4* in comparison to 25% in control women. However, this comparison did not reach significance. Also, distribution of alleles and genotypes of SNP G>A of *LILRB1* was similar in all tested groups. We found no association of *KIR2DL4* and *LILRB1* (SNP G>A, rs 41308748) with spontaneous abortion in Polish population.

P5.19.19
Potential role of circulating microRNAs as a biomarker for unexplained recurrent spontaneous abortion

***W. Qin**, N. Yang, Y. Wang, Z. Miao, R. Cui, X. Wang;*
Family planning research institution of Guangdong province, Guangzhou, China.

Unexplained recurrent spontaneous abortion (URSA), defined as three or more consecutive pregnancy losses before the 20th week of gestation, occurs in 1-5% of women of reproductive age. URSA is a complex disease, resulting from an array of diverse etiologies. Its diagnosis remains difficult because of lacking of specific indexes. MicroRNAs are small single-stranded RNA molecules which play an important role in the regulation of gene expression at the transcriptional level. Circulating microRNAs have been investigated in a wide variety of patient samples. Altered circulating microRNA expression in URSA patients was found using the miRCURY™ LNA Array (v.18.0), with 4 differentially up-regulated and 3 down-regulated microRNAs. These findings have been confirmed by real-time reverse transcription-polymerase chain reaction assays on select microRNAs, including miR-320b, miR-146b-5p, miR-204-3p and miR-22-5p.This is the first report that the expression of microRNAs is altered in peripheral circulating of patients with URSA, suggesting circulating microRNAs provide a new promising diagnostic tool for URSA.

P5.19.20
Pro-inflammatory and anti-inflammatory cytokine production patterns in intra-uterine growth restriction (IUGR)

***R. Raghupathy**[1], M. Al-Azemi Majedah[1], F. Azizieh[2];*
[1]Kuwait University, Faculty of Medicine, Kuwait, [2]Gulf University for Science and Technology, Kuwait, Kuwait.

Intrauterine fetal growth restriction (IUGR) is a serious complication putting the fetus and neonate at high risk for mortality and morbidity and the child at permanent risk for numerous disorders. Definite causes remain unidentified in nearly 40-50% of IUGR; insufficient

blood flow to the placenta is the primary etiology, but restricted fetal growth is not explained by placental insufficiency alone. It is of interest to examine immunologic reactivity that may cause IUGR with and without placental insufficiency.
Cytokine production by mitogen-stimulated and trophoblast antigen-stimulated maternal peripheral blood lymphocytes from 36 women with IUGR and 22 women with normal fetal growth was assessed. Pro-inflammatory cytokines (IFNγ, TNFα, IL-8, IL-12, IL-18, IL-23) and anti-inflammatory cytokines (IL-4, IL-10, IL-13), were measured by ELISA.
Mitogen-stimulated lymphocytes from normal pregnancy produced higher IL-4 levels compared to IUGR lymphocytes suggesting a bias towards Th2-type immunity. Levels of IL-6, TNFα and IL-12 were higher in IUGR with placental insufficiency compared to IUGR without placental insufficiency indicating a pro-inflammatory bias in IUGR with placental insufficiency.
Trophoblast-stimulated IUGR lymphocytes produced higher IL-8 levels and lower levels of IL-13 than normal pregnancy lymphocytes. IL-8, IFNγ and TNFα were higher in IUGR with placental insufficiency than in normal pregnancy. IL-12 levels were higher and IL-10 levels were lower in IUGR with placental insufficiency than in IUGR without placental insufficiency. This pattern of maternal cytokine profile suggests a proinflammatory bias in IUGR compared to normal pregnancy and in IUGR with placental insufficiency compared to IUGR without insufficiency.

P5.19.21
Trophoblast cells induce and recruit iTregs by VIP production and through a TGF beta dependent pathway

*L. Fraccaroli[1], E. Grasso[1], V. Hauk[1], G. Mor[2], C. Perez-Leiros[3], **R. Ramhorst**[4];*
[1]School of Sciences, University of Buenos Aires-CONICET, Buenos Aires, Argentina, [2]Reproductive Immunology Unit, Department of Obstetrics, Gynecology and Reproductive Sciences, School of Medicine, Yale University, New Haven, CT, United States, [3]School of Sciences and School of Dentistry, University of Buenos Aires-CONICET, Buenos Aires, Argentina, [4]Immunopharmacology Laboratory, School of Sciences and School of Medicine, University of Buenos Aires-CONICET, Buenos Aires, Argentina.

The inducible regulatory T cells (iTreg) population, essential for maternal tolerance of the conceptus, performs its suppressive actions in the critical peri-implantation phase of pregnancy. Vasoactive intestinal peptide (VIP) is synthesized and secreted by trophoblast cells and promotes anti-inflammatory and tolerogenic profiles through binding to specific receptors on immune cells. Here, we evaluated VIP contribution to the differentiation and recruitment of iTreg toward trophoblast cells. We used an in vitro model of maternal leukocyte-trophoblast cell interaction represented by cocultures of fertile women PBMC with human trophoblast cell line (Swan71). We observed that VIP increased the frequency of CD4+CD25+Foxp3+ cells after 48h of coculture (3.9±0.4 vs 8.3%±0.6, p<0.05) which was prevented by VIP antagonist. Moreover, iTreg differentiated upon interaction with trophoblast cells in the presence of VIP, suppressed the maternal alloresponse and increased CD4+IL10+ cell % but did not modulate IFNγ or IL-17 production. Getting insight into the mechanisms involved in iTreg differentiation, VIP induced the expression of the three isoforms of TGFβ in Swan cells with a peak at 12h and increased TGFβ1 secretion. The increase in iTreg frequency was prevented by an antiTGFβ Ab and VIP antagonist. Finally, Swan cells selectively recruited iTreg and the effect was higher in the presence of VIP through CCL5 (RANTES) production. These results suggest that VIP could have an active role in the immunoregulatory processes operating in the maternal-placental interface by contributing to the induction and recruitment of iTregs in a TGFβ dependent mechanism.

P5.19.22
CD4(+) CD25(high) Foxp3(+) cells increased in the peritoneal fluid of patients with endometriosis

***L. V. Rizzo**[1], S. Podgaec[1], L. F. Cordeiro Fernandes[2], E. Chada Baracat[2], M. Simoes Abrao[2];*
[1]Hospital Israelita Albert Einstein, Sao Paulo, Brazil, [2]Department of Obstetrics and Gynecology, University of Sao Paulo Medical School, Sao Paulo, Brazil.

CD4(+) CD25(high) Foxp3(+) cells and IL-6, IL-10, IL-17, and TGF-β in the peritoneal fluid of women with endometriosis. A total of ninety-eight patients were studied: endometriosis (n = 70) and control (n = 28). First, peritoneal fluid lymphocytes were isolated, and CD4(+) CD25(high) cells were identified using flow cytometry. Then, RT-PCR was performed to verify Foxp3 expression in these cells. Also, IL-6, IL-10, IL-17, and TGF-β concentration was determined. Of all the lymphocytes in the peritoneal fluid of women with endometriosis, 36.5% (median) were CD4(+) CD25(high) compared to only 1.15% (median) in the control group (P < 0.001). Foxp3 expression was similarly elevated in patients with the disease compared to those without (median, 50 versus 5; P < 0.001). IL-6 and TGF-β were higher in endometriosis group (IL-6: 327.5 pg/mL versus 195.5 pg/mL; TGF-β: 340 pg/mL versus 171.5 pg/mL; both P < 0.001). IL-10 and IL-17 showed no significant differences between the two groups. The peritoneal fluid of patients with endometriosis had a higher percentage of CD4(+) CD25(high) Foxp3(+) cells and also higher levels of IL-6 and TGF-β compared to women without the disease. These findings suggest that CD4(+) CD25(high) Foxp3(+) cells may play a role in the pathogenesis of endometriosis.

P5.19.23
Immune profile of Sudanese women with conception disorders: Possible role for T-helper cytokines

***H. M. A. Saad**;*
University of Medical Science and Technology, Khartoum, Sudan.

Objectives: This prospective, case-control, cross-sectional and hospital-based study aims to determine the cytokines profile of Sudanese women with infertility and recurrent abortions.
Background: Unexplained female infertility, recurrent miscarriages, premature delivery and pregnancy-induced hypertension may all, in some cases be linked to immune and cytokines networks of early pregnancy. Understanding these cytokines and their actions could be the new area of conception disorders treatment.
Materials & Methods: Following informed consent, 25 women with a history of unexplained conception disorders (15 infertile women, 10 women with recurrent miscarriages) were compared with 75 pregnant women with history of success pregnancy as controls. Blood samples and peripheral blood mononuclear cells (PBMCs) were stimulated by phytohaemaglutinin (positive controls) and trophoblast antigen in an in vitro culture system and secreted cytokines were determined using the ELISA technique.
Results: Significantly high concentrations of INF-γ cytokine were seen in women with a history of unexplained conception disorders compared to those with history of normal pregnancies (*p=0.00*). Significantly higher concentrations of IL-4 were seen in women with history of normal pregnancy compared to those who had conception disorders (*p=0.04*).
Conclusions: Women with conception disorders showed predominantly Th1 type of immune response in PBMCs when stimulated with trophoblastic antigen compared to women who had a history of normal pregnancy. Immunomodulation could be introduced as a treatment modality to induce normal pregnancy.

P5.19.24
Intravenous immunoglobulin treatment on expanded CD56$^+$ cells in women with recurrent reproductive failure

R. Ramos-Medina[1], A. Garcia-Segovia[2], A. Aguraron de la Cruz[3], J. Gil[4], J. Carbone[4], A. Seyfferth[5], J. Alonso[2], L. Ortiz-Quintana[3], E. Fernandez-Cruz[1], ***S. Sanchez-Ramon[1];***
[1]Unit of Clinical Immunology, Hospital General Universitario Gregorio Marañón, Madrid, Spain, [2]Clinica Tambre, Madrid, Spain, [3]Dept. of Gynecology and Obstetrics, Hospital General Universitario Gregorio Marañón, Madrid, Spain, [4]Unit of Clinical Immunology, , Hospital General Universitario Gregorio Marañón, Madrid, Spain, [5]Stat-Up Statistical Consulting and Services, Madrid, Spain.

Natural Killer (NK) cells are key players in maternal tolerance, whereas expansion of circulating cytotoxic NK cells is associated with recurrent reproductive failure (RRF). Intravenous immunoglobulin (IVIg) represents an immunomodulatory therapy for this selected group of patients with immunological pathophysiology.
Objectives: To study the clinical effect of IVIg on clinical pregnancy and live birth rates in women with RM and/or RIF after IVF and circulating NK/NKT-like cells expansion.
Patients & Methods: Retrospective real-life study of 428 women with past medical history of RM (n=217) and RIF after IVF (n=211). Only women with NK or NKT-like expansion above 12% or 10% cut-off levels, respectively, were assigned for IVIg. 157 patients received IVIg every 3-4 weeks from the date of known pregnancy or embryo transfer to 35-week gestation.
Results: Women with RM under IVIg therapy showed a live birth rate of 96.3%. Women with RIF under IVIg therapy showed clinical pregnancy and live birth rates of 93.8% and 80.0%, respectively. Significantly lower pregnancy and live birth rates were observed for patients with RRF and NK/NKT-like cells expansion without IVIg.
Conclusions and discussion: In women with RRF of unexplained etiology and preconception NK or NKT-like cells expansion, clinical pregnancy and live birth rates are significantly improved by IVIg therapy. Immunomodulation with IVIg of a well-selected group of RRF patients with immunological alterations enhanced clinical pregnancy and live birth rates.

P5.19.25
Expression profiling of vitamin D receptor in reproductive tissues of pregnant mice

M. Shabazi*, A. h. Zarnani;*
Department of Immunology, Faculty of Medicine, Tehran University of Medical Sciences, Tehran, Iran.

The presence of vitamin D receptor (VDR) and the identification of localized vitamin D3 synthesis in placenta and decidua implicate the importance of vitamin D3 in reproductive function. There is, however, no data on the expression profile of VDR in the mouse placenta and endometrium throughout the pregnancy period. In the present work expression of VDR in reproductive tissues of pregnant mice at different gestational phases has been addressed. Expression of VDR was determined by semi-quantitative RT-PCR, Western blotting and immunohistochemistry. The results showed that VDR mRNA and protein were expressed in decidua, placenta and ovary throughout the pregnancy. VDR gene expression in placenta was significantly elevated in late pregnancy when compared to that of mid pregnancy. Additionally, VDR expression level in decidua rose significantly as pregnancy progressed from early to mid stages. VDR expression in decidua of pregnant mice was higher in comparison to endometrium of non-pregnant mice. Immunohistochemical analysis revealed that VDR protein is consistently expressed by luminal and glandular epithelial cells of decidua, giant cells, glycogen rich cells and labyrinth cells of placenta and by almost all follicular cell types of ovary. Surveying the expression of VDR at the protein level by Western blotting confirmed PCR results. It seems that expression of VDR in reproductive organs is finely tuned during pregnancy indicating its eminent role in reproductive biology

P5.19.26
Immune cells functional disorder in case of preeclampsia

D. Sokolov*, Y. Onohina, V. Mikhaylova, O. Ovchinnikova, D. Korenkov, S. Selkov;*
Scientific research institute of Obstetrics and Gynaecology named after D.O.Ott Russian Academy of Medical Science, St.Petersburg, Russian Federation.

Preeclampsia is associated with functional disorder of immune cells that can affect their phenotype and influence their functions.
The aim was to assess expression of surface receptors on lymphocytes, NK- and NKT-cells, monocytes and its adhesion to endothelium.
Peripheral blood was obtained from 75 healthy non-pregnant women, 69 healthy pregnant women (38-39 weeks) and 79 pregnant women with preeclampsia (38-39 weeks). Peripheral blood mononuclear cells (PBMC) were stained with antibodies to CD3, CD4, CD8, CD16, CD56, CD14, CD11a, CD11b, CD11c, CD18, CD29, CD49d, CD31, CD44, CD47, CD54, CD58, CD62L, integrin β7, HLA-DR, CD119 and analyzed by FACSCantoII.
The adhesion of monocytes and lymphocytes to the intact and TNFα activated endothelial cells increased in preeclampsia as compared with physiological pregnancy. The amount of CD8+ T-lymphocytes and CD4+ T-lymphocytes expressing CD29, CD49d and CD54 decreased in case of preeclampsia comparing with healthy pregnant women. There was also a 6,5-fold increase of CD18 expression intensity by CD8+ T-lymphocytes. In case of uncomplicated pregnancy and in case of pre–eclampsia the amount of NK–cells expressing CD29 and CD49d was elevated. At preeclampsia the amount of NK–cells expressing CD11c, integrin β7 and CD47 and also expression of CD31 and CD11c by NKT-cells increased. The amount of monocytes expressing adhesion molecules didn`t differ between physiological pregnancy and preeclampsia. But the amount of CD119+ monocytes and their CD119-expression intensity were elevated in case of preeclampsia.
These results indicate that preeclampsia is associated with phenotypical changes of PBMC that facilitate their adhesion to uterine vessel endothelium.

P5.19.27
Influence of placental secretory factors to endothelial cell and monocyte phenotype and monocyte transendothelial migration activity

O. I. Stepanova[1]*, T. Lvova[1], K. Furaeva[1], E. Rebezova[2], A. Baldin[2], D. Sokolov[1], S. Selkov[1];*
[1]The D. O. Ott Research Institute of Obstetrics and Gynecology, Russian Academy of Medical Sciences, Saint Petersburg, Russian Federation, [2]Pre-conception and reproduction clinic, Saint Petersburg, Russian Federation.

Monocyte regulate placental development, but molecules that control differential monocyte migration to placental and decidual tissue during normal pregnancy and local placental inflammation during preeclamptic pregnancy are not defined yet.
Placental tissue samples were taken from healthy pregnant women on 9-11 weeks (abortion) and 38-39 weeks of gestation, pregnant women with preeclampsia on 38-39 weeks of gestation (both after Cesarean section) and were incubated in DMEM/F12, 10% FBS. The ECs line EA.hy926 was grown in DMEM/F12, 10% FBS. Monocyte cell line THP-1 was grown in RPMI-1640 medium, 10% FBS. Cells were incubated with placental supernatants to characterize its influence to ECs phenotype and transendothelial migration activity.
Third trimester placental supernatants caused decrease of CD54 ECs expression in comparison to first trimester placental supernatants, simultaneously monocyte transendothelial migration activity and CD11a monocyte expression were lower with third trimester placental supernatants in comparison with first trimester one. Placental supernatants of women with pregnancy, complicated preeclampsia, caused increased CD119 ECs expression in comparison to normal pregnancy supernatants. Simultaneously monocyte transendothelial migration activity was higher to placental supernatants of women with pregnancy complicated preeclampsia in comparison to normal pregnancy one and was accompanied with increased monocyte CD11b expression. Discovered ECs and monocyte cells phenotype alterations can contribute to monocyte migration regulation during normal pregnancy and to local placental inflammation initiation during

pregnancy, complicated preeclampsia. The work was sustained by the Ministry of education and science of Russian Federation GK №02.740.11.0711 and grant of President of Russian Federation №NSH-3594.1010.7 and MK-1580.2013.7.

P5.19.28
Parameters of cellular immunity in pregnant women with threatened abortion in early pregnancy, against the low level of progesterone

***I. I. Voronova**, T. N. Demina;*
Department of Obstetrics, Gynecology and Perinatology FIPOI Donetsk National Medical University name, Donetsk, Ukraine.

Results. In pregnant women with threatened abortion in the first trimester due to low level of progesterone, compared with rates of women with physiological pregnancy, was showed an increase in production of natural killer cells CD16+ (21.43% (19.2%-23.7%) and 8.91 % (8.2% - 9.6%), respectively, p<0,01), as well as the increase in the total population of T-lymphocyte CD3+ (53.9% (50.8%-56.9%) and 44,65% (42.59%-46.4%), respectively, <p 0,01) with the disturbance of the balance in the subpopulation composition of T-lymphocytes in the direction CD4+, which manifested by increased immunoregulatory index (IRI, CD4 + /CD8 +; 2,66 (2.36 - 2.78) and 1.63 (1.49-1.89), respectively, p<0,01).
Conclusions. By pregnant women with the presence of threatened abortion against low level of progesterone, was found an activation of cellular immunity, shown with overproduction of CD16+ natural killer cells and the prevalence of the potential helper T lymphocytes (CD4+) of the suppressor (CD8 +), which is extremely unfavorable to the gestational process in the future.

P5.19.29
Polymorphisms -725 C>G>T, -716 T>G of the HLA-G gene in spontaneous abortion and control women in Polish population

***M. Wagner**[1], I. Nowak[1], E. Barcz[2], A. Malinowski[3], J. Wilczynski[3], M. Banasik[3], A. Wisniewski[1], E. Wisniewska[4], P. Kusnierczyk[1];*
[1]Institute of Immunology and Experimental Therapy, Polish Academy of Sciences, Wroclaw, Poland, [2]Medical University of Warsaw, Warsaw, Poland, [3]Polish Mother's Memorial Hospital - Research Institute, Lodz, Poland, [4]Medical University, Wroclaw, Poland.

Human leukocyte antigen - G (HLA-G) has been found to contribute to modulation of maternal immune system during pregnancy and acceptance of the semi allogeneic fetus. Therefore, HLA-G is an attractive candidate for genetic studies in reproductive failure such as spontaneous abortion. We investigated whether -725C>G>T and -716T>G genetic polymorphisms in the promoter region of the HLA-G are risk factors for spontaneous abortion in Polish population. We tested 229 spontaneous abortion women: 152 with 3 or more spontaneous abortions (RSA), 77 with sporadic abortion (SSA, with 1 or 2 abortions), and 178 control women (with 2 or more healthy-born children). Temperature gradient gel electrophoresis (TGGE) was used for -725C>G>T, -716T>G typing. Statistical odds ratios (OR), and significance (p) were generated from two-by-two tables using two-sided Fisher's exact test or three-by-two tables.
We observed significant differences in genotype distribution for -716T>G polymorphism (p = 0.009). GG genotype was almost two-fold frequent in sporadic abortion women in comparison to control women. Carriers of -716G allele had over two-fold higher risk to sporadic abortion in comparison to non-carriers (p=0.006, OR=2.46, 95% CI = 1.35-4.51).
Our data suggest that genetic variation within HLA-G influence the risk of sporadic abortion.

P5.19.30
Spontaneous miscarriages are explained by the stress/glucocorticoid/lipoxin A4 axis

***J. Zhao**[1], X. Z. Ye[2], Z. H. Feng[3];*
[1]Department of Gynecology and Obstetrics, Tongji Hospital, Tongji Medical College, Huazhong Universit, Wuhan, China, [2]Department of Gynecology and Obstetrics, 1st Affiliated Hospital, Wenzhou Medical College,, Wenzhou, China, [3]Department of Biochemistry & Molecular Biology, Tongji Medical College; Huazhong University of Science & Technology;, Wuhan, China.

Despite various suspected causes, ranging from endocrine and genetic to infectious and immunological aspects, the molecular mechanisms of miscarriage still remain enigmatic. This report provides evidence that downregulation of 11β-hydroxysteroid dehydrogenase type 2 (HSD2), the key enzyme inactivating glucocorticoid activity, insults the pregnant inflammatory milieu by inhibiting the biosynthesis of lipoxin A4 (LXA4), a metabolite of arachidonic acid, leading to an early loss of the pregnancy. Both LXA4 and its biosynthetic enzymes were found to be decreased in women with spontaneous miscarriages, along the murine miscarriage model. Replenishing LXA4 reversed LPS-induced miscarriages in mouse models whilst blocking LXA4 signaling resulted in miscarriages in the pregnant mice. The protective effect of LXA4 might be explained by LXA4's role in regulating uterine and placental inflammatory factors and mast cells. The underlying molecular mechanism involved miscarriage-inducing infections or stresses that downregulated the expression of HSD2 but not HSD1, resulting in increases in glucocorticoid activity and decreases in LXA4. In conclusion, these findings suggest that the stress/glucocoticoid/lipoxin A4 axis might be a common pathway through which miscarriages occur. <!--EndFragment-->

P5.19.31
The role of systemic inflammation in the development of pregnancy and obstetric complications

***I. Zhuravleva**, L. Solomatina, A. Brazhnikov, E. Gusev;*
Institute of Immunology and Physiology of UB RAS, Ekaterinburg, Russian Federation.

Systemic inflammation (SI) is a typical process integrating some phenomena such as systemic inflammatory reaction, microthrombosis, tissue alteration, distress of neuroendocrine system.
Objective. To evaluate the role of SI in the development of critical pregnancy and obstetric complications.
Patients and methods. The study included follow groups: patients with pre-eclampsia, examined during the third trimester (n=22), patients with pre-eclampsia, examined during the first day after labor (n=15), patients with hemorrhage during labor above 10-15% of a blood volume without (n=13) and with hemorrhagic shock (n=26). Control group - 24 healthy women. A comparison group - patients with normal labor (n=12). Levels of interleukins-6,8,10, TNFα, C-reactivity protein, cortisol, myoglobin, troponin I, D-dimers were measured in plasma. On the basis of these markers we calculated, using our own procedure, integrated criterion - scale of SI, ranging 0 to 9.
Results. SI was diagnosed only in patients with hemorrhagic shock (76,9%). MODS (50%) and lethal outcomes (29,6%) were detected only in this group too. Meanwhile, SI developed in 100% dead persons and in 84,6% MODS-patients. Pre-eclampsia was attended an increased levels of proinflammatory cytokines and CRP (as systemic inflammatory reaction manifestation), but not other phenomena and SI in whole.
Conclusion. The hemorrhagic shock is a damage factor, caused SI development. SI determines state severity, probability of MODS and lethal outcomes.

Anti-tumor specific T-helper cell priming by CIITA-driven MHC-II-positive tumor cells in dendritic cell-depleted transgenic mice

L. Lombardo, G. Forlani, A. Tedeschi, ***R. S. Accolla****;*
University of Insubria, Varese, Italy.

We previously showed that anti-tumor protective immunity can be obtained by injecting Balb/c mice with H-2^d tumor cells of different histological origin expressing MHC-II molecules after transfection with the MHC-II transactivator CIITA. CIITA-tumor vaccinated mice potently rejected tumor challenges with untransfected, MHC-II-negative parental cells, and specific anti-tumor protection could be transferred to naïve recipients by immune CD4+ T helper (TH) spleen cells. These data indicated that MHC-II expression in tumor cells is instrumental to trigger TH priming, subsequent anti-tumor effector response and T cell memory *in vivo*. However the above data did not formally demonstrate that MHC-II-positive tumor cells could serve as antigen presenting cells (APC) for TH priming *in vivo*, a function generally attributed to dendritic cells (DC). By using CD11c.DTR transgenic mice (kindly donated by Natalio Garbi, University of Bonn, Germany) that can be conditionally depleted of DC, we now demonstrate that CIITA-driven MHC-II-positive H-2^b LLC tumor cells are dramatically reduced in their growth *in vivo* in absence of DC and as result of TH triggering and subsequent generation of anti-tumor effector T cell response, both CD4 and CD8. These results strongly suggest that tumor cells expressing CIITA-driven MHC-II molecules play a crucial role as APC in TH cell priming *in vivo*. The implications of these findings for the common belief of MHC-II-restricted T cell priming and in relation to novel strategies of anti-tumor vaccination will be discussed.

P5.20.002
Domination of Th17 subpopulation of lymphocytes during tumor progression.

M. Ajami*[1,2], R. Mansouri[2], J. Hadjati[1];*
[1]Tehran University of Medical Science, Tehran, Iran, [2]Shahid Sadoughi University of Medical Science, Yazd, Iran.

Background: Inflammatory responses play a decisive role in the early stages of tumor development, Progress, Invasion and metastasis. Inflammatory mechanism is also effective in immune surveillance and efficacy of the treatment. The tumor microenvironment consists of a complex network of various cell types including tumor-infiltrating lymphocytes. Tumor infiltrating lymphocyte, have a vast and dynamic relationship with the cancer cells. Similar to human, Th17 cells are found to infiltrate tumors in murine models of cancer. Th17 cells are known with potent pro-inflammatory activities, which are mainly mediated by its cytokines. The purpose of this study was to explore whether there is a linkage between the infiltration of Th17 cells and tumor progression in an experimental model of murine melanoma.
Methods: After induction of tumors in mice using B16F10 melanoma cell line subcutaneously, tumors and draining lymph nodes were extracts at 3 different time points during tumor progression. We quantified expression pattern of functional group of genes associated with Th17 Using Real-time PCR.
Results: Real-time PCR analysis of gene expression in tumor microenvironment and draining lymph node revealed increased expression of related genes, suggesting significant increase in Th17 infiltrating cell during tumor progression.
Conclusions: Along with the increase of Th17 cells, a pro-inflammatory microenvironment is performed, which contributed to the tumor progression. This tumor is characterized by a pro-inflammatory cytokine microenvironment. Evaluation of different subpopulation of T lymphocytes infiltrating the tumor site could be a valuable prognostic factor showing tumor progression and novel therapeutic strategies could be designed to change the microenvironment.

P5.20.003
Relation between Hepatitis B virus DNA load and quantitative HBsAg in HBV infected patient's sera

M. S. Alam*[1], A. Afrin[2], A. Hye[2], S. K. Saha[2], S. Choudhury[1], S. A. Khan[1], Z. F. Rahman[1], M. Hossain[3], M. S. Hassan[3], I. Mahmud[2];*
[1]BIRDEM Hospital, Dhaka, Bangladesh, [2]University of Dhaka, Dhaka, Bangladesh, [3]CARe Hospital, Dhaka, Bangladesh.

Hepatitis B virus (HBV) infection is a serious global health problem. Aim of this study was to find out correlation between quantitative Hepatitis B surface antigen (HBsAg) and HBV-DNA load in HBV infected patient's sera. HBV DNA test was performed by real time PCR using Cobas TaqMan48 (Roche, USA) and HBsAg quantitation by chemiluminiscence EIA (Roche, Switzerland). 280 HBV infected Bangladeshi patient's blood samples were tested for this study having viral load from low to high. Samples were divided among 5 groups, i.e., HBV DNA not detected (30), HBV DNA levels < 6 (50), > 6 to < 50 (50), > 50 to < 2000 (75), and > 2000 IU/mL (75) accordingly. HBsAg levels were found to be in between < 6.25 and > 16.25 IU/mL in this study. < 6.25 IU/mL is the sensitivity of the method. For practical constraint, we preferred to take > 16.25 IU/mL as upper limit of detection,
High levels of HBsAg were detected mostly in patients with HBV DNA above 2000 IU/mL. A very few samples with undetectable HBV DNA had HBsAg levels above detection limit. Overall correlation between quantitative HBsAg and HBV DNA load was not significant. Weak correlations were found in HBV patients with DNA level low to moderate. However, significant correlation ($p < 0.01$) was observed between quantitative HBsAg and group 5 (HBV DNA above 2000 IU/mL). Thus, Quantitative HBsAg assay appears to have a limitation because it cannot fully reflect the replication status of HBV.

P5.20.004
BRCA1 gene deletions and duplications in Omani Breast cancer cases

A. Alansari*[1], K. Al-Mawali[1], B. Al-Bahrani[2], M. Al-Moundhri[1];*
[1]Sultan Qaboos University, Al-Khoud, Oman, [2]Royal Hospital, Muscat, Oman.

Breast cancer (BC) is the most common cancer reported in females in Oman and usually occurs at a relatively younger age, presents at an advanced stage and behaves aggressively. BC occurs in hereditary and sporadic forms. Although germ-line mutations in BRCA1 and BRCA2 genes are rare in sporadic cases compared with hereditary cases, somatic molecular alterations are common. In this study, we investigated the potential association of molecular alterations with sporadic BC in Omani patients.
Methods. Fourty three sporadic BC cases were selected based on age ≤ 40 years, or bilateral breast cancer, or estrogen and progesterone receptor negative status, and HER-2/neu negative (Triple Negative phenotype) status. DNA extracted from peripheral blood was screened for molecular alterations using multiplex ligation-dependent probe amplification (MLPA).
Results. Genomic deletions and duplication in the BRCA1 gene were identified in four female patients. Two patients carried exon 1 and 2 deletions and two showed exon 1 and 2 duplications.
Conclusions. The detected BRCA1 gene deletions and duplications were previously reported in Italian cases with breast/ovarian cancer, which supports that different populations share common breast cancer molecular mechanisms.

P5.20.005
Interplay of Th17/Treg cells in immunopathogenesis of Urothelial carcinoma of bladder

V. Anand*[1], S. Chugh[1], L. Swaroop[2], A. Seth[2], A. Sharma[1];*
[1]Department of Biochemistry, All India Institute of Medical Sciences (Aiims), New Delhi, India, [2]Department of Urology, All India Institute of Medical Sciences (Aiims), New Delhi, India.

BACKGROUND: Bladder cancer is 2nd most common urologic malignancy amongst males after prostate cancer. Urothelial carcinoma of bladder accounts for 90% of all bladder cancer.

Crosstalk is observed between Th17 and Treg cells in inflammatory and autoimmune diseases. Recent studies suggest potential impact of Th17 & Treg cells in cancer. Probable role of these cells are not well studied in bladder cancer. Therefore, we aim to assess circulatory levels and molecular expression of Th17 and Treg related cytokines and transcription factors respectively, to understand their role in immunopathogenesis of bladder cancer.
METHODOLOGY: 20 patients with muscle invasive urothelial carcinoma of bladder (confirmed by clinical and histopathogical diagnosis) and 15 healthy individuals as controls were included. Serum IL-17, IL-23, IL-6 and TGF-β levels were analyzed by ELISA and molecular expression of IL17, RORγt, TGF-β and Foxp3 was observed by RT-PCR in blood and tissue.
RESULTS: Significantly higher circulatory levels of IL- 6 have been found in patient as compared to controls ($p<0.001$). Levels of IL-23, IL-17 and TGF-β were elevated in patients in comparison to controls. Molecular expression of IL17, RORγt and TGF-β was significantly high ($p<0.05$) whereas change in Foxp3 expression was insignificant.
CONCLUSION: These findings indicate possible interplay between Th17 and Treg cells in urothelial carcinoma of bladder. Further, data can be validated in larger patient cohort for better understanding, role of these cells in this disease which might be an aide to formulate a more efficient therapeutic strategy with Th17 & Treg cells as a target in future.

P5.20.006
Association some of the major histocombatibility complex class II alleles with breast cancer among Jordanian females

***M. F. Atoum**, R. Q. Tanashat;*
Hashemite University, Zarqa, Jordan.

Major Histocombatibility Complex (MHC) Class-II represents tumor antigenic peptides on the cell surface that is recognized by T lymphocytes. MHC molecules play a key role in the immune response to breast cancer tumor antigens.
The aim of this study is to determine whether MHC class-II alleles could confer susceptibility or resistance to breast cancer among Jordanian females. This study is a case control study that is consisted of 52 breast cancer patients and 40 healthy controls. DNA was extracted, nucleic acid were amplified for HLA-DQB1 and HLA-DRB1 alleles by muliplex INNO-LiPA kit and alleles typing was carried out by reverse hybridization. Comparison of HLA-DQB1 and HLA-DRB1 alleles' distribution was evaluated by paired t-test and chi-square. Risk factors were expressed by odd ratio with 95% confidence interval. Significant negative correlations were observed between HLADQB1* 02 alleles and breast cancer ($p = 0.022$). While no significant association were observed among HLADQB1* 03, 04, 05 and 06 or among HLA-DRB1 * 01, 03. 04, 07, 08, 10, 11, 13, 14, and 15. Four breast samples alleles could not been identified for any allele by LiRAS® for LiPA HLA software; which may suggests new alleles.
In conclusion, screening HLA-DQB1 alleles among breast cancer females may predict high risk females.

P5.20.007
Expression of CD95 and caspases activity in peripheral blood lymphocytes during breast cancer development

***U. S. Bagina**, K. S. Ignatyev, P. I. Kovchur, I. E. Bahlaev, T. O. Volkova;*
Petrozavodsk State University, Petrozavodsk, Russian Federation.

Rationale: Breast cancer is the most frequent cancer in women. It is known that breast tumorigenesis is accompanied by suppression of anticancer immune response. One way of this process is susceptibility of immune cells to apoptosis in which caspases play the main role. The aim of this study was to evaluate CD95 expression and caspase-8, -9, -6, -3 activities in peripheral blood lymphocytes (PBL) of women with the diagnosed breast cancer depending on a neoplasm stage.
Methods: Gene expression was assessed by qPCR. Caspases activity was measured using fluorogenic substrate. Cellular apoptosis was evaluated by means of cytofluorometric assay.
Results: No changes in caspases activity and CD95 expression were observed during the first stage of breast cancer. Caspase-6 was the only caspase to exhibit lower levels of activity. Beginning from the second stage of cancer, activity of casp-8 and casp-3 sharply increased (max St IIIA), activity of casp-9 and casp-6 changed insignificantly. In addition, the number of CD95+ cells was increased authentically (max St III B). Levels of membrane-associated phosphatidylserine in PBL significantly elevated during the tumor progression, apopotosis was activated.
Conclusions: 1. Apoptosis in PBL is possibly activated during breast tumorigenesis. The increase of CD95+ cells and intracellular activity of casp-8 and casp-3 is supportive of Fas-mediated apoptosis.
2. Differences in functional caspases activity in PBL might be used as a predictor marker of breast cancer development.

P5.20.008
Serum Amyloid A impacts the growth of melanoma cells and may be a link between inflammation and cancer outcome

***L. P. Bellé**, F. H. Knebel, R. C. Albuquerque, S. S. Maria-Engler, A. Campa;*
University of Sao Paulo, Sao Paulo, Brazil.

Serum amyloid A (SAA), an inflammatory protein, has been called attention due its increased concentrations in plasma of cancer patients. Recently, it was suggested an immune modulation mediated by SAA in melanoma patients (Nat Immunol., 11:1039-46, 2010). Previous study from our group showed increased proliferation of human glioma lines in the presence of SAA. Furthermore SAA also affected migration and invasion (Mediators of Inflammation, 2013, in press). To verify if these findings could be extended to other tumor we evaluate the effects of SAA (5 or 10 µg/mL) on proliferation, migration, invasion and cytokine release on melanoma cells (SK-Mel 19, 28, 103 and 147). We used [3H]-thymidine incorporation and clonogenic assay to evaluate proliferation, flow cytometry for necrosis and apoptosis, scratch test and Boyden chamber assay to evaluate mobility and ELISA for cytokine release. We observed that SAA inhibited proliferation without inducing cells death, however, by optical microscopy, we observed that SAA could cause morphologic alterations similar to cell senescence. Some of the cell lines seemed to be more sensitive to SAA in relation to cellular motility. In these cases it was observed decreased in migration and/or invasion. Furthermore, SAA induced the release of IL-6 and IL-8 cytokines on melanoma cells. Our finding demonstrated that SAA might, in some cases, impact melanoma growth and emphasizes the possibility to be one of the factors that links inflammation with cancer outcome.

P5.20.009
A relationship between soluble MICA and anti-MICA-Abs in nasophayngeal carcinoma patients

***A. Ben Chaaben**[1,2], H. Abaza[1], H. Douik[1], T. Mamoghli[1], G. Kablouti[1], L. Harzallah[1], S. Gritli[1], D. Charron[2], F. Guemira[1], R. Tamouza[2];*
[1]Salah Azaiez Institut, Tunis, Tunisia, [2]U940, Saint-Louis Hospital, Paris, France.

A soluble form of the major histocompatibility complex class I-related chain A (sMICA), released from tumor cell-surface, inhibits CD8+ T lymphocyte cytotoxicity through down-regulation of the NKG2D activatory receptor with consequent tumor escape. Conversely, MICA antibody (MICA Abs) not only promotes dendritic cell-mediated cross-presentation of tumor cells resulting in tumor cells lysis through complement fixation but also by neutralizing sMICA isoforms, favor NK- and T cell- related cytotoxicity. Here, we evaluated the presence of MICA antibody (Abs MICA) in NPC patients and controls and their potential relationship with sMICA serum level and the disease.
157 NPC patients compared with 43 healthy individuals sera. Serum levels of sMICA were determined using MICA ELISA kits. MICA Abs was performed using LABScreen® assay.
We found that among the cohort (157), 66 patients (42%) produced high serum levels of sMICA (>80pg/ml) while only 12 (8%) were found positive for MICA Abs (>3). Further Analysis accounting both high sMICA levels (> 80 pg/ml) and positive MICA Abs (>3), showed that

among the 12 patients positive for MICA Abs, 6 of them have also high levels of sMICA, (3% vs 42%, p< 4.4 10 -17). Interestingly, the patients with positive MICA Abs presented all a non-advanced stage of tumor.
The inverse relationship observed here may reflect a neutralizing effect of MICA Abs on sMICA isoforms with consequent NK-cell anti tumor defense. Altogether, these data, if confirmed in a larger patient cohort, may pave the way to novel immuno-therapeutic interventions involving MICA Abs in NPC treatement.

P5.20.010
Tertiary lymphoid tissue (TLT) in colorectal cancer: lymph node-like aggregates supporting the immune response

F. Bergomas[1], *G. Di Caro*[2], *F. Grizzi*[2], *A. Doni*[1], *P. Bianchi*[2], *A. Malesci*[3], *L. Laghi*[3], *P. Allavena*[1], *A. Mantovani*[4], *F. Marchesi*[1]; [1]*Department of Immunology and Inflammation, Humanitas Clinical and Research Center, Rozzano (MI), Italy,* [2]*Laboratory of Molecular Gastroenterology, Humanitas Clinical and Research Center, Rozzano (MI), Italy,* [3]*Department of Gastroenterology, Humanitas Clinical and Research Center, Rozzano (MI), Italy,* [4]*Department of Biotechnology and Translational Medicine, University of Milan, Milan, Italy.*

Tertiary lymphoid tissue (TLT) is a lymph node-like environment, which develops at sites of chronic inflammation and is involved in sustaining adaptive immune responses. Its occurrence in cancer is sporadically documented and its functional role in tumors is unknown.
Despite the recognized role of inflammation in colorectal cancer (CRC) and the evidence that a CD3+ T cell infiltrate correlates with a better prognosis in this tumor, the presence and biological function of TLT in CRC have been poorly investigated.
In human CRC, we identified highly organized lymph node-like aggregates, with compartmentalized B and T cell areas, a network of follicular dendritic cells, activated fibroblasts, lymphoid chemokines and haematic and lymphatic vessels. Notably, in a preclinical model of inflammation-driven colon carcinogenesis, TLT expansion was associated to CD3+ T cell increase, thus indicating an association among TLT and T cell infiltration in CRC.
In CRC patients, high density of TLT correlated with better prognosis. Intratumor lymphoid neogenesis occurred by formation of new vessels, including high endothelial venules and lymphatic vessels and correlated with increased T cell infiltration, suggesting an active contribution to T cell traffic to the tumor. Our results suggest that TLT is associated with a more favorable clinical outcome for CRC patients, rising the hypothesis that it may actively participate to leukocyte recruitment to the tumor and take part to the anti tumor immune response.

P5.20.011
Role of ATP and myeloid derived suppressor cells in neuroblastoma microenvironment.

G. Bianchi[1], *P. Pellegatti*[2], *D. Marimpietri*[1], *L. Emionite*[3], *I. Marigo*[4], *M. Cilli*[3], *F. Di Virgilio*[5], *V. Bronte*[6], *V. Pistoia*[1], *L. The biochemical composition of tumor microenvironment is crucial for the modulation of cancer cell growth as well as for the functions of immune cells. Recent findings have shown that solid tumors have an increased concentration of adenosine and extracellular ATP that may exert a pivotal role in the regulation and homeostasis of immunosuppressive cell populations.
Aim of this study was to investigate whether:
i) extracellular ATP is a component of neuroblastoma (NB) microenvironment,
ii) myeloid-derived suppressor cells (MDSCs) are involved in NB cell growth
iii) ATP exerts modulatory effects on MDSC functions.
The NXS2 murine NB cell line was stably transfected with plasma membrane luciferase probe and inoculated in mice. Bioluminescence imaging was used to detect extracellular ATP in living animals. MDSCs were phenotypically characterized in NB-bearing and healthy mice by flow cytometry and evaluated for the expression of immunosuppressive molecules such as arginase-1 and reactive oxygen species. The functional expression of P2X7 receptor was evaluated in MDSCs by PCR, immunofluorescence and spectrofluorimetric analysis. Extracellular ATP was detected in NB-bearing mice in amounts that increased as tumor progresses. The percentage of $CD11b^{+}/Gr\text{-}1^{+}$ cells was higher in NB-bearing mice compared to healthy animals and they produced higher levels of ROS and arginase-1. Finally, ATP was able to exert some modulator effects i.e. cytokines release and induction of apoptosis on MDSCs through interaction with the functional P2X7 receptor. Our findings identified MDSCs and ATP as new players of NB microenvironment, thus providing new information for the design of novel therapeutics approaches.

Enfermagem Materno-Infantil e Saúde Pública, EERP/USP, Ribeirão Preto, Brazil.*

The low responsiveness of melanoma to traditional treatments together with its increasing incidence makes the development of new therapeutic strategies against this type of cancer extremely important. In this study, we used a murine melanoma model to evaluate the effects of synthetic phosphoethanolamine (PEA) on the development of this tumor. *In vitro*, PEA had an inhibitory effect on the proliferation of B16F10 cells, inducing apoptosis after 24 to 72h stimulation. *In vivo*, oral treatment of melanoma-bearing animals with different doses of PEA (10, 20 and 40mg/Kg) during 20 consecutive days resulted in reduced tumor volumes (at least 70% compared to the control) and in expressive macroscopic differences. PEA also induced a dose-dependent increase of apoptosis and decrease in tumor cell proliferation. The treatment also resulted in hematological changes, such as increased numbers of platelets, erythrocytes and leukocytes. Among leukocytes, we observed a higher proportion of lymphocytes and monocytes. In addition, PEA induced higher levels of the pro-inflammatory cytokine IL-6 and of the anti-inflammatory cytokines IL-10 and TGF-β, and it also induced a lower production of the pro-inflammatory cytokine IFN-γ. No differences were observed in the levels of IL-1β, TNF-α, IL-12p70 and IL-17 upon treatment. Our results demonstrate an inhibitory role of PEA in the development of melanoma, contributing to a better understanding of its antitumor activity.

Early diagnosis remains the main strategy for reducing morbidity and mortality in renal cell carcinoma (RCC) patients, while high immunogenicity of these tumors renders cancer-associated autoantigens as attractive diagnostical biomarkers and promising targets for immunotherapy. In the present study we explored renal cell carcinoma autoantigenic repertoire by means of Serological Proteome Analysis (SEPRA) using A.704 and RCC68 cell lines and RCC patients/healthy donors' sera as primary (auto)antibody sources for two-dimensional Western-blot analysis. Proteins demonstrating differential immunoreactivity between groups of RCC patients and healthy donors were identified using LC-MS/MS analysis. Annexin A4 (ANXA4) was one of the most promising candidates and was selected for further examination of in vitro effector CD8+ T-cell response against five HLA-B (B13, B15, B18 and B27) - restricted ANXA4 peptides previously identified as a part of RCC-associated HLA class I peptidome. In a first screening, we were able to detect spontaneous effector CD8+ T-cell response against 2 HLA-B15-restricted peptides in 1 out of 7 HLA-B15+ carriers suffering from RCC. Moreover, ANXA4 was overexpressed in malignant versus normal kidney tissue (Oncomine database). Taken together, we identified a number of candidate autoantibody biomarkers of RCC and propose ANXA4 as a novel tumor associated antigen.

P5.20.014
Proliferative potential of double positive CD4+/CD8+ T lymphocytes in coculture with tumor cells

F. M. Bojin[1], *L. Cernescu*[1], *A. Cean*[2], *G. Tanasie*[2], *C. Panaitescu*[2], *V. Paunescu*[2];
[1]*Victor Babes University of Medicine and Pharmacy Timisoara, Timisoara, Romania,* [2]*Victor Babes University of Medicine and Pharmacy, Timisoara, Romania.*

Immune response involved in tumor progression is not fully understood yet. It seems that patients with tumors develop mechanisms to escape the immune surveillance, leading to abnormal anti-tumoral immune response. The purpose of this study was to investigate in vitro behavior of peripheral blood mononuclear cells from healthy individuals when placed in contact with breast cancer cells (SKBR3).
SKBR3 tumor cells were cultured in standard conditions and specific media. PBMCs were isolated from healthy donors using Ficoll density gradient and further cocultured with tumor cells for 5 days. Freshly isolated PBMCs were analyzed for expression of CD4, CD8, CD25, CD38, CD69, and HLA-DR. Adherent fraction and culture supernatant were harvested every day and analysed for the same phenotypical markers. Adherent SKBR3 were immunostained and flowcytometrically investigated.
We found that CD45 positive initial population was approximately 70% and remained constant. CD4+ T cells decreased progressively from 70% to 46%, while CD8+ T cells maintained constant proportion of 18%. From day two of coculture we identified presence of double positive CD4+/CD8+ T cells population with a tendency to increase. CD25 and HLA-DR, late activation markers, presented an increased expression towards day 5 of experiment. SKBR3 cells proliferation was inhibited and aggressive markers expression was decreased. We may conclude that occurrence and proliferation of double positive CD4+/CD8+ T cells population when in contact with tumor antigens can be associated with anti-tumoral response of T lymphocytes.

***Cis*-acting genetic elements at or near the *Pas1* locus control *Kras2* mutations and gene expression in lung tumors from mice selected for acute inflammatory response**

A. Borrego[1], *A. Galvan*[2], *J. R. Jensen*[3], *W. Cabrera*[3], *O. G. Ribeiro*[3], *N. Starobinas*[3], *M. De Franco*[3], *O. M. Ibañez*[3], *G. Manenti*[2], *T. A. Dragani*[2];
[1]*Laboratory of Immunogenetics - Instituto Butantan, São Paulo, Brazil,* [2]*Department of Predictive and Preventive Medicine, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy,* [3]*Laboratoty of Immunogenetics - Instituto Butantan, São Paulo, Brazil.*

AIRmax (high response) and AIRmin (low response) mice, genetically selected for the intensity of acute inflammatory response (AIR), show divergent susceptibility for chemically-induced tumors, suggesting that genes which control acute inflammatory reactivity may modulate predisposition to tumorigenesis. AIRmax and AIRmin carry the resistance and susceptibility haplotypes, respectively, at *Pas1* (*Pulmonary adenoma susceptibility 1*), the major locus regulating susceptibility to lung tumorigenesis in mice. The oncogene *Kras2* maps at *Pas1,* and mutations of this gene are associated to lung tumor development. Our objective was to identify, through linkage analysis, chromosomal regions which control the mutability of *Kras2* and the expression levels of *Kras4A* and *Kras4B* isoforms in lung tumors of intercrossed F2 (AIRmax x AIRmin) mice. Mice were treated at 7 days of age with 300 mg/kg urethane and after 9 months lung tumors were excised for DNA (n=500) and RNA (n=110) extraction. *Kras2* activating mutations at codons 12, 13 and 61 were identified by DNA pyrosequencing. Expression levels of *Kras* isoforms and *Lyrm5* (also mapping inside *Pas1*) were determined by qPCR. A panel of 1449 SNPs (single nucleotide polymorphisms) distributed in the whole genome, was tested for association with the mutability and expression phenotypes. One region at chromosome 6 (near to *Pas1*) was associated with *Kras* mutations (LOD 4.67). The expression levels of *Kras4A*, *Kras4B* isoforms and *Lyrm5* showed association with *Pas1* in chromosome 6 (LOD 3.16, 2.36 and 8.43 respectively). Results suggest the participation of *cis*-acting elements at or near *Pas1* in the regulation of *Kras2* mutability and expression.

P5.20.016
Inhibition of cell cycle progression and apoptotic activity of Ganoderma lucidum in oral cancer cell lines

M. Bostan, *M. Mihaila, G. Matei, L. Brasoveanu;*
Stefan St. Nicolau Institute of Virology, Bucharest, Romania.

In recent years, although the apparent improvement in the treatment of oral cancer with conventional strategies the rates of morbidity and mortality remain high. Current treatment for oral cavity cancer uses chemotherapeutic agents as Cisplatin, but it's possible that efficacy of cisplatin could be greatly increased in combination with natural compounds such as Ganoderma lucidum (GL) an oriental medical mushroom used in traditional Chinese medicine as a dietary supplement by cancer patients. In this study we analyzed the effects of GL on cell cycle progression, and apoptosis of two tumour cell lines (BICR-18 cell line - human larynx squamous cell carcinoma and FaDu cell line - human pharynx cell carcinoma) treated with cisplatin, and/ or GL. The cell cycle phase distribution, apoptotic events and expression of several molecular markers (e.g. p21,p53,Bax) in human tumour cells were assessed by flow cytometry. The apoptosis assay was carried out by using Annexin V-FITC/PI double staining kit, while cell cycle phases were investigated by using CycleTEST PLUS DNA reagent kit, than data were acquired on BD FACS Canto II flow-cytometer.
Cell cycle analysis showed that the growth inhibition effect was associated with G2/M arrest and up-regulation of p21 expression. In addition, GL induced apoptosis of oral tumor cells and an increase of the p53 and Bax proteins expression. Furthermore, the treatment with GL significantly amplifies the apoptosis induced by cisplatin in tumour cells analysed. Altogether, our findings suggest that G. lucidum exerts anti-tumor effects on oral tumor cells and enhances their sensitivity to cisplatin.

P5.20.017
Urethane-induced lung cancer and associated events

*D. Teixeira, G. N. Gomes, A. E. Hirata, **V. Bueno**;*
UNIFESP Federal University of São Paulo, São Paulo, Brazil.

Urethane-induced lung cancer is a model for human lung adenocarcinoma. Our aim was to identify markers in this model which could be used as key points for lung cancer therapy. BALB/c mice were injected with Urethane and followed for 120 days. Blood, bone marrow, and lung were harvested for evaluation. Histology showed that mice injected with Urethane (UR) presented lung nodules (number=5.25; area=14,570mm^2) whereas no nodule was observed in control mice (C). UR group presented an increase of myeloid-derived suppressor cells (MDSC, CD11+Gr-1+) in blood (UR=4.4% x C=2.9%), lung (UR=7.6 x C=4.5%), and bone marrow (UR=65% x C=60%). Alpha-smooth muscle actin (alpha-SMA) expression was observed in stroma and vessels of the lung tumor. The expression of TGF-beta was found in lung bronchioles epithelium both in C and UR groups. This marker was also observed in lung nodules. UR presented a higher expression of TLR4 protein in lung than control (UR=3.0$\pm$0.6, C=1.4$\pm$0.7) whereas TLR2 protein expression was similar (UR=0.72$\pm$0.04, C=0.74$\pm$0.07), and IL-6 protein expression decreased (UR= 0.21$\pm$0.04, C=0.61$\pm$0.13). Alpha-SMA is a marker of tumor-infiltrating myofibroblasts which facilitate tumor growth, invasion and metastasis by secreting growth factors and cytokines, produce matrix and matrix associated molecules. One of these factors is TGF-beta also found in our lung samples both in normal tissue and tumor stroma. TLR4 has a negative role when expressed in tumor and we found that UR group presented higher levels of TLR4 at the tumor site. In conclusion, new lung cancer therapies should focus on MDSC, alpha-SMA, TGF-beta and TLR4.

SIGIRR as a novel HER2-Regulated gene in breast tumors

L. I. Campesato[1,2], *A. M. Silva*[1], *F. C. P. Navarro*[1], *M. Marçola*[2], *R. P. Markus*[2], *A. Lepique*[2], *E. T. Costa*[1], *A. A. Camargo*[1];
[1]*Ludwig Institute for Cancer Research, São Paulo, Brazil,* [2]*University of São Paulo, São Paulo, Brazil.*

Introduction: Transcriptional changes associated with overexpression of the receptor tyrosine kinase HER2 in human breast tumors were investigated using an immortalized mammary epithelial cell (HB4a) and its HER2 overexpressing variant (HB4a-C5.2). Global analysis of gene expression identified SIGIRR, a negative modulator of pro-inflammatory signals triggered by IL-1R and TLRs, as an upregulated gene in the C5.2 variant. Given the dual role of inflammation in tumor initiation and progression, we hypothesize that HER2-dependent SIGIRR overexpression in breast tumors may fine-tune inflammation and attenuate the antitumoral adaptive response. **Methods and Results:** qPCR and Western Blot analysis in C5.2 cells treated with Lapatinib confirmed that SIGIRR upregulation was dependent on HER2 activity. In agreement, bioinformatic analysis of public microarray data confirmed both SIGIRR and HER2 strong correlation. EMSA assays showed that shRNA-mediated knockdown of SIGIRR in C5.2 cells resulted in a 2-fold increase of NFkB activity upon IL-1β stimulation, confirming SIGIRR as a negative modulator of IL1R-dependent NFkB activation. To address the role of SIGIRR upregulation in tumoral milieu we investigated the expression of the cytokines IL-1β, IL-8 and TNF-α after IL-1β stimulus. The expression of all the above mentioned cytokines were 2 to 3-fold upregulated in SIGIRR knockdown clones and higher levels of IL-6 and IL-8 were also detected in conditioned medium. Higher expression of chemokines (CCL2, CSF2, CSF3 and CXCL10) was also observed in SIGIRR knockdown cells. **Conclusion:** Our results indicate SIGIRR as a novel HER2-regulated gene that may fine-tune inflammation and adaptive immune response in tumor microenvironment.

ANGPTL4 is involved in the metastatic hepatoma cells' survival in the third microenvironment

L. Cao[1,2], *L. Han*[2], *Z. Zhang*[2], *W. Sun*[2];
[1]*Central Laboratory, Shandong Provincial Qianfoshan Hospital, Jinan, China,* [2]*Department of Immunology, School of Medicine, Shandong University, Jinan, China.*

The third microenvironment, which is also known as the vascular system, is of great importance during cancer cells' metastasis. Metastatic cancer cells have to conquer a lot of stresses including immune system of the body to survive in the vasculature before they arrive at the second sites. We established a three-dimensional cell model by using Poly-HEMA pre-coated plates to mimic the cells in the third microenvironment and found that these metastatic hepatoma cells were aggregated, non-proliferative, apoptosis-resistant, cell cycle arrested and much more invasive. They could settle down and proliferate again in suitable conditions. We analyzed the expression profile of the cell model and their control using microarray, which revealed that a lot of molecules were significantly different between the two groups. There are some increased apoptosis-related genes. One of these genes is ANGPTL4, which maybe help the metastatic cells acquire the ability of survival in the third microenvironment. We knockdown ANGPTL4 of metastatic hepatoma cells and found that cell viability of the metastatic hepatoma cells was decreased significantly and the percentage of dead cells was much higher after ANGPTL4 knockdown as compared with their control groups. Thus, we conclude that ANGPTL4 may play an important role in survival of metastatic hepatoma cells in the vascular system through a certain pathway.

Identification of Early Pancreatic Cancer-Associated Autoantibodies in Mouse and Human

M. Capello[1], *S. Ferri-Borgogno*[1], *P. Cappello*[1], *W. Zhou*[2], *G. Mandili*[1], *I. Sperduti*[3], *F. C. Linty*[1], *G. Maruccio*[4], *M. Milella*[3], *F. Novelli*[1];
[1]*University of Turin, Turin, Italy,* [2]*George Mason University, Manassas, VA, United States,* [3]*Regina Elena National Cancer Institute, Rome, Italy,* [4]*University of Salento, Lecce, Italy.*

Pancreatic ductal adenocarcinoma (PDAC) has a dismal prognosis and diagnostic markers have not yet been defined. In this study we performed a SERological Proteome Analysis (SERPA) to identify antigens that elicit a humoral response in PDAC patients. Nineteen tumor-associated antigens (TAAs), mainly metabolic enzymes and cytoskeletal proteins, induced with high frequency specific autoantibodies in PDAC patients. The protein most frequently recognized was α-enolase (ENOA), a glycolytic enzyme that can localize on the cell surface as a plasminogen receptor. Further studies revealed that in PDAC ENOA is subjected to specific post-translational modifications and PDAC patients specifically produce antibodies against two Ser-419- phosphorylated isoforms of ENOA. By exploiting a genetically engineered mouse model (GEM) spontaneously developing PDAC, we applied the SERPA approach with mouse sera to validate circulating antibodies to TAAs as early diagnostic tools in PDAC. Eight antigens able to induce the production of autoantibodies in pancreatic intraepithelial neoplasia were identified and five of them induced specific IgG also in PDAC patients. Ezrin, a plasma-membrane cytoskeleton linker molecule, which displayed the highest frequency of autoantibodies in both GEM with early disease and resectable PDAC patients, was also recognized by prediagnostic PDAC sera. ROC analysis demonstrated that the combination of anti-Ezrin autoantibodies in association with antibodies to Ser-419-phosphorylated-ENOA and CA19.9 serum levels achieved approximately 97% diagnostic accuracy. In conclusion, our results demonstrate that the simultaneous capture of autoantibodies against a panel of pancreatic cancer-associated antigens might have diagnostic value in this tumor.

P5.20.021
CD4+CD25highFoxP3+ regulatory T lymphocytes in peripheral blood of gastric cancer patients during chemoradiotherapy

A. Chwieduk[1], *A. Gdowicz-Kłosok*[2], *A. Namysł-Kaletka*[3], *P. Polanowski*[3], *R. Kawczyński*[3], *J. Wydmański*[3];
[1]*Department of Bone Marrow Transplantation and Oncohematology, Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Gliwice Branch, Gliwice, Poland,* [2]*Center for Translational Research and Molecular Biology of Cancer, Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Gliwice Branch, Gliwice, Poland,* [3]*Radiotherapy Department , Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Gliwice Branch, Gliwice, Poland.*

Gastric cancer is often diagnosed at advanced stages, patients have regional node involvement and/or extension of tumor through the stomach wall, or into the adjacent organs. Preoperative chemoradiotherapy may downstage the tumor and potentially increase the rate of resectability, but it causes inflammation and immune imbalance. Furthermore, the disorder of immune homeostasis may influence the effectiveness of radiotherapy and impede tissue repair.
Treg cells play an active and significant role in the progression of cancer, and have an important role in suppressing tumor-specific immunity. They down-regulated the activity of effector function against tumors, resulting in T cell dysfunction in cancer-bearing host.
The current study was designed to investigate the changes in peripheral Treg cells in cancer patients and the influence of chemoradiotherapy on immunity function. The treatment consisted of radiotherapy and chemotherapy encompassed the stomach and regional lymph nodes.
We showed increased populations of Treg (CD4+CD25highFoxP3+) in peripheral blood T cells in patients with gastric cancer in comparison with healthy donors. We investigated the change in Treg cells' number in peripheral blood lymphocytes in patients undergoing chemoradiotherapy and compared it with reduction in the absolute number of T cells and changes in other lymphocyte subsets. These results are correlated with clinical data pertaining to tumor progression and therapy-related radiatoxemia.
Because of the fundamental role of Treg cells in suppressing anticancer immunity and diminished survival, the monitoring of T-regulatory lymphocytes ratio during conventional anticancer therapies could become an important clinical index useful in prognosis of cancer patients.

Dendritic cells from mesothelioma patients are numerically and functionally impaired

S. M. Cornwall[1,2], *M. Wikstrom*[3], *A. Nowak*[3], *J. Alvarez*[4], *D. Nelson*[1,2];
[1]*Curtin University, School of Biomedical Sciences, Immunology and Cancer Group, Bentley, Australia,* [2]*Curtin Health Innovation Research Institute, Bentley, Austria,* [3]*University of Western Australia, Medicine and Pharmacology, Perth, Australia,* [4]*Mount Hospital, Perth, Australia.*

Malignant mesothelioma is an aggressive tumour affecting the mesothelium surrounding the pleura. Diagnosis occurs at a late stage of disease progression with death within twelve months. Current treatment options include surgery, chemotherapy and/or radiotherapy, however, no patients are cured and improved treatment strategies are needed. One possibility is immunotherapy. Dendritic cells (DC) are involved in inducing and maintaining adaptive immunity. Many immunotherapies target DCs yet their functional status in mesothelioma patients is unknown. Therefore, blood DC subsets from mesothelioma patients (n=48) and healthy age-matched controls (n=40) were analysed by flow cytometry. Mesothelioma patients had significantly lower $CD303^+$plasmacytoid (p)DC, $CD1c^+$myeloid (m)DC1 and $CD141^+$mDC2 numbers relative to controls. GM-CSF/IL-4-exposed monocytes from mesothelioma patients differentiated into monocyte-derived DCs (MoDCs) that expressed significantly lower levels of CD40, with decreased trends in CD11c/CD80/CD83/CD86 and HLA-DR expression compared with healthy-derived MoDCs. Mesothelioma-derived MoDCs demonstrated a significantly decreased capacity to process antigen. Stimulation with LPS+/-IFNγ induced incomplete maturation indicated by slight loss of antigen processing ability with limited upregulation of the maturation marker, CD83, and costimulatory molecules CD40/CD80 and CD86. Attempts to rescue DC function through CD40L stimulation did not fully restore CD1a/CD40/CD83/CD86 and HLA-DR expression and antigen processing function remained intact. Nonetheless, MoDCs from mesothelioma patients maintained their ability to induce allogeneic T cell proliferation. Our data suggests that mesothelioma patients have significant numerical and functional defects in their DC subsets and rescue with CD40L offers limited benefit. Furthermore, reduced capacity to process antigen and reduced costimulatory molecules suggests that T cells will be anergized/tolerized.

P5.20.023
High proportion of PMN-MDSCs within primary tumors correlates with disease aggressiveness in melanoma

L. Douguet, *A. Pommier, R. Lengagne, M. Avril, B. Lucas, A. Prevost Blondel;*
Institut Cochin, Paris, France.

Immune escape was recently recognized as one of the hallmarks of cancer. A heterogeneous population of myeloid cells characterized by CD11b+/ Gr1+ accumulates in tumor bearing hosts and promotes tumor escape by limiting T cell responses. To account for their potent immune-suppressive properties on T and NK lymphocytes, these cells were named myeloid derived suppressive cells (MDSCs). Two main populations were identified according to their phenotype and their morphology: monocytic MDSCs (CD11b+, Ly6Chigh, Ly6G-) and PMN-MDSCs (CD11b+, Ly6C+, Ly6G+). To study their role in tumor escape, we use the model of spontaneous melanoma driven by the RET oncogene (MT/Ret mice). In this model, primary uveal melanoma disseminates early, but remains dormant for several weeks. Then, MT/ret mice develop local and finally distant metastases. Moreover, vitiligo occurs in nearly 40% of MT/Ret mice and is associated to a better tumor control. PMN-MDSCs are significantly more frequent than monocytic MDSCs within primary tumors. Here, we show that MT/ret mice developing melanoma-associated vitiligo displayed less PMN-MDSCs within tumors and in periphery than mice without vitiligo. Moreover, depletion of PMN-MDSCs with an anti-Ly6G antibody leads to a critical increase in the occurrence of vitiligo associated to a decrease in metastases incidence. Altogether, our data suggest that a high density of PMN-MDSCs infiltrating primary melanoma contributes to disease progression and may be a poor prognosis factor in humans.

IL-18-Binding Protein (BP) is expressed in human ovarian cancer and may limit IL-18 activity

S. Ferrini[1], *G. Carbotti*[1], *M. Fabbi*[1], *A. Orengo*[1], *A. Brizzolara*[1], *G. Barisione*[1], *D. Mezzanzanica*[2], *P. Pinciroli*[2], *M. Bagnoli*[2], *I. Airoldi*[3];
[1]*IRCCS-AOU-San-Martino-IST, Genoa, Italy,* [2]*IRCCS-Fondazione-INT, Milan, Italy,* [3]*IRCCS-Gaslini, Genoa, Italy.*

Epithelial ovarian carcinoma (EOC) is associated to several immune-escape mechanims. IL-18, an immune-enhancing cytokine, which induces IFN-γ production, is studied in phase I-II trials of cancer immunotherapy. We reported that IL-18 processing is defective in EOC cells, which secrete the inactive precursor (pro-IL-18) in vitro. In addition, IL-18 levels were higher in EOC patients than in healthy women, particularly in the ascites. Hovever, only the 21 kDa inactive pro-IL-18 was detected and, accordingly, IFN-γ was not increased.
IL-18 and IFN-γ induce the production of IL-18 binding protein (BP), which can block IL-18 biological activity in a negative feed-back loop. Analysis of gene expression profiling indicated that IL18BP expression is increased in EOC tumors compared to normal ovary cells and cultured cell lines. In addition, we detected elevated levels of IL-18BP in the serum of EOC patients and even higher levels in the ascites, which suggested production at the tumor site. Immunochemistry of ascites cells or EOC tissues indicated IL-18BP expression in tumor cells and in reactive leukocytes. Cultured EOC cell lines show no constitutive IL-18BP production, while the same cell lines xenotrasplanted into ID mice showed IL-18BP production suggesting that IL-18BP expression in EOC may represent the outcome of a cross-talk between EOC cells and the

microenvironment. Indeed, different cytokines up-regulate IL-18BP expression in EOC cell cultures. High levels of IL-18BP may block the effects of endogenous or therapeutic IL-18 in EOC and contribute to the altered functionality of the IL-18 system in EOC.

P5.20.025
Proteolytic machinery involved in MICA and MICB processing in cervical Cancer

M. Garcia-Chagollan[1], *M. R. Bueno-Topete*[2], *S. Fujimura-Hernandez*[1], *R. A. Franco-Topete*[3], *B. E. Bastidas Ramirez*[2], *M. Fafutis-Morris*[1], *S. del Toro-Arreola*[1];
[1]*Laboratorio de Inmunología, Departamento de Fisiología, CUCS, Universidad de Guadalajara, Guadalajara, Mexico,* [2]*Instituto de Enfermedades Crónico-Degenerativas, Departamento de Biología Molecular y Genómica, CUCS, Universidad de Guadalajara, Guadalajara, Mexico,* [3]*Laboratorio de Patología, Departamento de Microbiología y Patología, CUCS, Universidad de Guadalajara, México., Guadalajara, Mexico.*

Introduction: MICA and MICB are upregulated in epithelial tumors. The activating NKG2D receptor, expressed on NK and cytotoxic T lymphocytes, recognizes MIC molecules leading to anti-tumor responses. However, it has been demonstrated that tumor cells use proteolytic cleavage to shed MICA/B as a mechanism to evade immunosurveillance. **Objective:** To identify the expression profiles of ADAM10, ADAM17, MMP9 and Erp5 in cervical cancer cell lines and to associate these with soluble MICA/B levels. **Methods:** Three different cervical cancer cell lines were used (HeLa, SiHa and C-33A) as well as non-tumorigenic keratinocytes (HaCaT). The transcriptional expression of ADAM10, ADAM17, MMP9 and Erp5 was evaluated using qRT-PCR. Identification at the protein level was assessed by Western blot. MMP9 activity was detected through zymography. Soluble MICA/B were quantified by ELISA. **Results:** All cell lines, including HaCaT, express the proteolytic machinery capable of shedding MICA/B. Interestingly, it was observed that the ADAM10 active form, and its zymogen, are mainly expressed in HPV-positive HeLa and SiHa cells, as compared to C33A, an HPV-negative tumorigenic cell line. The strongest MMP9 enzymatic activity was found in SiHa cells, which interestingly showed the highest soluble MICA/B levels. HaCaT did not show significant soluble MICA/B. **Conclusions:** While proteolytic machinery was present in all cell lines, soluble MICA/B was only found in tumor cell supernatants. This finding suggests that MICA/B processing is more complicated than expected and that additional mechanisms (such as different MICA/B variants, glycosylation or palmitoylation states) could facilitate the proteolytic cleavage from the tumor cell surface.

P5.20.026
Analysis of lymphocyte subpopulations in blood from gastric cancer patients during radiotherapy

A. Gdowicz-Klosok*, A. Chwieduk, A. Namysł-Kaletka, R. Kawczyński, P. Polanowski, J. Wydmanski;*
Maria Sklodowska - Curie Memorial Cancer Center and Institute of Oncology Gliwice Branch, Gliwice, Poland.

Gastric cancer is not only the serious issue from the epidemiological point of view, but also therapeutically and diagnostically. The only reasonable solution of this problem seems to rely on individualized and combined modality treatment. The treatment results may also be significantly improved by identification of new diagnostic and predictive markers.
The aim of the following project is the analysis of lymphocyte subpopulation changes in gastric cancer patients during radiotherapy and influence of different ionizing radiation doses on lymphocyte functioning in vitro.
Material: peripheral blood collected from 30 gastric cancer patients, and 10 healthy volunteers. The lymphocyte subpopulation analysis was performed during the whole 35 day cycle of radiotherapy. Different lymphocyte subpopulation changes were analyzed before radiotherapy and after each treatment week.
Lymphocyte phenotype was analyzed using fluorochrome labeled antibodies against human surface antigens CD45, CD3, CD4, CD25, CD16+CD56, CD19 and CD8. Analysis of phenotype and percentage of different lymphocyte subpopulation was performed using flow cytometer FACSCanto.
Comparison of lymphocyte subpopulation in peripheral blood of gastric cancer patients before treatment and healthy volunteers showed statistically significant differences in quantity of undifferentiated lymphocyte T - cytotoxic/suppressor as well as lymphocyte B. Level of lymphocyte T and lymphocyte B in blood of healthy volunteers was respectively ten times and twice higher than in cancer patients.
Monitoring of the percentage of different lymphocyte subpopulation during the treatment and individual assessment of ionizing radiation susceptibility may become significant predictive marker allowing on cancer treatment individualization.

P5.20.027
Involvement of the long pentraxin PTX3 in skin carcinogenesis

S. Gentile[1], *E. Bonavita*[1], *N. Polentarutti*[1], *F. Pasqualini*[1], *F. Feruglio*[1], *S. Tartari*[1], *M. Nebuloni*[2], *T. Schioppa*[3], *A. Mantovani*[1], *C. Garlanda*[1];
[1]*Humanitas Clinical and Research Center, Rozzano, Italy,* [2]*Department of Clinical Sciences, L. Sacco Hospital, University of Milan, Milano, Italy,* [3]*Department of Experimental Oncology, European Institute of Oncology, Milan, Italy.*

The role of the innate immune system on inflammatory carcinogenesis is a central issue for tumor biology and immunology. The long pentraxin PTX3 is a pattern recognition receptor that plays a fundamental role in regulation of the inflammation and in tissue remodelling. Available information in mouse and human suggest a protective role of PTX3 in cancer. In this study we showed that *Ptx3*-deficient (*Ptx3*$^{-/-}$) mice were more susceptible to DMBA/TPA-induced skin carcinogenesis than WT controls. Incidence and number of skin papillomas were significantly higher in *Ptx3* $^{-/-}$ mice compared to WT controls. ELISA revealed a strong PTX3 production in skin sample of WT mice during the acute phase of DMBA/TPA-induced cutaneous carcinogenesis. Furthermore immunohistochemical investigation showed PTX3 colocalization with lymphatic vessels and its specific deposition inside the skin papillomas. The deficiency of Ptx3 was associated to increased infiltration of neutrophils in skin papillomas and decreased infiltration of lymphocytes. Higher complement C3 deposition was observed in papillary lesions of *Ptx3*$^{-/-}$ mice compared to WT animals. Epidermal production of pro-inflammatory cytokines (IL-17 and TNFα) and chemokines, such as CXCL2, were increased in *Ptx3*$^{-/-}$ mice after TPA treatments. These data are in agreement with the protumorigenic role of IL-17 and CXCL2 in skin carcinogenesis. These results provide evidence that PTX3 is locally produced and has a protective role during skin carcinogenesis. The mechanisms of PTX3-mediated protection in this model could range from modulation of neutrophil recruitment to complement activation and are currently under investigation.

The major role played by the immune system in tumor immunosurveillance has been extensively documented. Several

clinical studies have notably demonstrated that a high density of effector T cells within the tumor is associated with an increased median survival. More recently, our team has described in some lung cancer (LC) patients the presence of tertiary lymphoid structures (TLS), composed of mature dendritic cells which home selectively in T-cell rich areas surrounded by B-cell follicles. By immunohistochemistry, we observed that these B-cell follicles are characterized by Ki-67+ proliferating germinal center B cells, a network of CD21+ follicular dendritic cells, and that a high density of follicular B cells is associated with favorable clinical outcome in early-stage LC patients. Consistent with their organization in TLS, we observed by flow cytometry all stages of B cell differentiation, namely a small proportion of naïve and germinal center B cells, and a larger proportion of memory and plasma cells. Importantly, we demonstrated in half of the patients considered that intra-tumoral plasma cells secreted IgG and/or IgA specific for several tumor-associated antigens (TAAs). For some patients, a specific reactivity of the antibodies has been observed against one to nine distinct TAAs among the 36 tested. Finally, a pilot study demonstrated that the antibody response developed against one of these TAAs was polyclonal. All together, these results demonstrate that B cell density represents a new prognostic biomarker for LC patient survival, and suggest a major role for TLS in the initiation of a protective humoral immune response.

P5.20.029
Development and optimization of an HPLC-UV assay for measurement of Indoleamine2.3-dioxygenase (IDO) activity

R. Ghedira Chkir[1], *M. H. Saadaoui*[2], *W. Douki*[2], *M. F. Najjar*[2], *S. Gabbouj*[1], *A. Zakhama*[1], *L. Chouchane*[3], *E. Hassen*[1];
[1]*Molecular Immuno-Oncology Laboratory, Faculty of Medicine, Monastir University,, monastir, Tunisia,* [2]*Biochemistry and Toxicology Laboratory, University Hospital Fattouma Bourguiba, monastir, Tunisia,* [3]*Department of Genetic Medicine, Weill Cornell Medical College, Doha, Qatar.*

Background: Indoleamine2.3-dioxygenase (IDO) is an intracellular enzyme that catalyses the initial rate-limiting step in tryptophan (Trp) degradation along the kynurenine pathway (Kyn). This enzyme plays a crucial role in regulating the immune response by inhibiting T-cell proliferation. This immunomodulatory function of IDO plays an essential role in different physiological, paraphysiological, and pathological states. Measurement of IDO activity in plasma could constitute a relevant biomarker for all these different states.
Objective: IDO activity has conventionally been represented as a ratio of Kyn to Trp. We developed a specific HPLC method with UV detection using experimental design methodology for simultaneous measurement of Trp and Kyn in human plasma in a single run.
Method: The chromatographic experiments were carried out on a VARIAN (ProStar). A strategy for experimental design (factorial design and desirability function) were used to allow analyses parameters (acetonitrile percentage, buffer pH and the flow rate of the mobile phase) to be simultaneously optimized in order to identify Trp and Kyn with a high resolution between peaks, reproducibility and short analysis time.
Results: Optimized analyses were run using the mobile phase consisting of 15mmol/L phosphate buffer (pH3.5) and 10.6% acetonitrile at a flow rate of 1.2ml/min. The eluate was monitored by the programmed wavelength detection setting at 360 nm from 0 to 6.5 min for Kyn and 280 nm from 6.5 to 8.5 min for Trp. Satisfactory precisions and recoveries were obtained by this method.
Conclusions: Experimental design methodology allowed to rationally and economically developing a simple, fast and reliable method.

P5.20.030
The heterogeneity of lung metastasis immune microenvironment according to the primary tumor location

N. A. Giraldo[1], *R. Remark*[1], *A. Lupo*[1,2], *D. Damotte*[1,2], *M. Alifano*[3], *I. Cremer*[1], *M. C. Dieu-Nosjean*[1], *C. Sautès-Fridman*[1], *W. H. Fridman*[1];
[1]*Centre de Recherche des Cordeliers de Jussieu (CRC), Paris, France,* [2]*Services d'anatomie-pathologie et de chirurgie thoracique, Hôpital Hôtel Dieu, Paris, France,* [3]*Services d'anatomie-pathologie, oncologie et de chirurgie thoracique, Hôpital Européen Georges Pompidou, Paris, France.*

Introduction: Recent evidence suggests that the tumor microenvironment of the primary and metastatic tumoral lesions can be heterogeneous. In the two scenarios the immune contexture might have different influence and prognostic impact. This study aim's was to give a broad description of the immune contexture of some common lung metastatic tumors.
Material/Methods: Up-to-date, 36 metastatic tumors (11=leimyosarcomas, 8=osteosarcomas, 5=breast, 4=liver, 4=prostate and 4=thyroid) have been analyzed by IHC for CD8 and CD20 with the quantitative automatic software Calopix, and through manual counting for DC-LAMP. The density (# of positive cells/mm2) of the analyzed populations was compared by non-parametric statistics.
Results: We did not find significant differences among CD8+ cell densities' among the analyzed tumors (354±593 leimyosarcomas, 48±71 osteosarcomas, 185±169 breast, 73±56 liver, 242±221 prostate and 209±301 thyroid). Nonetheless, the density of CD20+ cells in the osteosarcomas (2.2±2.2) was significantly lower than in thyroid (40.8±11.6, $P<0.005$) and prostate metastasis (422±372, $P<0.005$); similarly, the leimyosarcomas (33.1±53.4, $P<0.05$) displayed lower values of CD20+ cells than their prostate counterparts (422±372). No other differences were found for CD20+ densities among the analyzed groups (20.9±11.5 breast and 38.9±23.2 liver). Finally, the DC-LAMP densities in thyroid metastasis were significantly higher (3.5±3.8, $P<0.05$) than those from leimyosarcomas (0.3±0.3). No other differences on DC-LAMP expression were found (0.4±0.7 osteosarcomas, 1.2±2.4 breast, 0.9±0.7 liver, 3.5±3.8 prostate).
Conclusions: These preliminary results provide evidence than the tumor immune contexture of different types of lung metastasis is heterogeneous, and could be strongly influenced by the origin of the tumoral lesion.

P5.20.031
Azacytidine and Everolimus therapy reduces the high frequency of terminally differentiated CD38+HLADR- CD8 T cells in relapsed AML patients.

C. Govindaraj[1], *P. Tan*[2], *P. Walker*[2], *A. Spencer*[2], *A. Wei*[2], *M. Plebanski*[1];
[1]*Monash University, Melbourne, Australia,* [2]*Alfred hospital, Melbourne, Australia.*

T cells have a central role in anti-tumor immunity as demonstrated by the graft-versus-leukemia effect, however functionally impaired CD8 T cells are found at increased frequencies in AML patients. The effects of novel epigenetic treatments in AML patients, azacitidine and everolimus on CD8 T cell subset frequencies have not been previously investigated. Here, we demonstrate that relapsed AML patients have elevated overall levels of CD8 T cells when compared to healthy donors. We mapped this increase as due to a single cell subset, characterized by the expression of CD38, a marker associated with activation. However, these CD38+ CD8 T cells did not co-express other activation markers such as HLADR. The CD38+HLADR- T cell subset was found to express high levels of the senescence marker, CD57, with higher expressions found within AML patients. This subset also had low levels of CD28 in AML patients than healthy donors. These cells were not exhausted T cells, as they did not express high levels of PD-1. This suggests that CD38+HLADR- CD8 T cell subset represents a terminally differentiated CD8 T cell population. Upon treatment, there was a significant reduction of this sub-population within week 1, and these levels remained low for up to three months of treatment. This reduction was observed to be significantly lower in patients who had stable disease when compared to patients with disease progression.

P5.20.032
Panobinostat in combination with azacitidine reduces the frequency of TNFR2+ Tregs in newly diagnosed acute myeloid leukemia patients.

C. Govindaraj[1], *P. Tan*[2], *P. Walker*[2], *A. Wei*[2], *A. Spencer*[2], *M. Plebanski*[1];
[1]*Monash University, Melbourne, Australia,* [2]*Alfred hospital, Melbourne, Australia.*

Acute Myeloid Leukemia provides an environment that enables immune suppression, resulting in functionally defective effector T cells. Regulatory T cells (Tregs) are significant contributors to the impaired anti-tumor immunity. Expression of the TNF receptor TNFR2 on Tregs identifies a potent regulatory subset, and since TNF is present at high levels within AML patients, we hypothesized TNFR2+ Tregs may be a functionally relevant Treg subset in AML. Furthermore, the effect of the emerging epigenetic treatment drug combination, panobinostat and azacitidine on T cells and Tregs, particularly TNFR2+ Tregs has not been previously investigated in AML or other blood diseases. Here, we demonstrate that TNFR2+ Tregs are the dominant highly functionally relevant Treg population within AML patients. Treatment with azacitidine and panobinostat resulted in a decrease in TNFR2+ Tregs, but not TNFR2- Tregs in AML patients. Moreover, patients who had a reduction in their TNFR2+ Tregs in both the bone marrow and peripheral blood responded positively to treatment. These patients consequently also showed increased IFNγ and IL-2 production by effector T cells isolated from the bone marrow. In vitro mechanistic studies suggested that panobinostat and not azacytidine, primarily and dominantly drives the reduction in Tregs. AML patients who responded clinically to panobinostat and azacitidine therapy had an immune profile associated with decreased TNFR2+ Tregs and increased effector T cells.

The effects of Cancer Associated Fibroblasts on mechanisms of immune evasion in a rat chemical mammary carcinoma model

G. Gunaydin, *Y. Dolen, N. Unver, S. Kesikli, D. Guc;*
Hacettepe University Cancer Institute Department of Basic Oncology, Ankara, Turkey.

Objective: Fibroblast cells turn into cancer associated fibroblasts(CAFs) in tumor microenvironment. Tissue fibroblasts have previously been shown to affect T-cell functions. However, studies investigating the effects of CAFs on T-cells are limited in the literature.
Methods: N-Nitroso N-Methyl Urea(NMU) induced experimental mammary carcinogenesis model was utilized. Tumors were harvested surgically under sterile conditions for CAF isolation. CAFs and healthy tissue fibroblasts were immunostained to evaluate expression differences of markers like α-Smooth-Muscle-Actin(αSMA) and Vimentin. DNA damage of peripheral blood cells due to NMU were analyzed by Comet Assays. Cocultures of CAFs with lymphocytes employing Carboxyfluorescein-succinimidyl-ester(CFSE) proliferation assays were performed. Surface and intracellular expressions of immune activation markers (CD25, IFN-γ) of T-cells cocultured with CAFs were analyzed. Levels of IL-4 were analyzed in CAF-splenocyte cocultures. Gene expression levels of several immune activation markers like CD25 and costimulatory molecules like CD28 in splenocytes were investigated.
Results: The immunostainings showed that CAFs had significantly higher levels of αSMA expression. Comet Assays showed that levels of DNA damage in tumor-bearing animals were similar to control levels. CAFs decreased proliferations of splenocytes in cocultures. Flow cytometry experiments showed that CAFs decreased intracellular expressions of immune activation markers like IFN-γ in T-cells. Supernatants of CAF-splenocyte cocultures were shown to have increased levels of IL-4. Splenocytes cocultured with CAFs were found to have decreased gene expression levels of costimulatory molecules.
Conclusions: A rat chemical breast carcinogenesis model was successfully employed and CAFs were stably propagated. Coculture experiments suggested an immunomodulatory role for CAFs on immunity against breast cancer.

P5.20.034
Effects of Silymarin on frequency and function of Myeloid-derived suppressor cells in animal model of tumor

M. Hafezi[1], *A. Namdar*[2], *N. Khosravianfar*[3], *A. Razavi*[4], *J. Hadjati*[5];
[1]*Department of Immunology, School of Pathobiology ,Tehran University of Medical sciences, Tehran, Iran,* [2]*Department of Immunology, School of Medicine,Isfahan University of Medical Sciences, Isfahan, Iran,* [3]*Department of Pathobiology, School of Public Health ,Tehran University of Medical Sciences, Tehran, Iran,* [4]*Department of Immunology, School of Pathobiology ,Tehran University of Medical Sciences, Tehran, Iran,* [5]*Department of Immunology, School of Medicine,Tehran University of Medical Sciences, Tehran, Iran.*

Background: Myeloid-derived suppressor cells (MDSC) are identified as heterogeneous population of immature myeloid cells (IMCs) including precursors of macrophages, granulocytes, and dendritic cells (DC). These cells accumulate during tumor formation; facilitate immune escape, and therefore promote tumor progression. Silymarin, a plant flavonoid isolated from the seeds of milk thistle (Silybum marianum), has been indicated to possess antioxidant, anti-inflammatory and immunomodulatory properties. We sought to determine silymarin's effects on the frequency and function of MDSC population accumulated during tumor progression.
Methods: We isolated MDSCs from spleen of tumor bearing mice treated with silymarin by MACS method. Then, the number of MDSCs and also their ROS production were evaluated using flow cytometry and compared with untreated group. Moreover, the silymarin's effect on NO production was analyzed using ELISA.
Results: Our results showed that silymarin had some positive effects on number and function of MDSCs.
Conclusion: Silymarin, as an anti-inflammatory drug, may exert beneficial effects on T cell responses against tumors and should be considered as an agent that affects the number and function of MDSCs. Further studies are needed to shed light on adjuvant anti-cancer effects of this compound which potentially could be used as combination therapy of cancer.
Key words: MDSC, Silymarin, Anti-inflammatory, ROS, NO

P5.20.035
Formation of vascular mimicry in human gastric cancer and the corelation with LOX and MMP-9

M. Han, *Y. Cao, H. Sun, R. Bai;*
Ningxia Medical University, Yinchuan, China.

To explore the corelations of lysyl oxidase (LOX) and matrix metalloproteinases-9 (MMP-9) with formation of VM in gastric carcinoma tissue. Gastric cancer tissues were collected from 49 patients with diagnosis of gastric cancer. According to metastasis (include lymph node and distant metastasis), gastric cancer tissues were divided into the group of metastasis and the group of non-metastasis. According to the invasion, gastric cancer tissues were divided into the group of T1 + T2 and the group of T3 + T4. The formations of VM were measured through CD34 and PAS double staining on gastric cancer tissue slices. The distributions of LOX and MMP-9 were observed using immunohistochemistry. Relative levels of LOX and MMP-9 were surveyed by Western-blot and immunohistochemistry. The locations of LOX and MMP-9 were detected by Immunofluorescence. Results showed, in gastric carcinoma tissues, the VM formation in group with metastasis were more than that in group without metastasis ($P<0.05$), the level of LOX and MMP-9 protein were higher in group with metastasis than that in group without metastasis ($P<0.05$); the expression of LOX in group of T3 + T4 were more abundant than in T1 + T2 group($P <0.05$). The levels of LOX was positively correlated with VM formation in gastric carcinoma tissues, the levels of MMP-9 was positively correlated with VM formation. The immunofluorescence results suggested that LOX often located in the area that MMP-9 expressed. The results suggest that VM promotes the invasion and metastasis of gastric cancer, LOX and MMP-9 may be facilitative factors in VM formation.

P5.20.036
Aberrant expression of circulating PD-L1+CD14+HLA-DR-/low cells in esophageal squamous cell carcinoma patients: Immunosuppressive characteristics and tumor clinical relevance

***H. Huang**, G. Zhang, G. Li, H. Ma, X. Zhang;*
The First Affiliated Hospital of Soochow University, Suzhou, China.

Myeloid-derived suppressor cells (MDSCs) represent a heterogeneous population of immune-suppressive cells which play an important role in tumor immune-escape. Recently, a population of $CD14^{+}HLA\text{-}DR^{-/low}$MDSCs was identified in blood and tumor tissue of multiple types of cancer patients. In this study, we assessed the levels of $CD14^{+}HLA\text{-}DR^{-/low}$MDSCs in peripheral blood and tumor-draining lymphnode (TDLN) from patients with esophageal squamous cell carcinoma (ESCC). The level of circulating $CD14^{+}HLA\text{-}DR^{-/low}$MDSCs increased significantly in patients with ESCC and was correlated with lymphnode metastasis, TNM stage. Furthermore, circulating $CD14^{+}HLA\text{-}DR^{-/low}$MDSCs decreased with the surgical excision of tumor. Additionally, $CD14^{+}HLA\text{-}DR^{-/low}$MDSCs increased notablely in the tumor-positive TDLN comparing with corresponding tumor-negative TDLN. In vivo experiment showed that $CD14^{+}HLA\text{-}DR^{-/low}$MDSCs could effectively inhibit autologous T cell proliferation and downregulate the production of IL-2, IFN-γ comparing with corresponding $CD14^{+}HLA\text{-}DR^{high}$ cells. Subsequently, we examined surface expression of B7-family molecules on $CD14^{+}HLA\text{-}DR^{-/low}$MDSCs and found remarkable increase of PD-L1 expression. Furthermore, intervention PD-L1 pathway by a blocking antibody effectively reversed the suppression of autologous T cells. Our data indicate that a new population of $CD14^{+}HLA\text{-}DR^{-/low}$MDSCs with PD-L1 high expression accumulated in peripheral blood and tumor-positive lymphnode of patients with ESCC. This population is of immunosuppressive characteristics and correlated with tumor burden, lymphnode metastasis and TNM stage. And our data also confirmed that PD-L1 plays a key role in T cell suppression mediated by $CD14^{+}HLA\text{-}DR^{-/low}$MDSCs in patients with ESCC. PD1/PD-L1 pathway may be alternative immune checkpoint of tumor immune-escape mediated by $CD14^{+}HLA\text{-}DR^{-/low}$MDSCs.

P5.20.037
Microparticles: a road to antitumor immunity

***B. Huang**;*
Chinese Academy of Medical Sciences, Beijing, China.

Tumor cells are capable of changing their cytoskeletal structure and resulting in plasma membranes encapsulating cytosolic elements and expelling them or downloading them into the extracellular space. These specialized subcellular vesicles are called microparticles (MPs) and come in different sizes of 100 to 1000 nm in diameter. In line with the cellular components, MPs may contain numerous tumor messenger molecules, enzymes, RNAs and even DNA. This study explored the possibility of translating tumor information into antitumor immunity through the MP pathway.
Despite the critical role of dendritic cells in antitumor immune responses by cross-presenting tumor antigens to tumor-specific T cells, we found that DCs were vulnerable to take up apoptotic tumor cells but strongly captured tumor cell-derived MPs. As a result, DCs upregulated CD80, CD86 and MHC class II, concomitant with the activation of JNK, ERK and NF-κB, leading to activating tumor specific T cells. Vaccination of murine H22 hepatocarcinoma tumor cell-derived MPs prevented H22 tumor rather than MCA26 colon cancer or B16 melanoma formation in mice in a CD8 T cell dependent manner. Consistently, B16 cell-derived MPs selectively affected B16 melanoma, suggesting that tumor cell-derived MPs are tumor antigen specific. Undoubtedly, tumor cells are the roots of antitumor immune responses, however previous tumor cell-based vaccines only generated limited progress. The present study probably discloses tumor cell-derived MPs as a new generation of vaccine, leading to effective antitumor consequence.

P5.20.038
Mapping on chromosome 17 a novel major locus determining kidney cancer susceptibility in mice

*J. R. Jensen[1], A. Galvan[2], M. Colecchia[3], W. H. K. Cabrera[1], O. G. Ribeiro[1], N. Starobinas[1], A. Borrego[1], M. De Franco[1], T. A. Dragani[2], **O. M. Ibañez**[1];*
[1]Laboratory of Immunogenetics - Instituto Butantan, São Paulo, Brazil, [2]Department of Predictive and Preventive Medicine, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy, [3]Department of Pathology, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy.

Mouse lines derived by bidirectional phenotypic selection for inflammatory responsiveness differ in susceptibility to urethane-induced kidney carcinogenesis. High inflammation producing mice (AIRmax) are resistant whereas the low responder AIRmin are susceptible, showing 70% incidence of papillary kidney tumors (racemase positive) after sc treatment with 300 mg/kg bw urethane at 7 days of age. The difference is also observed in untreated 14 month-old mice, since AIRmax mice are unaffected and tumor incidence in AIRmin reaches 50%. Using a single nucleotide polymorphism (SNP) array for genome-wide linkage analysis, we mapped one quantitative trait locus (QTL) regulating kidney tumor incidence in an F2 (AIRmax x AIRmin) intercross population (n=693). This QTL mapped to chromosome 17 at 30 Mb (LOD score = 15.8, 13 Mb confidence interval), identified by SNP rs3693494 ($P= 2.1^{-16}$, per allele odds ratio = 2.9, 95% CI: 2.2 - 3.7). Several candidate genes mapping in this locus have been implicated in inflammation-related kidney pathologies in humans, such as *Pkd1,* encoding polycystin-1, responsible for the polycystic kidney disease and *Tsc2*, a tumor suppressor gene encoding tuberin that participates in signal transduction pathways involved in cancer development. Genes relevant to innate and acquired immunity such as the major histocompatibility complex (H2) and C2 and C4 complement system components also map to this QTL. Functional effects of allelic variants could contribute to the differential susceptibility to inflammation and kidney cancer of AIRmax and AIRmin mice.

P5.20.039
Anti-tumor effect of BCG-LM via activated eosinophils.

***T. Ito**[1], I. Yano[2], T. Nakayama[1];*
[1]Department of Immunology, Graduate School of Medicine, Chiba University, Chiba, Japan, [2]Japan BCG Laboratory, Kiyose, Japan.

Mycobacterium tuberculosis (tubercle bacilli) and the related acid-fast bacteria including Mycobacterium bovis Bacille Calmett-Guerin (BCG) contain a lipoarabinomannan (ManLAM or LAM) and lipomannan (LM). LAM and LM have been reported to activate type-I inflammatory responses via dendritic cells (DCs) through Toll-like receptor 2. However, the cellular and molecular mechanisms underlying the antitumor effect of LAM/LM are not well analyzed. In order to study the antitumor effect of LAM/LM, a B cell lymphoma cell line A20 and an OVA-expressing A20-OVA tumor cells were subcutaneously inoculated into the flanks of the mice. The mice were treated by intra-tumor injection of LAM, LM, or BCG cell wall (CW), or LAM-, LM-, or CW-pulsed dendritic cells. The most potent antitumor effect was observed by the treatment with LM with massive infiltration of eosinophils. Eosinophils can be activated by LM. Thus, these results indicate that LM from M. bovis BCG exerts an antitumor effect via the activation of eosinophils.

P5.20.040
Inducible nitric oxide synthase from prostate cancer stem/initiating cells inhibits T cell priming

***E. Jachetti**, M. Grioni, S. Mazzoleni, C. Brambillasca, R. Galli, M. Bellone;*
San Raffaele Scientific Insitute, Milan, Italy.

Consistent evidence supports the concept that, irrespective of the cell-of-origin, many cancers are hierarchically organized as a normal tissue, and originate from a population of stem-like initiating cells (CSC). According to this theory, CSC are essential to tumor evolution

and recurrence, and indeed, it is reasonable to hypothesize that evolution has supported these cells and/or their niches with mechanisms of immune evasion. Here we provide experimental evidence that prostate CSC (PCSC) from the prostate of transgenic adenocarcinoma of the mouse prostate (TRAMP) mice induce anergy in T lymphocytes. Indeed, PCSC-conditioned T cells showed reduced activation of TCR and IL-2 pathways, that resulted in inhibited proliferation and cytokine production. Inducible oxide synthase (iNOS), a molecule that has been already implicated in prostate cancer aggressiveness both in TRAMP and human prostate cancer, appeared to be one of the mechanisms adopted by PCSC to inhibit T cells, as treatment of PCSC with the iNOS inhibitor L-NAME reduced their immunosuppressive activity. This phenomenon was restricted to T cells in the phase of priming or ristimulation, being activated T cells resistant to PCSC immune suppression. Even if other candidate immunosuppressive molecules expressed by PCSC, such as Galectin-3, are being currently investigating, all together, these findings confirm iNOS as a strategic target molecule for therapeutic applications against prostate adenocarcinoma.

P5.20.041
Inflammatory stress upregulates chemokine expression in uveal melanoma cell lines and increases monocyte migration

T. Jehs[1,2]*, H. B. Juel*[1,2]*, C. Faber*[1,2]*, I. H. G. Bronkhorst*[3,4]*, M. J. Jager*[3,4]*, M. H. Nissen*[1,2]*;*
[1]University of Copenhagen, Copenhagen, Denmark, [2]Department of of International Health, Immunology and Microbiology, Copenhagen, Denmark, [3]Leiden University Medical Center, Leiden, Netherlands, [4]Department of Ophthalmology, Leiden, Netherlands.

Purpose: Uveal melanoma (UM) is the most common primary intraocular tumor in adults and the presence of infiltrating leukocytes is associated with a poor prognosis. This study investigates the effect of activated T-cells on UM cell differential gene and protein expression, and the ability to attract monocytes.Methods: T-cells were purified from healthy human donors, activated with anti- CD3/CD28 beads and co-cultured over three UM cell lines for 64 h in a membrane insert. Supernatants were collected and RNA was purified from the UM cell lines. Gene expression analysis was performed with microarrays. Protein expression in the supernatants was quantified with a multiplex bead array. For the migration assay, CD14+ monocytes purified from healthy human donors were added in the upper chamber of a transwell plate. Supernatants were added to the lower chamber and plates were incubated for 2.5 h. Migrated cells were counted using flow cytometry.Results: Gene expression analysis of UM cell lines co-cultured with activated T-cells resulted in an upregulation of chemokines such as CXCL8, CXCL9, CXCL10, CXCL11, CCL2 and CCL5. The expression of these was confirmed on the protein level. This increase of chemokines coincided with increased monocyte attraction towards co-culture supernatants in a migration assay.Conclusions: Soluble factors derived from activated T-cells shift the UM cell-transcriptome towards a more inflammatory state, including the upregulation of several chemokines, which lead to an increased migration of monocytes. Therefore, UM cells might actively participate in generating an inflammatory environment around the tumor which corresponds to a worse prognosis.

P5.20.042
Interleukin-33/ST2 Axis Promotes Breast Cancer Progression and Angiogenesis by Intratumoural Accumulation of Immunosuppressive and Natural Helper Cells

I. Jovanovic*, N. Pejnovic, G. Radosavljevic, J. Pantic, M. Milovanovic, N. Arsenijevic, M. Lukic;*
Faculty of Medical sciences, Kragujevac, Serbia.

Interleukin-33 through binding to its receptor ST2 promotes Th2 responses, but whether IL-33 signaling affects antitumour immunity is not fully understood. Using 4T1 mammary tumour model that shares many characteristics with human breast cancer we demonstrate that IL-33 is expressed in endothelial and tumour cells. Administration of IL-33 accelerated tumour growth and development of lung metastases which was associated with increased intratumoural accumulation of CD11b+Gr-1+ myeloid derived suppressor cells, CD4+Foxp3+IL-10+ Tregs and IL-13 expressing Lin-Sca-1+ natural helper cells. A marked reduction of NKp46+FasL+ tumoricidal cells with pronounced increase of PD-1 expressing NK cells were observed in tumours after IL-33 treatment. A deficiency of the ST2 gene significantly reduced myeloid suppressor cells and highly enriched FasL expressing NK cells at tumour site. IL-33 promoted intratumoural proliferation and neovascularization which was attenuated in ST2-deficient mice. Higher number of immune suppressor cells and IL-10 expressing immature CD11c+ dendritic cells in spleens and increased serum levels of IL-10 and IL-13 were observed only in IL-33 treated tumour-bearing mice. A significantly reduced NK cell, but not CD8+ T-cell cytotoxicity in IL-33-treated mice was observed and the dispensable role of CD8+ T cells in mammary tumour progression was confirmed by their in vivo depletion. We show a previously unrecognized role for IL-33 in promoting breast cancer progression through increased intratumoural accumulation of immunosuppressive cells and neoangiogenesis and by diminishing innate antitumour immunity. IL-33 may be therefore considered as an important mediator in regulation of breast cancer progression.

P5.20.043
The role of memory T lymphocytes during growth of SL2 tumours in DBA/2 mice

J. Jursenaite[1]*, I. Girkontaite*[1]*, M. Mauricas*[1]*, D. Characiejus*[1,2]*;*
[1]State Research Institute Centre for Innovative Medicine, Vilnius, Lithuania, [2]Faculty of Medicine, Vilnius University, Vilnius, Lithuania.

The purpose of this study was to evaluate the role of central memory (TCM) and effector memory (TEM) T lymphocytes in the murine DBA/2-SL2 concomitant immunity system.
Tumours were implanted by injecting 107 SL2 lymphoma cells subcutaneously on the left (primary tumour) and the right side (secondary tumour) of the chest with the interval of 2 days. Peripheral blood was collected from the tail vein of individual mice on day 0 (prior tumour implantation) and on day 9 after primary tumour implantation. Percentages of TCM (CD8+CD44highCD62L+) and TEM (CD8+CD44highCD62L-) lymphocytes in the CD8+ subset in peripheral blood of tumour-bearing mice were analysed by flow cytometry. The weights of the tumours were measured after sacrificing the mice on day 9.
The percentage of TEM lymphocytes in the CD8+ subset significantly increased in peripheral blood of tumour-bearing mice on day 9 of experiment compared to day 0. The percentage of TCM lymphocytes was lower on day 9 compared to day 0. No correlation between the level of TEM lymphocytes in peripheral blood and the mass of primary or secondary tumour was found. Significant negative correlation was found between levels of TCM in peripheral blood and the mass of the secondary tumour.
Thus, expanded TEM lymphocytes do not influence the growth of tumours in the murine DBA/2-SL2 concomitant immunity system. TCM seem to inhibit the growth of the secondary tumour, despite their failure to expand during tumour growth.

P5.20.044
Myeloma with biclonal IgG lambda and IgD kappa in serum : a case report

S. Khlif[1]*, H. Hachicha*[1]*, S. Ben jemaa*[2]*, S. Feki*[1]*, M. Medhaffer*[3]*, M. Ben Ayed*[1]*, S. Baklouti*[2]*, M. Elloumi*[3]*, H. Masmoudi*[1]*;*
[1]Departement of Immunology Habib Bourguiba University hospital, Sfax, Tunisia, [2]Departement of Rhumatology Hedichaker University hospital, Sfax, Tunisia, [3]Departement of Hematology Hedichaker University hospital, Sfax, Tunisia.

IgD myeloma is a rare entity (1-3%). Kappa subtype contributes only 10-30% of IgD myelomas and biclonal gammopathies involving IgD are even more rare. In fact, biclonal bands constitute only 3-4% of all myelomas.
Case report : We report the case of a 57 years old women, who presented inflammatory low back pain and experienced a severe decline in general health. The symptoms were present 3 months before diagnosis. Laboratory test abnormalities included an elevated erythrocyte sedimentation rate (100mm /h), normochromic normocytic aplastic anemia, hypercalcemia (2,92 mmol/l), hyper-β2-

microglobuline (2,87 mg/l). Serum protein electrophoresis showed hypergammaglobulinemia with a monoclonal peak in gamma region. Immunofixation detected an IgD Kappa band and a faint IgG lambda one. Bone marrow aspirated from the sternum was found to contain 30% of malignant plasma cells. Radiograph magnetic resonance imaging (MRI) disclosed myelomateous infiltration of dorsolumber spine and spondylolisthesis, with no evidence of spinal cord compression.
IgD myeloma is a particular severe form of myeloma often associated with poor prognosis. The pathogenesis is unclear. This case presents interesting findings regarding prognosis: We discuss, on one side, pronostic significance of biclonal gammopathy with IgD-Kappa comparing to the monoclonal IgD myelomas. On the other side, we analyze particularities of the IgD Kappa compared to the typical IgD lambda.

P5.20.045
Effect of SAA1, SAA2 and SAA4 knockdown on proliferation and invasion of glioblastomas multiformes cells

***F. H. Knebel**, L. P. Bellé, R. B. Haga, G. H. Kaihami, A. Campa; University of Sao Paulo, São Paulo, Brazil.*

Serum amyloid A (SAA) is an immunomodulatory protein produced in acute and chronic inflammatory process, such as cancer. Our research group showed that glioblastomas multiformes - A172 and T98G cells - produce SAA and have proliferation, migration and invasion affected by SAA treatment (Knebel, et al. Mediators of Inflammation, 2013, in press). To understand the significance of SAA produced by the tumor itself or by an inflammatory process, SAA1, SAA2 and SAA4 genes knockdown were prepared by lentiviral system using five different plasmids for each SAA gene. ^{3}[H] thymidine incorporation and Boyden chamber assay were used for proliferation and invasion measurements, respectively. Among the five plasmids of each gene, we were able to selected at least one that present a gene inhibition greater than 88%. SAA1 and SAA2 knockdown inhibited proliferation and invasion of glioblastomas multiformes cells when compared to the wild type. However the SAA4 knockdown only inhibited the A172 proliferation. Although preliminary, our data may suggest that SAA1 and SAA2 contribute more than SAA4 to tumor invasiveness. Addition of recombinant SAA (Peprotech) revert the effects of silencing in most but not all cases. At this point it is crucial to identify the roles of each SAA genes and the genetic or cellular uniqueness that outline SAA responsiveness to identify the potentiality of SAA as a therapeutic target in cancer.

P5.20.046
Inactivation of tumor-specific CD8+ CTLs within tumor-infiltrating lymphocytes by tumor-infiltrating immunosuppressive tolerogenic dendritic cells

***H. Kogo**[1,2], H. Harimoto[1,3], M. Shimizu[1], T. Date[1], Y. Nakagawa[1], K. Nakatsuka[3], A. Wakabayashi[1], C. Sakamoto[3], E. Uchida[2], H. Takahashi[1];*
[1]Department of Microbiology and Immunology, Nippon Medical School, Tokyo, Japan, [2]First Department of Surgery, Nippon Medical School, Tokyo, Japan, [3]Third Department of Internal Medicine, Nippon Medical School, Tokyo, Japan.

Insufficient activation of tumor-specific class I MHC molecule-restricted CD8+ cytotoxic T lymphocytes (CTLs) will permit tumor growing in vivo. DEC-205+ dendritic cells (DCs), having the ability to cross-presenting capacity, can present captured tumor antigens in association with class I MHC molecules alongside costimulatory molecules, and induce the priming and activation of tumor-specific CD8+ CTLs. It has been suggested that reduced levels of costimulatory molecules on DCs may be a cause of impaired CTL induction and that some tumors may induce the downregulation of costimulatory molecules on tolerogenic DCs. To examine such possibilities, we established two distinct types of murine hepatoma cell lines, Hepa1-6-1 and Hepa1-6-2 from Hepa1-6 cells, and confirmed that they display similar antigenicities, as well as identical surface expression of class I MHC molecules. Hepa1-6-1 had the ability to grow continuously after subcutaneous implantation into syngeneic C57BL/6 mice and did not prime CD8+ CTLs. While, Hepa1-6-2 cells, which display reduced levels of adhesion molecules, failed to grow in vivo and efficiently primed CTLs. Moreover, Hepa1-6-1-derived factors converted CD11c+ MHC-IIhigh DEC-205+ DC subsets into tolerogenic cells, with downregulated costimulatory molecules and impaired cross-presenting capacities. These tolerogenic DCs appeared to inhibit the induction of tumor-specific CD8+ CTLs and suppress their cytotoxic functions within the tumor. Taken together, the findings presented here provide a new method of cancer immunotherapy using the selectivesuppression, depletion, or alteration of immunosuppressive tolerogenic DCs within tumors.

P5.20.047
Systemic changes of cellular immune parameters as observed in patients with preinvasive/invasive cervical cancer before and after treatment

***O. V. Kurmyshkina**[1], P. I. Kovchur[1], I. E. Bakhlaev[1], T. O. Volkova[1], A. N. Poltorak[2,1];*
[1]Petrozavodsk State University, Petrozavodsk, Russian Federation, [2]Tufts University, Boston, MA, United States.

Experimental data accumulated to date suggest that individual's immune status serves as a background creating permissive conditions for HPV persistence and cervical cancer initiation. Immune disorders occurring both at local and systemic levels during cervical cancer development may comprise changes not only in subpopulation composition of immune cells but also changes of their functional state as, for example, increased susceptibility to apoptosis. Induction of apoptosis-related processes in circulating lymphocytes, their contribution to cervical cancer progression and applicability as predictive immunologic markers requires thorough investigation. In this work we were aimed to: a) analyze changes of subpopulation composition of peripheral blood lymphocytes (cytotoxic and regulatory T-cells, T-helpers, natural killer cells, B-cells) at successive steps of squamous cervical cancer progression (severe dysplasia, carcinoma in situ, microinvasive carcinoma and invasive cancer stages II-IV); b) to measure the changes of CD95-expression and activity of caspases; c) to trace the restoration of these parameters after surgical and immunomodulatory treatment by alloferon-alfa. We found that progression of cervical cancer, beginning from early precancerous lesions, is accompanied by significant reduction of circulating cytotoxic and helper T-cells and increase of regulatory T-cells (Tregs), natural killers and B-lymphocytes. Gradual up-regulation of proteolytic activity of extrinsically regulated initiator capase-8 and its downstream effector caspases -3 and -6 as well as surface CD95 expression was observed. Complex immune-based treatment resulted in more efficient normalization of Tregs, NK- and B-cells in patients with pre- and microinvasive lesions. The work was supported by the Government of the Russian Federation (contract numbers 11.G34.31.0052, 2012-1.2.1-12-000-1014-027)

Repurposing Na^+/K^+ pump blockers for *in vitro* suppression of tumor development

***R. Lazarovicz**[1], M. Toma[1], O. Gavriliuc[1], L. Marusciac[1], A. Gruia[2], C. Tatu[1], G. Tanasie[1], C. Panaitescu[1], F. Bojin[1], V. Paunescu[1];*
[1]Victor Babes University of Medicine and Pharmacy Timisoara, Timisoara, Romania, [2]Clinical Emergency County Hospital Timisoara, Timisoara, Romania.

It has become clear that progression of carcinomas depend not only on alterations on epithelial cells, but also on changes of microenvironment. Solid tumors survival and development is often based on vascular network sustaining such an intense metabolic process. Main purpose of our study was investigation of effects of Na/K pump blockers on tumor cells and tumor associated fibroblasts (TAF).
TAFs and breast tumor cell line SK-BR3 were used. Ouabain, Na^+/K^+-ATPase inhibitor, was added in cell culture media for 24 and 48 hours in concentrations ranging from 10 µM to 1 nM, and amount of cellular utilization was determined by HPLC. MTT-based viability assay showed decreased proliferation rates for higher concentration of Ouabain. Flowcytometric analysis investigated expression of phenotypical markers, including CD106, CD90, CD44, CD29, CD117, CXCR4 for TAFs, and Her2, CD44, VEGF-R and CD29 for SK-BR3 cells. Gene expression of α1 and β1 subunits of Na^+/K^+ pump, as well as VEGF were determined using qRT-PCR method. The results

showed that VEGF secretion was significantly reduced in Ouabain-treated SK-BR3 and TAFs. Although level of expression for α1 catalytic subunit was increased in SK-BR3, we could not find presence of corresponding protein, reflected also in high levels of Ouabain detected in cellular supernatant. Expression of adhesion molecules was decreased, and we found profound changes in phenotypic profile of both TAFs and SK-BR3 cells. Based on their anti-angiogenic and
anti-proliferative activity, Na^+/K^+ pump inhibitors could open novel anti-tumoral therapeutic strategies.

Down-regulation of EMT signal and invasive properties of colon cancer cells by SOCS1

C. Lee[1], *W. Kim*[1,2], *S. Ahn*[1], *B. Yoo*[2];
[1]*Sungkyunkwan University, Suwon, Republic of Korea,* [2]*Research Institute, National Cancer Center, Goyang, Republic of Korea.*

Growth-stimulatory and inflammatory cytokines promote the proliferation and progression of tumors via invasion and metastasis through multiple signaling pathways in tumor microenvironments. Using colon cancer cells over-expressing or knock-down for suppressors of cytokine signaling (SOCS) isoforms, we have studied the mechanism of anti-tumor effects of SOCS through the regulation of epithelial-mesenchymal transition (EMT) in vitro and metastasis in in vivo animal models. SOCS1 but not SOCS3 promoted radiation-induced G1 arrest and 5-FU-induced apoptosis in p53-sensitive manners. SOCS1 further inhibited the p53+/+ HCT116 cell migration and invasive properties under radiation assessed by wound-healing and Matrigel assays, respectively. The SOCS1-overexpressing cells exhibited upregulation of E-cadherin with reduced beta-catenine and Twist levels, while SOCS1 knock-down cells expressed increased vimentin and Twist levels. Although phosphorylation of STATs were variable, p-Src, p-Akt, p-Erk and p-4EBP and NF-kB levels were suppressed in SOCS1-expressing cells, suggesting a STAT-independent down-regulation of EMT signaling by SOCS1 in this system. In addition, the confocal analysis indicated that SOCS1 helps to retain epithelial morphology by suppressing EMT. Finally in tumor implantation animal models, SOCS1-transduced HCT116 tumor cells exhibited substantial retardation in growth and possible dissemination when introduced in spleen and I v injection into nude mice. The in vivo imaging of tumor cells by PET scanning is being employed to assess the metastatic behavior of SOCS-regulated tumor cells. <Supported by KRF grant #2012-02032067 and #2012-015258>

P5.20.050
B7-H4 modulates anti-tumor responses by limiting immunosuppression in the tumor microenvironment

J. Leung*, W. Suh;*
McGill, Montreal, QC, Canada.

B7-H4 belongs to the B7 family of T cell immunomodulatory molecules, and has been shown to inhibit T cell responses and neutrophil expansion. B7-H4 is highly overexpressed in multiple types of human cancers; as such, a pro-tumorigenic role has been implicated for B7-H4. However, its impact on the immune response during tumorigenesis is unknown. Here, we examine the host response in B7-H4-deficient mice upon injection of 4T1 carcinoma cells. We reveal that B7-H4 not only inhibits T helper 1 responses, but that it also inhibits the pro-tumor function of myeloid-derived suppressor cells (MDSC). As such, we observed greater expression of both anti-tumor immune effectors and MDSC-associated transcripts in 4T1 tumors grown in B7-H4 KO mice. Although the rate of 4T1 growth in B7-H4-deficient hosts was similar to that of WT mice, tumors derived from B7-H4 KO hosts grew much slower upon a secondary injection into wild-type recipients. This suggests that tumors grown in the absence of B7-H4 have reduced immune-evasive capacities. Consistently, MDSCs from B7-H4 KO mice suppressed T cell proliferation more effectively than WT MDSCs. Collectively, this implies that MDSCs from B7-H4 KO hosts suppress T cells during tumor growth, leading to greater immunosuppression in the tumor milieu, which allows outgrowth of 4T1 variants with diminished immune evasive capacity. Thus, our data show that B7-H4 has inhibitory roles for both anti-tumor and pro-tumor components of the immune system which may be counterbalanced if B7-H4 blockade is applied during cancer immunotherapy.

DcR3 gene polymorphisms are associated with sporadic breast infiltrating ductal carcinoma in chinese northeast women:a case control study

Z. Fu, D. Li, S. Chen, ***D. Li****;*
Harbin Medical University, Harbin, China.

Decoy Receptor 3(DcR3), which gene maps to a chromosomal region (20q13.3) is also called TNFRSF6b, can bind its ligands including FasL, LIGHT and TL1A. The expression of DcR3 is not detectable in normal tissues, but in some malignant tissues its expression is upregulated. In our research, there are 531 female breast IDC cases (age49.5±9.9) and 592 normal controls (age45.4±9.9). We chose five SNPs in DcR3 gene including rs3208008 in 5'-near gene region, rs41309931 in intron, rs2297441 in intron, rs909341 in exon and rs1291207 in intron. The minor genotype frequency of five SNPs was more than 5% in CHB population. From the result, we found that SNPs in rs41309931 and rs909341 had significant statistical differences in genotypes and alleles. The most frequent haplotype appeared in cases and controls were AGGTA (rs3208008 A, rs41309931 G rs2297441 G, rs909341 T, rs1291207 A) and the frequency of it was significant higher in cases. We also analyzed the relationship between the polymorphisms of DcR3 gene and a series of clinicopathologic features, including tumor size, lymph node metastasis, and the statuses of ER, PR, C-erbB2 and P53. In summary, our case-control study was the first report regarding the association between SNPs in DcR3 gene and breast IDC, especially in Chinese females.

P5.20.052
HVEM gene polymorphisms are associated with sporadic breast cancer in Chinese women

D. Li*, D. Li, Z. Fu, S. Chen;*
Harbin Medical University, Harbin, China.

As a costimulatory molecule, Herpesvirus entry mediator (HVEM) can bind with several costimulatory members, so it plays different roles in T cell immunity. HVEM and its ligands have been involved in the pathogenesis of various autoimmune, inflammatory diseases and tumors. In this research, we first investigated a case-control study between polymorphisms of HVEM and breast cancer, including 575 breast cancer females and 604 age-matched healthy controls. Six of HVEM SNPs (rs2281852, rs1886730, rs2234163, rs11573979, rs2234165 and rs2234167) were genotyped by PCR-RFLP. The results showed that rs1886730 and rs2234167 had significant differences in genotypes and alleles (P<0.05). In haplotypes analysis, we found that three haplotypes were associated with breast cancer. The association between polymorphisms of HVEM and clinicopathologic features were shown in our research, including lymph node metastasis, ER, PR and P53. Our results primarily indicated that polymorphisms of HVEM gene were associated with the risk of sporadic breast cancer in northeast Chinese females.

P5.20.053
Association of LTBR gene polymorphisms with sporadic infiltrative duct carcinoma in northeast Chinese Han population

S. Chen, W. Yuan, Z. Fu, ***D. Li****;*
Harbin Medical University, Harbin, China.

Background: LTBR signaling plays important roles in the formation of peripheral lymphoid organs, interferon responses to pathogens and dendritic cell regulation. Accumulating evidence indicates that LTBR signaling is also involved in inflammation-induced carcinogenesis and cancer development. Herein, we set out to investigate the association between LTBR gene polymorphisms and sporadic infiltrative duct carcinogenesis and tumor pathology.

Methods: Our research subjects consist of 516 patients with sporadic infiltrative duct carcinoma and 524 age-matched healthy controls. Four SNPs (Rs3759333, Rs11064157, Rs2302256, and Rs2364480) in the LTBR gene were genotyped by the polymerase chain reaction restriction fragment length polymorphism (PCR-RFLP) method. Differences in the genotypic distribution between patients and healthy controls were analyzed using unconditional logistic regression model. In addition, The associations between LTBR polymorphisms and the clinical features of patients including tumor size, clinical grade, lymph node metastasis, human epidermal growth factor receptor 2 (C-erbB2), estrogen receptor (ER), progesterone receptor (PR) and p53 statuses were further analyzed.
Results: In Rs3759333, the frequency of CT genotype and TT genotype were lower in cases than in controls (P = 0.027 and 0.001, respectively). Haplotype TCCA (Rs3759333-Rs11064157-Rs2302256-Rs2364480) has a lower distribution in patients than in controls (corrected P=0.026) . Significant associations were also observed between LTBR polymorphisms and ER, PR, C-erbB-2 statuses in patients.
Conclusion: Our data primarily indicates that LTBR polymorphisms contribute to sporadic infiltrative duct carcinogenesis in a northeast Chinese Han population.

P5.20.054
Association Analysis between HLA-DRB1 Allelic Polymorphisms and Age to Identify Genes Promoting the Early Onset of Solid Cancers

H. Liu;
Dalian Medical University, Dalian, China.

AIM: To explore relationships between the early-onset solid cancer and HLA-DRB1 allelic polymorphism and develop an efficient research method for identifying early onset solid cancer-related genes. **METHODS:** Patients with different solid cancers, including gastric, liver, and lung cancers, were recruited as the cancer group. On the basis of their age at the time of the first surgery, 70 patients were divided into the following 7 age groups with 5 males and 5 females in each group: < 50 years, 50-54 years, 55-59 years, 60-64 years, 65-69 years, 70-74 years, and 75-79 years. The 70 healthy subjects, who were also divided into 7 age groups as was the cancer group, were served as the control group. The samples were typed using an HLA-DRB1 PCR-SSP typing kit. The mean age of patients and healthy subjects with and without the alleles was calculated respectively. **RESULTS:** In the cancer group, the mean age of patients with HLA-DRB1*01 (52.5 years old) was less than that of patients without this allele (62.1 years old). There was an interaction between the mean age of patients in both groups (cancer and control) and the genes (positive and negative expression; $p < 0.05$). **CONCLUSIONS:** HLA-DRB1 alleles may be involved in the pathogenesis of early-onset solid cancer. The inherent anti-cancer mechanisms may be a common pathway for different cancers and are associated with the immune system and HLA.

P5.20.055
HLA-E is expressed and functional in melanoma but not melanocytes

E. Lo Monaco[1], *E. Tremante*[1], *P. G. Natali*[2], *M. Mottolese*[1], *P. Visca*[1], *M. Benevolo*[1], *P. Giacomini*[1];
[1]*Regina Elena National Cancer Research Institute, Roma, Italy,* [2]*CINBO Laboratories, University of Chieti, Chieti, Italy.*

Human Leukocyte Antigen E (HLA-E) is a ligand of both inhibitory (e.g. NKG2A) and activating (e.g. NKG2C) Natural Killer (NK) cell receptors. We have previously shown that HLA-E is often expressed in tumors (ovarian and testicular tumors, non-small-cell lung carcinomas and soft tissue tumors) deriving from an HLA-E-negative normal counterpart, and is expressed in a subset of colorectal carcinomas infiltrated by NKG2A+ T cells and characterized by a favorable outcome. Upon immunohistochemical testing of >100 nevomelanocytic lesions (conventional sections and tissue arrays), we now report that HLA-E gradually increases with tumor progression: from weak expression in 15% of nevi (including rare and atypical lesions), to low-intermediate expression in 57% of primaries, to a full range of expression levels (including high homogeneous staining) in 67% of metastatic lesions. Cell surface biotin labeling reveals higher surface HLA-E levels on melanoma than melanocyte cultures. Surface HLA-E partially protects (via NKG2A) most (8/10) melanoma cell lines from lysis by 30% of the tested polyclonal NK cell effectors, and functionally counteracts activating NK receptors. In contrast, all (7/7) the tested melanocyte cultures are fully protected independently of HLA-E, and can be lysed only following IL-2 treatment of NK cell effectors. Tumor-selective usage of HLA-E by NK cells, and the different intrinsic susceptibility of melanoma and melanocytes to NK cell lysis document an unprecedented 'threshold' strategy for the immune discrimination of normal versus neoplastic counterparts. Supported by AIRC.

Dendritic cell density and HMGB1 expression in non-small cell lung carcinomas

J. S. Lopez-Gonzalez[1], *D. Aguilar-Cazares*[1], *M. Meneses-Flores*[1], *H. Prado-Garcia*[1], *V. Rojo-Leon*[2], *L. Islas-Vazquez*[2];
[1]*Instituto Nacional De Enfermedades Respiratorias Ismael Cosio Villegas, Mexico city, Mexico,* [2]*Posgrado en Ciencias Biologicas, Universidad Nacional Autonoma de Mexico, Mexico city, Mexico.*

Lung cancer is the leading cause of cancer death worldwide and non-small cell lung carcinoma (NSCLC) is the most common type of lung carcinomas. In NSCLC, the adenocarcinomas and the squamous cell carcinomas are the most frequent histological types. In NSCLC no studies investigating the role of the alarmin high-mobility group box1 (HMGB1) and the density of intratumoral DCs recruitment have been done. In the present study, a total of 38 cases of advanced stages of NSCLC were included. Tissue samples were obtained from biopsies. DCs were detected by immunohistochemistry, and quantified in high power fields. Also, subcellular distribution of HMGB1 in tumor cells, and in NSCLC cell lines was studied. In addition, HMGB1 produced by NSCLC cell lines was detected by ELISA. Squamous cell carcinomas expressed HMGB1 into nucleus and no or very low infiltrations of DC were observed. In lung adenocarcinomas, high densities of infiltrating DCs were observed and were associated with lung adenocarcinomas expressing cytoplasmic or nuclear-cytoplasmic HMGB1. NSCLC cell lines constitutively produced HMGB1 and the addition of cisplatin (40 μM) induced apoptosis, membrane translocation of calreticulin and an increase of HMGB1 secretion. These results suggest that in adenocarcinoma patients, treatment with conventional chemotherapy may induce immunogenic apoptosis; in addition, the acute release of HMGB1 should attract more DCs, which engulf apoptotic cells to stimulate an antitumor immune response.

Studies on immunogenetic mechanism of hepatocellular carcinoma caused by Fas gene polymorphism

H. Mao[1], *J. Zhang*[2], *Y. Yang*[1], *J. Sun*[1], *C. Ma*[1], *W. Gao*[1], *B. Song*[1], *Q. Shao*[1], *X. Qu*[1];
[1]*Institute of Basic Medicial Sciences, Qi Lu Hospital, Shandong University, Jinan, China,* [2]*Department of hepatopathy,Shandong provincial hospital, Jinan, China.*

Background: To investigate the genetic pathogenesis of hepatocellular carcinoma (HCC) caused by Fas gene polymorphisms and explore the reason of negative expression of Fas in hepatocarcinoma cells. Methods: Forty-five chinese patients with primary HCC and 36 unrelated age matched control patients with benign liver disease participated in this study. One single nucleotide polymorphism (SNP) of Fas at position -670 in the promoter (Fas-670) was genotyped by polymerase chain reaction and restriction fragment length polymorphism (PCR-RFLP). Results: Our studies revealed the negative expression of Fas receptor on the surface of HCC cells. Moreover, the Fas-negative HCC cells showed resistance to Fas-mediated apoptosis. In present study, we found that the frequency of AG genotype at position Fas-670 was higher in HCC patients than in control individuals (60.0% vs 30.6%, p=0.013, OR=3.41, 95% Confidence Interval: 1.35-8.61). Meanwhile, there was a decreased frequency of genotype AA in patients compared with

controls (20.0% vs 58.3%, *p*=0.0005, OR=0.18, 95% Confidence Interval: 0.07-0.48). But there was no difference in the frequencies of GG genotype between patients and controls. Moreover, the frequencies of G allele and G allele carrier in Fas-670 site of patients with HCC were all higher significantly than that of controls. Conclusions: Our study suggested that replacement of A to G in Fas-670 site might affect the expression of Fas in hepatocarcinoma cells, thereby may be one of the susceptibility factors for HCC.

P5.20.058
Identification and characterization of candidate MDSCs in PBMCs of patients with lymphoproliferative malignancies

O. Marini[1], *M. A. Cassatella*[1], *G. Pizzolo*[2], *P. Scapini*[1], *C. Tecchio*[2];
[1]*Department of pathology and Diagnostics, Division of General Pathology, University of Verona, Verona, Italy,* [2]*Department of Medicine, Section of Hematology, School of Medicine, University of Verona, Verona, Italy.*

Myeloid derived suppressor cells (MDSCs) are a heterogeneous myeloid cell population with the ability to suppress immune responses that include two major subsets, monocytic and granulocytic MDSCs. Aim of this study was to characterize the morphological, immunophenotypical and functional features of myeloid cells in peripheral blood samples from a large cohort (110) of newly diagnosed patients with lymphoproliferative malignancies (LMs) in order to investigate the presence of candidate MDSC subsets. Based on the expression of CD11b, CD66b, CD33, CD16, CD14 and CD45 we evaluated the frequency/number of total myeloid cells (CD11b+ cells), granulocytes (CD11b+ SSChigh CD66b+) and monocytes (CD11b+ SSClow CD33++), as well as their subtypes, within the PBMC fraction of each sample. Our data revealed that the frequency and distribution of myeloid cells were strongly increased in PBMCs of patients with LMs, particularly for the granulocytic lineages. We also found that depletion of CD11b+myeloid cells from PBMCs of patients with LMs restored autologous T lymphocyte proliferation, suggesting the presence of candidate MDSCs within this population. These data reveal the presence of immunosuppressive CD11b+ myeloid cells, most likely of the granulocytc lineages, within the PBMC fraction of patients with active LMs.

Solid tumors represent an extreme example of tissue where immune cells, either resident or infiltrating, might get aberrantly activated and affect the clinical course of disease. We established an algorithm which allows to assess a link between the patient-specific immunological capacity and clinical outcome for patients with colorectal cancer liver metastases (CRCLM). The microscopy-based TissueFAXS system was used for automated scanning of the large-scale tissues sections, followed by identification of single cells in the complex tissue environment and quantification of positively stained immune cell subtypes using image analysis softwares. Tissue sections were analysed for CD45 to detect all classes of infiltrating immune cells; CD20, AID, CD138, and IgM to characterize the B cell populations; and CD68 to detect macrophages. For specimen's comparison, we applied a uniform strategy by defining subregions at tumor-liver border and within liver tissue. Results indicate massive infiltration of $CD45^+$ cells confined to tumor-liver border which showed patient-specific organization patterns. Important observation of the current study describes the formation/presence of ectopic follicular structures. Fully developed ectopic structures were characterized as $CD20^+$/AID^+ surrounded by IgM^+ mantel zone and $CD138^+$ plasma cells. Of importance, the recurrence free survival was found to be significantly better in patients with high CD45 and high CD20 content. The findings emphasize the impact of the B-cell driven local immune response on the CRCLM disease progression. In summary, the established algorithm allows to estimate the prognostic power of infiltrating immune cells within complex malignant tissue as new biomarker for clinical outcome.

P5.20.060
Melanoma cells produce adenosine through a CD38/CD73 pathway and suppress $CD4^+$ T cell proliferation

F. Morandi[1], *A. L. Horenstein*[2], *B. Morandi*[3], *P. Carrega*[4], *A. Chillemi*[2], *G. Zaccarello*[2], *M. C. Mingari*[3], *V. Pistoia*[1], *F. Malavasi*[2];
[1]*Laboratory of Oncology, Istituto Giannina Gaslini, Genoa, Italy,* [2]*Lab of Immunogenetics, Department of Medical Sciences, University of Torino, Torino, Italy,* [3]*Department of Experimental Medicine, University of Genoa, Genoa, Italy,* [4]*Istituto Giannina Gaslini, Genoa, Italy.*

Nucleotide-metabolizing ectoenzymes include CD38/CD157 (ADP ribosyl-cyclases) CD203a/PC-1 (ectonucleotide pyro-phosphatase/phosphodiesterase-1), CD39 (ecto-nucleoside triphosphate diphosphohydrolase-1) and CD73 (ecto-5'-nucleotidase). These ectoenzymes regulate the extra-cellular nucleotide/nucleoside balance. Adenosine (ADO), a purine nucleoside generated by this network, concentrates in different solid tumors and promotes their growth by promoting angiogenesis and inhibiting immune responses. Moreover, inhibition of CD73 in melanoma murine models limits tumor growth and restores anti-tumor immune responses.
We investigated the expression and function of the ectoenzyme network in 3 primary and 3 continuous human melanoma cell lines. CD38 and CD73 were highly expressed by all cell lines. CD39 and PC-1 expression was elevated only in 3 cell lines and low to intermediate in the others. CD157 expression was low in all cell lines. ADO was produced in cell lines from AMP and, to a lesser extent, from ATP and NAD^+. ADO production was increased after pre-treatment of cells with a specific inhibitor of adenosine deaminase (ADA). Three primary melanoma lines were tested for their ability to inhibit proliferation of $CD4^+$ T cells. The proliferation was significantly inhibited, both in co-culture and in transwell systems. The inhibitory effects were reverted when cell lines were pre-treated with specific inhibitors of CD38 or CD73 (but not of PC-1 or CD39).
In conclusion, we have demonstrated that melanoma (primary or established lines) cells induce immunosuppression *in vivo*. This effect is mediated by ADO produced via an ectoenzyme network, which hinges upon CD38 and CD73.

P5.20.061
Nasopharyngeal carcinoma-derived exosomes recruit, expand and up-regulate biological activities of human regulatory T cells

D. Mrizak[1], *O. Moralès*[1], *N. Martin*[1], *Y. De Launoit*[1], *P. Busson*[2], *N. Delhem*[1];
[1]*CNRS Institut de biologie de Lille, Lille, France,* [2]*Institut Gustave Roussy, Villejuif, France.*

Exosomes are nano-vesicles found in large quantities in biological fluids and tumors of patients with nasopharyngeal carcinoma (NPC). These tumor exosomes play an important role in tumor progression due to their immunosuppressive properties. In addition, it has been reported that the frequency and suppressor functions of CD4+CD25highFoxP3+CD127low Treg are also higher in NPC patients than healthy donors. As interactions between NPC-derived exosomes and Treg remain unknown, we investigated their ability to induce, expand, activate and recruit human Treg.

Treg were isolated from blood of healthy donors and co-incubated with exosomes purified from (i) culture supernatants of NPC cell lines (C15 exosomes) or (ii) the plasma of healthy donors (HD exosomes). C15 exosomes significantly increased Treg expansion and generated Treg Tim3low insensitive to the suppression induced by exosomes. C15 exosomes also significantly increased the level of expression of CD25high and FoxP3high on Treg and lead to the conversion of CD4+CD25- T cells into CD4+CD25high Treg. Moreover, C15 exosomes induces over expression of the genes associated with Treg phenotype, their suppressive activity and recruitment. These results are correlated with a significant increase in the suppressive activity of Tregs in the presence of C15 exosomes. Finally, the C15 exosomes are able to facilitate the recruitment of Treg cells in CCL-20 chemokine dependent manner.
Our results give new insights about NPC-derived exosomes immunoregulatory properties. Interactions of NPC-exosomes with CD4+ regulatory T cells represent a newly-defined mechanism that might be involved in regulating peripheral tolerance by tumor cells and supporting immune evasion of human NPC.

Evaluation of the use of the CA-15-3 in monitoring of Breast cancer in A B U teaching hospital, Zaria, northern Nigeria

B. O. P. Musa[1], *D. A. Dawotola*[2], *L. M. D. Yusufu*[3], *V. I. Odigie*[3];
[1]*Immunology Unit, Department of Medicine, A.B.U.Teaching hospital, Zaria, Nigeria,* [2]*2. Radiotherapy and Oncology center, Ahmadu Bello University teaching hospital (ABUTH), Zaria, Zaria, Nigeria,* [3]*3. Breast and Endocrine Unit, Department of General Surgery, Ahmadu Bello University teaching hospital (ABUTH), Zaria, Zaria, Nigeria.*

Introduction: Breast cancer is a traumatic and pathologically debilitating disease in northern Nigeria. Traditionally, diagnosis of breast cancer is done by clinical examination and histological confirmation. Immunological diagnosis of breast cancer using tumor molecular biomarkers is lacking. This pilot study was conducted to investigate and analyze the use of CA-15-3 marker in relation to disease in patients with breast cancer as a simpler, robust test which could have importance in clinical decision making. **Methodology:** All female patients sent to the Radiotherapy and Oncology center, between January 2009 and January 2013, were purposively and consecutively bled and tested for CA-15-3 in serum using a high sensitivity commercial enzyme immunoassay kit. Informed consent and ethical approval was obtained prior to testing. Levels of CA-15-3 were statistically compared with disease stage and tumor grade. **Results:** A total of 45 patients (33-75yrs) participated. Disease status of the patients included 40 invasive ductal Ca, 4 invasive lobular Ca and 1mixed Ca. There were 31 pre- and 14 post-menopausal women; 36 in non- metastatic and 9 in metastatic disease. There were no patients in disease stage I, 4 in stage II, 32 in stage III and 9 in stage IV (These same 9 patients had primary disease and values of CA-15-3 well above the cut- off limit of positive of 35 units/mL). Values of CA-15-3 correlated positively with disease staging. **Conclusion:** CA-15-3 is clinically relevant in the staging and monitoring of patients with breast cancer.

P5.20.063
Prediction of Radix Astragali immunomodulatory effects of CD80 expression on THP-1 cells from chemical chromatograms by Quantitative Pattern-Activity Relationship (QPAR)

C. Ng[1], *T. Lau*[1], *K. Fan*[2], *Q. Xu*[3], *F. Chau*[1], *M. Sze*[1];
[1]*The Hong Kong Polytechnic University, Hong Kong, Hong Kong,* [2]*University of Sydney, Sydney, Australia,* [3]*Central South University, Changsha, China.*

Our laboratory has previously shown that blood dendritic cells in cancer patients, particularly those in progressive phase, have reduced their CD80 costimulatory capacity. It is known that Chinese Herbal Medicines (CHM) such as Radix Astragali (RA) has a long history of clinical application for immunity enhancement. For quality control to ensure batch-to-batch consistency of CHM due to its complex mixture nature, single component as a representative marker is inadequate. In this Quantitative-Pattern-Associated-Relationship (QPAR) study, our aim is to build a chemometric-bioactivity-chemical predictive model for the CD80 expression due to RA on THP-1 cells. By correlating the chemical and biological data of 72 whole RA extracts, bioactivity of new RA extracts can be predicted by simply providing the chemical fingerprints. Using Elastic-Net-Partial-Least-Square algorithms, both chemical and biological data from 48 RA extracts as a training set were used to establish the CD80 bioactivity of RA predictive model. The remaining one-third (n = 24, test set) was used to validate the predictive power. This model gave a high statistical predictive quality (q2 = 0.92). More importantly, the regions on RA chromatographs with respect to their relative importance in contributing to the CD80 expressions were also identified. In this RA-QPAR study, we successfully explored and exploited the relationship between the chemical and biological fingerprints to successfully establish a predictive model; and revealed the features in the chromatographic profiles responsible for such bioactivities. This may bring novel insights into herbal vaccination-adjuvants preparation and may lead to correct the defective dendritic cell CD80 co-stimulatory capacity.

Myeloid-derived suppressor cells attenuate Th1 development through IL-6 production to promote tumor progression

H. Tsukamoto, S. Senju, ***Y. Nishimura****;*
Department of Immunogenetics, Graduate School of Medical Sciences, Kumamoto University, Kumamoto, Japan.

Collaborative action between tumor cells and host-derived suppressor cells leads to peripheral tolerance of T cells to tumor antigens. Currently, IL-6 and a soluble form of IL-6 receptor are increasingly attracting attention as the therapeutic targets because their levels rise in various cancer patients. Here, we demonstrated that in tumor-bearing mice, generation of tumor antigen-specific effector Th1 cells was significantly attenuated, and impaired Th1 differentiation was restored by the temporal blockade of IL-6 activity at the T-cell priming phase. We also found that Gr-1+ myeloid-derived suppressor cells (MDSC) served as a source of IL-6 in tumor-bearing mice. Adoptive transfer approach revealed that MDSC-sensitized effector CD4+ T cells were less potent to mount anti-tumor immune responses, although effectors T cells generated together with Gr-1+ cells from tumor-free mice eradicated established tumors. CD8+ T cells, IFN-γ and MHC-class II expression in host mice were indispensable for CD4+ T cell-mediated anti-tumor activity. Despite comparable suppressive activity of IL-6+/+ and IL-6-/- MDSC on primary T-cell activation, transfer of IL-6+/+ MDSC, but not IL-6-/- MDSC dampened the efficient induction of Th1 cells and counteracted CD4+ T cell-mediated anti-tumor immunity including cognate help for CD8+ T cells in vivo. These findings suggest that, apart from the inhibitory effects on primary T-cell activation, MDSC attenuate functional differentiation of tumor-specific CD4+ T cells into effector Th1 cells through IL-6 production to promote tumor progression. This novel mode of MDSC-induced tolerance of CD4+ T cells should be considered as basis for the rational design of T cell-mediated anti-tumor therapies.

P5.20.065
Evaluation of a hydroalcoholic extract of *Uncaria tomentosa* on dendritic cells and Th1/Th2/Th17 profile, IL-12 in breast cancer patients

C. E. Nuñez, ***C. E. Nuñez****, I. A. Lozada-Requena, T. P. Ysmodes, S. R. Davila, Y. P. Alvarez, C. Ocampo, J. L. Aguilar Olano;*
Universidad Peruana Cayetano Heredia, Lima, Peru.

The antitumor immunity uses dendritic cells (DC) activating lymphocytes and immunomodulatory cytokines. **Objective:** Determine the effect of the hydroalcoholic extract of *Uncaria tomentosa* (Cat's Claw-3% oxindole alkaloids) (UG) in subpopulations of DC, its HLA-DR/CD86 molecules and cytokines Th1/Th2/Th17, IL-12 (p70/p40) in mononuclear cells (PBMC) from patients with breast cancer (BC) and healthy women (HW). **Methods:** We isolated PBMC from 07 women with BC stage II (58±12years) and 10 HW (47±9years). Conditions: Baseline Control (CB); Stimulation with lipopolysaccharide (1ug/mL) (LPS) and LPS plus 50, 500 or 1000ug/mL. We cultivate 0.5x106cells/mL with/without UG for 2h and LPS for 24h. PBMC were labeled with anti-CD11c-APC, HLA-DR-

PerCP, CD86-PE and Lin1-FITC for measurements in supernatant by cytokine cytometric bead array (CBA) and ELISA. **Results:** Percentage of mDC (myeloid) in HW decreased at 500 and 1000ug/mL ($p<0.05$) but HLA-DR and CD86 with 1000ug/mL increased ($p<0.05$). Only DCp HLA-DR in HW increased at 1000 µg/mL ($p<0.05$). In both, BC and HW with 500 and/or 1000ug/mL ($p<0.05$) increased IFN-gamma, IL-2, IL-4 and IL-17A. Only in HW, IL-12p70 and IL-12p40 decreased at 1000µg/mL ($p<0.05$). **Conclusions:** BC DC do not respond to UG, but partially in HW had an immunomodulatory opposite effect. UG would encourage Th1/Th2/Th17 antitumor response.

Allelic variants in promoter region of FOXP3 gene as a protective factor in breast cancer development

***J. M. M. Oda**, K. B. de Oliveira, R. L. Guembarovski, C. E. C. de Oliveira, P. M. M. Ozawa, B. K. B. Hirata, C. B. Ariza, C. Z. Campos, D. R. Derossi, M. A. E. Watanabe;*
State University of Londrina, Londrina, Brazil.

Breast cancer is a heterogeneous disease and normally associated with immune cell infiltration. Regulatory T cells (Tregs) play important role promoting tumor growth and progress by inhibiting the immune response against cancer. One gene involved in various cellular processes on the function of Tregs is FOXP3 (transcription factor forkhead box3). Polymorphisms in FOXP3 promoter region are associated with breast cancer. TGF- β (transforming growth factor β1) is another important molecule that plays a central role in the generation and function of Tregs. An important allelic variant in the TGF-β1, is the +869 C/T (Leu10Pro) that interfere in the cytokine production. For this reason, we investigated the influence of polymorphisms in these genes in susceptibility and progression of human breast cancer. Genomic DNA was obtained from 162 breast cancer patients and from 218 healthy donors and was amplified by allelic specific polymerase chain reactions (ASP-PCR). The two polymorphisms of FOXP3 gene has a protective effect against breast cancer development: FOXP3 rs2232365 (OR = 0.49; 95% CI: 0.30-0.81) FOXP3 rs3761548 (OR= 0.28; 95% CI=0.11-0.77), FOXP3 haplotype (OR=0.08; 95% CI=0.01-0.60), otherwise no association was found with TGF-β polymorphism. A positive correlation between FOXP3 polymorphisms and clinical staging (p=0.011), HER-2 (p=0.033) and nuclear grade (p=0.004) was observed. The presence of allelic variants in promoter region of FOXP3 seems to have a protective effect in breast cancer susceptibility and also that the role of this gene as a marker of tumor progression must be more investigated, particularly in subtypes of breast tumors.

Modeling leukemia immunoediting in mouse-human chimeras

***G. Oliveira**, C. Toffalori, J. M. Garcia-Manteiga, B. Camisa, A. Bondanza, E. Stupka, F. Ciceri, K. Fleischhauer, C. Bonini, L. Vago;*
San Raffaele Scientific Institute, Milano, Italy.

Acute Myeloid Leukemia (AML) can be recognized and eliminated by the immune system, as demonstrated by the clinical efficacy of allogeneic hematopoietic stem cell transplantation. Still, immune-resistant variants of AML can outgrow upon the selective pressure of the transplanted immune system and determine clinical relapse, in a process called “leukemia immunoediting”, the biological bases of which remain largely unknown.
In the present study we engrafted primary human AML in immunocompromised NOD/SCID γ-chain null mice and modeled adoptive immunotherapy by serial infusions of human T cells, either autologous or allogeneic to the leukemic cells, with the ultimate aim of analyzing the alterations induced by immune pressure on leukemia gene expression profile.
HLA-mismatched allogeneic T cells eradicated AML from 6/6 treated mice, whereas HLA-identical T cells granted only temporary control in 3/3 mice and autologous T cells were completely inefficacious in 3/3 mice.
We examined the gene expression profile of AML blasts purified from the mice. Leukemic cells not subjected to immune pressure did not significantly differ from primary leukemia. On the contrary, upon escape from immune pressure, leukemic blasts showed a specific gene signature, significantly different from untreated controls. Gene enrichment analysis demonstrated the selective deregulation of genes involved in immune processes. The most importantly deregulated genes were related to proteolysis, to antigen processing and presentation, and to RNA transcription and translation.
Our findings provide a robust model to demonstrate that leukemic cells are able to shape their immunogenicity upon T cell pressure, and a valuable tool to investigate these processes.

P5.20.068
Breast and kidney-expressed chemokine (CXCL14) in breast cancer

***Z. Ou**, X. Gu, F. Lin, X. Yang, Y. Guo, Z. Shao;*
Fudan University Cancer Hospital, Shanghai, China.

Breast and kidney-expressed chemokine (BRAK), also known as CXC chemokine ligand 14 (CXCL14), was initially identified as a chemokine highly expressed in the kidney and breast. Although CXCL14 was first found in breast, very little is known about the detailed role of it in human breast cancer so far.
In this study, we tried to demonstrate the relationship between CXCL14 and breast cancer. Gene expression of CXCL14 is lower in breast cancer cell lines, and MDA-MB-231HM express lowest levels of CXCL14 mRNA. Overexpression of CXCL14 inhibited cell proliferation and invasion *in vitro* and attenuated xenograft tumor growth and lung metastasis *in vivo*. CXCL14 significantly decreased the intratumor microvessel density (MVD) by immunohistochemistry using the anti-CD34 antibody in the specimens of xenografted mice. In 208 patients with breast cancer, the positive rate of CXCL14 is about 25.5% (53/208). CXCL14 protein level is positively correlated to the overall survival (OS), and negatively correlated to lymph node (LN) metastasis. Our study showed for the first time that CXCL14 is a negative regulator of growth and metastasis in breast cancer, at least partly by inhibition of intratumor angiogenesis.

P5.20.069
Role and potential application of chemokine-binding proteins in breast cancer

***Z. Ou**, X. Zeng, F. Lin, X. Yang, Y. Guo, Z. Shao;*
Fudan University Cancer Hospital, Shanghai, China.

Many chemokines and chemokine receptors, such as CCL2 and CXCR4, participate in the growth, angiogenesis, distal metastasis of tumor. However, the recent failures in the clinical trials of some single target antagonists suggest that intratumor chemokine network is really complicated. Atypical chemokine receptors (ACR) as endogenous and physiological regulators, including Duffy antigen receptor for chemokines (DARC), D6 and ChemoCentryx chemokine receptor (CCX-CKR), may be the powerful candidates for this purpose. Our recent studies have already demonstrated that all of DARC, D6, CCX-CKR and other chemokine-binding proteins play protective role in breast cancer. In total of 558 breast specimens, coexpression of ACR in invasive breast carcinoma (55.9%) was much lower than that of noninvasive breast carcinoma (93.1%) and normal breast tissues (100.0%). The triple positive staining was significantly conversely correlated with lymph node metastasis, disease stage, RFS as well as OS. Interestingly, we also found that Duffy blood group phenotype (DBGP) is correlated with breast cancer incidence, axillary lymph node metastasis and OS. Furthermore, their coexpression is more favorable for the patients, suggesting that multiple ACR may provide better protection against metastasis and relapse by synergistically regulating chemokine network in breast cancer. It is possible that chemokine-binding proteins can be used as novel anti-cancer drugs based on the polypharmacological principle in the future.

Genetic variation in DNA repair genes: *ERCC4* and *XRCC3* and cervical squamous cell carcinoma risk

E. A. Pawlak-Adamska[1], *M. Bartosinska*[2], *I. Wlodarska-Polinska*[3], *A. Ignatowicz-Pacyna*[4], *J. Kornafel*[4], *I. Frydecka*[1];
[1]*Department of Experimental Therapy, Institute of Immunology and Experimental Therapy, Wroclaw, Poland,* [2]*Institute of Immunology and Experimental Therapy, Wroclaw, Poland,* [3]*EuroMedic Poland, International Oncological Center, Walbrzych, Poland,* [4]*Department of Oncology and Gynaecological Oncology Clinic, Medical University, Wroclaw, Poland.*

As reduced DNA repair capacity may lead to genetic instability and carcinogenesis, genes involved in DNA repair have been proposed as candidate cancer susceptibility genes including in cervical cancer.
ERCC4 (XPF) is one of central players in the NER, which counteracts the consequences of mutagenic exposure of cell. XRCC3 is known to participate in homologous recombination to maintain chromosome stability and repair DNA damage.
We investigated 4 tagSNPs in 2 DNA repair genes - *ERCC4*: rs3136176, rs1799798 and *XRCC3*: rs3212079, rs3212102 in 132 cervical squamous cell carcinoma (CSCC) patients and 196 healthy controls.
In single SNP analyses, we found that among studied SNPs 3 were directly associated with risk of CSCC: *ERCC4*rs3136176 and in *XRCC3*: rs3212079, rs3212102. With respect to *ERCC4* SNP, we found that carriers of [TT] genotype was 2.82 more prone to CSCC (p=0.01, 95%CI:1.21-6.59).
With respect to *XRCC3* SNPs, presence of rs3212102[CC] genotype 2.18 increased risk of cancer (p=0.04, 95%CI:1.03-4.65) and rs3212079[A] allele (genotype [AA] and/or [GA]) 2.37 increased risk of CSCC (p=0.006, 95%CI:1.27-4.42).
Haplotype *XRCC3*rs3212079[A]/*XRCC3*rs3212102[C] significantly increased risk of CSCC (p=0.0007).
Using multivariate logistic regression analysis, 3 of the investigated SNPs: *ERCC4*rs3136176, *XRCC3*rs3212079 and *XRCC3*rs3212102 showed a significant association with CSCC risk in the over all population.
Moreover, haplotype *XRCC3*rs3212079[A]/*XRCC3*rs3212102[C] showed a tendency to be more frequent in patients with carcimona planoepitheliale akeratodes (Cpa) as compared with keratodes type (Cpk) (p=0.07) and haplotype *XRCC3*rs3212079[A]/*XRCC3*rs3212102[C] showed an opposite tendency (p=0.07). None of studied SNPs were associated with grading or staging.

P5.20.071
Silencing of claudin-10 expression on B-1 cells impaired the increased metastatic behavior of melanoma cells an *in vitro* coculture system

E. C. Pérez[1,2], *P. Xander*[3], *M. F. Laurindo*[2], *R. Novaes e Brito*[4], *B. Vivanco*[2], *L. Osugui*[2], *M. Mariano*[1,2], *J. D. Lopes*[2];
[1]*Universidade Paulista, São Paulo, Brazil,* [2]*Universidade Federal de São Paulo, São Paulo, Brazil,* [3]*Universidade Federal de São Paulo - campus Diadema, São Paulo, Brazil,* [4]*Centro Universitário São Camilo Departamento de Medicina, São Paulo, Brazil.*

Recent studies in mice are beginning to reveal important immune – modulating functions of B-1 cells, a subset of B cells found predominantly in pleural and peritoneal cavities. Using an *in vitro* heterotypic coculture system we previously demonstrated that cocultivation of B16 melanoma cells with B-1 cells from C57BL/6 mice (wt), but not with C57BL/6 IL-10 knockout B-1 cells (IL-10KO), increases the metastatic potential of melanoma cells. However, the molecule expressed on B-1 wt cells able to affect the metastatic potential of B16 cells remain to be fully explored. Therefore, the aim of this work was to identify the molecule expressed by B-1 wt, but absent in B-1 IL-10KO cells, which triggers increased metastatic potential of melanoma cells. Three independent experiments of microarrays analyses demonstrated differential mRNA expression of seven (7) genes between wt and IL-10KO B-1 cells. Among these genes, claudin-10, involved with cell communication and cell adhesion, was upregulated in B-1 wt cells. Data was confirmed by western blot analysis and interference RNA assays were performed to evaluate the biological function of claudin-10 in this model. Interestingly, silencing of claudin-10 expression on B-1 wt cells reduced their levels of ERK phosphorilation and prevent their capacity to increase the metastatic behavior of melanoma cells. Together, these findings suggest that claudin-10 expression on B-1 cells is crucial for their commitment to affect the metastatic potential of B16 melanoma cell.

P5.20.072
Role of STAT3 signaling in MDSC-mediated immune suppression

L. Pinton[1], *S. Solito*[1], *L. Perilli*[1], *V. Damuzzo*[1], *S. Francescato*[2], *P. Zanovello*[1,3], *V. Bronte*[4], *S. Mandruzzato*[1,3];
[1]*Department of Surgery, Oncology and Gastroenterology, Oncology and Immunology Section, University of Padova, Padova, Italy,* [2]*Department of Woman and Child Health, Onco hematology Laboratory - University of Padova, Padova, Italy,* [3]*Istituto Oncologico Veneto IOV-IRCCS, Padova, Italy,* [4]*Verona University Hospital and Department of Pathology, Immunology Section, University of Verona, Verona, Italy.*

One of the mechanisms of immune tolerance induced by cancer is due to the expansion of myeloid-derived suppressor cells (MDSCs), a population of immature myeloid cells capable of inhibiting both innate and adaptive immunity. We recently demonstrated that MDSCs can be derived *in vitro* from fresh bone marrow (BM) cells and named these cells BM-MDSCs. As BM-MDSCs are a very heterogeneous population, we further characterized them, and found that only one immature subset (i-BM-MDSC) is responsible for the whole immunosuppression.
To dissect the molecular mechanisms involved in MDSC activity, we focused our attention on signal transducer and activator of transcription 3 (STAT3), a transcription factor known to be involved in immunosuppression. Our results show that STAT3 phosphorylation is present in the suppressive subset of BM-MDSCs and increases after co-culture with activated T cells, thus suggesting that the immunosuppression exerted by MDSCs is the result of a crosstalk with activated T lymphocytes. Since STAT-3 can be activated by the immunosuppressive cytokine IL-10, we measured IL-10 in the culture supernatant and found, accordingly, that its release is significantly enhanced when MDSCs are cultured in the presence of activated lymphocytes. Considering that IL-10 increases B7-H1 in myeloid cells, we investigated the expression of this molecule on i-BM-MDSCs and found that it is significantly increased only when these cells are co-cultured with activated but not with resting T cells. Our results suggest the existence of a loop between IL-10, STAT3 and B7-H1, involved in the immunosuppressive program exerted by MDSCs.

P5.20.073
Inhibition of Th17 cells and induction of regulatory T cells is mediated by SOCS-1 in the tumor microenvironment of breast cancer patients

A. Pourgholaminejad, *R. Eftekhari, R. Mirzaei, J. Hadjati;*
Department of Immunology, School of Medicine, Tehran University of Medical Sciences, Tehran, Iran.

Introduction: Suppressors of cytokine signaling (SOCS) are important negative feedback regulators of the JAK/STAT signaling pathway, and have been recently investigated for their role in the development of different cancers. It has been shown that SOCS-1 negatively regulates STAT-3 activation in breast cancer tissues and therefore it may be a regulator of Th17 cells in tumor area. In the preset study, we demonstrated that SOCS-1 is in associated with decrease of Th17 cells and increase of Tregs in breast cancer patients.
Methods and Materials: In this study, we examined the expression of SOCS-1 gene in normal and breast cancer tissue and correlated this with factors related to Th17 cells and Tregs. Human breast cancer tissues from 4 stages and normal tissues were collected. Afterward, mRNA was extracted from the tissues and cDNA was synthesized. Subsequently, the mRNA expression of genes related to Th17 cells (IL-17, RORc, STAT-3) and Tregs (FoxP3, IL-10, CTLA-4) and also SOCS-1 were determined by Quantitative Real-time PCR.
Results: The results showed that the expression of SOCS-1 gene is increased in breast cancer and it negatively associated with IL-17, RORc and STAT-3 gene expression significantly and also factors

related to regulatory T cells such as IL-10, FoxP3 and CTLA-4 is decreased.
Conclusion: We conclude that regulatory T cell responses increase in the tumor microenvironment and they inversely correlate with Th17 cells as a potent anti-tumor immune response. It seems that SOCS-1 inhibits Th17 and also induces Tregs in breast cancer patients with advanced stages.

P5.20.074
Characterization of Th17 cells and regulatory T cells in pleural effusions of lung cancer patients

***H. Prado-Garcia**, S. Romero-Garcia, J. Orozco-Gaytan, J. S. Lopez-Gonzalez, A. Arreola-Morales;*
National Institute of Respiratory Diseases Ismael Cosio Villegas, Mexico City, Mexico.

Lung cancer is the leading cause of cancer death worldwide. Pleural effusion is a common clinical manifestation of metastatic lung tumors and accumulation of lymphocytes, especially CD4+ T cells, frequently occurs. Th17 cells are a subset of CD4+ T cells that express the transcription factor ROR-γt, induce a variety of proinflammatory mediators and might promote tumor progression. Conversely, Tregs are another subset of CD4+ T cells, which posses immunosuppressor functions. In several types of cancer, Tregs play an important role in inhibiting antitumoral functions. The aim of this study was to investigate the role of Th17 cells and Treg in pleural effusion from lung cancer patients. Treg and Th17 cells were identified in pleural effusion of 30 lung cancer patients, for comparison, 12 tuberculous and 11 non-chronic pleural effusions were included. Th17 cells were identified by flow cytometry using: ROR-γt, CCR6 and CD45RA markers, and production of IL-17A. Tregs were identified using CD25, CD127 and FOXP3 markers. Proportions of Tregs (CD4+FOXP3+CD25+CD127-/low) were decreased whereas Th17 cells were increased in both tuberculous and malignant pleural effusions. The percentage of Th17 cells was significantly higher in malignant pleural effusions with respect to non-chronic pleural effusions; nevertheless, no significant differences were observed between malignant and tuberculous effusions. Our results suggest that the pleural compartment from lung cancer patients is characterized by a proinflammatory, rather than a immunosuppresive, microenvironment which supports the generation or recruitment of Th17 cells.

P5.20.075
Expression of at least one desmoglein is essential for multicellular tumor spheroid (MCTS) formation

***A. V. Prokhorov**, E. V. Svirshchevskaya;*
Shemyakin and Ovchinnikov Institute of Bioorganic Chemistry RAS, Moscow, Russian Federation.

MCTS represent small avascular tumors. They are used as an in vitro model for antitumor drug testing. Not all epithelial cell lines form MCTS. Expression of cadherins is thought to mediate MCTS formation. However, all epithelial cells express cadherins and thus there must be other adhesive contacts which determine MCTS formation. It is known that desmosomal cadherins desmogleins (DSG) and desmocollins (DSC) are responsible for desmosome formation between adjacent epithelial cells. Thus we hypothesized that DSG and DSC are the best candidates to assist MCTS formation. The aim of this work was to identify expression of DSG1,2,3 and DSC1,2,3 in cells forming and nonforming MCTS. MCTS were produced on anti-adhesive film poly-HEMA. DSG and DSC expression was analyzed in flat live cultures by confocal microscopy. We have demonstrated that cell lines expressing DSG2 and DSG3 (HaCaT, A431, BxPC-3, AsPC-1, M3T4, Colo357, Su86.86) form dense spheroids; cells expressing only DSG2 form loose large MCTS which can be easily disrupted into small ones by pipetting (HEK293, MeWo, MDCK); while cells which do not express on their cell surface any DSGs do not form MCTS (PANC-1, A537, MiaPaCa). In this case we found intracellular expression of some DSGs. We have not detected DSG1 membrane expression in any cell lines tested (intracellular in some cells was found). Expression of DSCs in many cases was found intracellular and not membrane associated. Thus, we have concluded that membrane expression of at least one DSG is essential for MCTS formation.
Work id funded by FP7 (SaveMe) project.

P5.20.076
Polyomavirus BK large tumor antigen exerts tolerogenic signatures with immunodominant p53-binding regions in prostate cancer

***M. Provenzano**;*
University of Zurich, Zurich, Switzerland.

Polyomavirus BK (BKV) large tumor antigen (L-Tag) has been recently identified as a potential co-factor in the development of prostate cancer (PCa) but its role as target of immune responses in this malignancy remains unexplored. A regulatory profiling elicited by L-Tag peptide-pool stimulation has been observed in BKV seropositive PCa patients bearing BKV positive lesions and evidence of biochemical recurrence. Differently, T cells against p53-binding regions of L-Tag exquisitely belong to effector/memory CD8+ T cells populations in BKV seropositive healthy donors. The ambiguous activity of L-Tag prompted us to investigate the role of functional regions within L-Tag in eliciting peculiar immune responses in PCa. Two peptides, L-Tag406-414 and L-Tag579-587, nested in the p53-binding regions of L-Tag and previously documented to induce pro-inflammatory responses in healthy donors, triggered an immune regulatory response (IL-10- and TGF-β-producing CD4+CD25+CD127- T cells) with suppressive properties in 61% and 54% of PCa patients studied (n=20), respectively. In contrast, four peptides identified within L-Tag regions non specifically required for virus-induced malignant transformation, recalled IFN-γ-producing effector/memory CD8+ and CD4+ T cells with cytotoxic (CD107+) and no-exhausted (PD-1-) phenotype, able to boost immunogenic activities in PCa patients with a BKV-driven tolerogenic signatures. These findings suggest that strategic regions of L-Tag appointed to carry out oncogenic activities might orchestrate tumor-promoting environment. However, it also gives evidence that a systemic boosting of BKV seropositive PCa patients with immunogenic portions of BKV L-Tag would generate potent antigen-specific immune responses and thereby break the tolerogenic potential governed by BKV L-Tag in this disease.

P5.20.077
Role of G-protein coupled receptor 120 in tumor-promotion of human colorectal cancer

*Q. Wu[1], **L. Qian**[2], M. Jin[1], J. Liu[2], Y. Zhang[2];*
[1]Institute of Health Sciences, Shanghai Institutes for Biological Sciences, Chinese Academy of Sciences & Shanghai Jiao Tong University School of Medicine, Shanghai, China, [2]Shanghai Jiao Tong University School of Medicine, Shanghai, China.

G-protein coupled receptor 120 (GPR120) functions as a receptor for unsaturated long-chain free fatty acids and plays an important role in regulating lipid and glucose metabolism. However, a role for GPR120 in
the development of tumors has not been clarified. Here, we show GPR120 signaling promotes angiogenic switching and motility of human colorectal carcinoma (CRC) cells. We show that the expression of GPR120 is significantly induced in CRC tissues and cell lines, which is associated with tumor progression. Activation of GPR120 signaling in human CRC promotes angiogenesis *in vitro* and *in vivo*, largely by inducing the expression and secretion of proangiogenic mediators such as vascular endothelial growth factor (VEGF), *interleukin-8*, and cyclooxygenase-2-derived prostaglandin E_2. The PI3K/Akt-NF-κB pathway is activated by GPR120 signaling and is required for GPR120
signaling-induced angiogenic switching in CRC cells. Furthermore, GPR120 activation enhances motility of CRC cells and induces epithelial-mesenchymal transition. Furthermore, *in vivo* study shows that activation of GPR120 promotes angiogenesis and tumor growth. Finally, we find GPR120 expression is positively correlated with VEGF expression and inversely correlated with the epithelial marker E-cadherin in CRC tissues. Collectively, our results demonstrate that

GPR120 functions as a tumor promoting receptor in CRC and, therefore, shows promise as a new potential target for cancer therapeutics.

P5.20.078
Role of ectoenzymes in the interaction between myeloma, bone cells and immune effectors: the potential role of adenosine and the oxytocin/oxytocin receptor

V. Quarona[1], *M. Lazzaretti*[2], *A. Chillemi*[1], *A. Zito*[1], *G. Zaccarello*[1], *A. L. Horenstein*[1,3], *F. Saccucci*[4], *V. Pistoia*[5], *N. Giuliani*[6], *F. Malavasi*[1,3,7];
[1]*Laboratory of Immunogenetics, Department of Medical Sciences, Univerity of Torino Medical School, TORINO, Italy,* [2]*Department of Genetics, Micro-organism Biology, Anthropology and Evolution, University of Parma, PARMA, Italy,* [3]*CeRMS, University of Torino Medical School, Torino, Italy,* [4]*Department of Clinical Sciences, Università Politecnica delle Marche, ANCONA, Italy,* [5]*Laboratory of Oncology, Department of Experimental and Laboratory Medicine, Istituto Giannina Gaslini, GENOVA, Italy,* [6]*Hematology and Blood and Marrow Transplantation (BMT) Center, University of Parma, PARMA, Italy,* [7]*Transplantation Immunology Service, "Città della Salute e della Scienza" Hospital, Torino, Italy.*

The aim of the study is to test the hypothesis that ectoenzymes exert regulatory effects in the complex interactions that take place in the myeloma microenvironment. The network of ectoenzymes includes molecules that are highly conserved in phylogeny and known to induce activation (e.g., CD38, CD157), that lead to the generation of adenosine (e.g., CD39, CD73) and others involved in the regulation of phosphatases (e.g., CD203a/PC-1).
This peculiar enzymatic chain has been analyzed in terms of surface expression and function in short-term cultures derived from bone biopsies of myeloma patients. The work also included immunohistochemical analyses of osteomedullary biopsies from patients with multiple myeloma (MM) or monoclonal gammopathy of unknown origin (MGUS). The soluble factors analyzed were adenosine (ADO) and oxytocin (OT) (a hormone controlled by CD38 in murine models) and the relative receptors.
The results obtained indicate that the ectoenzyme axis analyzed leads to the generation of ADO through an unconventional pathway, independent from CD39. Preliminary results show that the CD38/CD203a/CD73 axis exists in normal tissues in paraphysiological conditions (e.g., pregnancy) as well as in different disease models (CLL, seroma, recurrent pregnancy loss). CD38 may also represent an escape pathway for myeloma, in conjunction with oxytocin secreted by osteoblasts. This peculiar pathway of ADO generation may also became an appropriate therapeutic target in human myeloma.

P5.20.079
Mesenchymal sterm cells (MSCs) in head and neck squamous cell cancer (HNSCC)

V. Querci, *V. Santarlasci, L. Maggi, M. Capone, M. Rossi, L. Cosmi, F. Liotta, F. Annunziato;*
University of Florence, Florence, Italy.

It is well established that cancer is not simply a disease confined to transformed epithelial cells, but is deeply influenced by the stromal microenvironment. In this contest a major role is played by immune cells, and by cells of mesenchymal origin. One of the solid tumors in which a potential role of MSCs has been proposed, is HNSCC, that is the sixth leading cancer by incidence worldwide.
The aim of this study was to demonstrate MSCs' presence in HNSCC,to evaluate of their immunosuppressive properties *in vitro* and to correlate MSCs frequency tumors extent. 12 HNSCC affected patients has been enrolled in the study. The frequency of epithelial-, endothelial-cells, leucocytes, MSCs and fibroblasts, was determined by flowcytometry on fresh single cell suspensions: of cells in 12 tumors and 6 controls specimens; cells of mesenchymal origin resulting significantly enriched in tumors ($p<0.05$). Form 5 patients we derived homogeneous adherent cells sharing morphology, immunophenotype and, more importantly, *in vitro* differentation potential with bone marrow-MSCs. Interestingly tumor derived MSC (tumor-MSC) showed a significant inhibitory effect on T cell proliferation in in-vitro models, in a dose dependent manner; this activity was, in part, IDO dependent.Finally a positive and significant correlation was observed between tumor extent and the frequency of tumor-MSC.In conclusion we demonstrated that MSCsare enriched in HNSCC and have in vitro immunosuppressive activity on CD4+ T cells.

P5.20.080
Defective IL-23/IL-17 axis protects p47phox-/- mice from colon cancer

C. Richter[1], *J. Bandola*[1], *M. Herrero San Juan*[2], *B. Weigmann*[3], *H. Bonig*[4], *S. Brenner*[1], *H. H. Radeke*[2];

Medical Clinic, University of Erlangen-Nuremberg, Erlangen, Germany,* [4]*German Red Cross Blood Service and Institute for Transfusion Medicine and Immunohematology, Goethe University, Frankfurt, Germany.*

In the colon a sophisticated balance between immune reaction and tolerance is absolutely required. Dysfunction may lead to pathologic phenotypes ranging from chronic inflammatory processes to cancer development. Two prominent modulators of colon inflammation are represented by the closely related cytokines IL-12 and IL-23 which initiate adaptive Th1 and Th17 immune responses, respectively. In this study we investigated the impact of the NADPH oxidase protein p47phox, which negatively regulates IL-12 in dendritic cells, on colon cancer development in a colitis-associated colon cancer model. Initially, we found that mice deficient for IL-12 developed less severe colitis, but are highly susceptible to colon cancer. In contrast, p47phox-/- mice showed lower tumor scores and fewer high grade tumors than WT littermates. Treatment with Toll-like receptor 9 ligand CpG2216 significantly enhanced colitis in p47phox-/- mice, whereas tumor growth was simultaneously reduced. Moreover, in tumor tissue of p47phox-/- mice the IL-23/IL-17 axis was crucially hampered. In tumor tissue increased IL-23p19 protein expression correlated with tumor stage providing an explanation for the difference between p47phox-/- and WT mice. Reconstitution of WT mice with IL-23p19-/- bone marrow protected these mice from colon cancer, whereas transplantation of WT hematopoiesis into IL-23p19-/- mice increased the susceptibility to tumor growth.
In conclusion, our study strengthens the divergent role of IL-12 and IL-23 in colon cancer development. With the characterization of p47phox as a novel modulator of both cytokines our investigation introduces a promising new target for anti-tumor strategies.

P5.20.081
Epigenetic modifications of the long pentraxin PTX3 in human colorectal cancer

M. Rubino[1,2], *C. Greco*[1], *S. Vetrano*[1], *E. Barbati*[1], *L. Laghi*[1], *R. Papait*[1], *A. Mantovani*[1,3], *C. Garlanda*[1];
[1]*Istituto Clinico Humanitas, Rozzano (MI), Italy,* [2]*University of Milan, Milano, Italy,* [3]*Departement of Translational Medicine, University of Milan, Milano, Italy.*

The long pentraxin PTX3 is a fluid-phase pattern recognition receptor that participates in innate immunity and inflammation, by modulating complement activation and leukocyte recruitment, extracellular matrix deposition, and angiogenesis. In the context of cancer, PTX3 can be produced by tumor and stromal cells and is a potential biomarker of cancer. Our *in vivo* studies indicate that PTX3 has a protective role in different murine cancer models. Furthermore, in human esophageal squamous cell carcinoma, PTX3 is epigenetically down-regulated through pro[[Unsupported Character - Codename]]moter hypermethylation. The aim of this study was to investigate the relevance of PTX3 epigenetic modifications in cancer, focusing on human colorectal cancer (CRC). Gene expression analysis showed that PTX3 is not or less expressed in CRC than in epithelial control cells. The demethylating agent 5'aza DC, restored PTX3 expression was restored, whereas trichostatin A, a histone deacetylase inhibitor, was ineffective. PTX3 one CpG island (iCpG) in the promoter region and one ranging from the first to the second exon. By Methylated-CpG Island Recovery Assay, we found that the CRC lines had a

uniform and higher degree of methylation of the promoter compared to healthy epithelium. The second iCpG was differently levels of methylated in the CRC lines analysed, depending on tumor stage and instability status. All together these data suggest that iCpG methylation can be involved in regulation of PTX3 expression in CRC. Furthermore, the site specific methylation could potentially be a biomarker of tumor progression and of instability status.

P5.20.082

Targeting colon cancer cell NF-κB regulates tumor-associated macrophage polarization and enhances anti-tumor immune response

A. E. Ryan[1], *A. Colleran*[2], *A. O'Gorman*[1], *L. O'Flynn*[1], *J. Pindjacova*[1], *P. Lohan*[1], *M. Nosov*[1], *C. Mureau*[1], *M. D. Griffin*[1], *L. J. Egan*[1];
[1]*National University of Ireland, Galway, Galway, Ireland,* [2]*University College Cork, Cork, Ireland.*

Interactions between cancer cells and their microenvironment regulate tumourigenesis. The transcription factor NF-κB plays an important role in cancer, and its activation is increased in many tumours, however, its effects on the tumour microenvironment remains to be elucidated. In this study, we developed colon cancer cells expressing the NF-κB super-repressor to investigate the role of NF-κB on tumour infiltrating macrophage phenotype. Using co-culture systems, we show that medium conditioned by NF-κB-deficient CT26 cells induced expression of cytotoxic mediators nitric oxide (NO) (>15 fold) and IL-12 (> 3 fold) in macrophages, indicative of an M1-like phenotype. In contrast, incubation with NF-κB proficient conditioned media induced IL-10 and PGE2 ($p<0.01$), while IL-12p40 and NO was inhibited ($p<0.01$). Using a peritoneal metastasis model, tumour growth by NF-κB-deficient CT26 cells were significantly repressed ($n=16$, $p<0.001$) resulting in prolonged survival. Flow Cytometry analysis of tumours indicated significantly more M1-like inflammatory macrophages ($p<0.05$) and CD4+ and CD8+ CD62L- effector T-cells ($p<0.01$) in NF-κB deficient tumours. Increased numbers of iNOS-expressing mononuclear cells ($n=16$, $p<0.01$) and dramatic levels of intra-tumoural apoptosis ($n=16$, $p<0.001$) were identified by immunohistochemistry in NF-κB deficient tumours. Macrophage depletion in vivo inhibited tumours in mice treated with NF-κB-proficient cells ($n=5$; $p<0.01$) indicating that macrophages increased the metastatic potential of these tumours. This study provides novel evidence that tumour cell NF-κB regulates macrophage phenotype and supports the proposal that targeting an NF-κB regulated soluble mediator(s) that promotes 'alternative' activation of macrophages will enhance the anti-tumour immune response and prevent colon cancer metastasis

P5.20.083

Tumor-specific Th17 cells orchestrate anti-tumoral responses

J. J. Sáez[1], *S. Nuñez*[1], *F. Flores*[1], *D. Fernández*[1], *M. Rosemblatt*[1,2,3], *M. R. Bono*[1], *D. Sauma*[1,2];
[1]*Departamento de Biología, Facultad de Ciencias, Universidad de Chile, Santiago, Chile,* [2]*Fundación Ciencia & Vida, Santiago, Chile,* [3]*Facultad de Ciencias Biológicas, Universidad Andrés Bello, Santiago, Chile.*

Introduction: Th17 cells have been related to the development of inflammatory and autoimmune diseases, but their role in cancer is controversial. The production of angiogenic factors by Th17 cells suggest their involvement in promoting tumor growth however, their inflammatory activity supports the idea they may have a role in anti-tumoral responses as well. We tested the effect of the tumor microenvironment on Th17 cell phenotype and the potential anti-tumor effects of these cells in a murine melanoma model.
Methods: C57BL/6 and RORγt-deficient mice (lacking Th17 cells), were intradermally injected with B16-OVA melanoma cells. In vitro generated, OVA-specific Th17 cells were intravenously injected followed by a strict control over tumor progression. Mice with tumors over 100 mm2 were euthanized and their organs harvested for further analysis.
Results: We show an up-regulation of immunosuppressive markers on Th17 cells present in tumor associated tissues of tumor-bearing mice compared with healthy mice. RORγt-deficient mice present an increased tumor growth rate, which is reverted by the adoptive transfer of Th17 cells. In vitro-generated OVA-specific Th17 cells were able to infiltrate the tumor and associated tissues, secrete IFN-γ within the tumor and reduce the tumor growth rate.
Discussion: Even though the tumor microenvironment induces a regulatory phenotype on endogenous Th17 cells, the adoptively transferred in vitro-generated Th17 cells have the potential to reach the tumor and associated tissues, presenting a clear anti-tumoral effect. These results reveal an unexpected role of Th17 cells in anti-tumor responses and open new possibilities towards the development of new immunotherapeutic strategies.

The Inhibitory effects of Metformin on tumor cell growth in hypoxia conditions

Z. Safari[1,2], *M. H. Seyedzadeh*[3,2], *A. Zare*[2], *J. Arasteh*[4], *R. Safaralizadeh*[1], *G. A. Kardar*[2];
[1]*Animal Biology Depatment, Faculty of Natural Science, University of Tabriz, Tabriz, Iran,* [2]*Immunology,Asthma & Allergy Research Institute; Tehran University of Medical Sciences, Tehran, Iran,* [3]*Div. of Immunology, Dept. of Pathobiology School of Public Health and Institute of Public Health Research, Tehran University of Medical Sciences, Tehran, Iran,* [4]*Department of Biology, Faculty of Basic Sciences, Islamic Azad University Central Tehran Branch, Tehran, Iran.*

Background: Metformin is used as an anti diabetic drug for type II diabetes. Recently, a correlation has been observed between the widely used insulin-lowering drug metformin and decrease in .breast cancer incidence One of the characteristics of solid tumors is its survival ability on hypoxia. To investigate the quantitative response of energy metabolic pathways in human cancer cells to hypoxia we treated these cells with metformin in hypoxia conditions.
Method: The proliferation and apoptosis assay of MCF-7 and HEK293 cells treated with different concentrations of metformin were assessed by MTT assay and Annexin V in normoxic and hypoxic conditions, respectively.
Result: Our preliminary results indicate that metformin has higher inhibitory effects on tumor cell growth in hypoxic compared to normoxic condition.
Conclusion: These data suggest that in real in vivo hypoxic conditions, metformin may be more effective on cancer cells.

P5.20.085

Cooperation between adenosinergic and hypoxic axes in chronic lymphocytic leukemia cells (CLL)

S. Serra[1], *T. Vaisitti*[1], *A. L. Horenstein*[2], *F. Malavasi*[2], *S. Deaglio*[1];
[1]*Department of Medical Sciences, University of Torino and Human Genetics Foundation, Torino, Italy,* [2]*Department of Medical Sciences, University of Torino, Torino, Italy.*

Extracellular adenosine, produced through the concerted action of the ectoenzymes CD39 and CD73, elicits potent autocrine and paracrine cytoprotective and immunosuppressive effects.
Recent data indicate that $CD39^+/CD73^+$ cells from chronic lymphocytic leukemia (CLL) patients produce adenosine, creating an autocrine adenosinergic axis that favors growth and survival of leukemic cells. These effects are mediated by the A2A adenosine receptor, which inhibits chemotaxis and limits spontaneous and drug-induced apoptosis of CLL cells. We are currently expanding these observations by testing the hypothesis of a functional interplay between the adenosinergic axis and hypoxic signals.
Results indicate that the CLL-like cell line MEC-1 and purified CLL cells significantly increase HIF-1α expression when cultured in hypoxic conditions (1% O_2). RT-PCR analyses and cytofluorimetric data indicate that hypoxia increases expression of the adenosine-generating ectoenzymes CD73 and CD26 and of the A2A adenosine receptor. HPLC analyses confirm that hypoxic cultures are characterized by higher extracellular adenosine levels. Furthermore, activation of the A2A receptor under hypoxic conditions is followed by higher intracellular cAMP concentrations than in a normoxic situation. Conversely, activation of the A2A receptor using adenosine or

pharmacological agonists induces transcriprion of HIF-1a, suggesting the existence of a positive feedback loop.
Together, these results indicate the existence of an interplay between the adenosinergic and hypoxic axes in CLL cells. Future data are needed to understand the functional implications of these observations.

P5.20.086
Oxidative stress induces a temporary initial decrease of HSP70 content in EL4 lymphoma cells

***O. Shustova**, A. Boyko, A. Klinkova, N. Troyanova, E. Kovalenko, A. Sapozhnikov;*
Shemyakin–Ovchinnikov Institute of Bioorganic Chemistry, Moscow, Russian Federation.

HSP70 participate in intracellular processes maintaining cell homeostasis. On the other hand, under influence of various stress factors HSP70 are released from many types of cells into extracellular milieu. It was shown that extracellular HSP70 possess essential immunomodulatory properties. Besides, it was demonstrated that serum level of extracellular HSP70 circulating in organism was increased in patients with some types of diseases. Previously we demonstrated stress-induced HSP70 release in EL4 mouse lymphoma cell culture. In the present work we analyzed stress-induced alterations of intracellular level of HSP70 in the same model of EL4 cell culture. The cells were exposed to oxidative stress by using H2O2. Intracellular content of HSP70 was measured by flow cytofluorimetry. The results showed that EL4 cell reaction to oxidative stress had an initial temporary stage with a significant fall of intracellular HSP70 content. This stage was followed by expected increase of the level of intracellular HSP70. Initial decrease of intracellular HSP70 content in this model was registered also by using Western-blot analysis. We suppose that the phenomenon of temporary fall of intracellular HSP70 at the first stage of cell stress response is connected with the protein release to extracellular space. This supposition allows us to consider lymphoid cell populations as a source of soluble extracellular pool of HSP70 in serum of peripheral blood of stressed organisms.
This work was partly supported by RFBR, grants # 12-04-31578 and # 12-04-32065.

P5.20.087
Cancer/testis antigen HCA587 promotes the metastatic behavior of melanoma cells

***X. Song**, J. Hao, J. Chen, W. Song, Y. Li, Y. Zhang, Y. Yin;*
Peking university Health Science Center, Beijing, China.

HCA587 is a cancer/testis antigen and belongs to MAGE family. It is highly expressed in various types of tumors but not in normal tissues except in male germ-line cells. HCA587 has long been recognized as a tumor specific target for immunotherapy, however, its biological functions have been relatively understudied. In this study, we demonstrate that HCA587 expression correlates with metastatic potential of tumor cells. Suppression of HCA587 by siRNA resulted in decreased migration and invasion capabilities of human melanoma A375 cells *in vitro*, and overexpression of HCA587 in mouse melanoma B16 cells significantly increased the number of metastatic lung nodules upon tail vein injection of tumor cells. Further investigation for exploring the underlying molecular mechanism showed that HCA587 interacts with STAT3 (Signal Transducer and Activator of Transcription 3, STAT3)phosphorylated on Tyr705 in the nucleus, and increases the level of phosphoralated STAT3. Our findings suggested that cancer/testis antigen HCA587 might promote the tumor metastasis with regulating the activity of STAT3. Our study provides an innovative avenue for investigating the biological functions of the member of MAGE family in the progression of tumor.

P5.20.088
Immunophenotypes of Burkitt's lymphoma cell lines alter at different EBV infection latency types

***I. Spaka**[1,2], A. Spaks[1,3], S. Kozireva[1], J. Osmjana[1], M. Upmane[1,3], R. Birkenfelde[1], V. Kalnina[1], S. Lejniece[1,4,5], I. Kholodnyuk[1];*
[1]Riga Stradiņš University August Kirchenstein Institute of Microbiology and virology, Riga, Latvia, [2]Riga Stradiņš University, Riga, Latvia, [3]University of Latvia, Riga, Latvia, [4]Rīga Stradiņš University, Department of Internal diseases, Riga, Latvia, [5]Riga Eastern University Hospital, Chemotherapeutic and Hematological Clinic, Riga, Latvia.

Epstein-Barr virus (EBV) is involved in the pathogenesis of endemic Burkitt's lymphoma (BL). EBV-positive BL cell lines initially maintain the original tumor phenotype of EBV infection (latency I, LatI), but most of them drift toward a lymphoblast phenotype of EBV latency III (LatIII) during in vitro culturing.
The aim of this study was to characterize the immunophenotypes of BL cell lines and to verify whether particular cell subsets association with the type of EBV infection.
The phenotype analysis of two EBV-negative and eleven EBV-positive (three of LatI and eight of LatIII) BL cell lines was based on determination of CD19, CD10, CD38, CD27, and CD5 expression pattern by means of multicolor flow cytometry (pFC). The same approach was applied for the characterization of B-cell subpopulations in peripheral blood (PB) of 8 healthy adults. The EBV latency type was defined by RT-PCR using EBV transcript specific primers.
In EBV-negative and LatI BL cell lines all cells displayed the CD19+CD10+CD38+ phenotype. In contrast, in three LatIII cell lines that were established by a single cell cloning, more than 90% of the cells were CD19+CD10−CD38+. Four original BL tumor -derived cell lines of LatIII consisted of two cell subsets, CD19+CD10+ and CD19+CD10−, in proportion of 28%-84% and 17%-72% of the cells, respectively. A fraction of the cells in these four LatIII BL cell lines displays the phenotype of PB circulating mature B cells (CD19+CD10−CD38+ CD27+ CD5−). This observation may suggest that expression of the EBV LatIII genes may promote the differentiation of malignant cells.

P5.20.089
CD11b+Ly6G+Ly6Cint myeloid-derived suppressor cells become expanded by medroxiprogesterone acetate in mammary tumor bearing hosts and suppress NK cell effector functions

*R. G. Spallanzani, T. Dalotto, D. Avila, A. Ziblat, C. Domaica, M. Fuertes, X. Raffo Iraolagoitia, G. Rabinovich, M. Salatino, **N. Zwirner**; Instituto de Biologia y Medicina Experimental (IBYME), Buenos Aires, Argentina.*

The progesterone analogue medroxyprogesterone acetate (MPA) is being widely used in postmenopausal women, for the treatment of endometrial conditions, and as a contraceptive. However, hormone replacement therapy in postmenopausal women has been associated with increased incidence of breast cancer through ill-defined mechanisms. In this work, we explored whether prolonged exposure to MPA restrains immunosurveillance to tumors through mechanisms involving myeloid-derived suppressor cells (MDSCs; $CD11b^+Gr1^+$, composed by $CD11b^+Ly6G^+Ly6C^{int}$ and $CD11b^+Ly6G^-Ly6C^{high}$) and NK cells in mammary tumor-bearing mice. Using the highly metastatic 4T1 breast tumor (which does not express the classical progesterone receptor), we observed that MPA did not affect primary tumor growth but promoted lung metastasis burden. This effect was accompanied by a preferential expansion of spleen and bone marrow $CD11b^+Ly6G^+Ly6C^{int}$ but not $CD11b^+Ly6G^-Ly6C^{high}$ cells. Also, MPA significantly increased the percentage of spleen and lung NK cells in tumor-bearing mice with similar lung infiltration of $CD11b^+Gr1^+$ cells as compared to untreated tumor-bearing mice. However, sorted $CD11b^+Gr1^+$ cells (comprising more than 90% of $CD11b^+Ly6G^+Ly6C^{int}$ cells) from MPA-treated tumor bearing mice displayed a more pronounced suppressive activity on NK cell degranulation in response to YAC-1 cells and a stronger inhibition of IFN- production of NK cells in response to cytokines than those $CD11b^+Gr1^+$ cells isolated from untreated tumor-bearing mice. Thus, in breast cancer-bearing hosts MPA promotes the accumulation of $CD11b^+Ly6G^+Ly6C^{int}$ cells which display a suppressive activity on NK-cell effector functions, potentially contributing to tumor progression and metastasis.

P5.20.090
IL-12p40, IL-23 and IL-10 production from monocytes of patients with colorectal cancer: effect of inhibition of JNK signaling pathway

***N. S. Stanilov**, S. A. Stanilova, Z. Dobreva;*
Trakia University, Medical Faculty, Stara Zagora, Bulgaria.

Cytokine production in patients with colorectal cancer (CRC) has an important impact on CRC development. We investigated changes of IL-12p40, IL-23 and IL-10 production from monocytes of CRC patients depending on cancer stages. Isolated monocytes were stimulated with LPS or C3bgp. We also explored molecular regulatory mechanisms focusing on the JNK activation by using selective inhibitor SP600125. The quantity determination of IL-12p40, IL-23 and IL-10 was performed by ELISA.
IL-12p40 production from patients' monocytes was diminished in early and advanced stages of the disease. Similarly, independent of disease stage, patients' monocytes secreted significantly lower IL-23 quantity compared to monocytes from healthy individuals. We observed significantly decreased IL-10 production from monocytes of CRC patients in early stage, but not in monocytes from patients with advanced CRC. Moreover, patients in early stages showed significant lower IL-10 in comparison with advanced stages of CRC.
Inhibition of JNK is clearly upregulating IL-12p40 and IL-23 production from patients' monocytes, unlike healthy donors where inhibition of this kinase is slightly reduced IL-12p40 and IL-23 production is significantly downregulated. Regarding IL-10, the inhibition of JNK did not result in significant changes of its production, while the inhibition of JNK in monocytes from healthy donors led to downregulated IL-10 production.
In conclusion, this study showed altered functional activity of peripheral blood monocytes of CRC patients which are demonstrated through downregulation of IL-12p40 and IL-23, but not of IL-10. This different response of patients' monocytes is mediated partly by changes in involvement of JNK signaling pathway.

P5.20.091
Association of -1082 A/G promoter polymorphism of IL-10 gene with colorectal cancer development

***N. S. Stanilov**[1], J. P. Jovchev[2], L. D. Miteva[1], Z. G. Dobreva[1], T. S. Deliysky[3], A. V. Avramova[1], S. A. Stanilova[1];*
[1]Trakia University, Faculty of Medicine, Stara zagora, Bulgaria,
[2]Trakia University, University Hospital, Stara zagora, Bulgaria,
[3]Oncology Center, University School of Medicine, Pleven, Bulgaria.

The cancer-associated inflammation and anti-tumor immune response to colorectal carcinoma (CRC) is regulated by cytokines produced from activated immune cells. IL-10 is a Treg cytokine suppressing both Th1 immune response and anti-tumor immunity in hosts. The role of functional polymorphism of IL-10 gene in CRC development still remains elusive.
This study was designed to compare -1082 A/G *IL10* genotype distribution in 119 CRC patients to a group of 154 matched healthy donors using ARMS-PCR assay. We also investigated serum IL-10 levels in an association to genotype by ELISA. In the study population the slightly enhanced frequency of homozygous genotype GG (18% vs 13%; OR=1.414; 95%CI=0.64÷3.11; p=0.347) was seen in cases versus controls. When CRC patient's group was divided into stages of disease by TNM classification we observed higher risk of advanced CRC (III-IV stages) for individuals with GG genotype: OR=2.229; 95%CI= 0.828÷6.018; p=0.077. G allele was also overrepresented in advanced vs early CRC (OR=1.581; 95% CI=0.912÷2.743; p=0.082). According to the IL-10 serum levels, CRC patients with GG genotype produced higher IL-10 than AA and AG patients in early stages, similar to healthy control. Moreover, advanced cancer patients with AA and AG genotype produced significantly higher IL-10 compared to patients in early stage (p=0.002 for AA; p= 0.007 for AG genotype), whereas for advanced cancer patients with GG genotype this difference does not reach statistical significance. In conclusion, this study demonstrated that -1082 A/G polymorphism of IL-10 gene has a role in CRC progression rather then CRC genetic predisposition.

P5.20.092
Can humoral immunity enhance development of skin tumors?

*A. A. Lavezo[1,2], L. R. Carvalho[1,2], T. Canhamero[1,2], A. Borrego[1], W. H. K. Cabrera[1], J. R. Jensen[1], M. De Franco[1], O. G. Ribeiro[1], O. M. Ibañez[1], **N. Starobinas**[1];*
[1]Laboratory of Immunogenetics - Instituto Butantan, São Paulo, Brazil, [2]University of São Paulo - ICB, São Paulo, Brazil.

The incidence of tumor may be associated with interactions between innate and adaptive immune response. Evidences suggest that antibodies can generate inflammatory conditions facilitating malignant progression in a mouse model of skin cancer. Mice genetically selected for High (H) and Low (L) antibody production treated with 7, 12-dimethylbenzanthracene (DMBA) were used to study the association between humoral immunity and tumor susceptibility. Epicutaneous dorsal applications of DMBA (50 µg) in acetone for 5 days in H and L mice led to an intense initial vascularization in male mice and around 15 days all mice presented a superficial cutaneous inflammation. These lesions regressed in about 30 - 60 days in all mice and skin papillomas started to be detectable in H mice (76%, n= 30) and in L mice (14%, n= 29). Skin tumor multiplicity and malignancy increased with time and was significantly higher in H than in L mice. At 240 days after treatment, few L male presented lung tumors (25%, n=8) whereas all H male animals (100%, n=8) had multiple lung tumors. The High responder mice were more susceptible than low responder mice showing the effect of the genetic selection for humoral response on skin tumor susceptibility and predisposition to lung tumorigenesis.

P5.20.093
CMTM3 inhibits cell migration and invasion and correlates with favorable prognosis in gastric cancer

***Y. Su**[1], Y. Lin[2], L. Zhang[2], B. Liu[1], X. Wang[2], H. Li[1], X. Xing[2], X. Cheng[2], B. Dong[2], Y. Hu[2];*
[1]Peking University Health Science Center, Beijing, China, [2]Peking University Cancer Hospital & Institute, Beijing, China.

CKLF-like MARVEL transmembrane domain containing 3 (*CMTM3*) is a novel tumor suppressor gene (TSG) with frequent epigenetic inactivation by promoter CpG methylation. In this study, we demonstrated the roles played by CMTM3 in gastric cancer cells as a TSG, and examined the correlation between CMTM3 expression and clinicopathological parameters by immunohistochemistry in gastric cancer patients with different pathological stages (n = 350). We found that CMTM3 expression was reduced or silenced by methylation in several gastric cell lines, and restoration of CMTM3 significantly affected migration and invasion of AGS and SGC-7901 cells (P < 0.001). *In vivo* experiments showed that peritoneal disseminated metastases were significantly suppressed by CMTM3 (P < 0.001). We further showed that the expression of MMP2 and the phosphorylation of ERK1/2 was decreased when CMTM3 restoration, suggesting the potential mechanism of the effect caused by CMTM3 in gastric cancer cells. In addition, the expression of CMTM3 was remarkably weaker in gastric cancer tissues than that in normal mucosa (P = 0.008), and was significantly correlated with Gender (P = 0.033), Tumor Depth (P = 0.049), Stage (P = 0.021), Histologic Grade (P = 0.022). More importantly, CMTM3 expression was associated with prognosis in gastric cancer patients (P = 0.041), and was a significant independent prognostic indicator (HR = 0.704, 95%CI, 0.498 to 0.994; P = 0.046). Our findings indicate that CMTM3 regulates migration and invasion of gastric cancer cells. Moreover, CMTM3 is a candidate marker for gastric cancer prognosis.

Essential involvement of tumor-derived IDO in ovarian cancer progression

Y. Tanizaki[1], *A. Kobayashi*[1], *T. Yahata*[1], *M. Yamamoto*[1], *M. Shiro*[1], *Y. Mabuchi*[1], *S. Minami*[1], *M. Nosaka*[2], *T. Kondo*[2], *K. Ino*[1];
[1]*Departmnt of Obstetrics and Gynecology, Wakayama Medical University, Wakayama, Japan,* [2]*Departmnt of Forensic Medicine, Wakayama Medical University, Wakayama, Japan.*

Immune escape and acquisition of tolerance by tumor cells are essential for cancer growth and progression. Indoleamine 2,3-dioxygenase (IDO) is one of the key molecules to induce tolerance to the host immune surveillance through inhibiting the proliferation and killer function of effector T-cells and NK cells in the tumor microenvironment. In gynecological cancers, high IDO expression was closely correlated with poor clinical outcome through suppressing tumor-infiltrating lymphocytes (TILs) and NK cells. We investigated the functional role of IDO in ovarian cancer progression. We used the mouse ovarian carcinoma cell line, OV2944-HM-1 cells derived from B6C3F1 mice, and established IDO-overexpressed HM-1 (HM-1-IDO) by transfection of mouse IDO-cDNA, and HM-1-mock cells as control. B6C3F1 mice were intraperitoneally injected HM-1-IDO or HM-1-mock cells ($1x10^6$). Tumor size and ascites volume more increased in HM-1-IDO transplanted mice than in HM-1-mock ones. Moreover, HM-1-IDO group significantly impaired survival rate, compared with HM-1-mock one. Immunohistochemically, the accumulation of $CD8^+$ TILs were significantly reduced in HM-1-IDO group, compared with HM-1-mock one. We evaluated tumor-promoting cytokine profiles in ascites. In HM-1-IDO-injected mice, intra-ascitic levels of TGF-β, IL-10 and VEGF were significantly higher than in HM-1-mock-injected ones. However, there was no difference in IL-6 level between HM-1-IDO and HM-1-mock groups. These observations implied that tumor cell-derived IDO would play detrimental roles in the peritoneal dissemination of ovarian cancer through suppressing intratumor $CD8^+$ cell recruitment and reciprocal enhancement of TGF-β, IL-10 and VEGF levels. Collectively, our present results demonstrated that IDO may be a good molecular target for ovarian cancer therapy.

P5.20.095
Immune profiling of lung cancer tissues associated with COPD

E. Tassi*, C. Vegetti, P. Baldassari, A. Molla, G. Sozzi, U. Pastorino, A. Anichini;*
Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy.

Chronic obstructive pulmonary disease (COPD) is associated with the presence of chronic inflammation which remodels and narrows the small airways, and is strongly related with higher lung cancer risk. Several cellular immune subsets may contribute to the inflammatory processes involved in COPD and lung cancer development; nonetheless, the type and extent of T cell infiltrate in lung cancer is an independent prognostic factor in non-small cell lung cancer (NSCLC). Our aim was to better characterize the immune infiltrate in NSCLC and to evaluate the relationship between the amount and functionality of immune cells and the presence/severity of COPD. We analyzed by flow cytometry the immune infiltrate in tumor samples and in correspondent normal and/or adjacent lung specimens from 56 NSCLC patients with a known GOLD severity grading of COPD. Our data showed an accumulation of T and B lymphocytes and of conventional $CD4^+$ $FoxP3^+$ regulatory T cells, along with a reduction in monocytes, in tumors compared to normal/adjacent specimens. Interestingly, tumors also showed an increased frequency of $HLA\text{-}DR^+$ $CD69^+$ activated $CD8^+$ and $CD4^+$ T cells and a low frequency of $FoxP3^+$ $CD8^+$ T cells. This subset, recently found by us in melanoma, represents an early effector stage of T cell differentiation, consistent with the hypothesis of an ongoing immune response at tumor site. In agreement, preliminary results indicated recognition of autologous tumor by T cells as assessed by CD107a degranulation. Further investigation to evaluate the relationship between the extent/type of NSCLC immune infiltrate and the presence/severity of COPD is ongoing.

Targeted-Therapy attenuates local and systemic immune suppression in Solitary Fibrous Tumor patients

M. Tazzari[1], *T. Negri*[1], *F. Rini*[1], *B. Vergani*[2], *C. Camisaschi*[1], *A. Villa*[2], *S. Stacchiotti*[1], *L. Rivoltini*[1], *S. Pilotti*[1], *C. Castelli*[1];
[1]*Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy,* [2]*Consorzio MIA (Microscopy and Image Analysis) University of Milano-Bicocca, Milan, Italy.*

Purpose: For Soft Tissue Sarcomas (STS), Targeted-Therapy has evolved as a standard treatment option. The aim of this study is to characterize circulating immunoregulatory cell subsets and tumor immune infiltrate in patients with STS, to assess the immunomodulating potential of sunitinb in this clinical setting. Results observed in the subgroup of Solitary Fibrous Tumor (SFT) are here reported.
Material and Methods: PBMC were collected from patients with malignant SFT receiving sunitinib prior and at different time points during treatment and analyzed by multiparametric Flow Cytometry for the frequency and functional status of regulatory T cells (Treg) and myeloid-derived suppressor cells (MDSC). Local tumor immunity was evaluated by immunohistochemical characterization in tumor specimens surgically removed before or after drug treatments.
Results: Peripheral Treg (defined as CD4+CD25hiFoxp3+) and MDSC (detected as CD14+CD11b+HLADRlo/neg cells), present at significant higher frequency with respect to healthy donors were down-modulated by treatment. However, disease progression occurring during treatment induced a boost in MDSC that regained or exceed the pretreatment level. Moreover, statistical analysis revealed significant patient-to-patient correlations between improvements in T cell activation and declines in MDSC. Immunohistochemical analysis showed in post-treatment tumor lesions an increase of intratumoral CD3+ lymphocyte, undetectable in untreated samples, and the presence of CD163+ myeloid cells displaying a strong HLADR expression. These phenotypic traits are compatible with the acquisition of an adaptive immune response at tumor site.

P5.20.097
Flow cytometric analysis of the tumour microenvironment during immune mediated tumour rejection or persistence

A. M. Terry*, A. Buckley, J. Holst, B. Fazekas de St Groth, E. Shklovskaya;*
Centenary Institute, Camperdown, Australia.

The tumour microenvironment as a whole is usually highly immunosuppressive. However, it is not known whether pro-inflammatory elements within tumours exist and can be harnessed or recruited to aid in immune rejection of tumours. We have used several 7-10 colour flow cytometric panels to identify the diverse cell subsets comprising the tumour tissue, preliminary to testing their role in tumour immunity. Within the tumour tissue we were able to identify fibroblastic, endothelial and myeloid cell populations including granulocytes, eosinophils, dendritic cells and monocytes/macrophages. We have also analysed tumour-infiltrating B cells, T cells (CD4 and CD8), regulatory T cells and natural killer cells. Myeloid and immune cells have been isolated for further immunohistochemical analysis and effector cell function using 7-colour 6-way FACS sorting.
To follow changes in the tumour microenvironment during an ongoing anti-tumour immune response, we have used a mouse model of subcutaneous melanoma growth. B16 tumours expressing a Hen Egg Lysozyme-Moth Cytochrome C (HELMCC) fusion protein grew rapidly in immunodeficient RAG-knockout mice but were rejected after adoptive transfer of naive MCC-specific TCR transgenic CD4 T cells. Adoptive co-transfer of MCC-specific regulatory T cells delayed or prevented rejection of established tumours. We are now using a new 12-colour flow cytometric panel to compare the tumour microenvironment during CD4 T cell-mediated tumour rejection versus regulatory T cell-mediated tumour persistence in RAG-knockout mice.

P5.20.098
Antitumor and immunological effects of Nilotinib combined with Interleukin-2 in the B16 melanoma model involve IFN-g producing CD27$^+$ NK cells

*K. Geisler[1], A. Reischer[1], B. Jacobs[1], I. Kroeger[1], K. Meinhardt[1], R. Bauer[2], A. Mackensen[1], B. Ryffel[3], **E. Ullrich**[2,1];*
[1]University Hospital Erlangen-Nuremberg, Erlangen, Germany, [2]Children's Hospital, Frankfurt, Germany, [3]Institut Transgenose and University Orleans, Orleans, France.

The immune system may contribute to tumor cell killing which can be enhanced by cancer treatments such as tyrosine kinase inhibitors (TKI). Recently, a beneficial effect of NK cells has been reported by adding interleukin-2 to the TKI imatinib. The aim of this study was to address the antitumor and immunological effects of recently approved TKIs. Therefore, we focused on the comparison of imatinib and nilotinib alone or in combination with IL-2 in the murine B16F10 melanoma model. Both TKIs alone or in combination with IL-2 possessed antitumor activity *in vivo*. However, the combination of nilotinib and IL-2 showed a superior outcome. Importantly, not only use of immunodeficient Rag2xFcg$^{-/-}$ mice, which lack T, B and NK cells, but also NK cell-depletion in C57Bl/6 mice reduced the therapeutic effect of nilotinib. Flow cytometry revealed an increase of an IFN-g producing CD27$^+$ NK cell subpopulation by nilotinib and IL-2 and complete loss of the therapeutic effect in IFN-g$^{-/-}$ mice.
In sum, we conclude that nilotinib in combination with IL-2 confers high antitumoral activity involving a subpopulation of IFN-g producing CD27$^+$ NK cells.

P5.20.099
Tumor antigen-specific CD4+ T effectors are highly enriched at ovarian cancer sites and co-exist with, but are distinct from, tumor-associated Treg

*M. Ayyoub[1], P. Pignon[1], J. Classe[2], K. Odunsi[3], **D. Valmori**[1];*
[1]INSERM UMR 1102, Nantes-Saint Herblain, France, [2]Institut de Cancérologie de l'Ouest, Nantes-Saint Herblain, France, [3]Roswell Park Cancer Institute, Buffalo, NY, United States.

Whereas tumor infiltration by T effectors is generally associated with a more favorable prognosis, the accumulation of CD4$^+$ regulatory T cells (Treg) within tumors is instead often associated with poor disease outcome. Because approaches to improve anti-tumor immunity aim, on one hand, at expanding tumor antigen-specific T cells and, on the other, at eliminating or inactivating Treg, an outstanding question is whether, and to which extent, tumor antigen-specific CD4$^+$ T effectors present at tumor sites overlap with tumor-associated Treg. Here, we used MHC class II/peptide tetramers incorporating an immunodominant peptide from the human tumor-specific antigen NY-ESO-1 to assess antigen-specific CD4$^+$ T cells among conventional CD4$^+$ T effectors and Treg at sites of ovarian cancer. We found that, in patients who spontaneously respond to the antigen, the frequency of NY-ESO-1 tetramer$^+$ cells detected *ex vivo* was highly enriched in tumors as compared to the periphery. At tumor sites, NY-ESO-1 tetramer$^+$ cells were detected concomitant with high proportions of Treg but were distinct from the latter and displayed characteristics of T_H1 effectors. Thus, even in the presence of high proportions of Treg, tumor antigen-specific CD4$^+$ T cells can accumulate in ovarian tumors and maintain an effector phenotype.

P5.20.100
Tumors with processing defects display novel tumor antigens via the non-classical HLA-E

*E. Doorduijn, C. Oliveira, B. Querido, M. Sluijter, **T. van Hall**;*
Leiden University Medical Center, Leiden, Netherlands.

The non-classical HLA-E accommodates monomorphic leader peptides and functions as a ligand for germ line receptors CD94/NKG2, expressed by natural killer cells and CD8$^+$ T cells. We previously described that the conserved peptides are replaced by a novel peptide repertoire of surprising diversity as a result of impairments in the antigen processing pathway. Whereas the monomorphic peptide/HLA-E complex represents the 'innate face' of HLA-E, this novel peptide repertoire constitutes immunogenic neo-antigens for CD8$^+$ T cells. We found that T cells restricted by the mouse equivalent Qa-1^b dominantly participated in the response to tumors with processing deficiencies. A surprisingly wide spectrum of target cells, irrespective of transformation status, MHC background or type of processing deficiency was recognized by this T cell subset, complying with the conserved nature of Qa-1^b. Target cell recognition depended on T cell receptor and Qa-1^b interaction and immunization with identified peptide-epitopes demonstrated in vivo priming of CD8$^+$ T cells. Current investigations are focused on the involved rearranged TCRs that confer the tumor reactivity Although this CD8 T cell subset does arise in the periphery of TCR-transgenic animals, the thymic selection process seems to be very inefficient. Our data reveal that HLA-E and its mouse homolog Qa-1^b are important for the defense against processing deficient cells by displacing the monomorphic leader peptides, which relieves the inhibition through CD94/NKG2A on lymphocytes and by presenting a novel repertoire of immunogenic peptides, which recruits a subset of cytotoxic CD8$^+$ T cells.

P5.20.101
NLRP3 inflammasome activation is involved in breast cancer cell death in vitro

***N. M. Vasconcelos**, R. S. Fontenele, B. C. Guido, K. G. Magalhães, J. R. Correa;*
University of Brasilia, Brasília, Brazil.

Breast cancer is the most prevalent type of cancer diagnosed in women worldwide and their leading cause of cancer death. Chronic inflammation has been described as a risk factor for cancer development. Inflammasomes, which participate in innate and adaptive immune responses, have been described with contrasting roles in cancer development. However, the role of inflammasomes in breast cancer cells is still not understood. To investigate the presence of NLRP3 inflammasome and the phenotypic effect of its activation in breast cancer cell lines, MCF7 (non-invasive) and MDA-MB-231 (invasive) cells were primed with LPS overnight and stimulated with ATP/Nigericin for 4h/1h, respectively. Caspase-1 activation, expression of NLRP3 inflammasome proteins, cytokine secretion as well as cell viability were analyzed. Both cell lines presented caspase-1 activation, as assessed by FAM-YVAD-FMK probe staining, and NLRP3 and ASC expression and colocalization, observed by confocal microscopy. After stimulation, MCF7 cells secreted more IL-6, but neither of cells secreted IL-1β or TNF-α. Inflammasome activation reduced cell viability and increased nuclear fragmentation in MDA-MB-231 cells in early time points and in MCF7 after 48h, evaluated by MTT and PI counterstain, respectively. These results suggest that there is expression and activation of NLPR3 inflammasome in breast cancer cells, which can trigger cell death in a particular way depending on the cell type. Therefore, our data shows that breast cancer cell lines express and activate NLRP3 inflammasome complex, and suggests it could be involved in modulation of cell death in these cells, functioning as a potential pharmacological target. CNPq, FAP-DF.

Influence of natural killer cells in mammary tumor in female dogs

*A. Matsui, M. B. Bandarra, G. M. Magalhães, P. R. R. Moreira, A. C. Alessi, D. P. Munari, **R. O. Vasconcelos**;*
UNESP, Jaboticabal, Brazil.

Natural Killer cells (NK) induce an innate immune response and they are able to recognize tumor cells and determine the cell lysis. The aim of this study was to investigate the presence of NK cells in mammary tumors in different grades of malignancy (I, II and III). We used 39 samples from mammary glands of female dogs with mammary tumor, 13 samples for each grade malignancy and five samples of normal mammary tissue for the control group, all from the routine diagnosis. The histological classification of the tumors was established according to current World Health Organization for canine mammary tumors. The immunohistochemistry technique was performed on paraffin-embedded sections, using CD56 primary antibody (Serotec). The average NK cells was assessed by counting in five microscopic fields (40x Obj) / per animal /per histological group

(I, II, III and control). The nonparametric statistical methods used were Kruskal-Wallis and Dunn Tests, considering significant differences when P <0.05. The CD56 positive cells had cytoplasmic membrane granular stained. The epithelial cells of tumors had accentuated immunostained, especially those of higher grade malignancy (II and III groups). Positive cells for CD56 were not detected in inflammatory infiltrate. There was no significant difference between groups for the average CD56 immunostained cells. These findings suggested that tumor cells exhibit mimicry immune to CD56, characterizing a mechanism for evasion of the host immune system canine. Financial support: FAPESP (2010/02194-9).

P5.20.103
Antitumor activity of synthetic phosphoethanolamine in experimental colon cancer

L. C. Veronez[1], *L. R. Azevedo*[1], *D. O. Miranda*[2], *T. H. Geraldino*[1], *R. O. Lopes*[3], *S. B. Garcia*[3], *G. S. Bisson*[1,2];
[1]*Faculdade de Medicina de Ribeirão Preto (FMRP-USP), Ribeirão Preto, Brazil,* [2]*Escola de Enfermagem de Ribeirão Preto (EERP-USP), Ribeirão Preto, Brazil,* [3]*FMRP/USP. Depto. de Patologia e Medicina Legal, Ribeirão Preto, Brazil.*

Colon cancer has a long natural history of transition from normal crypts through adenoma to adenocarcinoma, providing a great opportunity for prevention and intervention strategies. In this study, we evaluated the effects of synthetic phosphoethanolamine (PEA) on chemically induced colon cancer. C57BL/6 mice were given four intrarectal deposits of 0.1 ml solution of N-nitroso-N-methylnitroguanidin (5mg/ml) twice a week for two weeks. At 24 weeks after initial carcinogen exposure, animals were treated orally (0.1ml/mouse) with PEA (10 and 40mg/kg) during 28 consecutive days. Treatment of tumor-bearing animals with 10mg/kg of PEA led to a 76% reduction in tumor volume compared to the control group. Increased apoptosis rate together with decreased tumor cell proliferation were also observed. Animals treated with the same dose exhibited increased numbers of CD4 and CD8 T lymphocytes, and macrophages in the intercrypt spaces. Among macrophages we observed decreased numbers of $CD206^+$ cells (M2 macrophage marker), but no differences in the number of $CD11c^+$ cells (M1 macrophage marker). Other markers of tumor progression like COX-2 and VEGF were less expressed in colon cells. In addition, PEA induced higher levels of the pro-inflammatory cytokines IL-1, IL-12, IL-6, TNF-α and IFN-γ, and a lower production of the anti-inflammatory cytokines IL-10 and TGF-β. Increased numbers of CD11c macrophages and decreased MMP9 expression were observed only in response to the highest dose of PEA (40mg/kg). Our results indicate that PEA has an antitumor activity associated with a pro-inflammatory response in colon cancer, and contribute to a better understanding of its immunomodulatory effects.

CCR5-expressing B-1 cells attract CD8 T cells to melanoma millieu and decrease tumor aggressiveness

B. C. Vivanco*, J. D. Lopes, E. Perez, P. Xander, M. Guereschi, F. T. d. Konno;*
UNIFESP, São Paulo, Brazil.

It has been shown by our group that B16F10 murine melanoma cell line, after physical contact with B-1 cells have increased metastatic potential. However the mechanism by which B-1 cells migrate towards melanoma cells is unknown. Objective: The aim of the work was to evaluate the influence of CCR5 expressed in B-1 cells on the course of B16F10 cells melanoma. Results: The present study demonstrated that B16F10 cells release soluble factors that are chemoattractant for B-1 cells. It was demonstrated that 10% of peritoneal B-1 cells express the chemokine receptor CCR5 on their surface. These cells, when inoculated into animals CCR5-/-, leads to in a 10-fold decrease in the number of metastatic nodules resulting from inoculation with B16F10 cells. Moreover, this approach promotes reduced rate of subcutaneous tumor growth, maintaining a stable volume of tumor while control animal presented exponential growth being that last day of measure in treated group show less tumor volume than first day of control group. Besides that, this treatment increased the survival of animals. When mice from treated group started to die, all mice from control groups already came to death. Analyzing leukocyte infiltration in the tumor we found a increased frequency of CD8 T cells in the treated group. Conclusion: Our data suggest that CCR5-expressing B-1 cells can change the development of murine melanoma, controlling it. So, this work contributed to a better understanding of B-1 cells chemotaxis and the influence of migration in evolution of melanoma.

P5.20.105
Devil Facial Tumour Disease, a devil of a cancer that is transmissible and fails to induce an immune response

G. M. Woods[1], *A. Kreiss*[1], *H. Siddle*[2], *L. Howson*[1], *T. Kobayashi*[1], *G. Brown*[1], *C. Tovar*[1], *J. Murphy*[3], *L. Corcoran*[3], *J. Kaufman*[2];
[1]*Menzies Research Institute Tasmania, Hobart, Australia,* [2]*University of Cambridge, Cambridge, United Kingdom,* [3]*Walter and Eliza Hall Institute, Melbourne, Australia.*

Devil facial tumour disease (DFTD) is a transmissible cancer of Schwann cell origin and has caused the death of approximately 80% of the Tasmanian devil population. Once a devil is 'infected' with DFTD cancer cells death always results. One of the remarkable features of this cancer is that the devil's immune system fails to recognise the allogeneic DFTD cancer cells. This is despite evidence that the devil has a fully competent immune system.
Lack of major histocompatibility complex (MHC) diversity may contribute to this lack of allo-recognition. To evaluate the severity of this we conducted mixed lymphocyte reactions and skin grafts. Detectable mixed lymphocyte reactions between some animals were obsered. All successful allografts were rejected within 14 days, even though little or no MHC I and II mismatches were found. Extensive T cell infiltration characterised the immune rejection. There is something unique about the DFTD tumour that allows it to be undetected by the devil's immune system. Preliminary results indicate that the DFTD tumour cells down regulate immune recognition genes and are therefore 'invisible' to the devil's immune system.
The inability of the devil's immune system to reject the transplanted tumours suggests that the tumour cells could be immunologically inert. Immunisation of Tasmanian devils with various formulations of tumour cells and adjuvants has met with limited success. But this limited success has provided evidence that some devils can produce a weak antibody and cytotoxic response. These antibodies are providing useful tools to screen for potential tumour antigens.

P5.20.106
Co-existence of HLA class I expression and CD8+ T cell infiltration is associated with favorable clinical outcomes in Ewing's sarcoma family of tumors (ESFT)

H. Yabe[1], *T. Tsukahara*[2], *S. Kawaguchi*[3], *T. Torigoe*[2], *N. Sato*[4], *H. Morioka*[5], *H. Yabe*[5];
[1]*Division of Rheumatology, First Department of Comprehensive Medicine, Jichi Medical University Saitama Medical Center, Saitama City, Japan,* [2]*Department of Pathology I, Sapporo Medical University School of Medicine, Sapporo City, Japan,* [3]*Department of Orthopaedic Surgery, Sapporo Medical University School of Medicine, Sapporo City, Japan,* [4]*Division of Rheumatology, First Department of Comprehensive Medicine, Jichi Medical University Saitama Medical Center, Sapporo City, Japan,* [5]*Department of Orthopaedic Surgery, Keio University School of Medicine, Tokyo, Japan.*

Ewing's sarcoma family of tumors (ESFT) is one of the most malignant bone and soft tissue tumors in young people. Human leukocyte antigen (HLA) class I displays endogenously processed peptides to CD8+ T lymphocytes and has a key role for host immune surveillance. In ESFT, the investigation concerning both HLA class I expression and T cell infiltration has yet to be reported. This study was designed to examine expression profile of HLA class I and CD8+ T cell infiltration in ESFT. Furthermore, we determined the prognostic significance of HLA class I expression in ESFT. Biopsy specimens from 28 ESFT patients were stained by immunohistochemical (IHC) study with the anti-HLA class I monoclonal antibody (mAb) EMR8-5 and the grade of infiltration of CD8+ T cells was evaluated

semiquantitatively by IHC study using anti-CD8 mAb. Expression of HLA class I was negative (positive cells < 5%) in 10 tumors and down-regulated (positive cells < 50%) in 22 tumors. The status of CD8+ T cell infiltration was closely associated with the expression levels of HLA class I. ESFT patients with down-regulated or negative expression of HLA class I showed significantly poorer survival than the rest of the patients. Our results suggested that CD8+ T cell-mediated immune response restricted by HLA class I might play an important role in immune surveillance of ESFT, and we revealed for the first time that the status of HLA class I expression affects the survival of the patients with ESFT.

P5.20.107
The Immunology of Ovarian Cancer

***A. Yassin**;*
University of Edinburgh, Edinburgh, United Kingdom.

Worldwide, more women die from epithelial ovarian cancer (EOC) than any other gynaecological malignancy. The disease is widely held to originate from the ovarian surface epithelium (OSE) and epidemiological evidence implicates recurrent ovulation as a causal factor. As ovulation is an inflammatory process, inflammation-associated damage of the OSE may predispose to malignant transformation. Following ovulation, the OSE undergoes connective tissue remodelling through up-regulation of lysyl oxidase (LOX), an enzyme essential for post-translational collagen cross-linking. In addition there is evidence that LOX may play an important role in progression and metastasis of several cancers. The aim of this study was to assess the pattern of LOX expression in EOC primary cell cultures and genes previously shown to influence LOX expression connective tissue growth factor (CTGF) and bone morphogenetic protein-1 (BMP-1).
IL-1α caused a significant up-regulation of LOX mRNA (4.7-fold induction over untreated control, P<0.01) which was abrogated by coincubation with cortisol. CTGF mRNA was not altered by IL-1α or F alone but in combination IL-1α+F caused a significant down-regulation (0.34-fold over untreated control, P<0.05). Both LOX and BMP-1 were localised by immunohistochemistry to the malignant component of ovarian cancers rather than the supporting stromal cells.
These data suggest that LOX is likely to be active in EOC and inflammation enhances LOX expression. Control of LOX expression appears to be independent of CTGF and BMP-1 in these primary cultures. It follows that LOX and gene products responsible for connective tissue remodelling might be future targets for the detection and treatment of EOC.

P5.20.108
Critical role of interleukin-27 in tumor immunology

***Z. Yin**;*
Nankai University, Tianjin, China.

Interleukin-27 (IL-27) plays critical roles in autoimmune diseases and infections; however, the contribution of endogenous, especially the host derived, IL-27 to tumor progression remains elusive. By using IL-27p28 conditional knockout mice, we have demonstrated that IL-27 is critical in protective immune responses against methyl-cholanthrene induced fibrosarcoma and transplanted B16 melanoma, and that dendritic cells are its primary source. DC-derived IL-27 is required for shaping the tumor microenvironment by inducing CXCL-10 expression in myeloid derived suppressor cells and regulating IL-12 production from dendritic cells, leading to the recruitment and functional maintenance of tumor infiltrating NK and NKT cells respectively. Indeed, reconstitution of either IL-27 or CXCL-10 in tumor site significantly restores the recruitment and function of NK and NKT cells and inhibits tumor growth. In summary, our study identifies a previous unknown critical role of DC-derived IL-27 in NK and NKT cells dependent antitumor immune surveillance by shaping the tumor microenvironment, and sheds light on developing novel therapeutic approaches based on IL-27.

P5.20.109
The role of the CXCR3 receptor ligand system in the immune escape of multiple myeloma

***C. Zelle-Rieser**[1,2], S. Thangavadivel[1], M. Lechner[1], A. Brunner[2], R. Greil[1,3], K. Jöhrer[1];*
[1]Tyrolean Cancer Research Institute, Innsbruck, Austria, [2]Department of Pathology, Innsbruck Medical University, Innsbruck, Austria, [3]Laboratory for Immunological and Molecular Cancer Research, IIIrd Medical Department, Paracelsus Medical University Salzburg, Salzburg, Austria.

Multiple Myeloma is a clonal B-cell neoplasm that affects terminally differentiated B cells. In this disease defects of the immune system including impairment of dendritic cell functions are well characterized. Tumour-derived chemokines might play a major role in the observed immune deficiency. The role of the CXCR3 receptor-ligand system in immunosurveillance is controversially discussed in different tumour entities. Here we investigated the role of myeloma-derived CXCR3ligands (*CXCL9*, *CXCL10*, *CXCL11*) on the functionality of dendritic cells bearing the appropriate receptor CXCR3 and their ability to stimulate T cells. We found that CXCR3ligand- activated dendritic cells showed a decrease in T-cell stimulatory capacity. Further, chronic stimulation of T cells led to diminished IFN-γ production and reduced CXCR3 receptor expression by T cell-subtypes. Experimental studies in various disease models show that CXCR3 deficiency significantly impairs cell-mediated immunity. Our observations indicate that the presence of CXCR3 ligands in multiple myeloma may lead to T cell exhaustion, possibly contributing to tumour immune escape.

P5.20.110
A Novel Subset of Tumor-infiltrating B7-H3+CD14+HLA-DR-/low Myeloid-derived Suppressor Cells Foster Immune Privilege and Tumor Progression in NSCLC

***G. Zhang**, H. Huang, X. Zhang;*
The First Affiliated Hospital of Soochow University, Suzhou, China.

Myeloid-derived suppressor cells (MDSCs) are potent immune-suppressive cells promoting tumor progression and metastasis. Although surface markers of Gr-1 and CD11b are widely used to define MDSCs in mice, human MDSCs lack definitive phenotypic markers. Here, we showed that CD14+HLA-DR-/low MDSCs were significantly increased in blood and tumor tissues of non-small cell lung cancer patients. Intriguingly, we found that B7-H3 molecule was exclusively expressed on a subset of tumor-infiltrating CD14+HLA-DR-/low MDSCs but not in peripheral blood or non-tumor tissue-infiltrating MDSCs. Both B7-H3+ and B7-H3- CD14+HLA-DR-/low MDSCs exhibited potent T cell suppressive activity. However, B7-H3+MDSCs, as compared to B7-H3- MDSCs, showed increased tumor-promoting activity and preferentially induced regulatory T cell (Treg) expansion in a manner of depending IL-10 signal. Further analyses revealed that B7-H3+MDSCs, but not B7-H3- MDSCs, were positively correlated with Treg infiltration in tumor. Moreover, in a murine lung cancer model, B7-H3+ MDSCs were found within the tumor microenvironment and increased during tumor progression. Similarly, we found levels of B7-H3+ MDSCs were associated with reduced survival in the patients with NSCLC. Taken together, we identify a novel subset of MDSCs within the tumor microenvironment that preferentially induces Treg expansion leading to tumor progression.

P5.20.111
A novel subset of tumor-infiltrating B7-H3+CD14+HLA-DR-/low myeloid-derived suppressor cells foster immune privilege and tumor progression in NSCLC

Myeloid cell-derived reactive oxygen species trigger ERK pathway-dependent parthanatos in human lymphocytes

A. A. Akhiani*, J. Aurelius, O. Werlenius, C. Movitz, A. Martner, K. Hellstrand, F. B. Thorén;*
Sahlgrenska Cancer Center, and Department of Infectious Diseases, The Sahlgrenska Academy, University of Gothenburg, Göteborg, Sweden.

Reactive oxygen species (ROS) are formed by myeloid cells as a defense strategy against microorganisms. ROS however also trigger poly(ADP-ribose) polymerase 1- (PARP-1) dependent cell death (parthanatos) in adjacent lymphocytes. The ROS-induced lymphocyte parthanatos has been forwarded as a mechanism of immune escape in several forms of cancer. The present study sought to evaluate the role of mitogen-activated protein kinases (MAPKs), in particular the extracellular signal-regulated kinase (ERK), in ROS-induced signal transduction leading to lymphocyte parthanatos. It was found that inhibitors of ERK1/2 phosphorylation rescued human natural killer (NK) cells and $CD8^+$ T lymphocytes from cell death induced by ROS-producing mononuclear myeloid cells. ERK1/2 phosphorylation inhibition also protected lymphocytes from cell death induced by exogenous hydrogen peroxide (H_2O_2) and from ROS generated by xanthine oxidase or glucose oxidase. Phosphorylation of ERK1/2 was observed in lymphocytes shortly after exposure to ROS. ROS-generating myeloid cells and exogenous H_2O_2 triggered PARP 1-dependent accumulation of poly ADP-ribose (PAR), which was prevented by ERK pathway inhibitors. ERK1/2 phosphorylation was induced by ROS independently of PARP-1. These findings imply that ROS-induced lymphocyte parthanatos follows the following scheme of events: ROS:ERK1/2:PARP-1:PAR:parthanatos and suggest that the ERK axis may provide a therapeutic target for the protection of lymphocytes against oxidative stress.

P5.21.02
Notch signalling controls leukemic cells

M. Antica[1], *M. Parad□ik*[1], *M. Kunštić*[1], *M. Konjević*[1], *M. Matulić*[2];
[1]*Ruđer Bo□ković Institute, Zagreb, Croatia,* [2]*Division of Biology, Faculty of Science, Zagreb, Croatia.*

Notch signaling and Ikaros transcription factors are implicated in lymphocyte differentiation. Experiments from genetically manipulated mice show that they have a critical role at specific check points of the lymphopoietic pathway. However, how developmental regulated changes are reflected in gene expression programs is still not well understood. The aim of this work is to analyze the genes which regulate differentiation at sequential developmental steps in hematopoietic cells and in leukemic cells with impaired development.
Using the monolayer culture system for T cell development in vitro (OP9-DL 1 cell line), we control and change the conditions of culturing leukemic cells either from cell lines or leukaemia patients. We monitored the influence of Notch and Ikaros family genes on hematopoietic cell differentiation and commitment, by stimulating or inhibiting their activity and measuring downstream gene expression levels in the cells. Our results indicate that Notch signaling is not only a master switch for T lymphocyte commitment, but is also important for survival of leukemic cells. Whether the downstream target genes are part of the HES1 activation pathway has been analyzed in leukemic cell lines and in primary leukemic cells from B CLL patients. We further analyzed whether differentiation and survival of these cells depends on proteins from the Ikaros family, Aiolos and Helios, since they maintain the spatial organization of chromosome structure and regulate cell commitment. Recognition of their expression pattern might help to understand the mechanisms of leukaemia development.

P5.21.03
Vasculitis associated myelodysplasia in a prospective 4 year study.

C. Belizna[1], *A. Ghali*[1], *D. Henrion*[2], *J. Voswinkel*[3], *N. Ifrah*[1];
[1]*CHU ANGERS, Angers, France,* [2]*INSERM 771 ANGERS, Angers, France,* [3]*Hopital Saint Antoine, Paris, France.*

The presence of systemic and/or immune manifestations in myelodysplasia is classical, even thought rarely presenting as initial clinical event.
Purpose:
We present a prospective study (2009-2012) with systemic and/or immune manifestations dominating the clinical presentation.
Patients and methods:
341 patients with a formal diagnosis of myelodysplasia were followed-up for 4 years. Among them 36 developped systemic and/or immune manifestations during the follw-up period (2009-2012). The clinical picture in these cases consisted in transient fever, not related to infections (25%), arthralgia or arthritis (17%), and especially cutaneous (purpura 35%, nodular 15%, papular 8%, and necrotic lesions 5%) related to cutaneous lymphocytary and/or leucocytoclasic vasculitis. Lung symptoms were occasional (2% of cases), the same as renal manifestations (3% of cases). Even though infrequently, some rare cases of systemic vasculitis have been reported in our series (one case of Wegener granulomatosis, two cases of microscopic polyangeitis and one case of Churg-Strauss syndrome).
Immune anomalies were recorded in 25% of the cases (antinuclear antibodies 20%, ANCA 10%, rheumatoid factor 12%). A corticosteroid treatment was efficient in 90% of the cases.
Discussion and conclusion: The association between myelodysplasic syndromes with systemic and immune manifestations seems to not be occasional and suggests the eventuality of a potential common primary immune disorder.

P5.21.04
CD137 ligand reverse signalling induces differentiation of primary acute myeloid leukaemia cells

K. Cheng[1], *S. Wong*[2], *Y. Linn*[3], *L. Ho*[3], *H. Schwarz*[1];
[1]*National University of Singapore, Singapore, Singapore,* [2]*Singapore Immunology Network, A-STAR, Singapore, Singapore,* [3]*Singapore General Hospital, Singapore, Singapore.*

The ligand for CD137 is expressed on hematopoietic progenitor cells and antigen-presenting cells such as monocytes, dendritic cells and B cells. Reverse signalling of CD137 ligand into the cell delivers a potent activating signal that results in the differentiation of hematopoietic progenitor cells into macrophages, and monocytes into dendritic cells. CD137 ligand is also expressed on acute myeloid leukemia cells, which characteristically possess a maturation block that leads to arrested differentiation and malignancy.
We hypothesize that CD137 ligand reverse signalling via stimulation with CD137 may also induce differentiation of the transformed myeloid cells in acute myeloid leukaemia. Primary acute myeloid leukemia blasts isolated from either the bone marrow or peripheral blood of patients at time of diagnosis were stimulated with a recombinant CD137 protein in vitro. Reverse signalling through CD137 ligand induces differentiation of these leukemic blasts based on morphology, immunophenotyping, cellular functions such as phagocytosis and oxidative burst, and cytokine release. These differentiated cells functionally demonstrate a more potent T cell co-stimulatory capacity as evidenced by up-regulation of co-stimulatory molecules, induction of increased T cell proliferation and cytokine release.
These results suggest that CD137, as a single factor, is able to induce differentiation of the immature blasts in acute myeloid leukemia into more effective antigen-presenting cells with enhanced T cell co-stimulatory potential.
The ability to overcome the block in myeloid maturation and drive differentiation of acute myeloid leukemia cells has implications for the development of differentiation therapies and anti-leukemia vaccines.

P5.21.05
Serum free light chains assays (sFLC) in immunoglobulin light chain monoclonal gammopathies diagnosis and assessment: an Algerian study

K. Cherguelaine*, N. Messaoudani, R. Djidjik, M. Ghaffor;*
Immunology department, Beni Messous Teaching Hospital, Algiers, Algeria.

Objectives: the usefulness of serum free light chains assays in the diagnosis and monitoring of monoclonal gammopathies has been reported in numerous papers. In this study, we aim to evaluate the clinical relevance of this assay in a cohort of 65 Algerian patients with immunoglobulin light chains monoclonal gammopathies (LCMG).
Methods: 65 patients (39 males, 26 females) with LCMG were selected from cases of known monoclonal gammopathies, at the immunology department of Beni Messous Teaching Hospital, Algiers, Algeria. The detection, measurement and identification of the monoclonal protein (M-protein) was performed using serum protein electrophoresis (SPEP), urine protein electrophoresis, immunofixation electrophoresis (IFE) and serum free light chains assays. The FLC immunoassay was performed using a nephelometer with the Freelite reagents.
Results: Free light chains ratio was abnormal in 64 patients. The detection of M-protein was not possible in 12 patients using SPEP, UPEP and IFE. sFLC assays enabled the identification of the monoclonal free light chain. The 12 patients were distributed as follows: 8 had multiple myeloma (MM), 1 had amyloidosis, 2 had plasmocytoma and 1 monoclonal gammopathy of undetermined significance (MGUS).
Conclusion: although SPEP and IFE remain the principal methods used to identify M-protein, they proved to be ineffective in some cases of our cohort. sFLC assays allowed the diagnosis of monoclonal gammopathies in patients with “normal” SPEP and IFE results, and thus, an accurate diagnosis and a faster management of the disease.

P5.21.06
Detection of two distinct MLL-AF4 fusion transcripts in a neonatal acute leukemia case undergoing a rapid lineage switch after diagnosis

V. A. Cianga[1], *E. Caranfil*[1], *M. Zlei*[2], *I. C. Ivanov*[2];
[1]*University of Medicine and Pharmacy "Gr.T.Popa" Iasi, Iasi, Romania,* [2]*Regional Institute of Oncology, Iasi, Laboratory of Molecular Biology, Iasi, Romania.*

Context: The importance of genetic events in the classification, therapy, and prognosis of ALL has gained recently growing credit. Amongst those events, mixed lineage leukemia (MLL) gene rearrangements may be found in leukemia cases of either lymphoid or myeloid phenotypes and translocation t(4;11)(q21;q23) is often associated with pediatric cases.
Objective: To present the clinical-laboratory particularities of a MLL-AF4 positive pediatric leukemia case in which the cell lineage switched early from ALL to AML. Material and Method: In a bone marrow sample of a two months old girl suspected of ALL, the presence of 4 fusion transcripts: BCR-ABL, MLL-AF4, E2A-PBX1, TEL-AML1 was assessed. Flow cytometry analyses were carried out on a FACSCanto-II cytometer.
Results: While at diagnosis a dominant malignant clone displaying a pro-B lymphoid phenotype was described, two weeks later, under corticotherapy, a malignant monocytoid population predominantly expanded. With both occasions, the patient was found to be positive for two distinct MLL-AF4 transcripts: e11-e4 and e10-e4. The bilineage nature of the case suggests that t(4;11) transforms a multipotential progenitor cell. Similar to other reports, this case is predictable to have an aggressive evolution, although expected to benefit from allogeneic HSCT. Two months after the initiation of induction therapy the patient has not achieved remission and has an indication for a more intensive chemotherapy.
Conclusion: Sensitive detection of MLL rearrangements, accurate lineage assignment, and early lineage switch prediction may have a crucial clinical impact, supporting the clinician in treatment making decisions and increasing the precision of minimal residual disease detection.

P5.21.07
Immune reconstitution with subcutaneous immunoglobulin in patients with lymphoproliferative disease and secondary hypogammaglobulinemia after anti-CD20 mAb therapy

N. Compagno*, F. Cinetto, C. Agostini;*
Allergology and Clinical Immunology, Department of Medicine, University of Padova, Padova, Italy.

Purpose: Intravenous immunoglobulin replacement therapy (IVIg) represents the standard treatment for hypogammaglobulinaemia secondary to B-cell lymphoproliferative disorders (LPDs). Subcutaneous immunoglobulin infusion (SCIg) is an effective, safe and well-tolerated approach in primary immunodeficiencies but no extensive data are available on their use in LPDs with hypogammaglobulinaemia, a frequent phenomenon after treatment with anti-CD20 mAb.
Methods: In this study we evaluated efficacy (serum IgG levels and number of infections/year) and safety (number of adverse events) of IVIg (250 mg/kg/4weeks) vs SCIg (70 mg/kg/week) replacement therapy in 55 patients with LPDs and hypogammaglobulinemia previously treated with anti-CD20 mAb. In addition, the impact of the infusion methods on the quality of life (QoL) was compared.
Results: Both treatments appeared to be effective in replacing defective Ig production (mean 3,89 g/L ± 1,65 before therapy) although SCIg achieved significantly higher levels of IgG (6,39 g/L ± 1,67) with respect to IVIg (4,71 g/L ± 1,38; p <0,05). Both infusion ways were efficacy in reducing the incidence of infectious events and, specifically, of serious infectious events. Noteworthy, SCIg reached a superior benefit, since SC administration was associated to an increased percentage of patients who did not complain infectious events. As expected, we registered a lower number of adverse events with SCIg with respect to IVIg, with no SAE. Finally, we observed an improvement in health-related QoL parameters after the switch to SCIg.
Conclusion: Our results suggest that SC immunoglobulin is safe and effective in patients with LPDs and hypogammaglobulinemia, confirming our previous report.

P5.21.08
Rituximab in the treatment of EBV-positive low grade B-cell lymphomas. Is there additive benefit regarding EBV infection?

***P. T. Diamantopoulos**, K. Polonyfi, M. Sofotasiou, V. Papadopoulou, K. Zervakis, T. Vassilakopoulos, M. Angelopoulou, M. Siakantaris, G. Pangalis, N. Viniou;*
Laikon General Hospital, National and Kapodistrian University of Athens, Athens, Greece.

The vast majority of Epstein-Barr virus (EBV) infections is subclinical, and the virus is capable of establishing a latent infection and causing malignant transformation of B-cells. CD21 is the receptor for EBV on the surface of B-cells, but the virus can also infect T-lymphocytes and monocytes. Following penetration and replication of the viral DNA by cell polymerases, the viral genome remains in the nucleus, and a latency phase is established, during which only a small part of the viral genes is expressed. LMP1 among them is essential for EBV transformation. Low grade B-cell lymphomas are considered non-EBV related although the virus and its gene products are detected in patients with chronic lymphocytic leukemia. Rituximab is a potent factor used in the treatment of these diseases and is also widely used for the treatment of post-transplant lymphoproliferative disorders caused by EBV. The effect of rituximab treatment in non-transplant lymphoma patients has never been studied. We studied the effect of rituximab-based immunochemotherapy in 48 patients with non-EBV related leukemic low grade B-cell lymphomas. Nineteen of the patients were EBV-positive (by qRT-PCR for the BXLF-1 gene). After 3 cycles of rituximab-based treatment, only 1/19 (5.26%) was still positive for EBV. Our results suggests that rituximab used in the treatment of EBV-positive low grade lymphomas is efficient in eradicating the virus from the peripheral blood, a fact that may be important in the course of the disease and the likelihood of recurrences.

P5.21.09
Severe phenotype of IgD multiple myeloma with acute renal insufficiency: report of 2 cases

***K. Djenouhat**[1], H. Messaoudi[2], M. Chahi[2];*
[1]Institut Pasteur of Algiers, Algiers, Algeria, [2]Hôpital Zmirli, Algiers, Algeria.

Introduction and aim: Despite its rarity, IgD multiple myeloma is known by its acute onset usually at a stage of renal complication. IgD remains the only isotype of immunoglobulin with undetermined function.
Our aim is to report clinical and prognosis features of 2 cases of IgD myeloma.
Observations: We reported two cases of IgD myeloma. One female (F) and one male (M). Their ages are 48 and 63 years respectively. They were admitted in internal medicine department for severe renal impairment of unknown etiology. Serum immunoelectrophoresis of F disclosed increases in IgD and the lambda type light chain and died 3 months after diagnosis. However, immunofixation of M serum showed an IgD with kappa type light chain, he died 5 weeks after diagnosis. Decreased of polyclonal immunoglobulin and high percentage of immature plasma cells was found on the myelogram of both patients.
Conclusion: Important issues of our observation are: - the fact that among the two patients, one is female, which is exceptional in IgD myeloma - Light chain could be Kappa or lambda - No improvement of patient's condition - Both patients had renal failure requiring hemodialysis before the diagnosis of IgD myeloma- The survival period after diagnosis of IgD myeloma is the shortest among all types of myeloma.

P5.21.10
CD27+IgM+IgD+ B cells in Persistent Polyclonal B-cell Lymphocytosis are hyperproliferated memory B cells with a distinctive immunophenotype

*M. Berkowska[1], **C. Grosserichter-Wagener**[1], H. Adriaansen[2], D. de Ridder[3], K. Pagano Mirani-Oostdijk[4], H. Agteresch[5], S. Boettcher[6], A. Orfao[7], J. van Dongen[1], M. van Zelm[1];*
[1]ErasmusMC, Rotterdam, Netherlands, [2]Gelre ziekenhuizen, Apeldoorn/Zutphen, Netherlands, [3]Delft University of Technology, Delft, Netherlands, [4]Franciscus Hospital, Roosendaal, Netherlands, [5]Admiraal De Ruyter Ziekenhuis, Goes, Netherlands, [6]University Hospital of Schleswig-Holstein, Kiel, Germany, [7]University of Salamanca, Salamanca, Spain.

Persistent polyclonal B-cell lymphocytosis (PPBL) is a rare benign disorder characterized by an expansion of CD27+IgM+IgD+ cells. Despite an increasing number of described cases, the nature of the persistent lymphocytosis and its relation to mature B-cell malignancies remain poorly understood. Therefore, we subjected PPBL patients and healthy controls to immunoglobulin (Ig) repertoire and replication history analyses, and gene expression profiling. In addition, we compared the immunophenotype of PPBL cells with B-cell malignancies and B-cell subsets from controls. Replication history analysis revealed that PPBL cells had undergone hyperproliferation in vivo. Still, the IGH gene repertoire of these cells was highly diverse without evidence for stereotypy. Moreover, the *IGHV* genes contained somatic hypermutations (SHM), albeit in low levels and without the selection for replacement mutations in complementarity determining regions that is found in control memory B cells. PPBL cells showed a gene expression profile reminiscent of memory B cells, accompanied by upregulation of Toll-like receptor signaling molecules and heterogeneous deregulation of oncogenes. Furthermore, we identified cell surface markers to discriminate PPBL cells from control B-cell subsets: IgD, CD38, CD73 and CD62L. These combined insights, especially the newly identified cell surface markers, can prove valuable for diagnosis of PPBL.

P5.21.11
Effect of a calcium channel blocker on matrix metalloproteinase-9 activity in human monocytic THP1 cells

***F. Hajighasemi**, N. Kakadezfuli;*
Department of Immunology, Faculty of Medicine, Shahed University, Tehran, Iran.

Background: Matrix metalloproteinase-9 (MMP-9) belongs to a big group of enzymes which have essential role in degradation of extracellular matrix and play a key role in inflammation. Verapamil as a calcium channel blocker has been widely used in treatment of cardiovascular diseases. Moreover the anti-inflammatory effects of verapamil have been demonstrated. In this study the effect of verapamil on MMP-9 activity in a human monocytic cell line has been assessed in vitro.
Methods: The human monocytic THP1 cells were cultured in complete RPMI medium. The cells at logarhytmic growth phase were stimulated with phorbol 12-myristate 13-acetate (PMA) at optimum concentration and then incubated with different concentrations of verapamil (0.001-10 µg/ml). Next the MMP-9 activity in cell culture supernates was measured by gelatin zymography.
Results: Verapamil significantly and dose-dependently decreased the MMP-9 activity in human PBMCs after 48 hour incubation time compared with untreated control cells.
Conclusion: In this study verapamil showed a dose- dependent inhibitory effect on the MMP-9 activity in human monocytic THP-1 cells. Thus it seems that the anti-inflammatory properties of verapamil may be in part due to its inhibitory effects on MMP-9 activity.

P5.21.12
Downregulation of IL17 producing T cells is associated with regulatory T cells expansion and disease progression in chronic lymphocytic leukemia

F. Jadidi-Niaragh[1], *G. Ghalamfarsa*[1], *A. Memarian*[2], *H. Asgarian-Omran*[2], *S. Razavi*[3], *A. Sarrafnejad*[1], *F. Shokri*[1];
[1]*Department of Immunology, School of Public Health, Tehran University of Medical Sciences, Tehran, Iran,* [2]*Department of Immunology, School of Medicine, Tehran University of Medical Sciences, Tehran, Iran,* [3]*Clinic of Hematology and Oncology, Firozgar Hospital, Faculty of Medicine, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran.*

Little is known about the immunobiology of interleukin-17 (IL17) producing T cells and regulatory T cells (Treg) in chronic lymphocytic leukaemia (CLL). In this study, the frequencies of Th17, Tc17 and CD39+Treg cells were enumerated in peripheral T cells isolated from 40 CLL patients and 15 normal subjects by flow cytometry. Our results showed a lower frequency of Th17 and Tc17 cells in progressive (0.99±0.12% of total CD3+CD4+ cells, 0.44±0.09% of total CD8+ cells) compared to indolent patients (1.57±0.24%, p=0.042, 0.82±0.2%, p=0.09) and normal subjects (1.78±0.2%, p=0.003, 0.71±0.09%, p=0.04). Decrease in IL17 producing T cells was associated with CD39+Treg cells expansion. Variation of IL17 producing cells and Treg cells in indolent and progressive patients was neither associated to the expression levels of Th1 and Th2 specific transcription factors T-bet and GATA-3 nor to the frequencies of IFNγ and IL4 producing CD4+ T cells in a selected number of samples. Additionally, suppressive potential of CD4+ Treg was similar in CLL patients and normal subjects. Our data indicates that progression of CLL is associated with downregulation of IL17 producing T cells and expansion of Treg cells, implying contribution of these subsets of T cells in progression of CLL.

P5.21.13
Common genetic variants of BAFF, APRIL, TACI, BCMA and BAFF-R genes and B-cell chronic lymphocytic leukaemia risk

M. Jasek[1], *A. Bojarska-Junak*[2], *M. Wagner*[1], *K. Radomska*[2], *B. Wilczynska*[2], *A. Pietkiewicz-Sworowska*[1], *I. Kania*[3], *J. Rolinski*[2], *I. Frydecka*[1], *P. Kusnierczyk*[1];
[1]*Institute of Immunology and Experimental Therapy, Polish Academy of Science, Wroclaw, Poland,* [2]*Medical University of Lublin, Lublin, Poland, Lublin, Poland,* [3]*Institute of Hematology and Transfusion Medicine, Warsaw, Poland, Warsaw, Poland.*

TNF superfamily members, B-cell activation factor (BAFF; TNFSF13B) and a proliferation-inducting ligand (APRIL; TNFSF13), may play an important role in B - cell chronic lymphocytic leukaemia (B-CLL) survival. BAFF and APRIL bind with high affinity BCMA (B-cell maturation antigen; TNFRSF17) and TACI (transmembrane activator calcium modulator and cyclophilin ligand interactor; TNFRSF13B) receptors. BAFF additionally interacts with BAFF-R (TNFRS13C) receptor. Abnormalities in the synthesis of these molecules or expression of their receptors have been associated with various B cell malignancies including B-CLL. Therefore, we conducted a case-control study (N=197 vs. N=326) to investigate the possible association of 17 SNPs: 3 SNPs in BAFF, 4 SNPs in APRIL, 3 SNPs in BCMA, 3 SNPs in TACI and 4 SNPs in BAFF-R with susceptibility to B-CLL. Of the 17 SNPs examined in this study, only one SNP rs4985726 of TACI gene was associated with B-CLL. The distribution of the alleles and genotypes of rs4985726 significantly differed between patients and controls (p=0,0004 and p=0,00027, respectively). Individuals possessing allele C had 2.27 times lower risk for B-CLL than homozygous GG (OR=0,44; 95%CI=0.28-0.70; p=0,0004). The features of the BAFF, APRIL, BCMA, TACI and BAFF-R genes were subjected to analysis for correlation with clinical data. Individuals carrying C allele in rs11078355 of TACI showed increased soluble APRIL level compared to TT individuals (p=0.052). Our results suggest that rs4985726 is significantly associated with B-CLL risk and rs11078355 may be involved in clinical course of this disease.

P5.21.14
monoclonal component revealed by a cryoglobulinemia

S. Kechoud[1], *K. Cheguelaine*[1], *D. Messaoudane*[1], *N. Ouari*[1], *A. Abdessmed*[2], *R. Djidjik*[1], *M. Ghaffor*[1];
[1]*Immunology Unit, Beni-Messous Hospital , Algeria, Alger, Algeria,* [2]*Department of Rheumatology, Ben Aknoun Hospital,, Alger, Algeria.*

Introduction: Cryoglobulins are immunoglobulins that precipitate below 37°C they may be responsible for vasculitis of small vessels. The mixed cryoglobulins of type II and III are associated to auto immune diseases, viral infectious diseases and can be found in some lymphoproliferative syndrome.
Patient, materials and methods: It is a woman aged 59, with rheumatoid arthritis a scleroderma and secondary Sjögren's syndrome, with clinical manifestations suggestive of strong suspicion of cryoglobulinemia such as petechial purpura, ulcers of the legs. A research of cryoglobulinemia and serum electrophoresis were requested.The search for cryoglobulinemia was done in the particular conditions (37 ° C), electrophoresis and immunosubtraction of serum proteins on Cappillarys was made. Electrophoresis, immunofixation on agarose gel (SAS3,SAS4) and assay of immunoglobulins for cryoprecipitate , rheumatoid factor by nephelometry laser (Immage). Quantification of cryoprecipitate (technique pyrogallol red).
Result and Discussion: Serum electrophoresis on capillary, at room temperature objectified a hypogammaglobulinemia. Cryoglobulinemia was positive after 10 days of observation, electrophoresis of serum cryoprécipitant heated at 37 ° C, objectified a monoclonal component isotype IgG lambda.
The agarose gel electrophoresis and immunofixation of cryoprecipitate, were used to classify the cryoglobulin in type IIa "mixed monoclonal".
We would have missed the monoclonal component if we did not search the cryoglobulin.
Conclusion: In front of the precipitating Character of immunoglobulins which occurs preferentially in hematological malignancies and auto immune diseases, the interpretation of serum electrophoresis should be done very carefully when the clinic strongly indicates cryoglobulinemia.

P5.21.15
Evaluation of urokinase Plasminogen Activator Receptor (uPAR), soluble uPAR, and β1 integrin in patients with Hodgkin's lymphoma

S. Kouhpayeh, *M. Gharagozloo, N. Esmaeil, A. Rezaei, M. Adib, A. Andalib;*
Isfahan University of Medical Sciences, Isfahan, Iran.

Several studies indicated the role of urokinase plasminogen activator receptor (uPAR), soluble uPAR (suPAR), and β1 integrin in tumor growth and invasion. In this study, the expression levels of β1 integrin and uPAR on lymph node mononuclear cells from 25 Hodgkin's lymphoma (HL) patients were evaluated using two-color flow cytometry. Moreover, the levels of suPAR in the serum samples of HL were measured and compared with 32 healthy controls. Results indicated no significant association of uPAR with tumor size, different stages, or different histological subtypes of HL; however, an increased expression of β1 integrin was detected in advanced stages of HL. Among different subtypes, higher expression of β1 integrin was detected in Nodular sclerosis compared to Lymphocyte Predominant. No significant difference was observed between serum levels of suPAR in patients with different stages of HL and healthy controls. Moreover, the levels of suPAR were significantly higher in Nodular sclerosis in comparison with other subtypes. In conclusion, this study showed that the levels of suPAR and β1 integrin varied between different histological subtypes of HL. Although uPAR may play only a minor role in growth and metastasis of lymphoma, β1 integrin may be important in predicting prognosis and metastasis in HL.

P5.21.16
In vivo imaging of B-cell chronic lymphocytic leukemia extravasation through high endothelial venules in lymph nodes

F. Lafouresse[1,2]*, E. Bellard*[1,2]*, C. Moussion*[1,2]*, L. Ysebaert*[3,4]*, J. P. Girard*[1,2]*;*
[1]CNRS, IPBS (Institut de Pharmacologie et de Biologie Structurale), Toulouse, France, [2]Université de Toulouse, Toulouse, France, [3]INSERM, U1037, CRCT (Centre de Recherches en Cancérologie de Toulouse), Toulouse, France, [4]Service d'Hématologie, CHU Purpan, Toulouse, France.

B cell chronic lymphocytic leukemia (B-CLL) is characterized by the progressive accumulation of B-CLL cells in the blood, bone marrow, spleen and lymph nodes (LNs). LNs are sites of malignant proliferation and LN enlargement is associated with poor prognosis in the clinics. Although chemotherapy is efficient on circulating B-CLL cells, LN resident B-CLL cells are refractory to treatment and are often the source of relapse. The aim of our study was to provide a better understanding of the mechanism of B-CLL cell entry and retention within LNs in order to reduce B-CLL residency within LNs during chemotherapy treatment. Using intravital microscopy, we studied the behavior of B-CLL patient cells within high endothelial venules (HEVs) of mouse peripheral LNs, the major gateways for lymphocyte entry into LNs (Moussion and Girard, Nature 2011, 479:542-546; Girard et al., Nature Rev Immunol, 2012, 12:762-773). We found that B-CLL cells from patients with clinical lymphadenopathy expressed a higher level of the LN homing receptor CD62-L than B-CLL cells from patients without LN enlargement. High levels of CD62-L expression correlated with an increased proportion of cells that rolled and sticked on LN HEVs. We are now using 2-photon intravital microscopy to visualize B-CLL extravasation through HEVs and B-CLL cell migration within LNs. We are also investigating the effect of drugs on B-CLL cells homing and distribution within LNs.

P5.21.17
The PI3K/ERK dual inhibitor AEZS-136 triggers a potent antitumor activity agains Hodgkin limphoma cells through a ROS-dependent mechanism

S. L. Locatelli[1,2]*, L. Rubino*[1]*, S. Tartari*[1]*, A. Santoro*[1]*, C. Carlo-Stella*[1,2]*;*
[1]Humanitas Clinical and Research Center, Rozzano, Italy, [2]Department of Medical Biotechnology and Translational Medicine, University of Milano, Milano, Italy.

Relapse of disease and resistance to established therapies remains a challenge in the treatment of Hodgkin Lymphoma (HL) and Diffuse Large B-Cell Lymphoma (DLBCL). Previous results from our phase II study in HL indicate that combining the PI3K/AKT inhibitor perifosine with the RAF/MEK/ERK inhibitor sorafenib can achieve remarkable responses in the relapsed/refractory settings. Here we aim to characterize the in vitro and in vivo activity and mechanism(s) of action of the novel dual PI3K/ERK inhibitor AEZS-136 (Æterna Zentaris GmbH, Germany, EU) in HL. AEZS-136 treatment resulted in a time and dose-dependent cell growth inhibition (range, 30% to 80%) and cell cycle arrest in HL cells (L-540, SUP-HD1, KM-H2 and L-428), as well as in germinal center (GCB) (SU-DHL-6, SU-DHL-10, SU-DHL-16) and activated (ABC) (RCK8, RIVA, U2932) DLBCL cells (range, 60% to 90%). Caspase-independent cell death was observed in L-540 and SUP-HD1 cells (62 ± 9% and 46 ± 2%, $P \leq .0001$, respectively) associated with severe mitochondrial dysfunction (up to 40%, $P \leq .001$). Besides downregulating phosphorylation of ERK and PI3K/AKT, AEZS-136 sustained activation of JNK, whose inhibition prevented cell death. These findings were attributed to AEZS-136 time-dependent induction of reactive oxygen species (ROS) and necroptosis. Necrostatin-1 or the ROS inhibitor YCG063 abolished AEZS-136-induced ROS production, mitochondrial injury, JNK activation and cell death. In vivo AEZS-136 dose-dependently inhibited the growth of L-540 nodules (from 22 to 55%, P≤.0001). These results indicate that AEZS-136 induces cytostatic and cytotoxic effects in HL cells and xenografts, suggesting further investigation in future HL trials.

P5.21.18
IgD multiple myeloma: Presenting clinical and biological features Review of 17 cases

Y. Lounici*, C. Khaled, Y. Berkouk, R. Djidjik, M. Ghaffor; Teaching hospital Beni Messous, Algiers, Algeria.*

IgD multiple myeloma (MM) is a rare subtype of myeloma≈(2%). To obtain clinical, biological features and prognostic value of serum free light chains (sFLC) analysis, we examined 17 cases of IgD myeloma. From 1998 to 2012, we had 590 multiple myeloma including 17 patients with IgD myeloma. Men predominate with a mean age at diagnosis: 59 ± 12 years. The presenting features: bone pain (75%), lymphadenopathy (16%), hepatomegaly (25%), splenomegaly (8%), associated AL amyloidosis (6%), renal impairment function (82%), infections (47%), hypercalcemia (37%) and anemia (93%). Patients with IgD myelomas have a short median survival (9 months). Serum electrophoretic showed an M-spike which are not high (Mean= 13,22 ± 10 g/L) in all patients associated to an hypogammaglobulinemia. The type of light chain was Lambda (65%), high β2microglobulin in 91% and Bence Jones proteinuria was identified in 71%. The median rate of sFLCs κ was 19.05 mg/L and 296,75 mg/L for sFLCs λ. sFLCR was abnormal in 93% of patients and it showed concordance between baseline sFLCR and the survival (P=0.034). The contribution of FLC assay is crucial for the prognosis of patients with IgD myeloma. However, IgD myeloma has a more aggressive disease course than other myelomas, this is why, a multi-center study is recommended to establish specific median survivals for this entity according to the recent ISS.

P5.21.19
Upregulation of CD200 is associated with Foxp3+ regulatory T-cell expansion and disease progression in acute myeloid leukemia

A. Memarian[1,2]*, M. Nourizadeh*[2]*, F. Masoumi*[2]*, S. Anvari*[1]*, A. Emami*[3]*, K. Alimoghaddam*[4]*, M. Mirahmadian*[2]*, M. Jeddi-Tehrani*[5]*;*
[1]Department of Microbiology, School of Medicine, Golestan University of Medical Sciences, Gorgan, Iran, [2]Department of Immunology, School of Medicine, Tehran University of Medical Sciences, Tehran, Iran, [3]Clinic of Hematology and Oncology, Vali-Asr Hospital, School of Medicine, Tehran University of Medical Sciences, Tehran, Iran, [4]Hematology, Oncology and Stem Cell Transplantation Research Center, Tehran University of Medical Sciences, Shariati Hospital, Tehran, Iran, [5]Monoclonal Antibody Research Center, Avicenna Research Institute, Tehran, Iran.

Immunosuppression in acute myeloid leukemia (AML) is an important mechanism of tumor escape. CD200, as an immunosuppressive molecule, is over-expressed in some hematological malignancies and it has also been shown to be an independent prognostic factor in AML. In the current study, simultaneous CD200 expression and Foxp3+ regulatory T-cell levels were investigated in Iranian patients with AML by Flow cytometry. We also assessed the effect of CD200-CD200R blockade on Th1 and T-reg cytokine production and T-cell proliferation in autologous AML- and monocyte-DC MLRs. ELISA assay was performed to detect IL-2, IL-12, IFN-γ, IL-10 and TGF-β production in MLR supernatants. Expression of Foxp3, IL-10 and TGF-β mRNAs in MLRs were detected by real-time PCR. Our results demonstrated significant over-expression of CD200 in association with higher frequencies of Foxp3+ T-cells in AML patients. Blocking of CD200-CD200R interaction demonstrated a significant decrease in TGF-β and IL-10 expression in AML-DC MLRs and a significant increase in IL-12 and IFN-γ expression in monocyte-DC MLRs. Elevated T-cell levels with lower Foxp3 intensity was also shown in CD200-CD200R blocked MLRs. Expression of IL-10 mRNA declined significantly only in AML-DC MLRs where CD200-CD200R interaction was blocked and the same result was observed for TGF-β and Foxp3 mRNA in both AML-and monocyte-DC MLRs. These data present a significant role for CD200 in suppressing anti tumor immune response through stimulation of regulatory mechanisms in AML patients and suggest that CD200 may have a prognostic value in this malignancy and its blockade may be used as a target for AML immunotherapy.

P5.21.20
The multiple myeloma in the region of Annaba (Algeria)

***H. Meriche**;*
Departement of Immunology, CHU Annaba, Annaba, Algeria.

Multiple myeloma (MM) or *Kahler's* disease is a malignant monoclonal proliferation of plasma cells that are actively secreting in inappropriate and exaggerated manner the entire structure of immunoglobulin (Ig) or any segment of it. MM is accounting nearly for 10 % of hematological malignancies. It is slightly more common in men than in women and a peak age at diagnosis is 64 years. The diagnosis of this condition is based on two elements: The detection of a monoclonal component in serum and / or urine, and dystrophic bone marrow plasma cell proliferation.
In our work, we report the clinical and biological and immunochemical characteristics of 165 cases of MM.
165 patients with MM (84M / 81F), aged between 25 and 90 years, 18 of which were age <45 years, the diagnosis occurred by myelogram and the identification of a monoclonal Ig by electrophoresis on agarose gel, immunochemical typing of the monoclonal Ig was held by immune-electrophoresis, immune-fixation and laser-nephelometry. The degree of bone marrow plasma cell proliferation was greater than 30% for all studied patients. The immunochemical study of 165 patients with MM showed that 48.49% have a monoclonal Ig with IgG isotype, 19.4% of samples have a monoclonal IgA and only 5.45% have a monoclonal IgM. Incomplete monoclonal Ig as light chains was found for 19.4% of the cases (14.54% kappa, lambda 12.12%).
Multiple myeloma is a disease affecting the elderly, it can however be observed in young adults, its diagnosis is confirmed by immunochemical study of monoclonal immunoglobulin.

P5.21.21
CXCL12 and TP53 genetic polymorphisms as possible markers of pediatric Acute Lymphoblastic Leukemia (ALL) susceptibility in Brazilian population

***C. E. C. Oliveira**, A. L. Perim, R. L. Guembarovski, J. M. M. Oda, C. B. Ariza, M. H. P. Fungaro, M. K. Amarante, G. A. F. Vitiello, K. B. Oliveira, M. A. E. Watanabe;*
Londrina State University, Londrina, Brazil.

Acute lymphoblastic leukemia (ALL) is the most common pediatric malignancy. Genetic polymorphisms in the 3'UTR region of the *CXCL12* (rs1801157) and *TP53* codon 72 (rs1042522) genes may contribute to susceptibility to childhood ALL because they affect some important processes, such as metastasis regulation and tumor suppression. Thus the objective of the present study was to detect the frequency of two genetic polymorphisms in ALL patients and controls and to clarify their impact on genetic susceptibility and prognosis. The *CXCL12* and *TP53* polymorphisms were tested in 54 ALL pediatric patients and in 59 controls by restriction fragment length polymerase chain reaction (RFLP-PCR) and allelic specific chain reaction techniques (ASP-PCR), respectively. The frequencies of both allelic variants were higher in ALL patients than in the controls and indicated a positive association: OR=2.44; CI95%=1.05-5.64 for *CXCL12* and OR=2.20; CI95%=1.03-4.70 for *TP53*. Furthermore, when the two genetic variants were analyzed together, they increased significantly more than 5 fold the risk of this neoplasia development, indicating their potential as susceptibility markers for ALL disease and the relevance of the allelic variant combination to increased risk of developing malignant tumors. Future studies may indicate a larger panel of genes involved in susceptibility and progression of pediatric ALL and other hematological neoplasias. Support: CNPq, CAPES, Fundação Araucaria and PROPPG-UEL.

P5.21.22
Significance of immunoglobulin B-cell receptor features in tumor dynamics of chronic lymphocytic leukemia

***K. Plevova**[1,2], H. Skuhrova Francova[1], K. Brazdilova[2,1], S. Pavlova[2,1], K. Burckova[1], M. Doubek[1,2], Y. Brychtova[1], B. Tichy[2], S. Pospisilova[2,1];*
[1]Department of Internal Medicine – Hematology and Oncology, University Hospital Brno, Brno, Czech Republic, [2]Masaryk University, Central European Institute of Technology, Brno, Czech Republic.

Chronic lymphocytic leukemia (CLL) is a malignant lymphoproliferative disorder characterized by monoclonal expansion of mature B-cells. Presence/absence of somatic hypermutations in clonal heavy chain immunoglobulin gene (IGH), specifically its variable region IGHV, represents a crucial prognostic marker stratifying patients into subgroups with different clinical outcome. Sporadically, cases with multiple IGHs are observed. From clinical point of view, they preclude conclusive prognostic interpretation. However, they constitute a remarkable model of CLL tumorigenesis.
Thus, we investigated biological cause of the multiple IGHs and over-time clone behavior in 31 CLL patients with respect to molecular features of B-cell receptor.
We identified definite co-existence of two clonal B-cell populations with different light chain restriction (9/31 cases), or highly likely co-existence of two or more independent clones with homogenous phenotype (16/31 cases). In cases with consecutive samples, we performed quantitative evaluation of over-time changes in clone proportions. Interestingly, we observed clonal drifts, mainly diminishing of a clone (18 cases) but also appearing of a new one (3 cases). Clones with specific immunogenetic features of IGH, namely (i) higher IGHV identity to germ-line and/or (i) longer HCDR3, were preferred during the disease evolution. Significantly, these clone characteristics are important markers of clinical outcome.
Our study allowed novel insight into biological causes of multiple IGH detection in CLL, typically monoclonal disease. Importantly, we observed clonal drift favoring specific molecular B cell receptor features, which might eventually provide further insight into disease evolution with implications for patient monitoring and therapy.
Supported by Sylica project 286154, NT13493-4/2012, CZ.1.07/2.4.00/17.0042, MUNI/A/0723/2012.

P5.21.23
Prevalence of monoclonal gammopathy detected in the Noor pathobiology lab of Iran

*M. Mohammadnia[1,2], **A. Sarrafnejad**[3,4,5], M. Ghavami Adel[5], Z. Matin[5], S. Bagheri[5];*
[1]Department of Immunology, Faculty of Medical Sciences, Tarbiat Modares University, Tehran, Iran, [2]Immunogenetic Research Center, Mazandaran University of Medical Sciences, Sari, Iran, [3]Department of Immunology, School of Health, Tehran University of Medical Sciences, Tehran, Iran, [4]The Molecular Immunology Research Center, Tehran University of Medical Sciences, Tehran, Iran, [5]Noor Pathobiology Lab, Tehran, Iran.

Background: We assessed the prevalence and isotype distribution of monoclonal gammopathy in the Noor pathobiology laboratory of Iran.
Participants and Methods: From June 21, 2011 to December 20, 2012, a total number of 8525 Iranian patients who referred to Noor pathobiology lab were included in our study. Serum protein electrophoresis was performed on all sera. Serum sample with discrete or localized band was subjected to capillary zone electrophoresis (CZE) and immunosubtraction by Capillarys 2 instrument. Sex- and age-related prevalence rates of monoclonal gammopathy were calculated.
Results: Monoclonal gammopathy was detected in 415 of the 8525 study participants, yielding a prevalence of 4.86% in the total population screened. The prevalence in men was significantly higher than in women. 124 samples of 415 samples were immunotyped. Isotype distribution of immunoglobulin were IgG/Kappa in 46% (n=57) of patients, IgG/Lambda in 23% (n=29), IgA/Kappa in 10% (n=12), IgA/Lambda in 7% (n=9), IgM/Kappa in 6% (n=8), IgM/Lambda in 2% (n=2), Lambda light chain in 5% (n=6) and Kappa light chain in 1% (n=1).
Conclusion: Among patients referred to our clinical lab, monoclonal gammopathy was found in 4.86 percent of persons. Our findings can be the basis of future screening programs and preventive strategies.

P5.21.24
Role of ABCB1 transport activity in the chronic lymphocytic leukemia cells sensitivity to the different anticancer drugs

A. V. Tamashevski[1], *N. V. Goncharova*[2], *T. F. Serhiyenka*[2], *E. I. Slobozhanina*[1], *A. I. Svirnovski*[2];
[1]*Institute of Biophysics and Cell Engineering of National Academy of Sciences of Belarus, Minsk, Belarus,* [2]*Republican Scientific and Practical Center for Transfusiology and Medical Biotechnologies, Minsk, Belarus.*

Chronic lymphocytic leukemia (CLL) is heterogeneous disease with variegated clinical finding, varying duration of illness and the answer to the therapy, caused by abnormal accumulation of the pathological and immunologically incompetent lymphocytes (usually B-cells) in the bone marrow, nodi lymphatici and peripheral blood. By present time this disease is considered incurable. Unfortunately, the basic barrier during cancer therapy is apoptosis failure in CLL-cells due to different molecular mechanisms. One of which is active drugs elimination from the cell mediated by the integral membrane protein P-glycoprotein (P-gp or ABCB1).
In this study we investigated P-gp transport activity (UIC2-shift assay) in the total population of B-CLL human lymphocytes, $CD19^+$ and $CD5^+CD19^+$ cells *in vitro* after treatment with therapeutic concentrations of anticancer drugs (analogues fludarabine and cladribine, doxorubicin and vincristine) and simultaneously assessed the sensitivity of these cells to used drugs and identified correlations.
It was shown that the percentage of P-gp, which was revealed on the B-CLL cells plasmatic membrane after therapeutic concentrations drugs exposure *in vitro* (during 20h) directly determines the survival of B-CLL lymphocytes total population (r_s=0,81; p=0,00015), $CD19^+$ (r_s=0,77; p=0,00048) and $CD5^+CD19^+$ cells (r_s=0,78; p=0,00034) after 44h incubation with investigated drugs (MTT-assay).
Thus, P-gp transport activity doesn't depend on the investigated anticancer drugs substrate specificity (nucleosides purine analogs are not substrates for P-gp). CLL-lymphocytes survival after 44h drugs exposure is mainly related with P-gp functioning in these cells and doesn't determine its further (after 20h) overexpression and exposition on the plasmatic membrane surface.

P5.21.25
Diffuse large B-cell lymphoma (DLBCL) presenting during maintenance therapy for acquired hemophagocytic lymphohistiocytosis (HLH) of unknown origin: a case report

P. Tartaro[1], *M. Gazzola*[1], *A. Branca*[1], *F. Cinetto*[1], *R. Marcolongo*[1], *F. Dalla Valle*[2], *C. Agostini*[1];
[1]*University of Padua, Department of Medicine, Clinical Immunology Branch, Padova, Italy,* [2]*University of Padua, Department of Medical and Surgical Sciences, 2nd Chair of Internal Medicine, Padova, Italy.*

Acquired HLH is a rare and challenging disorder characterized by activation of histiocytes in hematopoietic organs. It has been associated with infections, autoimmune disorders and malignancies (lymphomas and leukemias of T-cell lineage). Herein, we describe a late onset DLBCL during HLH treatment.
A Caucasian 58 y-old man presented with persistent fever and severe anemia. Blood tests showed marked anemia, increased LDH and sIL2-R, hyperferritinemia and hypertriglyceridemia; microbiological (included EBV-DNA) and immunological tests were negative. PET-CT and CT scan documented only mild splenomegaly. Bone marrow aspirate showed activated macrophages and hemophagocytosis. The expression level of perforin was decreased; mutational analysis excluded familial HLH. We concluded for acquired idiopathic HLH. During steroid therapy he developed respiratory symptoms and signs of cerebral vasculitis. We started treatment with etoposide and dexamethasone (HLH-94 protocol), with immediate clinical improvement. After induction therapy, anemia and neurological symptoms reappeared; thus etoposide treatment was resumed as a bridge to allogenic HSCT. Four months later, during maintenance therapy, he developed a bulky inguinal lymphadenopathy, consistent with DLBCL, and recurrence of HLH-symptoms. A combined therapy (R-CHOEP21) induced prompt clinical and bio-humoral improvement.
In our patient, there was no clear evidence of lymphoma at presentation. We can hypothesize the existence of smoldering lymphoma at the time of HLH presentation. Etoposide probably controlled the cytokine storm, but did not affected or might even have favoured lymphomagenesis. In conclusion, during work-up of HLH, occult malignancies should be aggressively ruled out as they can manifest at diagnosis or appear during or after treatment

P5.21.26
Defining antibody responses in normal and non-malignant human aging populations

S. M. Tete[1,2], *G. Horst*[1], *K. Wilting*[1], *M. Klijn*[3], *J. Westra*[1], *A. de Haan*[1], *H. Kluin-Nelemans*[1], *S. Sahota*[2], *M. Bijl*[4], *N. A. Bos*[1];
[1]*University of Groningen, University Medical Centre Groningen, Groningen, Netherlands,* [2]*Cancer Sciences Division, University of Southampton School of Medicine, Southampton, United Kingdom,* [3]*General Practitioners Practice, Huisartsen Boterdiep, Groningen, Netherlands,* [4]*Internal Medicine and Rheumatology, Martini Hospital, Groningen, Netherlands.*

Understanding immunosenescence in ageing is a pressing need to counter the increased susceptibility to infections, as apparent in the inadequate response to influenza virus that underlies>90% of deaths associated with infection in the elderly. The emergence of non-malignant conditions like Monoclonal Gammopathy of Undetermined Significance (MGUS) in the elderly may further alter this susceptibility, and remain poorly defined.
To investigate this, we examined linked B- and T-cell responses to influenza vaccination in a healthy elderly cohort (n=19) and contrasted these with aged individuals with MGUS (n=19), a benign plasma cell monoclonal expansion in the bone marrow that secretes elevated levels of monoclonal protein. Influenza H1N1- and H3N2-specific IgG levels were measured and the frequencies of H1N1- and H3N2-specific IFN-γ-secreting cells assayed by enzyme-linked immunospot.
Comparable influenza-specific IgG titers were seen in HCs and MGUS at a cohort level, and MGUS patients showed a significant increase in influenza-specific IgG responses post-vaccination. However, significant differences emerged in MGUS in relation to M-protein levels. MGUS with low M-protein showed increased influenza-specific IgG titers post-vaccination but MGUS with high M-protein had lower influenza-specific IgG titers which they failed to expand post-vaccination. Contrary to HCs, MGUS patients revealed impaired T-cell responses, as the number of IFN-γ-secreting cells didnot increase post-vaccination. M-protein concentration inversely correlated with influenza-specific IgG response at d7 (p=0.020) and d28 (p=0.012) as well as with the number of IFN-γ-secreting cells (p=0.018) at d28 post-vaccination.
MGUS, as a non-malignant clonal expansion, depresses immune responses to influenza vaccination that varies strikingly with M-protein levels.

P5.21.27
Oligomeric nucleophosmin forms as a marker of tumor cells and proliferating lymphocytes

N. M. Vladimirova[1], *N. L. Deineko*[2], *T. I. Bulycheva*[2], *O. M. Volpina*[1];
[1]*Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry, Russian Academy of Sciences, Moscow, Russian Federation,* [2]*Hematology Research Center, Russian Ministry of Public Health, Moscow, Russian Federation.*

Nucleophosmin plays a critical role in cell proliferation and apoptosis. Malignization of cells leads to overexpression of nucleophosmin and appearance of its abnormal forms. It has been demonstrated that the unique B23 conformation in liver tumor cells likely results from an N-terminal truncation of nucleophosmin that forms SDS-resistant, GB-sensitive oligomers (Ulanet et al., PNAS 2003). We revealed unusual SDS-resistant oligomers of nucleophosmin in human tumor cells of different type (HeLa, Hep G2, K-562, Jurkat, Ramos, U-87, JMR-32). We created antipeptide antibodies which allowed to differentiate monomers and oligomers and to reveal different intracellular localization of them in tumor cells. Immunochemical analysis of nucleophosmin in human peripheral lymphocytes stimulated to proliferation by phytohemagglutinin allowed us to show that during 48-72h treatment (when majority of the cells undergo the S-phase) not only dramatically increasing in nucleophosmin content but also appearance of SDS-resistant oligomers with nucleolar localization occurred. Immunocytochemical analysis of nucleophosmin in

lymphocytes from healthy donors and patients with non-malignant and malignant diseases of the blood revealed a significant nucleolar staining with antibodies specific for nucleophosmin oligomers only in samples of patients with malignant diseases. Staining intensity was correlated with the proportion of proliferating cells (according to Ki-67 staining cells). Thus, SDS-resistant oligomers of nucleophosmin can be used as markers of proliferating activity of lymphocytes, and our antibodies can be used as instruments for their detection. This work was supported by the programm of Basic Sciences to Medicine Foundation (projects 2011-2013) and by the RFBR (grant 13-04-00654).

P5.21.28
High polyunsaturated fatty acids diet promote myelopoiesis through regulating matrix metalproteinases in bone marrow

***S. Xia**;*
Jiangsu University, Zhenjiang, China.

N-6 polyunsaturated fatty acids (n-6 PUFAs), which are rich in western high fat diet, promoted obesity and chronic inflammation associated diseases. In contrast, n-3 polyunsaturated fatty acids (n-3 PUFAs) exert beneficial anti-inflammatory effects and widely used in tumor prevention and inflammatory diseses treatment. However, the effects of these PUFAs metabolism on hematopoiesis remain largely unexplored. Here we feed mice with HFD or high n-3 PUFAs diet, and the results showed that both HFD and high n-3 PUFAs diet increased the frequency and total number of CD11b+Gr-1+ myeloid cells in spleen. Compared with HFD mice, high n-3 PUFAs induced more myeloid cells even in early stage. Meanwhile, in high n-3 PUFAs group, more Lin-CD117+Sca-1+ hematopoietic stem cells(HSC) and Lin-CD117+Sca-1- hematopoietic progenitors can be detected in spleen, but only more HSC not hematopoietic progenitors can be found in bone marrow. Mechanically, high n-3 PUFAs diet promoted myelopoiesis tightly associated with high expression of matrix metalproteinase 12(MMP-12) in bone marrow, a protein known to regulate hematopoietic nich. Taken together, our study provides a novel insight into the physiological effects of high PUFAs metabolism on hematopoiesis.

P5.21.29
Effect of garlic consumption on AgNORs (argyrophilic nucleolar organizer regions) pattern in splenocytes and thymocytes of rats

***A. Zamani**[1], M. Hoseinipanah[2], H. Madadi[1], M. Arjipour[1];*
[1]Dept. of Immunology, School of Medicine, Hamadan University of Medical Sciences,, Hamadan, Iran, [2]Dept. of Anatomy, School of Medicine, Hamadan University of Medical Sciences, Hamadan, Iran.

Nucleolar organizer regions (NORs) are chromosomal segments which contain ribosomal genes and a set of argyrophilic acidic proteins. The number and size of argyrophilic NORs (AgNORs) are often related directly to the cellular demands for ribosome biogenesis and cell proliferation. To test the hypothesis that lymphocytes proliferation associate with garlic consumption, seventeen 6-week-old male rats were randomly separated into two groups. Eight rats were given garlic solution in distilled water (600 mg $kg^{-1}4mL^{-1}$) by gavage and nine received distilled water for 30 days. Silver staining of NORs was performed on the fixed tissues of spleens and thymuses of the animals. The images of 100 analyzable nuclei of lymphocytes from each tissue were transferred by means of a digital camera from light microscope to a computer and nuclear area (NA), nuclear length (NL), total AgNORs area (TAA), total AgNORs length (TAL) and total AgNORs number (TAN) were analyzed by image analyzer software. In spite of a decline in the means of NA and NL in thymocytes of garlic treated rats ($p<0.001$), TAA and TAL were increased significantly ($p<0.001$) in splenocytes and thymocytes of this group. In conclusion, garlic enhanced the lymphocytes proliferation rate in spleen and thymus and this effect was stronger in thymocytes compared with splenocytes.

P5.22 Primary immunodeficiencies

P5.22.01
Identification of B-cell defects using age-defined reference ranges for in-vivo and in-vitro B-cell differentiation

***D. J. aan de Kerk**[1], M. H. Jansen[1], I. J. M. ten Berge[2], E. M. M. van Leeuwen[3], T. W. Kuijpers[1];*
[1]Emma Childrens Hospital, Academic Medical Center (AMC), Amsterdam, Netherlands, [2]Academic Medical Center (AMC), Department of Nephrology, Amsterdam, Netherlands, [3]Academic Medical Center (AMC), Department of Experimental Immunology, Amsterdam, Netherlands.

Background: Primary immunodeficiencies consist to a large extent of B-cell defects, as indicated by inadequate antibody levels or response upon immunization. Many B-cell defects have not yet been well characterized.
Objective: To create reliable in-vivo and in-vitro assays to routinely analyze human B-cell differentiation, proliferation, and immunoglobulin production and to define reference ranges for different age categories. The in-vitro assays were applied to classify the developmental and/or functional B-cell defects in patients previously diagnosed with common variable immunodeficiency (CVID).
Methods: Apart from standard immunophenotyping of circulating human B-cell subsets, an in-vitro CFSE dilution assay was used for the assessment of proliferative capacity comparing T-cell-dependent and T-cell-independent B-cell activation. Plasmablast/plasmacell differentiation was assessed by staining for CD20, CD38 and CD138, and measurement of in-vitro immunoglobulin secretion.
Results: At young age, B-cells proliferate upon in-vitro activation but neither differentiate nor produce IgG. These latter functions reached 'adult' levels at 5 and 10 years of age for T-cell-dependent versus T-cell-independent stimulations, respectively. The capacity of B-cells to differentiate into plasmablasts and to produce IgG appeared to be contained within the switched memory B-cell pool. Using these assays, we could categorize CVID patients into subgroups and identified a class-switch recombination defect caused by an UNG mutation in one of the patients.
Conclusion: We defined age-related reference ranges for human B-cell differentiation. Our findings indicate that in-vivo B-cell functionality can be tested in-vitro and help to diagnose suspected B-cell defects.

P5.22.02
Autoimmune lymphoproliferative syndrome in a patient with homozygous mutation associated to normal Fas expression

***N. Agrebi**[1], I. Ben Mustapha[1], M. Medhaffar[2], M. Ben Ali[1], B. Larguèche[1], R. Barbouche[1];*
[1]Department of Immunology, Institut Pasteur de Tunis, Tunisia, TUNIS, Tunisia, [2]Department of Hematology, CHU Hédi-Chaker, Sfax,Tunisia, Sfax, Tunisia.

Autoimmune lymphoproliferative syndrome (ALPS) is a primary defect in programmed cell death, characterized by tumoral syndrome, autoimmune manifestations and accumulation of double-negative T cells (DNT). The majority of patients have heterozygous germline mutations in the *FAS* gene associated to a normal Fas expression. Few descriptions of a complete lack of Fas protein expression caused by homozygous mutations in the *FAS* gene have been reported. Here we report a novel homozygous *FAS* gene mutation associated to normal Fas expression.
The patient was 22-year-old Tunisian female. She presented since the age of 7 days with splenomegaly. She developed later multiple adenopathy, anemia and thrombocytopenia. Flow cytometric immunophenotyping showed a high percentage of DNT cells (9%) and a normal expression of the Fas receptor. Very high levels of plasma IL10 (119 pg/ml) and sFasL (>5 ng/ml) were found. Molecular analysis of the *FAS* gene identified a homozygous cytidine to thymidine transition at exon 4 in the second cystein-rich–homology domain (c.C581T/p.R120W). This mutation is probably deleterious as predicted by Polyphen 2 software and was not found in 50 healthy control subjects ruling out the possibility of irrelevant polymorphisms. A previous study describes three affected siblings which carry the (c.C581T) mutation but in a heterozygous state, associated to another missense mutation on the second allele.

This mutation does not affect Fas protein expression but seems to be associated to severe clinical and immunological phenotype. Further molecular and immunological investigations are required in patient and her parents to assess a new autosomal recessive ALPS pattern.

P5.22.03
Evaluation of CD4+CD25+FOXP3+ regulatory T cells function in patients with common variable immunodeficiency

N. Arandi[1], *A. Mirshafiey*[1], *M. Jeddi-Tehrani*[2], *H. Abolhassani*[3], *B. Sadeghi*[3], *M. Shaghaghi*[3], *A. Aghamohammadi*[3];
[1]*Department of Immunology, School of Public Health, Tehran University of Medical Sciences, Tehran, Iran,* [2]*Monoclonal Antibody Research Center, Avicenna Research Institute, ACECR, Tehran, Iran,* [3]*Research Center for Immunodeficiencies, Pediatrics Center of Excellence, Children's Medical Center, Tehran University of Medical Sciences, Tehran, Iran.*

Common variable immunodeficiency (CVID) is one of the predominant antibody disorders where abnormalities in regulatory T cells (Tregs) may result in autoimmunity and chronic inflammation. To evaluate Tegs frequency and function, 13 CVID patients and 10 age- and sex-matched healthy volunteer were enrolled. The percentages of Tregs were calculated using flow cytomety method. For assessment of Treg function, Tregs were isolated and their suppressive functions were determined using Tregs suppression assay. The levels of immunoregulatory cytokines IL-10 and TGF-β produced by Tregs were also measured. Our results revealed that Tregs frequency ($P<0.001$) and the expression of FOXP3 protein based on its mean fluorescence intensity (MFI) ($P=0.02$) were significantly lower in CVID patients than that in controls. Also, the suppressive functions of Tregs were impaired in CVID patients ($P<0.001$). The level of TGF-β did not differ between CVID patients and controls ($p=0.09$); while the amount of IL-10 was remarkably decreased in CVID patients ($P = 0.007$). Our findings suggest that disturbed Tregs frequency and their functional characteristics might account for aberrant immune responses observed in CVID patients.

P5.22.04
AK2 deficiency in zebrafish recapitulates human reticular dysgenesis

A. Rissone, J. Jagadeesh, K. Bishop, T. Blake, R. Sood, ***F. Candotti****; NHGRI-NIH, Bethesda, MD, United States.*

The adenylate kinase (AK) gene family members are critical players in ensuring cellular energy homeostasis by converting ATP+AMP to 2ADP. The AK2 member is uniquely located in the mitochondrial intermembrane space and is mutated in reticular dysgenesis (RD), an autosomal recessive form of severe combined immunodeficiency characterized by early differentiation arrest in the granulocyte lineage and impaired lymphoid maturation. The mechanisms underlying the pathophysiology of RD remain unclear. No AK2 deficient animals have been reported in the literature, but we have found that murine lines carrying homozygous inactivating retroviral insertions are embryonically lethal. We used zebrafish to perform a comprehensive study of the effects of AK2 deficiency using morpholino oligomer (MO) injections and two different AK2 mutants (a ENU-induced T371C/L124P missense mutant and a null mutant generated using Zinc-finger nuclease technology). In-situ hybridization analyses of AK2-deficient embryos indicated that only erythroid development was affected during primitive hematopoiesis. Conversely, during definitive hematopoiesis, the loss of AK2 function resulted in abnormalities in all hematopoietic lineages suggesting an impairment of hematopoietic stem cell (HSC) development. Moreover, AK2 deficiency induced increased level of reactive oxygen species triggering oxidative stress and consequent apoptosis in primitive hematopoietic progenitor cells and definitive HSCs. Our data suggest a broader role of AK2 during hematopoiesis and provide new insights into the AK2 function. Moreover, they indicate that zebrafish represents a good model for studying the molecular mechanisms involved in RD. To date, our mutant lines represent the first example of animal models of this rare and unique human disease.

P5.22.05
Monoclonal T proliferation associated with a diffuse and invalidant *Sezary-like* skin-infiltration in a patient with Hyper-IgM syndrome

S. Di Maggio[1], *A. Parolo*[1], *M. Gazzola*[1], *N. Compagno*[1], *V. Ferri*[1], *R. Scarpa*[1], *F. Cinetto*[1], *M. Putti*[2], *M. Alaibac*[3], *C. Agostini*[1];
[1]*Department of Medicine, Clinical Immunology Branch, Padua University Hospital, Italy, Padova, Italy,* [2]*Department of Pediatry, Oncoematology Branch, Padua University Hospital, Italy, Padova, Italy,* [3]*Dermatology Unit, Padua University Hospital, Italy, Padova, Italy.*

Hyper-IgM syndromes are a group of primary immunodeficiency disorders characterized by a defective Ig class switch recombination. Signalling through CD40 is the most commonly affected, thus leading to a combined immunodeficiency. Clinical phenotype is dominated by recurrent sinopulmonary and opportunistic infections. An increased risk of malignancies is also observed, including liver and biliary-tract carcinoma and peripheral neuroectodermal tumors. Lymphoproliferative diseases have been rarely described.
We report a case of a 28-years-old man with an X-linked Hyper-IgM syndrome diagnosed at the age of 3, after a meningeal criptococcal infection which led to a complete blindness. Since then, the patient has been totally asymptomatic under Ig replacement therapy. During the latter years the patient developed psoriasiform lesions on the trunk and upper limbs, treated with topical steroids, UVB and Toctino®. In December 2012, the patient experienced heavy worsening of cutaneous lesions, in terms of extension and symptoms. A skin biopsy showed an "atopic-like dermatitis". Blood flow cytometric immunophenotyping showed a population of $CD4^+/CD3^+/CD25^+/CD7^{dim}$ immature T-cells, resulting negative for CD5, CD8, CD10, CD27, TCR^- and class-II MHC. T-cell clonality was confirmed by molecular biology analysis. PET-CT scan showed a moderately increased FDG-uptake in subcutaneous tissues and inguinal lymph nodes. The first chemotherapy administration (according to VACOP-B regimen) was ineffective and complicated by severe and febrile neutropenia. A second-line attempt with cyclosporine was complicated by renal failure and sepsis, which led the patient to death.
The case herein described represents the first report of a peripheral T-cell lymphoma in this rare B-cell immunodeficiency.

P5.22.06
Investigation of ITGB2 gene in 9 Iranian patients with LAD-1 with two new mutations

B. Esmaeili[1], *M. Ghadami*[2], *M. Fazlollahi*[1], *M. Badalzadeh*[1], *Z. Alizadeh*[1], *L. Atarod*[3], *Z. Chavoshzadeh*[4], *S. Niroomanesh*[5], *Z. Moradi*[1], *Z. Pourpak*[1];
[1]*Immunology,Asthma and Allergy Research Institute, Tehran, Iran,* [2]*Endocrinology and Metabolism Research Center, Tehran, Iran,* [3]*Department of Pediatric, Imam Khomeini Hospital, Tehran, Iran,* [4]*Pediatric Infection Research Center, Mofid Hospital, Tehran, Iran,* [5]*Department of Prenatalogy, Zanan Hospital, Tehran, Iran.*

Objective: The ITGB2 gene codes for the CD18 antigen (integrin β2 subunit). Any defect in this gene leads to Leukocyte Adhesion Deficiency type-1, an autosomal recessive immunodeficiency disorders. These patients have defects in adherence and migration of leukocytes, in particular of neutrophils, through the intravascular space. In this study, we have evaluated molecular diagnosis of 9 Iranian patients with diagnosis of LAD-1.
Methods: All patients with definite diagnosis of LAD-1 (based on clinical finding, screening tests for primary immunodeficiency diagnosis and flowcytometric analysis) who referred to the Immunology, Asthma and Allergy Research Institute (IAARI) from September 2006 to April 2011 entered this study. After informed consent, the ITGB2 gene was investigated on genomic DNA by PCR and direct sequencing for patients and their parents.
Results: All of the nine patients had significant decreases in expression of CD18 on neutrophils with WBC counts more than 16000 cells/µl. Mutation analysis of ITGB2 gene in nine patients revealed nine different homozygote mutations, including six missense mutations (c.382G>A, c.2146G>C, c.715G>A, c.1777C>T, c,691G>C and novel c.1336G>T), Two frameshift (c.1907delA and novel c. 474dupC) and a splice site mutation (c.1877+2G>A). All of parents were heterozygous for these mutations.

Conclusion: Our findings show two new mutations in the ITGB2 gene. Up to now, over than 60 mutations have been reported for the ITGB2 gene. This report can be used for decisive genetic diagnosis, genetic counseling and also prenatal diagnosis for all patients who are suspected to have LAD-1.

P5.22.07
Adenosine deaminase deficient severe combined immunodeficiency: evidence from three case reports

F. Genel[1]*, E. Özbek*[1]*, S. Keskin Gözmen*[1]*, N. Gülez*[1]*, O. Tascı*[1]*, M. Hershfield*[2]*;*
[1]Dr.Behcet Uz Children's Hospital, Izmir, Turkey, [2]Duke University Medical Center, Durham, NC, United States.

Adenosine deaminase (ADA) deficiency is a complex metabolic and immunological disorder, characterized by a severe immunodeficiency due to the accumulation of purine metabolites. Here we report three cases of severe combined immunodeficiency due to ADA deficiency.
Three children 8 days, 50 days and 5,5 months old admitted to our hospital with pulmonary infection. They had severe lymphopenia and decreased IgG, IgM, IgA levels with reduced CD3, CD4, CD8, CD19 and CD16+56 positive lymphocytes. Metabolic findings and mutation analyses were consistent with ADA deficiency.
A matched bone marrow transplant donor could not be found and ADA replacement therapy was initiated for the first and third patients. B lymphocyte and natural killer cell counts reached to normal values in the second week of PEG-ADA therapy in both patients. In follow up the third patient died from pulmonary insufficiency at two month of ADA enzyme replacement treatment. At three years of age, diffuse large B cell lymphoma developed in the first patient and on the twentieth day of treatment the patient died from septic shock and intracranial hemorrhage. The second patient underwent bone marrow transplantation from an HLA identical healthy sister.
Within this report we want to emphasize the importance of screening for adenosine deaminase deficient severe combined immunodeficiency in children with lymphopenia.

P5.22.08
Plasmablasts in peripheral blood after antigen challenge serve as a diagnostic marker for assessing response to vaccination in CVID patients

E. Grywalska*, J. Rolinski, A. Surdacka, A. Grafka;*
Medical University of Lublin, Lublin, Poland.

Common variable immunodeficiency (CVID) is characterized by hypogammaglobulinaemia and impaired antibody production. Poor vaccination response is essential for the diagnosis of CVID. Determination of antibody production in serum from CVID patients after vaccination and investigation of B cell function in vivo is complicated due to substitution therapy. Therefore we investigated changes in B-cell subpopulations in CVID patients, including plasmablasts, in peripheral blood by flow cytometry after vaccination. Twenty CVID patients and fifteen healthy volunteers were immunized with 23-valent pneumococcal polysaccharide vaccine (PPSV23). Specific antibody levels and B cell subpopulations were measured before vaccination and on day 30 by ELISA assay, and day 7 by flow cytometry after vaccination, respectively.
100% CVID patients lacked detectable changes in the serum level of anti-pneumococcal IgG antibodies against PPSV23 (mean: 122.41±41.94 mU/ml vs. mean: 128.37±52.13 mU/ml, respectively; p=0.24). In none of patients an increase of plasmablasts was noted. In the control group, an increase in circulating plasmablasts on day 7 post immunization corresponded with the appearance of specific antibody levels on day 30 post immunization (r=0.823, p=0.000001) and was statistically significantly higher than before a dose of PPSV23 (before vaccination: 20.12±14.93%, 0.46±0.36x10^3/mm^3; after vaccination: 46.81±26.87%, 1.15±0.77x10^3/mm^3; p=0.01). In contrast, CVID patients failed to increase plasmablasts in peripheral blood after antigen challenge.
Our findings indicate that CVID patients have a block in terminal B-cell differentiation and that flow based assessment of plasmablasts in peripheral blood after vaccination serves as a surrogate diagnostic marker for assessing in vivo antibody responses in patients suspected to have CVID.

P5.22.09
Clinical features and immunological immunophenotyping in Hyper IgE syndrome patients

L. Guadrini[1]*, M. Giacomelli*[1,2]*, D. Moratto*[1]*, S. Negri*[1]*, A. Prandini*[1,2]*, R. Kumar*[1,2]*, O. Scomodon*[1,2]*, A. Plebani*[1]*, R. Badolato*[1]*;*
[1]Institute of Molecular Medicine "A. Nocivelli", University of Brescia, Brescia, Italy, [2]Scuola di Dottorato in Scienze della Riproduzione e dello Sviluppo, University of Trieste, Trieste, Italy.

Hyper-IgE syndrome (HIES) is a primary immunodeficiency caused, mostly, by autosomal dominant STAT3 mutations; in contrast, DOCK8 mutation is responsible for the less common autosomal recessive form. Both conditions are characterized by eczematoid rash, high serum-IgE levels, recurrent respiratory infections and candidiasis. The dominant form shows prevalence of cold abscesses, recurrent pulmonary pyogenic infections and skeletal malformations, while in the recessive form prevail skin viral infections, neurologic symptoms and T-cell lymphopenia.
We studied the T cell phenotype in 13 HIES patients, including 6 affected with the dominant disease and 7 with the DOCK8-deficient form.
Because Th17 is a subset of CD4+ CD45RO+ T-cells, with CCR6+ and CCR4+ receptor chemokine expression which is essential for immune response to mycotic infections, we evaluated chemokine receptors expression in T cells and generation of Th17 in these patients.
We found that Th17 cells were absent or extremely low in both forms. Analysis of CD4+ subset showed that CCR4 expression, a marker associated with Th2 commitment, was higher in HIES patients with DOCK8 mutations than STAT3-mutated patients. Moreover, a low number of CD4+ memory cells expressing CCR6+ were observed in both groups of Hyper-IgE forms. A further distinctive feature observed in DOCK8 form was a higher incidence of allergies to cow's milk protein airborne allergens. Finally, in STAT3-deficient form a lower IL-10 production in CD4 stimulated cells culture was detected.
Taken together, our results suggest that the detailed analysis of CCR6 and CCR4 expression on T-cells can help to characterize the two forms of HIES.

P5.22.10
Long survival of a patient with IPEX syndrome (Immunodysregulation, Polyendocrinopathy, Enteropathy, X-linked)

C. Felice[1]*, A. Papa*[1]*, R. Bacchetta*[2]*, A. Armuzzi*[1]*, M. Marzo*[1]*, G. Andrisani*[1]*, D. Pugliese*[1]*, I. De Vitis*[1]*, G. Rapaccini*[1]*,* ***L. Guidi***[1]*;*
[1]Università Cattolica del Sacro Cuore, Roma, Italy, [2]Ospedale San Raffaele, Milano, Italy.

We report the case of a 30-year-old man with a history of intractable diarrhea associated to atopic eczema since he was 5-month-old; a diagnosis of autoimmune enteritis associated to autoimmune thrombocytopenia and arthritis was later made. After several years of artificial nutrition and systemic steroids, a partial clinical remission was obtained and maintained with oral cyclosporine. He was admitted to our Hospital in January 2010 presenting a relapse of intestinal symptoms, severe weight loss (BMI 17.9) and renal failure. Laboratory tests showed malabsorption signs and altered inflammation indexes. Cyclosporine was discontinued and intravenous steroid therapy was started associated with enteral nutrition, with partial benefit. No macroscopic lesions were found at endoscopic examination, whereas severe acute and chronic inflammation was documented at histological analysis. Considering all clinical and laboratory findings, an IPEX syndrome was hypothesized. Serological tests confirmed the positivity of antienterocyte IgG antibodies by indirect immunofluorescence on primate jejunum. Peripheral level of CD4+CD25+FOXP3+ T cells was 1.5% (normal value 3%). At genetic analysis the patient resulted hemizygote for c.816+2delT, a new splicing mutation on FOXP3 gene, confirming the diagnosis of IPEX syndrome. Immunosuppressive therapy with sirolimus (0.03 mg/kg/die) was started, with clinical benefit. After 3

months of treatment, the patient developed a persistent not nephrotic proteinuria, that resolved after replacing sirolimus with tacrolimus (0.1 mg/kg bid). During last 3 years of follow-up, the patient was in clinical remission continuing treatment with tacrolimus, without other complications. This represents the most long-lived case of IPEX syndrome reported so far.

P5.22.11
Clinical features and immunological abnormalities of GATA2 deficiency in Japan

K. Honma[1], *K. Imai*[2], *T. Kato*[1], *C. Kamae*[1], *S. Nonoyama*[1];
[1]*Department of Pediatrics, National Defense Medical College, Tokorozawa, Japan,* [2]*Department of Pediatrics, Tokyo Medical and Dental University, Tokyo, Japan.*

Introduction: GATA2 is a transcription factor involved in the differentiation of hematopoietic precursor cells. Heterozygous GATA2 mutation has been recently reported to cause MonoMAC syndrome, DCML deficiency, and Emberger syndrome in human. GATA2 mutation is also reported to cause familial MDS/AML.
Objective: The purpose of this study is to identify GATA2 mutations in Japan and to clarify their clinical features and immunological abnormalities.
Methods: We search the dendritic deficiency in PIDJ (Primary Immunodeficiency Database in Japan) registered patients.
Results: We identified five different GATA2 mutations in six patients. These mutations include one missense mutation, two nonsense mutations and three frameshift mutations. All mutations affect the zinc finger domain of GATA2. Four Patients with GATA2 mutations manifested MonoMAC syndrome. Three of them suffered from severe or persistent VZV infections. Two patients had severe salmonella enteritis. One patient infected by Mycobacterium kansasii at 27 years old and Mycobacterium intracellulare at 31 years old. One patient manifested Emberger syndrome with lymphedema. Two of six patients (father and son) progressed into familial MDS though they lack DC, B, NK cells.
Conclusions: Clinical manifestations are variable in GATA2 deficiency though the lack of DC, B, NK cells are common features. Analysis to explain this variability is understudy.

P5.22.12
GATA 2 transcription factor deficiency predisposing to severe disseminated Coccidioidomycosis

T. F. Imran*, C. Chongwei;*
University of Medicine & Dentistry of New Jersey, Newark, NJ, United States.

Severe disseminated coccidioidomycosis is rare, while localized disease is more commonly seen. We report the case of a 28-year-old man with severe disseminated coccidioidomycosis who was found to have an underlying GATA 2 (3q21.3) transcription factor deficiency. This case illustrates that when a patient presents with invasive fungal disease without clear predisposing factors, the clinician should consider underlying immunodeficiencies so that proper treatment may be initiated to control spread of the disease to other organs and prevent further complications. Interferon-gamma plays a vital role in anti-fungal immunity, and is involved in both innate and active immune responses (1). GATA2, a transcription factor active in myeloid development, has been shown to be crucial in anti-mycobacterial and anti-fungal immunity. Its deficiency has been reported to be associated with a rare immunodeficiency-MonoMAC syndrome (2). Since there are only a handful of cases, no standard guideline is available for the treatment of patients with GATA2 deficiency and disseminated fungal disease. The patient in this report was successfully treated with multiple anti-fungal medications and Interferon-gamma injections. Hematopoietic cell transplantation may serve as a last resort in the management of such patients (3). This report is intended to increase clinician awareness of the possibility of underlying immunodeficiency syndromes in patients who present with disseminated fungal disease with an unclear etiology and may provide insight in diagnosing and further managing patients with similar presentations.

P5.22.13
Common variable immunodeficiency classification by quantifying T-cell receptor and immunoglobulin κ-deleting recombination excision circles

C. Kamae[1], *N. Nakagawa*[1], *H. Sato*[2], *K. Honma*[1], *N. Mitsuiki*[3,4], *O. Ohara*[3], *H. Kanegane*[5], *T. Morio*[4], *K. Imai*[6], *S. Nonoyama*[1];
[1]*Department of Pediatrics, National Defense Medical College, Tokorozawa, Japan,* [2]*Department of Preventive Medicine and Public Health, National Defense Medical College, Tokorozawa, Japan,* [3]*Department of Human Genome Research, Kazusa DNA Research Institute, Kisarazu, Japan,* [4]*Department of Pediatrics, Tokyo Medical and Dental University, Tokyo, Japan,* [5]*Department of Pediatrics, University of Toyama, Toyama, Japan,* [6]*Department of Medical Informatics, National Defense Medical College Hospital, Tokorozawa, Japan.*

Introduction: Common variable immunodeficiency (CVID) is the most frequent primary immunodeficiency associated with hypogammaglobulinemia and other various clinical manifestations. Moreover combined immunodeficiency (CID) involving both defective B and T cells is often misdiagnosed as CVID originally reported as defective B cells.
Objective: The aim is to identify novel markers to better classify CVID and distinguish CID from CVID.
Methods: We recently performed real-time PCR based quantification of T-cell receptor excision circles (TREC) and signal joint immunoglobulin κ-deleting recombination excision circles (KREC) for mass screening of severe combined immunodeficiency (SCID) and B-lymphocyte deficiency in neonates. Forty CVID patients referred to our hospital were analyzed. TREC and KREC quantification was performed using DNA extracted from peripheral blood.
Results: Based on TREC and KREC copy numbers, the 40 patients with CVID were classified into 4 groups (A, B, C, D). The cumulative events of complications (opportunistic infections, autoimmune diseases and malignancies) per 10 patient-years were highest in group D (0.98 events/10 patient-years), followed by group C (0.63), group B (0.30), and group A (0.04) (group A vs group D: $P = 0.0022$; C: $P = 0.0092$; B: $P = 0.0692$).
Conclusion: TREC and KREC are good markers to assess the clinical severity and pathogenesis of each patient with CVID and to distinguish CID from CVID. Thus TREC/KREC levels would provide a helpful tool for deciding on an effective treatment plan for each patient with CVID.

P5.22.14
Candida antibiotic resistance in Primary Immunodeficiency Disease

S. Kamali Sabzevari[1], *Z. Pourpak*[1], *S. Roodbar Mohammadi*[2], *N. Fakhr Mousavi*[2];
[1]*Immunology,Asthma and Allergy research Institute, Tehran, Iran,* [2]*Department of Mycology,Medical science of Tarbiat Modaress University, Tehran, Iran.*

Infections due to *Candida* spp. are common, especially in patients with primary Immunodeficiency diseases (PID) .The aim of this study was to evaluate susceptibility of candida spp. Isolates from PID patients who referred to Immunology,Asthma and Allergy Research Institute to 4 known antifungal antibiotics (Amphotricin B,Fluconazole,Voriconazole and Itraconazole).
During 2011-2012 from twenty PID patients who had lesion on their body took samples and cultured. Amphotricin B,Fluconazole,Voriconazole and Itraconazole were tested in this assay. Broth microdilution tests were performed according to the CLSI (Clinical and Laboratory Standards Institute).Each well was inoculated with 1 ml of RPMI-1640 Medium, 1 ml of antifungal agent with 10 serial dilution of each antifungal antibiotics and a fungal suspention contains 10^3 Cell/ml. Positive control well contained fungal suspention, RPMI-1640 Medium and negative control well contained RPMI-1640 Medium and distilled water.
During this study, twenty patients with PID were interred the study who had skin lesion with positive culture.Among these PID patients, 9 male and 11female with meadian age of 7years. Seven positive candida were observed in specific culture that they confirmed with Germ tube test and PCR. An antifungal susceptibility test were done with four antibiotics. Candida spp were susceptible to Amphotricin B; but resistant to the Fluconazole,Voriconazole and Itraconazole

respectively. Consideration of PID patients showed that patients who referred with recurrent infection resulted in hospitalized , may be resistance to antibiotic because of excessive prescription of antifungal antibiotics ,so prevalence of antibiotic resistance significantly increased in PID Patients.
Key word : candida ,antibiotic resistance, PID

P5.22.15
Subgroup of Common Variable Immunodeficiency patients with distinct clinical and biological features revealed by B-cell immunophenotyping

V. Kanderova[1], *E. Fronkova*[1], *J. Stuchly*[1], *M. Vlkova*[2], *I. Hermanova*[1], *L. Krol*[1], *O. Hrusak*[1], *A. Sediva*[3], *J. Litzman*[2], *T. Kalina*[1];
[1]*Charles University, 2nd Faculty od Medicine, Dpt. Pediatric Hematology/Oncology, CLIP-Cytometry, Prague, Czech Republic,* [2]*Department of Clinical Immunology and Allergology, St Anne's University Hospital and Faculty of Medicine, Masaryk University, Brno, Czech Republic,* [3]*Charles University, 2nd Faculty od Medicine, Dpt. of Immunology, Prague, Czech Republic.*

Common Variable Immunodeficiency (CVID) is characterized by low levels of IgG, IgA, and/or IgM, impaired specific antibody response after antigen challenge and the resulting bacterial infections. Investigation of peripheral blood cellular compartments revealed abnormalities in B- and T-cells. Due to high number of analysed parameters it is difficult to define CVID subgroups that possibly share the same ethiopathological mechanisms.
We have compared distribution of cells within all possible immunophenotypes with 8 color flow cytometry and probability binning to reduce CVID heterogeneity. Ninety-eight patients and 47 healthy donors have created hierarchical tree according to B-cell phenotype similarities. The cohort has split into 11 phenotype clusters. B-cell cluster no.5 has been distinguished by aberrant phenotype of T-cells. Cluster 5 CD4+ T-cells have been reduced and presented with decreased proportion of naive cells and increased proportion of intermediate effector memory cells (CD27-CD28+). Increased expression of CD57, PD-1, CD69 and CD70 has suggested a chronic activation but activating cytokine levels have not been elevated.
Moreover cluster 5 patients suffer from autoimmunity and splenomegaly. Similar clinical presentation and phenotypic profile have supported the idea that similar pathological mechanism might be responsible for this phenotypically defined subgroup of patients. Whole-exome sequencing has yielded 23 possibly damaging gene alterations (e.g. single-nucleotide polymorphisms) presented in three cluster 5 patients, but not in control samples that are currently being investigated.
B-cell profiling of large group of CVID patients revealed subcluster with distinct T-cell profile, clinical presentation and shared germline genetic variations.

Hax-1 deficiency in Turkish children

S. Kilic[1], *O. Gozukmez*[1], *D. Hafizoglu*[1], *C. Y. Aydogmus*[2], *F. Cipe*[3], *T. Yakut*[1];
[1]*Uludag University Medical Faculty, Bursa, Turkey,* [2]*Kanuni Sultan Süleyman Eğitim Ve Araştırma Hastanesi, İstanbul, Turkey,* [3]*Kanuni Sultan Süleyman Eğitim Ve Araştırma Hastanesi, istanbul, Turkey.*

Severe congenital neutropenia (SCN) is characterized by absolute neutrophil count below 0.5 x 10/l. SCN is caused by mutations in the ELA2 and *HAX1* genes.
Purpose: The proposed study aims to analyse neutrophil elastase (ELA2) gene and HAX-1 gene mutations in 11 sporadic cases and four familial cases of SCN and their family members.
Methods: Genomic DNA will be extracted from the patients' and family members' peripheral blood and the coding sequence of the ELA2 gene and HAX1 gene will be amplified by polymerase chain reaction and subjected to direct sequencing. Imaging tests for CNS will be done, if the patient has neurological problem.
Results :W44X mutation in Exon 2 of HAX1 gene was determined in 9 of 15 patients with congenital neutropenia that are in the same family. This mutation was also determined at the same region in five of sporadic cases. We found heterozygous mutations at W44X, 10 of 49 index family members, and an homozygous mutation one of them. ELA 2 mutations were not detected in any of the patients examined. Mild Mental Retardation (MMR) was observed in 5 of the patients with HAX1 mutation. The results of cranial MRI were normal in 9 of the patients with HAX1 mutation. Neurological examinations of HAX1 carriers and of patients without HAX 1 mutation were normal.
Conclusion : At variance with European publications, we suggest that HAX 1 mutations are widespread in our country and may be related to MMR.

P5.22.17
Investigation on frequency of mutation in the gene segments of immunoglobulin in CD40 knockout mice

Y. Kodera, *M. Matsushima, H. Ogiso, N. Ogasawara, K. Takemura, H. Nose, T. Yamaguchi, M. Shiga, T. Kawabe;*
Department of Pathophysiological Laboratory Sciences, Nagoya University Graduate School of Medicine, Nagoya, Japan.

Activation-induced cytidine deaminase (AID) is essential for class-switch recombination (CSR) and somatic hypermutation (SHM). AID is selectively expressed in germinal center B cells and its activation is dependent upon CD40 engagement. AID KO mice show defective CSR as well as SHM. Although deficiency of CD40 caused a complete loss in CSR and showed a hyper IgM phenotype as in AID KO mice, the role of CD40 on SHM is still unclear. In the present study, we investigated whether CD40 regulate SHM using CD40 KO mice. WT and CD40 KO mice were immunized with nitrophenylated chicken gammaglobulin (NP-CGG) absorbed to Freund's complete adjuvant (FCA) or alum. In the absence of CD40 gene, SHM was not affected in both spectra and frequency in V_H gene of IgM although the expression of AID was markedly reduced in CD40 KO mice. Based on these results, we are engaged in the investigation of AID-dependent and independent pathway in CD40-mediated SHM in B cells.

P5.22.18
Frequency of lymphomas in a cohort of Common Variable Immunodeficiency (CVID) patients

B. C. Sini, ***C. M. Kokron****, D. Levy, J. Pereira, A. K. B. B. Marinho, A. Cohon, J. Kalil, S. Bydlowski, M. T. Barros;*
University of São Paulo, São Paulo, Brazil.

Our objective was to evaluate the frequency of lymphomas in a cohort of CVID followed at the PID Clinic. Methods: Analysis of data obtained from medical records. Results: We analyzed 144 CVID patients followed between 1985 and 2012, being 80 men, aged 15-72 years at diagnosis. Seven lymphoma cases were diagnosed (0.5% - 5 men, 2 women) being 1 Hodgkin lymphoma, 6 non-Hodgkin lymphomas. Age of onset of CVID symptoms ranged from 2 - 53y, age at CVID diagnosis from 5 - 55y, age of lymphoma diagnosis from 19 - 53y. The time period between CVID onset of symptoms and lymphoma diagnosis ranged from 7 to 24 years in 4 patients and in 3 the diagnosis of CVID and lymphoma nearly overlapped, preceding CVID diagnosis in only 1 to 6 months. Lymphoma´s manifestations like fever of unknown origin, weight loss, splenomegaly and lymphadenopathy occurred in 100% of patients. Other manifestations observed: renal infiltration (2), hepatic infiltration (4), pulmonary infiltrates (3) and mediastinal mass (1). Three deaths due to lymphoma occurred during the study. Two patients presented lymphocytosis with inversion of CD4/CD8 ratio and one lymphopenia. Increased NK cells were observed in 3. Three patients in whom diagnosis of lymphoma and CVID were simultaneous presented undetectable B lymphocytes while in one, B cells were present at CVID diagnosis but undetectable at lymphoma diagnosis. Conclusions: Patients with absence of B cells in recently diagnosed CVID or vanishing B cells in long term follow-up CVID demands a screening for the presence of lymphomas.

P5.22.19
Genetic analysis of the TNFRSF13B gene in a numerous Italian CVID population

V. Lougaris[1], *M. Vitali*[1], *M. Baronio*[1], *G. Tampella*[1], *A. Bergbreiter*[2], *U. Salzer*[2], *A. Soresina*[1], *R. Badolato*[1], *A. Plebani*[1];
[1]*Pediatrics Clinic and Lab. for Molecular Medicine "A.Nocivelli",University of Brescia, Brescia, Italy,* [2]*Centre of Chronic Immunodeficiency (CCI), University Medical Center Freiburg and University of Freiburg, Germany, Freiburg, Germany.*

Introduction: Common variable immunodeficiency (CVID) is characterized by hypogammaglobulinemia, recurrent bacterial infections and defective antibody response. Mutations in ICOS, TACI, CD19, CD20, CD21, CD81 and BAFF-R have been associated with CVID; mutations (homozygous, heterozygous and compound heterozygous) in the gene coding for TACI (TNFRSF13B), are found in 8-10% of CVID cases.
Objective. Analyze TNFRSF13B in Italian CVID patients in order to determine the frequency of TACI mutations and compare the results to the ones reported in literature.
Methods. 115 Italian CVID patients were included in this study. Diagnosis of CVID was made according to ESID criteria. Informed consent was obtained. TNFRSF13B coding regions were amplified through PCR and direct sequencing was performed using an ABI130 sequencer.
Results. The genetic screening evidenced the presence of 14 known variants, 3 synonymous and 11 determining amminoacidic change. **T**he frequencies of A181E and S277S mutations in our cohort are statistically increased when compared to the general population, while C104R and I87N incidences were more frequent, also compared to CVID population. Rare mutations **(**Y164X , L171R and C172Y) normally not found in the general population, were present in our patients although with low frequencies. Regarding compound heterozygous mutations we identified some already documented ones (C104R/C104Y, c204insA/C104R) and two novel ones (C104R/L171R; I87N/C104R).
Conclusions. Our genetic analysis of TNFRSF13B gene reports new compound heterozygous mutations in a large Italian CVID population. The other mutations reported in literature are well represented even if, in some cases, with differences in incidence.

P5.22.20
Hypomorphic mutation in RAG2 gene affects dendritic cell distribution and migration

V. Maina[1], *V. Marrella*[2,3], *S. Mantero*[2,3], *B. Cassani*[3], *E. Fontana*[4], *A. Anselmo*[3], *A. Del Prete*[4,3], *S. Sozzani*[4,3], *L. Poliani*[4], *A. Villa*[1];
[1]*Telethon Institute for Gene Therapy, Hospital San Raffaele, Milan, Italy,* [2]*Milan Unit, Istituto di Ricerca Genetica e Biomedica, Consiglio Nazionale delle Ricerche, Milan, Italy,* [3]*Humanitas Clinical and Research Center, Rozzano, Milan, Italy,* [4]*Department of Molecular and Translational Medicine, University of Brescia, Brescia, Italy.*

Omenn Syndrome (OS) is a severe combined immunodeficiency characterized by erythrodermia and protracted diarrhea due to infiltration of oligoclonal activated T cells, caused by hypomorphic mutations in recombination activating genes (RAGs). $RAG2^{R229Q}$ mouse model fully recapitulates the clinical OS phenotype. We evaluated whether T and B cell defects, together with the abnormal lymphoid structure, could affect dendritic cells (DCs) homeostasis and function. High density of Langerhans cells (LC) was observed in skin biopsies of Omenn patients and in the derma of $RAG2^{R229Q}$ mice, correlating with the presence of erythrodermia. *In vivo* models of cutaneous skin painting and contact hypersensitivity (CHS) demonstrated a decreased migration of $RAG2^{R229Q}$ DCs, in particular LCs, into draining lymph nodes. Interestingly, $RAG2^{R229Q}$ mice showed a reduction in DCs number in all hematopoietic organs, except lymph nodes. Analysis of MHCII marker revealed a diminished expression at steady state and upon LPS driven inflammatory condition. Despite the decreased number of peripheral DCs, conventional DCs bone marrow precursors (pre-cDCs) were present in normal number as compared with $RAG2^{+/+}$ controls, whereas plasmacytoid DCs (pDCs) and monocytes were significantly reduced. Overall, these results point to a secondary defect in DC compartment, which contributes to clinical manifestations and autoimmunity in OS.

P5.22.21
8 patients of ataxia-telangiectasia in Azerbaijan

V. R. Mammadova;
Azerbaijan Medical University,Immunology department, Baku, Azerbaijan.

Introduction: Ataxia-telangiectasia is pathology of the immune system that occurs as a result of a genetic defect. This disease is autosomal recessive and a large mutant AT (ATM) gene was identified on chromosome 11q22-q23. In these patients the nervous, immune and other systems are damaged and the risk of cancer is high.
Objective: In 2009-2012 8 children with frequent infectious diseases, developed ataxia and dementia, telangiectasia in the eyes were analyzed by immunological parameters.
Methods: We used flow cytometer for leucocyte subset identification in peripheral blood and ELISA for measuring serum IgM, IgG, IgA, IgE levels. Phagocytic activity of neutrophils was performed by NBT. Circulated Immune Complex was examined by photometric method.
Results: It was found that in patients aged 7-16 years the number of CD3+, CD4+, CD8+, CD19+ cells and CD4/CD8 ratio were seriously low than normal, the quantity of CD16/56 + was many times higher. Results of NBT test were low. Especially it should be noted, that only 16 years old patient has normal CD3+, CD4+, CD19+ and CD16|56+, but increase of CD8+ cells. In all patients were determined very low levels of IgA, IgG, IgE, the level of IgM in many patients was much higher than norm. Four of patients had genetic analyses and ATM mutations gene was detected. 6 of patients were died. in ages 5-12 from bacterial complications or cancer.
Conclusion: In the country with many congenerous marriage the frequency of genetic pathology is high. Timely prenatal diagnose and adequate therapy are very important.

P5.22.22
Good's syndrome: First case report in Algeria

N. Messaoudani[1], *R. Djidjik*[1], *L. Baough*[2], *A. Nekhla*[3], *F. Benserai*[4], *M. Boubrit*[5], *F. Asselah*[4], *N. Zidouni*[2], *M. Ghaffor*[1];
[1]*Immunology department, Beni Messous Teaching Hospital, Algiers, Algeria,* [2]*Matiben Pneumology department Beni-Messous Teaching Hospital, Algiers, Algeria,* [3]*Thoracic surgery department, Mustapha Pacha Teaching Hospital, Algiers, Algeria,* [4]*Pathology department, Mustapha Pacha Teaching Hospital, Algiers, Algeria,* [5]*Radiology department, Mustapha Pacha Teaching Hospital, Algiers, Algeria.*

Good's syndrome is a rare adult- onset cause of combined T and B immunodeficiency. Clinically, it is revealed either by a thymoma, or by a recurrent respiratory infection. Patients with Good's syndrome show a high susceptibility to common and opportunistic infections, particularly, respiratory ones which may be life-threatening. We report the case of a 61 years old man, referred to us for the investigation of a mediastinal bulge demonstrated earlier by a chest X- ray. The patient has been healthy until the age of 45, when he developed a pneumococcal chronic otitis. Three years ago, he started to experience recurrent bronchitis. At presentation, the patient had fever, chronic bilateral otitis complicated by a facial palsy, thrush with cutaneous mycosis. High-resolution CT scan showed a rounded mass, bilateral bronchiectasis infected by Pseudomonas aeruginosa and vertebral bodies hemangiomas. Culture of pleural fluid yielded Klebsiella pneumoniae. Serology for HIV was negative; CMV serology came back positive for IgG. Immunological tests revealed a severe hypommaglobulinemia, absence of B cells and T CD4+ lymphopenia. The patient was put under antibiotics according to the antibiogram results. A cyclic IVIG replacement therapy was initiated. After the otitis and bronchitis symptoms improved, the patient was admitted for surgical removal of the thymoma which was labeled type AB upon histological examination, according to the WHO classification. The immunodeficiency found in our patient persisted after the resection of the tumor.
Thymoma association with hypogammaglobulinemia in this patient allowed the diagnosis of Good's syndrome, first case ever described in Algeria.

P5.22.23
Influence of genetic alterations in the WASP gene on the maturation of the B cell compartment

*D. Moratto, **G. Lanzi**, L. Gazzurelli, C. Mazza, L. D. Notarangelo, S. Giliani;*
"A.Nocivelli" Institute of Molecula Medicine, Brescia, Italy.

The Wiskott-Aldrich syndrome protein (WASp) is a multifunctional domain protein expressed in all hematopoietic cell lineages. Mutations in WASp coding sequence are causative of a variety of X-linked disorders, among which Wiskott-Aldrich syndrome (WAS) and X-linked thrombocytopenia (XLT) are the most frequent. Both these diseases are characterized by microthrombocytopenia, eczema and immunological defects, affecting also humoral immunity.
Our analysis on 40 XLT/WAS patients showed a general impairment in forming a normal "IgM"-memory compartment, while generation of an adequate number of switched cells correlate with the severity of WASp mutations. Moreover, the flow cytometric measure of WASp expression allowed us to confirmed the presence of this impairment in two different in vivo systems in which wt and mutated cells coexist. In fact, we observed a progressive increase of the ratio between WASp+ and WASp- cells during B cell differentiation both in female carriers of WASP mutations and in WAS patients who display a mixed chimerism in the B cell compartment after hematopoietic cell transplantation.
Despite the inability to form an adequate memory B-cell compartment, we could demonstrate that the percentage of effector B cells (plasmablasts/plasmacells) in our cohort of WAS/XLT patients is in the normal range when not increased. The hypothesis of a normal capacity to generate immunoglobulin secreting cells is supported also by the in vitro generation of an adequate amount of WASp-plasmacells in females carrier of WASP mutations, thus suggesting that differentiation into effector B cells may occur through a WASp independent pathway.

P5.22.24
A normal T cell receptor beta CDR3 length distribution in patients with APECED

***H. J. Niemi**, T. Koivula, S. M. Laakso, P. Arstila, A. Tuulasvaara;*
Haartman Institute, University of Helsinki, Helsinki, Finland.

Autoimmune polyendocrinopathy-candidiasis-ectodermal dystrophy (APECED) is a monogenic autoimmune disease caused by mutations in the AIRE gene. AIRE is thought to control the ectopic expression of tissue specific antigens in the thymus. This would lead to generation of autoreactive T cells in APECED patients. Alternative models suggest that AIRE deficiency might lead to more profound changes in thymic architecture or premature activation of T cells in the thymus. Our objective was to assess these possibilities using TCR CDR3β length repertoire analysis. The repertoire is known to shorten during normal thymic development and therefore a comparison between patients and healthy controls should reveal the existence of a profound developmental defect.
TCR repertoire spectratyping and sequencing were used to calculate average CDR3β lengths of thymocytes and peripheral blood T cell populations.
To analyse the normal thymic shortening further, we examined CDR3β repertoires of DP $CD3^{low}$, DP $CD3^{high}$ and CD4 SP thymocytes. Significant shortening was observed between each stage, demonstrating coupling of the shortening to positive and negative selection processes. We then proceeded to compare the CDR3β repertoires of $CD4^+$ and $CD8^+$ T cells of patients and controls and their $CD45^{RA}$ and $CD45^{RO}$ subsets, which represent activated and resting or memory cells, respectively. In each case we observed no significant difference in the length repertoires.
Our results suggest that the defect in T cell development in APECED patients is more likely a subtle one, not affecting the overall CDR3β length repertoire of peripheral T cell populations.

P5.22.25
Clinical and laboratory evaluation of patients with common variable immunodeficiency before and after immunization with polysaccharide and protein antigens

***A. K. B. Oliveira**, M. Pedreschi, A. Cohon, G. S. Brito, L. M. Fonseca, J. Kalil, M. T. Barros, C. M. Kokron;*
University of São Paulo, São Paulo, Brazil.

This study aims to evaluate the clinical response to immunization with protein and polysaccharide antigens (*influenza*, *H1N1* and *pneumococcus*) in CVID patients followed at the Primary Immunodeficiency outpatient clinic of the Division of Clinical Immunology and Allergy, Hospital das Clínicas, FMUSP. CVID patients were diagnosed according the IUIS criteria. Thirty-seven patients were immunized against influenza (H2N3), H1N1 and pneumococcal polysaccharide vaccine while another group with 16 CVID patients were not vaccinated. Clinical evaluation was performed through a *score* with assessment of the following parameters: pneumonia, sinusitis, otitis media, upper respiratory infections (URI), tonsillitis, diarrhea, bronchiectasis, hospitalizations, use of antibiotic therapy, use of prophylactic antibiotics, sepsis and meningitis. Determination of IgG antibodies to pneumococcal serotypes was made by ELISA. H1N1-specific IgG was detected by indirect hemagglutination. The determination of influenza-specific IgG was performed by ELISA. The group of patients who were vaccinated included 37 patients (51% women), aged 20 to 78 years (mean 33 years). We observed a significant reduction in the *score* of URI, sinusitis and pneumonias in the year post administration of the vaccines ($p < 0.001$). Conversely, there was no difference in the infections pre and post supposed vaccination *scores* in the group of CVID patients who were not immunized. There was no significant change in specific antibody titers to *influenza, H1N1* and *pneumococcus* after vaccination. In conclusion, there was a reduction in the number of infections, mainly sinusitis, URIs and pneumonias in patients with CVID vaccinated. The clinical improvement observed in CVID patients reinforces the benefit of vaccination.

P5.22.26
Skin sarcoid-like lesions in CVID with poor outcome

***R. Paganelli**, M. C. Turi, M. D'Urbano, E. Celletti;*
Dept. of Medicine and Sciences of Aging, University "G. D'Annunzio" and Ce.S.I, Chieti scalo, Italy.

Common variable immunodeficiency (CVID) is a heterogenous immunodeficiency disorder characterized by different clinical presentations. In about 10% of cases they present with granulomatous lesions occurring in spleen, lymphnodes, liver, lungs, skin or conjunctiva. Most patients belong to group-I CVID classification, either with B cells<1% or absent CD21low. The histopathology is similar to sarcoidosis, but its association with CVID occurs in a limited percentage of cases.
We describe a CVID case, female aged 56yrs observed in November, 2009, but with clinical history dating from before 1988, with recurrent sinopulmonary infections, chronic diarrhea, low IgG (403 mg/dl) with absent IgA and IgM, treated since 2004 with IVIgs (20g every 2 months); she was diagnosed with cutaneous sarcoidosis in 2006 after a biopsy of a lesion on the left leg. Cutaneous granulomatous lesions appeared soon after in the periocular and perioral regions of the face and in both legs. Calcium levels, ACE, G6PDH were normal, Mantoux test neg, no visceral granulomas were detected by HRTC and US.
We started sc Igs which allowed reconstitution of protective levels (to 686 mg/dL serum IgG), and treatments (HCQ, steroids and dapsone) unsuccessful for cutaneous and sinopulmonary new lesions suggesting sarcoidosis. An ocular CMV infection developed, leading to severely impaired sight, lip basal carcinoma and granulomatous lesions of the tongue. Leukopenia was constantly present, with 23% lymphocytes, 88% CD3+, 34% CD4+, 1,3% total and no memory switched B cells. Malignant lymphoma developed late in 2012. Management of this CVID subgroup is difficult and controversial.

P5.22.27
Severe combined deficiency of innate and acquired immunity caused by an IKBKB mutation

U. Pannicke[1], *B. Baumann*[2], *S. Fuchs*[3], *P. Henneke*[3], *A. Rensing-Ehl*[3], *H. Schrezenmeier*[1,4], *T. Wirth*[2], *S. Ehl*[3], *M. Schroeder*[5], *K. Schwarz*[1,4];
[1]*University of Ulm, Institute for Transfusion Medicine, Ulm, Germany,* [2]*University of Ulm, Institute of Physiological Chemistry, Ulm, Germany,* [3]*University of Freiburg, Centre of Chronic Immunodeficiency (CCI), Freiburg, Germany,* [4]*Institute for Clincal Transfusion Medicine and Immunogenetics, German Red Cross Blood Service Baden-Wuerttemberg – Hessen, Ulm, Germany,* [5]*University of Manitoba, Department of Pediatrics and Child Health, Winnipeg, MB, Canada.*

We analyzed the molecular basis of severe combined immunodeficiency (SCID) in four patients from four independent families of a small population of homogenous ethnicity. The patients presented within the first months of life with failure to thrive, oral thrush and invasive bacterial and viral infections.
All patients showed normal numbers of B and T cells and suffered from agammaglobulinemia. Three patients had markedly reduced numbers of NK cells. B and T cells were of naïve phenotype. T cells showed reduced responses to anti-CD3/CD28 treatment. Reactivity of NK cells against K562 target cells was extenuated.
Assuming an autosomal recessively inherited monogenetic defect, we performed homozygosity mapping. We identified a region of interest around the centromere of chromosome 8. We detected a homozygous insertion of one nucleotide in the open reading frame of IKBKB in all patients predicting a frameshift with premature termination of the protein.
Western Blot analysis for the encoded IKKβ protein did not show any residual protein in fibroblasts and PBMC suggesting a null mutation. IKKα and NEMO expression was reduced.
Functional testing of NF-κB pathways was performed in fibroblasts. Phosphorylation of IκBα following stimulation with TNFα was considerably decreased. The binding of NF-κB to DNA after stimulation with TNFα or PMA was markedly reduced. Moreover, TLR4 and TLR5 triggered expression of IL-6 was decreased whereas IL-6 production following stimulation with TNFα or IL-1β was normal.
These data indicate that IKKβ is not necessary for human B and T cell development but it is indispensable for lymphocyte activation.

P5.22.28
Reduced NK cell activity and abnormal expression of CCR7 and CXCR1 by NK cells analysis in patients with DOCK8 deficiency

S. Parolini*, G. Tabellini, S. Caracciolo, O. Patrizi, M. Benassi, S. Negri, M. Giacomelli, V. Lougaris, A. Plebani, R. Badolato;*
University of Brescia, Brescia, Italy.

DOCK8-deficiency is an autosomal recessive primary immunodeficiency that is characterized by multiple abnormalities of the immune system, including a defect of NK cell cytotoxicity which could not be restored after IL2 stimulation. Nevertheless, unanswered questions remain regarding how the absence of DOCK8 leads to predisposition for malignancy, viral, fungal, and bacterial infections.
To address these questions we have analyzed NK cell phenotype and functions in patients with DOCK8 deficiency. We observed that NK cells derived from five DOCK8-deficient patients displayed dramatically reduced cytotoxicity which was partially restored after IL-2 stimulation.
Analysis of activating and inhibitory NK receptors, including KIRs molecules, chemokine receptors and activation markers on gated CD56+cells by cytofluorimetric analysis showed a substantial defect of CCR7 expression by CD56bright NK cells. Noteworthy, we have also detected the expression of NKG2C and of the chemokine receptor CXCR1 on CD56dull NK cells in DOCK8-deficient cells.
Because CCR7 expression by NK cells can be induced after cell culture with IL18 we stimulated NK cells from DOCK-8 deficient patients with IL18. Despite unstimulated CD56bright NK cells from DOCK8 patients showed reduced CCR7 expression, we could not detect any increase of CCR7 on CD56 dull and bright NK cells of DOCK8-deficient patients, whereas CCR7 expression on NK cells derived from healthy donors significantly increased from 5% to 17%.
Taken together our results suggest that NK cells of DOCK-8 deficient patients show reduced cytotoxicity and abnormal expression of the chemokine receptors CXCR1 and CCR7 suggesting an abnormal recruitment of these cells to secondary lymphoid organs.

P5.22.29
Establishment of newborn screening for SCID / severe T lymphocytopenia in São Paulo

M. Pyles Patto Kanegae[1], *A. Miyashiro Nunes dos Santos*[2], *B. Tavares Costa Carvalho*[2], *I. Rugue Genov*[2], *A. L. Acquesta*[3];
[1]*Department of Immunology, Institute of Biomedical Sciences, University of São Paulo, Brazil, Sao Paulo, Brazil,* [2]*Department of Pediatrics, São Paulo Federal University, Sao Paulo, Brazil,* [3]*Hospital Geral de Pirajussara, Sao Paulo, Brazil.*

The aim of newborn screening (NBS) is to identify pre-symptomatic newborns with potentially serious or fatal disorders that can be successfully treated. Since its implementation in 2008 in the USA, SCID NBS has detected many immunodeficiencies others than SCID. We currently develop a pilot for a routine NBS protocol for SCID through the quantification of T-cell receptor excision circles (TRECs) from dried blood spots (DBS) on NBS cards in São Paulo city. Newborns´ samples from 2 hospitals in São Paulo were collected after parents' consent. DNA was extracted from DBS and TRECs were determined by real-time quantitative PCR (RT-qPCR). Until now, 1,495 DBS were collected and TRECs quantification ranged from 70 to 2,181 TRECs/μL of blood. The mean and median numbers of TRECs/μL of blood were 433 and 355 respectively. No TRECs were detected in 3 confirmed SCID controls despite the beta-actin normal amplification.
As already proved in some studies, RT-qPCR is a reliable method to quantitate TRECs and screen for SCID/ T lymphocytopenia. In our study, the estimated cost of reagents used for TRECs determination per sample is R$8.00 (equivalent to US$4 and to the cost of screening for cystic fibrosis). Thus, we are going to implement this technique in large scale on São Paulo state major newborn screening laboratory as a mean to call authorities attention for the problem of undiagnosed SCID patients in Brazil.

P5.22.30
Targeted detection of chronic immunodeficiencies by flow cytometry

U. Sack[1], *S. Borte*[1], *M. Borte*[2], *F. Kahlenberg*[1], *A. Boldt*[1];
[1]*Institute of Clinical Immunology, Medical Faculty, Leipzig University, Leipzig, Germany,* [2]*Department of Pediatrics, Municipal Hospital St. Georg, Leipzig, Leipzig, Germany.*

The targeted and rapid identification of immunodeficiencies represents a diagnostic challenge. Based on high biological variance in reference ranges, stepwise approaches starting with a simple immune status have been proofed to be commonly misleading.
We introduced an 8-tube-8-colour based approach including general immune status, B-cell subpopulations, CD4+ and CD8+ subpopulations, regulatory T cells, recent thymic emigrants, and subpopulations as well as activation of NK-cells. Based on age-adjusted samples, calculation of age matched reference values is ongoing.
We collected information about: (i) CD3+,4+,8+,19+,16/56+ and activated CD4/8 cells (ii) immature, naive, non-switched, switched, memory, (activated) CD21low, transitional B-cells, plasma blasts, plasma cells (iii) naïve, central memory, effector, effector memory, TH1, TH2, CCR5+ CD4-cells (iv) naïve, central memory, effector, effector memory, CCR5+ CD8-cells and TH17, (v) regulatory T-cells and CD25+, CD69+ T-cells, (vi) naïve (CD62L) and recent thymic emigrants of CD4/CD8, α/β - and γ/δ -T-cells, (vii) immature, mature, CD56bright, single CD16+ NK-cells, CD94/NKG2D+ (viii) Nkp30, 44, 46 and CD57+ NK-cells.
This screening panel allows quickly detecting and differentiating abnormalities or developmental shifts in subpopulations. This approach can be adapted according to clinical signs, speeds up detection of immunodeficiencies, and supports specific therapeutic decision making.

P5.22.31
A New Mutation associated to Bruton Amammaglobulinemia

F. R. Mora, R. de la Varga, E. Garcia Moreno, C. Rodriguez, ***A. Sampalo****;*
HOSPITAL PUERTA DEL MAR, Cadiz, Spain.

X linked agammaglobulinemia (XLA) or Bruton agammaglobulinemia (OMIM 300300), is an inherited immunodeficiency disease caused by mutations in the gene coding for the Bruton`s tyrosine-kinase (Btk). Btk is critical for the maturation of pre-B cells into mature B lymphocytes. The human BTK gene has been mapped to the long arm of the X chromosome, it comprises 19 exons and an open reading frame of 1980 nucleotides. A database of BTK mutations lists 341 mutations.
A 5 years old male was admitted to the hospital for pneumonia caused by *Haemophilus influenzae* type B and pleural effussion. Before this admission he has suffered recurrent upper and lower respiratory infections and chronic diarrhea. Thomography study showed bronchiectasis. Immunologic study was performed: no B cells was detected (<0.01%) and very low levels of IgG (241 mg/dl), IgM (17 mg/dl) and IgA (<5 mg/dl) were found. Parents were not consanguineous. Clinical and laboratory data raised the suspicion of an XLA. Flow cytometry analysis of Btk on monocytes and genetic study confirmed the diagnosis.
BTK gene messenger RNA was analysed and sequenced in c-DNA (copy-DNA) showing the skipping of exon 16. Genomic DNA sequencing detected a T>C change in the donor splice site of exon 16 (IVS16+2T>C or c.1750+2T>C). The sequence variant found in the patient has not been previously reported, however, we consider it is a pathogenic mutation, as it affects the mRNA splicing and the tirosin-kinase domain of the protein.

P5.22.32
Clinical and Genetic heterogeneity of Chronic Mucocutaneus Candidiasis Disease in four Patients with Heterozygous STAT1 mutations

O. Scomodon*[1,2], D. Vairo[1], M. Giacomelli[1,2], L. Tassone[1], G. Maggiore[3], A. Soresina[1], V. Lougaris[1], D. Dinwiddie[4], S. Kingsmore[4], R. Badolato[1];*
[1]Institute of Molecular Medicine "Angelo Nocivelli", Department of Pediatrics, University of Brescia, Brescia, Italy, [2]Scuola di Dottoratao in Scienze della Riproduzion e dello Sviluppo, University of Trieste, Trieste, Italy, [3]Pediatric Department, University of Pisa, Pisa, Italy, [4]Children's Mercy Hospital, Kansas City, MO, United States.

We have analyzed four patients with Chronic Mucocutaneus Candidiasis Disease (CMCD) affected by persistent and recurrent infections of nails, skin, oral or genital mucosae caused by Candida albicans. Sanger sequencing of CARD9 and Dectin-1, both genes causative of an increased susceptibily to candida infection did not show any genetic alteration. Therefore in two of them, mother and son, we decided to use a whole-exome approach looking for a relevant heterozygous mutation inherited in a dominant trait. Among different targets we identified a missense heterozygous mutation in STAT1 coiled-coil domain L283M.
Based on this finding we screened two other unrelated patients affected by CMCD with direct sequencing of STAT1. We found other two mutations: R274W in Coiled-Coil domain and L351F in DNA-Binding domain.
In order to investigate how these mutations could affect the ability of the immune system to response against Candida we characterized STAT1 phosphorylation in response to interferon alpha (IFN-alpha) and then the ability of CD4+ T-lymphocytes to polarize to Th17.
These experiments showed a persistent hyper-phosphorylation in response to IFN-alpha stimulation in PBMC of CMCD patients, and the complete loss of polarization toward Th17 in CD4+ T-lymphocytes. These data suggest that heterozygous missense gain of function mutations in Coiled-Coil and in DNA-Binding domain of STAT1 gene can cause CMCD.
Mucocutaneous Candida infections were observed in all the patients. However, one of them did also present Cryptococcal lymphadenopathy and visceral leishmaniasis, suggesting that heterozygous STAT1 mutations can be associated to heterogeneous clinical features.

P5.22.33
T regulatory cells and Helios expression in patients with diGeorge syndrome

A. Sediva*, K. Sismova, A. Klocperk, J. Grecova, A. Skalicka, R. Zachova;*
Motol University Hospital, Prague, Czech Republic.

Objective: Syndrome diGeorge is a complex disorder caused by an embryopathy based on del22q11. Due to hypo/aplasia of a thymus resulting immunodeficiency affects mainly T cells. In this study we focused on T regulatory cells, with particular attention to Tregs expressing Helios, previously suggested as a potential marker of natural Tregs arising in thymus.
Patients and Methods: We investigated 26 patients with syndrom diGeorge with confirmed 22q11 deletion, age 9 months to 15 years. Tregs were selected as CD25+Foxp3+ cells. Helios expression was measured in 22 patients in this cohort.
Results: We observed a tendency to higher values of Tregs (1,3-7,5% in diGeorge patients, normal values 1-5%). Helios expressing cells ranged from 60 to 89% in diGeorge cohort. Lowest value 42% of Helios expressing cells was detected only in one patient with complete diGeorge syndrome with a lack of T cells, who, however, underwent hematopoetic stem cell transplantation 1 year prior investigation.
Conclusions: Despite abnormalities in thymic development, patients with diGeorge syndrome present with normal of higher values of Foxp3+ Tregs, including Tregs expressing Helios. We, therefore, confirm recent reports demonstrating that Helios expression does not appear suitable as a marker to distinguish natural and induced Treg cells.
Supported by IGA MZČR NT13287-4/2012

P5.22.34
B cell dysregulation in autoimmune lymphoproliferative syndrome

S. Sharapova*[1], O. Pashchenko[2], A. Migas[1], I. Gyryanova[1], A. Nevmerzhitskaya[1], I. V. Kondratenko[2], M. Belevtsev[1];*
[1]Belarusian Research Center for Pediatric Oncology, Hematology and Immunology, Minsk region, Belarus, [2]Russian Children's Clinical Hospital, Moscow, Russian Federation.

Introduction: Autoimmune lymphoproliferative syndrome (ALPS) is a primary immune deficiency of T cell dysregulation caused by defective Fas-mediated apoptosis witch associated with multiple autoimmune disorders, main of that autoimmune hemolytic anemia (AIHA) and/or immune thrombocytopenia (ITP).
Objective: To analyze B-cell subsets and related cytokines (BAFF, IL10) in a cohort of patients with ALPS in order to characterize B cell differentiation in human model of inborn immunedysregulation.
Methods: Flowcytometric analysis of the following B-cell subset was performed in 11 children from Belarus and Russia, compared to age-matched controls: transitional (CD19+CD38++IgM++), $CD21^{low}$, $CD21^{low}CD38^{low}$, naïve (CD19+CD27-IgM+/IgD+), switched memory (CD19+CD27+IgM-/IgD-), marginal zone B cells (CD19+CD27+IgM+/IgD+), putative self-reactive B cells ($CD19+IgD+IgM^{low}$), putative regulatory B cells (CD19+CD24++CD38++) and BAFF, IL10 serum levels were evaluated by ELISA assay.
Result: Diagnosis of 11 patients was established according to revised NIH criteria and abnormal Fas-apoptosis, 7 pt had mutation in *FAS* gene. The majority of patients had reduced percentage of circulating marginal zone B cells, switched memory B cells and increased percentage of $CD21^{low}$, putative self-reactive and putative regulatory B cells. Serum levels of IL10 and BAFF were increased.
Conclusion: Data show a significant disregulation of B cells subsets in ALPS patients and suggest that intact CD95 signaling is important for normal human B cell differentiation and contribute to breakdown of peripheral tolerance and the entry of autoreactive B cells into the naive B cell compartment.

P5.22.35
Linking the endosome to primary immunodeficiency - a congenital neutrophil defect syndrome associated with mutations in *VPS45*

*T. Vilboux[1], A. Lev[2], M. Malicdan[3], A. Simon[2], N. Amariglio[2], G. Rechavi[2], Y. Anikster[2], C. Klein[4], W. Gahl[3], **R. Somech[2]**;*
[1]National Human Genome Research Institute, Bethesda, MD, United States, [2]Edmond and Lily Safra Children's Hospital, Tel Hashomer, Israel, [3]National Human Genome Research Institute, National Institutes of Health, Bethesda, MD, United States, [4]Department of Pediatrics, Dr von Hauner Children's Hospital, Ludwig-Maximilians-University, Munich, Germany.

Primary immunodeficiencies, affecting the neutrophils, illuminate basic mechanisms of immune protection against infections. These defects involve different steps throughout the development, maturation and function of the neutrophils, including the endocytosis process. Primary endosomal defect, responsible for severe immunodeficiency without associated dysmorphism, has not been yet described.
We now describe a defective endosomal intracellular protein trafficking due to inherited mutations in *VPS45* gene which encodes a protein regulating membrane trafficking through the endosomal system. Our study underlies a new immunodeficiency syndrome involving impaired neutrophil function. 7 members of 5 families with neutropenia, neutrophil dysfunction, bone marrow fibrosis, and nephromegaly, were clinically investigated. To identify the causative gene, we performed homozygosity mapping using single-nucleotide polymorphism arrays and whole exome sequencing. All 7 affected children of two different ethnic origins had homozygous mutations (THR224ASN or GLU238LYS) in the *VPS45* gene. Patient's fibroblasts showed defective motility and increased apoptosis. Both cellular phenotypes were rescued by transfecting mutant fibroblasts with wild type VPS45 gene. In patient cells, VPS45 protein level was reduced, as well as its binding partners Rabenosyn-5 and syntaxin16. Beta-1 integrin, which its recycling is regulated by VPS45, was reduced on the surface of patient's cells. A zebrafish model with reduced vps45 protein exhibited severe neutropenia, resembling that of our patients. The cellular defects in this new disease suggest that other immunodeficiency disorders may also result from impaired vesicle trafficking. This primary immunodeficiency may provide useful insights and complementing experimental approaches to study the endosome function in health and disease.

P5.22.36
Antibody deficiency in Ataxia Telangiectasia is caused by disturbed B and T cell homeostasis and reduced immune repertoire diversity

*G. J. A. Driessen[1], H. IJspeert[1], C. M. R. Weemaes[2], Á. Haraldsson[3], A. Warris[2], N. Wulfraat[4], M. Taylor[1], J. J. M. Van Dongen[1], M. van Deuren[2], **M. van der Burg[1]**;*
[1]Erasmus MC, Rotterdam, Netherlands, [2]UMC-St Radboud, Nijmegen, Netherlands, [3]Landspitali University Hospital Reykjavík, Reykjavik, Iceland, [4]UMCU, Utrecht, Netherlands.

Ataxia Telangiectasia (AT) is a multisystem DNA-repair disorder caused by mutations in the *ATM* gene. AT patients have reduced B- and T-cell numbers and a highly variable immunodeficiency. ATM is important for V(D)J recombination and immunoglobulin class switch recombination (CSR), however, little is known about the mechanisms resulting in antibody deficiency severity. The aim of this study was to examine the immunological mechanisms responsible for antibody deficiency
heterogeneity in AT. We included patients with classical AT plus early onset hypogammaglobulinemia (n=3); classical AT (n=8); and variant AT (late onset; n=4). We studied peripheral B- and T-cell subsets, B-cell subset replication history, somatic hypermutation frequencies, CSR patterns, B-cell repertoire and ATM kinase activity. Classical AT patients lacked ATM kinase activity, while variant AT patients showed residual function. Most patients had disturbed naive B-cell and T cell homeostasis as evidenced by low cell numbers, increased proliferation, and decreased antigen receptor repertoire diversity. Impaired formation of T-cell dependent memory B-cells was predominantly found in AT plus hypogammaglobulinemia. These patients had extremely low naive CD4+ T-cell counts, which were more severely reduced compared to classical AT patients without hypogammaglobulinemia. Finally, AT deficiency resulted in defective CSR to distal constant regions that might reflect impaired ability of B-cells to undergo multiple germinal center reactions In conclusion, the severity of the antibody deficiency in AT correlates with disturbances in B and T-cell homeostasis resulting in reduced immune repertoire diversity, which consequently affects the chance of successful antigen-dependent cognate B-T interaction.

P5.22.37
Expression of Bruton's tyrosine kinase gene and endoplasmic reticulum stress markers in X-linked agammaglobulinemia

*V. D. Ramalho, M. A. Teocchi, B. M. Abramczuk, T. N. Mazzola, **M. M. S. Vilela**;*
State University of Campinas Medical School - UNICAMP, Campinas, Brazil.

Introduction: X-linked agammaglobulinemia (XLA) is characterized by a B lymphocyte differentiation block in the bone marrow, leading to hypogammaglobulinemia with few, or the absence of, peripheral B lymphocytes. Mutations in the *BTK* gene are responsible for XLA and in most cases lead to low protein expression. Misfolded proteins can trigger stress pathways in the endoplasmic reticulum (ER).
Methods: We evaluated eight male Brazilian patients whose diagnosis was based on recurrent infections, markedly reduced levels of IgM, IgG and IgA, and circulating B cell numbers <2%. *BTK* mutations were identified by sequencing and the mRNA expression of *BTK* and ER stress markers was assessed with real-time quantitative PCR (RT-qPCR) technology.
Results: We detected four missense mutations, one nonsense mutation, two frameshifts and one splice site defect. Quantitative real-time detection PCR measurements showed a reduced expression of *BTK* mRNA in patients with mutations that result in a stop codon. However, we found that missense mutations do not affect *BTK* mRNA expression. XLA patients showed an increased level of *XBP-1* mRNA and a reduced expression of *HSP90B1* mRNA, which could be a mechanism to revert cellular ER stress.
Conclusions: The quantification of *BTK* mRNA expression is an interesting tool to identify and differentiate the mutational consequences in XLA patients. It can also contribute to the study of transcripts in other genetic diseases with different types of mutation.
FINANCIAL SUPPORT: FAPESP and CAPES.

P5.22.38
Up-regulation of LY6E expression on monocytes attenuates innate immunity by down-regulating CD14 and is associated with HIV disease progression

***J. Xu**, X. Zhang;*
Fudan University, Jinshan, Shanghai, China.

Background: Lymphocyte antigen 6 complex locus E (LY6E) is a type I interferon-inducible gene and has been shown to enhance viral replication (Nature 2011, 472:481). However, the underlying mechanism and its role in HIV-1 infection remain to be determined.
Methods: LY6E expression was quantified in HIV-infected subjects and HIV-seronegative individuals, its associations with CD4+ T cell counts and viral loads in HIV-infected subjects were determined. In addition, the roles of LY6E in regulating innate immune responses in HIV-1 infection were further investigated in vitro in monocytes.
Results: LY6E was significantly up-regulated in HIV-infected subjects, its expression was reversely correlated with CD4+ T cell counts and positively with the viral loads; Higher LY6E expression in HIV-1 infected subjects resulted in a more rapid decline of CD4+ T cells than lower LY6E expression individuals during the subsequent 33-month following up visit. LY6E is constitutively expressed on monocytes. Knocking down LY6E expression on both monocyte line and primary monocytes by siRNA profoundly enhanced the production of proinflammatory cytokines and Type 1 interferonand, the enhanced innate responses were suppressed by re-introducing LY6E into monocytes. LY6E down-regulated CD14 expression, accordingly, over-expression of CD14 could overcome the LY6E-mediated suppression. In addition, in HIV-infected subjects, LY6E expression was reversely associated with CD14 expression, successful HAART could reduce LY6E expression.

Conclusion: For the first time we identified that LY6E is an inhibitory molecule on monocytes and is correlated to HIV disease progression; Down-regulation of innate immunity by LY6E was accomplished by reducing CD14.

P5.22.39
Lymphoid Intestitial Pneumonia in CVID -oligoclonal expansion of lymphocytes with preferential CMV-specific immune response and lymphorpoliferative disease promotion. Successful rituximab therapy

P. Zdziarski[1]*, A. Lange*[2]*, D. Dlubek*[3,4]*, K. Suchnicki*[1]*;*
[1]Dept Clin Immunol Lower Silesian Center for Cellular Transplantation, Wroclaw-46, Poland, [2]Lower Silesian Center for Cellular Transplantation, Dept Clin Immunol Institute of Immunology & Experimental Therapy, Wroclaw-46, Poland, [3]Lower Silesian Center for Cellular Transplantation, Institute of Immunology & Experimental Therapy, Wroclaw-46, Poland, [4]Dept Clin Immunol Lower Silesian Center for Cellular Transplantation, Institute of Immunology & Experimental Therapy, Wroclaw, Poland.

Lymphoid interstitial pneumonia (LIP) is a rare diseases with lymphocytic infiltration of the alveolar interstitium and air spaces, sometimes classified as a lymphoproliferative disease.
In the case report LIP arise primarily from the CVID: at the age of 13 multiple nodules, areas of consolidation was observed and the LIP was confirmed by histological examination. 10 years later the progression to B-lymphoproliferative disease with massive splenomegaly and soft tissue infiltration, coincide with oligoclonal increase of IgM (3340mg/dl), cold agglutinin disease, serum sickness-like reaction.
Immune response polarization was observed in humoral and cellular compartment: high anti-CMV IgM corresponds with high CMV-Quantiferon, terminal CD8 differentiation (75% of CD8 cells was CD57 positive) and clonal expansion: 10, 8% of lymphocytes are CMV pp65-pentamer positive. Surprisingly weak immune response to EBV was observed: specific antibodies did not detected, LMP-1- and BMLF-1-pentamer positive cells show below 0,1%. Interestingly clonality analysis shows oligoclonal serum immunoglobulins (κ/λ=2,84), heavy chain and TCRβ gene rearangation with limited repeitoire.
Taking together this case shows that LIP is consequence of immune deficiency i.e. vigorous immune response to CMV, then asymmetric lymphocyte development after V-D-J rearrangation.
Successful prolonged rituximab therapy with regression of lymphoproliferative disease, nodules and consolidations, unexpected increase FVC (2,59à3,78l) several years after LIP onset prompts the use this monoclonal antibody as a first line therapy.

Prevalence of Tuberculosis among HIV/AIDS Patients In Obafemi Awolowo University Teaching Hospital Complex (OAUTHC). ILE - IFE

O. N. Olaniran*;*
Obafemi Awolowo University, Ile-Ife, Nigeria.

The prevalence of Tuberculosis (TB) among HIV/AIDS patients in ObafemiAwolowo University TeachingHospital Complex (OAUTHC) Ile-Ife was investigated. In addition, the comparison between microscopical and radiological techniques of TB diagnosis was studied as well as the specimen of most diagnostic value. Out of 86 confirmed Acquired Immunodeficient Syndrome (AIDS) patients examined microscopical with Ziehl Neelson (ZN) cold staining method for Acid Fast Bacilli (AFB) in sputa, were positive for AFB showing a prevalence of 13.8%. the prevalence of TB in AIDS patients with regards to age group and sex distribution showed the highest number of positive cases to be in age group 21-30 yr (5.8%), males made up of 7 (8.1%) and females 5(5.8%). The radiological technique proved more sensitive with 52 (60%) positive cases than the microscopic technique with only 12 (13.9%). In the study of the most valuable specimen, early morning specimens (Collection samples) were of more diagnosis value than others (collected at the clinic between 9am 12 noon) and gave the highest positive result of 13.9% while samples I and III were 10.5% and 9.3% respectively. The high proportion of negative results (86%) obtained from microscopic examination underscores the need for cultural method and clinical diagnosis to accurately identify and confirm TB in HIV/AIDS patients who are sputum negative but may be co-infected. This work confirms that there is a close link existing between active tuberculosis and HIV/AIDS infection in Ile-Ife, Nigeria.

Vitamin D deficiency increases macrophage polarization and inflammatory infiltrates in epicardial adipose tissue of atherosclerotic swine

D. K. Agrawal*;*
Creighton University School of Medicine, Omaha, NE, United States.

Purpose: Patients with obesity and insulin resistance develop accelerated atherosclerosis and pro-inflammatory changes in epicardial adipose tissue (EAT) resulting into increased release of pro-inflammatory mediators that might mediate coronary artery disease, develop endothelial dysfunction and exaggerate intimal hyperplasia following coronary intervention. Here, we examined inflammatory phenotype of epicardial fat and coronary artery function in vitamin D-deficient atherosclerotic swine.
Methods: Yucatan microswine were fed with high fructose high-cholesterol diet. Atherosclerotic lesions were confirmed by coronary angiography and histology. Immunostaining was performed in the adipose tissue and coronary arteries for macrophage phenotype. Contraction and relaxation of coronary arteries was examined in organ bath studies.
Results: In obese swine fed with high-fructose high-cholesterol diet, there was significant infiltration of CD86+ cells (M1 macrophages) with minimal immunostaining to CD206 (M2 macrophages) in adipocytes, which was increased in adipocytes of vitamin D-supplemented swine. Similar pattern was found in coronary arteries. Compared to vitamin D-sufficient high-cholesterol diet, vitamin D-deficient high-cholesterol swine EAT showed dense inflammatory cell infiltrate with significantly decreased expression of SOCS3 protein and marked increase in TNF-α, MCP-1, and IL-6 expression in EAT. The contractile response to serotonin in both carotid and coronary arteries of atherosclerotic swine was much higher in the vitamin D-deficient than in vitamin D-sufficient group. Norepinephrine (NE)-induced contraction in carotid and dilatation in coronary arteries, which was lower in vitamin D-deficient than vitamin D-sufficient swine.
Conclusion: High-fructose high-cholesterol diet enhances pro-inflammatory macrophages, increases vasoconstriction and decrease vasodilatation. Vitamin D supplementation could be beneficial in preventing metabolic effects in atherosclerosis.

P6.01.02
Impact of zinc supplementation on the production of IL-17 in perinatal stages

A. E. Aguilar*, M. T. C. Sanchez, B. Muñoz, R. Pastelin;*
School of Chemistry, Mexico DF, Mexico.

The suboptimal contribution of micronutrients may damage the immune response. In the particular case of zinc, this microelement has shown their participation in various immunological processes around perinatal stages. In this regard, it is interesting to know the impact of zinc may have on proinflammatory cytokines such as IL-17 for its role in delayed hypersensitivity and its possible effect in the induction of autoimmunity. This study aimed to evaluate the effects of zinc supplementation on the production of IL-17 over early life stages. For this, we used an experimental model of zinc supplemented mice (500 microgram/mL zinc acetate, F1 Balb/c AnN inbred mice at 21 and 42 days). We measured the microelement concentration in lymphoid organs by Atomic Absorption Spectrometry and also the cytokine production in serum by double antibody immunoenzime assay. Results showed that female group of supplemented mice diminished the cytokine production 13.65% whereas male group of supplemented animals showed a reduction of 28.61 % at 6 weeks of treatment. While at 9 weeks of supplementation female mice

diminished the cytokine production 74.71% and male group of supplemented animals showed a reduction of 76.25%, each group compared with control. Further, zinc concentration showed a noticeable increment in the spleen of female supplemented mice (80%). We concluded that zinc supplementation in neonate mice has the effect to diminish the production of IL-17 by Th17 cells, this means a regulatory response to supplemented individuals and probably effects over thymocytes differentiation and Th17-mediated autoimmune diseases.

P6.01.03
Uncaria tomentosa Willd. DC (Cat's claw) immunostimulatory activity in splenic B lymphocytes

*D. F. Zegarra Ruiz, **J. L. Aguilar**;*
Universidad Peruana Cayetano Heredia, Lima, Peru.

INTRODUCTION: B lymphocytes play a crucial role in humoral immunity; their activation provides the basis of immunizations against different diseases. This study assessed the immunostimulatory activity of a Cat's claw (Uncaria tomentosa Willd. DC) hydro-alcoholic extract with 5% of pentacyclic oxindole alkaloids (UT) on splenic B cells.
OBJECTIVES: 1. Calculate the UT IC50 value in splenocytes. 2. Evaluate the effect of UT in mononuclear cells activation. 3. Evaluate the effect in splenic B cells.
METHODOLOGY: Spleens were obtained from 7-week-old C57BL/6 mice. Splenocytes were treated with different concentrations of UT. IC50 value was calculated after 72h UT incubation and adding 7AAD. Subsequently, splenocytes were stimulated under the same conditions and the activation of mononuclear cells and B lymphocytes (B220+/CD25+CD69+) was assessed by flow cytometry. Data was analyzed with Graphpad Prism 5.
RESULTS: The IC50 value obtained for UT in splenocytes was 140.9ug/ml. A dose-dependent activation was shown after UT stimulation. Mononuclear cells were significantly activated by UT (18.3% for UT 90ug/ml vs. 2.5% CN). Furthermore, B lymphocytes were also activated (20.45% for UT 90ug/ml vs. 1.8% CN); nevertheless, their population percentage remained the same for all the treated and control groups (65% of total splenocytes in average).
CONCLUSION: These results support the immunostimulatory activity of UT and demonstrate specificity towards B cell activation, suggesting that UT could be used as a potent adjuvant to trigger humoral immunity.

P6.01.04
Leucocytes and Oxidative Stress by Non-Thermal Plasma

***S. Bekeschus**[1,2], J. Kolata[2], K. Masur[1], K. Weltmann[1], B. M. Bröker[2];*
[1]Leibniz Institute for Plasma Science and Technology (INP), Greifswald, Germany, [2]Institute of Transfusion Medicine and Immunology, Department of Immunology, Greifswald, Germany.

Plasma is ionized gas and is the so-called 4th state of matter. In nature it comes in form of lighting, aurora borealis, or fire. Intensive research has led to "cold" plasma sources operating at room temperature. These plasma sources are already efficiently applied in industry for decontamination of food and heat sensitive materials. The mechanism of action - although not fully understood - is mediated through RONS. Liquid and gas phase plasma chemistry is highly complex but plasma diagnostics revealed dose-dependent levels of hydrogen peroxide, nitric peroxide, superoxide, and others. In plasma medicine, plasma applied to cells and tissues. So far, increased proliferation of fibroblasts in vitro and in vivo anti-tumor activity could be shown. More interestingly, first in vivo and clinical studies revealed a plasma-aided increase in the healing of (chronic) wounds. It is thought that mild oxidative stress may modulate skin and immune cell behavior to resolute chronic inflammation while RONS still being toxic enough to have an anti-microbial activity. The plasma - human-leucocyte interaction has not been elucidated yet. Therefore, we treated human blood PBMC and PMN in vitro with an atmospheric pressure argon plasma jet (kinpen09, CE-marked and safety tested) and monitored viability, proliferation, activation, and cytokine secretion. Differential sensitivity to external oxidative stress of plasma of individual leucocyte subpopulations was observed.

P6.01.05
The sensitivity to different types of milk in patients with Ulcerative colitis

***I. Besu**[1], A. Konic-Ristic[2], N. Jojic[3], D. Popovic[4], Z. Juranic[1];*
[1]Institute of Oncology and Radiology of Serbia, Belgrade, Serbia, [2]Institute for Medical Research, Belgrade, Serbia, [3]KBC Zvezdara, Belgrade, Serbia, [4]Clinical Center of Serbia, Belgrade, Serbia.

Objective: Ulcerative colitis (UC) is a form of inflammatory bowel disease, which is treated as an autoimmune disease. The aim of this study was to determine the prevalence of the increased levels of serum antibodies to different types of milk: fresh cow's milk (FCM), fresh goat's milk (FGM), boiled cow's milk (BCM) and boiled goat's milk (BGM) in patients with UC.
Methods: Seventeen patients with UC (15 with proven increased, mainly IgG and IgE immunity to cow's milk proteins (CMP) and 2 without it) were included in this research. Levels of serum IgA, IgG and IgE antibodies to FCM, FGM, BCM and BGM antigens were determined by ELISA test. The statistical analysis of data was performed by Wilcoxon rank sum test.
Results: The levels of serum anti-FCM IgA, IgG and IgE antibodies were significantly higher than levels of serum anti-BCM (p=0.0313; p=0.0256; p=0.0029) respectively. Statistical analysis of IgG and IgE immunoreactivity to BGM and BCM showed that the levels of anti-BCM IgG and IgE antibodies were significantly higher in comparison to levels of anti-BGM IgG and IgE antibodies (p=0.0066; p=0.0005). The level of serum anti-FCM IgG antibody was significantly higher than level of serum anti-FGM (p=0.0125). The level of IgE immunity to FGM is significantly higher than level of IgE immunity to BGM (p=0.0231).
Conclusion: These results indicate that patients with UC with increased immunity to cow's milk proteins, could consider the use of boiled goat's milk as the alternative protein source.

New therapeutic strategies using xCELLigence system in colon cancer

***L. I. Brasoveanu**[1], D. Hotnog[1], I. Iancu[2], C. Hotnog[1], A. Botezatu[2], M. Bostan[1], M. Mihaila[1], G. Anton[2];*
[1]"Stefan S. Nicolau" Institute of Virology, Center of Immunology, Bucharest, Romania, [2]"Stefan S. Nicolau" Institute of Virology, Genetic Engineering Laboratory, Bucharest, Romania.

The chemo-preventive efficacy was associated to enhanced apoptosis, a cellular "suicide" mechanism that keeps cell number in tissues between normal limits and allows elimination of cells predisposed to malignant transformation. Any therapeutic strategy that specifically triggers apoptosis in cancer cells might have immunotherapeutic value. Anti-cancer drugs exert their cytotoxic action during physiological pathways of apoptosis, leading to tumor cell destruction, which might be added by natural compounds, and apoptosis pathways influenced. Our study focuses on the influence of treatment with drugs and/or natural compounds on antigen *vs.* gene expression of molecules involved in cell proliferation and apoptosis (p53, Bcl-2, Bax) in colon tumour cell lines with different rates of proliferation (LoVo, HT29). The xCELLigence System, a cell-based label-free platform technology that utilizes the inherent morphological and adhesive characteristics of the cell, was used to screen new therapeutic strategies and dose-response models by combining drugs (5-fluorouracyl, cisplatin) with natural compounds (resveratrol, genistein). The system continuously monitored viability/toxicity to pinpoint the optimal time points and concentrations for conducting endpoint assays like flow-cytometry, Western blot for evaluation of nuclear antigen expression, or qRT-PCR for detection of gene expression. In addition, percentages of apoptotic cells were analyzed using Annexin V/ FITC and propidium iodide (PI) double staining, while DNA progression through cell cycle phases was estimated by PI staining, both followed by flow-cytometry analysis. Therefore, new therapeutic approaches could be used for destruction of tumor cells and renewal of the cellular pathways that lead directly to apoptosis, contributing to the immunotherapeutic management of cancer.

P6.01.07
Beta-glucans Uptake by Human Dendritic Cells via a Variety of Endocytotic Mechanisms

***J. Cao**, G. C. F. Chan;*
The University of Hong Kong, Pokfulam, Hong Kong.

β-glucans are natural polysaccharides carrying β-glycosidic bonds and exist diversely in cell wall of bacteria and fungi. *Ganoderma Lucidum* (*G.lucidum*) is a kind of mushrooms fungus that has been consumed for ages with potent immunomodulatory effects on human immune cells. Since the β-1-3 and 1-6 glycosidic linkages of β-glucans cannot be digested by human, how β-glucans are uptaken and then stimulate dendritic cells (DCs) remains elusive. We therefore explored whether its uptake involves various endocytotic pathways. We utilized human monocyte-derived DCs as *in vitro* models and investigated the involvement of three known endocytosis mechanisms: clathrin-mediated, caveolae-dependent and macropinocytosis. Chlorpromazine (CPZ), genistein (GNS) and cytochalasin D (CCD) were selected as their respective inhibitors. *G.lucidum* β-glucans (GL-PS) were used due to its high potency in stimulating the DCs maturation. Cell colonies were observed by microscopy and selected CD markers expression were assessed by Flow Cytometry. Our results showed that all inhibitors exerted suppressive effects on DCs maturation by downregulating a panel of surface maturation markers expressions. The suppression indirectly suggested that GL-PS was internalized via these 3 mechanisms. Therefore, we hypothesized that clathrin, caveolae and macropinocytosis pathways were all potentially involved in β-glucans uptake into DCs. Further study is ongoing to confirm our findings.

P6.01.08
Nourishment and its relation with immunitary response and oxidative stress

***E. Catellanos**;*
University Hospital "General Calixto García", La Habana, Cuba.

These last decade's articles were reviewed, all related to the topic and written in English and Spanish, well available at the Infomed intranet.
Background and objectives: It is a systematic bibliographic review about nutrition. Nutrients are classified as proteins, carbohydrates, fat, vitamins and minerals, needed in diet for the well functioning of the human being briefly discuss the design of the study/ program and how it was conducted. We would like to development some projects of investigation to establish a useful therapeutic conduct which allow the patients to take the appropriate diet and prevent lots disorders in the immunological system. **Methods:** We performed a wide and systematic bibliographic revision abaut nutrition immunity and oxidative stress, on the second place we compiled and prosecuted the information.
Results: An analysis is done about the main antioxidants ingested by diet, due to the harmful effect that free radicals cause in the organism ; on the other hand it is explained how nutritional manipulation of immunity may have clinical (cellular immunodeficiency, humoral and phagocitic weakness), biological and therapeutic implications. Besides, it is approached the effect that an adequate nutrition may have on the main defense mechanisms of the organism, present the main results with appropriate statistics/ data analysis and pertinent discussion. **Conclusions:** We analyzed the information of all current studies and in this bibliographic review, it is deductible the importance of an adequate nutrition to maintain a proper physical appearance and to diminish the oxidative stress mechanisms and improve our defenses.

P6.01.09
Inflammatory pattern, vitamin D level and cognitive performance in adults and older adults.

***H. Darwish**, S. J. Khoury;*
American University of Beirut, Beirut, Lebanon.

Age-related and neurodegenerative cognitive decline are associated with increased inflammation, hippocampal atrophy and low serum vitamin D level. The pathological inflammatory mechanisms leading to the neuronal damage and cognitive impairment are direct, secondary to the involvement of various cytotoxic T-lymphocytes activities, or indirect as a result of microglial activation. Vitamin D is an endogenous hormone that depends on adequate sun exposure and food intake. Recently, basic and clinical research studies showed that Vitamin D supplementation up regulates anti-inflammatory cytokine levels. In addition, there is evidence of functional vitamin D receptors found mainly in hippocampal neurons and glia. Also, increased inflammation is positively correlated with hippocampal atrophy. Yet, levels of vitamin D and inflammatory cytokines, known mediators of cognitive performance, have not been fully explored clinically. The aim of this study was to investigate the correlation between serum levels of vitamin D and cytokines (IL10, IL6, IL-1β and IL-1ra) using Luminex technology with cognitive performance in adults (> 30 years) and older adults (> 60 years). Cognitive performance was measured using the Montreal Cognitive Assessment tool, the Rey complex figure test and Symbol digit modalities. Since age-related cognitive decline is associated with increased inflammatory cytokines and low vitamin D levels, we expected that older adults will have more prominent deficits in vitamin D, higher pro-inflammatory cytokines and impaired cognitive function, so they were investigated as a separate group. Preliminary results showed a significant positive correlation between cognitive performance and vitamin D level. The cytokine analysis and patterns are in progress.

P6.01.10
Comparative study of the antiinflammatory effect of Inca Inchi oils (*Plukenetia volubilis* and *Plukenetia huayllabambana*)

***S. R. Dávila Paico**, C. Pitot, D. Zegarra Ruiz, M. A. Cabello Napurí, F. Saldaña Morales, T. Ysmodes Nastasi, Y. Álvarez Valdivia, C. Ocampo Acuña, I. Lozada Requena, J. Aguilar Olano;*
Universidad Peruana Cayetano Heredia, Lima, Peru.

Due to the high content of omega-3 contented in both varieties of Inca Inchi oil, its anti-inflammatory capacity was measured at different concentrations in vivo.
METHODS: It was orally administered 10, 17.4, 30.2, 52.5, 91.2 and 150mL/kg orally of both oil varieties to determine the median lethal dose (LD50). The animals were observed for 7 days. The LD50 value was determined by statistical Probits method.
It was orally administered 5, 10, 20 and 40mL/kg of both oils for 7 days to determine the anti-inflammatory effect. In addition, there were three control groups: negative (no inflammation, no treatment), anti-inflammatory (inflammation + indomethacin) and Positive control (inflammation + no treatment). One hour after administration of the last dose it was applied 0.05ml of λ-carrageenan 1% into the right paw. The inflammation was measured 2 hours after administration of λ-carrageenan, using a micrometer. All mice were taken for histological analysis.
RESULTS: LD50 for *P. volubilis* was 68,723mL/kg, and for *P. huayllabambana* was 80,505 ml/kg, concluding the product as Non-toxic (William´s classification). Histopathological analysis showed villous atrophy and hyperplasia of intestinal epithelium in the last two doses for both oils. In the antiinflammatory assay we found a statistically significant inflammation reduction for both oils. Obtaining the following inhibition percentage: *P. huayllabambana*= 52%, *P. volubilis*= 45% y Indomethacin= 49%. Histopathological study showed fewer inflammatory cells at the last two doses for both oils.
CONCLUSIONS: Both Inca Inchi oils are non-toxic products and reduce inflammation. The variety *P. huayllabambana* appears to be the most effective.

P6.01.11
Iron overload can suppress IL-23 expression from human monocyte-derived dendritic cells and subsequent downstream Th17 expansion

***C. M. A. Dee**, K. W. Cheung, J. Shen, G. C. F. Chan;*
The University of Hong Kong, Pokfulam, Hong Kong.

Introduction: Thalassemia, the most common monogenic disease in the world, has a global carrier rate of 1.5%. The 70,000 infants born with thalassemia major present with severe, transfusion-dependent anemia that, left untreated, is incompatible with life. Iron overload is the most common complication arising from treatment. It is also a

significant risk factor for infection. Infection due to iron overload is a major cause of death in these children. We investigated the role of iron overload on dendritic cells, the most potent antigen-presenting cells.
Methodology: We treated human monocyte-derived dendritic cells (moDC) with various doses of iron citrate in order to investigate the effect of iron overload on moDC maturation, cytokine production and CD4 T cell activation. IL-23 was measured by qRT-PCR and ELISA. Mixed leucocyte reaction was done with iron-treated moDCs; CFSE cell proliferation and immunofluorescent staining of intracellular cytokines IFN-g and IL-17 were measured by flow cytometry.
Results and Conclusion: Addition of iron citrate suppresses IL-23 expression at both mRNA and protein levels whereas it does not affect moDC maturation. Iron treated moDC significantly reduced T helper 17 (Th17) cell differentiation as measured by mixed leukocytes reaction. In conclusion, our study demonstrated that iron-overloaded human moDCs can suppress IL23 production and downstream expansion of Th17 cells, possibly a contributing factor to increased susceptibility to infection in transfusion-dependent thalassemias.

Antioxidant compounds suppress activity of diamine oxidase (DAO)

J. M. Gostner[1]*, K. Becker*[1]*, F. Überall*[1]*, D. Fuchs*[2]*;*
[1]*Division of Medical Biochemistry, Center for Chemistry and Biomedicine, Medical University Innsbruck, Innsbruck, Austria,*
[2]*Division of Biological Chemistry, Center for Chemistry and Biomedicine, Medical University Innsbruck, Innsbruck, Austria.*

About 1 % of the population presents with histamine intolerance or sensitivity, a suffering characterized by the appearance of various allergy-like symptoms. Histamine is a biogenic amino acid that is contained in many foods, but can also be synthesized and released by a variety of cell types. In healthy people, histamine is degraded by the enzyme diamine oxidase (DAO) that is secreted into circulation upon stimulation. Inefficient degradation gives rise to high intestinal histamine, which is suggested to be responsible for the symptomatology, as histamine is a potent mediator of inflammation and allergic reactions.
Several studies already have discussed the involvement of exogenous antioxidants and “antioxidative stress” in the development of allergies. To analyse the influence of selected compounds on DAO, DAO enzyme activity was examined by using radiolabelled putrescine dihydrochloride as substrate. Plasma samples from healthy human donors or DAO purified from porcine kidney were pre-incubated with curcumin, sodium benzoate or sodium sulphite. After liquid extraction, the reaction product Δ1pyrroline has been measured. The exposure to the compounds resulted in a dose-dependent reduction of enzyme activity. If this in vitro effect of a suppression of DAO can be extrapolated to in vivo, it opens another possibility how overload with antioxidants may promote allergy development.
Although in vitro only, our results emphasize an additional effect to the suppression of Th1-type immune reactions and cytokines by antioxidant compounds, which was demonstrated earlier for food preservatives, colorants, phytochemicals and drugs, thus promoting a shift of the Th1-Th2-type immune balance towards Th2-type immunity.

P6.01.13
Ayurvedic myrobalane extracts inhibit LPS-induced tryptophan breakdown in THP-1 cells

K. Becker[1]*, **J. M. Gostner***[1]*, A. Klein*[1]*, S. Schröcksnadel*[2]*, B. Magnus*[1]*, M. Jenny*[1]*, D. Fuchs*[2]*, F. Überall*[1]*;*
[1]*Division of Medical Biochemistry, Center for Chemistry and Biomedicine, Medical University Innsbruck, Innsbruck, Austria,*
[2]*Division of Biological Chemistry, Center for Chemistry and Biomedicine, Medical University Innsbruck, Innsbruck, Austria.*

Triphala, a traditional multicomponent preparation composed of the three fruits amla (Phyllanthus emblicae fructus), chebulic (Terminalia chebula fructus) and beleric myrobalan (Terminalia bellirica fructus), is recognized for its beneficial action in the treatment of intestinal disturbances, impaired liver function and inflammation. The impact of aqueous-ethanolic fruit extracts on cell viability, tryptophan breakdown, neopterin and the activation of the redox-sensitive transcription factor nuclear factor-κB (NF-κB) was determined in human myelomonocytic leukemia THP-1 and THP-1-blue cells.
During human immune response, pro-inflammatory cytokines stimulate the enzyme indoleamine 2,3-dioxygenase (IDO) to convert the essential amino acid tryptophan into kynurenine. In parallel, GTP-cyclohydrolase I (GCH) is induced to produce neopterin. Increased neopterin concentrations and accelerated tryptophan breakdown indicate the activation of the cell-mediated immune system.
THP-1 cell treatment with fruit extracts (25, 50 µg/ml) resulted in a partial reduction of lipopolysaccharide (LPS) induced enhanced neopterin formation and tryptophan breakdown in comparison to non treated stimulated controls. Furthermore, all extracts induced a slight but significant suppression of NF-κB basal activity in unstimulated THP-1-blue cells (NF-κB reporter cells). Interestingly, in LPS-stimulated cells, an adverse effect could be observed for Terminalia chebula and Triphala extract at the highest concentration (200 µg/ml), while lower concentrations (25 - 100 µg/ml) did not achieve significant effects on the expression of NF-κB.
Our in vitro data show immunmodulatory effects of Triphala components that are exerted mainly on the response of stimulated THP-1 cells in a suppressive manner. It could relate to the anti-inflammatory properties of the extracts described from traditional medicine applications.

P6.01.14
Resveratrol enhances TNF-α production of human monocytes upon TLR-stimulation

G. Gualdoni*, J. Kovarik, D. Doberer, F. Dose, P. Steinberger, M. Wolzt, G. J. Zlabinger;*
Medical University Vienna, Vienna, Austria.

Objectives
Resveratrol has been shown to possess anti-oxidant, anti-aging, anti-cancer and anti-inflammatory properties. Although numerous data is available concerning in vitro effects and animal studies, only limited data is available in humans. The purpose of this study was to analyze immunomodulatory properties of the substance in humans and elucidate its molecular action.
Materials and Methods
A pilot study was performed including 10 healthy probands (8=Resveratrol, 2=placebo). Serum cytokine levels (IL-12p40, IL-6, IL-8, IL-10 and TNF-a) were measured over 48 hours after oral application of 5g Resveratrol.
To elucidate the in vivo findings, cytokine release of human PBMCs and monocytes (cytokines as above plus IL-1ß) was measured after incubation with Resveratrol and stimulation with different TLR-agonists. Signaling pathways involved were analyzed utilizing a monocytic NF-κB Reporter cell line and by western blotting of NF-κB pathways components and MAPKs.
Results
Resveratrol treated volunteers presented with significantly elevated levels of TNF-α 24 hours after the application, whereas cytokine levels in the placebo group remained equal. The in vitro analysis of human PBMCs and monocytes showed potently enhanced TNF-α production by Resveratrol treated cells upon LPS stimulation on protein and gene transcription level. Enhanced TNF-α production was also observed upon TLR-2 and TLR-5 targeting. Evaluation of the molecular mechanisms revealed an intense enhancement of alternative p105 dependent NF-κB signaling in Resveratrol treated monocytes, while canonical activation of NF-κB via IκB was unaffected.
Conclusions
Our data suggest not exclusively anti-inflammatory, but differential modulatory effects of Resveratrol on cytokine release of innate immune cells.

P6.01.15
Inhibition of matrix metalloproteinase-9 activity in a leukemic cell line by Mentha spicata extract in vitro

***F. Hajighasemi**;*
Department of Immunology, Faculty of Medicine, Shahed University, Tehran, Iran.

Introduction: Angiogenesis has an important role in cancer growth and metastasis. Matrix metalloproteinases (MMPs) are a large family of proteases degredate the extracellular matrix and have a significant role in tumor angiogenesis. The essential role of angiogenesis in leukemic patients has been reported. Current therapeutic methods in leukemia have not been very successful. Medicinal plants are widely used in treatment of cancers. Mentha spicata is a herb with known anti-tumor activities. In the present study, the effect of aqueous extract of Mentha spicata on MMP-9 activity in leukemic U937 cells has been assessed in vitro.
Materials and methods: U937 cells were cultured in RPMI with 10% FBS. Then the cells at logarithmic growth phase were incubated with different concentrations of aqueous extract of Mentha spicata (0.1 - 10 mg/ml) in the presence or absence of phorbol 12-myristate 13-acetate (PMA) (25 ng/ml) for 24, 48 and 72 hours. The MMP-9 activity in conditioned medium was evaluated by gelatin zymography.
Results: Mentha spicata aqueous extract significantly decreased the PMA-induced MMP-9 activity in leukemic U937 cells dose and time dependently.
Conclusions: The aqueous extract of Mentha spicata showed inhibitory effect on MMP-9 activity in U937 leukemia cells. So the anti-tumor effects of Mentha spicata may be in part due to its inhibitory effects on MMP-9 activity and consequently angiogenesis. Therefore Mentha spicata might have potential implication in leukemia treatment. Identification the effective element (s) in the Mentha spicata extract with anti-MMP activity could be valuable in designing new natural MMP suppressors.

P6.01.16
Labdane-type diterpene, constituent from myoga which are traditional Japanese food inhibit enzyme activity and gene expression of indoleamine 2,3-dioxygenase 1

***S. Imai**[1], R. Yamamoto[2], Y. Yamamoto[2], M. Abe[3], Y. Ozawa[3], Y. Katayanagi[4], T. Nakayama[1], K. Saito[2];*
[1]University of Shizuoka, Suruga-ku, Shizuoka, Japan, [2]Kyoto University, Sakyo-ku, Kyoto, Japan, [3]Takasaki University of Health and Welfare, Takasaki, Japan, [4]Nisshin Pharma Inc., Fujimino, Tsurugaoka, Japan.

The activity of indoleamine 2,3-dioxygenase 1 (IDO-1), that catalyzes the degradation of tryptophan (Trp) into kynurenine (Kyn) increases after various inflammatory diseases. IDO-1 has an important immunomodulatory function in certain immune-related diseases.
We have developed a cell-based assay to evaluate the suppressive effect of phytochemicals or plant extracts on IDO-1 expression. When stimulated by INF-γ and LPS, profound high expressions of IDO-1 mRNA were detected in human monocyte THP-1 cells and were verified by quantitative real-time PCR.
Twenty two kinds of plants extracts and eleven kinds of phytochemicals were examined by the cell-based assay. As a result, the methanol extracts of Myoga flower buds which are traditional Japanese foods, and labdane-type diterpene galanal derived from the Myoga flowers significantly suppressed IDO-1 expression. The experiments using IDO-1-transfected HEK293 cells clarified that galanal inhibits not only the gene expression but also the enzyme activity. Galanal inhibited IDO-1 enzyme activity in a concentration-dependent manner with an IC_{50} value of 7.7 μM. The Lineweaver-Burk plot analysis indicated competitive inhibition of recombinant IDO-1 by galanal. Galanal decreased the Kyn concentration and recovered the Trp concentration in THP-1 cells stimulated with IFN-γ and LPS. Galanal suppressed the expression levels of pro-inflammatory cytokines. Interestingly, galanal up-regulate IFN-β, IL-2 and IL-3 gene expression levels. Galanal induced apoptosis in T cells by reduction of the Bcl-2: Bax ratio. Because the inhibitory activity of galanal is stronger than 1-methyl Trp which is a Trp analog, galanal may have a great potential as the novel drug for various immune-related diseases.

HemoHIM, a novel composition of medicinal herbs, restores the lasting imbalance of Th1- and Th2-related immune response in *gamma*-irradiated mice and in aged mice

***S. Jo**, H. Park, U. Jung;*
Korea Atomic Energy Research Institute, Jeongeup-si, Republic of Korea.

Whole body irradiation brings down-regulation of the Th1-like immune response, resulting in an immunological imbalance for the long term. In ageing, one of serious problems is a shift towards a dominance of Th2 related response. HemoHIM, a mixture of 3 edible herbs, had been previously developed to protect the self-renewal tissues and promote the recovery of immune system against acute radiation syndrome. The current study was to evaluate the possibility of HemoHIM to restore the lasting immunological imbalance in γ-irradiated mice and in aged mice. The mice were exposed to γ-rays twice a week for a total dose of 5Gy. 12-month-old mice were used as aged mice. The irradiated mice were administrated orally with HemoHIM (100 mg/kg BW) from 1 week before the first irradiation for 4 or 6 months. The aged mice were intubated with HemoHIM for 3 weeks. HemoHIM ameliorated the lasting imbalance between Th1- and Th2-related immune responses that showed up in irradiated mice and in aged mice. In irradiated mice and in aged mice, HemoHIM restored the NK cell activities despite not changing the NK cell percentages. Moreover, the lasting low levels of IL-12p70 in irradiated mice and in aged mice were ameliorated by administrating HemoHIM. HemoHIM enhanced the phosphorylation of STAT4 that was decreased in the irradiated mice. Our findings showed that HemoHIM can ameliorate the lasting down-regulation of Th1-like immune responses by modulating IL-12p70/pSTAT4 signaling pathway in irradiated mice and in aged mice.

P6.01.18
Implications of the O-GlcNAc modification in the regulation of nuclear apoptosis in T cells

***B. Johnson**, J. Bernier;*
INRS-IAF, Laval, QC, Canada.

O-linked β-N-acetylglucosamine (O-GlcNAc) is a nutrient-/stress-sensitive post-translational modification that affects nucleocytoplasmic proteins. Glucose, glucosamine and glutamine are the three major carbon and nitrogen donors for UDP-GlcNAc production. O-GlcNAcylation plays a role in fundamental regulatory mechanisms through the modification of proteins involved in cell division, metabolism, transcription, cell signaling and apoptosis. The aim of our research is to determine the implications of O-GlcNAc on T cell apoptosis. Human T lymphoblastic HPB-ALL cells were treated with an O-N-acetylglucosaminidase inhibitor (PUGNAc) or with glucosamine (GlcN) to increase O-GlcNAcylation. Apoptosis was induced in the presence of tributyltin (TBT) and DNA fragmentation was observed by cell cycle analysis. O-GlcNAcylated proteins were precipitated using succinylated wheat germ agglutinin (sWGA) for further western-blot identification. Our results showed that HPB-ALL cells treated with PUGNAc displayed a significant reduction in DNA fragmentation after TBT-induced apoptosis. DFF45, the protein that inhibits the endonuclease DFF40 in the heteromeric DNA fragmentation factor (DFF) complex, was identified as an O-GlcNAcylated protein. This modification appears to give DFF45 a stronger resistance to caspase cleavage during apoptosis. O-GlcNAcylation of DFF45 may represent a mechanism to control the accidental activation of DFF. Several publications in the last decade have shown a similar protective role of O-GlcNAc against different kinds of stress. Previous work from our laboratory showed that an enteral supplementation of glutamine helped reduce the morbidity and mortality of burn patients. The next step in our research will be to investigate the role of O-GlcNAc modifications in this protection.

P6.01.19

Alliin diminished pro-inflammatory cytokines in supernatants of an in vitro model of adipose tissue.

R. I. Lopez-Roa[1], *S. M. Quintero-Fabian*[2,3], *T. M. Garcia-Iglesias*[4], *J. M. Viveros-Paredes*[1], *D. Ortuño-Sahagun*[5];

[5]*Departamento de Biologia Celular y Molecular, CUCBA,Universidad de Guadalajara, Guadalajara, Mexico.*

Obesity is accompanied by chronic inflammation and is characterized as a disorder having an imbalance between pro-inflammatory and anti-inflammatory mediators. A high -fat diet can increase LPS absorption from gut in to the circulation. On the other hand, different functional foods and phytochemicals have been associated with various health benefits when consumed. The main active component in garlic is the S-allyl cysteine sulfoxide, commonly called alliin, has been reported as a potent anti-diabetic and anti-inflammatory. Pre-adipocyte murine 3T3-L1 cell line has been considered for years, an in vitro model of adipose tissue (AT). We differentiated cells with a hormonal cocktail to mature adipocytes. We added a treatment with alliin (0.1mM) to adipocytes for 24 hours, after that we stimulated cells with LPS (100ng/ml) for an hour. Finally IL-6 and MCP-1 were evaluated in supernatants collected at 6, 12 and 24 hours after LPS stimulus and stored at -20°C until quantification by Luminex technology. Aliin diminished significantly the synthesis of MCP-1and IL-6 in the group Alliin+LPS compared to LPS group. Our recent observations indicated that exposure of 3T3-L1 adipocytes to the phytochemical alliin, is able to suppress LPS-evoked molecular inflammatory signals by causing a decrease in the levels of pro-inflammatory cytokines like IL-6 and MCP-1 on the supernatants of this in vitro model of AT.

P6.01.20

The activity of autoreactive IgG antibodies may be blocked by human serum and breast milk immunoglobulins

I. Manoylov[1], *I. Djoumerska-Alexieva*[1], *J. Dimitrov*[2], *A. Tchrobanov*[1];
[1]*The Stephan Angeloff Institute of Microbiology, Sofia, Bulgaria,*
[2]*INSERM, Paris, France.*

In the immune system of healthy individuals can be found B cells that produce IgG antibodies specific to a variety of self antigens. These natural autoreactive antibodies are found in the serum and in the intravenous immunoglobulin preparations. They are able to interact with antigens which are target of some pathological autoantibodies. The auto reactivity of natural IgG antibodies can be induces by extreme environmental conditions during purification (high and low pH values). This activity is not observed when using non-denaturating methods of purification.
The in vitro interactions between human serum from a healthy individuals, or pooled human IVIg or breast milk immunoglobulins and human liver antigens were investigated. IgG antibodies were purified by two different methods: immunoaffinity elution (using low pH value buffers) and soft salt precipitation (without extreme value buffers). Based on their molecular mass, the purified IgA and IgM molecules were obtained from the different fractions of serum and colostral proteins.
Serum or breast milk IgM and IgA isolated by immunoaffinity elution can block the interaction of eluted IgG antibodies or pooled IVIg preparation to human liver antigens. The fraction containing immunoglobulin F(ab')2 fragments has the same ability.
The results show that binding of auto-reactive IgG antibodies to self-antigens can be inhibited by serum as well as mucosal IgA and IgM. Our study supports previous findings that IgM has a major role in blocking the IgG autoantibodies. We suppose that pooled human IgM and IgA preparations may have a positive immunomodulatory activity in patients with autoimmune diseases.

P6.01.21

Difference in reaction patterns of M1 and M2 macrophages induced by quercetin

M. Matsushima, *A. Oomura, K. Mori, N. Ogasawara, K. Takemura, H. Nose, T. Yamaguchi, Y. Kodera, M. Shiga, T. Kawabe;*
Department of Pathophysiological Laboratory Sciences, Nagoya University Graduate School of Medicine, Nagoya, Japan.

Macrophages show significant heterogeneity in function and are classified into two groups: M1 and M2 macrophages. M1 macrophages mainly produce proinflammatory mediators whereas M2 macrophages produce high amounts of anti-inflammatory mediators. Quercetin, one of the flavonoids, exhibits an anti-inflammatory effect via heme oxygenase (HO)-1-dependent pathway in M1 macrophages stimulated with lipopolysaccharide (LPS), a ligand for toll-like receptor (TLR) 4. Although the anti-inflammatory action of flavonoids in M1 macrophages has been studied elsewhere, less is known about the effect of quercetin in M2 macrophages. In this study, we investigated the difference in reaction patterns between M1 and M2 macrophages stimulated with TLR, especially TLR3, 4, and 7 and the effect of quercetin on these TLR-induced activation of M1 or M2 macrophages. M1 macrophages increased the expression of IL-1β, IL-6, and IFN-β more than M2 macrophages after stimulation with LPS. In contrast, M2 macrophages strongly induced the expression of IL-1β, IL-6, and IFN-β compared to M1 macrophages after stimulation with imiquimod, a ligand for TLR7. The extent of induction of these cytokines were comparable in M1 and M2 macrophages when stimulated with poly I:C, a ligand for TLR3. Quercetin inhibited IL-1β, IL-6, and IFN-β expression induced by TLR3, 4, or 7 via HO-1-dependent manner. Based on these results, M1 and M2 macrophages exhibited different responsiveness to TLRs, and quercetin inhibited macrophage activation by TLR3, 4, or 7 via HO-1-dependent pathway.

P6.01.22

Expression of cytokines that regulate immune responses in alpaca (Vicugna pacos)blood leukocytes stimulated by clostridial antigens and retinoic acid

J. More Bayona, *A. Manchego, K. Chiok, R. Lázaro, N. Sandoval, H. Rivera, M. Ramírez;*
Universidad Nacional Mayor de San Marcos, Lima, Peru.

Expression levels of cytokines involved in humoral and cellular responses were determined *in vitro* in blood leukocytes from alpacas, stimulated with *Clostridium perfringens* (AgCP) antigens and retinoic acid (ATRA) as adjuvant. Different treatments were tested as follows: 10ng AgCP and 0.25mUI ATRA; 1ng AgCP and 2.5mUI ATRA; 100pg AgCP and 25mUI ATRA; 10pg AgCP and 250UI ATRA. Treated and untreated leukocytes were incubated at 37C for 24 hours after which total mRNA was extracted. We used real time RT-PCR and relative quantification to assess difference in expression of cytokines in leukocytes in comparison with untreated cell controls. We found increasing expression of IFNγ and Interleukin-2 (IL-2) in all treatments up to 100pg of AgPC and 25UI ATRA (8:1 y 7.5:1, respectively). In case of Tumoral Necrosis Factor alfa (TNF-α), increasing expression was observed until 10pg of agCP and 250mUI of ATRA (10.3:1) were used. As for Interleukin 10 (IL-10), it reached maximum expression when 1ng of AgCP and 2.5mUI of ATRA were used (27.4:1). Taken together, our results suggest clostridial antigens and ATRA confer good stimulation of cellular immune responses in alpaca leukocytes; however, lower concentrations of both, antigen and adjuvant, were able to induce maximum expression of IL-10. We thank Consejo Nacional de Ciencia y Tecnología (CONCyTEC - Perú) for financial support.

P6.01.23
Expression of humoral and cellular immune response cytokines in alpacas (*Vicugna pacos*) treated orally with a combination of clostridial antigens and retinoic acid

***J. More Bayona**, A. Manchego, K. Chiok, D. Pezo, N. Sandoval, H. Rivera, M. Ramírez;*
Universidad Nacional Mayor de San Marcos, Lima, Peru.

Enterotoxemia is a deadly enteric disease caused by *Clostridium perfringens* which can affect up to 80% of newborn alpacas raised extensively in the highlands of Peru. Mucosal immunization could be a feasible alternative to control this disease. We assessed the expression levels of the main cytokines controlling humoral and cellular immune responses in gut tissue collected from animals treated orally with a combination of retinoic acid and clostridial antigens in dose of 0.25mg/Kg of antigen and 0.067mM/Kg of retinoic acid (ATRA). Animals were treated twice with this combination; second dose was given 7 days after the first one as a boost. We extracted total ARNm from gut tissue samples of treated animals and performed real time RT-PCR aided by relative quantification, comparing treated animals with non-treated controls. We observed greater expression of Interferon-γ (IFN-γ) ($p<0.013$), Interleukin-2 (IL-2) ($p<0.027$) and Tumoral Necrosis Factor alfa (TNF-α) ($p<0.007$) in treated animals compared to controls. No difference was observed between these groups in expression of Interleukin-4 (IL-4)or Interleukin-10 (IL-10). Our results suggest this treatment is effective in stimulating cellular immune responses in gut tissue of alpacas. We thanks to Consejo Nacional de Ciencia y Tecnología (CONCyTEC - Perú) by financing support.
Key words: enterotoxemia, retinoic acid, cytokines, alpaca.

P6.01.24
Immune-modulatory properties of cinnamaldehyde are associated with the induction of apoptosis in immune cells

***A. Moskovskich**[1], C. Gomez-Casado[2], A. Willensdorfer[1], J. Singer[3], H. C. Fuchs[4], F. Roth-Walter[1], E. Jensen-Jarolim[1,3];*
[1]University of Veterinary Medicine Vienna; Messerli Research Institute; Comparative Medicine, Vienna, Austria, [2]Technical University Madrid, Center for Plant Biotechnology and Genomic, Madrid, Spain, [3]Medical University of Vienna, Department of Pathophysiology and Allergy Research, Vienna, Austria, [4]University of Applied Sciences Technikum Wien, Department of Biochemical Engineering, Vienna, Austria.

Background: Cinnamaldehyde (CA) has been reported to have anti-inflammatory, anti-bacterial, anti-fungal, anti-mutagenic, chemoprotective and anticarcinogenic activity. Here, we further investigated the immune-modulating capacity of CA.
Methods: NF-κB activation by CA (0-10µg/ml) alone or in combination with lipopolysaccharide (LPS) was assessed using the THP1XBlue© human monocytic cell line transfected with an alkaline phosphatase reporter. IL10 and nitric oxide (NO) secretion in murine RAW264.7 cells and human peripheral blood mononuclear cells (PBMCs) stimulated with CA alone or in conjunction with LPS were analyzed. Human PBMCS were stimulated with different concentrations of CA alone or in combination with LPS for 24h and subsequently stained with AnnexinV and propidium iodide to assess cell death and apoptosis.
Results: Incubation with CA resulted in a concentration-dependent inhibition to a maximum of 50% of NFκB in LPS-stimulated THP1-cells. Similarly, NO as well as IL10 secretion induced by LPS in RAW264.7 cells were blocked by addition of CA. Induction of apoptosis in human PBMCS was triggered by CA alone or in conjunction with LPS. These results correlated with a dose-dependent decrease in IL10 by addition of CA in LPS-stimulated PBMCS.
Conclusion: Anti-inflammatory properties of CA are likely due to blocking of NFκB-pathway and induction of apoptosis in immune cells.

P6.01.25
The effect of quercetin on the activated alveolar macrophages

***H. Nose**, M. Matsushima, A. Oomura, K. Mori, N. Ogasawara, K. Takemura, T. Yamaguchi, Y. Kodera, M. Shiga, T. Kawabe;*
Nagoya University Graduate School of Medicine, Nagoya, Japan.

Alveolar macrophages (AMs) belong to M2 type macrophages and play an important role in innate and adaptive immunity in lung by phagocytosing, killing of microorganisms, and activation of other inflammatory cells. We have previously reported that quercetin, one of the flavonoids, exhibited an anti-allergic action via upregulation of heme oxygenase (HO)-1 activity in mast cells. HO-1 is known to exert protective effect against lung injury. In the present study, we determined whether quercetin could lead to an anti-inflammatory effect through induction of HO-1 expression against the oxidative stress in AMs. We showed that quercetin induced the expression of HO-1 in AMJ2-C11 cells, an AM cell line, and mouse bronchoalveolar lavage fluid (BAL) macrophages. When activated by LPS/IFN-γ stimulation, quercetin significantly suppressed nitric oxide (NO) generation and inducible NO synthase (iNOS) expression, and these cytoprotective effects were HO-1-dependent. Furthermore, quercetin inhibited TNF-α, IL-1β, and IL-6 expression induced by LPS/IFN-γ in HO-1-dependent manner in AMJ2-C11 cells. In conclusion, quercetin may well be one of the therapeutic agents to prevent the early stage of lung injury. We are now investigating the signaling mechanisms of quercetin that increase HO-1 expression, focused on Nrf2, Keap1, and Bach1, the molecules that regulate HO-1 expression.

P6.01.26
***Cucumis sativus* aqueous extract protects against different metabolic syndrome- associated pathologies**

***G. Rosas**[1,2], P. Nuñez[1], A. Arteaga[1], M. Martínez[1], C. Trejo[1], A. Zamilpa[3], J. Tortoriello[3], G. Arrelín[1], E. Jimenez[3], G. Fragoso[4];*
[1]Universidad Autónoma del Estado de Morelos, Mexico, Mexico, [2]Facultad de Medicina, UAEM, Mexico, Mexico, [3]Centro de Investigación Biomédica del Sur, IMSS. Xochitepec, Morelos, Mexico, Mexico, [4]Universidad Nacional Autonoma de México, IIB, Mexico, Mexico.

Metabolic syndrome (MS) is an ensemble of disorders including visceral obesity, dyslipidemia, hyperglycemia, and hypertension. Chronic inflammatory alterations and oxidative stress have been identified as major components of MS. Cucumber (*Cucumis sativus*) is a popular vegetable, widely used in traditional medicine as anti-diabetic. This study is aimed to evaluate whether oral treatment with aqueous extracts of *C. sativus* (AqECs) on murine obesity or hypertension models could control the inflammatory response and the pathophysiological damage derived from these two MS-associated pathologies. The protective effects of the daily administration of AqECs were evaluated on obesity or hypertension murine models induced by a hyper-caloric fat intake diet and AgII chronic administration, respectively. Blood pressure, serum glucose levels and tissue IL6, IL10, IL4, and IL1β levels were studied. Tissue damage and immunolocalization of cytokines were also evaluated by histological examination. AqECs were able to reduce systolic and diastolic blood pressure; they controlled weight and Body Mass Index increase, and lowered serum glucose concentrations and tissue pro-inflammatory cytokines (IL6 and IL1β) with respect to non-treated obese or hypertensive mice. Increased levels of the anti-inflammatory IL10 cytokine were also observed in AqECs-treated animals. Also, kidney and liver damage induced by AgII chronic administration was controlled. Overall, this study suggests that AqECs possess anti-inflammatory, antiglycemic and anti-hypertensive effects that may be relevant in controlling the several disorders associated with MS. Project supported by CONACyT CB-169011

P6.01.27
Cytoprotective activity of Georgian Red Grapes Extract in mitogen-activated Jurkat cells

***T. Sanikidze**, G. Sharashenidze, L. Ratiani;*
Tbilisi State Medical University, Tbilisi, Georgia.

The aim of the study – establishment of the cytoprotective action of Georgian Red Grapes Extraxt (GRGE) on incubated in oxidative stress conditions and mitogen-activated Jurkat cells (Intensively proliferated Jurkat leukemic T cell line, DSMZ-Deutshe Sammulung von Mikroorganismen und Zellkulturen (Germania)) modeling systems. Experiments were conducted on intact, Hydrogen peroxide(H_2O_2)- and phytohaemagglutinin(PHA)-stimulated Jurkat cells. Cytoprotectiv activity of GRGE was established according viability of the cells (activity of mitochondrial dehidrogenases (MTT test)) and intensity of apoptosis, calculated on the basis of MTT test data.
It was revialed the dose and time-related decrease of viability of Jurkat cells incubated in high oxidative stress conditions. GRGE reveal static activity on viability of Jurkat cells incubated in moderate oxidative stress condition (H_2O_2 25 µl, 50 µl); in intensive oxidative stress condition (H_2O_2 100 µl), the cytoprotective activity of GRGE was rather low.
The viability of Jurkat cells decreases (apoptosis intensity increases) with rising ratio of PHA-activated and nonactivated cells in incubation medium ($[Jurkat]_{PHA}/[Jurkat]_{intact}$). GRGE increases viability of PHA-stimulated Jurkat cells and prevents their apoptosis.

P6.01.28
Chrysin regulates mast cell activation via HO-1-independent pathway

***M. Shiga**, M. Matsushima, A. Teranishi, H. Nose, N. Ogasawara, K. Takemura, T. Yamaguchi, Y. Kodera, T. Kawabe;*
Department of Pathophysiological Laboratory Sciences, Nagoya University Graduate School of Medicine, Nagoya, Japan.

Flavonoids are a kind of polyphenolic compounds and ubiquitously present in vegetables, fruits, and teas. Flavonoids possess many beneficial effects including anti-oxidant, anti-tumor, anti-inflammatory, anti-allergic, and anti-viral actions. We previously reported that quercetin, one of the flavonoids, exerted anti-allergic effects via heme oxygenase (HO)-1 activity in mast cells. Chrysin, also one of the flavonoids, is contained in propolis, blue passion flower, and fruits. Although several studies have reported that chrysin had anti-allergic activities, the precise mechanism is unclear. In this study, we investigated the mechanism by which chrysin could exhibit an anti-allergic activity in rat basophilic leukemia (RBL-2H3) cells and mouse bone marrow-derived mast cells (BMMC). Our results demonstrated that chrysin did not increase the expression of HO-1 despite the significant inhibition of degranulation and cytokine mRNA expression. Chrysin-induced inhibition of degranulation was unaffected by the addition of HO-1 inhibitor. These findings suggested that chrysin showed anti-allergic activities via HO-1-independent pathway in mast cells. Chrysin inhibited the translocation of stromal interaction molecule (STIM) 1, an endoplasmic reticulum Ca^{2+} sensor controlling store-operated Ca^{2+} entry, to the plasma membrane after stimulation with thapsigargin. These findings suggested that chrysin might regulate calcium mobilization by inhibiting STIM1 activation to exhibit anti-allergic effects in mast cells.

P6.01.29
Methanol extract of *Origanum vulgare* ameliorates autoimmune diabetes in mice

***I. D. Stojanovic**[1], M. Vujicic[1], I. Nikolic[1], V. Kontogianni[2], P. Charisiadis[2], A. G. Tzakos[2], S. Stosic-Grujicic[1];*
[1]Institute for Biological Research "Sinisa Stankovic", University of Belgrade, Belgrade, Serbia, [2]Department of Chemistry, University of Ioannina, Ioannina, Greece.

Type 1 diabetes (T1D), an autoimmune inflammatory disorder, develops as a consequence of pancreatic beta cell destruction mediated by various pro-inflammatory mediators. Since current T1D therapy mainly involves insulin replacement, constant efforts are being directed toward establishing novel therapeutic approaches. Plants or plant extracts are inexhaustible source of medicinal compounds. In this study we have used methanol extract of *Origanum vulgare* (oregano - OE) that has already shown immunomodulatory and cytoprotective properties *in vitro*. OE was prepared from oregano leaves by sequential extraction of four solvents of gradually increasing polarity (hexane, ethyl acetate, dichloromethane and methanol). To evaluate the effect of OE on diabetes development, the extract was administered intraperitoneally to C57BL/6 mice that were subjected to T1D induction by multiple low doses of steptozotocin (MLDS). Results indicate that 10-day OE treatment significantly reduced the incidence and the level of hyperglycemia in MLDS-treated mice and preserved physiological insulin concentration (measured by ELISA). Flow cytometric analysis revealed a reduction in $CD4^+$ cell number within spleen and pancreatic lymph nodes of OE-treated mice. This was accompanied by a significant inhibition of *ex vivo* Th17-related IL-17 secretion, while proto-typical Th1 and Th2 cytokines (IFN-γ and IL-4, respectively) remained unchanged. Further, the presence of $FoxP3^+$ T regulatory cells in lymphoid tissues of OE-treated mice was similar to diabetic mice as well as the percentage of pro-inflammatory $F4/80^+CD40^+$ M1 and anti-inflammatory $F4/80^+CD206^+$ M2 macrophages. In conclusion, our results indicate that OE protected mice from diabetes development through direct blockade of IL-17-mediated lymphocyte response.

P6.01.30
Evaluation of of crude extracts of sea cucumbers *Holothuria lecospilota* Genus in persion gulf effects on COX-2 and VEGF genes expression and PGE2, VEGF secretion levels in comparison with celecoxib on colorectal cancer cell line

***M. Taghdiri**[1], A. Khodadadi[1,2], M. Assarehzadegan[1], N. Adibpour[3];*
[1]Department of Immunology ,School of Medicine of Ahvaz Jundishapur University of Medical Sciences., Ahvaz, Iran, [2]Cancer and Bioenvironmental Pollutants Research Center of Ahvaz Jundishapur University of Medical Sciences., Ahvaz, Iran, [3]Department of medical chemistry, School of pharmacy, ahvaz jundishapur university of medical science., Ahvaz, Iran.

The sea cucumber is an important food and traditional medicine in Asian countries But The Persion Gulf Sea cucumber *Holothuria lecospilota* is largely un-know for its cytotoxic and anti-inflammatory activities. The aim of this study was determine cytotoxic and anti inflammatory effect of persion sea cucumber and compare with celecoxib.
Colorectal cancer cell line SW 742 were expose to Body wall, Culomic fluide, Internal viscera extraction of sea cucumber, (10, 50, 100 µgr/ml) for 18 h. Following exposure to the sea cucumber, expression levels of COX-2 and VEGF were determined with Real-Time PCR and PGE2 and VEGF secretion levels were determined by ELISA. The capacity of extracts to inhibit SW 742 growth was tested by MTT assay.
Body wall extract of *Holothuria lecospilota* siginificantly inhibited the secretion of VEGF and PGE2 by inhibiting VEGF and COX-2 at their protein and gene levels. All three fractions showed no significant ($p < 0.05$) cytotoxicity on SW 742.
In general, in this study we found that *Holothuria leucospilota* can acts as an anti-inflammatory and anti-cancer agent and no toxicity and could be entering it to food chain and taking advantages of this food.

P6.01.31
In vitro immunomodulatory and cytoprotective effects of Origanum vulgare methanol extract

***M. Vujicic**[1], I. Stojanovic[1], I. Nikolic[1], V. Kontogianni[2], P. Charisiadis[2], A. G. Tzakos[2], S. Stosic-Grujicic[1];*
[1]Institute for Biological Research, Belgrade, Serbia, [2]University of Ioannina, Ioannina, Greece.

In addition to being a spice, Origanum vulgare is recognized as a source of natural antioxidants and exerts anti-fungal, anti-bacterial

and anti-inflammatory actions. In this study we focused on the immunomodulatory effects of methanol fraction of Origanum vulgare (oregano extract - OE) and on its influence on cellular viability. The methanol OE was prepared from ground oregano leaves by sequential extraction of four solvents of gradually increasing polarity (hexane, ethyl acetate, dichloromethane and methanol). Our results indicate that 48-hour treatment of spleen mononuclear cells with OE (25 - 100 μg/ml) did not alter their basic or concanavalin A-triggered proliferation (MTT assay), as well as IFN-γ and IL-4 secretion determined by ELISA. However, OE treatment decreased IL-17 secretion implying a potential inhibitory effect on Th17 cells. Additionally, OE seemed to affect macrophage cytocidal function since it down-regulated production of nitric oxide (NO) in peritoneal cells (PC) (measured by Griess reaction) without an effect on PC viability. However, PC-related IL-1β and TNF-α remained unchanged after OE treatment. Finally, apoptosis measurement by histone-DNA ELISA showed that OE rescued isolated pancreatic islets from cytotoxic effect of cytokines. Furthermore, OE fully preserved beta cell function judging by impaired insulin secretion. The mechanism of OE-exerted protection of pancreatic islets was NO-independent since OE did not change islet NO production. In conclusion, OE alters secretory pattern of immune cells and protects pancreatic islets from cytokine-mediated destruction. The observed immunomodulatory and islet cytoprotective effects of OE are being further explored for potential application for diabetes treatment.

Evaluation of the relationship between obesity and pro- and anti-inflammatory cytokines in postmenopausal breast cancer patients

***R. Andrade**, H. C. do Nascimento, A. B. Santana, M. S. C. Gurgel, F. L. P. Costa, S. de Barros-Mazon;*
State University of Campinas, Campinas, Brazil.

Aim: This study evaluated the circulating levels of TNF alpha, IL17, IL10 and IL27 in breast cancer patients and their association with obesity and with the clinical-pathological characteristics of the disease.
Method: Seventy-six consented patients, aged 45 to 80 years, were enrolled and classified in two groups based on the anthropometric criteria: body mass index (BMI) plus absence or presence of abdominal fat. Serum samples from both groups were analyzed for TNF alpha, IL17, IL10 and IL27 by Luminex (Millipore). The cytokines levels were also evaluated in relation to clinical-pathological information (TNM staging, estrogen and progesterone receptor status(ER,PR) and HER-2 expression). Data were analyzed using SPSS 16 and the probability value (p) of 0.05 or less was considered significant.
Results: All patients expressed serum TNF alpha and IL27, but only 53.4% and 11.8% presented IL10 and IL17 respectively. The levels of all cytokines were not different between the groups classified by anthropometric measures and they were not associated with TNM staging, RE status or HER-2 expression, except for TNF alpha that showed a tendency (p= 0,0695) to be higher in patients with RP negative tumors. There was also a tendency of direct correlation between TNF alpha and IL27 (p= 0.0540).
Conclusion: The results showed that in the present study there was no association of TNF, IL27, IL17 or IL10 levels with obesity. The absence of detection of IL10 and IL17 in some patients might suggest that the production of these cytokines is down regulated in them.

P6.02.02
Arginine depletion during ocular autoimmune responses: in vitro study on bovine explants

***H. Belguendouz**[1], K. Lahmar-Belguendouz[1], L. M. Ahmedi[1], D. Messaoudene[1], Z. Djeraba[1], O. S. Lahlou-Boukoffa[2], C. Touil-Boukoffa[1];*
[1]Cytokines and NO Synthase team, LBCM, FSB, USTHB, Algiers, Algeria, [2]Clinique d'Ophtalmologie, CHU Ibn Rochd, Annaba, Algeria.

During ocular autoimmunity, the local and the infiltrated cells express NOS2, which produce high amounts of nitric oxide (NO). We have previously shown that this reactive molecule has deleterious effects on ocular structures in vitro. Arginase can compete with NOS for their shared substrate, L-arginine. In order to investigate in vitro arginases involvement in the down modulation of ocular NO production in response to ocular auto-antigens, different explants from enucleated bovine eyes were cultured in either MEM or DMEM with FBS (10%) in presence or absence of purified S antigen (ocular auto-antigens) (20μg/ml) with or without hydrocortisone (10μg/ml). After incubation at 37°C in humidified atmosphere with CO2 (5%) during 24h and 48h, NO and urea were assessed in culture supernatants by modified Griess and Berthelot methods respectively. We observed that S antigen increases significantly NO and urea concentrations in all explants culture supernatants ($p<0.01$). However, our results showed different production kinetics depending on the culture medium ($p<0.01$) and the explants' type ($p<0.05$). We noticed with interest that NO production was earlier than urea production. Furthermore, hydrocortisone significantly increased urea production while reduced NO concentrations ($p<0.01$). Our study suggests that arginases may act in NOS inhibition during ocular inflammation by arginine depletion and act as one of the anti-inflammatory molecular mechanism of glucorticoids in situ.

P6.02.03
Respiratory complex III (CIII) or Adenin-Nucloeotide Transporter (ANT) inhibition diminishes human monocyte inflammatory capacity

***E. D. Cerezo**[1,2], L. A. Flores-Mejía[3,2], F. J. Sánchez-García[1], C. R. López-Macías[2], A. Isibasi[2], L. A. Arriaga-Pizano[2];*
[1]Laboratorio de Inmunorregulación, Departamento de Inmunología, Escuela Nacional de Ciencias Biológicas, Instituto Politécnico Nacional, Mexico City, Mexico, [2]Unidad de Investigación Médica en Inmunoquímica, Hospital de Especialidades "Bernardo Sepúlveda", Centro Médico Nacional Siglo XXI IMSS, Mexico City, Mexico, [3]Departamento de Inmunología, Escuela Nacional de Ciencias Biológicas, Instituto Politécnico Nacional, Mexico City, Mexico.

Metabolic failure associated with mitochondrial dysfunction has been reported in sepsis, severe sepsis and septic shock. In peripheral blood mononuclear cells, enzimatic activity of respiratory chain is decreased in sepsis, and ATP synthase and oxygen consumption are reduced during septic shock. Circulating monocytes with mitochondrial depolarization is found in septic shock. It remains unknown if mitochondrial dysfunction is related with poor inflammatory response, allowing development of secondary infections. We decided to analyze whether inhibition of mitochondrial function is associated with the inflammatory capacity of circulating monocytes. Peripheral blood obtained from healthy adults, was incubated with or without antimycin A or bongkrekic acid for one hour. Afterwards, lipopolysaccharide (LPS), peptidoglycan (PGN) or polyI:C was added; two hours later CD14, TREM-1, HLA-DR and CD16 was determined. Plasma was collected to measure IL-8, IL-1β, IL-6, TNF and IL-10 at 6hrs. Viability and mitochondrial membrane potential ($\Delta\Psi m$) was verified at all times and conditions. Viability of leukocytes was over 95%. Depolarization induced by antimycin A was associated with decreased expression of CD14, TREM-1 and HLA-DR; after LPS stimulation, we observed no secretion of IL-8, IL-1β, IL-6, IL-10 and TNF, and no secretion of IL-8 and IL-6 after polyI:C treatment. Bongkrekic acid-induced hyperpolarization prevents LPS-induced augmentation of TREM-1 and HLA-DR in monocytes; in LPS condition diminished IL-1β and TNF and no IL-8, IL-6 and IL-10 secretion was observed. Inhibition of CIII or ANT decreases inflammatory capacity of human circulating monocytes in ex vivo stimulation, probably collaborating with so called "immune paralysis".

P6.02.04

The human intermediate monocyte subset can be further subdivided on the basis of HLA-DR expression revealing a distinct abnormality in obesity and diabetes

M. C. Dennedy[1]*, E. Connaughton*[1]*, S. Slevin*[1]*, S. A. Hanley*[2]*, T. O'Brien*[1]*, R. Ceredig*[1]*, M. D. Griffin*[1]*;*
[1]Regenerative Medicine Institute, School of Medicine, National University of Ireland, Galway, Galway, Ireland, [2]Flow Cytometry Core Facility, NCBES, National University of Ireland, Galway, Galway, Ireland.

Current monocyte classification recognises "classical" ($CD14^{++}/CD16^{-}$), "intermediate" ($CD14^{++}/CD16^{+}$) and "non-classical" ($CD14^{+}/CD16^{++}$) subsets. In this study, proportions and absolute numbers of monocyte subsets were compared by flow cytometry among: Healthy, non-obese adults (n=33); Obese, non-diabetic adults (n=40) and Obese adults with type 2 diabetes (n=53). In addition to CD14 and CD16, monocytes were stained for a range of surface markers and were analysed for uptake of acetylated low density lipoprotein (LDL) using bodipy® labelling.
Among healthy, non-obese adults, intermediate monocytes contained distinct sub-groups with mid- and high-level expression of HLA-DR subsequently referred to as DR^{mid} and DR^{hi} intermediate subpopulations. These represented 14% and 7% of the total monocytes respectively. DR^{mid} intermediates were also distinguishable from DR^{hi} by higher side scatter, higher expression of CCR2, PSGL1, TLR4 and CD36 and lower expression of CD45 and CX3CR1. Obese, non-diabetic adults had significantly lower classical and higher intermediate monocyte numbers compared to non-obese adults, but the increase in intermediates was entirely accounted for by the DR^{mid} subpopulation. A similar abnormality was observed in obese diabetics although total monocyte numbers were lower in this group. In multivariable analyses, DR^{mid} intermediate numbers and proportions correlated significantly with key metabolic indicators (BMI, LDL level, glycosylated haemoglobin). Of all monocyte subpopulations, DR^{mid} intermediates exhibited the highest uptake of acetylated-LDL *in vitro*.
Further subdivision of intermediate monocytes based on HLA-DR expression identifies two distinct subpopulations. Analysis of these subpopulations in the context of obesity and diabetes demonstrates a potentially important clinical relevance to such a subdivision.

P6.02.05

Clinical-immunological assessment of therapy effect of the neuro-sensory-motor integration program of reflex patterns in airway chronic inflammatory diseases

S. K. Masgutova[1]*, N. K. Akhmatova*[2]*,* ***O. V. Lebedinskaya***[3]*;*
[1]Educational Institute for Neuro-Sensory-Motor and Reflex Integration, Denver, FL, United States, [2]I.I. Mechnikov Research Institute for Vaccines and Sera, RAMS, Moscow, Russian Federation, [3]Acad. E.A. Wagner Perm State Medical Academy, Perm, Russian Federation.

Airway chronic inflammatory diseases and recurrent exacerbations are mainly caused by damage of immune regulation mechanisms. Treatment of chronic inflammatory diseases of respiratory tract in children and adults was carried out by combining complimentary therapy using the method of neuro-sensory-motor reflex patterns integration (NRI), which works with primary motor system activation and conventional treatment; the parameters of the immune status and the cortisol level in children suffering from of a recurrent obstructive bronchitis are studied, as well as the assessment of therapy efficiency based on NRI method is done. It is established that combining the therapy using primary motor system/reflex integration with the conventional treatment allows correcting the immune system mechanisms' damage to a certain extent mainly to normalize the amount of T lymphocytes (CD3, CD4, CD8) and NK-cells, metabolic function of leukocytes, the level of regulatory and anti-inflammatory cytokines. The therapy based on neuro-sensory-motor reflex patterns integration (NRI) improves the effect of standard therapy on immune system cells and strengthens the polarization of immune response to Th-1 type. It decreases the frequency of airway viral inflammatory diseases, leads to positive dynamics of chronic respiratory diseases and prolongs their remission.

P6.02.06

Diet enriched with small carbohydrate and saturated fat is able to alter immunological parameters in C57BL/6 mice

M. C. G. Miranda, J. L. Goncalves, T. G. Moreira, L. G. Teixeira, A. L. Souza, D. C. Cara, ***T. U. Maioli****, A. C. Faria;*
Universidade Federal de Minas Gerais, Belo Horizonte, Brazil.

The World Health Organization defines obesity as an excess of body fat accumulated in the white adipose tissue with implications for health. Adipose tissue promotes a chronic inflammatory process with progressive infiltration of lymphoid and myeloid cells during his expansion. These features suggest the relevant communication between metabolism and inflammation. This study aimed to evaluate different dietary formulations, using butter and sugar and their effects on metabolic parameters and inflammatory infiltrate in the adipose tissue. At the end of 11 weeks, the percentage of weight gain was 27.36±6.14 (standard commercial diet, SCD), 39.00±3.00 (standard purified diet, SPD), 32.92±3.41 (high sugar, HS) 67.67±2.75 (high fat, HF) 64.00 ± 4.60 (high sugar fat, HSF). We found increasing in epididymal fat tissue of the groups HF and HSF compared to the SCD, SPD and HS. Insulin resistance was observed in the groups HF and HSF. We also observed an increase fasting glucose levels of HSF compared to the SCD, SPD and HS. Animals submitted to HF and HSF had a reduction in frequency of spleen NK. Animals fed with HSF diet showed a reduction in frequency in Foxp3+ regulatory T cells compared to the other groups. We could not find differences in frequency of CD4+, CD8+ and CD19+ cells in all tissue evaluated. In conclusion HF diet and HSF were efficient in inducing obesity, insulin resistance and up regulate the inflammation by reducing the frequency of Foxp3+ cells in C57BL6 animals.

P6.02.07

Macrophages, but not adipocytes, express TNFa in diet induced visceral obesity

M. F. McInerney*, L. A. Ebke, B. Slotterbeck, A. L. Nestor-Kalinoski, A. G. Al Dieri, S. Ghosh, S. M. Najjar, H. von Grafenstein;*
University of Toledo, Toledo, OH, United States.

In this study, the role of macrophages, adipocytes, and cytokines in diet-induced obesity was investigated. Laser scanning confocal microscopy analysis of adipose tissue, from mice fed a high-fat diet or a high-fat/high carbohydrate diet, detected macrophages in inflammatory crown-like structures surrounding adipocytes, and at high magnification many of the macrophages were lipid laden. The majority of macrophages in white adipose tissue expressed TNFa and a few expressed both TNFa and IL-10. Occasionally adipocytes expressed IL-10, but not TNFa. Adipose tissue from obese mice was digested by collagenase treatment and fractionated by density centrifugation into an adipocyte floating layer and a pellet of stromal vascular cells. qPCR analysis revealed a high level of adiponectin mRNA, which is an adipocyte marker, in the floating layer, and no adiponectin in the stromal vascular cells indicating cleanly separated cell populations. The floating adipocyte layer did have a high level of TNFa mRNA, but also contained a high level of F4/80 mRNA indicating the persistent presence of macrophages. Further investigation, by laser scanning confocal microscopy of the floating layer cells, revealed that macrophages either ingest sufficient lipid to be buoyant or remain tightly adherent to adipocytes even after digestion to single adipocytes. The majority of the adherent macrophages expressed TNFa and thus were proinflammatory, while there was no evidence for adipocyte expression of TNFa. Therefore, our data do not support previous reports indicating TNFa expression in adipocytes. We believe that contamination by macrophages in the purified adipocyte floating layer explains the TNFa expression.

P6.02.08
Activation markers show greater expression on adipose tissue resident T-lymphocytes with increased adiposity

*R. Travers[1], **A. C. Motta**[2], J. Betts[1], D. Thompson[1];*
[1]University of Bath, Bath, United Kingdom, [2]Unilever R&D, Vlaardingen, Netherlands.

The presence of T-lymphocytes in human adipose tissue has only recently been demonstrated and relatively little is known of their potential relevance in the development of obesity-related diseases. We aimed to further characterise these cells and investigate how they vary with increased adiposity and other markers of metabolic health. Subcutaneous adipose tissue samples were obtained from 17 'healthy' male subjects with waist circumferences ranging from 80.9 to 117.2 cm. Cells comprising the stromovascular fraction were obtained by collagenase digestion of adipose tissue and analysed by flow cytometry. CD4+ and CD8+ T-lymphocyte populations together with macrophages were identified and T-lymphocytes were further characterised by their expression of activation markers CD25 and CD69.
Although the overall proportions of CD4+ and CD8+ T-lymphocytes as a percentage of total cells within the SVF were not correlated with measures of adiposity, there were significant correlations between waist circumference and expression of activation marker CD69 on CD4+ ($R=0.775$, $p<0.001$) and CD8+ cells ($R=0.618$, $p<0.01$) and CD25 on CD4+ ($R=0.602$, $p<0.01$) and CD8+ cells ($R=0.478$, $p<0.05$). In addition, the proportion of macrophages correlated with waist circumference ($R=0.638$, $p<0.005$) and other measures of adiposity. The increased T-lymphocyte activation and proportion of macrophages further correlated with measures of adipocyte size and serum leptin. Our results suggest that T-lymphocyte populations in the SVF are more activated with increased adiposity and we propose that leptin may be important in their regulation as part of metabolic and immune system cross-talk within adipose tissue.

P6.02.09
Galectin-3 deficiency accelerates high-fat diet induced obesity and diabetes by amplifying metaflammation

***N. Pejnovic**[1], J. Pantic[1], I. Jovanovic[1], G. Radosavljevic[1], M. Milovanovic[1], I. Nikolic[2], N. Zdravkovic[1], A. Djukic[3], N. Arsenijevic[1], M. Lukic[1];*
[1]Faculty of Medical Sciences, University of Kragujevac, Kragujevac, Serbia, [2]Institute for Biological Research 'Sinisa Stankovic', University of Belgrade, Beograd, Serbia, [3]Center for Endocrinology, Diabetes and Metabolic Diseases, Clinical Center Kragujevac, Kragujevac, Serbia.

Obesity-induced diabetes is associated with low-grade inflammation in adipose tissue and infiltration of macrophages in pancreatic islets. Galectin-3 (Gal-3), a galactoside-binding lectin, has a role in inflammation, uptake and removal of metabolic compounds. We show that ablation of Gal-3 accelerates high-fat diet-induced obesity and diabetes. Wild-type and $LGALS3^{-/-}$ mice on a C57BL/6J background were fed either high-fat (60% fat) or a low-fat diet (3% fat) for 11 or 18 weeks. The increased body weight, amount of total visceral adipose tissue (VAT), fasting blood glucose and insulin levels, homeostasis model assessment of insulin resistance and systemic inflammation were observed in high-fat diet-fed $LGALS3^{-/-}$ mice compared to diet-matched WT animals. Obese $LGALS3^{-/-}$ mice had increased incidence of Type-1 T and NKT lymphocytes and pro-inflammatory $CD11c^{+}CD11b^{+}$ macrophages and decreased $CD4^{+}CD25^{+}FoxP3^{+}$ Tregs and M2 macrophages in VAT. The severe insulitis, increased expression of NLRP3 inflammasome and IL-1ß in macrophages and increased accumulation of advanced glycation endproducts (AGE) and receptor for AGE (RAGE) expression in pancreatic islets of obese $LGALS3^{-/-}$ animals were associated with elevated expression of phospho-NFκB p65 and mature Caspase-1 protein in pancreata and VAT. $LGALS3^{-/-}$ peritoneal macrophages stimulated with lypopolysaccharide (LPS) and saturated fatty acid palmitate *in vitro* produced increased Caspase-1 dependent IL-1β and had increased expression of NLRP3 inflammasome and phospho-NFκB p65 compared to WT macrophages. Transfection of $LGALS3^{-/-}$ macrophages with NLRP3 inflammasome siRNA attenuated IL-1β production in response to palmitate and LPS plus palmitate. Obtained results suggest important protective roles for Gal-3 in obesity-induced inflammation and diabetes.

P6.02.10
P2X7 receptor expression and potential role in T cells in Type 1 Diabetes

***L. Perruzza**, F. Grassi;*
Institute for Research in Biomedicine IRB, Bellinzona, Switzerland.

The P2X7 receptor is an ATP-gated ion channel expressed in a variety of cell types. In the immune system, the function of P2X7 has been mostly studied in macrophages and T cells. ATP-mediated P2X7 activation facilitates macrophage maturation and IL-1β secretion. Moreover P2X7 stimulation by high concentration of ATP induces T cell apoptosis.
Although *p2rx7* has been proposed as a type 1 diabetes (T1D) susceptibility gene in NOD mice, its potential pathogenic role has not been directly determined. To test this possibility we investigated *p2rx7* expression in various T cells subsets namely $CD4^{+}CD62L^{high}CD44^{low}$ naive and $CD4^{+}CD62L^{low}CD44^{high}$ effector from pancreatic lymph nodes of healthy , prediabetic and overtly diabetic NOD mice. *p2rx7* expression significantly increases in $CD4^{+}$ T effector cells of prediabetic NOD mice but dramatically decreases in NOD mice with overt disease. Since *p2rx7* is silenced by cognate antigen stimulation these observations underscore the relevance of pancreatic epitope spreading in the development of T1D in NOD mice. Down regulation of *p2rx7* would render effector T cells resistant to apoptosis induction by extracellular ATP generated by inflammatory tissue damage, thereby propagating and sustaining tissue destruction. The role of P2X7 activity in limiting the T cell diabetogenic potential was supported by T1D induction with low-dose of streptozotocin in *p2rx7* knock-out mice, which developed a significantly more severe disease than the wild-type counterpart. Our study suggests that P2X7 could constitute a therapeutic target in the early phases of T1D by promoting apoptosis of potentially diabetogenic effector T cells.

P6.02.11
Insulin resistant obese individuals have increased frequency of CD14++CD16+ monocytes, what is modulated by a bout of aerobic exercise

***E. Rocha-Vieira**, M. Matos, T. Duarte, V. Ottone, K. Costa, G. Brito-Melo, F. Amorim;*
Federal University of Jequitinhonha and Mucuri Valleys, Diamantina, Brazil.

The expansion of the CD16+ monocytes has been suggested to occur in human obesity, a low-grade chronic inflammation condition. In this study the frequency of different monocytes subpopulations in obese insulin-sensitive (OB, n=9) (BMI 33.5 ± 2.8 kg/m2, HOMA-IR 0.5 ± 2 mmol.μU/L²) and insulin-resistant individuals (OBR, n=9) (BMI 34.8 ± 2.7 kg/m2, HOMA-IR 4.0 ± 1.0 mmol.μU/L²), before and after a session of aerobic exercise (AE) (3 sets of 20 minutes, at 60% of VO2 peak, in cycle ergometer) was determined. Control eutrophic individuals (CTRL, n=9) (BMI 22.7 ± 2 kg/m2, HOMA-IR 1.0 ± 0.3 mmol.μU/L²) were also enrolled in the study. At baseline, the frequency of intermediate monocytes was higher in the OBR (22.26 ± 12.26%) than in CTRL (7.67 ± 5.37%) ($P = 0.013$, two-way Anova), and AE reduced the frequency of these cells ($P = 0.003$), with a tendency of time versus condition interaction ($P = 0.060$). Additionally, reduced values ($P = 0.051$) were found for OBR (-7.8 ± 8.72%) compared to CTRL (-1.54 ± 1.92%) considering the effect of exercise on the frequency of intermediate monocytes (delta of variation). For classical and nonclassical monocytes, no differences were observed among the groups nor there was effect of exercise. A positive correlation between the frequency of intermediate monocytes and the percentage of body fat, BMI and HOMA1-IR was observed. These data demonstrate that obese insulin resistant individuals, but not insulin sensitive ones, have increased frequency of intermediate monocytes, what is modulated by a single session of exercise.

P6.02.12
The regulatory role of amino acids in the immune response

***N. Salyha**;*
Institute of Animal Biology, Lviv, Ukraine.

L-glutamic acid (L-Glu) plays an important role in maintaining of lymphocytes homeostasis and their function. Metabolic processes occurring in the organism at stresses and diseases lead to use of a large number of L-Glu. The deficiency of L-Glu reduces resistance to infections but additional input of L-Glu enhances the activity of lymphocytes, including increased synthesis of interleukin (IL)-2 and γ-interferon. Further, as an immediate precursor for glutathione synthesis, glutamate plays an important role in the removal of oxidants and regulation of the immune response.
Our research has focused on studying of the additional introduction of L-Glu on the functional activity of T-and B-cell immunity for the actions of the stress and under normal conditions, on the analysis of correlative links between the immune and antioxidant systems, elucidation of the mechanisms involved in this process. Immunological reactivity of the organism was evaluated.
Our results have shown that L-Glu stimulated processes of cell activation, proliferation and differentiation. Total number of T-lymphocytes and rosette forming T lymphocytes with a high density of receptors decreased in animals subjected to stress and which did not received L-Glu. L-Glu affected the functional activity of T-helpers. Introduction of L-Glu lead to the activation of T- and B-cell immunity and receptor structures of lymphocytes. In particular, activation of the immune system led on improvement of parameters antioxidant defense system. L-Glu promotes increasing protective forces of organism, which may indicate a likely increase in T-helper cells with low and medium density of receptors.

P6.02.13
The peptide hormone Insulin-like growth factor-1 affects the immune system during physiological and pathological inflammatory responses

***S. Sattler**[1], B. Johannesson[2], J. Tonkin[1], E. Gallego-Colon[1], D. Bilbao[2], E. Semenova[3], N. Rosenthal[1];*
[1]Imperial College London, London, United Kingdom, [2]European Molecular Biology Laboratory (EMBL), Monterotondo, Italy, [3]Kings College London, London, United Kingdom.

The peptide hormone Insulin-like growth factor-1 (IGF-1) is an essential regulator of survival, growth and differentiation. It is produced in several isoforms that differ in their N-terminal signal peptide as well as their C-terminal sequences termed extension (E) peptides. In adult mammals, IGF-1 is synthesized in the liver as a systemic growth factor as well as locally in a variety of extrahepatic tissues.
We have demonstrated previously that locally generated IGF-1 accelerates wound healing and enhances regeneration in skeletal muscle and the skin. This effect is partially due to the mitogenic properties of IGF-1 which induces increased proliferation in structural cell types, such as myocytes and keratinocytes. In addition however, accumulating evidence strongly suggests an effect of IGF-1 on a variety of immune cells and the immune system is well established as a crucial factor in orchestrating wound healing and tissue remodelling processes. Both innate cell types, including monocytes and macrophages, as well as adaptive immune cells such as T cells, express the IGF-1 receptor and are therefore able to directly respond to IGF-1 stimulation. Improved regeneration indicates a regulatory effect of IGF-1 on the immune response after tissue injury and in line with this we find that locally acting IGF-1 in the skin dampens the hyper-inflammatory reaction during contact hypersensitivity.
We therefore propose a role of IGF-1 on physiological immune responses during wound healing after tissue trauma as well as a potential therapeutic effect on hyper-inflammatory pathologies.

P6.02.14
Unsuspected relationship between Ferritin Heavy Chain and NK cells tumor susceptibility

***R. Sottile**[1,2], F. Santoro[1], C. M. Faniello[1], C. Garofalo[1], R. Tallerico[1,2], F. S. Costanzo[1], E. Carbone[1,2];*
[1]Department of Experimental and Clinical Medicine, University Magna Graecia of Catanzaro, Catanzaro, Italy, [2]Department of Microbiology, Tumor and Cell Biology, Karolinska Institutet, Stockholm, Sweden.

The iron metabolism is crucial for the success of microbial infections. Here, we explored the possible role of iron metabolism in modulating effector immune functions. The ability of pathogens to obtain iron from iron containing proteins of their host is central to whether they live or die. Ferritin is the major intacellular iron storage protein and serves to store iron in a non-toxic form, to deposit it in a safe form, and to transport it to areas where it is required. Ferritin concentrations increase drastically in the presence of ongoing infection or cancer. Previous work have shown that that ferritin plays a regulatory role immune system homeostasis. Here we report an ususpected role of Ferritin Heavy Chain (FHC) on tumor immunogenicity and NK cell susceptibility. By using several cancer cell lines in which FHC was downregulated we have demonstrated an increase in NK tumor cell specific lysis when FHC lack into cells. This correlate with the downregulation of the Major Histocompatibility Complex Class I (MHC class I), and an increased expression of the two DNAM1 NK recepror ligands, PVR and NECTIN 2, that we observe in all the downregulated cell lines.

P6.02.15
Modulation of lipid metabolism and colon cancer cell growth by Cyclosporin A

***M. B. F. Werneck**[1,2], M. C. Augustin[1], J. P. B. Viola[1], P. T. Bozza[2];*
[1]Instituto Nacional de Câncer, Rio de Janeiro, Brazil, [2]Fundação Oswaldo Cruz, Rio de Janeiro, Brazil.

Lipid droplets (LD) are inducible organelles that modulate cell signaling, lipid metabolism, membrane trafficking and synthesis and secretion of inflammatory mediators. LD accumulation within non-adipocytic cells is a frequently observed phenotype in inflammatory conditions. Conversely, chronic inflammation, as seen in obesity, is associated with carcinogenesis, being accumulation of LD a common feature of transformed cells and tissues. The Calcium/calcineurin signaling pathway, through activation of NFAT, is essential for effective immunity, and its inhibitors cyclosporin A (CsA) and FK506 are used in the clinics as immunosuppressants. Moreover, NFAT activity is associated with tumorigenesis. We therefore investigated the impact of NFAT inhibition in the expression of genes related to lipid metabolism and growth of four different human colon carcinoma cell lines in vitro. We found that in steady-state conditions, CsA treatment prevented PGE_2 production, slowed cell cycle progression and induced necroptosis in a TGF-β-, NF-κB- and PI3K/mTOR-independent fashion. Interestingly, these effects were calcineurin and NFAT independent since they were not reproduced by FK506 treatment. Upon stimulation with PMA+Iono, the up-regulation of fatty acid synthase, perilipin, ADRP and COX-2, and the accumulation of LD, were abolished by CsA pre-treatment. We conclude that treatment of human colon adenocarcinoma cells with CsA impairs cell cycle progression and necroptosis, besides altering activation-induced changes in lipid metabolism and LD biogenesis. It remains to be shown if the latter events are dependent on NFAT transcriptional activity or an NFAT-independent CsA effect.

P6.02.16
Enhanced glycogen synthase kinase 3beta phosphorylation modulates leukocyte Toll-like receptor-mediated cytokine secretion in obesity

C. Yen[1]*, C. Chang*[2]*, C. Wu*[2]*, C. Shieh*[3,4]*;*
[1]*Institute of Basic Medical Science, National Cheng Kung University, Tainan, Taiwan,* [2]*Department of Family Medicine, National Cheng Kung University Hospital, Tainan, Taiwan,* [3]*Institute of Clinical Medicine, National Cheng Kung University, Tainan, Taiwan,* [4]*Department of Pediatrics, National Cheng Kung University Hospital, Tainan, Taiwan.*

Obesity is a widespread disease which leads to type II diabetes mellitus and cardiovascular diseases. However, the impacts of obesity on immune function and infectious diseases have not been fully understood. To clarify the role of obesity in the immune responses, we investigated the relationship between insulin-induced signaling and Toll-like Receptors (TLRs)-induced leukocyte cytokine secretion in obese subjects. We found decreased TLR-induced IFN-γ, IL-6 secretion and elevated TLR-induced IL-1β, IL-10 secretion by leukocytes isolated from obese subjects when compared with normal leukocytes. Peripheral blood mononuclear cells (PBMCs) collected from obese subjects showed enhanced basal Akt/Glycogen Synthase Kinase 3β (GSK3β) phosphorylation which was not further increased by insulin and lipopolysaccharide (LPS). We also found that LPS-induced IκBα degradation was inhibited in obese subjects. We further investigated the role of GSK3β on transcription factors NF-κB and CREB activation. We found that insulin plus palmitate stimulation increased GSK3β phosphorylation and IκBα level in THP-1 cells. LPS-induced IκBα degradation was inhibited by GSK3β inhibitor LiCl and insulin plus palmitate stimulation. Moreover, NF-κB nuclear translocation was reversed by insulin plus palmitate stimulation and by GSK3β knockdown using lentiviral delivery of shRNA in THP-1 cells. GSK3β knockdown also enhanced CREB phosphorylation. These findings indicate that GSK3β is important in the regulation of NF-κB and CREB activation in cells under abnormal metabolic environment. Our study provides a possible mechanism of how metabolic abnormalities compromise leukocyte functions in humans with obesity.

P6.03 Pathogenesis and immunointervention in diabetes

P6.03.01
B-1 cells produce a insulin-like factor and regulate blood glucose levels in STZ-induced diabetic mice

A. M. Alvares[1]*, M. C. T. Novo*[1]*, J. T. Maricato*[1]*, A. Popi*[1]*, M. Mariano*[1,2]*;*
[1]*UNIFESP, São Paulo, Brazil,* [2]*UNIP, São Paulo, Brazil.*

A regulatory role of CD5+ B cells was described in diabetes model, although the role of these cells in diabetes is discordant. This study aims to investigate the involvement of B-1 cells in murine streptozotocin (STZ)-induced diabetes. C57/BL, BALB/c and BALB/xid (B-1 cells-deficient mice) male mice strains were treated intraperitoneally (i.p.) with STZ (40mg/kg) for 5 days. BALB/c mice do not develop diabetes when this dose of STZ was used. Animals were evaluated for blood glucose levels (BGL) and cell populations in the pancreas by flow citometry. Our findings show that in BALB/xid mice BGL were higher than C57/BL or BALB/c mice. To evaluate the role of B-1 cells in diabetes induction, peritoneal B-1 cells obtained from BALB/c mice were purified based on expression of CD19+ CD23- and adoptively transferred i.p. to BALB/xid mice before or after the STZ-treatment. BALB/xid mice adoptively transferred were not diabetic after STZ-treatment and B-1 cells infiltrate pancreatic islets in these animals. To investigate the mechanism that B-1 cells protect BALB/xid of STZ-diabetes, we treated BALB/xid diabetic mice with B-1 cells culture supernatants. BGL decrease in these animals 2 hours after injection and begins to return 4 hours after injection. In conclusion, our data show that B-1 cell-deficient mice showed higher reactivity to STZ-treatment. In addition, B-1 cells migrate to pancreatic islets of STZ-treated mice and are able to regulate BGL by secretion of a insulin-like factor.

P6.03.02
Regulation of inflammasome activation and its implication in diabetes-induced microangiopathies

B. Baban[1]*, F. Lamoke*[1]*, L. Di Renzo*[2]*, J. Liu*[1]*, A. Alvari*[1]*, M. Bartoli*[1]*;*
[1]*Georgia Regents University, Augusta, GA, United States,* [2]*University of Rome, Rome, Italy.*

Sterile inflammation and activation of the inflammasome are implicated in the development of diabetes complications. Oxidative stress has been shown to be a key pathogenic factor in the development and progression of diabetic microangiopathies such as diabetic retinopathy (DR). In this study we have analyzed the specific relationship between altered endogenous antioxidant activities and induction of sterile inflammation in diabetic patients and human post-mortem retinas from diabetic donors and normoglycemic control donors. Western blotting, immunohistochemistry, flow cytometry assay along with proteomic-based analysis were used to analyze protein level and activity of components of the thioredoxin (Trx) system in correlation with the expression pattern and protein-protein interaction of TLR4, NLRP3, and the thioredoxin-interacting protein (TXNIP). TLR4 expression was significantly increased in monocytes and lymphocytes of diabetic patients presenting clinical signs of DR. Analysis of human post-mortem diabetic retinas revealed impaired thioredoxin activity in diabetic retinas which correlated with increased expression of TXNIP, TLR4 and NLRP3. Proteomic analysis of TXNIP interactome revealed that TXNIP interacted with NLRP3 and TLR4 in the human diabetic retinas and that TXNIP was phosphorylated at specific serine residues. In conclusion our results show that sterile inflammation through activation of the NLRP3-inflammasome is directly involved in the pathogenesis of DR. In addition, our data reveal for the first time that TXNIP-induction of the inflammasome activation could be regulated by post-translational modifications such as serine phosphorylation.

P6.03.03
Autoimmune Anti-prothrombin Antibodies in Type 1 Diabetes Mellitus

F. Bakar[1]*, U. Ünlütürk*[2]*, N. Başkal*[2]*, S. Nebioğlu*[1]*;*
[1]*Ankara University School of Pharmacy, Department of Biochemistry, Ankara, Turkey,* [2]*Ankara University School of Medicine, Department of Endocrinology and Metabolism, Ankara, Turkey.*

Type 1 diabetes mellitus is a chronic autoimmune disease caused by specific immune destruction of the insulin producing pancreatic β-cells. The thrombotic factors and hypercoagulable state may be the cause of morbidity and mortality in diabetes mellitus. In the last decades, antiphosphoslipid (aPL) antibodies have been identified in various autoimmune diseases and prothrombin (PT) is recognized as one of the major antigenic target for aPL antibodies. Some studies have reported an association of anti-prothrombin (aPT) antibodies with thrombosis. The objective of this study is to evaluate the prevalence of autoimmune aPT antibodies in patients with Type 1 diabetes mellitus.
This study was performed with 125 patients with type 1 diabetes and 92 healthy volunteers were formed our control group. The quantitative determination of aPT IgG, IgM antibodies were performed by enzyme-linked immunosorbent assay.
aPT IgG antibodies were present at 50.57% of type 1 diabetic group whereas it was 2.16% for controls. The circulating levels of aPT IgG was significantly higher in type 1 diabetics (22.75±9.88 AU/ml) when compared to controls (4.65±2.05 AU/ml, $p<0.001$). We found elevated aPT IgM levels at 85.40% of type 1 diabetic patients.
In conclusion, we found high prevalence of aPT antibodies in type 1 diabetic patients. These findings may indicate the presence of high thrombotic risk in type 1 diabetes.

Ursolic acid effect on proinflammatory cytokines in response to diet-induced obesity in rats

***B. E. Bastidas-Ramírez**, A. S. González-Ballesteros, A. López-Vázquez, J. J. García-Bañuelos, A. S. Sandoval-Rodríguez, J. F. Muñoz-Valle, M. R. Bueno-Topete, S. Del Toro-Arreola, R. Del Angel-Meza, J. S. Armendáriz-Borunda;*
Universidad de Guadalajara, Guadalajara, Mexico.

BACKGROUND. Obesity represents a major metabolic alteration of worlwide impact. Inflammation constitutes a molecular feature in obesity mediated by the expression of TNF-α, IL-1 and MCP1, among other proinflammatory cytokines, which contributes to the development of associated morbidities. Antiinflammatory activity of Ursolic acid (UA), a pentacyclic triterpenoid, has been evidenced both *in vivo* and *in vitro* models. OBJECTIVE. The aim of this work was to evaluate the antiinflammatory effect of UA on diet-induced obese rats. MATERIAL AND METHODS. Antiinflammatory preventive effect of AU was assayed by intragastrically administering UA (50 mg/kg/day) together with a high-fat diet (HFD) to Wistar rats weighing 150-180 g during 3, 6, or 9 weeks. Antiinflammatory reversal effect of AU was evaluated by administering AU (50 mg/kg/day) during 3 weeks to previously HFD fed animals during 6 weeks. Control group received only HFD. ELISA and QPCR to quantify proteins and cytokines expression respectively, were performed. RESULTS. Comparisons were always assessed between experimental and control group. Adipose tissue relative expression of TNF-α was statistically lower ($p<0.05$) after 9 weeks of preventive treatment. Significantly ($p<0.05$) lower expression of IL-1 and MCP-1 was appreciated after 6 and 9 weeks of preventive treatment and also after reversal treatment. Circulating levels of TNF-α and IL-1 were not detectable. CONCLUSIONS. AU is capable to counteract obesity-induced inflammatory cytokine expression in animals fed HFD.

P6.03.05
Syngenic anti-idiotypic and anti-anti-idiotypic monoclonal antibodies raised against the rat monoclonal autoantibody IC2 and their role in prevention of autoimmune diabetes

*K. L. Jensen, C. P. Engmose, K. Engkilde, **C. Brogren**;*
The Bartholin Institute, Rigshospitalet, Copenhagen N, Denmark.

A pancreatic beta-cell surface specific monoclonal autoantibody IC2 has earlier been developed by hybridoma fusion of unimmunized diabetic BioBreeding (BB)-rat spleen cells with the HAT-sensitive rat myeloma cell line Y3-Ag123. We have now reinjected this IgM monoclonal autoantibody back into syngenic diabetes resistant BB rats and created new hybridomas from spleen cell fusion with the rat HAT-sensitive myeloma cell line YB2/O. We have thereby obtained both anti-idiotypic and anti-anti-idiotypic monoclonal antibodies against IC2. Eleven such anti-Id and 6 anti-anti-Id monoclonal antibodies are now under further investigation and preparative production for in vivo therapeutic trials. The monoclonal autoantibody IC2 has in vitro shown an almost 100% inhibition of Type-I NKT cell cytokine release most likely through binding to CD1d, which has recently been found on pancreatic beta-cells. Studies in animal models of autoimmune diabetes as well as diabetic children show that NKT functionality and number is affected. The in vitro observed inhibitory effect of IC2 on NKT cells is therefore interesting in vivo as well. We are currently purifying the newly developed anti-idiotypic antibodies for therapeutic trials in BB-rats to investigate further if some of our new monoclonal anti-idiotypic antibodies might have a preventive effect on diabetes. Futhermore, we have isolated anti-anti-idiotypic antibodies with similar specificity to the beta-cell surface as seen with the original IC2 autoantibody from the same fusion, leading us to believe that the idiotypic network could have an important role in diabetes prevention.

P6.03.06
Differential expression of microRNAs in type 1, type 2 and gestational diabetes pinpointed miR-142-5p as potential biomarker for diabetes mellitus

*C. V. A. Collares[1], A. F. Evangelista[2], D. J. Xavier[2], D. M. Rassi[1], M. C. Foss-Freitas[3], M. C. Foss[3], E. T. Sakamoto-Hojo[2], G. A. Passos[2], **E. A. Donadi**[1];*
[1]Division of Immunology - Faculty of Medicine of Ribeirao Preto, RIbeirao Preto, Brazil, [2]Department of Genetics - Faculty of Medicine of Ribeirao Preto, RIbeirao Preto, Brazil, [3]Division of Endocrinology - Faculty of Medicine of Ribeirao Preto, RIbeirao Preto, Brazil.

MicroRNAs are involved in several biological functions and processes following a tissue-specific expression, and control gene expression of one third of the genome. Several studies have been conducted to evaluate specifically expressed microRNAs in the diverse types of diabetes. In the present study we performed a meta-analysis of microRNA profiles of peripheral blood mononuclear cells (PBMC) from patients with type 1 (T1D), or type 2 (T2D), or gestational (GDM) diabetes mellitus using the microarray technology and *in silico* analyses for pinpointing specifically biomarkers for diabetes. Human microRNA microarray kits (v3) 8x15K were used to perform hybridizations of samples from T1D (n=7), T2D (n=7), and GDM (n=6) patients. Differentially expressed microRNAs were identified using the Rank products non-parametric method by the R package RankProd. Nine microRNA (hsa-miR-126, hsa-miR-1307, hsa-miR-142-3p, hsa-miR-142-5p, hsa-miR-144, hsa-miR-199a-5p, hsa-miR-27a, hsa-miR-29b, and hsa-miR-342-3p) were differentially expressed between T1D, T2D and GDM. Between them, the hsa-miR-142-5p had the best score of area under curve for roc curve in all comparisons. This microRNA was demonstrated to be a negative regulator of CD4 T cells, and was overexpressed in systemic lupus erythematosus CD4 T cells, which may reverse T cells hyperactivity and inhibit antibody production. No study described miR-142-5p in association with diabetes yet and we observed an increase expression of miR-142-5p from GDM to T1D to T2D. Taken together all data and literature information, we may suggest that miR-142-5p may be a good candidate for further studies aiming to find a biomarker for diabetes mellitus.

P6.03.07
TCRγδ T cells in human type 1 diabetes: evidence or clue ?

***G. Giamporcaro**[1,2], A. Valle[1,3], A. Stabilini[1], M. Battaglia[1];*
[1]San Raffaele Scientific Institute, Diabetes Research Institute, Milan, Italy, [2]University of Rome Tor Vergata, Rome, Italy, [3]Vita-Salute San Raffaele University, Milan, Italy.

TCRγδ T cells share features of both innate and adaptive immune responses. In humans, two main subsets of TCRγδ T cells have been described so far: Vδ2 cells, mainly circulating in the peripheral blood and Vδ1 cells, mainly tissue-resident. While the function of this (often neglected) cell subset in anti-tumor and anti-pathogen responses is well-established, their role in human autoimmune pathologies, including autoimmune type 1 diabetes (T1D), remains controversial. In this study we analysed the peripheral blood of paediatric patients with T1D at onset, paediatric subjects at-risk of developing T1D, and age-matched healthy donors. TCRγδ-cell frequency was decreased in patients with T1D (mainly due to Vδ1-cell reduction) while it increased in at-risk subjects (mainly due to Vδ2-cell expansion) as compared to those in healthy donors. The expression by TCRγδ T cells of membrane receptors such as NKG2D, CCR5, CXCR3, CXCR4, CD31 and CD161 was similar between all the groups of donors tested. Murine TCRγδ T cells $CD27^{neg}$ have been recently shown to produce high levels of IL-17 and infiltrate the pancreas of non-obese diabetic (NOD) mice, worsening the disease. We found that Vδ1 $CD27^{neg}$ T cells were present only in healthy donors and not in patients with T1D nor in at-risk subjects, suggesting a possible role for this subset also in human T1D. It is still unclear whether our findings corroborate a role for TCRγδ T cells in the pathogenesis of T1D or if they represent only an indirect and early marker of disease progression.

P6.03.08

Resistance of Diabetes in Aged NOD Mice is Mediated by $CD4^+CD25^+Foxp3^+$ Regulatory T Cells

Z. Guo[1], *B. Liu*[2], *L. Tian*[3], *B. Tian*[4], *A. Ansarullah*[1], *Y. Lu*[1], *M. Holstein*[1], *B. Deruyter*[1];
[1]*Sanford Research/USD, Sioux Falls, SD, United States,* [2]*Sheng Jing Hospital of China Medical University, Shenyang, China,* [3]*First Hospital of Guangxi Medical University, Nanning, China,* [4]*West China Hospital of Sichuan University, Chengdu, China.*

Some female NOD mice do not develop diabetes in pathogen-free housing facilities. We investigated the role of $CD4^+CD25^+$FoxP3+ regulatory T cells in diabetes resistance in aged NOD mice. At 60 weeks age, diabetes was developed between 74% and 79% NOD mice in 6 groups (n=600). Adoptive transfer of lymphocytes from diabetic NOD mice to aged nondiabetic NOD mice did not significantly increase the onset of diabetes. When $1x10^7$ lymphocytes from age NOD mice were co-transferred with $5x10^6$ lymphocytes from diabetes NOD mice into NOD.scid mice, all mice developed diabetes at 6 weeks. When $2x10^7$ lymphocytes from aged NOD mice were co-transferred, none developed diabetes at 6 weeks and only 50% NOD.scid mice developed diabetes at 12 weeks. When $1x10^6$ $CD4^+CD25^-$ T cells was co-transferred with $5x10^6$ lymphocytes from diabetic NOD mice, diabetes was developed in all NOD.scid mice. When $1x10^6$ $CD4^+CD25^+$ T cells were used, only 17% mice developed diabetes at 12 weeks. The percentages of $CD4^+CD25^+Foxp3^+$ T cells in the pancreatic lymph nodes, spleen and peripheral blood were 20.1±5.3%, 14.6±4.1% and 9.8±3.5% in aged NOD mice; and 5.8±1.5%, 8.6±0.7% and 6.4±1.7% in control diabetic NOD mice. When a low dose of cyclosphamiade was given, diabetes was developed in 75% young NOD mice and in 18% aged NOD mice. However, when the high dose was given, 58% aged NOD mice had diabetes and $CD4^+CD25^+Foxp3^+$ T cells in pancreatic lymph nodes were 7.0±1.7%. Our data demonstrated that immunoregulation through $CD4^+CD25^+Foxp3^+$ T cells mediated the resistance of diabetes in aged NOD mice.

The effect of induced hyperglycemia on the expression levels of TLR2 and TLR4 genes in the hippocampus of male Wistar rats during a time course induction of diabetes type 1

A. Haghparast[1,2], *A. Dehghani Firoozabadi*[1], *S. Shojaei*[1], *M. Behnam Rasouli*[1], *N. Mahdavi Shahri*[1];
[1]*Ferdowsi University of Mashhad, Mashhad, Iran,* [2]*Institute of Biotechnology, Mashhad, Iran.*

The relationship between inflammation and diabetic neuropathy progression included the processes and complex molecular networks. In this study the time course expression of toll like receptors (TLR2 and TLR4 (in hippocampal brain tissue of diabetic male Wistar rats were studied. Hyperglycemia was induced in male wistar rats with intraperitoneal (I.P.) injection of Streptozotocin. In different time points (4, 6, 8 and 20 weeks) post diabetes type 1 induction, rats were euthanized and hippocampal brain tissues was removed for further analysis. RNA was extracted from hippocampal brain tissues samples followed by cDNA synthesization using oligo-dT primers. Exon specific TLR2 and TLR4 primers were used to amplify rat TLR2 and TLR4 cDNA. After performing semiquantitative RT-PCR, the expression level of TLR4 mRNA was quantified by real time quatitative PCR (qPCR). Up-regulation of TLR2 and TLR4 transcripts during the time course after diabetes induction as compared to the control group was shown. Our results demonstrate that the expression of TLRs may play a decisive role in the pathogenesis and expansion of diabetes. It is possible that the expression of TLRs can eventually lead to neurodegenerative disease such as Alzheimer. Therefore, studies on the precise role of TLRs in neurodegenerative disease may yield potential molecular targets for developing therapeutics for control and prevention of diabetic neurodegenerative disorders.

P6.03.10

Appearance of beta cell autoantigen primed CD4+ T cells is synchronous to circulating islet autoantibodies in early pre-type 1 diabetes

D. Kuehn[1], *A. Heninger*[1], *C. Wilhelm*[1], *A. Eugster*[1], *S. Dietz*[1], *A. G. Ziegler*[2], *E. Bonifacio*[1];
[1]*Center for Regenerative Therapies Dresden, Dresden, Germany,* [2]*Helmholtz Zentrum, Muenchen, Germany.*

Islet autoantibody seroconversion is the first detectable evidence of ongoing autoimmunity in the process leading to type 1 diabetes. The incidence of islet autoantibody seroconverion is highest at around 1 year of age in genetically at risk children. Autoantibodies are markers of pre-diabetes, whereas beta cell destruction is mediated by T cells. Little is known of the timing of autoreactive T cell activation to beta cell antigens in the prediabetic period.
The BABYDIET study followed children with a strong genetic predisposition for type 1 diabetes frequently during infancy and offered the possibility to search for T cell activation against islet antigens. Samples were tested for CD4+ T cell responsiveness to GAD65 and Proinsulin before, at and after islet autoantibody seroconversion in antibody positive children and matched islet autoantibody negative children. CD4+ T cells responsive to GAD65 or Proinsulin with characteristics of memory in vivo primed cells were restricted to samples from children who had islet autoantibodies. Moreover, for both GAD65 and Proinsulin, these responsive cells were rare in samples taken prior to islet autoantibody seroconversion but appeared in significant numbers from the time of seroconversion. Cytokine gene expression in autoantigen responsive cells from one child was tested and showed a shift from IL-10 producing cells toward IFNγ producing cells with progression of autoimmunity.
Activation of T and B cell islet autoimmunity is synchronous in children. This implies that the peak incidence of islet autoimmunity around one year of age reflects a period of susceptibility to beta cell immunization.

P6.03.11

Relationship between BK_{Ca} channel and the apoptosis of NIT-1 cells induced by IFN-γ/IL-1β treatment

T. Yu[1], *J. He*[1], *S. Huang*[2], *H. Zhu*[1], *G. Shen*[1], *F. Gong*[1], ***P. Lei***[1];
[1]*Tongji Medical College, Wuhan, China,* [2]*Wuhan Institute of Biological Products Co.,Ltd, Wuhan, China.*

Increased evidence has suggested that apoptosis is likely to be the main form of β-cell death in early type 1 diabetes in rodents and human beings. Sub-cellular and mitochondria regulation of β-cell apoptosis has been extensively studied, while little attention has been paid to the ionic regulation mechanisms. The current density of high voltage-activated Ca^{2+} currents and cytosolic Ca^{2+} concentration ($[Ca^{2+}]_i$) in NIT-1 cells were increased by IFN-γ/IL-1β treatment. Blockade of L-type Ca^{2+} channel by nifedipine abrogated apoptosis of NIT-1 cells induced by cytokines. Chronic treatment with cytokines also increased the current density of K^+ currents in NIT-1 cells and the steady-state open probability (NPo) of the large-conductance Ca^{2+}-activated K^+ channel (BK_{Ca} channels). Low concentration TEA and IBTX (BK_{Ca} channels blockers) attenuates apoptosis of NIT-1 cells by IFN-γ/IL-1β. These results indicate that L-type Ca^{2+} channels and BK_{Ca} channels may play important roles in the apoptosis of NIT-1 cells and suggest new therapeutic strategies in type 1 diabetes.

P6.03.12

Anti-inflammatory and anti-diabetic activities of the methanolic fraction of *Centratherum anthelminticum* seed in STZ-nicotinamide-induced type 2 diabetic rat

C. Looi, *A. Arya, M. Mustafa;*
University of Malaya, Kuala Lumpur, Malaysia.

This study aimed to ascertain the potential of *Centratherum anthelminticum* seeds methanolic fraction (CAMF) for the management of type 2 diabetes and its associated complications. CAMFs was initially tested on β-TC6 cells for H_2O_2-induced nuclear factor-κB (NF-κB) translocation effects. The results showed that

CAMFs significantly inhibited NF-κB translocation from cytoplasm into the nucleus, dose-dependently. Furthermore, a 12-week sub-chronic CAMFs study was carried out on streptozotocin (STZ)-nicotinamide-induced type 2 diabetic rat model to evaluate glycemia, essential biochemical parameters, lipid levels, oxidative stress markers, and pro-inflammatory cytokines level. Our study result showed that CAMF reduced hyperglycemia while significantly increasing serum insulin, C-peptide, total protein, and albumin levels. Blood glucose, glycated hemoglobin, lipids and enzyme activities were restored to near normal levels. CAMF confirmed its antioxidant potential by elevating glutathione (GSH) and reducing malondialdehyde (MDA) levels in diabetic rats. Interestingly, CAMF down-regulated elevated tumor necrosis factor α (TNF-α), interleukin (IL)-1β, and IL-6 levels in tissues and serum of diabetic rats. We conclude that CAMF exerts apparent antidiabetic effects and represents a valuable nutraceutical candidate for insulin-resistant type 2 diabetes and its associated complications, such as dyslipidemia, oxidative stress, and inflammation.

P6.03.13
Can dietary intervention with whole grain decrease risk of type 2 diabetes by reducing inflammasome assembly and IL1β secretion by circulating human neutrophils?

R. B. Maerkedahl[1,2], *S. B. Metzdorff*[2], *C. B. Nielsen*[2], *M. Stenbæk*[2], *R. J. Gøbel*[3], *M. Kristensen*[1], *L. Lauritzen*[1], *H. Frøkiær*[2];
[1]*Department of Nutrition, Exercise and Sports, Faculty of Science, University of Copenhagen, Frederiksberg, Denmark,* [2]*Department of Veterinary Disease Biology, Faculty of Health and Medical Sciences, University of Copenhagen, Frederiksberg, Denmark,* [3]*The Novo Nordisk Foundation, Center for Basic Metabolic Research, Faculty of Health Sciences, University of Copenhagen, Copenhagen, Denmark.*

Central obesity, hypertension, dyslipidemia, and dysglycaemia are all common risk factors for development of type 2 diabetes (T2D) and have been suggested to induce a state of chronic low-grade systemic inflammation (CLGSI), driven by the proinflammatory cytokine interleukin 1β (IL1β), released by the predominant leukocyte in the blood, the neutrophils. Cell and animal studies suggest secretion of IL1β can be reduced by binding of short chain fatty acids (SCFAs) to the free fatty acid receptor 2 (FFAR2/GPR43) on the surface of neutrophils. In the human gut, fermentation of dietary fibers results in formation of SCFAs. These are capable of crossing the epithelial barrier and enter the blood stream. In the current study, we hypothesize that a diet rich in whole grain will increase SCFA-levels in the blood, reduce proinflammatory cytokine-levels (incl. IL1β) in the blood, and thus alleviate the state of CLGSI. Sixty adult study participants (SPs), harboring at least two of the risk factors for T2D development, are subjected to a cross-over dietary intervention. SPs will consume >75 g of whole grain (WG) daily for 8 weeks, and <10 g of WG daily for 8 weeks, separated by 6 weeks of wash-out. Flanking each 8-week period, a fasting blood sample will be taken and the immunological state will be evaluated by measuring blood cytokines levels (e.g. IL1β, TNFα, IL6, IL18, and INFγ), surface availability of IL1β-receptors on neutrophils, and expression levels of proinflammatory cytokines and regulatory components of IL1β, such as NLRP3 and caspase-1.

P6.03.14
Carbon monoxide-releasing molecule CORM-A1 attenuates the development of autoimmune diabetes in mice induced by multiple low doses of streptozotocin

I. Nikolic[1], *T. Saksida*[1], *I. Stojanovic*[1], *F. Nicoletti*[2], *S. Stosic-Grujicic*[1];
[1]*Department of Immunology, Institute for Biological Research "Sinisa Stankovic", University of Belgrade, Belgrade, Serbia,* [2]*2Department of Biomedical Sciences, School of Medicine, University of Catania, Catania, Italy.*

Recent studies identified carbon monoxide (CO) as a potential therapeutic molecule due to its anti-inflammatory and anti-apoptotic abilities. CO-releasing molecule CORM-A1 is a compound designed to liberate controlled quantities of CO in the cellular systems. However, its biological activity in autoimmune type 1 diabetes (T1D) has not been examined so far. Therefore, in the present study we investigated possible therapeutic value of CORM-A1 in the model of diabetes induced in C57BL/6 mice by multiple low doses of streptozotocin. Administration of CORM-A1 during diabetes induction, or even after the induction of the disease, improved clinical and histological signs of the disease. The interference with the disease was accompanied with reduced proinflammatory cytokine (IFN-γ, IL-2, IL-17 and TNF-α) production concurrent with increased IL-4 and TGF-β secretion. In addition to anti-inflammatory properties, *in vitro* studies revealed that CORM-A1 reduced cytokine-induced cell death of pancreatic islets, as well as beta cells (MIN and RINm5F insulinoma cells). However, a cytoprotective effect was lost when inactive CORM-A1 form, that does not liberate CO, or hemoglobin, a scavenger of CO, was employed. Although the molecular mechanisms involved in the drug action remain to be established, our results suggest that the observed beneficial effect of CORM-A1 in the disease process could be attributed, at least partly, to the interference of CORM-A1-released CO with cytokine-mediated pro-apoptotic stimuli within endocrine pancreas. CORM-A1 may thus represent a novel treatment strategy that would operate through interfering with an islet-directed autoimmune response.

Activation of Natural Killer T Cells Promotes Th2 Immune Response in Adipose Tissue of Obese Galectin-3 Deficient Mice and Improves Systemic Glucose Homeostasis

J. Pantic[1], *N. Pejnovic*[1], *I. Jovanovic*[1], *G. Radosavljevic*[1], *G. Besra*[2], *N. Arsenijevic*[1], *M. Lukic*[1];
[1]*Faculty of Medical Sciences, Kragujevac, Serbia,* [2]*School of Biosciences, University of Birmingham, Birmingham, United Kingdom.*

Diet induced obesity leads to inflammation in adipose tissue and insulin resistance. After shorter high-fat diet feeding (15 weeks) these effects, accompanied with an increase in IFN-γ expressing NKT cells, were seen in Galectin-3 deficient (LGALS3$^{-/-}$) mice but not in wild type C57BL/6 mice. To elucidate the role of NKT cells activation and the role of Galectin-3 in this process we treated mice with lipid agonist α-galactosylceramide (α-GalCer). We found that activation of NKT cells by α-GalCer significantly decreased fasting blood glucose and insulin levels and homeostasis model assessment of insulin resistance (HOMA-IR) in obese LGALS3$^{-/-}$ mice fed high-fat diet for 15 weeks. After treatment, visceral adipose tissue (VAT) of obese LGALS3$^{-/-}$ mice exhibited increased incidence of CD3^{+}NK1.1^{+} NKT, NK1.1^{+} and CD11c^{+} dendritic cells, while F4/80^{+} macrophages were decreased. In addition, the number of IL-4 and IL-5 expressing NKT cells were increased in VAT and was associated with higher levels of IL-4 and IL-13, and lower IL-1β in sera of obese LGALS3$^{-/-}$ mice. α-GalCer increased NK1.1^{+} and CD11c^{+} dendritic cells and significantly reduced pro-inflammatory F4/80^{+}CD11c^{+}CD206^{+} and F4/80^{+}IL-6^{+} macrophages in livers of obese LGALS3$^{-/-}$ mice. *In vitro* stimulated splenocytes by anti-CD3 and anti-CD28 antibodies from obese LGALS3$^{-/-}$ mice treated with α-GalCer produced significantly higher amounts of IL-4 and IL-10 compared to saline-treated diet-matched controls. These findings suggest that activated NKT cells skew the immune response to a Th2 phenotype where Th2 cytokines and anti-inflammatory IL-10 could be responsible for the improvement of insulin resistance in obese Gal-3 deficient mice.

IL-2 and rapamycin in immunotherapy of type 1 diabetes: friends or foes ?

L. Pérol[1], *A. Baeyens*[2,3], *G. Fourcade*[2,3], *N. Cagnard*[4], *W. Carpentier*[5], *J. Woytschak*[6], *O. Boyman*[6], *A. Hartemann*[7,8], *E. Piaggio*[1];
[1]*U932 - Institut Curie, PARIS, France,* [2]*U7211/U959 - Pitié-Salpêtrière, PARIS, France,* [3]*UPMC, Paris, France,* [4]*INSERM U580, PARIS, France,* [5]*Plate-forme Post-Génomique P3S - UPMC, PARIS, France,* [6]*Laboratory of Applied Immunobiology, ZURICH, Switzerland,* [7]*Department of Endocrinology, Nutrition and Diabetes - APHP, PARIS, France,* [8]*Department of Medicine Faculty - UPMC, Paris, France.*

Administration of low-dose IL-2 alone or combined with rapamycin (RAPA) prevents type 1 diabetes (T1D). Also, low-dose IL-2 cures

recent onset T1D in NOD mice, partially by boosting pancreatic regulatory T cells (Treg cells). These approaches are currently being evaluated in humans. Here, we studied the mechanism of action of higher IL-2 doses and low-dose IL-2 and RAPA (RAPA/IL-2) combination. We assessed the effect of high doses of IL-2 or the combined treatment in NOD T1D evolution, including flow cytometric analysis of immune-competent cells and glucose metabolism assessment by glucose tolerance tests and microarray analysis of liver response to glucose. We show that high doses of IL-2, despite further boosting Treg cells, rapidly precipitated T1D in pre-diabetic female and also male mice and induced a striking increase in pancreatic myeloid cells. RAPA counteracted IL-2 effects on Treg cells, failed to control IL-2-boosted NK cells and broke IL-2-induced tolerance in a reversible way. Notably, RAPA/IL-2 combination failure to cure T1D was associated to an unexpected deleterious effect on glucose homeostasis at multiple levels. Our data help understand the therapeutic limitations of IL-2 alone or RAPA/IL-2 combination and could lead to the design of improved therapies for T1D.

P6.03.17
Treg CD39+ and Th17 cells in Type 2 Diabetes Mellitus Patients

N. Cortez-Espinosa, S. E. Medellin-Garibay, J. D. Cortes-Garcia, A. Nuñez-Ruiz, R. González-Amaro, ***D. P. Portales-Pérez****;*
UASLP, San Luis Potosí, Mexico.

Type 2 diabetes mellitus (T2D) represents a chronic and progressive syndrome characterized by hyperglycemia which results from insulin resistance and pancreatic β-cell dysfunction. It is clear that inflammation and cytokine production by the immune system and adipose tissue plays an important role in the pathogenesis of T2D. On the other hand, naturally occurring regulatory T (Treg) cells maintain the tolerance to self-antigens. A dysregulation in the number or function in Treg cells contributes to autoimmune diseases, chronic inflammatory diseases, and cancer. CD39, an ectonucleotidase which hydrolyzes ATP is expressed on a subset of human natural Treg cells. IL-17-producing $CD4^+$ T cells (Th17 cells) could be pathogenic in many diseases and are resistant to suppression by human $Foxp3^+$ Treg cells. The aim of this work was to evaluate the expression of Treg CD39+ and Th17 cells in peripheral blood mononuclear cells from T2D patients. We found similar levels of CD4+Foxp3+CD39+ and CD4+Foxp3+CD39- Treg, in healthy subjects (n=24) and T2D patients (n=24). In contrast, Th17 cells were found significantly diminished in T2D patients compared to healthy subjects. T2D patients were classified according to the WHO body mass index categories and patients with overweight and obesity showed the lowest levels of CD4+IL-17+ T cells, compared to T2D patients with normal weight. These data are in agreement with the levels of mRNA IL-17. In conclusion, our results indicate that decreased expression of Th17 cells could be important in understanding the defective regulation of inflammation in diabetes.

Immunohistochemical study of the pancreas of patients with long termed diabetes mellitus type 1

A. Proshchina, ***Y. Krivova****, V. Barabanov, S. Saveliev;*
FSBI Human Morphology SRI RAMS, Moscow, Russian Federation.

Pathological findings in the pancreases of diabetes mellitus type1 (DM1) patients include peri-and intra-insular inflammatory infiltrates, namely insulitis. Although considered to be pathognomonic for recent onset disease, insulitis has only been described in approximately 150 cases over the past century.
We have studied the autopsy samples of the pancreas of 5 adult patients with long termed DM1 and of 9 adults not suffering from disorders of carbohydrate metabolism as a control. Antibodies to insulin and glucagon were used for the detection of hormones of the endocrine cells. Antibodies to CD8, CD16, CD20, CD25 and CD71 were used as immunological markers.
In the control samples of the pancreas as well as in the pancreas of two patients with DM1 CD16-, CD25-, CD8-, CD20- and CD71-positive cells were observed only in a small number among the blood cells.
We have identified the inflammation in the acinar part of three patients with DM1. CD16+ and CD25+ cells have made the largest contribution to this reaction. The number of cells positive for antibodies to the transferrin receptor (CD71) was increased compared to the control. The amount of cells positive for antibodies to CD8 and CD20 in these samples was small.
It is believed that insulitis is characteristic for the islets, which have retained a significant part of the b-cells. We have detected the inflammation in exocrine part of the pancreas in 2 patients with DM1 with absolutely absence of b-cells. Therefore, this reaction can hardly be regarded as directed only against insulin-containing cells.

P6.03.19
ST2 deficiency enhances diet-induced inflammation in visceral adipose tissue and obesity in mice

G. Radosavljevic*, N. Pejnovic, J. Pantic, I. Jovanovic, I. Jeftic, N. Jovicic, N. Arsenijevic, M. Lukic;*
Faculty of Medical Science, Kragujevac, Serbia.

Obesity associated low-grade chronic inflammation in adipose tissue and may contribute to type 2 diabetes. Although interleukin (IL)-33 may have protective role in obesity and atherosclerosis, the contribution of IL-33/ST2 axis in metabolic disorders needs to be elucidated. We investigated the role of ST2 in high-fat diet (HFD)-induced obesity using ST2-deficient ($ST2^{-/-}$) and wild type mice on BALB/c background relatively resistant to HFD-induced obesity. The deletion of ST2 enhanced systemic and visceral adipose tissue (VAT) inflammation and was associated with significantly higher weight gain and amount of total VAT in $ST2^{-/-}$ mice fed HFD for 18 weeks. More numerous M1 macrophages and markedly decreased M2 macrophages were observed in VAT of HFD-fed $ST2^{-/-}$ mice. Additionally, VAT of $ST2^{-/-}$ mice fed HFD had increased percentage of $CD3^+$ T cells with lower incidence of $CD4^+CD25^+FoxP3^+$ T regulatory cells and $CD4^+PD\text{-}1^+$ T cells in comparison with low-fat diet fed controls and a pronounced increase of the percentage of $CD19^+$ B cells. The incidence of IL-5 and IL-17 expressing stromal vascular fraction cells were significantly lower in HFD-fed $ST2^{-/-}$ mice. Serum levels of pro-inflammatory cytokines IL-1β and IFN-γ were also increased in HFD-fed $ST2^{-/-}$ mice, while the levels of IL-6 and CRP did not differ among groups. Importantly, the levels of anti-inflammatory IL-10 and IL-13 were significantly lower in the sera of $ST2^{-/-}$ mice compared with wild type controls. Our findings suggest that protective role of IL33/ST2 signaling in diet-induced adipose tissue inflammation is mediated by downregulating M1 macrophages and Th1 cell induction.

P6.03.20
Oral administration of L. Lactis secreting $hGAD65_{370\text{-}575}$ and hIL-10 can revert diabetes in recent-onset NOD mice when combined with low-dose anti-CD3

S. Robert*[1], T. Takiishi[1], k. Van Huynegem[2], L. Steidler[3], H. Korf[1], C. Gysemans[1], T. Van Belle[1], P. Rottiers[3], C. Mathieu[1];*
[1]KU Leuven, Leuven, Belgium, [2]ActogeniX, Zwijnaarde, Belgium, [3]ActoGeniX, Zwijnaarde, Belgium.

In type 1 diabetic patients insulin-producing pancreatic beta-cells are destroyed by self-reactive autoantigen-specific T cells. As a therapy, reinstalling antigen (Ag)-specific tolerance is considered the favorable approach. Previous studies show that orally-administered genetically-modified *lactococcus lactis* (*L. lactis)* secreting human pro-insulin and human IL10 (hIL10) induce diabetes remission in NOD mice when combined with low-doses of anti-CD3. Using *L. lactis* as an innovative protein carrier this study aimed to determine whether another islet autoAg, GAD65, could establish or increase this diabetes reversal rate in new-onset NOD mice. Based on epitope spreading, bacterial secretion and growth profile, a bacterial strain secreting hIL10 and $hGAD65_{370\text{-}575}$ was evaluated *in vivo*. New-onset diabetic NOD mice were given a subtherapeutic dose of anti-CD3 for 5 consecutive days (clone 145-2C11, 2.5 µg/d, iv.) and *L. lactis* 5 times weekly for 6 weeks (10^9 CFU/d, by gavage). Treatment with low-dose anti-CD3 and $hGAD65_{370\text{-}575}$ plus hIL10 (n=36) significantly induced 67% diabetes reversal in new-onset diabetic NOD mice compared to 31% and 37% using anti-CD3 alone (n=42) or with empty vector (n=32),

respectively. In addition, $CD4^+CD25^+$ T-cells isolated from combi-GAD cured animals could counter the proliferation and IFNy secretion of polyclonally stimulated $CD4^+CD25^-$ responder T-cells. In conclusion, like pro-insulin also GAD65 when combined with hIL-10 and a systemic low-dose of anti-CD3 stably reverses diabetes in recent-onset NOD mice.

Transfer of type 1 diabetes by bone marrow transplantation

E. Tresoldi[1,2], *P. Monti*[3], *P. Piatti*[4], *B. Mfarrej*[2], *F. Onida*[5], *E. Bosi*[2,4], *M. Battaglia*[2];
[1]*San Raffaele Telethon Institute for Gene Therapy, Milan, Italy,* [2]*San Raffaele Scientific Institute, Diabetes Research Institute, Milan, Italy,* [3]*San Raffaele Scientific Institute, Diabetes Research Institute, Milano, Italy,* [4]*San Raffaele Hospital, Internal Medicine Department, Milan, Italy,* [5]*Ospedale Maggiore Policlinico di Milano, Hematology and Oncology Department, Milan, Italy.*

Transfer of autoimmune type 1 diabetes (T1D) between HLA-identical siblings by bone marrow transplantation (BMT) has been previously described (Lampeter et al. Lancet 1993). However, the mechanism at the basis of disease transfer has never been investigated. Here we report a case in which T1D was developed following allogeneic BMT in a patient affected by mycosis fungoides. The donor was an HLA-identical brother with T1D. Full donor engraftment was reported 1 year after BMT and confirmed annually up to 7 years after transplantation. Nine years after BMT, the recipient was diagnosed with T1D. Anti-GAD and anti-IAA autoAbs were negative in the recipient before transplantation, while 9 year after transplant autoAb levels were high and almost superimposable to those found in the donor. The frequency and functional activity of T cells specific for GAD, Pro-insulin and tetanus toxoid (TT) (as control) were tested. Donor and recipient had similar frequencies of circulating diabetogenic T cells and Ag specific T-cell clones had similar cytokine profile. On the contrary, the frequency of TT-specific T cells was very different between donor and recipient. Data from TCR deep sequencing are being generated and will help to understanding whether auto-reactive T cells isolated from the donor and the recipient originate from the same clone or not. This rare phenomenon of T1D transfer after BMT represents a unique opportunity for better understanding the origin and, potentially, the cure of autoimmune T1D.

Characterization of monoclonal ZnT8-specific antibody

J. Ustinova[1], *D. Belitskin*[2], *E. Juronen*[3], *E. Zusinaite*[4], *M. Utt*[1], *R. Uibo*[1];
[1]*Institute of Biomedicine, Tartu, Estonia,* [2]*Institute of Molecular and Cell Biology, Tartu, Estonia,* [3]*Department of Biomedicine, Tartu, Estonia,* [4]*Institute of Technology, Tartu, Estonia.*

Immune-mediated destruction of insulin-producing beta cells of pancreas leads to autoimmune type 1 diabetes mellitus (T1D). Recently, ZnT8 (zinc transporter 8) has been identified as an autoimmune target in T1D. ZnT8 is expressed in the pancreatic tissue and regulates Zn metabolism in beta cells. Zn is critical for normal storage of insulin in the secretory vesicles of islet beta cells. ZnT8 autoantibodies are directed mostly against the C terminal domain. Molecular biological tools for basic research of ZnT8 role in T1D are needed. In this report, we characterize a new monoclonal antibody to the ZnT8 C-terminus. Mice were immunized with Semliki Forest virus-like particles expressing full-length ZnT8 and hybridomas were obtained and cloned. Hybridomas were tested using LIPS (Luciferase Immunoprecipitation system) and ELISA using purified recombinant C-terminal domain of ZnT8. One of the hybridomas giving a very high signal was selected for further analysis. Protein A purified Mab was used to characterize binding epitope using 18 overlapping peptides designed according to C-terminal sequence of ZnT8. Binding epitope was identified using four methods: LIPS assay, ELISA, biosensor binding test, and immunohistochemistry assay with monkey pancreatic iselets. In conclusion, we have characterized a new monoclonal antibody usable as a molecular biological tool for ZnT8 research.

P6.03.23
Autocrine CCL2, CXCL4, CXCL9 and CXCL10 signaling in retinal endothelial cells is enhanced in diabetic retinopathy

K. Van Raemdonck[1], *M. I. Nawaz*[2], *M. Gouwy*[1], *G. Mohammad*[2], *D. Kangave*[2], *J. Van Damme*[1], *A. M. Abu El-Asrar*[2], *S. Struyf*[1];
[1]*Rega Institute, KULeuven, Leuven, Belgium,* [2]*College of Medicine, King Saud University, Riyadh, Saudi Arabia.*

Chemokines influence many biological processes, including immunological reactions and angiogenesis, both physiological and pathological. Different chemokines contribute to either side of the angiogenic/angiostatic balance. CXCR3 ligands for instance favour angiostasis, inhibiting endothelial cell proliferation and chemotaxis. This study aimed at examining the production of chemokines (angiogenic CCL2/MCP-1 and angiostatic CXCL4/PF-4, CXCL9/Mig and CXCL10/IP-10) in proliferative diabetic retinopathy (PDR), an inflammatory condition characterized by exaggerated retinal neovascularisation leading to blindness. Chemokine production in human retinal microvascular endothelial cells (HRMEC) and chemokine levels in vitreous samples from PDR patients were analyzed. CCL2, CXCL4, CXCL9 and CXCL10 as well as the angiogenic factor VEGF were elevated in vitreous fluid from PDR patients. Additionally, we found HRMEC to produce CCL2, CXCL9 and CXCL10 *in vitro*, namely after IFN-γ, IL-1β or lipopolysaccharide stimulation. IFN-γ synergistically enhanced CXCL9 and CXCL10 production in response to IL-1β or lipopolysaccharide. CCL2 was also produced in response to VEGF. Further we wanted to improve our understanding of the contradictory role of angiostatic chemokines produced in angiogenic pathologies. Interaction of angiostatic chemokines and angiogenic factors (VEGF and the chemokines CCL2 and CXCL12) was investigated at the level of signal transduction. The MAPK family was shown to be a link between angiogenic and angiostatic signaling. Phosphorylation of ERK induced by angiogenic factors was inhibited by CXCL4, CXCL9 and CXCL10. Finally, in accordance with inhibition of angiogenic signaling, CXCL4 inhibited *in vitro* migration of HRMEC. Our study thus reveals enhanced autocrine signaling of CCL2, CXCL4, CXCL9 and CXCL10 in HRMEC in PDR.

Protein S attenuates streptozotocin-induced diabetes mellitus

T. Yasuma[1], *C. Gabazza*[2], *T. Matsumoto*[2], *A. Yasukawa*[2], *Y. Matsushima*[2], *L. C.G.Ayshwarya*[2], *Z. Roeen*[2], *M. Toda*[2], *Y. Yano*[1], *E. Gabazza*[2];
[1]*Department of Dibetes and Metabolism, Mie University Graduate School of Medicine, Tsu-city, Japan,* [2]*Department of Immunology, Mie University Graduate School of Medicine, Tsu-city, Japan.*

OBJECTIVE: Protein S (PS) is an important cofactor of activated protein C (APC) in the inhibition of coagulation cofactors Va and VIIIa. PS can also regulate the inflammatory response and apoptosis. The effect of PS on glucose tolerance is unknown. In this study, we evaluated the effect of PS on streptozotocin (STZ)-induced diabetes mellitus.
METHODS: PS transgenic mice were used in the experiments. Diabetes was induced in PS transgenic and wild type mice by intraperitoneal (i.p.) injection of STZ for five consecutive days. Mice were categorized into four groups: wild type/saline (WT/SAL), PS/saline (PS/SAL), wild type/STZ (WT/STZ) and PS/STZ (PS/STZ) groups. Blood glucose was measured weekly. Four weeks after STZ or saline treatment, glucose tolerance test and glucose-stimulated insulin secretion test were performed and mice were sacrificed. Serum insulin level at sacrifice and islet area in hematoxilin-eosin stained pancreatic tissue section were measured.
RESULTS: The blood glucose levels were significantly lower on days 14 and 21 in PS/STZ mice compared with WT/STZ mice. Improved glucose tolerance and insulin secretion were observed in PS/STZ mice compared with WT/STZ mice. The islet area was significantly decreased in WT/STZ mice compared with other groups.
CONCLUSION: PS attenuates diabetes probably by inhibiting the effect of STZ on pancreatic islets.

P6.03.25
Effects of OPN and its cleavage products on human monocyte differentiation and survival

M. Zeyda[1,2]*, K. Schuch*[1,2]*, T. M. Stulnig*[1,2]*;*
[1]Christian Doppler Laboratory for Cardio-Metabolic Immunotherapy, Vienna, Austria, [2]Dept. Medicine III, Medical University of Vienna, Vienna, Austria.

Passive immunization against osteopontin (OPN), an inflammatory mediator increased in adipose tissue by obesity, counteracts obesity-associated adipose tissue inflammation and insulin resistance by reducing macrophage abundance in metabolic tissues, in part due to augmented macrophage apoptosis. Protease cleaved forms (cOPN) occur after thrombin or matrix metalloprotease cleavage at inflammatory sites and expose specific cryptic epitopes. Here we show that presence of OPN for 2 days in vitro increased the number of metabolically active human primary monocytes by 400%. TUNEL assays revealed that the percentage of apoptotic monocytes was reduced to 20% with OPN compared to untreated cells 24 hours after isolation. Furthermore, OPN induced a massive cytokine response of IL-1β, IL-10, TNF-α, RANTES and MCP-1. Monocytes differentiated for 8 days in presence of OPN up-regulated CD206 and CD163 but also CD40 and CD80. Cytokine analysis of supernatants taken on day 8 after isolation following 24 hours of stimulation revealed an increase in IL-1β and MCP-1 production but a strong down-regulation of IL-10 secretion mediated by OPN. The effects of cOPN were qualitatively very similar, but quantitatively less pronounced. In conclusion, OPN is a survival factor for human monocytes that may, independently of protease cleavage, considerably contribute to obesity-induced adipose tissue inflammation. Moreover, OPN may contribute to the peculiar phenotype of human adipose tissue macrophages with M2-like surface marker expression but M1-like cytokine production.

Modulation of the oxido-inflammatory and immunomodulatory cascade contributes to the anti-arthritic activity of curcumin loaded solid lipid nanoparticles in CFA-induced arthritis in rats

R. Arora*, A. Kuhad, K. Chopra, I. Kaur;*
University Institute of Pharmaceutical Sciences, Chandigarh, India.

Rheumatoid arthritis (RA) is a systemic inflammatory disorder which is characterized by chronic inflammation of the joints and destruction of cartilage. Effectiveness of curcumin has been established in a wide variety of human diseases including inflammatory disorders, but it is yet to be approved as a therapeutic agent due to its poor absorption, instability at physiological pH, rapid metabolism and systemic elimination. To overcome the compromised physicochemical properties of curcumin, we proposed to evaluate curcumin loaded solid lipid nanoparticles (C-SLNs), on mobility scores, biochemical, hematological and radiological alterations in complete Freund's adjuvant (CFA)-induced arthritis in rats. CFA injected rats exhibited marked decrease in reaction time (thermal hyperalgesia) in hot plate test along with significantly decreased paw withdrawal threshold in Randall-Sellito test (mechanical hyperalgesia) and von-Frey hair test (mechanical allodynia). Arthritic rats also showed a significant joint hyperalgesia, joint stiffness and increased paw volume along with marked decrease in mobility score. CFA-induced arthritis was associated with significantly enhanced blood leukocyte count, oxidative-nitrosative stress, tumor necrosis factor-α (TNF-α), C-reactive protein and radiological alterations in tibio-tarsal joint. All these alterations were significantly and dose-dependently ameliorated by Curcumin-SLNs administration (10 and 30 mg/kg). Plain curcumin 30 mg/kg showed some protection whereas plain curcumin 10 mg/kg failed to show any significant effect. In conclusion, the current findings suggest the protective potential of curcumin in ameliorating CFA-induced arthritis in rats through modulation of oxido-inflammatory & immunomodulatory cascade. Further, the results emphasize that SLNs are a novel approach to deliver curcumin into the inflamed joints.

P6.04.02
Efficacy and safety of biologic agents in adult-onset Still's disease: a long-term follow-up of 19 patients at a single referral Center

G. Cavalli*, S. Franchini, A. Berti, C. Campochiaro, B. Guglielmi, M. Sabbadini, E. Baldissera, L. Dagna;*
Vita-Salute San Raffaele University, Milano, Italy.

Background: Long-term outcome of biological drugs treatment in Adult-Onset Still's Disease (AOSD) is undetermined. We evaluated efficacy and safety of different biological agents in a large cohort of AOSD patients.
Methods: Nineteen AOSD patients treated with biological agents were followed-up between 1998 and 2013. We evaluated disease courses, efficacy of treatments, and adverse effects. Efficacy was evaluated as 'Complete response' (CR: absence of disease manifestations/inflammatory indexes;>50% reduction in corticosteroid dosage), 'Partial response' (PR: clinical improvement without normalization of inflammatory markers, nor>50% reduction in corticosteroid dosage), or 'Treatment failure' (TF: persistence/worsening of disease manifestations/markers; increased corticosteroid dosage).
Results: Average follow-up was 5 years. Overall, biologic drugs induced an improvement in 17(89%) patients. Anakinra was used in all patients; etanercept, tocilizumab and adalimumab in 6, 4, and 1, respectively. Fifteen patients responded to anakinra (79%, with, 68% CR and 11% PR). Four patients (21%) did not respond to anakinra; 3 (16%) responded to tocilizumab, and 1 (5%) to adalimumab. Etanercept proved unsuccessful in six patients. Corticosteroids dose was decreased in all patients; immunosuppressants dose in 14 (74%). Three patients experienced herpes zoster reactivation.
Conclusion: Biological agents represent an effective and safe therapeutic resource for AOSD refractory to conventional treatment. Anakinra represented the mainstay of treatment. Both anakinra and tocilizumab were more effective than TNF-α blockers. IL-6 blockade may be particularly effective in patients with chronic articular involvement. Patients unsuccessfully treated with biologics had already developed irreversible structural damages prior to initiation of treatment. Thus, a more prompt initiation of biological agents could be beneficial in severe AOSD.

P6.04.03
Modulations in the Expression of Leukocyte Complement Receptors (CR1 and CR2) in Rheumatoid Arthritis

R. Dash[1]*, U. Kumar*[2]*, M. Kanjilal*[2]*, B. Biswal*[3]*, N. Das*[1]*;*
[1]Department of Biochemistry, All India Institute of Medical Sciences, New Delhi, India, [2]Department of Medicine, All India Institute of Medical Sciences, New Delhi, India, [3]School of Life Sciences, Sambalpur University, Jyoti Vihar, Orissa, India.

Rheumatoid arthritis (RA) is a chronic systemic autoimmune disorder of unknown etiology. The complement proteins have been known to play complex roles in the pathogenesis of RA. The growing importance of complement receptor 1 (CR1) and complement receptor 2 (CR2) not only in modulation of complement activation at several levels but also in B-cell activation and immune complex localization, suggests that its expression may have significant effects on health and disease. We conducted a case-control study to explore the role of Leukocyte CR1 and CR2 ((L- CR1& L-CR2) in human RA. The L-CR1 and L-CR2 expression in 57 healthy controls and 57 RA patients was evaluated at mRNA levels by RT-PCR. Disease activity scores (DAS28) were monitored in RA patients using swollen and tender joint counts and the ESR. The circulating immune complex (CIC) levels were spectrophotometrically determined and levels of C3 were measured by nephlometry in both controls and patients. The correlations of L- CR1 and L-CR2 expression with clinical parameters (DAS28, CIC and C3) were evaluated. The L-CR1 and L-CR2 transcripts declined significantly in patients. A significant negative correlation of CR1 and significant positive correlation of CR2 transcript were observed with CIC only in patients. C3 was correlated

positively with CR2 transcript in both patients and controls. In essence, our findings suggest a close relationship of CR1 and CR2 with the pathophysiology and disease activity of RA. The findings also may have important diagnostic, prognostic and therapeutic implications.

P6.04.04
APL-1, an altered peptide ligand derived from HSP60 in combination with methotrexate, attenuates murine collagen induced arthritis associated with an increment of regulatory T cells

M. M. Dominguez-Horta, M. M. Dominguez-Horta, ***M. Dominguez-Horta****;*
CIGB, Havana, Cuba.

Activation of autoreactive T cells induced by autoantigens play an important role in the pathogenesis of rheumatoid arthritis (RA). Recent studies have identified defects in the number or activity of regulatory T cells (Treg) in patients with this disease. In this sense, induction of peripheral tolerance has been considered a promising approach to the treatment of RA. Previously, we demonstrated that an Altered Peptide Ligand (APL) derived from Hsp60, an autoantigen involved in the pathogenesis of RA, efficiently inhibited the course of adjuvant induced arthritis model. This effect was associated with an increase of the proportions of Treg. In this work, we aimed to evaluate the therapeutic effect of this APL in combination with metotrexate (MTX) in collagen induced arthritis (CIA). MTX is considered the gold standard treatment for RA. CIA was induced in male DBA/1 mice at eight weeks of age by immunization with chicken collagen. APL, MTX or both were administrated beginning from arthritis onset. Therapeutic effect was evaluated by arthritis and joint pathologic scores. In addition, TNFα in sera was measured with ELISA and Treg induction was assessed by FACS analysis. Therapy with APL, MTX or the combination reduced arthritis scores and histological lesion. This effect was associated with a decrease of TNFα levels. However, only the combination of APL and MTX increases the proportions of the Treg. These results indicate a therapeutic potentiality of APL with MTX and support further investigation of this combination for treatment of RA.

P6.04.05
Interplay between TWEAK and IL-17 biology: a novel therapeutic concept for treatment of autoimmune diseases (e.g. RA and Lupus)

J. A. A. Fischer[1]*, W. Baum*[2]*, M. Galm*[1]*, C. Kitson*[3]*, S. Wilson*[4]*, A. Hueber*[2]*, A. C. Tissot*[1]*, J. Auer*[1]*, S. Lorenz*[1]*, S. Seeber*[1]*, A. Pashine*[4]*, M. Bader*[1]*, G. Schett*[2]*;*
[1]Roche Large Molecule Research pRED Penzberg, Penzberg, Germany, [2]University of Erlangen-Nuremberg, Erlangen, Germany, [3]Roche pRED Inflammation Discovery Therapeutic Area, Nutley, NJ, United States, [4]Roche Inflammation Discovery Therapeutic Area, Nutley, NJ, United States.

Rheumatoid arthritis is a systemic autoimmune disease characterized by synovial inflammation and neovascularization, resulting in cartilage/bone damage and joint destruction. There remains a high unmet medical need for novel therapeutics to achieve sustained remission as there is a high rate of non-responders to standard therapies. One approach could be the targeting of synergistic and/or complementary disease pathways. In this study, we assessed the impact of TWEAK and Interleukin-17 in several pre-clinical models as these two cytokines are found at elevated levels in the serum/inflamed tissue of patients suffering from autoimmune diseases such as RA and Lupus. Interestingly, in addition to effects of the single cytokines, combination of TWEAK and IL-17 clearly demonstrated additive or synergistic effects on cytokine and MMP production by different RA-relevant cell types (synovial fibroblast and chondrocytes), osteoclast activation and reduced osteoblast differentiation in vitro, whereas ICAM-1 expression and FLS proliferation was more TWEAK-dependent. Parallel blockade of both pathways in an in vivo RA-model demonstrated beneficial impact on osteoclast and osteoblast numbers and bone formation markers (in the range of TNFα blockade), but lower effects in the reduction of inflammation, bone erosion ad cartilage damage.
Finally, inhouse generated bispecific antibodies that efficiently neutralized both cytokines showed higher inhibitory potential also upon combinational cytokine treatment in vitro.
In summary, our data demonstrate that TWEAK and IL-17 are crucial players in RA pathogenesis. We hypothesize that dual targeting of these cytokines will result in complementary anti-inflammatory and bone/cartilage regenerative activity, representing a novel and attractive treatment strategy for RA.

P6.04.06
Generation of recombinant antibodies with TCR-like specificity directed toward autoimmune epitopes

A. Fridman*, R. Dahan, Y. Reiter;*
Technion - Israel Institute of Technology, Haifa, Israel.

Rheumatoid arthritis (RA) is a chronic inflammatory process of the joints that progressively leads to functional impairment and bone erosions. This autoimmune disease occurs with relative high frequency in individuals expressing Human Leukocyte Antigen (HLA) DR4 (DRB1*0401 allele). While presented by HLA-DR4 molecule, residues 261-273 of Collagen Type 2 (CII) represent an RA immunodominant T cell epitope. By using phage display technique and antibody engineering approaches we aim to isolate recombinant antibodies (rAbs) that recognize HLA-DR4/CII-261-273 autoreactive epitope. These rAbs, termed T Cell Receptor-Like (TCRL) rAbs, bind the autoimmune-associated peptide only in the context of the MHC class II in a TCR-Like specificity pattern. A major advantage of TCRLs is that while mimicking the specificity of the TCR they have significantly higher binding affinity. TCRL rAbs against autoantigen bound to its HLA-DR4 molecule can be significance for two major research directions: as a tool to study autoantigen presentation during the autoimmune disease with the ability to detect and image antigen-presenting cells that present the autoantigen. Second, for translational-clinical applications, where TCRL rAbs potentially will be able to regulate the proliferation of autoreactive T cells in a highly selective manner. By establishing our TCRL technology, we intend to generate TCRL rAbs against HLA-DR4/CII-261-273 epitope. These TCRL rAbs will represent a valuable research tool for studying autoantigen presentation during RA. Additionally, by blocking presentation of this epitope, TCRL rAbs potentially will be able to regulate pathogenic T cells responses in a highly selective manner and may constitute novel RA therapeutic agents.

P6.04.07
Therapeutic effects of adiponectin-mediated trimeric sTNFRII on collagen-induced arthritis

J. Gao[1]*, M. Luo*[2]*, Z. Hu*[3]*;*
[1]Wenzhou Medical College, Wenzhou, China, [2]Jinggangshan University, Ji An, China, [3]Southern Medical University, Guangzhou, China.

We have developed a novel trimeric sTNFRII, named sTNFRII-gAD fusion protein, which exhibits a higher in vitro antagonistic efficacy for TNFα compared with sTNFRII-Fc. This study was aimed to investigate the anti-arthritic capacity of sTNFRII-gAD in a rat collage-induced arthritis model (CIA). The rats were injected intradermally with 200μg collagen type II (CII) at day 0 and day 7. Three days post the second CII injection (day 10), the rats were intraperitoneally given 200μg of sTNFRII-gAD or sTNFRII-Fc, or sterile saline. Effects of sTNFRII-gAD treatment were evaluated by CIA incidence, severity and pathological changes. Serum TNFα, IL-17A and regulatory T cell (Treg) in periphery were examined at day 10 and 16, respectively. Our results showed that sTNFRII-gAD significantly decreased CIA incidence and severity ($p<0.05$), and that sTNFRII-gAD treatment led to a dramatic reduction in cartilage and bone damage. Moreover, the increase in serum anti-CII and IL-17A, and the reduction in Treg population were suppressed ($p<0.05$) by the administration of sTNFRII-gAD or sTNFRII-Fc. TNFα was found to be accumulated in serum in the groups treated with sTNFRII-gAD or sTNFRII-Fc compared with the group treated with saline ($p<0.05$). Noteworthily, sTNFRII-gAD showed a better efficacy than sTNFRII-Fc in CIA

incidence, pathological changes in cartilage and the elevation of anti-CII antibody, indicating that sTNFRII-gAD is potentially a more efficacious TNFαantagonist for rheumatoid arthritis.

P6.04.09
TRAIL reduced joint inflammation, osteoclast activation and bone loss in experimental arthritis

*H. Liao[1], H. Tsai[2], **P. Hsu**[1];*
[1]Graduate Institute of Immunology, National Taiwan University, Taipei, Taiwan, [2]Graduate Institute of Clinical Medicine, Taipei Medical University, Taipei, Taiwan.

TNF-related apoptosis-inducing ligand (TRAIL) induces apoptosis in diverse tumor cells. Recent studies have shown TRAIL also regulate osteoclast activation and inflammation, suggesting that it may be involved in the pathogenesis of rheumatoid arthritis (RA). We investigated whether treatment with TRAIL would modulate the severity of the disease in a collagen-induced arthritis (CIA) rat model. Rats with CIA were treated subcutaneously with recombinant TRAIL, with the tumor necrosis factor (TNF) blocker etanercept, or with TRAIL in combination with etanercept. Arthritis severity was determined according to the hind paw thickness, arthritis severity score, degree of cartilage damage, bone mineral density, and cytokine production, which were evaluated using microfocal computed tomography, and enzyme-linked immunosorbent assay. Our results demonstrated that treatment with TRAIL alone or in combination with etanercept significantly reduced the severity of arthritis by decreasing the hind paw thickness and swelling, preventing cartilage damage and bone loss, and reducing the expression of IL-1β, IL-6 and TNF in synovial tissue. In vitro, TRAIL inhibited RANKL-induced osteoclast activation. Taken together, treatment with TRAIL inhibited inflammation and bone loss in rats with CIA. Treatment with TRAIL combined with etanercept protected rats from CIA better than treatment with etanercept alone. Our findings provide evidence that TRAIL may be a potential therapeutic agent for RA

P6.04.10
Diacerein ameliorates the evolution of inflammatory periodontal bone loss by inhibiting RANKL-induced osteoclastogenesis

***R. Huang**[1], J. Chen[2], W. Yang[3], C. Chu[4];*
[1]Department of Periodontology, School of Dentistry, Tri-Service General Hospital and National Defense Medical Center, Taipei city, Taiwan, [2]Center for Nanomedicine Research, National Health Research Institutes, Zhunan, Taiwan, [3]Agricultural Biotechnology Research Center, Academia Sinica, Taipei city, Taiwan, [4]Graduate Institute of Immunology, College of Medicine, National Taiwan University, Taipei city, Taiwan.

Diacerein (DAR) a purified anthraquinone derivative, which is found originally in plants with anti-inflammatory and analgesic activities, therefore it also known as “disease-modifying osteoarthritis drugs (DMOAD)” or “chondroprotective agents”. Both in vitro and in vivo experiments have also revealed that DAR possesses anti-inflammatory properties. Therefore, in the present study, we investigated the therapeutic effects of DAR in a rat model of periodontal disease induced by ligature placed around the maxilla second molars of each animal. Male S-D rats were divided into three groups: 1) animals without ligature placement receiving administration of empty vehicle (control); 2) animals with ligature receiving administration of empty vehicle; 3) animals with ligature receiving administration with oral DAR (100 mg/kg/day). The animals were sacrificed after 3, 7, 10 14 days after induction of periodontal disease, and maxillae and gingival tissues were removed for further analysis. An in vitro assay was also employed to test the inhibitory effects of DAR on osteoclastogenesis. Histomorphological analyses of periodontal tissue demonstrated that DAR-treated animals presented ameliorated alveolar bone destruction, compared to those animals with ligature, but treated with empty vehicle. Corresponding to such results obtained from in vivo experiments, DAR also suppressed in vitro osteoclast differentiation in the presence of RANKL in osteoclast precursor cells, along with the down-regulation of the expression of RANKL-induced TRAP mRNA. These data indicated that DAR may suppress the bone resorption by inhibiting RANKL-mediated osteoclastogenesis elicited during the course of experimental periodontitis in rats.

P6.04.11
Therapeutic effect of proteoglycan/vitamin D association in experimental arthritis

***L. L. W. Ishikawa**, L. C. B. Tavares, P. M. Colavite, L. C. Rosa, S. F. G. Zorzella-Pezavento, T. G. D. França, F. Chiuso-Minicucci, A. Sartori;*
Univ Estadual Paulista (UNESP), Botucatu, Brazil.

Rheumatoid arthritis (RA) is a chronic inflammatory systemic autoimmune disease that compromises the joints. Current RA treatment consists in general suppression of immune response which increases susceptibility to infections. Considering the immunomodulatory properties and tolerogenic effects of active vitamin D (VitD3), this study aimed to evaluate if the association of the specific antigen (proteoglycan) with VitD3 has a therapeutic effect on experimental arthritis. For disease induction, female BALB/c retired breeder mice were intraperitoneally injected three times (21 days interval) with 100µg of bovine proteoglycan (PG) and 1mg of dimethyldioctadecyl ammonium bromide adjuvant. Ten days after the second injection, mice received 0,1µg of VitD3 (i.p.) every other day during 15 days. PG (50µg or 100µg) was co-administered on second and on eleventh day of treatment. After the third injection, disease severity was daily assessed by score evaluation. Although there was no difference on RA incidence, the association of PG and VitD3 determined lower scores and later disease onset. However, similar disease amelioration was also observed in animals treated with PG or VitD3 alone. Spleen cells from all groups produced similar levels of IL-6 and IL-5 and no detectable levels of TNF-alpha and IL-17 in response to stimulation with the specific antigen. Mice treated with PG/VitD3 association produced similar levels of IFN-gamma comparing to the untreated arthritic group. However, IL-10 levels were significantly increased in those treated animals, suggesting the contribution of regulatory T cells to the tolerogenic effect triggered by PG/VitD3 association.

P6.04.12
Metformin downregulates Th17 cells differentiation and attenuates murine autoimmune arthritis

***K. Kang**[1], Y. Hong[1], J. Ju[2];*
[1]Catholic University of Korea, Incheon St. Mary's hospital, Incheon, Republic of Korea, [2]Catholic University of Korea, Seoul St. Mary's hospital, Seoul, Republic of Korea.

Introduction: This study was undertaken to determine whether metformin has anti-inflammatory effects in the collagen antibody-induced arthritis (CAIA) murine model. The effect of metformin on Th17 cell differentiation was also investigated.
Methods: CAIA mice were treated with 100 and 150 mg/kg i.p. metformin (low- and high-dose groups, respectively). Arthritis activity and histological joint destruction were studied. Flow cytometry was used to (i) determine RORγt-expressing CD4+ percentages in draining axillary lymph nodes (ALNs) from metformin-treated and untreated mice with CAIA, (ii) determine Th17 percentages in splenic CD4+ T cells cultured *ex vivo* for 3 days in Th17-differentiation-inducing conditions, and (iii) determine the percentages of RORγt+ CD4+ T cells when normal splenic T cells from DBA/1 mice were cultured in Th17-differentiation-inducing conditions together with various metformin doses. Western blot analysis was used to assess the intracellular signaling of the metformin-treated splenocytes.
Results: Metformin attenuated both arthritis scores and bone destruction in CAIA mice, decreased the serum levels of the pro-inflammatory cytokines, TNF-α and IL-1, and reduced the number of RORγt+ CD4+ T cells in the ALNs. Splenocytes from metformin-treated CAIA mice differentiated less readily into Th17 cells upon *ex vivo* stimulation. Metformin treatment of normal cells cultured in Th17-differentiation-inducing conditions decreased the number of RORγt-expressing CD4+ cells in a dose-dependent manner and downregulated STAT3 phosphorylation *via* the AMPK pathway.

Conclusions: Metformin had an anti-inflammatory effect on murine autoimmune arthritis due to the inhibition of Th17 cell differentiation. Metformin may have a possible therapeutic value for treatment of rheumatoid arthritis.

P6.04.13
Sinomenine inhibits osteoclastogenesis and attenuates LPS-induced osteolysis

*L. He[1], H. Duan[1], S. Wang[2], X. Li[1], L. Liu[1], S. Liu[1], **X. Li**[1];*
[1]School of Pharmaceutical Sciences, Southern Medical University, Guangzhou, China, [2]Department of Surgery,Guangdong Hospital of Traditional Chinese Medicine, Guangzhou, China.

Sinomenine (SIN) is an anti-inflammatory and anti-arthritic alkaloid derived from the Chinese medicinal plant Sinomenioumacutum. Osteoclasts can resorp bone and are involved in the bone destruction in rheumatoid arthritis (RA). SIN is an active compound to treat RA, but its effect on osteoclasts has been hitherto unknown. In the present study, we observed that SIN suppressed RANKL and LPS-induced osteoclast formation and survival in vitro. The osteoclastic specific marker genes in RAW264.7 cells and osteoclast-like cells (OCLs), including TRACP, MMP-9, c-Src, integrin αVβ3 and cathepsin K, were also inhibited by SIN dose dependently. Furthermore, SIN inhibited LPS-induced TNF-α production in vitro. Mechanistic studies revealed that SIN obviously suppressed LPS-induced NF-κB activation, as well as the expression of TLR4 and TRAF6. In addition, SIN could selectively block LPS-induced phosphorylation of the MAPK including p38, and suppress the intracellular Ca2+ influx. Moreover, SIN abrogated LPS-induced over activation of AP-1 and NFATc1. Later, the therapeutic effects and molecular mechanisms of SIN on lipopolysaccharide (LPS)-induced osteolysis was investigated. We found that SIN could block LPS-induced osteolysis and TNF-α production in mouse calvarial model. Taken together, it demonstrated that SIN could inhibit osteoclastogenesis and relative signaling pathways to reduce LPS induced osteolysis. SIN might potentially treat bacterial or inflammation induced osteolysis, and might ameliorate RA partly via attenuating the inflammation-induced bone destruction.

P6.04.14
Carbon monoxide exposure improve immune function in lupus prone mice

***J. P. Mackern**[1], C. Llanos[1], L. J. Carreño[1], S. H. Jacobelli[1], I. Anegon[2], A. M. Kalergis[1];*
[1]Millennium Institute on Immunology and Immunotherapy, Santiago, Chile, [2]INSERM UMR 1064-Center for research in Transplantation and Immunology, Nantes, France.

Systemic Lupus Erithematosus (SLE) is an autoimmune disease characterized by multiple alterations affecting the normal function of immune cells, such as lymphocytes, dendritic cells (DCs) and monocytes. Although the understanding of autoimmunity has been significantly increased recently, the breakthrough in effective therapies has been modest, making necessary the development of new therapeutic strategies. Here we propose that a new potential target for therapy is hemeoxygenase-1 (HO-1), an enzyme that catalyzes the degradation of the heme group into biliverdin, carbon monoxide (CO) and Fe+2. These products exhibit immunosuppressive and anti-inflammatory effects, which can contribute to improving tolerance during organ transplantation. The aim of this study was to evaluate whether CO administration could ameliorate disease in the FcγRIIb KO mouse model for SLE. We found that CO administration decreased the expansion of CD11b+ cells and prevented the decline of regulatory T cells (Tregs) observed in untreated FcγRIIb KO mice. Furthermore, CO-treated animals showed reduced anti-histone antibodies and less kidney damage as compared to untreated mice. These data suggest that CO administration can ameliorate autoimmunity and prevent the lupus symptoms shown by FcγRIIb KO mice, underscoring HO-1 as a potential new target for autoimmune therapy.

P6.04.15
Prostaglandin D2 in inflammatory arthritis and synovial myeloid dendritic cells as a source of hematopoietic prostaglandin D-synthase

***M. Moghaddami**[1], E. Ranieri[2], M. James[1], J. Fletcher[2], L. G. Cleland[1];*
[1]Rheumatology Unit, Royal Adelaide Hospital, Adelaide, Australia, [2]Genetics and Molecular Pathology, Women's & Children's Hospital Campus, Adelaide, Australia.

Prostaglandin (PG)D_2 has been shown to be an active agent in the resolution of experimentally induced inflammation. This study was undertaken to determine the presence of PGD_2 in chronic joint effusions and to explore the potential contributions of myeloid dendritic cells (mDC) and monocytes to the intra-articular synthesis of PGD_2.
Synovial fluid (SF) was obtained from patients with inflammatory arthritis and knee effusions. PGD_2 and PGE_2 were detected in SF by ultrahigh performance-tandem mass spectrometry. Cellular fractions in SF were separated by density-gradient centrifugation and flow cytometry. The expression of hematopoietic prostaglandin D synthase (hPGDS) and PGE synthase (PGES) mRNA was determined by RT-PCR.
Both PGD_2 and PGE_2 were detected in blood and SF, with PGD_2 being more abundant than PGE_2 in SF. mRNA for hPGDS was more abundant in SF mDC than SF monocytes (p<0.01) or PB monocytes (p<0.001). SF PGD_2 and hPGDS mRNA in SF mDC were inversely associated with serum C-reactive protein (p<0.01) and erythrocyte sedimentation rate (p<0.01) and a positive correlation was found between SF PGD_2 and expression of hPGDS by SF mDC (p<0.02).
The findings suggest synovial mDC may be an important source of hPGDS and that systemic disease activity may be influenced by actions of PGD_2 in RA and other arthropathies.

P6.04.16
Immunomodulatory activity of vitamin D on dendritic cells in patients with inflammatory arthritis

***M. Moghaddami**, M. James, L. G. Cleland;*
Rheumatology Unit, Royal Adelaide Hospital, Adelaide, Australia.

Excessive activity of myeloid dendritic cells (DC) is postulated to be a central disease mechanism in rheumatoid arthritis (RA). *In vitro* studies were undertaken to explore a possible influence of 1α,25-dihydroxyvitamin-D3 (1,25OHD) on expression of mRNA encoding the synthase for the pro-resolution mediator prostaglandin D2 (PGDS) and certain inflammatory mediators in synovial fluid (SF) DC and peripheral blood monocyte-derived DC (MDDC) in patients with inflammatory arthritis.
SF aspirated from knees with effusions. DC in SF were separated by flow cytometry. DC were activated by LPS and the expression of mRNA was determined by RT-PCR.
The presence of 1,25OHD during *in vitro* differentiation of MDDC inhibited markedly expression of co-stimulatory molecule CD80, maturation marker CD83 and pro-inflammatory cytokine TNFα. During LPS activation of MDDC, 1,25OHD enhanced expression of hPGDS and CD14 mRNA and suppressed expression of RelB, a subunit of NFkb. Combined treatment with 1,25OHD and LPS had a synergistic effect on expression of IL1β and IL6 mRNA in SF mDC and MDDC compared stimulation with LPS alone. There were no significant changes in expression of prostaglanidin E synthase, IL23 and CD86 mRNA.
These *in vitro* studies suggest that 1,25OHD has complex effects on inflammation and may enhance resolution of chronic inflammation through increased expression of hPGDS but may also enhance expression of effector molecules. These latter effects may enhance innate defence against acute infection.

P6.04.17
Diagnostic value of Immunoblotting assay for determination of anti nuclear antibody (ANA) concentration in rheumatologic diseases

M. Naghavi - Behzad[1], *M. Ghojazadeh*[2], *R. Piri*[1], *A. Naghavi-Behzad*[1];
[1]*Students' Research Committee, Tabriz University of Medical Sciences, Tabriz, Iran,* [2]*Tabriz University of Medical Sciences, Tabriz, Iran.*

Background: Antinuclear antibodies (ANAs) are common features of autoimmune connective tissue diseases. Various detection methods are used and there are newer techniques that are continuously put forward to facilitate diagnosis and therapeutic monitoring in connective tissue disease (CTD) patients. Immunofluorescence (IF) or Fluorescent Antibody Technique the most used and "gold standard" test for diagnosis. Enzyme-Linked Immunosorbent Assay (ELISA) is another routine test. For Immunoblotting (IB) assay, autoimmune ANA profiles are used which provide a qualitative in vitro assay for human autoantibodies to 15 different antigens. This study was conducted to compare three techniques (IF, IB, ELISA) in detection of ANA. If the sensitivity and specificity of IB superior to other methods, we can replace IF and ELISA with IB.
Materials and Methods: An analytical cross-sectional study of 85 sera from patients with Systemic lupus erythematous (SLE), Systemic sclerosis (SSc) and Dermatomyosities(DM) was undertaken at rheumatology and nephrology department and clinic of Emam Reza hospital from 89/11/1 to 90/10/30. Sera collected and stored at -80°c. Then they were used to detection of ANA with three techniques.
Results: Of all sera 63 (74.1%) were ELISA positive and 22 (25.9%) had negative ELISA.74 (87.1 %) IF and IB positive and 11 (12.9%) IF and IB negative were observed. The sensitivity and specificity of IB in comparison with IF was 98.65% and 90.91%, respectively. In comparison, with ELISA we found 93.65% and 31.82% of sensitivity and specificity.
Conclusion: Immunoblotting has high sensitivity and specificity, and it can be used in the screening of ANA.

P6.04.18
In vitro evaluation of infliximab-specific T cells in patients with acute infusion reaction

F. Nencini[1], *A. Vultaggio*[2], *S. Pratesi*[1], *G. Petroni*[1], *A. Matucci*[2], *E. Maggi*[1];
[1]*Centre for Research, Transfer and High Education DENOTHE and Departments of Internal Medicine, Florence, Italy,* [2]*Immunoallergology Unit, Department of Biomedicine, Careggi Hospital, Florence, Italy.*

Infliximab (IFX), a chimeric anti-TNFα monoclonal antibody, is an established targeted therapy for immuno-mediated inflammatory diseases. As other biotherapeutics, it carries potential risks of immunogenicity, with the production of specific anti-IFX antibodies (ATI) that can lead to loss of response or acute infusion reactions. Our study was aimed to analyse the memory T-cell response to IFX in patients who developed ATI.
We investigated the presence of IFX-specific T cells in 50 subjects (16 reactive ATI+, 8 non responder ATI+, 17 tolerant ATI- and 9 non exposed healthy donors), using different T-cell proliferation assays. Drug-specific T cell clones (TCC) were also generated from PBMC of 2 reactive patients.
PBMC obtained from 11 (9 reactive and 2 non responder) out of 24 (45.8%) ATI+ patients displayed a proliferative to IFX, while no proliferation was detectable in both ATI- patients and healthy donors. Cytokine (IL-13, IFNγ, IL-17) production by PBMC, as well as by TCC, upon in vitro re-stimulation with IFX, was highly variable between the patients. The analysis of Vβ usage analysis of drug-specific TCC revealed an oligoclonal expansion. An high proportion of IFX-specific TCC, showed a regulatory phenotype and function. Cross-reactivity of IFX-specific TCC with other chimeric mAbs and murine IgG was also detected.
Overall, our study provide evidence of both effector and regulatory memory T cells specific for IFX and contributes to the understanding of pathogenic mechanisms of immunogenicity of biological agents.

P6.04.19
Immunological mechanism of IL-7R antibody on collagen II-induced arthritis

H. Nie*, Y. Wang, X. Huang, X. Hu;*
Shanghai Institute of Immunology, Shanghai JiaoTong University School of Medicine, Shanghai, China.

In this study, we used collagen II-induced arthritis (CIA) model in DBA-1 mice to investigate the potential effects of IL-7Rα antibody on rheumatoid arthritis. Our results showed that in vivo treatment of CIA mice with IL-7Rα antibody had great protective benefit at both clinical and histological levels. Disease suppression was associated with inhibition of CII-specific $CD4^+$ T cell proliferation and decrease of inflammatory cytokine secretion (such as IFN-γ, IL-17 and TNF-α). We further analyzed the mechanism of IL-7Rα antibody on $CD4^+$ T cell subsets. The results showed that the amount of Th1 and Th17 subset from treatment group were decreased, accompanied by the down-regulation of transcriptional factor T-bet and RORγt. In conclusion, this study provided evidence that IL-7Rα antibody had great therapeutic effect on CIA through its inhibition actions on pathogenic Th1 and Th17 cells. These results suggest that IL-7Rα antibody may be of potential therapeutic value in rheumatoid arthritis and provide a basis for further research on mechanism of IL-7Rα antagonists for rheumatoid arthritis therapy. (This work was supported by grants from National Natural Science Foundation of China 81273307 and 81072470).

P6.04.20
Regulatory T cells are essential for the anti-arthritic effects of Methotrexate in experimental arthritis

R. S. Peres[1], *F. Y. Liew*[2], *J. Talbot*[1], *V. Carregaro*[1], *L. G. Pinto*[1], *J. S. Silva*[1], *T. M. Cunha*[1], *J. C. Alves-Filho*[1], *P. Louzada-Junior*[1], *F. Q. Cunha*[1];
[1]*University of São Paulo, Ribeirão Preto, Brazil,* [2]*University of Glasgow, Glasgow, United Kingdom.*

Rheumatoid arthritis (RA) is an autoimmune disease characterized by chronic inflammation of the joints. The first line pharmacotherapy for RA comprises the use of methotrexate (MTX), an anti-metabolic drug. Moreover, it's suggested that anti-arthritic effects of MTX in RA may be related with number/suppressive activity of regulatory T (Treg) cells. Our aim was to investigate the role of Treg cells on the anti-arthritic effects of MTX in antigen-induced arthritis (AIA) model. mBSA-immunized C57BL/6 mice were pretreated with MTX (2 mg/kg-orally) weekly for 5 weeks before challenge with mBSA (30 µg/cavity) at day 21 after first immunization. Articular hyperalgesia, neutrophil migration to the joint, plasma titers of specific IgG and Treg cells frequency in the spleen and draining lymph nodes (DLNs) were evaluated 7h after challenge with mBSA. For Treg cells depletion, mBSA-immunized C57BL/6 mice pretreated or not with MTX were undergoing administration of anti-CD25 (250 µg/ml) three times per week during the immunization protocol. MTX-treated mice showed a reduction of arthritis development, evidenced by reduction of neutrophil migration into the joint and mechanical hyperalgesia. The effect of MTX-treatment was not due to impaired mBSA priming, since the plasma titers of specific anti-mBSA IgG were similar between the groups. Interestingly, while the frequency of CD4+FoxP3+ cells in the DLNs was similar, MTX-treated mice had an increase of this population frequency in the spleen. Furthermore, Treg cells depletion with anti-CD25 treatment reversed anti-arthritic effects triggered by MTX. These findings show that the anti-arthritic effects of MTX are Treg-dependent in AIA.

P6.04.21
Development and kinetic of anti-Infliximab antibodies: their high levels are related to adverse infusion reactions

G. Petroni[1], *S. Pratesi*[1], *F. Nencini*[1], *M. Milla*[2], *E. Maggi*[1], *A. Matucci*[3], *A. Vultaggio*[3];
[1]*Centre for Research, Transfer and High Education DENOTHE and Departments of Internal Medicine, Univ, Florence, Italy,*
[2]*Gastroenterology Units, Careggi Hospital, Florence, Italy,*
[3]*Immunoallergology Units, Careggi Hospital, Florence, Italy.*

Infliximab (IFX), a chimeric anti-TNFα monoclonal antibody, carries potential risk of immunogenicity with the production of specific anti-IFX antibodies (ATI), leading to potential loss of response or acute infusion reactions.
In this study a panel of 187 patients suffering from immuno-mediated inflammatory diseases treated with IFX were enrolled to analyse the development of ATI. They were categorized into 5 groups: responder (I), non responder [totally (II) or partially (III)], reactive (IV) and reactive/non responder (V) patients. Non isotype-specific ATI were measured by Elisa.
Decreased percentages of positivity were shown in different groups of patient: 100% in V, 82.16% in IV, 38.% in II, 22.2% III and 9.9% in I. When evaluated for their titres, the reactive patients exhibited the highest amounts of ATI. A longitudinal study of more than 30 patients showed that the development of ATI occurred after the initial infusions of IFX in all groups of patients, even after the interruption of therapy. In the group of patients who interrupted IFX for adverse infusion reactions or unresponsiveness we evaluated the kinetics of ATI in the absence of therapy or in the presence of alternative regimens. The presence of cross-reactive ATI before the treatment with IFX and their correlation with relapse of chronic viral infections have been also evaluated.
The direct correlation between the titre of ATI and the adverse drug reactions, as well as their onset during the first infusions or different cycles of therapy, are relevant issues for prevention and management of such patients.

P6.04.22
Interleukin-6 targeting strategy for immune-mediated diseases

T. Tanaka[1], *A. Ogata*[2], *A. Kumanogoh*[2], *T. Kishimoto*[3];
[1]*Department of Clinical Application of Biologics, Osaka University Graduate School of Medicine, Suita, Japan,* [2]*Department of Respiratory Medicine, Allergy and Rheumatic Diseases, Osaka University Graduate School of Medicine, Suita, Japan,* [3]*Laboratory of Immune Regulation, Immunology Frontier Research Center, Osaka University, Suita, Japan.*

Interleukin (IL)-6, a typical cytokine featuring redundancy and pleiotropic activity, when produced transiently, contributes to host defense by inducing immune responses and acute phase reactions. However, dysregulated persistent IL-6 production of mostly unknown etiology has been demonstrated to play a significant pathological role in various immune-mediated diseases, so that tocilizumab, a humanized anti-IL-6 receptor antibody, was developed. Clinical trials have proved the outstanding efficacy and tolerable safety of tocilizumab for patients with rheumatoid arthritis, resulting in its approval in more than 100 countries worldwide. It is likely to be broadly applicable for the treatment of various other immune-mediated diseases. Indeed, our experience of off-label use with tocilizumab has suggested this possibility. The skin sclerosis of two patients with systemic sclerosis softened in association with the reduction of the number of activated myofibroblasts in the dermis after 6 injections of tocilizumab. The prominent effects of tocilizumab were also observed in several intractable diseases such as polymyositis, relapsing polychondritis, polymyalgia rheumatica, reactive arthritis, amyloid A amyloidosis or Behcet's disease. The mechanism(s) through which IL-6 blockade is effective for various phenotypically different diseases remain to be determined. It is suggested that IL-6 blockade can repair the imbalance of Th17 over Treg and/or inhibit autoantibody production. Further clinical trials to evaluate the efficacy of tocilizumab on immune-mediated diseases, as well as research to elucidate the therapeutic mechanisms of tocilizumab and to clarify the cell source of IL-6 and the mechanisms through which dysregulated continuous IL-6 synthesis is induced are important issues for future studies.

P6.04.23
Rheumatoid arthritis: physical activity and disease-activity scores

P. Triggianese*, P. Conigliaro, F. Ippolito, R. Perricone;*
University of Rome Tor Vergata, Rheumatology, Allergology and Clinical Immunology, Department of "Medicina dei Sistemi", Rome, Italy.

Regular moderate intensity Physical Activity (PA) has significant benefits for health. The present study aimed to explore the role of PA in Rheumatoid Arthritis (RA). Thirty RA patients matched for therapy (mean disease-duration 90.87±66.73 months) and thirty age-, sex-, BMI-matched controls were enrolled. PA -including daily occupation and physical exercise- was assessed through validated self-complete questionnaire. Metabolic Equivalents (METs) and Energy Expenditure (EE) were calculated. Disease Activity Score (DAS-28), Functional Status (HAQ), Pain Visual Analogue Scale (VAS), Fatigue VAS, Stiffness VAS, Disease-activity VAS, Short-Form-36 Health Status (SF-36), General Health Assessment, Arthritis Impact Measurement Scales were measured. Biochemical markers included erythrocyte sedimentation rate, C reactive protein, rheumatoid factor, anti-CCP antibodies. Proportion of occupations was significantly lower in patients compared with controls ($p=0.0006$); nevertheless sedentariness (MET 1-1,5) did not significantly differ. A lower number of patients performed high intensity physical exercise ($p<0.05$) compared with controls. However the same proportion performed regular moderate intensity exercise (MET 3-5.9) and the difference of EE for physical exercise between the two groups was not statistically significant (388.54 kcal/day/patient, 584.12 kcal/day/control). RA patients performing physical exercise showed significantly lower DAS-28 ($p=0.004$), Stiffness VAS ($p=0.005$), Disease-activity VAS ($p=0.003$), SF-36 ($p=0.01$) than other patients. There was no statistically significant difference in biochemical markers and in other disease-activity scores. Despite the reduced number of patients, this study represents a proof of concept for the most recent evidences concerning the association between PA and disease-activity scores in RA suggesting that physical exercise may represent a favourable therapeutic strategy.

P6.04.24
Combination therapy of methotrexate with ellagic acid attenuates the over expression of Pro-inflammatory Cytokines and modulates antioxidant status in collagen induced arthritis

S. Umar[1], *S. Ahmad*[1], *C. K. Katiyar*[2], *H. A. Khan*[1];
[1]*Jamia Hamdard, New Delhi, India,* [2]*Dabur Research Centre, Ghaziabad, India.*

The inclusion of antioxidant for the treatment of arthritis, especially under the therapy with immune-suppressant, is motivated because antioxidant plays an essential role in disease progression and moreover, immunosuppressive treatment suffers redox homeostasis balance of the organism. The present study was designed to evaluate the combinatory effect of methotrexate (MTX) and ellagic acid (EA) on the progression of collagen induced arthritis. Arthritis was induced in Wistar rats by collagen induced arthritis (CIA) method. CIA rats were treated with methotrexate (1 mg / kg / week) and EGCG (60 mg / kg) daily, and combination of MTX and EGCG for a period of 28 days. Paw swelling changes, scoring and histopathological was assessed to evaluate the antiarthritic effect. The effects of treatment in the rats were assessed by biochemical (articular elastase, MPO, LPO, GSH, Catalase, SOD and NO) in joint tissue homogenate to observe the modulation of antioxidant and inflammatory status, inflammatory mediators (IL-1β, TNF-α, IL-10, and PGE_2) and histological studies in joints. MTX and EA combination potentiated the antiarthritic (decrease of hind paw volume and scoring) and the antioxidant effect (GSH, Catalase, SOD) as well as suppression of lipid peroxidation. Combination therapy of MTX and EA significantly inhibited the development phase of arthritis, which is supported by histopathological and attenuation of pro inflammatory cytokines. EA act as potent antioxidant and immunomodulator, suggesting that combined administration of MTX along with EA suppressed the development of arthritic progression in rats.

The Role of Bioinformatics in Allergenicity Assessment of Recombinant Proteins

***N. Allahyari Fard**;*
National Institute of Genetic Engineering and Biotechnology (NIGEB), Tehran, Iran.

Allergy is an important health issue, which is caused by certain food proteins, including recombinant proteins. The prevalence of allergic diseases has grown in many industrialized and urbanized countries during the last 50 years and almost 30 to 40 percent of the world's populations suffer from allergic diseases. Accordingly, an international regulation evaluating the allergenicity of recombinant proteins is necessary. Bioinformatics analysis has been considered a main section for the safety assessment of recombinant proteins expressed in food plants, food animals, food mushrooms, drugs, etc. Use of bioinformatics screening in allergenicity assessment of recombinant proteins in allergen databases is recommended by the World Health Organization, the European Food Safety Authority and the US Environmental Protection Agency. Bioinformatics allows two questions to be asked: Is the recombinant protein an existing allergen? Is the recombinant protein likely to cross-react with an existing allergen? A weight of evidence approach is recommended by the Codex Alimentarius Guidelines to assess the risk of allergenicity of any recombinant proteins, including bioinformatics analysis, digestibility and animal models. Bioinformatics analysis for allergenicity assessment of proteins is carried out via allergen databases and other in silico tools. Until now many allergen databases have approved for identification of allergens and bioinformatics allergenicity assessment of recombinant proteins in many countries. Thus, bioinformatics has an important role in allergenicity assessment of recombinant proteins. This role will increase with additional studies of 3d structure of proteins, proportion of amino acids of allergen proteins, and sequencing of allergen epitopes.

Background: We have recently identified Der p 23 as new, major house dust mite (HDM) allergen with an IgE-binding frequency of more than 70% and high allergenic activity. Therefore, Der p 23 is an essential component in a vaccine for HDM immunotherapy.
Objective: To construct and characterize a hypoallergenic vaccine for Der p 23-sensitized patients.
Method: Non-allergenic Der p 23 peptides were identified from a panel of synthetic Der p 23 peptides by IgE serology and basophil activation testing. A synthetic gene coding for a fusion protein consisting of non-allergenic Der p 23 derived peptides with reduced capacity to induce T-cell proliferation and the hepatitis B virus-derived PreS domain for providing T cell help was expressed in E. coli and purified to homogeneity (Der p 23/P4P5). The IgE-reactivity and allergenic activity of the Der p 23/P4P5 was compared with rDer p 23 in IgE dot blot assays and basophil activation tests using blood from HDM allergic patients. Rabbits were immunized with Der p 23 or Der p 23/P4P5 to investigate whether the molecules induce specific IgG antibodies which are able to inhibit patients' IgE binding to Der p 23.
Result: A recombinant Der p 23/P4P5 fusion protein lacking allergenic activity was expressed and purified. Upon immunization of rabbits, Der p 23/P4P5 induced IgG antibodies that inhibited the binding of patients' IgE to Der p 23 comparable to IgG antibodies induced with Der p 23.
Conclusion: Der p 23/P4P5 represents a promising candidate for the treatment of sensitized HDM allergic patients.

P6.05.03
Assessment of physiochemotoxic reactions after the injection of contrast media

***M. Barzegar**, S. Yazdan parast, F. Saeedi;*
Tehran University Medical Science, Tehran, Iran.

Although contrast media (CM) is known to cause adverse reactions, the actual reason for adverse reactions remains unknown. There are two common theories that are used to describe adverse reactions to intravenous iodinated contrast media. Adverse reactions are classified as physiochemotoxic or idiosyncratic in nature. The cardiovascular system is most commonly affected by physiological changes that can be produced by CM.
Physiochemotoxic reactions are commonly related to the following: 1. Physical properties of CM; 2. Iodine concentration of CM; 3. Volume of the CM injected; 4. Rate or injection speed.
-The physical properties of the CM include the ions or other particles. The chemical composition of ionic and non-ionic CM contains iodine. CM is primarily divided into two categories, high osmolar contrast media (HOCM) and low osmolar contrast media (LOCM).
-The iodine concentration is determined by the number of iodine molecules in mg/ml. The higher the iodine concentrations are more radiopaque than comparative low iodine concentrated agent and greater the risk of an adverse reaction.
-Increasing the injected volume increases the possibility of an adverse reaction occurring.
-Increasing the speed or rate of injection may increase the risk of an adverse reaction occurring.
Anytime CM is introduced into the body there exists a possibility of a reaction. The radiologic technologist's immediate recognition and response to an adverse reaction is very important because it can save a patient's life. Technologists must become familiar with radiology department protocols regarding adverse reactions to CM as well as all emergency situations that may arise.

P6.05.04
Microwave irradiation of bovine milk reduces allergic response in mouse model of food allergy

***I. Bouayad Debbagh**, H. Kaddouri, K. El Mecherfi, H. Negaoui, A. Chekroun, L. Amier, O. Khéroua, D. Saidi;*
Department of biology, Oran, Algeria.

Introduction: Cow's milk (CM) contains many proteins that are considered allergenic and capable of inducing immune responses in allergic subjects. Heating, a commonly used method in dairy technology, are likely to induce changes in milk allergens. Microwave irradiation (MWI) is an alternative method to a conventional heating. The purpose of this study was to determine MWI effects on bovine milk protein allergenicity .
Methods: Cow's milk was irradiated by Microwave or heated by conventional method. Whey samples were analysed by Poly-Acrylamide Gel Electrophoresis in the presence of Sodium Dodecyl Sulfate. Immunoreactivity was estimated by indirect enzyme-linked immunosorbent assay (ELISA) using murine sera. Allergenicity was studied in vitro in chamber Ussing by intestine challenge in a murine model of β-lactoglobulin allergy.
Results: The electrophoretic patterns of heated and irradiated samples revealed a considerable decrease in intensity of the bands corresponding to whey proteins. Bovine whey antigenicity was clearly reduced by MWI as well as by conventional heating. The allergenic potential of bovine whey was markedly reduced after MWI as shown by short circuit current (Isc) and conductance (G) which remained unchanged after intestine challenge with irradiated whey. However, whey allergenicity was enhanced by heating whey at 102°C.
Conclusion: MWI as well as conventional heating may reduce whey proteins antigenicity. Moreover, bovine whey allergenicity was significantly increased by conventional heating but markedly reduced by MWI.

P6.05.05
Effect of static magnetic field on pollen-induced allergic airway inflammation in a murine model

A. Csillag[1], *B. V. Kumar*[1], *K. Szabó*[1], *K. Pázmándi*[1], *É. Rajnavölgyi*[1], *J. László*[2], *A. Bácsi*[1];
[1]*University of Debrecen, Department of Immunology, Debrecen, Hungary,* [2]*University of Debrecen, Department of Computer Science, Debrecen, Hungary.*

It has been demonstrated that pollen NAD(P)H oxidases generate oxidative stress in the airway epithelium and this immediate oxidative insult is crucial for the development of allergen-driven airway inflammation. In this study we aimed to define the effect of inhomogeneous static magnetic field (iSMF) on pollen-induced allergic airway inflammation since several lines of evidence suggest that iSMF is able to trigger biological responses at least partly through free radical reactions. BALB/c mice were sensitized by two intraperitoneal injection of ragweed pollen extract (RWE) and challenged with RWE intranasally. Inflammation was evaluated by determining inflammatory cell accumulation and mucin levels, as well as histological analysis of the airways. iSMF was generated with an apparatus optimized to small experimental animals. We found that iSMF did not affect the sensitization phase of the allergic responses; however, even a single 30-min exposure to iSMF after i.n. RWE challenge was able to reduce the airway inflammation. In addition, prolonged exposure to iSMF after RWE challenge decreased more effectively the severity of inflammation. In animals exposed to iSMF immediately after challenge, RWE induced a lower increase in the total antioxidant capacity of the airways suggesting that effects of iSMF on allergic inflammation were mediated at least partly by modulation of ROS levels. These data indicate that iSMF is able to reduce the inflammation in an *in vivo* system, despite the fact that it does not interfere with ROS-production of RWE NAD(P)H oxidases directly in cell free conditions.

P6.05.06
Allergy-protective activation of dendritic cells by the cowshed bacteria *L. lactis* G121 requires endosomal acidification *in vitro* and *in vivo*

K. Stein[1], *S. Brand*[2], *O. Holst*[1], *M. Kauth*[2], ***H. Heine***[1];
[1]*Research Center Borstel, Borstel, Germany,* [2]*Protectimmun GmbH, Gelsenkirchen, Germany.*

It is well established that farming environment in early childhood reduces the occurrence of allergic reactions later in life. The Gram-positive cowshed isolate *Lactococcus lactis* G121 has been shown to prevent allergic immune responses in a mouse model of acute allergic inflammation. However, the molecular mechanisms by which this allergy-protective immune response is achieved are mainly unknown. Experiments with HEK293 cells indicated no involvement for TLR2 in *L.lactis*-mediated cell activation but rather for intracellular receptors such as Nod2 and TLR8. Stimulation of DCs with *L.lactis* led to release of several cytokines including IL-12p70, IL-23, IL-10, and IFN-β. DCs preincubated with the inhibitors Cytochalasin D and Bafilomycin A1 (Baf) showed a strong decrease of overall cytokine production, indicating the importance of not only the uptake of bacteria but also of the endosomal acidification. Moreover, Baf-treatment of DCs inhibited the *L.lactis*-induced upregulation of costimulatory molecules as well as IFN-γ and IL-10 release when these DCs were co-cultured with T-cells. To investigate the importance of endosomal acidification in *L.lactis*-mediated allergy protection *in vivo,* we transferred *in vitro*-derived BMDCs stimulated with *L.lactis* in presence or absence of Baf intranasally into naïve mouse recipients. While *L.lactis*-stimulated BMDCs prevented mice from the development of allergic inflammation, pretreatment with Baf significantly reduced the protective effect, as indicated by eosinophils in BAL and goblet cell number. Overall, we found that uptake and endosomal acidification are essential for the allergy-protective effect of the cowshed bacteria *L.lactis* G121 (supported by DFG, TR22-project A2).

P6.05.07
Chitosan-alginate core-shell caged vaccines for allergy Treatment

E. I. Kashirina*, P. D. Reshetov, R. S. Grynevich, A. V. Prokhorov, D. Y. Ryazntsev, T. V. Dimitrieva, V. M. Berzhets, E. V. Svirshchevskaya;*
Shemyakin and Ovchinnikov Institute of Bioorganic Chemistry RAS, Moscow, Russian Federation.

Type I allergy is manifested by the release of vasoactive factors induced by IgE contact with full-length allergen. IgE usually do not recognize linear epitopes of allergens. We used this property to produce a caged vaccine against house dust mite (HDM) allergy constructed from full-length Dermatophagoides farina (Der) allergens hidden inside the polymeric core particle and Der peptides exposed on the polymeric shell. Proteins carry both T and B cell epitopes making vaccine immunogenic; while peptides represent linear B-cell epitopes which cannot trigger IgE-dependent degranulation of must cells but can collect B-cells from circulation during immune synapse formation. Hydrophobic laurylchitosan with immobilized Der f 1 and Der f 2 (ChDer) was used to form core particles and alginate conjugated to Der f 1 and Der f 2 hydrophilic peptides (AlDerp) to form a shell layer. Slow mixture of ChDer with AlDerp induced polyelectrolyte complex formation consisting of Der proteins caged inside the particle, and Der peptides exposed to the environment. As a control we also produced particles with core Der proteins and shell irrelevant (Alir) peptides to study IgE binding. We demonstrated that sera from patients with HDM allergy bound pure Der proteins and did not bind: i) pooled Der peptides; ii) ChDer-AlDerp particles; iii) ChDer-Alir particles showing that neither Der peptides (free or immobilized) nor caged Der proteins were recognized by IgE specific to HDM. Such constructs can be used to conduct specific immunotherapy of HDM allergy in a rush protocol.
Work was supported by RFBR grants 12-04-32094, 12-03-31803.

P6.05.08
Selective elimination of allergen-specific B lymphocytes with chimeric protein-engineered molecules

N. S. Kerekov[1], *A. Michova*[2], *M. Nikolova*[3], *G. Nikolov*[3], *M. Muhtarova*[3], *B. Petrunov*[3], *A. Tchorbanov*[1];
[1]*Institute of Microbiology "Stefan Angelov", Bulgarian Academy of Sciences, Sofia, Bulgaria,* [2]*National Specialised Hospital for Active Treatment of Haematological Diseases, Sofia, Bulgaria,* [3]*National Center of Infectious and Parasitic Diseases, Sofia, Bulgaria.*

Background: DerP1 is one of the major allergenic molecules of *Dermatophagoides pteronyssinus* which causes the widespread house dust allergy. The pathological DerP1-specific B cells produce allergen-specific IgE antibodies that mediate most of the hypersensitivity allergic reactions.
Aim: The selective elimination of allergen-specific B cells by artificial protein molecules which inhibit Dpt-recognizing IgE antibodies production is a legitimate therapeutic goal for allergy. Co-crosslinking of the immunoglobulin receptor and the inhibitory B cell receptor CR1 (complement receptor 1) on the DerP1-specific B cells by this molecule have the potential to deliver suppressive signal, selectively silencing these B-cells only.
Methods: A synthetic peptide, DerP1 p52-71, containing a B and T cell epitopes and anti-CR1 monoclonal antibody were used for the construction of DerP1 chimera. We analysed the effects of the chimeric molecule on PBMC from allergy patients.
Suppression of DerP1-specific IgE antibody production was measured by ELISpot.
Apoptosis assay was performed by FACS using AnnexinV-FITC/PI staining.
Results: We observed significant inhibition of allergen-specific proliferation and reduction of specific IgE antibodies after treatment of PBMC from allergic patients with DerP1-peptide chimera. Culturing of these PBMC in the presence of the same chimera increased the percentage of apoptotic (Annexin V-positive) B lymphocytes, but not T lymphocytes.
Conclusion: The constructed protein-engineered chimeric molecule binds DerP1 specific B lymphocytes via their BCR and suppresses selectively the production of anti-DerP1 IgE antibodies by co-crosslinking of the BCR and CR1. This way we could alter the allergic immune response towards a milder outcome.

P6.05.09
Bet v 1 and homologous food allergens are similarly processed by antigen-presenting cells but differ in T cell reactivity

C. Kitzmueller[1], *N. Zulehner*[1], *A. Roulias*[2], *P. Briza*[2], *F. Ferreira*[2], *B. Bohle*[1];
[1]*Medical University Vienna, Vienna, Austria,* [2]*University of Salzburg, Salzburg, Austria.*

Background: Various plant foods, e.g. hazelnut, apple and celery, express proteins that are homologues of the major birch-pollen allergen Bet v 1, e.g Cor a 1, Mal d 1 and Api g 1. These proteins share a common 3-dimensional structure. Despite the great molecular similarity, Bet v 1 is the only one among its homologues with the ability to sensitise atopic individuals.
Aim: To assess whether differences in the uptake and processing by antigen-presenting cells and in the presentation to T cells could be responsible for the ability to sensitise.
Methods: Uptake of allergens by PBMC, surface binding to and degradation by monocyte-derived dendritic cells (mdDC) were assessed. Peptides derived from digestion of Bet v 1, Cor a 1, Mal d 1 and Api g 1 by endo-lysosomal extracts were analysed by mass spectrometry. Epitope-specificity of allergen-specific T cell lines from birch pollen-allergic individuals with associated food-allergies was mapped using synthetic 12-mer peptides. Binding of allergen-derived peptides by HLA class II molecules was analysed in silico.
Results: Significant differences were found neither in surface binding, in the kinetics of uptake by PBMC, the intacellular degradation by mdDC nor in the degradation by endo-lysosomal extracts. An immunodominant T cell epitope was found only in Bet v 1, but could not be referred to preferential binding to the most common HLA class II molecules.
Conclusion: The ability of Bet v 1 to sensitise is not conferred by differential antigen-processing but might stem from differences in T cell reactivity.

P6.05.10
Influence of administration route and polysaccharide addition on adjuvanticity of AFPL1 to allergens of Dermatophagoides siboney

M. Lastre[1], *E. Facenda*[2], *A. Labrada*[2], *V. Bourg*[2], *G. Sierra*[1], *O. Pérez*[1];
[1]*Finlay Institute, Havana, Cuba,* [2]*BioCen, Mayabeque, Cuba.*

Background. AFPL1 is a pro Th1 adjuvant containing proteoliposome of Neisseria meningitidis and alum. Previous work has shown its anti-allergic effect in a murine model of respiratory allergy. Aim. To determine the influence of Polysaccharide C (PsC) and immunization route on to the antibody response to Dermatophagoides siboney allergen.
Materials and Methods. Balb/C mice were administered s.c or i.m with two doses of three variants: AFPL1, Der s1 (5 µg) and PsC (50 or 25 µg). The second dose was injected 14 days afterward. The antibody response was assessed starting from 21 days. D. siboney specific IgG, IgG1, IgG2a, and IgE were measured by ELISA.
Results: No significant differences (p=0.05) were obtained between the three variants by i.m route, i.e., in absence of PsC, or containing 25 or 50 µg of it. In contrast, the addition of PsC by s.c route induced a marked and significant raise of allergen-specific and total IgE, as well as, IgG1 and IgG, and a decrease of IgG2a, as compared to i.m route. This increase was dose- dependent with respect to PsC content. The s.c route in absence of PsC showed the highest value of IgG2a/IgG1 ratio indicating a higher pro-Th1 effect.
Conclusion. PsC is able to modulate and partially counteract the AFLP1 pro-Th1 adjuvant effect, raising the IgE response, although, only when is administered by s.c route. Since this route is preferred for allergen vaccines due to safety reasons, an optimal formulation of an AFLP1-adjuvanted antiallergic vaccine should avoid the presence of PsC.

P6.05.11
Is allergy to peanut important in Cuba?

M. Maytee, *R. Cruz, R. L. Castro, M. Reyes, D. Torralba, Y. Oliva, A. Labrada;*
National Center of Bioproducts (BioCen), Mayabeque, Cuba.

Introduction: Peanut allergy is alarmingly increasing in developed countries. Roasted peanut (Arachis hypogaea) is a common food in Cuba. Nevertheless, reported values of sensitization to peanut are usually Objective: To perform a preliminary assessment of allergic sensitization and IgE specificity profile to peanut allergens in Cuban allergic patients Methods: The Skin Prick Test was performed to each patient/subject, using two glycerinated allergenic extracts, prepared from raw or roasted peanuts, BIOCEN, Cuba. Two groups of subjects were studied: a cohort of general adult population (N=292), and patients attending allergy services at 4 hospitals in Havana, comprising 16 adults (above 16 years old) and 66 children (2-16 years). The IgE binding profile of 10 selected SPT positive patients was further analyzed by Western Blotting Results: In general adult cohort the prevalence of sensitization was 2.7% and 4.7%, to raw and roasted peanut, respectively ($p<0.05$, McNemars). Unexpectedly, among patients suspecting food allergy, the positivity rate was higher to raw peanut (62%) versus roasted (51%). Interestingly, sensitization to roasted, but not to raw peanut, increased from 45% in children, to 75% in food allergic adults. IgE binding was shown mostly by the 60-64 KDa bands, tentatively identified as (Ara h1 and Ara h3), known as clinically relevant allergens Conclusions: Allergic sensitization to peanut seems not to be as important in Cuba as in developed countries, although it should be taken into account for improving the specific diagnosis of food allergy. Differences between sensitization to raw or roasted peanut deserve further investigation.

P6.05.12
Tamoxifen a new therapeutic approach for allergy airway disease

G. Moran, *H. Folch, B. Perez, N. Morales, J. Sarmiento, C. Henriquez, J. Galecio;*
Universidad Austral de Chile, Valdivia, Chile.

Recurrent airway obstruction (RAO) is an asthma-like condition that develops in mature horses following stabling and exposure to dusty hay and straw. The hallmark of this disease is that hay/straw exposure induces clinical airway obstruction, airway neutrophilia and increased airway mucous production in. Our previous study indicated that tamoxifen has the ability to induce apoptosis in vitro in granulocytic cells from peripheral blood and broncheoalveolar lavage fluid (BALF). Therefore, we propose that tamoxifen, when used as a treatment in RAO-affected horses, induces a resolution of allergy airway inflammation through action on polymorphonuclear neutrophils. For this purpose, nine RAO-susceptible horses sensitized to Aspergillus fumigatus (RAO herd) will be selected for use in this study. The animals will be exposed to dusty/moldy hay, and once the signs of the disease appear. Later, the horses will be treated with 100 mg PO of tamoxifen every other day in a remission environment. During treatment and after drug administration has ended, periodical evolution of RAO clinical signs will be conducted to evaluate the effect of tamoxifen on airway inflammation (clinical score, mucus score, endoscopic examination and BALF for apoptosis evaluation). Our results indicate that RAO-affected horses treated with tamoxifen displayed a significant reduction of neutrophils in BALF and a concomitant improvement in their clinical status. This reduction in neutrophils BALF is related to the percentage of cells positive Anexin-V. These results indicate that the apoptotic mechanisms under these experimental conditions would affect blood and BALF granulocytic cells, particularly in early apoptosis (positive Anexin–V).

P6.05.13
Effect of depletion of 33D1+ dendritic cells on allergic airway sensitization in mouse model

R. Murakami[1,2], *Y. Nakagawa*[1], *A. Wakabayashi*[1], *Y. Kumagai*[1], *K. Ohkubo*[2], *H. Takahashi*[1];
[1]*Department of Microbiology and Immunology, Nippon Medical School, Bunkyoku,Tokyo, Japan,* [2]*Department of Otorhinolaryngology, Nippon Medical School, Bunkyoku,Tokyo, Japan.*

Th2 dominance in Th1/Th2 balance in the acquired arm plays a central role in the induction of allergic sensitization as well as in the chronic inflammatory cascades of allergic diseases. It has been shown that two major distinct subsets of dendritic cells (DCs) in the innate arm are arranged to regulate the immune responses in vivo; DEC 205+ DCs having the capacity to establish the Th1 polarization and 33D1+ DC to establish Th2 dominance.
We have previously reported that 33D1+ DCs could be successfully depleted from mice by anti-33D1-specific monoclonal antibody treatment [Cancer Immunol. Immunother., 59:1083-1095,2010] and recently demonstrated that the fetal loss was induced by the depletion of 33D1+ DCs during perinatal period mediated through Th1 up-regulation via transient IL-12 secretion [Immnobiol., 217:951-961, 2012]. Based on these findings, we studied the effect of 33D1+ DC depletion on allergic airway sensitization against ovalbumin (OVA) in vivo mice model. Mice were sensitized i.p. with OVA plus alum, and were intranasal challenged with OVA solution. The results showed that, when 33D1+ DCs were depleted, anti-OVA IgE level in the serum and allergic symptoms such as sneezing or nasal scrubbing times were apparently decreased as compared with control mice . These results suggest that innate 33D1+ DCs may induce Th2 polarization on allergic airway sensitization in acquired immunity and modulation of DC subsets may offer a new therapeutic strategies for various allergic diseases by altering Th2 polarization.

P6.05.14
Characterization of airway inflammation and hyperreactivity induced by sole aeroallergen exposure in humanized allergy mice expressing a human mugwort-specific T-cell receptor and HLA-DR1

A. Neunkirchner[1,2], *D. Wojta-Stremayr*[1,2], *K. G. Schmetterer*[2], *L. F. Mager*[2], *V. M. Leb-Reichl*[1,2], *E. Rosloniec*[3], *G. Dekan*[4], *B. Jahn-Schmid*[5], *B. Bohle*[1,5], *W. F. Pickl*[1,2];
[1]*Christian Doppler Laboratory for Immunmodulation, Vienna, Austria,* [2]*Institute of Immunology, Medical University of Vienna, Vienna, Austria,* [3]*Veterans Affairs Medical Center, Memphis, TN, United States,* [4]*Institute of Clinical Pathology, Vienna, Austria,* [5]*Department of Pathophysiology, Medical University of Vienna, Vienna, Austria.*

T-cells play a key role in the development of allergic diseases thus representing a promising target for therapeutic interventions. While mice expressing an I-A^d restricted murine T-cell receptor (TCR) specific for chicken ovalbumin (Ova) are frequently used to mimic allergic disease induced by aeroallergens *in vivo,* implications for human allergic diseases remain questionable, since Ova is not a human-relevant aeroallergen. We here created double tg mice expressing a human TCR specific for the major mugwort (*Artemisia vulgaris*) pollen allergen Art v 1 and HLA-DR1. In tg mice ninety percent of peripheral blood $CD4^+$ T-lymphocytes expressed the Art v 1-specific TCR, while $CD14^+$ monocytes and $B220^+$ B-lymphocytes revealed HLA-DR1 expression. Splenocytes of tg mice specifically proliferated upon incubation with the human-relevant immuno-dominant Art v 1_{25-36} peptide or whole Art v 1 protein when compared to control mice. *In vivo*, after allergen-specific sensitization, only tg mice showed enhanced airway-hyperreactivity (AHR) as assessed by methacholine or allergen-specific challenge. Three consecutive exposures to nebulized allergen were found to be sufficient for induction of altered airway function, as mirrored by airway and lung inflammation, due to massive peribronchiolar and perivascular infiltration with immune cells. The detailed results of bronchoalveolar lavage (BAL) fluids, lung histology and specific antibody titers will be described and discussed. Humanized allergy models are amenable to the evaluation of human-relevant allergen formulations or cellular intervention protocols and will contribute to the further understanding of allergic diseases and their cure.

P6.05.15
Development and affinity maturation of human scFvs against IL-4 and IL-13 by phage display

S. Nian, *Q. Yuan, L. Huang, Y. Ye, Y. Wu;*
Luzhou Medical College, Luzhou, China.

Interleukin-4 and Interleukin-13 shared receptor chain IL-4Ra, and the intracellular signal transducer and activator of transcription, STAT6, promote the IL-4 and IL-13 responsive genes, such as those associated with, T-helper type 2 (Th2) cell differentiation. IL-4/IL-13 pathway is key components in the development of air way inflammation, mucus roduction, and airway hyper responsiveness in asthma. The human scFv 68 against IL-4 and scFv 101 against IL-13 were selected from a large non-immune scFv library by phage display. Subsequently, by in vitro mutagenesis of a gene encoding for the scFv 68 and scFv 101, two new libraries was established, and new scFv antibodies with improved affinity towards the IL-4 or IL-13 were selected and characterized. The scFv 68 against IL-4 was affinity-maturated by in vitro mutagenesis and the new scFv clone M3 was isolated. And the scFv 101 against IL-13 was affinity-maturated by in vitro mutagenesis and the new scFv clone M46 was isolated. The Biacore results showed that the M3 and M46 have over 10 times higher affinity with the antigen IL-4 or IL-13, compared to scFv 3 or scFv 68. And the western blot with serial dilutions IL-4 or IL-13 showed that the intensity of eveloped color was increase when affinity-maturated scFvs was used for staining.

P6.05.16
Induction of Th1 immune response and suppression of IgE via immunotherapy with recombinant hybrid molecule encapsulated in Liposome-protamine-DNA nanoparticles in a model of experimental allergy

H. R. Nouri[1], *J. M. Davies*[2], *M. Jaafari*[3], *A. Varasteh*[4], *F. Vahedi*[5], *M. Sankian*[6];
[1]*Department of Immunology and Microbiology, School of Medicine, Babol University of Medical Sciences, Babol, Iran,* [2]*Lung and Allergy Research Centre, School of Medicine, The University of Queensland, Princess Alexandra Hospital Clinical Division, Woolloongabba, Queensland, Australia,* [3]*Biotechnology Research Center, Nanotechnology Research Center, School of Pharmacy, Mashhad University of Medical Sciences, Mashhad, Iran,* [4]*Allergy Research Center, School of Medicine, Mashhad University of Medical Sciences, Mashhad, Iran,* [5]*Biotechnology Department, Razi Vaccine and Serum Research Institute, Mashhad, Iran,* [6]*Immunobiochemistry Lab, Immunology Research Center, School of Medicine, Mashhad University of Medical Sciences, Mashhad, Iran.*

Background: Liposome-protamine-DNA nanoparticles (LPD) are safe, effective, and non-toxic adjuvant that induce Th1-like immune responses. We hypothesize that encapsulation of allergens into liposomes could be an appropriate option for immunotherapy. The present study evaluated the immunotherapeutic potential of a recombinant hybrid molecule (rHM) encapsulated in the LPD nanoparticles in a murine model of Chenopodium album allergy.
Methods: BALB/c mice sensitized with allergen in alum and immunotherapy procedure was performed with two subcutaneous injections of either the LPD-rHM or rHM or emty LPD with weekly interval. Humoral immune responses were examined through specific antibodies measurement in serum. The splenocytes of immunized mice were stimulated in vitro and cell proliferative responses along with cytokine secretion determined. Expression of genes involved in immunotherapy was examined by real-time PCR.
Results: Sensitized mice developed a Th2-biased immune response that characterized with strong specific IgG1 and IgE production, and presence of IL-4 as well as GATA3 transcription factor in the culture of spleen cells. Treatment with the LPD-rHM was led to reduction of IgE level and markedly increased ratio of IgG2a/IgG1 antibody level. The LPD-rHM induced strictly Th1 allergic responses with strong IFN-γ production as well as T-bet expression in stimulated splenocytes. In addition, LPD-rHM treated mice induced higher lymphoproliferative

responses than other groups. Removal of nanoparticle from the rHM resulted in decreased allergen immunogenicity.
Conclusion: These results indicate that the rHM complexed with LPD nanoparticles has a marked suppressive effect on the allergic response and causes a shift towards a Th1 pathway.

Wheat is an important staple food that can cause IgE-mediated food allergy. In-vitro diagnostic tests using wheat allergen extracts frequently give false positive test results. Aim of this study was the expression of alpha purothionin (rTri a 37) as a recombinant protein in two different expression systems, to compare their IgE reactivity and to evaluate their usefulness in the diagnosis of wheat-dependent food allergy.
Recombinant alpha purothionin was expressed in a prokaryotic system using E.coli cells (EcTri a 37) and in a eukaryotic system (i.e. in baculovirus infected insect cells - BvTri a 37) producing rTri a 37 as a secreted protein. The purified recombinant allergens were characterized regarding molecular, structural and immunological properties.
Alpha purothionin was identified as a new wheat food allergen. Structural analysis showed that EcTri a 37 is unfolded whereas BvTri a 37 is an α-helical protein. EcTri a 37 was recognized by approximately 20% of wheat food allergic patients (n=103). When we compared the IgE binding capacity of both recombinant allergens, comparable results were observed. Clinical data indicated that the risk of developing wheat-induced anaphylaxis is more than four-fold higher in the rTri a 37- reactive patients.
Tri a 37, a new wheat food allergen, comprises non-conformational epitopes and may be a new tool for in-vitro diagnosis of potentially severe wheat food allergy.

P6.05.18
Gene expression of innate cytokines in response to probiotic treatment in allergen-sensitized mice as an experimental model

A. Pishdadian*, M. Sankian, A. Varasteh;*
Bu-Ali research institute, Mashhad, Iran.

Chenopodium album is one of the main sources of pollen allergy in desert and semi-desert areas and contains three identified allergens. Respiratory effects of Lactococcus lactis, as probiotics, in animal models have included attenuating allergic airway responses. IL-33 and IL-25 are type 2 cytokines that promote airway allergic responses. After allergen insult these two cytokines are produced and released from lung epithelial cells and trigger the downstream responses that aggravate allergic symptoms.
We used a protocol previously established in our lab for inducing airway allergy using recombinant form of C. album allergen number 2, rChe a2,. Three groups of BALB/C mice were sensitized and two of them were treated orally with Lactococcus lactis (L.L) and L.L plus rChe a2 respectively. Animal were sacrificed and RNA extracted from lung tissues. cDNA synthesis and real-time PCR for IL-33 and IL-25 were performed.
Relative quantity based on dR in two treated groups (L.L and L.L+ rChe a2) compared with sensitized but not-treated group, are 0.745 and 0.880 for IL-33 and 0.191 and 0.257 for IL-25. Fold relative quantity based on dR are -0.425 and -0.184 for IL-33 and -2.380 and -1.960 for IL-25.
In our study, probiotic therapy caused to a reduction in IL-33 and IL-25 gene expression. Lactococcus lactis therapy was more effective when it was used alone than mixed with rChe a2.

Preventative and therapeutic anti-allergic effect of a novel House-Dust-Mite vaccine based on a combination adjuvant.

W. Ramírez González[1], *B. Tamargo*[2], *V. Bourg*[1], *D. Torralba*[1], *A. Más*[1], *J. Infante*[3], *G. Sierra*[3], *M. Lastre*[3], *O. Pérez*[3], *A. Labrada*[1];
[1]*National Center of Bioproducts, Mayabaque, Cuba,* [2]*Institute of Pharmacy and Foods, Havana University, Havana, Cuba,* [3]*Finlay Institute, Havana, Cuba.*

Current allergen-specific immunotherapy is based on repeated allergen injections. The adjuvant effect of the outer membrane proteoliposome (PL) of *Neisseria meningitides* is attractive for designing novel vaccines, with fewer administrations. The aim was to assess the immunomodulatory effect of a novel vaccine based on *Dermatophagoides siboney* allergens and a combination adjuvant, containing PL and alum, in prophylactic and therapeutic models of respiratory allergy. Balb/C or C57/BL6 mice were administered with 3 doses of the vaccine (2µg Der s1) by subcutaneous route. In the therapeutic model, mice were previously sensitized to *D.siboney* by ip injection plus exposure to aerosolized allergen. A challenge test was used after receiving the vaccine in the prophylactic or therapeutic models. Allergen-specific antibody response was assessed by ELISA, and the cytokine response, by FACS. The vaccine induced IgG2a and IgG1 antibodies in both, naïve and sensitized animals, and prevented the development of systemic (IgE) and local allergic response in mice subjected to allergen challenge, regarding histological signs of lung inflammation. In sensitized mice, it was noted a significant increase of the IgG/IgE ratio, and a decrease of blood eosinophils. Moderate levels of IFN-γ were induced in Der s1-stimulated lymphocyte cultures, whereas IL-13 levels decreased as compared to non-treated controls. IL-10 levels showed no significant ($p>0.05$) differences. The adjuvanted vaccine does not exacerbate the allergic response, nor promote Th1 inflammation, supporting a satisfactory safety profile for further clinical trials. This immunomodulatory effect suggests clinical benefits in cellular and blocking antibody responses for treatment or prevention of respiratory allergy.

P6.05.20
Differences in the IgE- and IgG-reactivity profile of asthmatic and non-asthmatic house dust mite-allergic patients revealed with micro-arrayed HDM allergens

Y. Resch[1], *S. Michel*[2], *M. Kabesch*[3], *R. Valenta*[1], *S. Vrtala*[4,1];
[1]*Department of Pathophysiology and Allergy Research, Center for Pathophysiology, Infectiology and Immunology, Vienna, Austria,* [2]*Department of Pediatric Pneumology, Allergy and Neonatology, Hannover Medical School, Hannover, Germany,* [3]*KUNO University Children's Hospital Regensburg, Regensburg, Germany,* [4]*Christian Doppler Laboratory for the Development of Allergen Chips, Medical University of Vienna, Vienna, Austria.*

Background: House dust mites (HDM) represent one of the most important inducers for respiratory allergies worldwide.
Objective: To investigate the IgE- and IgG-reactivity profiles of HDM-allergic individuals suffering only from allergic rhinitis or from allergic asthma.
Methods: This study included sera from clinically well characterized asthmatic (n=105) and non-asthmatic (n=53) HDM-allergic patients. IgE- and IgG-reactivity to seven HDM-allergens (nDer p 1, rDer p 2, rDer p 5, rDer p 7, rDer p 10, rDer p 21 and rDer p 23) were measured using a customized allergen microarray (i.e., ISAC chip, Thermofisher, Vienna, Austria).
Results: HDM-allergic individuals suffering from asthma showed striking differences regarding their IgE reactivity profiles compared to the non-asthmatic group. First, the frequency of IgE reactivity to the tested HDM allergens was up to 3-fold higher in the asthmatic than in the non-asthmatic group. Seventy percent of the asthmatics reacted with 3 to 6 of the tested allergens compared to only 45% in the non-

asthmatic group. Furthermore, IgE-levels to nDer p 1, rDer p 2, rDer p 5 and rDer p 23 were significantly higher in the asthmatic group. In contrast, HDM-allergic asthma patients showed a lower IgG-binding frequency to the seven HDM allergens than HDM-allergic patients without asthma.
Conclusion: The IgE and IgG reactivity profiles to HDM allergens differ considerably in patients with mild (i.e., rhinitis) and severe (i.e., asthma) respiratory symptoms due to HDM allergy.

P6.05.21
Naproxen alleviates anaphylactoid reactions to N-acetylcysteine in healthy volunteers

M. Sattari[1,2]*, S. Mashayekhi*[3,2]*;*
[1]*Neuroscience Research Centre, Tabriz University of Medical Sciences, Tabriz, Iran,* [2]*Faculty of Pharmacy, Tabriz University of Medical Sciences, Tabriz, Iran,* [3]*Tabriz Health Management Service, Tabriz University of Medical Sciences, Tabriz, Iran.*

A relationship has been demonstrated between a low serum paracetamol at the time of treatment and the development of anaphilactoid adverse reactions to N-acetylcysteine (NAC). Paracetamol itself might actually offer some protection against the development of adverse effects to NAC. Naproxen inhibits the production of thromboxane by 95% and platelet aggregation by 88%. To inhibit the cyclo-oxygenase activity before starting an NAC trial on healthy volunteers, at least 7g paracetamol would be need. Since administration of this dose to healthy volunteers was not feasible, an alternative option was to use a NSAID instead of paracetamol before the trial. Therefore, we decided to use a cyclo-oxygenase inhibitor (naproxen) for this purpose. Ten healthy male volunteers, age between 23-40 (median 32) and weight between 63-87kg (median 78.5) were recruited from the general population after fully informed and written consent and after ethical approval. Each volunteer was asked to participate on two separate occasions: pre-treatment with naproxen prior to infusion of NAC using the recommended UK regimen and without naproxen pre-treatment. Data were analysed by using Excel, Prism, and WinNonlin software packages as appropriate. Plasma histamine concentration was determined during intravenous administration by an ELISA method. A paired t-test showed that plasma histamine was significantly higher at 10 and 15min in the control phase compared with the naproxen pre-treatment phase ($P<0.05$). In conclusion, histamine release may not be the only mechanism of adverse events associated with NAC, but also the release of some other factors e.g. prostaglandines or tromboxanes could be involved.

P6.05.22
Oxygen therapy of a murine model of atopic dermatitis

H. Kim[1]*, S. Lee*[1]*, H. Kim*[1]*, E. Choi*[1]*, B. Moon*[2]*, J. Kim*[3]*, M. Jang*[3]*, J. Kie*[4]*,* ***J. Seoh***[1]*;*
[1]*Department of microbiology, Ewha Womans Univiersity Medical Center, Seoul, Republic of Korea,* [2]*Department of surgery, Ewha Womans Univiersity Medical Center, Seoul, Republic of Korea,* [3]*Department of gastrointestinal immunology, POSTECH, Pohang, Republic of Korea,* [4]*Department of pathology, NHI Cooperation Ilsan Hospital, Koyang, Republic of Korea.*

Atopic dermatitis (AD) is a chronic inflammatory disease of skin resulting from excessive stimulation of immune cells by external antigens due to disruption of epidermal barrier. Most cases of AD are managed by corticosteroid or calcineurin inhibitors, but complications and intractable cases still remain as problems. Recently, many evidences are accumulating on the protective role of reactive oxygen species (ROS) in autoimmunity. There are also many reports on the therapeutic effects of hyperbaric oxygen therapy (HBOT) in chronic inflammatory or autoimmune diseases. We hypothesized that HBOT may improve AD symptoms by increasing tissue ROS level. We also applied another measure to increase tissue ROS level, an oxygen-carrying chemical, perfluorodecalin (PFD). Dihydroethidum staining demonstrated both HBOT (100% O_2, 3 atm for 90 min daily) and PFD increased tissue ROS level. Immunohistochemistry showed indoleamine 2,3-dioxygenase (IDO) was also increased. Mouse model of AD is developed by mechanical stripping of an ear followed by repeated application of 1% 2,4-dinitrochlorobenzene and *Dermatophagoide farinae* extract. The results showed both HBOT and PFD significantly decreased ear swelling of AD as much as 0.1% prednicarbate. Histological examination showed severe epithelial hyperplasia, exocytosis, hyperkeratosis, parakeratosis, perivascular inflammatory cell infiltration and dermal fibrosis in the AD model. Meanwhile, HBOT or PFD-treated group showed only mild epithelial hyperplasia and perivascular inflammatory cell infiltration without telangiectasia. Increased expression of IDO and decreased level of hypoxia-inducible factor-1α, demonstrated by immunohistochemistry and RT-PCR, might be involved in the molecular mechanisms of oxygen therapy in AD.

P6.05.23
Effects of JSP-TCM on IL-13 and IL-17 levels in a murine model of asthma

C. Shen*, H. Wang, Q. Dai, H. Cai, Q. Wang, X. Ding, S. Wang;*
Shanghai TCM-integrated Hospital, Shanghai, China.

Jade Screen Powder (JSP), a traditional Chinese medicinal prescription, has been widely used about 7 centuries to treat asthma in China. Its
efficacy and action mechanisms in asthma attack prevention remain nonetheless to be further explored. In this study, asthma was induced exposing ovalbumin (OVA) sensitized mice to repeated OVA challenges for 4 weeks. Mice were treated with JSP for 1 week just after the final challenge. In this murine model of asthma, were accompanied with suppression of the IFN-gamma level and increase of IL-13 and IL-17 levels in the lung homogenized thick liquids (LHTLs) even four weeks after the final challenge, indicating that the airway structural changes continued to develop even after interruption of OVA challenges. However, after JPS treatment, the airway hyperresponsiveness (AHR) was sharply relieved, accompanied by IL-13 and IL-17 levels were decreased, meanwhile the inflammatory cells were decreased but the IFN-gamma level increased in LHTLs. In conclusion, JSP could prevent the development of asthma, thus reducing asthma attacks. Our results indicated that it should be used as a supplementary therapy on preventing asthma attacks from asthma patients.

P6.05.24
Efficacy of experimental allergen-specific immunotherapy in mouse model of atopic dermatitis

N. Shershakova*, A. Babakhin, E. Bashkatova, I. Shilovskiy, S. Andreev, M. Khaitov;*
NRC Institute of Immunology FMBA, Moscow, Russian Federation.

Background: Atopic dermatitis (AD) is a chronic inflammatory skin disease. In this study we examined whether allergen-specific immunotherapy (ASIT) is effective in a mouse model of AD.
Methods: Female BALB/c mice were epicutaneously (e.c.) sensitized by three applications (lasted 7 days each) with 1 mg/ml of ovalbumin (OVA). Between 1st and 2nd applications mice were subcutaneously (s.c.) treated with increasing doses of: non-modified OVA (group 1 «ASIT OVA»); OVA modified with succinilation (85 % of modification) (group 2 «ASIT sOVA») or sham treated with PBS (control group 3). The levels of anti-OVA IgE, IgG1, IgG2a antibodies in sera obtained before, during and after ASIT were detected by ELISA. After the last application IL-4, IL-5, IL-17 and IFN-γ were detected in the spleen cell culture by ELISA and skin samples from patch areas were removed for histological examination.
Results: Anti-OVA IgE and IgG1 levels in treated groups 1 and 2 were gradually decreased during ASIT, while the level of anti-OVA IgG2a antibodies increased during ASIT in compare to control group 3. IL-4, IL-5 were decreased after ASIT in both treated groups while IL-17 decreased in group 1 only. The level of IFN-γ was significantly higher in group 2 compared with other groups. The ratios of IgG1/IgG2a and IL-4/IFN-γ support idea that ASIT with sOVA can shift response to allergen towards Th1-like. Histological picture of skin in all ASIT groups demonstrated suppressing of allergic inflammation.
Conclusion: ASIT is effective treatment in experimental AD that may be relevant for the clinical practice.

P6.05.25
Maternal allergen immunization in mice: prevention of offspring allergy is possible mediated by Breg and Th17 cells

***J. R. Victor**, L. M. Oliveira, A. A. L. Lira, B. P. Muniz, A. J. S. Duarte, M. N. Sato;*
School of Medicine - USP, Sao Paulo, Brazil.

Background:Previously we have been observed that pre-conceptional immunization with Ovalbumin (OVA) is able to prevent the development of allergy in offspring.
Methods: Femalemice immunized with OVA were mated with non-immunized males. Offspring were evaluated at 3 and 20 days-old (d.o.) or immunized with OVA at 3 d.o. and assessed at 20 d.o for B and TCD4+ cytokines secreting cells.
Results: Maternal immunization up-regulates the expression of FcγRIIb on offspring B cells at 3 and 20 d.o. This effect was maintained even when neonates were immunized. It was in parallel to decreased sera IL-6 levels. Although offspring from immune mothers showed similar levels of IL-10+, IL-4+ and IFN-γ+ B cell frequency, but median fluorescence intensity analysis revealed higher IL-10 intensity, regardless neonatal immunization. Moreover, newborns from immune mothers showed an increased number of TCD4+-secreting IL-17 as well as IFN-γ. After OVA-immunization only IFN-γ levels were augmented on offspring from immune mothers.
Conclusion: Up-regulation of FcγRIIb on offspring B cells occurred concomitantly to the B-cell IL-10 response and TCD4-secreting IL-17 suggesting that maternal immunization could induce the generation of B regulatory and Th17 cells in offspring. The role of these populations on offspring in the allergy development must be investigated.

***H. pylori* induced immune suppression**

***S. M. Walton**, B. J. Marshall, M. Benghezal, A. Fulurija;*
Pathology and Laboratory Medicine, University of Western Australia, Nedlands, Australia.

Helicobacter pylori are the dominant members of the gastric microbiota and have persistently colonized the stomach in humans since our early evolution out of Africa. There is now emerging evidence that *H. pylori* could be beneficial to the host with increasing evidence of *H. pylori* protection against esophageal and cardial pathologies, childhood asthma and allergies and inflammatory bowel disease. More recently, partial protection by *H. pylori* has been confirmed in mouse models of acute allergic asthma and colitis. The major outcome of these studies identified regulation of the host immune system by regulatory T (Treg) cells and a contribution of NKT cells. Our data complements these studies by identifying a systemic immune suppression based on decreased CD8 T cell and antibody responses towards a superinfection in *H. pylori*-infected mice. Protection from asthma in mice could be reproduced using a cagPAI negative VacA positive strain that is very well tolerated by human volunteers. Our result opens up the possibility to apply *H. pylori* in treatment of asthmatic and allergic patients.

P6.05.27
Construction of a naive human phage scFv library and selection, identification of human scFvs

***Q. Yuan**, S. Nian, X. Guo, Y. Gao, J. Liu;*
Luzhou Medical College, Luzhou, China.

The IL-4, IL-13 and IL-33 are key components in the development of allergic disease such as asthma. To construction of human non-immune library and selection of human scFvs against the three cytokines, the mRNA of human peripheral blood cells (PBMC) was extracted from healthy volunteer, and then the cDNA library was constructed. The variable region of heavy chain (V_H) and light chain (V_L, including Vκ and V_λ) were amplified from full length cDNA library. The V_H and V_L were ligated with linker and the DNA library of single-chain Fv fragments (scFvs) was developed. After transforming into *E.coli* TG1, the phage library was constructed. The antigen IL-4, IL-13 and IL-33 were cloned, expressed and identified. The scFv library was enriched for three rounds by phage display for selection of human scFvs against IL-4, IL-13 and IL-33. By PCR, forty two bands of V_H, sixteen bands of Vκ and eighteen bands of V_λ were got. And the scFv library was constructed successfully with $2.5x10^8$ development clones with full length scFv inserts. Through three rounds of phage display, 30% clones showed positive using ELISA for detection. Four to five scFvs with high affinity against IL-4, IL-13 and IL-33 respectively were screened, expressed, and identified by Biacore, western blot and sequencing. The results showed the size of proteins of identified scFvs were about 32 kDa and the sequences were correct. The human non-immune library was constructed and the scFvs specific to IL-4, IL-13 and IL-33 respectively were selected successfully.

P6.05.28
Establishment of a simple method for Japanese cedar pollinosis and sublingual immunotherapy in mice

***C. Zhang**, S. Yanagisawa, T. Tomoda, S. Kang, T. Ohno, M. Azuma;*
Molecular Immunology, Tokyo Medical and Dental University, Tokyo, Japan.

Japanese cedar (*Cryptomeria japonica)* pollinosis (JCP) is one of the most common allergic diseases in Japan. A number of therapeutic strategies are currently being developed to induce allergen-specific immune tolerance. Sublingual immunotherapy (SLIT) has been performed as a safer and more beneficial treatment. However, immunological mechanisms and therapeutic biomarkers for SLIT remain unclear. In this study, we have established a new murine model of JCP that resembles human JCP using crude pollen grains in the absence of adjuvant and examined the effects of SLIT. SLIT was performed by the graded doses of cedar pollen extract painting onto the ventral surface of tongue for 28 days. [Results] The frequency of sneezing and the duration of rubbing for 10 min after the final challenge, serum IgE and pollen-specific IgG1titers, thickness of nasal mucosae, infiltrated eosinophils in BALF and nasal mucosae were significantly elevated in the pollinosis mice. However, SLIT efficiently reduced the above manifestations. SLIT significantly inhibited Th2 cytokines and pollen-specific Th1 & Th2 cytokines production by splenic T cells as well as APC-abilities in DC like MHC class II, CD86 expression in the regional lymph nodes. Histological examination revealed that repeated pollen extract painting onto the sublingual mucosae replaced sublingual resident DCs with newly recruited $CD11b^+$ DCs. These results suggest that our new pollinosis model brings benefit to develop a new immunotherapy and to evaluate therapeutic biomarkers.

Inhibitory effects of single chain fragment variable (scFv) antibodies against prostate stem cell antigen (PSCA) on prostate and pancreatic cancer cell lines

***S. Abdi**[1,2], F. Nejatollahi[2];*
[1]Ilam University of Medical Sciences, Ilam, Iran, [2]Shiraz University of Medical Sciences, Shiraz, Iran.

Background: PSCA is a cell surface antigen with limited expression in normal tissues and overexpression in some human malignancies. In this study, we evaluated inhibitory effects of a PSCA specific scFv on proliferation of PSCA expressing as well as PSCA negative cells.
Materials and Methods : Specific scFvs against an immunodominant epitope of PSCA were isolated from phage-displayed library of scFv antibodies. Panning followed by PCR and DNA fingerprinting were applied for isolating scFvs and one clone (C9 scFv) was selected and used as source of specific scFv. Phage ELISA determined specific binding of C9 to its corresponding peptide. DU-145and AsPC-1 cells (as PSCA expressing) and LNCaP (as PSCA negative cells) were treated with different concentrations of C9 for 24 and 48h. Inhibitory and apoptosis inducing effects of C9 were assessed by MTT and Annexin-V assays, respectively.
Results: After 24h and 48h treatment, all concentrations of C9 resulted in significant inhibition of proliferation of DU-145 and AsPC-1

cells, whereas it had no inhibitory effect on LNCaP cells. The results of Annexin-V showed that C9 significantly induced apoptosis in DU-145 cells but not inAsPC-1 cells.
Discussion: The results showed that C9 was effective against the growth of PSCA expressing cells, while the remaining PSCA negative cells were unaffected. It was also shown that inhibitory effects of C9 on DU-145 cells resulted from apoptosis induction rather than decreased cell proliferation. These results provide remarkable evidence for usefulness of PSCA targeting with scFvs for the treatment of PSCA-expressing cancers, including prostate and pancreatic cancers.

P6.06.002
Application of palm-tocotrienol adjuvanted dendritic cell in cancer therapy

S. Abdul Hafid[1,2]*, K. Nesaretnam*[1]*, S. Chakravarthi*[2]*, A. K. Radhakrishnan*[2]*;*
[1]*Malaysian Palm Oil Board (MPOB), Bandar Baru Bangi, Kajang, Selangor, Malaysia,* [2]*International Medical University, Kuala Lumpur, Malaysia.*

We have reported previously that murine bone marrow-derived dendritic cells (DC) pulsed with whole tumour lysate and with combination of tocotrienol rich-fraction (TRF) can mediate potent anti-tumour immune response in in-vivo as well as in-vitro studies.
In our present study, we demonstrate that a combination treatment of tumour lysate-pulsed DC and TRF (DC+TL+TRF) are able to mediate regressions of pre-established s.c. tumours, leading to significant cure rates and prolonged survival of treated mice. Systemic administration of one milligram TRF daily is capable of mediating significant increases in DC based immunizations. The efficacy of TRF supplementation in tumour lysate-pulsed DC induced protective immunity to lethal tumour challenge as well as enhanced splenic cytotoxic T lymphocyte activity in treated mice. Furthermore, interferon gamma (IFN-γ) and interleukin 12 (IL-12) increased in TRF group compared to others in splenic culture. In addition, the same treatments were used in microarray study to look at regulation of related genes to cancer. We found one interesting gene called special AT rich binding protein 1 (SATB1) from microarray analysis. This gene was reported to have dual function in different cells and ability to induce aggressive breast cancer cells. Validation of this SATB1 was done through Real-Time RT-PCR and currently we are in progress of silencing the gene expression in order to look at the clear functions of SATB1 in both 4T1 mammary cancer cells and dendritic cells.

P6.06.003
GMP-production of an allogenic DC-based cancer vaccine (COMBIG-DC) for treatment of patients with metastatic renal cancer using the ELUTRA Platform

L. Adamson[1]*, R. Kiessling*[1]*, B. Andersson*[2]*, B. Näsman-Glaser*[1]*, A. Karlsson-Parra*[3]*;*
[1]*Dep. of Oncology and Pathology Karolinska Institutet, Stockholm, Sweden,* [2]*Dep. of Immunology, Gothenburg University, Gothenburg, Sweden,* [3]*Dep. of Immunology, Genetic and Pathology, Uppsala University, Uppsala, Sweden.*

The aim of this Phase I/II study in patients with metastatic renal cancer is to evaluate adverse effects and anti-tumor effects of a therapeutic vaccine-concept that is based on intratumoral injections of activated allogenic dendritic cells (DCs) produced from healthy donors.The strong allogenicity of such cells and their sustained production of pro-inflammatory mediators is expected to create a local inflammatory environment that promotes recruitment, antigen-loading and activation of endogenous DCs, As clinical studies require protocols where a sufficient number of well characterized dendritic cells are produced according to Good Manufacturing Practice (GMP) guidelines, we validated the COMBIG-DC GMP platform using ELUTRA® -enriched monocytes from leukapheresis products obtained from healthy donors as starting material.Collected fractions were phenotypically analysed for cell content by flow cytometry. The enriched monocyte fractions were differentiated into immature DC in culture bags using GM-CSF and IL-4 and matured for 18 hours using a cocktail of Poly-IC, R 848 and IFNγ. DC-generation was determined using phenotypic markers and expression of cytokines. Our results show that the COMBIG-DC vaccine production platform is very robust and reproducible resulting in high initial monocyte purity, high recovery and efficient differentiation/maturation of phenotypically and functionally mature DCs. Delivered frozen vaccine cells show a high and reproducible quality after thawing. This work was supported by Immunicum AB, Gothenburg, Sweden

Breast cancer immunopathology to immunotherapy in Northern Emirates of the United Arab Emirates

M. Alhomssi*, A. Mohamad, H. Hamdy;*
University of Sharjah, Sharjah, United Arab Emirates.

Retrospective study of 81 cases of breast cancer identified in northern emirates of the United Arab Emirates (UAE). Female to male ratio was 80:1. These cases came from several hospitals, but the final diagnosis was established in our referral hospital. The sections were stained with monoclonal antibodies for estrogen receptors, progesterone receptors, and ERBB2 (HER2/neu), and to be stained for SATB1, basal cytokeratins, p53, androgen receptor, E-cadherin, P-cadherin, EGFR, Bcl2, Cathepsin D, and cyclin E.
Breast cancer was more commonly seen in UAE nationals 14 cases (17%), Philippinos 14 cases (17%), Egyptian 9 cases (11%) and Indians 7 cases (9%). It was more common in age group 30-50 (50 cases). Invasive ductal carcinoma NST (no special type) was seen in 51 cases (62%), 11 cases (14%) were invasive lobular carcinoma, 12 cases (15%) were mixed invasive ductal and lobular, and 7 cases (9%) were ductal carcinoma insitu. Majority of cases (51 cases; 63%) were staged as stage II, 17 cases (21%) as stage I and 13 cases (16%) as stage III. Lymph node involvement was noted in 29 cases (36%). Estrogen receptors (ER) were positive in 11 cases (13%) and 5 cases (6%) overexpressed ERBB2 (HER2/neu).
Overall breast cancer in Northern Emirates presented at earlier age and its incidence is less in nationals than in non-nationals. Most cases presented with breast lump. Invasive ductal carcinoma, NST was more commonly seen and showed more aggressive behavior. This behooves us to individualize the diagnosis and use specific biotherapy such as trastuzumab.

P6.06.005
Generation and characterization of a new chimeric antibody against Her2

M. M. Amiri[1]*, M. Jeddi-Tehrani*[2]*, M. Bahadori*[2]*, M. Hojjat-Farsangi*[3]*, J. Khoshnoodi*[1]*, H. Rabbani*[3]*, F. Shokri*[1,2]*;*
[1]*Department of Pathobiology, School of Public Health, Tehran University of Medical Sciences, Tehran, Iran,* [2]*Monoclonal Antibody Research Center, Avicenna Research Institute, ACECR, Tehran, Iran,* [3]*Immune and Gene Therapy Lab, Cancer Center Karolinska, Karolinska Hospital, Stockholm, Sweden.*

Her2 proto-oncogene encodes a receptor tyrosine kinase overexpressed in a variety of solid tumors. Amplification of this gene has been shown to correlate with poor prognosis in breast cancer patients. Immunotherapy with anti-Her2 antibody has shown promising results in patients with Her2-positive breast cancer. We have recently reported characterization of a mouse monoclonal antibody (1T0) directed against Her2, which binds to an epitope different from that recognized by Trastuzumab, and specifically inhibits proliferation of tumor cells overexpressing Her2. In the present study, we report chimerization of this antibody. The VH and VL genes of 1T0 hybridoma cells were amplified and inserted into a mammalian expression vector containing cDNA of human gamma-1 and kappa constant regions using Splice Overlap Extension (SOE) PCR. The construct was subsequently transfected in the mammalian CHO cell line and the chimeric antibody was characterized by ELISA, Western blot and flow cytometry. The purified chimeric antibody specifically binds to recombinant Her2 and Her2 positive tumor cells. Binding of this antibody to tumor cells inhibited proliferation of these cells. The affinity of the chimeric Ab was comparable to the parental mouse mAb. This chimeric anti-Her2 mAb is potentially a valuable tool for targeted immunotherapy of Her2 positive malignancies.

P6.06.006
Annexin A2 is a Glioma Damage-Associated Molecular Pattern Enriched in Physiologic Oxygen

B. M. Andersen[1], *M. R. Olin*[1], *C. E. Seiler*[1], *X. Junzhe*[1], *A. L. Epstein*[2], *W. Chen*[1], *B. R. Blazar*[1], *J. R. Ohlfest*[1];
[1]*University of Minnesota, Minneapolis, MN, United States,* [2]*University of Southern California, Los Angeles, CA, United States.*

Cross priming remains a major hurdle for the majority of brain tumor patients on cell-based vaccine immunotherapy. Through the culture of glioblastoma cells in 5% (physiologic) oxygen, we enhanced the adjuvant cross priming ability of whole cell lysate vaccines from these cells. 5% oxygen-derived lysate vaccines lack efficacy in mice deficient in toll-like receptor 2 (TLR2), suggesting enrichment of a TLR2-binding damage associated molecular pattern (DAMP) under 5% oxygen. Through subtractive proteomics, we identified annexin A2 (ANXA2) as a TLR2-binding DAMP. ANXA2 monomer induced TLR2 signaling and TLR2-dependent expansion of surrogate antigen-specific CD8 T cells. ANXA2 was also capable of robust cross presentation and cross priming to surrogate antigens. These mechanisms likely underly the extension of median survival and increased cure rate seen when ANXA2 is combined with poorly immunogenic lysate vaccines from atmospheric oxygen. Many gene expression differences exist due to oxygen tension, with potentially many molecules contributing to the cross priming activity of lysates from 5% oxygen. However, surrogate antigen-specific CD8 T cell expansion was no longer enhanced if cells for lysate vaccination express a short hairpin RNA construct targeting ANXA2, indicating its requirement for the adjuvant cross priming activity of lysates from 5% oxygen. Lastly, ANXA2 enrichment occurs in 5% oxygen cultures of primary human glioma cells, and ANXA2 can enhance cross presentation of the pp65 cytomegalovirus antigen to peripheral blood mononuclear cells of serum-positive donors. These data indicate an important role for oxygen and ANXA2 in glioblastoma cells cultured for vaccine production.

P6.06.007
MHC I multimer assay: Optimized double staining for improved sensitivity in detection of low affine CD8+ antigen-specific T cells by flow cytometry

S. Andersen*, K. Jacobsen, L. Brix, H. Pedersen;*
Immudex, Copenhagen, Denmark.

Sensitive and reliable monitoring of cellular immune responses is highly important in cancer vaccine and immunotherapeutic development. Flow analysis using conventional fluorescent MHC multimers like Tetramers and Pentamers has made a great impact in this field, enabling visualization, enumeration and phenotypic characterization of antigen-specific T cells. However, difficulties in detecting low-affinity interactions such as in tumor-specific T-cell responses, and low reproducibility and stability are still prominent problems. MHC-Dextramer® reagents, the next generation of fluorescent MHC multimers, can minimize these issues due to a higher number of MHC-molecules and fluorochromes than conventional MHC multimers.
Here, we show how a double-color staining method can increase the sensitivity of the Dextramer even further, by improving resolution and separation between the antigen-specific T-cell population and the negative population. A staining protocol for the use of PE- and APC-labeled MHC Dextramers of the same specificity in the same tube has been developed. Using this approach the Dextramer population will be “double positive”, allowing for detection of positive cell populations that are not bright enough to be identified with a single color due to poor separation from background staining.
The double staining method makes it easier to identify and enumerate low-affinity antigen-specific T-cell populations such as cancer-specific T cells, and opens up for more accurate measurements than previously seen. It is useful in the improvement of immune monitoring of cancer immunotherapeutics, and together with the high sensitivity of the MHC Dextramers, it makes a valuable tool in cancer research.

Increased efficacy of dendritic cells by protein components compared to total extract of *Listeria monocytogenes* in experimental tumor Immunotherapy

S. Arab*, M. Motamedi, J. Hadjati;*
Immunology, Tehran, Iran.

Using dendritic cells (DCs) loaded with tumor antigens as a therapeutic strategy against tumors has been proposed. In order to increase the efficacy of DCs, a variety of factors such as TLR ligand molecules and bacterial products are used. In this study, the protein components of the bacteria *Listeria monocytogeneses* (LM) for induction of dendritic cell maturation were used.Bone marrow cells of Balb/c mice in the presence of IL-4 and GM-CSF were cultured for 5 days. On day 5, tumor lysate and then protein components or total extract of LM was added to immature DCs. In order to survey the maturation status of DCs, on day 7,the expression of CD80, CD86 AND MHC-II on the cell surface was evaluated. After induction of tumors in mice using WEHI-164 cell line, 10^6 mature dendritic cells subcutaneously injected. Tumor growth rate,survival rate and cytotoxic activity of spleen cells were evaluated in the studied groups.In mice vaccinated with protein components matured-DCs,delayed tumor growth rate and increased survival were seen. In addition,in these mice, the cytotoxic activity of spleen cells was higher compared to other groups. In all groups receiving protein components or total extract mature-DCs, increased cytotoxic activity and decreased tumor growth rate were seen compared to controls. *Listeria monocytogenes* protein components compared to total extract have higher ability to increase the efficacy of DCs for tumor immunotherapy in mouse model.

Green tea polyphenols modulate certain indices of nonspecific anticancer resistance

A. B. Artamonova*, S. P. Zaletok, O. V. Karnaushenko, A. V. Verbinenko;*
R.E.Kavetsky Institute of experimental pathology, oncology and radiobiology of NAS of Ukraine, Kyiv, Ukraine.

Introduction. Green tea polyphenols are of increasing interest in relation to their anticancer and antioxidant properties. Our previous investigationd have demonstrated significant anticancer activity of green tea polyphenolic extract (GTE) as to different experimental tumors and it's ability to diminish anticancer drugs' toxicity.
Aim of the work was to investigate GTE effect on certain immunity indices in healthy and tumor-bearing animals.
Methods. Experiments were performed in adult hybrid CDF mice, healthy and grafted with P388 or L1210 lymphatic leukemia. GTE were applied as 0.1% solutions in drinking water. Peritoneal macrophages cellularity (M), their metabolic activity (MAM) and splenocytes' cytolytic activity (CTL) were measured.
Results. GTE-treated healthy mice, after 24 hours, were shown to have 2.5 times higher M value versus control; at 7-21 days this value was some lower. Also, both CTL and MAM values was increased in these mice, with a maximum at 1-st and 21-th day (CTL) and 7-th day (MAM). GTE significantly (for 25%-30%) retarded development of L1210 and P-388 leukemias. In GTE-treated leukemias-bearing mice, M value at 8-th and 11-th days after leukemia have been grafted was 3-6 times higher and CTL value _ for 25-35% higher versus nontreated animals.
Conclusion. The data have been obtained show immunomodulating GTE effect to be one of the it's possible anticancer pathways.

P6.06.010
Polysaccharides of the Lentinus edodes modulate certain indices of specific anticancer resistance

A. B. Artamonova*, V. O. Shlyakhovenko;*
R.E.Kavetsky Institute of Experimental Pathology, Oncology and Radiobiology of NAS of Ukraine, Kyiv, Ukraine.

Polysaccharides isolated from fruiting bodies and mycelia of higher fungi are increasingly being used in immunotherapy of cancer. In our

previous studies have shown that the polysaccharide fraction isolated from the fruiting body of the fungus Lentinus edodes (PSFLE) has strong antitumor activity. The aim was to investigate the effect of PSFLE on some parameters of the immune system. Research carried out on intact outbred mice males and animals with transplanted sarcoma 37 (S 37). The study found that PSFLE significantly increases metabolic and phagocytic activity of macrophages in vivo. It also has a positive effect on splenocytes and thymocytes CLA. The study DTH and CLA serum as indicators of specific answers revealed statistically significant increase after the introduction DTH PSFLE doses 250mkh/kh and 5 mg / kg. The animals of these groups did not affect tumor growth as the value index DTH (I DTH) as in control animals, and even at the end of the experiment DTH level in animals with experimental groups was significantly higher (P <0.01) than in control Although the indicator showed a downward trend when compared with previous values. In addition, mice immunized cytolytic index (CLi) was significantly increased compared with the control. The most pronounced effect was obtained at 21 days of the experiment. Conclusions. Polysaccharide fraction isolated from the fruiting body of the fungus Lentinus edodes effect on tumor growth indirectly through activation of specific and non-specific components of the immune system.

P6.06.011
Anti-Metastatic Effect of Anti-HER2 scFv Antibodies on Breast Cancer Cells

***M. Asgharpour**, F. Nejatollahi;*
Department of Immunology, Shiraz University of Medical Sciences, Shiraz, Iran.

Introduction: Breast cancer is the most common malignancy and the second leading cause of cancer death in women. In addition, 70% of patients with advanced breast cancer develop metastases in bone marrow and bone. Since the expression of CXCR4/CXCL12, CXCR3/CXCL10, and MMP2 in breast tumors has been correlated with increased metastasis, we assessed the effect of three specific single-chain antibodies against HER2, a tumor antigen which overexpression is associated with markedly aggressive forms of cancer, on the expression of these factors in vitro.
Methods: HER2 overexpressed breast cancer cell line, SKBR3, treated with three specific and high affinity anti-HER2 scFv antibodies and quantification of CXCR4, CXCL12, CXCR3, CXCL10, and MMP2 transcripts was performed by RealTime-PCR. Furthermore, western blot was done to evaluate the expression level of CXCR4 and CXCL12 proteins as the key pro-metastatic axis in breast cancer.
Results: After 48h treatment of cells with anti-HER2 scFvs all three scFvs significantly down-regulated the expression level of CXCR4, CXCR3, CXCL10, and MMP2 transcripts, individually and in combination. Moreover, Western blot outcomes confirmed this down-regulation and demonstrated a reduction in CXCR4 protein expression. Furthermore, scFv-II and combination of all three scFvs significantly decreased the expression of CXCL12 at both the mRNA and protein levels.
Conclusion: The expression of CXCR4/CXCL12, CXCR3/CXCL10, and MMP2 in breast tumors is associated with poor prognosis and increased metastasis. However, effective anti-metastatic therapy remains a challenge. Regarding our results, three anti-HER2 scFvs have shown a good promise to be considered for anti-metastatic therapy in HER2-positive breast cancer.

P6.06.012
ImmTACs: bi-specific TCR-anti-CD3 fusions for potent re-directed killing of cancer cells

***R. Ashfield**, G. Bossi, D. Baker, J. Harper, J. Dukes, N. Liddy, Y. McGrath, A. Vuidepot, N. Hassan, B. Jakobsen;*
Immunocore Ltd, Abingdon, Oxfordshire, United Kingdom.

The human immune system has the potential to clear tumours but fails to do so in many patients, as thymic selection removes high avidity T cell responses to self-antigens. This problem is compounded by the immunosuppressive tumour microenvironment, involving a complex array of mechanisms including Treg cells and MHC down-regulation. To address the issues of low T cell avidity, tumour tolerance and absence of tumour specific target antigens, we have engineered bi-specific ImmTAC reagents comprising soluble, pico-Molar affinity T cell Receptors (TCRs) fused to an anti-CD3 specific scFv. The TCRs target peptide epitopes derived from cancer-associated antigens presented on the cell surface by Class I MHC, and the anti-CD3 moiety re-directs a potent anti-tumour T cell response. Target epitopes are selected to meet several criteria including a) Mass Spectrometry validated tumour presentation, b) highly restricted expression in normal tissues, and c) frequent expression in common tumour types. We have demonstrated that ImmTACs are very sensitive, recognising as few as 10 epitopes per cell; this sensitivity far exceeds that of tumour-specific T cell clones isolated from cancer patients. ImmTACs demonstrate potent (pico-Molar EC_{50}) activity *in vitro* and *in vivo*, re-directing T cell killing of cancer cells with very low levels of cell surface MHC whilst sparing normal, antigen negative tissue cells. IMC-gp100, an ImmTAC specific for the HLA-A2 presented $gp100_{280-288}$ epitope, is undergoing Phase I/IIa clinical testing in melanoma patients; it is well tolerated and induces T cell mobilisation and tumour shrinkage.

P6.06.013
Oroxylin A affects frequency and function of myeloid-derived suppressor cells in experimental model of cancer

***M. Ashourpour**[1], A. Namdar[2], J. Hadjati[1];*
[1]Tehran University of Medical Sciences, Tehran, Iran, [2]Isfahan University of Medical Sciences, Isfahan, Iran.

Background: Myeloid derived suppressor cells (MDSCs) are a heterogeneous population of myeloid progenitors. These cells have essential role in tumor development that specially related to chronic inflammation. Different studies characterized MDSC as immature myeloid cells that are precursors of DCs, macrophages, and granulocytes. They can suppress innate and adaptive immune response that would otherwise eliminate abnormal cells.
There are many herbal products with anti-inflammatory properties which could interfere with tumor progression. Oroxylin A is one of these products as a natural flavonoid isolated from Scutellariae radix, which has been indicated to possess antioxidant, anti-inflammatory and immunomodulatory properties. We sought to determine Oroxylin A effects on the frequency and function of MDSC population in tumor bearing hosts.
Methods: MDSCs were isolated from the spleen of tumor bearing mice, and then the frequency of MDSCs was evaluated using flow cytometry and compared with untreated group. Moreover, the Oroxylin A's effect on NO production was analyzed using Griess reagent.
Results: Based on our experiments, Oroxylin A had a modulatory effect on MDSCs.
Conclusion: Oroxylin A, as an anti-inflammatory drug, may exert beneficial effects on immune responses against tumors and should be considered as an agent that affects the frequency and function of MDSCs.

P6.06.014
T cell tolerance as function of tumor progression

***M. Azulay**, E. Tzehoval, E. Vadai, L. Eisenbach;*
Weizmann Institute of Science, Rehovot, Israel.

Peripheral tolerance to tumor antigens is a major obstacle in antitumor immunity. Among the possible mechanisms are presentation of tissue-derived proteins by quiescent dendritic cells, suppression by regulatory immune cells and secretion of factors that suppress T cells leading to anergy or deletion. To investigate anti-tumor immune responses, Tumor (B16 transfected with ovalbumin) bearing mice were transferred with admixed naïve splenocytes from pmel-1 and OT-I.GFP mice. At several time points, cells were isolated from mice and tested. Tumor growth sufficiently induce proliferation and effector phenotype acquisition of pmel-1 and OT-I.GFP cells in the draining lymph nodes (T-DLNs). Pmel-1 cells were unable to mediate tumor regression and show impaired capacity of killing target cells or secretion of IFNγ. Within the tumor, pmel-1 cells proliferated extensively while their frequencies were decreasing rapidly. In contrast, OT-I.GFP cells were able to mediate tumor regression and

killing capacity both in the tumor and in the periphery. While OT-I.GFP cells in the DLNs proliferated at low rates, extensive proliferation was detected in the tumor. Suggesting that tolerance followed by elimination of pmel-1 T cells develops already in the T-DLNs; indicating that lack of anti-tumor response efficacies are not solely due to general immunosuppressive mechanisms in the tumor microenvironment. Recently, we tested the involvement of the lymph node stroma in mediating CD8 T cell peripheral tolerance. We demonstrated that LN-resident lymphatic endothelial cells express peripheral tissue antigens and directly present the melanocyte protein PMEL17/gp100, to pmel-1 cells, resulting in their deletion, thus preventing a protective immune response.

P6.06.015
TLR3/BATF3 axis in CD8α+DC induces anti-tumor CTLs by dsRNA

***M. Azuma**, M. Matsumoto, T. Seya;*
Hokkaido University Graduate School of Medicine, Sapporo, Japan.

Many clinical trials using TLR ligands for tumor immunotherapy are in progress. The use of TLR3 ligand, e.g. Poly(I:C), has been examined in various experimental models in mice, which results in promising. Poly(I:C) is recognized by TLR3 in endosome and MDA5 and RIG-I in cytoplasm, and recruits TICAM-1/TRIF and MAVS/IPS-1 as an adaptor protein, respectively. Both signaling pathways activate three types of transcription factors, IRFs, NF-kB and AP-1, that participate in the induction of type I IFN which promotes the formation of Th1 immunity and CTL activation. Alternatively, it has been reported that BATF3, one of the AP-1 family molecules, functions as a master transcription factor for CD8α+DC in 129S6/SvEv mice, but not in C57BL/6J mice. We previously reported that poly(I:C) could induce anti-tumor CTL through the TICAM-1/IRF-3/7 pathway and retard tumor growth in vivo. However, it is currently unknown whether BATF3 is activated under TLR3/TICAM-1 signaling and involved in CTL activation. Therefore, we tried to investigate the role of BATF3 in dsRNA-induced tumor immunity. In this study, we found that the hallmarks of CD8α+DC, such as TLR3 expression and IL-12p40 production, were markedly decreased in Batf3-/- CD8α+DC. Furthermore, tumor retardation by poly(I:C) was abolished in Batf3-/- C57BL/6J, and the adoptive transfer of WT CD8α+DC to Batf3-/- mice successfully recovered tumor retardation activity in Batf3-/- mice. Collectively, our data revealed that BATF3 is important for not only the development but also the function of CD8α+DC. Moreover, these data underscored the importance of TLR3/BATF3 signaling in CD8α+DC in dsRNA-induced tumor immunity.

P6.06.016
Anti-tumor effects of heat shock proteins, Bacillus Calmette-Guérin, angiogenesis inhibitor, Bifidobacterium and Immuno-Modulator Drug on fibrosarcoma in mice

***B. Baradaran**, J. Majidi, T. Kazemi, L. Aghebati, M. Orangi;*
Immunology Research Center, Faculty of Medicine, Tabriz University of Medical Sciences,, Tabriz, Iran.

Introduction: Despite the major advances in conventional forms of treatment (surgery, radiotherapy and chemotherapy), there are still many patients that are resistant to standard treatments. Immunotherapy is one of the best strategies in cancer therapy. Five important current methods include: using of HSP, BCG, angiogenesis inhibitors, Bifidobacterium and IMOD.
Materials and Methods: For this study, Balb/c mice (male, age, 6-8 weeks) were provided and were divided to 12 groups.WEHI-164 tumoral cells were used for creation of fibrosarcoma tumor. First, 1×106 cells\100µl of WEHI-164 cells were injected to mice and after 11 days, tumors were created. Then, surveys were carried out on the study protocol.
Results: Nevertheless injection of certain amount of tumoral cells to all of mice, tumor was not created in 5 mice and the size of tumors was different. The size of tumors was measured each week in special day and the volume of tumor was yielded by the formula: length×width2×π/6 in mm3. The survey of tumors was continued until end of 14th week. In some of groups, drugs showed synergistic effects and inhibited tumoral growth significantly. Mice in group 10 (IMOD, Thalidomide) had the least lifetime and the group 11 (BCG, HSP, Thalidomide) had the longest lifetimes.
Conclusion: In some groups, drugs showed synergistic effects and inhibited tumor growth significantly. The HSP, BCG, Thalidomide Group showed very good results. In this group, Thalidomide inhibited angiogenesis and HSP had role in presentation of tumoral antigens to immune system and BCG had a role in enhancing of immune system.

P6.06.017
Maternal immunization: transfer of a protective anti-tumor immunity from mothers to the offspring; a first evidence

***G. Barutello**[1], M. Arigoni[1], C. Curcio[2], M. Spadaro[1], R. Clynes[3], R. Trovato[1], E. Bolli[1], F. Riccardo[1], F. Ria[4], F. Cavallo[1];*
[1]University of Turin, Torino, Italy, [2]University of Chieti, Chieti, Italy, [3]Columbia University Medical Center, New York, NY, United States, [4]Catholic University of Rome, Roma, Italy.

Recent studies involving maternal immunization against neonatal tetanus and influenza virus have shown that this approach was very effective in providing newborns with protection from these pathogens. We studied the effect of an anti-tumor DNA vaccine on the progression of carcinogenesis in cancer prone Her-2/neu transgenic (BALB-neuT) mice born from mothers immunized against the extracellular and transmembrane domain of neu. High levels of specific anti-neu IgGs were detected in both milk from vaccinated mothers and in sera of their offspring. The progression of spontaneous mammary carcinogenesis was hampered in BALB-neuT female offspring born and fed by vaccinated mothers as compared to controls. Immunized mothers KO for the µIg chain, thus unable to produce antibodies, failed to transfer protection to their offspring. Likewise the protection was nil when the newborns were KO for FcγRI/III, thus unable to develop antibody-dependent cytotoxicity. Furthermore, in neu-vaccinated mothers' pups we observed the expansion of low avidity $CD8^+$ T cells bearing a TCR rearrangement reacting with neu dominant peptide (p63-71) and usually not expanded in neu-vaccinated BALB-neuT mice. Moreover a T-cell-mediated cytotoxic response against p63-71 was found. This phenomenon could be due to the transfer of immune complexes of IgGs together with part of the neu protein shed from transfected cells after DNA vaccination. Taken together our results show for the first time that maternal immunization against a tumor associated antigen could offer effective protection to the offspring genetically predestined to develop mammary carcinoma, indicating the potential application of this approach in neonatal cancer diseases.

P6.06.018
The peripheral blood compartment of patients with Diffuse Large B Cell Lymphoma (DLBCL) at diagnosis is characterized by distinct phenotypic and functional Immunological alterations

***S. Battella**[1], S. Pelliccia[2], R. La Scaleia[1], A. Di Napoli[3,4], A. Porzia[1], L. Ruco[3,4], F. Mainiero[1], A. Santoni[5], M. C. Cox[2], G. Palmieri[1];*
[1]Department of Experimental Medicine, La Sapienza University, Rome, Italy, [2]Hematology Unit, S'Andrea Hospital, Rome, Italy, [3]Department of Clinical and Molecular Medicine, La Sapienza University, Rome, Italy, [4]Pathology Unit, S'Andrea Hospital, Rome, Italy, [5]Department of Molecular Medicine, La Sapienza University, Rome, Italy.

Tumor ability to modify the immune competence of the host may be particularly relevant in the case of hematological malignancies, such as B-cell lymphoma. This phenomenon might hamper the efficacy of chemo-immunotherapy.
We analyzed the phenotypic and functional asset of PBMC in 30 DLBCL at diagnosis (as compared with 23 healthy, age- and sex-matched controls), and the possible correlation of the immunological profile with pathological and clinical traits.
Patients showed a higher absolute monocyte number, and a lower lymphocyte count, mostly due to the selective diminution of CD4+ T cells (but not of Treg cells) and B lymphocytes. Accordingly, lymphocyte/monocyte and CD4/CD8 ratios decreased, while NK percentage increased.
The phenotypically skewed profile of PBL was associated with functional alterations: 1) IFN-γ producing cells were increased among

CD4+ and CD8+ T cell subsets, but not in CD56+ T and NK cell populations; 2) a higher frequency of Granzyme B-expressing cells characterized T and NK subsets; noteworthy, natural and CD16-dependent NK cytotoxic activities were unchanged. IL-6 and IL-10 plasma levels were significantly higher in DLBCL.
Selected alterations differently correlated with the DLBCL Germinal Genter B (GCB) vs non GCB-type and with the presence of bulky disease or extranodal involvement.
Our findings show a deeply altered phenotypic and functional profile in DLBCL PBMC populations, with the lymphocyte compartment showing traits of chronic activation; moreover, distinct immunological alterations correlated with histological subtypes and other clinical features. SB and RLS equally contributed to the study; MCC and GP equally contributed to the study.

P6.06.019
Adenosine receptor blockade potently suppresses the metastasis of CD73$^+$ tumours

P. A. Beavis[1,2], *U. Divisekera*[1,2], *C. Paget*[1,2], *M. T. Chow*[1,2], *L. B. John*[1,2], *J. Stagg*[3], *M. J. Smyth*[1,2], *P. K. Darcy*[1,2];
[1]*Peter MacCallum Cancer Centre, Melbourne, Australia,* [2]*Sir Peter MacCallum Department of Oncology, University of Melbourne, Melbourne, Australia,* [3]*Centre de Recherche du Centre Hospitalier de l'Université de Montréal; Faculté de Pharmacie et Institut du Cancer de Montréal, Montreal, QC, Canada.*

It is now accepted that tumours utilize multiple mechanisms to suppress anti-tumour immunity. One such mechanism is the generation of adenosine by CD73 which inhibits anti-tumour immunity through the activation of adenosine receptors expressed on multiple immune subsets. CD73 has previously been shown to enhance tumor metastasis, although the immune subsets and adenosine receptor subtypes involved are unknown. In this study, we revealed that both adenosine receptor 2_A (A_{2A}) and A_{2B} antagonists significantly reduced the metastasis of CD73$^+$ tumors. A_{2A}/A_{2B} receptor antagonists were effective in reducing the metastasis of tumours expressing CD73 endogenously (4T1.2) and when CD73 was ectopically expressed (B16F10). CD73-generated adenosine promoted metastasis, in part, through A_{2A}-mediated suppression of NK cell cytotoxicity. Treatment with an A_{2A} antagonist increased the expression of granzyme B in NK cells isolated from tumour-bearing mice and significantly reduced the metastasis of CD73$^+$ tumours in a perforin-dependent manner. A_{2B} blockade had no effect on NK cell cytotoxicity indicating that an NK cell-independent mechanism also contributed to the increased metastasis of CD73$^+$ tumours. Preliminary data suggests that A_{2B} blockade enhances the expression of MHCII on CD11b$^+$CD11c$^+$ cells within the metastatic site. Our data indicates that CD73 promotes tumour metastasis through multiple mechanisms including suppression of NK cell cytotoxicity and that A_{2A} or A_{2B} antagonists may be useful for treatment of tumour metastases. This data has potential therapeutic implications given that A_{2A}/A_{2B} receptor antagonists have already entered clinical trials for other therapeutic settings whereas there are no anti-CD73 mAbs currently in clinical development.

P6.06.020
Development of a DC-based therapeutic vaccine for AML patients: characterization of GMP-grade TLR-agonist matured 3-day DCs expressing the leukemia-associated antigens WT1 and PRAME

B. Beck[1], *C. Geiger*[2], *I. Bigalke*[3], *F. S. Lichtenegger*[1], *G. Kvalheim*[4], *M. Subklewe*[1], *D. J. Schendel*[5];
[1]*Department of Internal Medicine III, University of Munich, Campus Großhadern, Munich, Germany, Munich, Germany,* [2]*Institute of Molecular Immunology, Helmholtz Zentrum München, Munich, Germany, Munich, Germany,* [3]*GMP Unit, Helmholtz Zentrum München, Munich, Germany, Munich, Germany,* [4]*Department of Cellular Therapy, Oslo University Hospital, Oslo, Norway, Oslo, Norway,* [5]*Institute of Molecular Immunology and GMP Unit, Helmholtz Zentrum München, Munich, Germany, Munich, Germany.*

We have designed a new generation of dendritic cells (DCs) optimized for the use in cell-based immunotherapy of cancer patients. Our goal was to tailor these DCs to be used for vaccination in acute myeloid leukemia (AML) patients with a high risk of relapse after intense induction/consolidation therapy in order to eradicate minimal residual disease (MRD).
We have developed a three-day manufacturing protocol using a cytokine cocktail containing a synthetic TLR7/8-agonist for generation of monocyte-derived mature DCs (mDCs) with improved immunogenicity. For induction of a specific T cell-based anti-AML response against residual tumor cells, our mDCs are loaded with RNA encoding the leukemia-associated antigens WT1 and PRAME. Additionally, DCs transfected with RNA encoding CMV-pp65 will be included as a surrogate antigen.
In this study, we present the careful evaluation of our 3d mDCs generated from healthy donors following RNA electroporation and cryopreservation, ensuring a fully functional phenotype of the autologous vaccine formulation. Our studies demonstrate a high and controllable expression of all three antigens following RNA loading. To ensure functional integrity of our DCs, the ability to secrete the critical cytokine IL12p70 upon T cell encounter was analyzed.
Furthermore, cryopreserved DCs expressing the different antigens also displayed a high capacity both for reactivation of antigen-specific pre-primed effector cells and for priming of naïve T cells in vitro, showing proper processing and presentation of the introduced antigens. These studies demonstrate that our manufacturing protocol yields improved DCs with a high potential to initiate long-lasting anti-leukemic responses in patients with AML.

P6.06.021
Development of new therapeutic antibodies formats directed against the folate receptor alpha.

D. Bernareggi, *E. Luison, A. Satta, B. Frigerio, M. Colombo, S. Canevari, M. Figini;*
Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy.

In our laboratory two mAbs directed against the folate receptor alpha (FRα), MOv18 and MOv19 were discovered, providing the foundation upon which to build new human Abs. Using phage display technology were developed fully human Fab fragments with the same specificity of the murine Ab MOv19 and two of them, AFRA4 and AFRA5.3 were later engrafted in complete immunoglobulins. These new reagents were assessed for binding properties and specificity on FRα and epithelial ovarian cancer cell lines. AFRA complete antibodies of IgG1 and IgE isotype were compared with ChiMOv19 for their binding properties and the IgG1 for the ability to enhance the effectors functions, as evaluated by antibody dependent cell-mediated cytotoxicity (ADCC) assays. Enhancement of ADCC on high FRα expressing cells, comparable to that of ChiMOv19, was observed for AFRA Abs despite their reduced binding affinity and different binding kinetics. The complete human structure could be probably more efficient in inducing ADCC, balancing the reduced binding activity. In order to assess the effects *in vivo* in immunocompetent mouse models we built “reverse chimeric” (RC) forms of AFRA, composed of human Fabs and murine Fc and we assessed the RC AFRA5.3 IgG2A in two immunocompentent mouse models. In the first model C26 cells expressing human FRα were injected subcutaneusly but, although we noticed a trend in reducing tumor growth by AFRA, we encountered problems with control mice. Therefore we shifted to a transgenic immunocompetent mouse model which expresses FRα on breast cancer cells and experiments are ongoing.

P6.06.022
Toxoplasma gondii protein fractions for the generation of dendritic cell based cancer vaccine

R. Boghozian, *A. Saei, R. Mirzaei, J. Hajati;*
Department of Immunology , School of Medicine, Tehran University of Medical Sciences, Tehran, Iran.

Dendritic cell (DC) based immunotherapy appears to be a promising approach to successfully induce an antitumor immune response. Therefore, DC vaccines frequently used in many cell based therapy protocols. DCs are the most potent antigen-presenting cells and up on maturation with different stimulators exhibit an increased ability to activate Th1-polarized immune responses. Several protocols have

been developed to generate mature DCs. In our previous studies it has been shown that Toxoplasma gondii (T.G) can induce competent mature DCs. In this study we have investigated that fractionated protein components of T.G stimulated DC maturation. Materials and Methods: T.G was sonicated and exposed to stepwise precipitation to increased amount of ammonium sulfate to obtain four distinct protein fractions. Fractionation was followed by ion exchange chromatography method. DCs were generated from C57/BL6 mouse bone marrow in the presence of IL-4 and GM-CSF, immature DCs were exposed to T.G protein fractions. After 24 hours DC maturation markers CD80, CD86 and MHC II and IL-12p70 production were evaluated. Mouse splenic cell proliferation assay also were performed and compared with immature DCs. Tumor growth rates and vaccinated mice survival were followed. Results and Conclusion: The results indicate that maturation of DCs with certain T.G protein fractions induce higher expression of CD86, CD80, MHC II and production of IL-12p70 by DCs. In addition these mature DCs significantly increased the splenic cell proliferation and survival in vaccinated animals. Further fractionation may lead to identification of some protein components of TG with strong DC maturing properties.

P6.06.023
Comparison of DNA-based vaccine and non-pathogenic live vaccine strategies using the mini-chaperones for the prevention of HPV16 E7-overexpressing cancers

***A. Bolhassani**, S. Hosseinzadeh, A. Daemi;*
Pasteur Institute of Iran, Tehran, Iran.

Immunotherapy potentiating host immunity against human papillomavirus (HPV) is a promising strategy for the prevention and treatment of cervical cancer. The efficient antigen delivery systems including biological carriers (e.g., the attenuated or non-pathogenic live vectors) and physical carriers (e.g., electroporation) are the key issue of developing an effective cancer vaccine. Furthermore, heat shock proteins (HSPs) including Gp96 act as potent immuno-adjuvant to enhance antigen-specific tumor immunity. Recently, we generated DNA- and live *Leishmania tarentolae* (*L.tar*)-based vaccines containing the N-terminal and C-terminal domains of gp96 fused to HPV16 E7 and compared their immuno-stimulatory activity in C57BL/6 tumor mice model. We found that subcutaneous DNA injection with E7-CT (gp96) followed by electroporation generates the significant E7-specific IFN-γ immune responses as well as the best protective effects as compared to E7 or E7-NT (gp96) DNA vaccines. In addition, we observed that subcutaneous injection with *L.tar*-E7-CT (gp96) produces similar IFN-γ immune responses as well as insignificant protective effect in comparison with *L.tar*-E7-NT (gp96). Both recombinant *L.tar*-E7-CT (gp96) and *L.tar*-E7-NT (gp96) could not induce complete protective effects against HPV16 E7-overexpressing cancers. Our studies indicated that subcutaneous administration of E7 DNA linked to CT (gp96) fragment followed by electroporation can significantly enhance the cellular immune responses and the protective effects in comparison with non-pathogenic live *L.tar*-E7-CT (gp96). Briefly, DNA-based vaccine was more efficient than non-pathogenic live *leishmania tarentolae*-based vaccine. Moreover, the structural domains of immuno-chaperones show the potential of generating effective immune responses against different clinical disorders such as cancer.

P6.06.024
Antitumor potential of novel betulin derivative on human A375 melanoma cells

***M. Bulatovic**[1], M. Mojic[1], G. Kaluđerović[2], D. Miljković[1], S. Sto□ić-Grujičić[1], R. Paschke[2], S. Mijatović[1], D. Maksimović-Ivanić[1];*
[1]Department of Immunology, Institute for Biological Research "Sinisa Stankovic", University of Belgrade, Belgrade, Serbia, [2]Institute of Chemistry, Martin-Luther-University Halle-Wittenberg, Halle (Saale), Germany.

There is increasing evidence that chronic inflammation causes most of chronic diseases, including cancer and that one out of seven malignant tumors today is a result of chronic inflammation. Betulinic acid is a betulin derivative, pentacyclic triterpene with lupane skeleton, which is one of the first natural product isolated from birch bark. It has a number of pharmacological effects including anti-inflamatory, antitumor and anti-HIV. Betulinic acid induces mitochondrial pathway of apoptosis by directly interacting with permeability transition pore complex and through production of ROS which facilitates opening of the pore. It downregulates NF-κB controlled proinflammatory genes such as COX-2, MMP9 and *i*NOS. In this study we evaluated antimelanoma effect of novel betulin derivative, 3-O-ethylcarbamate-28-O-acetyl-betulin. We found that novel compound significantly reduced viability of *i*NOS$^+$ A375 human melanoma cells, with IC50 value four times lower than betulinic acid. Cell cycle analysis demonstrated considerable accumulation of cells in *sub*G phase after two days of treatment with IC50 dose, while Ann/PI staining demonstrated that cells undergo apoptosis much faster under treatment with novel compound compared to betulinic acid. Real-time PCR analysis revealed enhanced caspase 9 and pro-apoptotic Bax gene expression accompanied with general caspase activation confirmed by apostat staining. DHR and DAF-FM staining demonstrated massive production of reactive oxygen and nitrogen species indicating that mechanism of cell death induction is not related with inhibition of *i*NOS. In conclusion, novel betulin compound has a much stronger antimelanoma effect realized through mitochondrial dependent apoptosis synchronized with production of reactive oxygen and nitrogen species.

P6.06.025
Early growth response gene 2 acts as an intrinsic negative regulator of DC immunogenicity

*M. A. Miah[1,2], **S. E. Byeon**[1], Y. S. Bae[1];*
[1]Sungkyunkwan University, Suwon, Gyeonggi-do, Republic of Korea, [2]Bangladesh Agricultural University, Mymensingh, Bangladesh.

Early growth response gene 2 (Egr2) is an immediate early gene encoding a zinc finger transcription factor. Egr2 is rapidly and transiently induced in various cell types independent of *de novo* protein synthesis. Although Egr2 is well established in T cell development, Egr2 expression and its biological function in dendritic cells (DCs) have not yet been described. Here we demonstrate Egr2 expression during DC development, and its role in DC-mediated immune responses. Egr2 is expressed in the later stage of DC development from bone marrow (BM) precursor cells. Even in a steady state, Egr2 is highly expressed in mouse spelnic DCs. Egr2-knockdown DCs showed increased levels of major histocompatability complex (MHC) I & II and co-stimulatory molecules and enhanced antigen-uptake and migratory capacities. Furthermore, Egr2-knockdown abolished SOCS1 expression and STAT5 activation during DC development, probably resulting in the enhancement of IL-12 expression and Th1 immunogenicity of the DC vaccine. DC-mediated cytotoxic T lymphocyte (CTL) activation and anti-tumor immunity were significantly enhanced by Egr2-knockdown, while impaired by Egr2-overexpression of antigen-pulsed DC vaccines. These data suggest that Egr2 acts as an intrinsic negative regulator of DC immunogenicity and can be an attractive molecular target for better DC vaccine development.

P6.06.026
ENO1-DNA vaccine significantly delays pancreatic tumor progression by eliciting complement-dependent cytotoxicity

***P. Cappello**[1,2], S. Rolla[1,2], R. Curto[1,2], E. Tonoli[1], M. Principe[1,2], H. Carnevale[1], M. Giovarelli[1,2], F. Novelli[1,2];*
[1]University of Turin-CeRMS, Torino, Italy, [2]Dept of Molecular Biotechnologies and Health Sciences, Torino, Italy.

Pancreatic ductal adenocarcinoma (PDA) is a very aggressive malignancy characterized by rapid progression, invasiveness, and resistance to treatment. By SERological Proteome Analysis we have identified novel PDA-associated antigens recognisable by either CD4 and CD8 T cells. We have also in vitro characterized one of these antigens, alpha-enolase (ENO1). PDA patients with serum IgG against ENO1 showed T cells secreting IFN-γ in response to ENO1 and Ag-specific T cells were able to inhibit the in vivo growth of HLA matched PDA cells in immunocompromised mice. By using genetically engineered mice (GEM) developing spontaneously PDAC, we investigated the potential of ENO1 as therapeutic vaccine. In GEM

vaccinated with a vector expressing cDNA for human ENO1, a specific ENO1 immune response improves antitumor responses and survival. The immune response is associated with an increased level of anti-ENO1-specific IgG, an augmented frequency of ENO1-specific Th1/Th17 cells, and a decrease of suppressor cells. The induced anti-ENO1 IgG are able to recognize and bind surface of murine PDA cells and elicit complement-dependent cytotoxicity, which has been proposed as an effector mechanism of anti-tumor immunity (e.g rituximab and ofatunumab). Moreover, ENO1 vaccine elicited a Th1/Th17 response that had a limited effector function but an important helper role in driving autoantibody isotype switching. To elucidate the role of Th17 in PDA progression and DNA-vaccine-induced responses we are breeding GEM with IL17 KO mice.

NK cells contribute to melanoma cell recognition and anti-tumor immunity, which is traditionally analyzed using human peripheral blood NK cells1. An important checkpoint in the progression of malignant melanoma is the metastasis to lymph nodes. To investigate the role of lymph node NK cells in disease progression, we analyzed frequency, phenotype and functions of NK cells purified from either tumor infiltrated lymph nodes or tumor-free ipsilateral lymph nodes of the same patients. Lymph node NK cells were compared to peripheral blood NK cells from either melanoma patients or healthy donors. The data showed an expansion of CD56dimCD57+CD69+CCR7+KIR+ NK cells in tumor infiltrated lymph nodes. This phenotype corresponds to a recently described fully mature and highly cytotoxic NK cell population2,3, and indeed we found that these lymph node NK cells displayed robust anti-tumor activity against autologous melanoma cells. Moreover, a high proportion of KIR+CD57+CD56dim in the infiltrated lymph nodes was associated with improved patients' survival. Our data suggest that NK cells from tumor infiltrated lymph nodes are attractive candidates to improve current NK cell-based immunotherapy of melanoma.

Multiple Myeloma cells in Vk*MYC mice are highly susceptible to WT1 and MAGE-A specific cytotoxic T lymphocytes

E. Cattaneo[1], *A. Calcinotto*[1], *M. Grioni*[1], *A. Gasparri*[1], *M. Bianco*[1], *S. Bertilaccio*[1], *M. Chesi*[2], *L. Bergsagel*[2], *A. Corti*[1], *M. Bellone*[1];
[1]*San Raffaele Hospital, Milano, Italy,* [2]*Comprehensive Cancer Center, Mayo Clinic Arizona, Scottsdale, AZ, United States.*

The need to improve the clinical outcome in multiple myeloma (MM) patients has led to a renewed interest in immunotherapy. The identification of primary models of the human disease in which novel immunotherapeutic approaches can be tested is pivotal. As the Wilms tumor (WT1) and the MAGE-A antigens are overexpressed in MM cells, we investigated their presence and immunogenicity in Vk*Myc mice, a primary model of autochthonous MM. We demonstrated that both antigens are overexpressed in neoplastic plasma cells from Vk*Myc mice. We have also found that upon injection with dendritic cells either pulsed with the WT1 or the MAGE-A CTL epitope, wild-type C57BL/6 mice were able to mount a consistent antigen-specific cytolytic response. WT-1- and MAGE-A-specific CTL were able to kill Vk*Myc bone marrow plasmacells in an in-vivo cytotoxicity assay. These findings prompted us to investigate in Vk*Myc mice the efficacy of a protocol that combines vascular targeting and adoptive immunotherapy. Indeed, we reported that systemic administration of picograms of the Cys-Asn-Gly-Arg-Cys (NGR)-TNF conjugate, which targets TNF to an aminopeptidase N (CD13) isoform selectively expressed by endothelial cells in tumor vessels, increases the penetration of tumor specific CTL (Calcinotto et al. 2012). Thus, Vk*Myc mice affected by MM, stage at which neoangiogenesis is active, have been treated with NGT-TNF and splenocytes from WT-1-MAGE-A-sensitized C57BL/6 mice. This experiment will be concluded in a few months. So far, our data demonstrate that WT-1 and MAGE-A are optimal targets of immunotherapy in Vk*Myc mice, and support further investigation in MM patients.

P6.06.029
Vaccination with human CSPG4 DNA induces an anti-tumor antibody response and prolongs survival in dogs with oral malignant melanoma

F. Riccardo[1], *S. Lorda Mayayo*[2], *S. Prestigio*[1], *S. Iussich*[2], *G. La Rosa*[2], *R. De Maria*[2], *S. Ferrone*[3], *P. Buracco*[2], ***F. Cavallo***[1];
[1]*University of Torino, Molecular Biotechnology Center, Torino, Italy,* [2]*University of Torino, Department of Animal Pathology, Grugliasco, Italy,* [3]*Harvard Medical School, Boston, MA, United States.*

Chondroitin sulfate proteoglycan-4 (CSPG4) is a membrane-bound chondroitin sulfate proteoglycan with a restricted distribution in both human and canine normal tissues, but highly expressed by human melanoma cells and by about 60% of canine malignant melanomas (CMM). Human and canine CSPG4 amino acid sequences have 82% homology, and 88% similarity. CMM is a spontaneous, aggressive, and metastatic neoplasm, sharing many characteristics with its human counterpart, thus representing a valuable clinical model to assess the efficacy of novel anti-cancer strategies.
The capability of DNA electroporation of a plasmid coding for the human CSPG4 (hCSPG4) in inducing an effective immune response in dogs with stage II-IV surgically resected CSPG4-positive oral CMM was evaluated. Vaccination did not cause any clinically relevant local or systemic side effects. All vaccinated dogs developed antibodies against hCSPG4 cross-reacting with the canine orthologue, demonstrating the ability of this vaccine to overcome host immune tolerance to dog CSPG4. The overall survival time of vaccinated dogs (n=12) was significantly longer as compared to that of non vaccinated dogs with either CSPG4-positive (n=13) or CSPG4-negative (n=7) stage II-IV surgically resected oral CMM, thus suggesting that vaccination against hCSPG4 by DNA electroporation is efficacious against CMM when used in an adjuvant setting.

Correlation between the high expression of cancer testis antigens and the prognosis in patients with esophageal carcinoma in China

X. Chen[1], *J. Liu*[1], *M. Wang*[1], *Y. Zhang*[2];
[1]*Biotherapy center ,the the First Affiliated Hospital of Zhengzhou University, Zheng Zhou, China,* [2]*Biotherapy center ,the the First Affiliated Hospital of Zhengzhou University;Department of Oncology, the First Affiliated Hospital of Zhengzhou University;Department of Biological Engineering, Zhengzhou University, Zheng Zhou, China.*

Background: Survival rates after esophageal cancer diagnosis still remain poor, despite standardization of surgery and adjuvant treatment. Cancer testis (CT) antigens as targets for immunotherapy in cancer patients have been heavily investigated. We aim to evaluate the expression of CT antigens in Chinese esophageal carcinoma and the correlation with the prognosis. **Methods:** The expression of MAGE-A3, MAGE-A4, MAGE-C2 and NY-ESO-1 in fresh cancer tissues from 103 patients with esophageal carcinoma were analysed by RT-PCR. The expression of HLA-A2 was detected by flow cytometry. **Results:** 59.8% esophageal cancer samples were HLA-A2 positive. CT antigens were frequently expressed in esophageal carcinoma. The expression percentage of each gene in cancer tissues samples were as follows: MAGE-A3, 87.9%; MAGE-A4, 57.1%; MAGE-C2, 67.0%; and NY-ESO-1, 22.0%. In all, 93.4% of samples expressed at least one of CT genes analysed. The percentage of samples co-expression HLA-A2 and CT genes were: MAGE-A3, 51.6%; MAGE-A4, 36.3%; MAGE-C2, 44.0%; and NY-ESO-1, 12.1%. MAGE-A3 expression was associated with age, tumor stage and tumor differentiation ($P<0.05$); MAGE-C2 was associated with tumor stage ($P<0.05$). There was no correlation MAGE-A4 or

NY-ESO-1 expression with clinical characteristics such as gender, age, HLA-A2 positive, clinical stage, grade of differentiation and lymph node metastasis (P>0.05). **Conclusion:** CT antigens might be prognostic markers and factors related to the progress of esophageal carcinoma, and also be served as the immunotherapeutic targets of esophageal carcinoma, especially in multi-antigen vaccine preparations and tumor antigen specific lymphocytes infusion.

CD38 is a suitable cell surface target in the design of monoclonal antibody (mAb)-mediated therapy. CD38 is an appealing target in virtue of its bi-functional roles of receptor and ectoenzyme. This work presents a range of perspectives and caveats in the challenges encountered while conducting a pre-clinical studies for anti-CD38 mAb therapy. The disease models chosen for in vitro analysis were multiple myeloma (MM) and chronic lymphocytic leukemia (CLL). The first step was to study events occurring at the cell membrane, where antigen-antibody complexes were internalized. The second step was the analysis of the effects triggered by mAb ligation on the trascriptome and on miRNAs (33a-5p and 340-5p are up-modulated, while 193b-5p and 629-3p are decreased). The next possibility was to increase CD38 surface expression by using retinoids. CD38 was increased in both MM and CLL, where only the CD38+ samples responded to retinoids. The last hypothesis tested was that CD38 may generate adenosine, inducing local immunosuppression. This was confirmed by using an in vitro bone marrow model with stromal cells, osteoblasts, osteoclasts and lymphocytes. This model consented the identification of an ectoenzyme (CD38/CD203a/CD73) network which generates adenosine, explaining survival of myeloma cells in closed systems. The role of oxytocin (controlled by CD38 in mouse models) is under analysis. The data obtained allow to define the safety of pre-clinical anti-CD38 mAb therapy plans. Added values are that antibody-mediated therapy may be used directly, as a drug carrier or to redirect nanovescicles, and could be applied in association with other drugs.

P6.06.032
Combination immunotherapy with tumor-specific CD4+ and CD8+ T cells decreases CD8+ T cell exhaustion and augments therapeutic efficacy

S. E. Church[1,2], *S. M. Jensen*[1], *B. A. Fox*[1,2];

[2]*Oregon Health and Science University, Portland, OR, United States.*

Adoptive immunotherapy with tumor-specific TRP-1-CD4$^+$ TCR-Tg T-cells (TRP-1-CD4$^+$) and pmel-CD8$^+$ TCR-Tg T-cells (pmel-CD8$^+$) cured mice with established experimental metastases of the poorly immunogenic B16BL6-D5 melanoma. However, when the same dose of either TRP-1-CD4$^+$ or pmel-CD8$^+$ were transferred alone they were non-therapeutic. Characterization of T cells post adoptive transfer found that TRP-1-CD4$^+$ significantly ($p<0.001$) increased the total number and function of memory pmel-CD8$^+$. We examined whether TRP-1-CD4$^+$ maintained effector pmel-CD8$^+$ by sorting CD62L^{lo}CD44$^+$ (effector) pmel-CD8$^+$ and combining the sorted or total pmel-CD8$^+$ with TRP-1-CD4$^+$ for adoptive immunotherapy. Both were equally therapeutic suggesting CD4$^+$ T cells are maintaining activated effector pmel-CD8$^+$. We examined when CD4$^+$ T cells were necessary for enhancing therapeutic efficacy of CD8$^+$ T cells by administering anti-CD4 Mab at different times (day 3 and 10) following adoptive transfer. Depletion of CD4$^+$ cells 3 days after adoptive transfer eliminated therapeutic efficacy and correlated with loss of function and increased expression of the exhaustion marker PD-1 on pmel-CD8$^+$ ($p<0.05$). Depletion of CD4$^+$ cells 10 days after transfer led to elimination of metastases at day 18 but animals did not survive long-term. Since blocking PD-1 may increase survival of pmel-CD8$^+$, mice were given combination treatment with pmel-CD8$^+$ and anti-PD-1. PD-1 blockade significantly ($p<0.05$) increased total and memory pmel-CD8$^+$ compared to treatment with pmel-CD8$^+$ alone, however, this did not improve therapeutic efficacy. These data show that tumor-specific CD4$^+$ T cells are helping to reduce CD8$^+$ T cell exhaustion and underscores the clinical relevance of generating both tumor-specific CD4$^+$ and CD8$^+$ T cells.

P6.06.033
A new pathway of tumor antigen loading of human dendritic cells via intercellular communication

M. Ciranna*, L. Morelli, C. Pozzi, G. Penna, M. Rescigno;*
IEO, Milano, Italy.

Most cancer cells down-regulate gap junctions resulting in loss of communication with their surrounding microenvironment.
Recent data obtained in a mouse melanoma model (Saccheri et al., Sci TM 2010) showed that infection of tumors with Salmonella could induce, in tumor cells, the up-regulation of connexin 43 (Cx43), a ubiquitous protein that forms gap junctions. This up-regulation leads to the formation of functional gap junctions between tumor cells and dendritic cells. Herein, we show that the formation of this intercellular way of communication could be used, in vitro, to load human autologous dendritic cells with tumor antigens and generate a cancer vaccine. Indeed, human dendritic cells cocultured with salmonella-infected SKmel24 melanoma cell line were able to elicit a tumor-specific CD8 T-cell response in vitro. The transfer of tumor antigens was gap junction dependent because abolished by the presence of specific inhibitor. Tumor-specific CTLs recognized other melanoma cell lines indicating that dendritic cell were loaded with tumor-associated antigens shared among melanoma cell lines. Moreover, the in vitro generated CTL were melanoma specific because they were unable to lyse colorectal adenocarcinoma cell lines.
We exploited an antimicrobial response present in tumour cells to activate cytotoxic CD8 T cells specific for tumour-peptides through a new pathway of antigen loading of human dendritic cells via intercellular communication channels that can be used clinically as therapeutic vaccine.

P6.06.034
A phase Ib clinical trial of cisplatin and pemetrexed in combination with the CD40 activating antibody CP-870,893

A. McDonnell[1], ***A. Cook***[1], *B. W. S. Robinson*[1], *R. A. Lake*[1], *J. Creaney*[1], *A. Hasani*[2], *M. Millward*[1], *A. K. Nowak*[1];
[1]*University of Western Australia, Perth, Australia,* [2]*Sir Charles Gairdner Hospital, Perth, Australia.*

CD40 is a co-stimulatory molecule expressed on antigen presenting cells. Pre-clinical data supports synergy between cytotoxic chemotherapies and CD40 activation in mouse tumor models however, little is known regarding their combination in human disease. Here we investigate the safety profile, maximum tolerated dose (MTD) and immunological activity of the CD40 activating antibody, CP-870,893 combined with pemetrexed and cisplatin in a Phase 1b study. Patients with advanced malignant pleural mesothelioma (MPM) received standard does of cisplatin and pemetrexed on day 1 and CP-870,893 in escalating doses from 0.1 mg/kg on day 8 of a 21 day cycle for a maximum of 6 cycles. Fifteen patients received combination therapy at three dose levels of CP-870,893. Three patients were treated at dose level 1 (0.1mg/kg) with no dose limiting toxicities (DLT). Three patients were treated at dose level 2 (0.2mg/kg), with 2 DLTs (hyponatremia and confusion; splenic infarction). Three patients were treated at dose level 1.5 (0.15 mg/kg) with no DLTs observed, and an additional 6 patients were accrued to an expansion cohort at this dose level. The best radiological response was partial response in 6 patients (40%), and stable disease in 8

patients (53%). Two patients showed progression followed by subsequent prolonged stabilisation of disease (>24 months). The proportion of Tregs, $CD4^+$ and $CD8^+$ T cells remained consistent throughout treatment with updated DC and B cell analysis to be presented. A combination of cisplatin, pemetrexed, and CD40 activation with CP-870,893 can be safely administered in patients with MPM with clinical responses observed.

P6.06.035

Optimising regulatory T cell (Treg) depletion in combination with chemotherapy for enhanced anti-tumour immunity

***A. Cook**, B. Robinson, A. McDonnell, M. Millward, R. A. Lake, A. K. Nowak;*
University of Western Australia, Perth, Australia.

Cytotoxic chemotherapy, widely used to palliate many malignancies, can enhance anti-cancer immunotherapy as shown by abundant preclinical data. Tregs are immunosuppressive $CD4^+$ T cells thought to inhibit anti-tumour immune responses; murine data suggests that Treg eradication may augment existing anti-tumour immunity. Cyclophosphamide (CTX) is immunostimulatory and at low doses selectively depletes Tregs in mice and humans.
In this phase 1b study we investigate an optimum dose and schedule of iterative low dose oral CTX for Treg depletion, in the context of pemetrexed-based chemotherapy, and how treatment affects the function and phenotype of the cellular immune response. Thirty-one patients with advanced malignant pleural mesothelioma (MM) or non-small cell lung cancer (NSCLC) received standard doses of pemetrexed ± cisplatin or carboplatin on a 21 day schedule (6 cycles max.). From the second cycle, escalating doses of oral CTX were administered, initially with 50 mg daily. Weekly peripheral blood samples were collected, and the proportion of Tregs within the $CD4^+$ population (Treg%) determined, amongst other immunological parameters.
Following commencement of CTX the peripheral blood Treg% decreased (maximum Treg depletion occurred during Cycle 3), then increased back toward baseline. Optimal Treg depletion was achieved with alternating 50/100 mg per day, with increasing doses up to alternating 100/150 mg daily not resulting in further depletion. Analysis of PBMC T cell populations shows cell proliferation (Ki67) and activation (inducible co-stimulator; ICOS) to peak and trough with each cycle of chemotherapy. Combining CTX with routine cytotoxic chemotherapy is feasible with no additional haematological or other toxicities.

P6.06.036

Radiation therapy plus IL-2 in patients with metastatic melanoma is associated with release of danger associated molecular patterns when compared to IL-2 alone but not an increase in circulating inflammatory cytokines

***M. R. Crittenden**[1], M. Gough[1], B. Fox[1], S. Seung[2], B. Cottam[1], J. Walker[1], W. Urba[1], B. Curti[1];*
[1]Earle A. Chiles Research Institute, Portland, OR, United States, [2]The Oregon Clinic, Portland, OR, United States.

We completed a Phase I study combining high-dose per fraction radiation therapy (SBRT) to metastatic lesions in the lung and liver of patients undergoing high dose IL-2 treatment for metastatic melanoma or renal cell carcinoma. This study demonstrated a response rate of 66%. We have an ongoing randomized Phase II study of SBRT followed by IL-2 versus IL-2 alone in patients with metastatic melanoma. To understand the higher response rate associated with radiation therapy we undertook analysis of serum markers of inflammation and adjuvant release. We analyzed the serum of the first 16 patients enrolled in our phase II study. We demonstrated a significant increase in the release of danger associated molecular patterns (DAMPS), including Uric Acid and HMGB-1, in the serum of patients undergoing radiation and IL-2 when compared to IL-2 alone. Conversely, 24 hours following IL-2 administration patients receiving IL-2 alone showed a significantly higher level of circulating pro-calcitonin levels when compared to patients receiving combined therapy as well as significantly higher levels of circulating IL-12 and IL-15. On day 8, circulating RANTES was significantly higher in patients receiving combined therapy when compared to patients receiving IL-2 alone.
We conclude that radiation therapy in combination with IL-2 is associated with an increase in DAMPS. Yet, combined therapy results in a dampening of systemic inflammatory cytokines. We hypothesize that this reflects a change in location of the immune response from the blood to the tumors and is supported by the higher circulating RANTES level in patients receiving combined treatment.

P6.06.037

RIL-21 combined with CD4-T cell depletion reprograms CD4+ T cells from an immune regulatory to an anti-tumor phenotype in syngeneic neuroblastoma

***M. Croce**[1], A. Brizzolara[1], V. Rigo[1], A. Orengo[1], B. Carlini[2], M. Corrias[2], S. Ferrini[1];*
[1]IRCCS-AOU-San-Martino-IST, Genoa, Italy, [2]IRCCS-Gaslini, Genoa, Italy.

Tumors sustain the expansion of immune suppressive cells, including CD4+CD25+FoxP3+ regulatory T (Treg), through factors such as TGF-beta, PGE2 or IL-10. IL-21 is an immune enhancing cytokine showing promising results in pre-clinical and clinical cancer immunotherapy. We previously observed that CD4+CD25+ FoxP3+ Treg cells increased in a syngeneic model of disseminated neuroblastoma (NB). In addition, the administration of anti-CD4 cell-depleting antibody strongly enhanced the anti-tumor effects of an IL-21-engineered NB cell vaccine, by inducing depletion of Treg cells. In this study we addressed the effects of a therapeutic combination of recombinant (r)IL-21 and anti-CD4 antibodies in disseminated NB. rIL-21 administered s.c. at two dose levels had a limited effect, while the co-administration of a cell-depleting anti-CD4 mAb allowed to cure 28% to 70% of mice receiving 0.5 or 1 µg/dose levels, respectively. Anti-CD4 antibody treatment completely depleted CD4+CD25+FoxP3+ Treg cells and their CD25- precursors. The co-administration of rIL-21 by-passed the requirement of CD4+ T helper cells and allowed the development of a CD8+ T cell response, which was required for tumor eradication and for long-lasting immunity. Nonetheless reconstitution of the CD4+ T cell pool after combined immunotherapy was also required for immunity to NB antigens, as indicated by CD4+ T cell depletion and re-challenge experiments in cured mice. In conclusion, our data support a role of immune suppressive CD4+ T cells in a syngenic NB model and suggest that rIL-21 combined with CD4-T cell depletion reprogams CD4+ T cells from immune regulatory to an anti-tumor memory phenotype.

P6.06.038

Pre-clinical development of an agonistic CD40 antibody (ADC-1013) for local immunotherapy of cancer

***E. Dahlén**[1], C. Furebring[1], S. Broos[2], T. Berggård[1], P. Norlén[1], M. Lindstedt[2], T. Tötterman[3], S. Mangsbo[3], P. Ellmark[1];*
[1]Alligator Bioscience, Lund, Sweden, [2]Department of immunotechnology, Lund University, Lund, Sweden, [3]Immunology, Genetics and Pathology, Uppsala University, Uppsala, Sweden.

Local administration of immune activating antibodies may increase the efficacy and reduce the immune-related adverse events associated with systemic immunotherapy of cancer. Here we report the development of a fully human agonistic CD40 antibody, ADC-1013, which has been optimized for local immunotherapy by FIND® recombination, thereby increasing potency and tumor retention.
ADC-1013 activates CD40 receptors on antigen-presenting cells such as dendritic cells, resulting in up-regulation of the co-stimulatory molecules CD80 and CD86, and induction of IL-12. In addition, ADC-1013 induces direct tumor killing of $CD40^+$ tumors. The anti-tumor effects of ADC-1013 have been assessed in a bladder cancer model (EJ) in immunodeficient NSG mice. Significant anti-tumor responses were demonstrated, and further augmented in mice repopulated with human monocyte-derived dendritic cells and T cells.
To our knowledge, ADC-1013 represents the first immunomodulatory antibody optimized for local immunotherapy of cancer. It is currently in late pre-clinical development and will enter clinical trials in 2014.

P6.06.039
Th1/Th2/Th17 profile and T cell phenotype of an in vitro antigen presentation system in response to DC functionality, IL-2 and IGF-1 presence

***A. de Lastic**, M. Rodi, A. Mouzaki;*
University of Patras, Patras, Greece.

T cells play an important role in controlling tumor growth and mediating tumor regression. The aim of this study was the generation of tumor-specific CD4+ and CD8+ lymphocytes by the use of combined MHC class I and class II epitopes of the tumor antigen MAGE-3. The construct that has been used consists of a CD8/MHCI epitope and a CD4/MHCII epitope, joined on an oligopeptide carrier. This construct has been used as a model, dual MHC, foreign antigen to assess the dynamics of antigen presentation.
Monocytes have been isolated from healthy donors, have been cultured in the presence or absence of IGF-1 and have been transformed to dendritic cells. The peptide has been added to the DC culture, and the pulsed cells have been transferred to a co-culture with lymphocytes from the same donor, either as irradiated feeders or untreated, and were cultured in the presence or absence of IL-2. Several rounds of restimulation followed. The lymphocytes were analyzed by Flow Cytometry, ELISA and Cytometric Bead Array for Th1/Th2/Th17 profiling. The results showed that the lymphocytes in culture upregulated their activation markers and produced Th1 proinflammatory cytokines in response to the peptide, optimally when it was presented by non-irradiated dendritic cells in the presence of IL-2. After prolonged stimulation the culture displayed a Th17 polarization but only in the presence of the peptide. IGF-1 displayed a “rescue” potential for the dendritic cells after the irradiation and also acted as upregulator of co-expression molecules, resulting in improved antigen presentation.

P6.06.040
The predictive role of αβ-double negative T cells in clinical outcome of patients with lymphoma: preliminary data

***G. De Tullio**, C. Minoia, S. Serratì, F. Merchionne, G. Loseto, A. La Pietra, A. Rana, A. Iacobazzi, P. Iacopino, A. Guarini;*
National Cancer Research Centre, Istituto Tumori "Giovanni Paolo II", 70124, Italy.

Numerous aspects of lymphoma pathophysiology indicate mutual interactions between the host immune system and lymphoma cells.An unconventional subset of CD4−CD8− double-negative T cells (DNTs) has been described to specifically contribute to anti-tumor immunity,acting as both regulatory T cells and/or cytotoxic T cells.No data are available on their role in human anti-lymphoma immunity,their interaction with other immune cells, functional attitude and on their prognostic significance in lymphomas.
The aim of study is to assess the frequency and the functional attitude of circulating DNTs in Lymphoma patients (pts) in order to evaluate their predictive role on clinical outcome.
Peripheral blood of 25 Lymphoma patients and healthy donors age as controls were prospectively collected to perform phenotypic and functional characterization of circulating DNTs.For functional studies DNTs were purified from PBMCs using specific MACS microbeads.
A significantly reduction of circulating (TCRαβ) DNTs in Lymphoma patients compared with healthy controls (1,482%±2,60, p<0,01) was observed and they correlate with disease relapse/progression.Moreover,Hodgkin's Lymphoma showed higher number of αβ−DNTs as compared with other histotypes.Furthermore in preliminary data was observed a characteristic cytokines profile with a cytotoxic potential in ex-vivo expanded DNTs, mainly with an increase of IFN-γ and granzyme B secretion,known to be the main immune effectors for anti-tumor activity.
This study suggest that the reduction of αβ−DNTs in untreated lymphoma patients may correlate with the suppression of tumor-specific immune response and the clinical outcome.However ex-vivo expanded DNTs likely possess a cytotoxic attitude, suggesting their possible use as new strategy for immune therapy

P6.06.041
Deciphering adaptive anti-tumor immunity induced by anti-CD20 mAb treatment

***C. Deligne**, A. Metidji, J. Teillaud;*
Centre de Recherche des Cordeliers, Paris, France.

We have previously demonstrated that anti-CD20 monoclonal antibody (mAb) exerts a long-lasting anti-tumor protection in tumor-bearing mice through the induction of an adaptive immune response (1). Using a mouse model in which immune competent mice are injected i.v. with human $CD20^+$ tumor cells and then treated with an anti-huCD20 mAb, we have shown that $CD4^+$ T cells are central to tumor protection by depletion and adoptive transfer experiments. We have then investigated whether anti-CD20 mAb treatment modifies the balance between $CD4^+$ T cell subsets. Strikingly, analyses of spleen T cells at different time points after tumor injection revealed that the initial expansion of Treg ($FoxP3^+$ $CD4^+$) observed in both untreated and mAb-treated mice is reversed in anti-CD20-treated mice that exhibit an increase of the Th1 cell subset (IFN-γ^+ $CD4^+$). Concomitantly, anti-CD20-treated mice showed an increased in IL-12 serum level. IL-12 neutralization abolished the protection induced by anti-CD20 mab and decreased the number of Th1 cells, demonstrating the critical role of this cytokine. Neutralization of IL-10 or TGF-β or depletion of Treg with an anti-CD25 mAb that ameliorate protection of tumor-bearing animals per se, did not lead to an increase in the survival rate of mAb-treated mice, indicating no synergy when combining anti-immunosupressive and anti-CD20 treatments. Altogether, these data demonstrate that the balance between Treg and Th1 compartments, essential in the control of tumor progression, can be fine-tuned by therapeutic mAbs to switch the immune response from a pro- to an anti-tumor response.

The tumor microenvironment can vary with anatomical site to affect responses to therapy

***C. Devaud**, J. A. Westwood, L. B. John, J. K. Flynn, S. Paquet-Fifield, M. J. Smyth, P. K. Darcy, M. H. Kershaw;*
PeterMacCallum Cancer Centre, East Melbourne (VIC), Australia.

Besides cancer cells, tumors comprise a complex assortment of molecular and cellular components called the microenvironment. How surrounding normal tissues at different anatomical sites affect tumor microenvironments and their subsequent response to therapy is not known. We studied the microenvironments of the same type of tumor developed in different tissues.
We found that established tumors in the skin could be eradicated in the majority of mice using a combination of three antibodies, whereas the same tumors developing in visceral organs responded much less. Analyses using flow cytometry together with gene and protein arrays demonstrated that tumors in visceral locations had a microenvironment with a higher frequency of immunosuppressive alternatively activated macrophages (AAM) and increased levels of their associated molecules (such as CD206, IL-10 or Arginase) relative to tumors growing in the skin. Indeed, we demonstrated that the therapeutic effect of antibodies on visceral tumors could be improved by targeting some key AAM-associated molecules using a CCL2-neutralizing antibody and IL13-KO mice. Importantly, a much reduced therapeutic response of subcutaneous tumors was observed when kidney tumors were simultaneously present in the same mice, suggesting a negative impact of immunosuppressive-tumors on distant responsive-tumors.
The tissue-specific response observed in this system suggests that the anatomical location of tumors can affect the tumor microenvironment and highlights the importance of normal tissues in sculpting the tumor microenvironment. Also, the observation that distant tumors are able to influence each others’ response to therapy may be an important clinical consideration when in the design of treatment strategy.

P6.06.043
Antitumor activity of PEGylated Fab-fragments of GD2-specific antibody

***I. I. Doronin**, I. Kholodenko, I. Molotkovskaya, R. Kholodenko;*
Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry of the Russian Academy of Sciences, Moscow, Russian Federation.

Monoclonal antibodies against tumor-associated ganglioside GD2 are attractive tools for researchers and clinicians as an agent for anti-cancer immunotherapy. Despite some success of their application, there are a number of side effects associated with Fc-fragment of GD2-mAb. Recently, it was shown that the GD2-mAb has direct strong cytotoxic activity against tumor cells expressing GD2. The fact that these effects did not associated with antibody's Fc-fragment allows the use of active antibody fragments without Fc-region (Fab-fragments). Purpose of the study is to evaluate the possibility of applying Fab-fragments of GD2-mAb for tumor therapy.
In our work, we have obtained purified fraction of Fab-fragments from GD2-mAbs. Using flow cytometry assay, we showed their antitumor effects on GD2-positive tumor cell lines. The main drawback of smaller Fab-fragments in comparison to whole antibodies is their drastically shorter elimination half-life. In order to increase the half-life of Fab-fragment GD2-mAb we produced their site-specific PEGylation. Maleimide-based reaction allows to covalently attach PEG (from 1 to 3 molecules per Fab) to cysteines of Fab-fragment far away from the epitope binding region. Using ELISA, flow cytometry assays and confocal microscopy, we have shown that PEGylation does not lead to significant changes in the binding of GD2 compared to unmodified Fab-fragments. Thus the use of this method has allowed us to maintain the activity of Fab-fragment GD2-mAb.
We have established a syngeneic mouse model of GD2-positive tumor. Using different criteria for evaluating of tumor progression, we analyzed antitumor effects of full-size GD2-mAb, their Fab-fragments and PEGylated Fab-fragments of GD2-mAb.

P6.06.044
Generating Stronger T cells for Adoptive Immunotherapy

***C. P. M. Duong**[1,2], J. A. Westwood[1], C. S. M. Yong[1,2], C. Devaud[1], L. B. John[1], P. K. Darcy[1,2], M. H. Kershaw[1,2];*
[1]Peter MacCallum Cancer Centre, East Melbourne, Australia,
[2]University of Melbourne, Melbourne, Australia.

Adoptive immunotherapy mediates effective regression of advanced metastatic melanoma in patients. To target other cancers, we engineered T cells to express chimeric antigen receptors (CARs) empowering them with anti-tumour activity, specifically to the tumor-associated antigen, erbB2. Our current CAR, utilising CD28-CD3ζ signaling domains, although promising, mediates lower activity compared to endogenous TCR responses against foreign antigens. Therefore, we hypothesized that incorporating multiple alternate signaling domains into CARs could result in significantly enhanced anti-tumor responses. To investigate this, we generated a library of approximately 30,000 CARs that incorporated 14 different signaling molecules randomly ligated together directionally and in-frame flanked by SfiI sites and inserted into an anti-erbB2 CAR retroviral vector. The Jurkat T cell line was then retrovirally transduced to express the library and screened for increased CD69 expression or IL-2 secretion in response to antigen specific stimulation. Genomic DNA of selected clones was then extracted, sequenced and cloned into the pSAMEN vector to transduce human peripheral blood mononuclear cells. A diverse range of CARs containing different signaling chains were identified. A particular CAR, containing the tripartite signaling domains DAP10-CD3ζ-CD27 endowed human T cells with the ability to mediate significantly enhanced killing of erbB2+ tumor cells in vitro compared to the CD28-CD3ζ CAR ($p<0.05$). Strikingly, adoptive transfer of T cells expressing this novel receptor induced significantly increased anti-tumor activity in vivo ($p<0.01$). In conclusion, it is anticipated that the generation of CARs with novel combinations of signaling domains will lead to stronger T cells for the treatment of cancer.

P6.06.045
Chimeric protein of IL-2 linked to light chain of anti-IL-2 mAb S4B6 that structurally mimics IL-2/S4B6 immunocomplexes: design and production

***B. Dvorakova**, J. Tomala, J. Kovarova, M. Kabesova, P. Votavova, H. Chmelova, B. Rihova, M. Kovar;*
Institute of Microbiology, v.v.i., Academy of Sciences of the Czech Republic, Prague 4, Czech Republic.

IL-2/anti-IL-2 mAb immunocomplexes were reported to have significantly higher biological activity than free IL-2 *in vivo*. Depending on the mAb used they show different selectivity of their stimulatory activity. However, possible dissociation of IL-2 from mAb or excess of either substance in prepared immunocomplexes are general disadvantage. In order to overcome such problems, we designed and produced protein chimera consisting of IL-2 linked to light chain of anti-IL-2 mAb S4B6 through flexible oligopeptide spacer $(Gly_4Ser)_3$. The intramolecular interaction of IL-2 and mAb part in our protein chimera is similar to that in immunocomplexes of IL-2 and anti-IL-2 mAb S4B6 (henceforth IL-2/S4B6), but dissociation of IL-2 too far away from mAb is prevented by covalent attachment to S4B6 mAb.
We showed the produced protein chimera has predicted molecular weight slightly higher than to IL-2/S4B6, contains both IL-2 and S4B6 mAb in one molecule and IL-2 interacts with binding site of S4B6 mAb in *cis*.
Thus, we conclude that IL-2-S4B6 protein chimera mimics IL-2/S4B6 immunocomplexes in terms of structure and cytokine-mAb interactions.

Enhanced efficacy of a cancer vaccine by blocking TGF-β-dependent induction of regulatory T cells with a retinoic acid receptor-α antagonist

***L. Dyck**, K. C. Galvin, K. H. G. Mills;*
School of Biochemistry and Immunology, Trinity College Dublin, Dublin, Ireland.

A major goal of cancer immunotherapy is to direct effector immune responses against tumour cells, leading to tumour eradication and enhancing survival. However, tumours have evolved immunosuppressive mechanisms to overcome effector immune responses. For example, TGF-β has been shown to induce the conversion of naïve $CD4^+$ T cells into regulatory T (Treg) cells and this is enhanced by retinoic acid (RA), a Vitamin A metabolite. In the present study we investigated the capacity of a RA receptor-alpha antagonist (RARi) to block the induction of Treg cells and thus to enhance anti-tumour immunity. We found that RA and TGF-β induced conversion of naïve $CD4^+$ T cells into Treg cells could be blocked by RARi. TGF-β in combination with RA converted committed $CD4^+$ T cells into Treg cells, decreasing the effector T cell population and IFN-γ production. Furthermore, RARi suppressed the secretion of the anti-inflammatory cytokine IL-10 and enhanced IL-12 production from TLR-activated dendritic cells (DCs). Using a B16 melanoma murine tumour model, we found that RARi enhanced the therapeutic efficacy of a TLR-activated antigen-pulsed DC vaccine, significantly attenuating tumour growth and enhancing survival. Furthermore, treatment with RARi reduced the frequency of $Foxp3^+$ and $IL\text{-}10^+$ Treg cells, while enhancing IFN-γ-secreting $CD4^+$ and $CD8^+$ T cells infiltrating the tumours. Our findings demonstrate that blocking RARα is promising approach to enhance the anti-tumour effect of cancer vaccines and immunotherapeutics.

Lymphocyte imprinting with melanoma antigens acquired by trogocytosis facilitates identification of tumor-reactive T cells

G. Eisenberg[1], *R. Uzana*[1], *A. Pato*[1], *S. Frankenburg*[1], *S. Merims*[1], *E. Yefenof*[2], *S. Ferrone*[3], *T. Peretz*[1], *M. Lotem*[1], *A. Machlenkin*[1];
[1]*Sharett Institute of Oncology, Hadassah Medical Organization, Jerusalem, Israel,* [2]*Lautenberg Center for General and Tumor Immunology, Hebrew University of Jerusalem, Jerusalem, Israel,* [3]*Department of Surgery, Massachusetts General Hospital, Boston, MD, United States.*

Trogocytosis is a contact-dependent inter-cellular transfer of membrane fragments and associated molecules from antigen presenting cells to effector lymphocytes. We previously demonstrated that trogocytosis also occurs between tumor target and cognate melanoma antigen-specific cytotoxic T cells (CTL). Here we show that, following trogocytosis, immune effector cells acquire molecular components of the tumor, including surface antigens, which are detectable by specific monoclonal antibodies. We demonstrate that CD8+ and CD4+ T cells from melanoma patients' PBMC and tumor infiltrating lymphocytes (TIL) capture melanoma antigens, enabling identification of trogocytosing lymphocytes by staining with antigen-specific antibodies. This finding circumvents the necessity of tumor pre-labeling, which in the past was mandatory to detect membrane-capturing T cells. Through the detection of melanoma antigens on TIL, we sorted trogocytosing T cells and verified their preferential reactivity and cytotoxicity. Furthermore, tumor-antigen imprinted T cells were detected in fresh TIL cultures, shortly after extraction from the tumor. This feature is of special relevance regarding cell-based immunotherapy, as it may provide an efficient way to identify and isolate tumor-reactive lymphocytes at the initial stages of TIL propagation. Thus, T cell imprinting by tumor antigens may serve as a tool to detect and isolate melanoma antigen-specific T cells for immunotherapy of cancer.

Inhibition of intercellular communication between prostate cancer cells by anti-STEAP-1 single chain antibody

A. Esmaili[1,2], *F. Nejatollahi*[1,3];
[1]*Recombinant antibody laboratory, Department of Immunology, School of Advanced Medical Sciences and Technologies, Shiraz University of Medical Sciences, Shiraz, Iran, Shiraz, Iran,* [2]*Student research Committee, Shiraz University of Medical Sciences, Shiraz, Iran, Shiraz, Iran,* [3]*Shiraz HIV/AIDS research center, Shiraz University of Medical Sciences, Shiraz, Iran, Shiraz, Iran.*

Background: Six-transmembrane epithelial antigen of the prostate-1 (STEAP-1) located at the cell-cell junction on the secretory epithelium of prostate cancer, acts as a transporter protein in intercellular communication and has been introduced as appropriate tumor antigen for immunotherapy. scFv with properties such as human origin, high affinity and small size provides a suitable tool for immunotherapy .In this study we selected specific single chain antibodies against STEAP-1 and showed role of this antibody to block gap junction between the prostate cancer cells.
Materials and Methods: Phage rescue was performed on a diverse non immune library of single chain Fv. Phage supernatant was used to enrich the library against immunodominant epitope of STEAP-1 using panning process. PCR and DNA fingerprinting were done to select the specific clones against the epitope. Phage ELISA was performed to show the specificity of the selected clone. Intercellular communication assay was done to show the role of scFv in inhibition of dye transferring between the cancer cells.
Results: One predominant pattern with frequency 35% selected for intercellular communication assay in PC3 and LNCaP cell lines. Results showed the concentration of 1000scFv/cell could inhibit intercellular communication between cells.Anti-STEAP-1 scFv in LNCaP more than PC3 in comparison of controls.
Conclusions: In the current study we used intercellular communication assay to show the role of this scFv in inhibition of dye transferring between the cells. Blockage of this channel that implicated in progress of prostate cancer suggests that scFv can be helpful to prevent from advance prostate cancer.

P6.06.049
Soluble MICA serum levels as predictive biomarkers of anti-CTLA-4 melanoma immunotherapy

J. Felix[1], *R. Porcher*[2], *C. Pages*[3], *I. Sidina*[3], *V. Kheav*[1], *G. Maki*[4], *M. Viguier*[3], *A. Toubert*[1], *C. Lebbe*[3], *H. Moins-Teisserenc*[1];
[1]*INSERM UMRS940, IUH, AP-HP, Université Paris Diderot, Paris, France,* [2]*Biostatistic Department AP-HP, Paris, France,* [3]*Department of Dermatology, AP-HP, Paris, France,* [4]*Laboratoire d'Immunologie et Histocompatibilité, AP-HP, Paris, France.*

Ipilimumab, which blocks CTLA-4, has demonstrated an improvement in overall survival (OS) in patients with advanced melanoma. Cinical responses responses and disease control rate are reported in 15%-30% of patients, but major adverse events are frequent.
This study aimed to find possible correlations between positive outcome under anti-CTLA-4 and the MHC class-I polypeptide-related sequence A (MICA) molecule, broadly expressed on tumors and whose shedding from tumor cells promotes tumor escape.
41 consecutive patients with an inoperable state III or IV melanoma and receiving 3 mg/kg of Ipilimumab were included in a non-randomized prospective study. Ipilimumab was administered every 3 weeks until week 12. Sera levels of soluble MICA (sMICA) and anti-MICA antibodies (Abs) were determined longitudinally and clinical evaluation was performed at week 16, assessing response to treatment (from complete response to progressive disease). Levels of sMICA and anti-MICA Abs were analyzed according to response to Ipilimumab and overall survival. Positive outcomes or stable disease were reported in 46% of cases. No association between either sMICA or anti-MICA and OS was found. Levels of anti-MICA Abs were similar in all groups of response. Serum concentrations of sMICA were significantly lower in patients responding to Ipilimumab and were particularly high in the group of progressors. This difference was observed at each time point and even before the beginning of treatment (P = .017).
Our data suggest that sMICA may be an early predictive marker in the context of anti-CTLA-4 immunotherapy with a significant inverse correlation between serum levels and clinical response.

P6.06.050
Bispecific single-chain diabodies for T cell retargeting to solid tumors

S. Fellermeier, *R. E. Kontermann;*
Universität Stuttgart, Institut für Zellbiologie und Immunologie, Stuttgart, Germany.

Current research in the field of cancer immunotherapy focuses on the development of strategies inducing a powerful, target-dependent immune response at the tumor site. This effect can be achieved with bispecific antibody formats that act as adaptor between tumor cells and cytotoxic T lymphocytes by simultaneously binding to a tumor-associated antigen and the T cell specific receptor CD3. We have developed different bispecific single-chain diabodies targeting the EGF receptor family members EGFR and HER2 or the cancer stem cell marker EpCAM as well as CD3. ScDbEGFRxCD3, scDbHER2xCD3 and scDbEpCAMxCD3 were produced in HEK293 cells and showed highly specific binding to their respective recombinant antigen as well as antigen-expressing human cancer cell lines. Functional activity of all single-chain diabodies was shown by IL-2 release of activated PBMCs upon cross-linking with tumor cells. Remarkably, the use of scDbEpCAMxCD3 resulted in significantly better T cell activation compared to scDbEGFRxCD3 and scDbHER2xCD3. Our results indicate that bispecific single-chain diabodies, especially in combination with EpCAM targeting, are suitable tools for initiation of tumor-directed T cell responses and are therefore further investigated.

P6.06.051

Natural Killer adoptive cell transfer targeting bladder cancer stem cells: preliminary results for fine-tuning strategy

M. Ferreira-Teixeira[1,2]*, B. Parada*[3,4]*, F. Reis*[2,5]*, C. Gomes*[2,5]*, P. Rodrigues-Santos*[1,6,5]*;*
[1]Inst Imunologia, Fac Medicina Univ Coimbra, Coimbra, Portugal, [2]Lab Pharmacol Exp Therapeutics, Inst Biomed Research in Light and Image (IBILI), Fac Medicine Univ Coimbra, Coimbra, Portugal, [3]Lab Pharmacol Exp Therapeutics - Inst Biomed Research in Light and Image (IBILI), Fac Medicine Univ Coimbra, Coimbra, Portugal, [4]Urology and Renal Transplantation Dep - Centro Hospitalar Universitário de Coimbra, Coimbra, Portugal, [5]Center of Investigation in Environment, Genetics and Oncobiology (CIMAGO), Fac Medicine, Univ Coimbra, Coimbra, Portugal, [6]Immunology and Oncology Lab - Center for Neurosciences and Cell Biology, Univ Coimbra, Coimbra, Portugal.

Bladder cancer (BC) is characterized by an aggressive phenotype with high propensity for recurrence and/or metastasis, probably related with the presence of Cancer Stem Cells (CSC). Natural Killer (NK) cells are lymphocytes able to kill a wide range of cancer cells due to its powerful cytolytic activity, being considered suitable candidates for adoptive immunotherapy.
We aim to explore the role of BC-CSC in the susceptibility to NK cell mediated-based immunotherapy.
Two human BC cell lines (HT-1376 and UM-UC3) were assayed for their susceptibility to NK cells-induced lysis, using the CD107a-based degranulation assay. The presence of CSC was analyzed using the sphere-forming assay. Cells' chemosensitivity cisplatin (CIS) and methotrexate (MTX) was determined using the MTT-colorimetric assay.
A subset of CSCs was identified in the HT-1376 cell line. Surface expression of CD107a in NK cells increased significantly ($p<0.05$) compared to the baseline activity (17.44±2.17%) when exposed to UM-UC3 cells (59.51±8.17%) and the sphere forming HT-1376 cells (43.81±8.65%). MTT results showed that HT-1376 cells are more resistant to CIS and MTX than the UM-UC3 cells. Drugs concentration required to inhibit cell viability in 50% (IC50) for HT-1376 cells was of 7.45±1.20µM (CIS) and 0.18±0.03µM (MTX), significantly higher ($p<0.05$) as compared with the UM-UC3 cell line (CIS:IC50=3.98±0.70µM; MTX:IC50=0.04±0.01µM).
The sphere-forming HT-1376 cells are more chemoresistant than the UM-UC3 cells, probably due to the presence of CSC. Both BC cell lines are susceptible to NK cell-mediated cytotoxicity, independently of the presence of CSC.

P6.06.052

A Dendritic Cell (DC) microRNA signature predicts clinical outcome in Melanoma Patients treated with DC vaccine

L. Fiammenghi[1]*, E. Bandini*[2]*, F. Fanini*[1]*, M. Petrini*[1]*, E. Pancisi*[1]*, A. M. Granato*[1]*, V. Ancarani*[1]*, L. Ridolfi*[1]*, M. Guidoboni*[1]*, M. Fabbri*[3,4]*;*
[1]IRCCS-IRST, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori, Meldola, Italy, [2]Istituto Oncologico Romagnolo Coop. Soc. ONLUS, Forlì, Italy, [3]IRCCS-IRST, Meldola, Italy, [4]Department of Molecular Microbiology and Immunology, Keck School of Medicine, Norris Comprehensive Cancer Center, University of Southern California, CA, United States.

Background: MicroRNAs (miRNAs) are short non-coding RNAs with gene regulatory functions, whose expression is de-regulated in melanoma. It has been reported that patients treated with DC vaccine have a better clinical outcome and a longer overall survival if positive to the delayed-type hypersensitivity (DTH) cutaneous test. The present preliminary study aims to observe whether a different expression of miRNAs occurs in iDC and mDC of metastatic melanoma patients, and whether this expression correlates with the response to treatment, evaluated by the DTH test.
Methods: iDC and mDC were collected from 10 patients. DC maturation was obtained with a standard cocktail of cytokines (PGE2, IL-6, TNFa, IL-1b). Total RNA was extracted and hybridized with the 4.0 version of the non-coding RNA array developed at the Ohio State University, which is able to determine the expression of 476 different human miRNAs.
Results: We identified a signature of 24 de-regulated miRNAs (10 down- and 14 up-regulated) in iDC of DTH-positive patients (better prognosis) versus DTH-negative patients (worse prognosis), and a signature of 31 de-regulated miRNAs (9 down- and 22 up-regulated) in mDC of DTH-positive versus DTH-negative patients. Interestingly, 5 miRNAs (miR-182, miR-150, miR-330-5p, miR-548-3p, miR-556-3p) were common to the two signatures.
Conclusions: Our study indicates that miRNome aberrations at the DC level may account for a different response to treatment, and that miRNA expression in iDC and mDC can suggest which patients will benefit of a DC vaccination.

P6.06.053

Anti folate receptor Ab conjugated iron-oxide nanoparticles for tumor localization in an ovarian cancer models

M. Figini*;*
Fondazione IRCCS Istituto Nazionale dei Tumori, Milano, Italy.

The European project Magnifyco aimed at producing multifunctional magnetic nanoparticles (MNP) to perform antitumor therapy with focal hyperthermia and controlled drug release. MNP were functionalized with human Fab recognizing folate receptor α (FRα) that is overexpressed in ovarian carcinoma. MNP-Fab were used for *in vivo* studies in two different mouse models. Mice were either inoculated subcutaneously with FRα+/- cells and MNP given intravenously or, in order to allow ascites formation and better mimic the human disease, injected intra-peritoneum (IP) with OVCAR3 cells followed by IP administration of MNP. Accumulation of MNP was assessed by using analysis of elemental iron. The first *in vivo* model verified the specific localization of MNP-Fab to the FRα-positive tumor, indicating that functionalized MNP may reach and penetrate tumor mass. Likewise, in IP model, the MNP-Fab , but not the control, specifically localized in tumor cells and in regions usually infiltrated by the tumor, such as mesenteric tissue and the genito-urinary tract. The iron levels increased over time in target organs and tumor cells while a lower iron amount was concomitantly detected in the ascitic fluid, suggesting that, from the peritoneal fluid, targeted MNP were selectively uptaken by FRα+ cells and maintained inside the target. Our experiments are a proof of principle of the MNP-Fab ability to target specifically FRα positive cells *in vivo*. Since MNP are superparamagnetic and retain heat-generation capability, we may possibly design and study a system capable of releasing drugs *in situ* by increasing temperature after magnetic field application.

Combining prime-boost anti-tumour vaccination with debulking surgery for the treatment of solid tumours

S. A. Fisher*, A. Cleaver, A. Khong, T. Connor, B. Wylie, D. Lakhiani, C. Boylen, B. W. S. Robinson, R. A. Lake;*
University of Western Australia, Perth, Australia.

The development of effective anti-cancer immunotherapies is of critical importance. While many anti-cancer immunotherapies have had limited success as monotherapies, their efficacy may be enhanced when combined with conventional therapies such as surgery or chemotherapy. Here we describe the development of a prime-boost (P/B) anti-tumour vaccination protocol that significantly improved survival outcome when combined with partial debulking surgery and targeted suppression of regulatory T cells (Treg).
Using our well established AB1-HA mouse tumour model, tumour bearing mice received prime (influenza A PR/8/34/H1N1; PR8) and boost (HA expressing recombinant modified Vaccinia Ankara; rMVAHA) vaccinations either before (neoadjuvant) or after (adjuvant) 75% debulking surgery. Only neoadjuvant P/B vaccination induced tumourspecific immunity that resulted in significantly delayed tumour growth when combined with debulking surgery; although this was not sufficient to prevent tumour outgrowth. Depletion studies demonstrated that CD8 T cells were essential for the delay in tumour growth. Interestingly, depletion of CD4 T cells and more specifically Treg during neoadjuvant P/B vaccination lead to cures in greater than 60% of treated mice. These surviving mice also resisted tumour rechallenged indicating the establishment of long term anti-tumour immunological memory.
Taken together, these data suggest that vaccine induced anti-tumuor immunity is "restrained" by Treg and can be enhanced by the targeted removal of Treg. Based on these findings we are actively

investigating whether combining novel immunotherapies with conventional treatments in the absence of "immunological restrainers" such as Treg and myeloid derived suppressor cells (MDSC) may generate effective therapy for MM and other solid cancers.

Anti-PSMA scFv as theranostic tool for prostate cancer

B. Frigerio[1], *E. Luison*[1], *A. Satta*[1], *D. Bernareggi*[1], *F. Caroli*[1], *E. Bombardieri*[1], *G. Fracasso*[2], *S. Canevari*[1], *M. Figini*[1];
[1]*Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy,*
[2]*University of Verona, Verona, Italy.*

Prostate carcinoma (PCa) is the most common malignant tumor diagnosed in men and the second leading cause of cancer related mortality. As a result of the limited efficacy of conventional treatments for advanced PCa, other strategies are needed. Antibody-based reagents represent a promising approach to provide the clinic with potentially effective diagnostic and therapeutic tools. To date, the most extensively tumor associate antigen studied for PCa immunotherapy is the Prostate-Specific Membrane Antigen (PSMA). PSMA expression and enzymatic activity are increased in PCa and are also correlated with aggressive disease.
The D2B monoclonal antibody directed against h-PSMA extracellular domain was produced by hybridoma technology. Preliminary diagnostic specificity of the IgGD2B has been investigated in xenograft murine models by imaging. Overall, the low penetration rate from vasculature into solid tumor mass and their prolonged residence in circulation limit the application of whole antibody for imaging or radio immunotherapy.
For these reasons we re-shaped the IgGD2B into scFv format. Due to its smaller size, scFv represents the ideal candidate as diagnostic reagent because shows a faster blood clearance and a better penetrability in the tissue. ScFvD2B functionality was successfully tested on PC3 cell line expressing h-PSMA and BIAcore showed that the antibody fragment retains a good strength of binding despite its monovalent binding.
For the potential use of scFvD2B for radioimaging we have firstly set the radiolabelling procedure with ^{131}I and then we have performed the pre-clinical studies in animals bearing tumors expressing or non expressing PSMA with conventional radio localization experiments.

P6.06.056
Generation of EBV/CMV bi-specific T cells using retroviral T cell receptor (TCR) gene transduction for adoptive immunotherapy

A. Z. Gad, *X. Liang, A. Moosmann;*
Clinical Cooperation Group Immunooncology, Helmholtz Zentrum München, and Klinikum der Universität München, Munich, Germany.

Immunocompromised patients after allogeneic haematopoietic stem cell transplantation are prone to reactivation of latent CMV infection, resulting in pathogenesis, because they lack CMV-specific T cells. This complication is particularly frequent when CMV-positive patients receive transplants from CMV-negative donors. Transfer of CMV-specific T cells can control viral reactivation, however CMV-specific T cells usually cannot be isolated from a CMV-negative donor. Alternatively, TCR gene transfer can be performed to generate CMV-specific T cells. Previously, polyclonal T cell populations with irrelevant specificities were used for this approach. As the majority of donors are EBV-positive, gene transfer of CMV-specific TCRs into EBV-specific T cells promises to be a reliable improvement. Hypothetically, the adoptive transfer of CMV/EBV bi-specific T cells has several advantages. The risk of stimulating alloreactive TCRs co-expressed with the CMV TCR in the same cell is reduced. Moreover, EBV/CMV bispecificity will limit the probability of TCR mispairing to two possibilities that can be analyzed for alloreactivity. Furthermore, activation of bi-specific cells by either pathogen will sustain these cells and thus maintain immunity against both pathogens. We compared different methods to generate CMV/EBV bi-specific T cells, with a view to minimize generation time and the number of required technical steps. T cells specific for different lytic and latent EBV antigens were enriched according to different protocols and transduced at different time points in order to optimize bi-specific TCR expression. Transduced cells were stimulated and thus selectively expanded using B cells presenting CMV antigens. Functional analyses of the cellular products are ongoing.

P6.06.057
Sub-lethal irradiation of human colorectal carcinoma cells imparts enhanced and sustained expression of important modulators of effector CTL activity

C. Garnett-Benson, *A. Kumari;*
Georgia State University, Atlanta, GA, United States.

Sub-lethal doses of radiation can alter the phenotype of target tissue by modulating gene products that may make tumor cells more susceptible to T-cell-mediated immune attack. Previously, we demonstrated that colorectal cancer lines responded to radiation by up-regulating surface expression of CTL relevant proteins including numerous death receptors, cell adhesion molecules and tumor-associated antigens. The present study was designed to determine the extent of CTL relevant changes induced by radiation in human carcinoma cells. Here, several tumor cell lines (SW620, HCT116, Caco-2, Colo205 and WiDr) were examined for their response to various sub-lethal doses of radiation (0-10 Gy). Experiments quantified changes in the expression of genes that could result in enhanced effector CTL activity (OX40L, 41BBL, ICOSL and CD70) against irradiated tumor cells. One to 7 d post-irradiation, changes in expression of effector costimulatory molecules was examined. All cell lines altered expression of one or more of these molecules post-irradiation. Increased expression could be observed as long as 7-days post-irradiation. In some tumor cell lines, altered expression of these gene products correlated with enhanced killing of irradiated tumor cells by both TAA-specific CTLs in an in vitro cytotoxicity assay. This lysis was reversed by gene-knockdown. Furthermore we saw enhanced activation and survival of CTLs exposed to irradiated tumor cells. Overall, the results of this study suggest that non-lethal doses of radiation can be used to make human tumors more amenable to immune system attack even in the absence of innate immune response to 'danger' from dying cells.

P6.06.058
Differential regulation of B-cell proliferation by IL21 in different subsets of chronic lymphocytic leukemia

G. Ghalamfarsa[1], *F. Jadidi-Niaragh*[1], *M. Hojjat-Farsangi*[1,2], *M. Yousefi*[1], *S. Razavi*[3], *A. Saboor-Yaraghi*[4], *H. Rabbani*[5], *M. Jeddi-Tehrani*[5], *F. Shokri*[1];
[1]*Department of Immunology, School of Public Health, Tehran University of Medical Sciences, Tehran, Iran,* [2]*Immune and Gene Therapy Lab, Cancer Center Karolinska, Karolinska Hospital, Stockholm, Sweden,* [3]*Clinic of Hematology and Oncology, Firozgar Hospital, Faculty of Medicine, Tehran University of Medical Sciences, Tehran, Iran,* [4]*Department of Nutrition, School of Public Health, Tehran University of Medical Sciences, Tehran, Iran,* [5]*Monoclonal Antibody Research Center, Avicenna Research Institute, ACECR, Tehran, Iran.*

Interleukin-21 (IL-21) plays an important role in B-cell proliferation, survival and differentiation. Contrary to its stimulatory effect in normal B cells, it has been shown to induce proapoptotic effect in leukemic B cells from CLL patients. Little is known regarding the biological function of IL-21 in leukemic B cells from progressive and non-progressive CLL patients. In the present study, the proliferative effect of IL-21 in combination with TLR9 agonist (CpG) was investigated in B cells isolated from 24 CLL patients and 8 normal subjects by radioactive thymidine incorporation assay. Patients were broadly classified into either progressive (n=6) or non-progressive (n=18) and immunoglobulin heavy chain variable region (IGHV) gene mutated (n=16) or unmutated (n=8) subtypes. B cells were enriched from peripheral blood mononuclear cells by negative selection using magnetic beads (MACS) and immunophenotyped by flow cytometry. Our results showed that IL-21 enhanced the proliferative effects of CpG in both normal and leukemic B cells, though no significant differences were observed between CLL patients and healthy controls. Comparison between different subsets of patients revealed that while the combination of IL-21 and CpG significantly inhibited the proliferation of B cells from progressive compared to non-progressive

patients (p=0.001), it enhanced proliferation of leukemic B cells from IGHV mutated compared to unmutated patients (p=0.001). Our findings suggest differential effects of IL-21 in different subsets of CLL patients and suggest its potential therapeutic implication in patients with a more progressive disease.

Lysis-on-chip of single cells after programmed interaction with cytotoxic T-lymphocytes (CTLs) or natural killer (NK) cells on a dielectrophoresis (DEP) based array

*M. Abonnenc[1], M. Borgatti[2], F. Destro[3], N. Manaresi[1], G. Medoro[1], E. Lo Monaco[4], **P. Giacomini**[4], R. Guerrieri[5], R. Gambari[6];*
[1]Silicon Biosystems, Bologna, Italy, [2]Biotechnology Center, University of Ferrara, Ferrara, Italy, [3]Department of Biochemistry and Molecular Biology, University of Ferrara, Ferrara, Italy, [4]National Cancer Institute Regina Elena, Rome, Italy, [5]ARCES, Bologna, Italy, [6]Biotechnology Center, University of Ferrara, Rome, Italy.

Guiding single cells acting as partners in heterotypic interactions (e.g. effectors and targets of immune lysis), and monitoring the outcome of these interactions may be regarded as crucial bio-medical achievements. Using a dielectrophoresis (DEP)-based Lab-on-a-chip platform (the DEP array) we generated closed DEP cages entrapping cytotoxic T lymphocytes (CTLs) and natural killer (NK) cells as either single cells or clusters. A single virus-presenting or tumor cell can be reversibly immobilized within the chip at a pre-determined position. Cages and their content are moved to pre-determined spatial coordinates by software-guided routing, and a cytotoxic effector is forced to physically interact with a putative target within a secluded area by merging their respective cages. Alternatively, cages can be generated containing effector and target cells at pre-determined effector:target ratios. Cytotoxicity is accurately assessed by real-time quantitation of the release kinetics of the fluorescent dye calcein from single target cells. More than 50 lytic events may be simultaneously tested, and assay endpoint is reached within 16 minutes of initial effector:target cell contact. These observations provide the proof of principle that antibody-based phenotyping and on-chip lysis can be simultaneously assessed, that lytic and non-lytic effector:target combinations can be discriminated on the single-cell level, and that non-lytic effector phenotypes can be resolved from target refractoriness to immune lysis. Thus, highly cytotoxic, virus-specific CTL clones, as well as tumor cells resistant to NK cell lysis can now be directly identified. These features are of primary interest in targeted immunotherapy. Supported by EU FP6 COCHISE and AIRC.

P6.06.060
Anticancerogenic and immunotropic properties of GA-40 preparation

***A. Giorgi**;*
St. Andrews Georgian University, Tbilisi, Georgia.

The nontoxic natural substance with antitumor and immunotropic properties GA-40 preparation has been derived from Georgian endemic medical plant. GA-40 is a standardized polypeptide complex. Preclinical and clinical tests have shown that GA-40 possesses anticarcinogenic and immunotropic properties. It shows direct necrotic action on malignant tumor cells by stimulating apoptosis. GA-40 has no negative effect in the normal cells. GA-40 has direct action on human myeloleukemic cells; it stimulates transformation of myeloleukemic cells into a normal cell. GA-40 stimulates expression of CD11b antigens on the surface of a leukemia cell (HL-60 strain). GA-40 causes activation of immune status of the organism and restores the quantitative distribution of T and B lymphocytes, T-helper, T-cytotoxic, T-killers cells, macrophages and granulocytes. GA-40 causes activation of mononuclear cells and stimulates production of cytokines, Tumor Necrosis Factor-α and Interferon-γ). GA-40 provides normalization of the blood biochemical indicators. GA-40 has positive influence on the dynamic of carcinoembryonic antigens, alphafetoprotein and prostate-specific antigen; it inhibits the development of tumor cells growth and stimulates regression of the metastases.

P6.06.061
Chronic exhaustion of tumor-specific CD4+ T cells leads to recurrence of melanoma.

***S. R. Goding**, K. A. Wilson, K. M. Harris, P. A. Antony;*
University of Maryland, Baltimore, MD, United States.

Although many strides have been made in treating primary tumor occurrence, treatment of cancer recurrence has remained elusive. We developed a B16 melanoma mouse model in which ~50% of mice receiving adoptive cellular therapy (i.e. cytolytic CD4+ T cells recognizing the tumor/self antigen, TRP-1) demonstrate tumor relapse following initial tumor regressions. Upon analysis of TRP-1-specific CD4+ T cells from mice with relapsing tumors, levels of the exhaustion markers, PD-1, LAG-3, Tim3 and TIGIT were markedly increased, compared to CD4+ T cells from naïve and cured mice. The numbers of TRP-1-specific Foxp3+ CD4+ regulatory T (Treg) cells (comprising 5-15% of the original CD4+ T cell pool at the time of transfer) were also elevated in tumor relapse mice. By taking advantage of the diphtheria toxin receptor (DTR) expressed on these Foxp3+ Treg cells, it was evident that Treg cell ablation, with DT injection, was not sufficient in treating tumor recurrence. In addition, targeting exhaustion pathways, i.e. with anti-PD-L1 (the ligand for PD-1) or anti-LAG3 antibodies, provided no therapeutic benefit against the recurring tumor. However, when single modality therapies were combined, i.e. Treg depletion/anti-PD-L1 or anti-LAG-3/anti-PD-L1, relapsing tumors regressed. The regression of advanced-stage recurrent tumors through dual therapy resulted from decreases in PD-1, LAG-3, Tim3 and TIGIT, and increases in IL-7Rα expression and dual production of IFNγ/TNFα, in TRP-1-specific CD4+ T cells compared to cells from monotherapy- and non-treated mice. Taken together, these data clearly illustrate the reinvigoration of exhausted tumor-antigen-specific CD4+ T cells in the setting of recurring B16 melanoma treatment.

P6.06.062
Effect of polychemotherapy on leukocytes under acute lymphoblast leukosis in children

*O. V. Lebedinskaya, N. B. Merzlova, **A. P. Godovalov**, I. A. Baranova, A. V. Proskuryakov;*
Acad. E.A. Wagner Perm State Medical Academy, Perm, Russian Federation.

The aim of investigation was the search for toxicity criteria of cytotoxic preparations while using the analysis of blood values' dynamics following the chemotherapy with cytostatics' inclusion.
The analysis of hematological parameters was carried out in 24 patients at different terms of treatment during the chemotherapy according to AII-MB-2005 protocol.
On completion the first course of treatment the sharp decrease in leukocyte number as observed in a day that corresponds to 2-grade hematotoxicity according to WHO's classification.
Thereafter, the parameter elevation was detected that retained to the end of first therapy cycle. During the treatment it was found that the increment in neutrophil content was realized at the expense of the increase in the number of their mature forms. The initial level of peripheral blood blast cells comprised 25% prior to therapy, 7% (3rd day), and 1% (8th day), then all of patients demonstrated 0% that maintained further. Meanwhile the efficient bone marrow hemopoiesis suppression occurred as well. Given that 4% is a standard value and initial background is 89% in average, the amount of bone marrow blast forms was retained at 1,7% level for the 36 days of therapy. All the patients examined after the first course of polychemotherapy (induction of remission) demonstrated the state of hematological remission.
Thus, the suppression of bone marrow hemopoiesis under cytostatic therapy according to AII-MB-2005 protocol is not excessive and is maintained at the level that allows achieving remission.
This work was supported by RFBR grant №11-04-96037r_ural_a and administrative body of Perm Region.

Identification and validation of hypoxia-specific tumor associated antigens in prostate cancer

*T. Ma[1], A. Elkhattouti[1], S. Vuk-Pavlović[2], **C. R. Gomez**[1];*
[1]University of Mississippi Medical Center, Jackson, MS, United States, [2]Mayo Clinic, Rochester, MN, United States.

Prostate cancer (CaP) is characterized by unique prostate–associated antigens; hence, it has been considered a prime candidate for immunotherapy. Despite numerous laboratory advances, clinical outcomes have been partial and transient. The overall goal of this study is to optimize the effectiveness of therapeutic whole–cell CaP vaccines by taking into consideration tumor–associated hypoxia as a relevant determinant of tumor antigenicity. We propagated CaP cells at pO_2 = 2 kPa and 20 kPa. To identify potential tumor-associated antigens (TAAs), we prepared CaP cell lysates, resolved them by 2D electrophoresis and immunoblotting using spontaneous antibodies from plasma derived from CaP patients and control subjects. Antibody-labeled spots were analyzed by MALDI-TOF mass spectrometry and validated by ELISA. Three potential TAAs; two hypoxia-specific (HSP70 and hnRNP L) and one hypoxia-nonspecific (HSP60) were selected for validation. The frequency of HSP60 autoantibodies was elevated in the CaP patient plasma; however the frequency of HSP70 autoantibodies was not elevated in CaP patients relative to healthy controls; even more, higher autoantibodies frequencies were found in other tumors and in rheumatoid arthritis. Protein expression for hnRNP L (detected by Western Blot technique) was elevated in CaP tissue. Our results suggest the value of selected candidates (i.e. HSP60 and hnRNP L) as potential TAAs and immunotherapeutic targets for CaP. Additionally, their overexpression in tumors suggests their role in tumor growth and progression. Hypoxia may be used as a tool in the development of cellular vaccines and to identify novel diagnostic and prognostic tools for CaP.

A melanoma cell lysate induces CCR7 expression on human dendritic cells and its in vivo migration to draining lymph nodes

***F. González**[1,2];*
[1]Universidad de Chile, Santiago, Chile, [2]Karolinska Institute, Stockholm, Sweden.

Recently, we developed an original method for production of therapeutic dendritic-like cells named Tumor Antigen Presenting Cells (TAPCells) using an allogeneic melanoma-derived cell lysate (TRIMEL) as activation factor and antigen provider. TAPCells-based immunotherapy induced T cell-mediated immune responses and improved long-term survival of stage IV patients in studies involving more than one hundred individuals. Dendritic cell (DC) migration from the injected site to the lymph nodes is an important requirement for an effective antitumor immunization. Herein, we investigated if the TRIMEL was capable to induce the expression of the C-C chemokine receptor type 7 (CCR7) on human therapeutic DCs and enhance their migration to the lymph nodes in an animal model. Our results confirmed that TRIMEL induced the maturation and increased expression of surface CCR7 on the monocytic/macrophagic line THP-1 and also on TAPCells derived from melanoma patients. Moreover, in vitro assays showed that TRIMEL stimulated THP-1 cells and patients derived TAPCells were capable to specifically migrate in the presence of CCL19. Finally, we demonstrated by flow cytometry and immunohistochemical methods that TAPCells could migrate in vivo from the injection site into draining lymph nodes in an ectopic xenograft mouse model. This work contributes to understand the biology of ex vivo produced DCs allowing the study of new strategies for a more effective DC-based vaccine design.

Low-dose conventional chemotherapeutics synergizes with dendritic cell - based immunotherapy in antitumor activity

***A. I. Gorbach**[1], N. M. Khranovska[2], V. K. Pozur[1], O. V. Skachkova[2], N. M. Svergun[2], R. I. Sydor[1], V. V. Nikulina[1];*
[1]Kyiv National Taras Shevchenko University, Kyiv, Ukraine, [2]National Cancer Institute of Ukraine, Kyiv, Ukraine.

Background. The benefit of combining low-dose chemotherapeutics with cancer vaccine therapy has not been established. Here we investigated the antitumor effect of conventional chemotherapeutics cyclophosphamide (CP) or doxorubicin (DOX), or cisplatin (CIS) in combination with DC-based immunotherapy in murine tumor models. Methods. Studies have been performed with 100 C57Bl/6 and 213 CBA mice with lethal dose of Lewis lung carcinoma (LLC) or sarcoma 37 (S37) respectively. DCs loaded with mechanoactivated lyophilized tumor cells have been used as immunotherapy agent. DCs were administered i/v three times with two-day interval. Low-dose chemotherapeutics were administered in “metronomic” regimen before DC-immunotherapy. Results. Addition of CP improved DC-immunotherapy leading to a significant decrease in the number and volume of metastases in lungs. Combination of DC-immunotherapy with DOX or CIS significantly improved median survival time of animals with S37 in comparison with control group. Metronomic chemotherapy resulted in a significant reduction in the proportions of T-reg cells and mRNA levels of immunosuppressive cytokines in the peripheral blood and lymph nodes lymphocytes. Addition of chemotherapeutics to DC-immunotherapy also augments Th-1 immune response, increases number of activated CD69+, CD54+, CD25+ splenocytes, enhance spleen macrophages phagocyte activity and reactive oxygen species (ROS) production, cytotoxic activity of NK-cells and CTL ($p<0,05$). Antitumor effectiveness of DC-immunotherapy combined with low-dose chemotherapeutics are associated with significant decrease in mRNA levels of TGF-β, VEGF, IL-10 in the residual tumor sites. Conclusions. Low-dose chemotherapeutics enhance the antitumor effect of DC-based immunotherapy. These findings form the basis to a new multimodality treatment in cancer patients.

P6.06.066
Targeting effector CD8 T cells to the tumor using high dose radiation therapy in mice

***M. Gough**[1], K. Young[2], B. Cottam[1], T. Savage[1], P. Newell[1,3], K. Bahjat[1], M. Crittenden[1,3];*
[1]Earle A Chiles Research Institute, Portland, OR, United States, [2]Oregon Health and Sciences University, Portland, OR, United States, [3]The Oregon Clinic, Portland, OR, United States.

Adoptive transfer of T cells and tumor-targeted vaccine therapies are effective means to introduce tumor antigen-specific cells into tumor-bearing hosts. However, tumor-specific T cells have a limited ability to traffic to and function in tumors due to the suppressive tumor immune environment. We hypothesize that radiation therapy provides both a means to prime tumor-specific T cell responses through release of tumor antigens and adjuvants, and a means to target these T cells to the tumor environment. To test this hypothesis, we treat transplantable and spontaneous tumors in immunocompetent mice with targeted radiation, using both clinical linear accelerators and an advanced treatment platform to deliver conformal radiation to tumors in mice. We demonstrate that high dose radiation therapy can be targeted to tumors in mice and can change the immune and inflammatory environment of tumors. Radiation therapy results in production of inflammatory chemokines and recruitment of activated T cells to the treatment site. We demonstrate that the efficacy of radiation depends in part on these T cells, and that immunotherapy to increase T cell activity improves tumor control by radiation therapy. These studies demonstrate that radiation therapy synergizes with immunotherapy, acting to both prime and target effector cells to control residual cancer cells.

P6.06.067
Vaccination with autologous glioma lysate induces tumor-reactive IgG antibody response and increases survival in dogs with glioma

M. R. Goulart[1]*, B. M. Andersen*[2]*, C. E. Seiler*[1]*, M. A. Hunt*[2]*, M. G. O'Sullivan*[1]*, C. Johnson*[1]*, Z. Zhang*[2]*, J. R. Ohlfest*[2]*, G. E. Pluhar*[1]*;*
[1]University of Minnesota, St. Paul, MN, United States, [2]University of Minnesota, Minneapolis, MN, United States.

Gliomas are invasive primary brain tumors for which there is currently no cure or very effective therapy. In spite of widespread and intensive ongoing investigations for improved glioma treatments, there is disappointingly little progress in translational medicine. Pet dogs can serve as an outstanding comparative animal model for study of novel therapies because they develop spontaneous brain tumors that faithfully recapitulate human disease.
We have undertaken a clinical trial using immunotherapy with autologous glioma cell lysate vaccines, combined with the TLR9 agonist (CpG oligodeoxynucleotides) to treat canine patients with glioma. The objective of this trial is to induce specific anti-tumor immunity directed at residual tumor and to reduce recurrent tumor after resection. Treatment groups consist of surgery and vaccination with or without gene therapy (intracranial injection of ad-INF-γ vector). Dogs treated with palliative therapy alone (historical controls) or with surgery and chemotherapy (temozolomide) served as control groups. No severe toxicities have been observed, validating the safety of the treatment. Our preliminary results demonstrate the ability of this vaccine to activate specific humoral antitumor responses with concurrent extension of survival times in the treated dogs compared to controls. Tumor-reactive IgG antibody responses were detected post vaccination in all dogs.
Examination of immune responses in therapeutic trials of dogs with glioma can greatly aid in predicting outcomes of similar treatments in humans. Data from these trials also provide an opportunity to accelerate the development of more efficient immunotherapeutic strategies for treatment of intracranial malignances.

P6.06.068
"First AID" for T cell adoptive transfer: TCR affinity maturation by somatic hypermutation.

Y. M. Gozlan*, E. Tzehoval, L. Eisenbach;*
Weizmann Institute of Science, Rehovot, Israel.

Adoptive cell transfer of tumor specific T lymphocytes, was shown to mediate objective cancer regression of metastatic melanoma. Effective T cell activation depends, among other factors, on the functional avidity of the peptide-MHC complex to the T cell receptor (TCR), i.e. on the affinity and the number of pMHC-TCR contacts. Since the T cell repertoire is controlled by negative and positive selection in the thymus, naturally occurring TCRs have mostly low affinities. Moreover, unlike antibodies whose affinities improve over time by somatic hypermutation (SHM), TCR do not undergo SHM. In our research we developed a system that can increase the affinity of a TCR to its ligand by subjecting TCR genes to SHM, directed by the mutator enzyme Activation Induced cytidine Deaminase (AID). Affinity maturation reactions are performed in easy transfectable cells and affinity maturated TCRs are selected by tetramer staining followed by FACS sorting. The affinity maturation system is designed to be modular so the maturation can be done in several cycles in order to optimize TCR affinity. The affinity maturated TCRs are used to create anti-tumor reactive T cells by means of gene transfer into naïve lymphocytes. These transformed T cells are then functionally tested in-vitro and in-vivo with murine melanoma models. Using this system we are trying to define the parameters that govern the changes in affinity as well as the biological consequences of these changes. Such systems can potentially be used to augment T cell responses to Tumor Associated Antigen peptides, for the treatment of cancer.

P6.06.069
HPV-derived T-helper epitopes for therapeutic HPV vaccine design

A. K. Grabowska*, S. Hoppe, R. Blatnik, A. B. Riemer;*
German Cancer Research Center (DKFZ), Heidelberg, Germany.

Persistent infection with high-risk types of human papillomavirus (HPV) can lead to malignant transformation and the development of various human malignancies, such as cervical cancer. Fortunately, most HPV infections are successfully eradicated by the immune system. Accumulating data show that both cytotoxic T cell and T helper cell responses play a pivotal role in the clearance of HPV infection. To date, therapeutic HPV vaccines have mostly been developed to elicit tumor-specific CTL responses. The exclusive targeting of HLA class I-restricted HPV epitopes might be insufficient, as HLA class I surface expression can be reduced as a result of HPV immune evasion strategies. In contrast, HLA class II molecules are expressed in high-grade cervical lesions and cervical cancer. Therefore in this study, with the help of immune-bioinformatic approaches, we aim to identify novel E2-, E5-, E6- and E7-derived CD4+ T cell epitopes that bind to multiple HLA-DR alleles, are naturally processed and presented, and immunogenic. Promiscuous 15-mer candidate epitopes from HPV16 E2, E5, E6 and E7 proteins were analysed in silico for their affinity to bind seven different HLA-DR molecules. Candidate peptides were evaluated in vitro for their immunogenicity in a panel of immunoassays. T cells isolated from the majority of healthy donors responded to at least one of these HPV-derived peptides. We conclude that the identified CD4+ T-helper epitopes most likely represent a memory response that correlated with viral clearance in healthy donors. They could complement the development of epitope-specific HPV immunotherapy approaches.

P6.06.070
CpG-activated pDCs contribute as APCs in the generation of Th17 cells that control tumor growth

L. Guery*, J. Dubrot, C. Lippens, D. Brighouse, M. Irla, W. Reith, J. Waldburger, S. Hugues;*
department of pathology and immunology, Geneva, Switzerland.

Plasmacytoid dendritic cells (pDCs) rapidly and massively produce type I interferon and other inflammatory cytokines in response to foreign nucleic acids. Consequently, pDCs indirectly influence adaptive T cell responses by modulating the immune functions of other professional antigen (Ag) presenting cells (APCs). In addition, pDCs can present Ag to naïve T cells and directly regulate T cell differentiation. Depending on the immune environment, pDCs exhibit either tolerogenic or immunogenic properties. Here we show that CpG-activated pDCs promote efficient Th17 differentiation in vivo. Th17 responses are impaired in mice selectively lacking MHCII on pDCs upon antigenic challenge. Furthermore, TLR-triggered production of inflammatory cytokines is not altered in MHCII deficient pDCs, demonstrating that MHCII sufficient pDCs function as APCs and directly modulate T cell outcome. Importantly, upon vaccination with tumor Ag in the presence of CpG, the absence of MHCII expression by pDCs leads to impaired number of tumor infiltrating TH17 cells, and consequently, increased tumor growth. Our results highlight a new role for tumor Ag presentation by CpG-activated pDCs to CD4+ T cells in inducing potent anti-tumor Th17 cells, and suggest that pDCs could be used not only as inflammatory cytokines producers, but also as efficient APCs, to improve tumor vaccine efficacy.

Role of B cells in anti-tumour immunity

T. V. Guy[1], *A. J. Buckley*[1], *J. Holst*[1], *R. Brink*[2], *B. Fazekas de St Groth*[1], *E. Shklovskaya*[1];
[1]*Centenary Institute, Sydney, Australia,* [2]*Garvan Institute of Medical Research, Sydney, Australia.*

The role of B cells in anti-tumour immunity remains controversial, with positive and negative effects reported in animal models. In humans, B cell infiltration of tumour samples correlates with a better prognosis in some cancers.
We have developed a transgenic animal model to study the interaction of naïve tumour-specific B cells and CD4 T cells during an anti-tumour response. The model utilises B16.F10 melanoma cells engineered to express the model antigen Hen Egg Lysozyme-Moth Cytochrome C (B16.HELMCC), together with MCC-specific TCR transgenic CD4 T cells and HEL-specific BCR transgenic B cells. Growth of subcutaneous B16.HELMCC tumours in RAG-/- mice was controlled by adoptive transfer of T and B cells, T cells alone but not B cells alone. Anti-HEL serum IgM, IgG1, IgG2a, IgG2b and IgE were detected in the T+B group, IgM only in the B group and no antibodies in the T group. Anti-HEL IgG1 delivered intraperitoneally protected both RAG-/- and WT mice against tumour growth. Thus in our system, CD4 T cell help allows for the production of protective antibodies with anti-tumour reactivity.
We next assessed the role of naive tumour-specific B cells in T cell priming in RAG-/- hosts in which only transferred B cells expressed cognate MHCII. B cells induced only weak T cell proliferation, whereas strong proliferation was seen when RAG-/- host DCs could present antigen. Thus although B cells with anti-tumour reactivity cannot prime naive CD4 T cells, CD4-B cell interactions during an ongoing anti-tumour response may result in the production of protective antibodies.

P6.06.072
Comparison of monocyte derived dendritic cells versus leukemic blasts derived dendritic cells for immunotherapy of AML

J. Hadjati, *F. Masoumi, M. Nourizadeh, R. Mirzaei;*
Tehran University of medical sciences, Tehran, Iran.

Background: Despite consolidation chemotherapy, relapse occurs in majority of patients with acute myeloid leukemia (AML) due to the presence of minimal residual disease. Dendritic cell (DC) based immunotherapy can help to maintain patients in remission. DCs can be generated from peripheral leukemic blasts (AML-DC) as well as peripheral blood monocytes(mo-DC). The aim of this study was to compare mo-DCs with AML-DCs in terms of maturation and functional properties.
Methods: Isolated blasts from 15 AML patients and monocytes from 20 healthy donors were differentiated into DCs in the presence of rhGM-CSF and rhIL-4. Different TLR agonists were used for DC maturation. Generated DCs were compared for efficiency of production, percent of recovery, maturation and functional properties.
Results: Results demonstrated that AML-DCs could be generated from 73% of patients versus 100% of that mo-DCs. Median recovery of mo-DCs was higher compared to AML-DCs. Also Mo-DCs showed higher expressions of surface molecules (HLA-DR, CD40, CD11c, CD83, CCR7 or CD86). However AML-DCs showed lower but reasonable capacity to stimulate allogeneic T cells in vitro as well as higher production of IL-12p70.
Conclusion: Although production of AML-DC is not feasible in all patients, once generated can be used as a proper alternative in immunotherapy of patients in which production of mo-DCs is not possible.

P6.06.073
IMCgp100: a novel bi-specific biologic for the treatment of malignant melanoma

N. J. Hassan[1], *G. Bossi*[1], *K. Adams*[1], *J. Harper*[1], *D. Baker*[1], *N. Steven*[2], *J. Evans*[3], *M. Middleton*[4], *Y. McGrath*[1], *B. Jakobsen*[1];
[1]*Immunocore Ltd, Abingdon, United Kingdom,* [2]*University of Birmingham, Birmingham, United Kingdom,* [3]*Beatson Institute, Glasgow, United Kingdom,* [4]*Churchill Hospital, Oxford, United Kingdom.*

Despite significant advances in the treatment of metastatic melanoma, long-term remission for the majority of patients remains elusive. Kinase inhibitors provide potent but short-term responses for a significant proportion of patients and immunotherapy elicits long-term responses with the prospect of cure, but only in a minority.
IMCgp100 is a novel bi-specific immunotherapy comprising a soluble, affinity enhanced, T cell receptor (TCR) specific for the melanoma-associated antigen gp100, fused to an anti-CD3 specific antibody fragment (scFv). The engineered TCR portion of the drug targets and binds the gp100 peptide 280-288 antigen, which is over-expressed and presented by HLA-A2 on the surface of melanoma cells. The anti-CD3 scFv portion captures and redirects T cells to kill the melanoma cells; normal antigen negative tissues are spared destruction. *In vitro*, IMCgp100 potently redirects T cells from late stage cancer patients to target melanoma tumours exhibiting HLA-down regulation even in the presence of high numbers of regulatory T cells. Target cell killing is observed within hours, and, is associated with the release of pro-inflammatory cytokines and dendritic cell cross-presentation of gp100 and other melanoma-associated antigens. Thus, IMCgp100 demonstrates the potential to elicit potent short term responses and trigger longer-term anti melanoma activity *in vivo*.
IMCgp100 is undergoing Phase I clinical testing in advanced melanoma patients; 22 patients have received single IV infusions so far and 7 patients have subsequently received weekly infusions for 6 weeks. The drug is well tolerated with evidence of T cell mobilisation, specific cytokine release and tumour shrinkage after dosing.

RNActive® technology is a novel vaccination approach using self-adjuvanted mRNA molecules. Pre-clinical experiments showed that intradermal-injection of RNActive® vaccines induces boostable and balanced effector and memory immune responses and provide a strong anti-tumor effect. We already tested CV9201 and CV9103, therapeutic RNActive cancer vaccines for non-small cell lung cancer (NSCLC) and castrate-resistant prostate cancer (PCa) in clinical phase I/IIa trials.
CV9201 is composed of mRNAs coding for NY-ESO-1, MAGE-C1, MAGE-C2, Survivin, 5T4; CV9103 of mRNAs coding for PSA, PSCA, PSMA, STEAP-1. For phase I/IIa trials, blood samples were taken before and after vaccination. Humoral and cellular responses were assessed *ex vivo* by IgG and IgM ELISA, ELISPOT , ICS (IFN-gamma, TNF-alpha,IL-2), tetramer analysis. Phenotyping was performed to identify various lymphocyte subsets.
Immune monitoring of CV9103 demonstrated antigen-specific T- and/or B-cell responses against at least one antigen in 79% of the patients. Importantly, 58% of responders reacted against more than one antigen. In the CV9201 trial, antigen-specific immune responses were detected in 65% of patients, 65% thereof were multiple responders. A significant 2-13 fold shift from naïve B cells to pre-germinal center B cells was detected in 61% of patients. Overall 84% of the treated NSCLC patients had a detectable antigen-specific immune response and/or an increase in germinal center B cells. The

presence of antigen-specific memory B cells was demonstrated with an antigen-specific B cell proliferation assay.
These results suggest that intradermal immunization with self-adjuvanted mRNA vaccines constitutes a highly immunogenic, novel vaccination approach able to induce antigen-specific B-and T-cell responses.

Limitation of systemic exposure to transgenic interleukin-12 upon local treatment with armed oncolytic adenoviruses

M. Bunuales[1], J. Quetglas[1], E. Garcia-Aragoncillo[1], R. Casado[1], S. Bortolanza[1], J. Prieto[2,1], ***R. Hernandez-Alcoceba[1];***
[1]Foundation for Applied Medical Research. CIMA., Pamplona, Spain, [2]CIBERehd. Clinica Universitaria, Pamplona, Spain.

Oncolytic viruses armed with immunostimulatory transgenes are attractive therapeutic agents against cancer. We have developed oncolytic adenoviruses (OAVs) adapted as vectors for interleukin-12 (IL-12). However, high expression of IL-12 mediated by the replicative vector causes severe toxicity in permissive hosts such as Syrian hamsters. With the aim of increasing the therapeutic index of these agents, we have performed modifications in the expression cassette to reduce systemic exposure to the cytokine. Target sequences for microRNA 122 were introduced in the 3'UTR of IL-12 to prevent expression in hepatocytes. In addition, membrane anchoring of IL-12 was attempted by incorporation of the glycosylphosphatidylinositol (GPI)-anchor signal from the folate receptor or a transmembrane (TM) domain from the CD4 protein.
These modifications achieved membrane display of IL-12 in the surface of pancreatic cancer cells and specific inhibition of transgene expression in hepatocytes in vitro. However, only the TM-dependent anchorage was able to reduce the release of IL-12 in the supernatant of cells.
OAVs carrying these constructs were administered locally in different pancreatic cancer models. In hamsters bearing intra-hepatic tumors, the virus carrying the IL12-TM-miR122 cassette were well tolerated and caused lower seric concentrations of IL-12, compared with non-modified IL-12. However, these differences were less pronounced when the viruses were inoculated in orthotopic (intra-pancreatic) tumors. These results suggest that the main mechanism for reducing IL-12 in serum is the miR122-dependent inhibition of transgene expression in hepatocytes.
Therefore, membrane anchoring of IL-12 may be limited by local factors in the tumor microenvironment.

P6.06.076
Isolation of T cell receptors specific for validated cancer epitopes for cancer immunotherapy.

L. Hibbert*, L. U. Wiegand, S. Paston, D. E. Baker, J. D. Dukes, J. V. Harper, G. Bossi, F. H. Grand, T. M. Mahon, B. K. Jakobsen;*
Immunocore Ltd., Abingdon, United Kingdom.

The human immune system can theoretically identify malignant cells by inspecting cell surface Class I HLA -peptide complexes for the presence of disease-associated epitopes. Indeed, many cancer patients generate CD8 cytotoxic T cell responses to tumour-associated antigens; the majority of patients, however, fail to clear tumours since T cell avidity for self-antigens tends to be weak, and cancer cells employ escape mechanisms for avoiding destruction by T cells. To overcome these issues, we have engineered novel, bi-functional protein therapeutics termed ImmTACs (Immune Mobilising mTCR Against Cancer) which re-direct the immune system to target and destroy tumour cells with a high degree of potency and specificity. An ImmTAC comprises a high affinity 'monoclonal' T cell Receptor (mTCR) targeting a cancer-associated HLA-peptide complex, fused to an anti-CD3 scFv domain which activates an anti-tumour T cell response.
We have developed an integrated in-house process leading to the isolation of TCRs specific for validated cancer epitopes forming the starting material for ImmTAC production. The critical steps in this process are: antigen selection, epitope identification, T cell cloning, TCR isolation and binding to soluble peptide:MHC on the BIAcore. We describe each of these areas in more detail and show data to illustrate the successful isolation of a number of TCRs specific for various tumour associated antigens such as prostate and cancer testis antigens leading from this procedure.

Dichloromethane fractions of Scrophularia oxysepala induce apoptosis in MCF-7 human breast cancer cells

B. Hosseini[1]*, B. Baradaran[1], J. Majidiz Zolbanin[1], A. Pasdaran[2], T. Kazemi[1], M. Orangi[1], L. Mohamadnejad[1];*
[1]Immunology Research Center,Tabriz University of Medical Sciences, Tabriz, Iran, [2]Department of Pharmacogenosy ,Faculty of Pharmacy ,Guilan University of Medical sciences, Rasht, Iran.

Background: Breast cancer is the most common malignancy in women, especially in developing countries. It has been observed that some of the plants contain a rich source of anti-cancer drugs ingredients. This paper tends to evaluate the effect of cytotoxic activity of Scrophularia oxysepala fractions, which is located at induction of apoptosis in MCF-7 breast cancer cell line on the breast cancer. Hence, a herbal based treatment for breast cancer is mostly stipulated in this work.
Method: Dichloromethane fractions were examined based on MTT (3-(4,5-dimetylthiazol-2-yl)-2,5-diphenyltetrazolium bromide) and Trypan-blue assays were performed in MCF-7 breast cancer cell line to analyze the cytotoxic activity of the extract of Scrophularia oxysepala. In addition, the apoptosis inducing action of the extract was determined by TUNEL (terminal deoxy transferase (TdT)-mediated dUTP nick- end labeling) test and DNA fragmentation.
Results: The results revealed that the dichloromethane fractions effectively inhibited cell growth and viability in dose (30, 50, 100 , 200, 300 µg/µl) and time (12, 24 and 36 hours) dependent manner, regardless of the inducing damage to non-cancerous cell lines. Furthermore, cell death assay and DNA fragmentation analysis using TUNEL indicated induction of apoptosis by dichloromethane fractions of Scrophularia oxysepala in MCF-7 cell.
Conclusions: The results obtained illustrate for the first time that Scrophularia oxysepala fractions may cause apoptosis in breast cancer. The findings indicate that Scrophularia oxysepala fractions contain potential anti-cancer components inhibiting breast cancer cell proliferation through DNA damage.

P6.06.078
Targeted multivalent scTRAIL fusion proteins for tumor therapy

M. Hutt*, M. Siegemund, O. Seifert, K. Pfizenmaier, R. E. Kontermann;*
University of Stuttgart, Institute of Cell Biology and Immunology, Stuttgart, Germany.

In contrast to other TNF superfamily members, TNF-related apoptosis inducing ligand (TRAIL) shows selective cytotoxicity on tumor cells sparing normal cells and has therefore been extensively investigated for the treatment of cancer. Clinical trials, however, revealed only limited therapeutic efficacy of recombinant soluble TRAIL. Thus, there is need for new formats of TRAIL-based therapeutics with increased activity. Functionality can be improved by targeted delivery to the tumor via fusion to a recombinant antibody. Simultaneously, these fusion proteins mimic, with respect to its activity, the membrane-bound form of TRAIL and thus efficiently activate both death receptors 4 and 5. Especially, formats displaying single-chain versions of TRAIL in a dimeric assembly show increased cytotoxicity. We created two new targeted formats of scTRAIL that force dimerization by either using a bivalent diabody (Db) or via fusion of a single-chain variable fragment (scFv) to a homodimerization domain derived from IgE (IgE heavy chain domain 2, EHD2). We could show that these targeted and dimeric versions of scTRAIL exert improved selectivity towards antigen-expressing tumor cells and enhanced apoptosis induction in vitro and in vivo. These results indicate that Db-scTRAIL and scFv-EHD2-scTRAIL fusion proteins are promising candidates for next generation TRAIL therapeutics showing increased efficacy.

P6.06.079
Long-term CTL induction and therapeutic tumor suppression by antigen- and adjuvant-carrying polymer nanoparticles

P. Ilyinskii, *C. Roy, C. O'Neil, D. Altreuter, K. Kishimoto; Selecta Biosciences, Watertown, MA, United States.*

Encapsulation of a model antigen and a TLR agonist (adjuvant) within a polymer-based nanoparticle (NP) leads to strong and rapid induction of adaptive immune responses. Efficient CTL response is induced after a single inoculation, with an NP-encapsulated antigen being a peptide, several peptides or a protein. Prime immunization followed by a tumor injection and repeated therapeutic immunizations at a tumor-distant site resulted in 100% survival in a mouse model. At the same time, a strictly therapeutic regimen was only weakly protective when NPs were administered at a tumor-distant site with peritumoral delivery being more efficient. An improved manner of antigen formulation within the NP led to augmented survival upon tumor-distant subcutaneous therapeutic immunization with 25-70% animals staying tumor-free for >6 weeks after inoculation with 0.25x106 EG.7-OVA cells. This enhanced survival corresponded to a preferred NP uptake by several classes of APC and to prolonged kinetics of CTL induction with a strong systemic in vivo CTL activity (75-90% specific cytotoxicity) seen up to 21 days after a single NP administration and being still detectable at 31 days. This superior long-term CTL induction was demonstrated by several approaches to persist both locally (draining lymph nodes) and centrally (spleen) and to parallel the induction of cells with T cell effector memory phenotype at the same locations. Similar approach using NPs carrying dominant immunogenic peptides and TLR agonist has shown a protective potential against intravenously delivered B16-F10 melanoma cells.

P6.06.080
Antitumor activity of Her2 liposomes

*M. Yazdani[1], A. Badiee[2], S. Jalali[3], **M. R. Jaafari**[2]; [1]Department of Basic Science, Science and Research Branch, Islamic Azad University, Tehran, Iran, [2]School of Pharmacy, Mashhad University of Medical Sciences, Mashhad, Iran, [3]School of Medicine, Mashhad University of Medical Sciences, Mashhad, Iran.*

The purpose of this study is to determine the potential benefit of liposomes as a delivery vehicle for HER2/neu-derived peptide and it' s adjuvant activity to induce CD_8^+ T cell response. P5 peptide encapsulated in nanoliposome consisting DSPC/DSPG/Chol were prepared as a cancer vaccine. Mice were immunized subcutaneously with peptide encapsulated in nanoliposome. 4 mice per group were sacrificed for immunological assays and 6 mice per group were transplanted subcutaneously with TUBO cell line. ELISPOT and flow cytometric analysis were used for the detection of intracellular cytokines (IFN-γ and IL-4) both in CD_4^+ and CD_8^+ T cells as a means to determine the antigen-specific response. An *in vitro* CTL activity assay was also performed to determine the effectiveness of peptide-liposomal vaccine in stimulating CD_8^+ T cells. ELISPOT results showed that immunization with P5 encapsulated in nanoliposome enhanced the antigen-specific IFN-γ response more than mice immunized with P5 alone. Also using CD_8 as a second marker and intracellular flow cytometric analysis, it was found that the IFN-γ response was contributed by CD8 T cells, confirming the induction of cytotoxic T lymphocytes by this vaccination method. Also results from *in vitro* CTL assay shown that encapsulated form of peptide caused more CTL stimulation compares to other groups. The group immunized with encapsulated P5 has a lower tumor size and longer survival time. Our results demonstrated that liposomal construct with Tc peptide antigens can induce efficient antigen-specific antitumor immunity and represent promising synthetic delivery systems for the design of specific antitumor vaccines.

P6.06.081
Antitumor activity of HER2-MPL Liposomes

*S. Shariat[1], S. Mortazavi[1], A. Badiee[2], S. Jalali[3], **M. R. Jaafari**[2]; [1]School of Pharmacy, Shaheed Beheshti University of Medical Sciences, Tehran, Iran, [2]School of Pharmacy, Mashhad University of Medical Sciences, Mashhad, Iran, [3]School of Medicine, Mashhad University of Medical Sciences, Mashhad, Iran.*

The induction of potent antigen-specific $CD8^+$ T lymphocyte (CTL) response is a major requirement in the development of efficient anti tumor peptide-based vaccines . To this aim in the present study we coupled P5 , the new designed peptide containing CTL multi epitope derived from the rat HER2/neu oncogene to phosphatidylethanolamine-based pH-sensitive nanoliposomes by using DSPE-mPEG-maleimide. Monophosphoryl lipid A (MPL) was incorporated to liposome formulation (DMPC,DMPG,Chol,DOPE) as an adjuvant. The immunization of BALB/c mice with MPL adjuvanted peptide-liposome conjugate resulted in significantly higher IFN-gamma production and CTL responses in comparison with control groups .In this work, intracellular flow cytometric analysis, ELISpot assay and in vitro CTL activity test with using TUBO tumor cells were performed to evaluate antigen -specific CTL responses. CTL responses induced by effective formulation also led to the lowest tumor size and the longest survival time in mice with TUBO tumor model. These results suggest that P5 peptide coupled to adjuvanted pH-sensitive liposome might be promising approach as an anti tumor vaccine.

P6.06.082
Antitumor activity of Her2/CpG liposomes

*M. Mansourian[1], A. Badiee[1], S. Jalali[2], **M. R. Jaafari**[1]; [1]School of Pharmacy, Mashhad University of Medical Sciences, Mashhad, Iran, [2]School of Medicine, Mashhad University of Medical Sciences, Mashhad, Iran.*

The rat HER2/neu peptide (P5) is a synthetic, hydrophobic short peptide which can induce tumor -specific immunity against HER2-over expressing breast tumor in mice. Typical methods used for encapsulating peptides in lipid vesicles result in very low encapsulation efficiencies. In this study a highly efficient method for encapsulating peptide (P5) into liposomes composed of different molar ratios of DOTAP / DOPE /Cholesterol with or without CpG-ODN as an adjuvant was developed and their efficiencies in CD8+ T-cell response induction were evaluated in-vivo. Dried lipid film were hydrated with HEPES-Dextrose-Urea buffer containing P5 and sonicated for 10 minutes at 45° and further down sized by extrusion through 200 and 100nm polycarbonate membrane. In order to remove urea, DMSO and un-entrapped peptide, large unilamellar vesicles (LUVs) were dialyzed against HEPES-Dextrose buffer. All the preparation was characterized for their size, zeta potential and percent P5 encapsulation. Female BALB/c mice were immunized with three times SC injection with two weeks interval. Two weeks after the last booster CD8+ T-Cell responses were evaluated by Flow cytometeric and Enzyme-linked immunospot assay (ELISPOT). The results indicate that P5 encapsulated in Colestrol:DOTAP:DOPE liposomes with CpG enhances the CTL epitope delivery and induces CD8+ mediated immune response.

P6.06.083
Apoptosis induction in head and neck squamous cell line with combined drug therapy

*N. Cruz de Victo[1], D. Pinto Junior[2], G. Amarante-Mendes[3], **J. Jacysyn**[1,4]; [1]Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [2]Faculdade de Odontologia da Universidade de São Paulo, São Paulo, Brazil, [3]ICB- Universidade de São Paulo, São Paulo, Brazil, [4]Departamento de Imunologia - ICB/USP, São Paulo, Brazil.*

Introduction: Apoptosis or programmed cell death plays an essential role in the development and homeostasis of multicellular organisms. Because many anticancer drugs kill tumor cells by inducing apoptosis, mutations or deregulation of pro- and anti-apoptotic

proteins can contribute to the acquisition of chemoresistance. Head and neck cancer is a relatively well characterized human tumor, more than 90% of this cancer type has squamous origin and common sites include hypopharynx, larynx, oral cavity, nasopharynx, oropharynx, paranasal sinus, nasal cavity, parathyroid and salivary glands. The cause of head and neck squamous cell carcinoma (HNSCC) is multifactorial and, despite recent advances in treatment, the long-term survival rate has remained at 50% with high rates of associated mortality. Late presentation of lesions, lack of suitable markers for early detection and failure of available chemotherapy response in advanced lesions contribute to a poor outcome of HNSCC. In addition, little is known about the molecular mechanisms underlying this type of cancer. The aim of this study was to investigate the anticancer efficacy of drugs in HNSCC cells treatment.
Methods and Results: HNSCC cells (FaDu, SCC-25 and HaCat) was maintained in DMEM containing 10% fetal bovine serum and were treated with actinomicin-D, ara-C, etoposide and cycloheximide (CHX), for 18, 24 and 48 hours and the apoptotic cells were detected by DNA fragmentation analysis. We observed that tumor cells treated with apoptogenic stimulus in vitro showed decreased in the resistance of death.
Conclusion: HNSCC cells are sensitive when treated with actinomicina-D and CHX.

P6.06.084
Murine CTL response using rHER2/neu-petide

*S. Jalali[1], H. Ghaffari –Nazari[1], S. Tahaghoghi-ghorbani[1], **A. Jafari**[2], M. R. Jaafari[3];*
[1]1Immunogenetic and Cell Culture Department, Immunology Research Center, School of Medicine, Mashhad University of Medical Sciences, Mashhad, Iran, [2]School of Medicine, Mashhad University of Medical Sciences, Mashhad, Iran, [3]School of Pharmacy, Mashhad University of Medical Sciences, Mashhad, Iran.

One way to improve the immunogenicity of peptide vaccines is employment of multiepitope long peptide (MLP). MLPs are knows as exogenous peptides so taking up, processing and presenting by professional APCs, therefore, able to generate immune responses with longer survival. In this study BALB/c female mice were vaccinated with effective rHER2/neu-specific CTLs epitopes (p5 and p435) that was designed in previous study and conjugated together by double-Arg (RR) sequence as multiepitope long peptide by or without CpG-ODN adjuvant and PBS as control. 14 days after last vaccination 4 mice per group were euthanized and Immune responses were studied in their spleens for CTL cytotoxicity and IFN- by Elispot. Six mice per group challenged by live TUBO cell line and were followed for tumor size and survival. We observed that mice vaccinated with p5/p435 multiepitope long peptide in combination with CpG as adjuvant induced higher antigen-specific T-cell responses compared with group without CpG or groups vaccinated with P5 or P435 alone and PBS control group. Also tumor in the mice that received the long peptide vaccine grew slowly compared to those received the p5 or p435 or PBS and survival rate was significantly improved. Results of this study revealed that vaccination with p5/p435 multiepitope long peptide in combination with CpG is capable of generating potent antigen-specific CTL immune responses and antitumor effects in vaccinated mice.

P6.06.085
Synergistic effect of combined local irradiation and dendritic cell vaccine in murine fibrosarcoma tumor

***A. Jamali**[1], A. Amari[2], A. Pourgholaminejad[2], A. Saei[3], R. Boghozian[3], Z. Gheflati[3], N. Sepanlou[4], J. Hadjati[3];*
[1]School of Allied Medical Siences-Tehran University of Medical Sciences, Tehran, Iran, [2]Tarbiat Modarres University, Tehran, Iran, [3]School of Medicine -Tehran University of Medical Sciences, Tehran, Iran, [4]School of Medicine -Imam Khomeini Hospital, Tehran, Iran.

Objective: Neither radiotherapy alone nor dendritic cell (DCs) vaccination can successfully eradicate the tumor. Radiation induces tumor cells apoptosis, resulting in tumor antigens and danger signals releasing which are favorable for DC capturing antigens. Hence,combined irradiation and activated DC vaccine may be a novel strategy for treating solid tumors.
Methods: WEHI-164 a Balb/c derived fibrosarcoma cells were injected subcutaneously (SC) to female Balb/c mice. Bone marrow cells were cultured with GM-CSF and IL-4 for 5 days, Followed by adding Listeria monocytogenes antigens and tumor cell lysate for another 2 days. 7 days after tumor challenge, localized single dose (10 Gy) irradiation was applied. Activated DCs were injected SC around the tumor site, the day after irradiation. Tumor size was monitored every other day. Two weeks after immunization cytotoxic activity of splenocytes was measured with a LDH cytotoxicity detection kit. Intercellular INF_γ assessment was performed using a FACScalibur cytometer with WinMDI2.9 software.
Results: Immunotherapy with activated DCs after irradiation has a potent cellular response. The cytotoxicity of splenocytes in combined therapy specially which received complete cocktail was more than other groups (P< 0.016). Evaluation of intra-cellular INF-γ staining showed significant increase in animal which had received combined therapy (P<0.001).
Tumor size monitoring and mice survival showed reduced tumor size and increased survival in group which received both treatment (P=0.011, P <0.001).
Conclusion: Combination therapy using activated Listeria monocytogenes DCs and local irradiation induced noticeable efficient cellular antitumor response against poorly immunogenic tumor as well as tumor regression.

P6.06.086
Molecular diagnosis of human papilloma virus (HPV) infection in Tunisian women with various types of cervical lesions

***M. Jendoubi**;*
Viral and Molecular Tumor Diagnosis Unit, Habib Thameur Hospital, Tunis, Tunisia.

The human papilloma viruses (HPVs) are recognized as the main etiologic agents of cervical cancer.
In this work, we assessed the prevalence of high and low risk HPV types in cervical samples of two groups of Tunisian women: a first group of 50 legal sex workers at high risk of HPV infection and a second group of 50 women from the general population presenting with various types of genital lesions. A group of 11 women without genital lesions was taken as control. We used simple and nested conventional PCR in parallel, to detect HPV DNA in cervical samples. We used the MY09/MY11 and GP5 +/ GP6 + primers for PCR.
HPV typing was performed by sequencing of the amplified DNA. Our results show that none of the women in the control group were positive for HPV DNA by both PCR techniques whereas 60% of the sex workers and 30% of the second group were positive for HPV DNA by nested PCR. On the other hand, only 50% of sex workers and 8% of the second group appeared positive for viral DNA by simple PCR. This discrepancy between the simple and nested PCR data may be explained by a relative lack of sensitivity of the simple PCR or a difference in detectability and distribution, in the two populations studied, of the various HPV types. This is in line with the preliminary sequencing data which showed a predominance of high-risk HPV types in the sex workers group.

P6.06.087
Anti-PD-1 antibody therapy potently enhances the eradication of established tumors by gene-modified T cells

***L. B. John**, C. Devaud, C. P. M. Duong, C. S. Yong, P. A. Beavis, N. M. Haynes, M. T. Chow, M. J. Smyth, M. H. Kershaw, P. K. Darcy;*
Peter MacCallum Cancer Centre, East Melbourne, Australia.

Genetic modification of T cells with chimeric antigen receptors (CAR's) has emerged as a powerful approach for enhancing cancer immunotherapy. However, the existence of different immunosuppressive mechanisms restricts the full potential of adoptive T cell therapy. Given that engagement of the PD (Programmed Death)-1 receptor with its ligands PD-L1/PD-L2 can dramatically reduce T cell immunity we examined whether administration of a PD-1 blocking antibody could increase the therapeutic activity of CAR T cells. In this study we first demonstrated

a significant increase in the level of PD-1 expressed on transduced anti-Her-2 $CD8^+$ T cells following antigen-specific stimulation with PD-$L1^+$ tumor cells. Furthermore, enhanced proliferation and function of CAR T cells cocultured with Her-2^+ PD-$L1^+$ tumor in combination with anti-PD-1 antibody was observed *in vitro*. In adoptive transfer studies in Her-2 transgenic recipient mice, we demonstrated a significant improvement in growth inhibition of two different Her-2^+ tumors treated with anti-Her-2 T cells in combination with PD-1 blockade. Strikingly a significant decrease in the percentage of $Gr1^+$ $CD11b^+$ MDSC cells was observed in the tumor microenvironment of mice treated with the combination therapy. Importantly, anti-tumor effects were not associated with any autoimmune pathology in normal tissue expressing Her-2 antigen. This study demonstrates that specifically blocking PD-1 immunosuppression can potently enhance CAR T cell therapy which has significant implications for potentially improving therapeutic outcomes of this approach in cancer patients.

Immunostimulatory properties and antitumor activity of short double-stranded RNA against hepatocarcinoma G29 and melanoma B16

T. O. Kabilova[1], *L. V. Kovtonyuk*[1], *E. I. Ryabchikova*[1], *E. V. Zonov*[1], *N. A. Popova*[2], *V. P. Nikolin*[2], *M. A. Zenkova*[1], *V. V. Vlassov*[1], *E. L. Chernolovskaya*[1];
[1]*Institute of Chemical Biology and Fundamental Medicine, SB RAS, Novosibirsk, Russian Federation,* [2]*Institute of Cytology and Genetics, SB RAS, Novosibirsk, Russian Federation.*

Short double-stranded RNAs containing specific sequences are able to activate the mammalian innate immune system. Here we identified a set of 19-bp RNA duplexes with 3-nucleotid overhangs in the 3'-ends with original sequence (here and after immunostimulating RNA, or isRNA), which has no significant homology with human mRNAs.
The results in vitro experiments demonstrate that isRNAs under study efficiently inhibit growth of human cancer cells (KB-3-1, SK-N-MC), and induce synthesis of IFN-α and pro-inflammatory cytokines IL-6 and TNF-α in the human PBMCs. The examination of isRNAs sequence/activity relationships revealed that the introduction of substitutions in the middle part of the isRNA sequence does not alter the antiproliferative and immunostimulating activities, while substitutions in the 3'-end region of isRNA substantially reduce the activities.
The results of in vivo experiments show that single intravenous injection of isRNA complexed with transfection reagent efficiently increases the level of IFN-α, and to a lesser degree the level of pro-inflammatory cytokine IL-6 in mice blood serum. We found that isRNA reduces the metastases area in the liver, kidneys and heart of CBA/LacSto mice with hepatocarcinoma G-29 and cause a slight, but reliable inhibition of the tumor growth. The results of experiments with C57BL mice with implanted melanoma B16 show that isRNA efficiently inhibits tumor growth (3.5-5-fold) and metastasis spreading in the lungs (5-fold).

EXOLIGOS: a CpG oligonucleotide loaded exosome nanovesicle delivery platform suitable for effective immune modulation

T. Kahraman[1], *G. Gucluler*[1], *D. Bayik*[1], *A. Gursel*[1], *I. Gursel*[1,2];
[1]*Biotherapeutic ODN Research Lab., Department of Molecular Biology and Genetics, Bilkent University, Ankara, Turkey,* [2]*Bilgen Research Center, Bilkent University, Ankara, Turkey.*

Exosomes are naturally occurring, membranous nanovesicles of 40-100 nm in diameter. To explore the therapeutic potential of exosomes, we investigated whether cell line-derived exosomes could be used to deliver, protect and enhance activity of CpG ODNs.
Exosomes were isolated supernatants RAW264.7 cell lines and loaded with D-CpG ODNs. FACS and confocal microscopy studies established the binding and uptake kinetics of loaded vesicles into RAW264.7 cells. In vitro, ex-vivo, and in vivo performances of CpG-loaded vesicles, compared to free ODN were analyzed by Th1 cytokine production profiles. ODN encapsulation led to resistance from nuclease digestion (>90% activity retention). Internalization mechanism was found to be dependent on the scavenger receptors.
Immunization experiments against OVA in C57BL/6 mice revealed that anti-OVA IgG production was Th1-biased and this trend was persisting even after 4 months post-booster injection. OVA immunized mice were challenged with OVA expressing EG-7 cells (5 million cells/animal, s.c.) and D-ODN loaded exosomes treated mice demonstrated >85% tumor clearance.
As a result, exosome-mediated vaccine delivery is a promising source of individualised and biocompatible therapeutic vaccine vehicle suitable for immunotherapy of aggressive tumors.

In vitro treatment of colon cancer cells with non-toxic concentration of 5-fluorouracil enhances the effectiveness of tumor RNA-transfected DC vaccine

C. A. Araujo[1,2], *J. C. L. Frederico*[1,2], *G. G. Romagnoli*[1], *M. B. Magalhães*[1], *J. P. Araujo Jr.*[1], ***R. Kaneno***[1];
[1]*Department of Microbiology and Immunology, Institute of Biosciences, UNESP - Univ Estadual Paulista, Botucatu, Brazil,* [2]*Department of Pathology - School of Medicine, UNESP, Botucatu, Brazil.*

We have recently observed that human DCs treated with low doses of antitumor chemotherapeutic agents became them more efficient to stimulate T lymphocytes, whereas treatment of tumor cells with low concentrations of drugs made them more immunogenic than wild type cells. In this study we aimed to evaluate whether transfection of DC with drug-treated tumor cells RNA, enhances the effectiveness of DC-based vaccine. Human colon cancer cells HCT-116 were *in vitro* treated with non-toxic concentration of 5-fluorouracil (%-FU) and their total RNA was transfected to human monocyte-derived DC obtained from health donors. Phenotyping showed that DC transfected with tumor RNA had an increased HLA-DR expression. Analysis of their ability to stimulate the alloreactivity showed that RNA from drug-treated cells are more effective for sensitizing DC than untransfected control. Transfection of RNA obtained in such conditions was also effective to induce the *in vitro* generation of tumor-specific cytotoxic T cells in a 14 days DC:T autologous co-culture. Analysis of cytotoxic activity showed significant improvement compared with untransfected control DC. Specific antitumor activity of these T cells also resulted in higher levels of IFN-y production but not on IL-10. In conclusion, our results showed that a) 5-FU is able to increased the immunogenicity of tumor cells; b) immunogenicity of tumor cells can be transferred to normal DC by transfection of tumor RNA, and c) RNA of drug-treated tumor cells is more effective for sensitizing DC.

Clever-1/Stabilin-1 controls cancer progression by regulating migration of tumor-infiltrating leukocytes and tumor cells

M. Karikoski[1], *F. Marttila-Ichihara*[1], *P. Rantakari*[1], *K. Elima*[1,2], *H. Gerke*[1], *M. Hollmen*[1], *V. Huovinen*[1], *H. Irjala*[1,3], *M. Salmi*[1,2,4], *S. Jalkanen*[1,4,5];
[1]*MediCity Research Laboratory, University of Turku, Turku, Finland,* [2]*Department of Medical Biochemistry and Genetics, University of Turku, Turku, Finland,* [3]*Department of Otorhinolaryngology, Turku University Hospital, Turku, Finland,* [4]*National Institute of Health and Welfare, Turku, Finland,* [5]*Department of Medical Microbiology and Immunology, University of Turku, Turku, Finland.*

Common Lymphatic Endothelial and Vascular Endothelial Receptor-1 (Clever-1/Stabilin-1) is a scavenger receptor present on type II macrophages and lymphatic endothelium. The aim was to study whether Clever-1/Stabilin-1 is involved in tumor immunity and tumor cell trafficking, and ultimately if Clever-1/Stabilin-1 can be used as a target for anti-cancer therapy.
Blocking the function of Clever-1/Stabilin-1 inhibited the migration of tumor cells via lymphatics to the draining lymph nodes. Clever-1/Stabilin-1 expression was induced in the intratumoral vessels, where it mediated the binding of blood leukocytes. Antibody therapy targeting Clever-1/Stabilin-1 selectively decreased the number of type

2 macrophages and FoxP3 positive lymphocytes within the tumors. This enhanced the activation status of tumor-infiltrating leukocytes and led to apoptosis of tumor cells. As a result, both the primary tumors and metastases remained small. Same results were also observed in Clever-1 knockout mice.
These results indicate that anti-Clever-1/Stabilin-1 treatment targets two different mechanisms controlling cancer behavior: the entrance of immunity-regulating leukocytes via the blood vessels into the tumors, and tumor cell traffic within the lymphatics. In conclusion Clever-1/Stabilin-1 is a potential target to suppress tumor growth and metastatic spread.

P6.06.092
Harnessing the IgA FcαRI receptor for antibody therapy

W. Kelton[1], *N. Mehta*[1], *T. Kang*[1], *J. Lee*[1], *T. Kojima*[2], *O. Lungu*[1], *M. Donkor*[1], *G. Georgiou*[1];
[1]*University of Texas at Austin, Austin, TX, United States,* [2]*Nagoya University, Nagoya, Japan.*

Humans express large quantities of monomeric serum IgA in contrast to most other mammalian species where dimeric IgA predominates. Interestingly, in monomeric form these antibodies can engage FcαRI receptors bound on the surfaces of numerous innate immune cells to potentiate both activating and inhibitory function depending on the multimericity of the interaction. Here we investigate the potential to harness FcαRI function in the context of an engineered IgG/IgA chimera which retains FcγR affinity. Using this new antibody we aim to both open new avenues of therapeutic treatment by recruiting neutrophils for the killing of cancer cells and investigate further the role FcαRI plays with FcγRs in innate immunity.
Our engineered antibody variant shows near wildtype binding to FcαRI, FcγRI and FcγRIIa and significantly reduced binding to FcγRIIb by SPR. We used alanine scanning to determine the most critical residues at the IgA:FcαRI interface to guide our design. Antibody performance is to be evaluated in ADCC assays to determine the efficacy of neutrophil activation. The biochemical nature of the mutations that enable binding to the receptors will be discussed and the nature of ADCC elicited by these antibodies in the killing of Her2+ tumor cells will be described.

Background: Gastrointestinal (GI) cancer is one of the most common cancers in worldwide. Cell and gene therapy of cancer has received much attention in past decade. One of the recent applications in immunotherapy of tumors is human natural killer (LAK) cells.
Objective: In this study we consider the effects of PC_1 and G_2 adjuvants on NK cells, inducing them to become LAK cells, and the effect of LAK cell cytotoxicity.
Methods: Patients with GI cancer, including stomach cancer or colorectal cancer, were qualified to this study. PBMCs from each patient (10^5 cell/ml) were seeded in triplicate in 96-well plates. In each well either IL-2, G_2 adjuvant or PC adjuvant were added separately and cytotoxicity was evaluated by LDH assay.
Results: Results of this study indicate that G_2 and PC_1 stimulate NK cell and increase their cytotoxicity.This study indicates that PC and G_2 induce a powerful NK cell stimulation in gastro intestinal cancer.
Conclusion: This finding suggests that G_2 and PC_1 adjuvants may be potentially useful for cancer immunotherapy. Further in vivo studies to assess their potential use in clinical settings need to be carried out prudently.

P6.06.094
KLF6-SV1 is overexpressed in T-cells from patients with chronic lymphocytic leukemia

P. Kokhaei[1,2], *E. Mikaelsson*[1], *F. Mozaffari*[1], *A. Mosfegh*[1], *M. Hojat Farsangi*[1], *F. Pak*[2], *A. Österborg*[1], *H. Mellstedt*[1];
[1]*Department of Oncology and Pathology, Cancer Centre Karolinska, Karolinska University Hospital Solna, Stockholm, Sweden, Stockholm, Sweden,* [2]*Dept. of Immunology, Semnan University of Medical Sciences, Semnan, Iran.*

Communication between the tumor cells and the surrounding microenvironment are of importance for the survival of Chronic Lymphocytic Leukemia (CLL) cells. T-cells seem to be a key player in the pathogenesis of CLL contributing to the development of a microenvironment in which the leukemic clones evade apoptosis. In this microenvironment the leukemic cells exhibit an increased proliferative activity that sustains the growth of the malignant B-cells. The Krüppel-like transcription factor (KLF) family has been identified as important regulators of proliferation, differentiation, tumorgenesis and cell death.
In the present study we examined the expression of KLF6 and the KLF6-splice variant 1 at the mRNA and protein level in CD4+ (purity≥96%) and CD8+ (purity≥94%) T-cells from 39 patients with CLL and 10 patients with multiple myeloma as well as 10 normal donors. siRNA technology was used to down-regulate KLF6-SV1 mRNA. Sequence specific siRNA treated purified T cells and non-treated leukemic B cells were cultured together or alone for 5 days. Apoptosis of tumor cells was analysed using flow cytometry.
Western blot showed the expression of KLF6 wild-type in purified CD4+ and CD8+ T-cells. Real time PCR revealed a significant overexpression of KLF 6-SV1 in CD8+ T- cells of CLL patients compared to normal donors (p=0.002). siRNA KLF6-SV1 transfection of T cells induced a significant downregulation of KLF6-SV1 and in co-culture experiments a significant increase of apoptosis of B cells was noted. The results may indicate that the KLF6-SV1 might be involved in a dysregulated microenvironment supporting the growth of CLL cells.

ImMucin, anti-MUC1 therapeutic Vaccine: Interim analysis from a phase I/II study in myeloma patients

R. Kovjazin[1], *O. Moran*[1], *I. Avivi*[2], *M. Y. Shapira*[3], *L. Carmon*[1];
[1]*Vaxil, Nes-Ziona, Israel,* [2]*Rambam Medical Campus, Haifa, Israel,* [3]*Hadassah- Hebrew University Medical Center, Jerusalem, Israel.*

Ideal cancer vaccines should induce robust, diverse and long lasting B and T-cell responses in the majority of the patient population. Signal peptide (SP) domains were found to have exceptionally high number of MHC class I and II epitopes per sequence length which relies on their hydrophobic nature but also bare antigen specificity. Namely, SPs exhibit antigen specificity while maintaining their consensus motif as chaperones.
ImMucin, is a 21-mer peptide, encoding the entire SP domain of MUC1, a tumor-associated antigen expressed by most solid and hematological tumors including multiple myeloma (MM).
A phase I/II study was initiated to assess the safety and efficacy of ImMucin, in 15 MUC1-positive patients with a biochemical relapse MM following ASCT. Patients received 12 bi-weekly vaccination of 100µg ImMucin plus 250µg hGM-CSF. Interim analysis conducted on 7 patients completed the treatment suggests a high safety profile for the vaccine with temporary mostly local mild adverse events which resolved spontaneously. Immunomonitoring analysis by ICS-IFN-gamma, and anti-SP antibodies demonstrated a unique combination of robust ImMucin-specific CD8+ and CD4+ T-cell response with pan HLA in all patients after 2-4 vaccinations, along with increase in anti-ImMucin sera concentration in 5/7 patients. Moreover, a sharp decrease in soluble MUC1's levels was observed in all patients who had abnormal levels at screening. Lastly, stabilization or reduction in

disease markers and tumor cells in patient bone marrow was detected in 4/7 patients.
Our results, confirm a safety profile, robust and diverse immunity and hints of efficacy for ImMucin in MM patients.

P6.06.096
Enhanced tumor antigen specific T cells in prostate cancer patients received in situ gene therapy of repeated HSV-tk injection and ganciclovir administration

M. Kubo[1], *T. Satoh*[2], *K. Tabata*[2], *K. Matsumoto*[2], *N. Yanagisawa*[3], *M. Saegusa*[3], *I. Okayasu*[3], *M. Iwamura*[2], *S. Baba*[2], *F. Obata*[1];
[1]*Division of Immunology, Kitasato University of Allied Health Scineces, Sagamihara, Japan,* [2]*Department of Urology, Kitasato University School of Medicine, Sagamihara, Japan,* [3]*Department of Pathology, Kitasato University School of Medicine, Sagamihara, Japan.*

(OBJECTIVE) The high relapse rate of the prostate cancer has been a problem after the radical prostatectomy. For the reduction of relapse rate, various neoadjuvant therapies are examined. Previous report has showed that immune responses were increased in patients treated with adenoviral vector-mediated herpes simplex virus-thymidine kinase (HSV-tk) gene delivery followed by ganciclovir (GCV) injection. However, the details of immune responses after gene therapy were not clear from that study. This study is designed to evaluate it.
(METHODS) This study was approved by the ethical committee of Kitasato University, and by the Ministry of Health, Labour and Welfare. Five patients who agreed this Phase I/II trial were repeatedly given 2 weeks of intravenous GCV administration following the intraprostatic HSV-tk injection. Peripheral blood samples were periodically collected after treatments. The lymphocyte subsets were analyzed by flow cytometry. We also measured intracellular IFN-γ produced by T cells to responding prostatic acid phosphatase and NY-ESO-1 overlapping peptides. Local immune responses were evaluated by Immunohistochemistory.
(RESULTS) The activated and central memory CD8+T cells of three patients markedly increased during second treatment. In three patients, tumor antigen-specific T cells were clearly increased after treatments. Macrophages and CD8+ T cells invasion were highly observed in apex and mid of all prostates.
(CONCLUSION) Immune cells were effectively infiltrated to prostate gland by repeated HSV-tk + GCV treatments. Prostate cancer antigen-specific T cells and increased memory CD8+ T cells may cotribute to reduce relapse rates. This gene therapy could be expected as one of effective neoadjuvant therapies.

P6.06.097
Development of the approach based on dendritic cells transfected with polyepitope DNA-construction for stimulation of antitumor cytotoxic response in colorectal cancer.

E. Kulikova[1], *V. Kurilin*[1], *I. Obleuhova*[1], *Y. Shevchenko*[1], *V. Yakushenko*[2], *A. Sokolov*[3], *S. Sennikov*[1];
[1]*Institute for Clinical Immunology, Siberian Branch of Russian Academy of Medical Sciences, Novosibirsk, Russian Federation,* [2]*Municipal clinical hospital №11, Novosibirsk, Russian Federation,* [3]*Municipal clinical hospital №1, Novosibirsk, Russian Federation.*

Currently the scientists are searching and developing effective cancer vaccines based on dendritic cells (DC) loaded with various tumor antigens, including DNA-constructions that carry certain sequences of tumor antigen epitopes. These vaccines can efficiently and selectively activate the T-cell immune response. The aim of the study was to evaluate the effect of DCs transfected polyepitope DNA-construction pCI-UB-POLYEPI on the immune response in the culture of mononuclear cells (MNC) in patients with colorectal cancer. In this study we used venous peripheral blood of patients and a sample of the tumor. Dendritic cells were obtained from mononuclear adherent cells of peripheral blood by culturing in the presence rhGM-CSF, rhIL-4. Further we added rhTNF-α to the culture. Thereafter mature DCs were exposed to magnetic transfection with DNA-construction pCI-UB-POLYEPI. Then we cultured non-adherent MNCs with transfected DCs and performed the test for cytotoxicity of MNCs to autologous tumor cells and assessed the relative content of perforin-positive lymphocytes. By assessing the cytotoxic test we found a significant increase in tumor cell death in culture of MNCs cultured with DC transfected with pCI-UB-POLYEPI in comparison with control group by 1.9 times. By evaluating the content of perforin-positive cells we showed the greatest increase in their number in MNCs cultured with DC transfected with pCI-UB-POLYEPI, indicating that one of their mechanisms for realization the cytotoxic effect of the MNCs. Thus, mature DCs transfected with DNA-construction pCI-UB-POLYEPI stimulate cytotoxic response and increase content of perforin-positive cells in the culture of MNCs in patients with colorectal cancer.

P6.06.098
Receiving mature dendritic cells in vitro in patients with tumors of different localization

V. V. Kurilin[1], *I. A. Obleuchova*[1], *E. V. Kulikova*[1], *J. N. Khantakova*[1], *J. A. Shevchenko*[1], *V. K. Yakuchenko*[2], *A. V. Sokolov*[3], *S. V. Sennikov*[1];
[1]*FSBI RICI RAMS SB, Novosibirsk, Russian Federation,* [2]*Hospital №11, Novosibirsk, Russian Federation,* [3]*Hospital №1, Novosibirsk, Russian Federation.*

In this study we used peripheral venous blood of patients with epithelial tumors of different localization (gaster, lung, colon, ovary). MNCs were isolated from peripheral blood on gradient. Then isolated monocytes by adhesion on plastic, followed by culturing for 48h in the presence GM-CSF (50 ng/ml), IL-4 (100ng/ml) and for 24h in presence TNF-α (25ng/ml). Maturation of DCs was assessed by flow cytometry on the expression of maturation markers (CD83, CD86, CD11c, HLA-DR) on cells and capture FITC-dextran. The protocol used cultivation DC with mature phenotype (high expression of CD83, CD86, CD11c, HLA-DR, low endocytic activity), which was shown in experiments in vitro on cells conditionally healthy donors. This protocol is used to assess the ability of cancer patients to MNCs maturation and differentiation into mature DCs. It was shown that in the culture of patients with epithelial ovarian cancer and colorectal cancer is significantly increased expression of CD83, HLA-DR, CD86, and decreased endocytic activity, which may indicate the ability of intact cell precursors of dendritic cells (monocytes) to differentiate into mature forms of DC. In patients with gastric cancer or lung when cultured DCs was no significant increase of maturation markers and changes in endocytic activity, which points to a violation of differentiation and maturation of dendritic cells in cancer of the stomach and lung.
Thus, in the used cellular protocol has been shown that the various types of cancer can vary the capacity for maturation of dendritic cells in vitro conditions in the presence of IL-4, GM-CSF, TNFa.

P6.06.099
Recombinant lipidated HPV E7 induces a Th-1-biased immune response and protective immunity against cervical cancer in a mouse model

C. Huang[1], *J. J. Chen*[2], *K. Shen*[1], *L. Chang*[1], *Y. Yeh*[1], *Y. Chen*[1], *P. Chong*[1], *S. Liu*[1], ***C. Leng***[1];
[1]*National Institute of Infectious Disease and Vaccinology, National Health Research Institutes,, Zhunan Town, Miaoli,, Taiwan,* [2]*Institute of Molecular Biology, National Chung Hsing University, Taichung, Taiwan.*

The E7 oncoprotein of human papillomavirus (HPV) is an ideal target for developing immunotherapeutic strategies against HPV-associated tumors. However, because protein-based immunogens alone are poor elicitors of the cytotoxic T-lymphocyte (CTL) responses, they have been difficult to exploit for therapeutic purposes. In this study, we report that a recombinant lipoprotein consisting of inactive E7 (E7m) biologically linked to a bacterial lipid moiety (rlipo-E7m) induces the maturation of mouse bone marrow-derived dendritic cells through toll-like receptor 2 (TLR2), skews the immune responses toward the Th1 responses and induces E7-specific CTL responses. We further studied the ability of rlipo-E7m to provide protection against a TC-1 tumor cell challenge in an animal model. Mice prophylactically immunized with two 10-μg doses of rlipo-E7m were

found to be free of TC-1 tumor growth. Experiments in a therapeutic immunization model showed that the tumor volume in mice receiving a single dose of rlipo-E7m was less than 0.01 cm^3 on day 40, whereas the tumor volume in mice treated with rE7m was 2.28 ± 1.21 cm^3. The tumor volume of the entire control group was over 3 cm^3. In addition, we demonstrated that the CD8+ T cells play a major role in anti-tumor immunity when administration of rlipo-E7m. These results demonstrate that rlipo-E7m could be a promising candidate for treating HPV-associated tumors.

P6.06.100
In-vivo testing of PSMA-targeted T-cell immunotherapy for prostate cancer

***Z. Liu**, S. Papa, J. Morris, J. Maher;*
King's College London, London, United Kingdom.

The aim of this project is to develop prostate cancer immunotherapy using T-cells that express the P28z chimeric antigen receptor, targeted against prostate-specific membrane antigen (PSMA). The first step in this process is to develop an animal model of metastatic PSMA+ prostate cancer. The PC3LN3 prostate cancer cell line undergoes metastatic spread to draining lymph. When engineered to express PSMA, the resultant PC3LN3-PSMA cells are highly metastatic, but do not spread predominantly to bone. Increasing evidence suggests that bone metastasis requires the interaction between E-selectin on bone marrow endothelium with sialyl Lewis antigen-containing E-selectin ligands, expressed on cancer cells. However, neither cell line expresses E-selectin binding ligands or sialyl Lewis antigens. To investigate the mechanism underlying this, we quantified expression of glycosyltransferases required for sialyl Lewis antigen expression. Using real-time PCR, low fucosyltransferase (FT) 3 expression was consistently found. In preliminary studies, we have observed that delivery of a FT3-encoding retroviral vector to PC3LN3 and PC3LN3-PSMA enables them to express sialyl Lewis X and to acquire E-selectin binding activity. We also showed that FT3 promotes increased PC3LN3-PSMA motility and invasiveness in vitro. Bioluminescence imaging result showed their pattern of metastatic spread in SCID Beige mice. This was served as a platform to test immunotherapy using P28z+ T-cells. Next, SPECT imaging will be used to track tumour status (Tc-99m MDP) and T-cell migration (Tc-99m pertechnetate) in the same mouse. Using this approach, we hope to test and optimize the efficacy of P28+ T-cell immunotherapy against PSMA-expressing prostate cancer.

P6.06.101
Effects on apoptosis and cell cycle arrest contribute to the antitumor responses of interleukin-27

***L. Liu**[1], S. Baoen[2];*
[1]Department of Biotherapy, the Fourth Hospital of Hebei Medical University/Hebei provincial Cancer Institut, Shijiazhuang, China, [2]1. Research Cencer, the Fourth Hospital of Hebei Medical University/Hebei provincial Cancer Institut, Shijiazhuang, China.

Objective: Interleukin (IL)-27, composed of p28 and Epstein-Barr virus-induced gene 3 (EBI3) subunits, has diverse functions in regulating immune systems. To observe the effect and mechanisms on cell cycle and apoptosis of IL-27 through IL-27 treated on human esophageal carcinoma cells.
Methods: The expression of IL-27 in different esophagel carcinoma cells was detected by RT-PCR and Western-blot, rIL-27 was added to the high expression of IL-27R of esophagel carcinoma cells. Flow cytometry was used to analyze cell cycle and apoptosis, the relating gene and protein was detected by RT-PCR and Western-blot.
Results: The high (TE-1 and Yes-6) and low expression (TE-2) of IL-27R of esophagel carcinoma cells line were obtained. After the the high expression of IL-27R stimulated by IL-27, the apoptosis was increased. The cell cycle was arrested in G0 and G1($P < 0.05$), the expression of cell cycle relating protein p21 was increased, but the expression of survivin was reduced ($P < 0.05$), the apoptosis relating protien Bcl-2 was up-regulated, while Bax was down-regulated ($P < 0.05$).
Conclusion: IL-27 could have a direct role on high expression IL-27R of esophagel carcinoma cells, and induction of cell cycle arrest and apoptosis could be the mechanism of IL-27 in tumor regression.

P6.06.102
Anti-tumor effect of folate-conjugated chitosan nanoparticles containing the IP-10 gene in mice with hepatocellular carcinoma

*X. Yu, Y. Xie, C. Lai, J. He, Y. Peng, S. Zhou, X. Xie, G. Luo, N. Zhou, Y. Zhao, **X. Lu**;*
Guangxi medical university, Nanning, China.

The relative insensitivity of hepatocellular carcinoma (HCC) to chemotherapy and radiotherapy has initiated great efforts to make proper immunotherapeutic strategies. Interferon-inducible protein-10 (IP-10) is a chemotactic factor which exerts its anti-tumor activity via recruitment of T lymphocytes and inhibition of angiogenesis. IP-10 is known to be associated with strongly liver fibrosis in hepatocellular carcinoma resected patients with chronic hepatitis C. It is also known to have prognostic utility as a marker of treatment outcome in chronic hepatitis C patients. In this study, chitosan, an economic and degradable natural nano-biomaterial, was applied as a vector for immunotherapy of HCC. A novel ion template method was used to prepare chitosan nanoparticles which were then modified with folic acid (FA) to confer tumor specificity. With conjugation of FA-chitosan with mouse IP-10 cDNA (FA-CS-IP-10), it generated nanoparticles which could target cancer cells and protected the IP-10 gene from endonuclease degradation. The underlying mechanisms of the antitumor effect of intravenous FA-CS-IP-10 in HCC-bearing BALB/c mice were investigated. FA-CS-IP-10 had shown significantly inhibited cancer growth, suppression of angiogenesis, increased apoptosis of cancer cells, and prolonged the survival time of HCC mice. FA-CS-IP-10 also reduced the proportion of regulatory T cells and induced cytotoxic T lymphocytes (CTL) to upregulate IFN-γ secretion. FA-CS-IP-10 also showed a good safety profile. We demonstrated the feasibility of using FA-modified chitosan nanoparticles to target IP-10 DNA to HCC tumors and suggested that FA-CS-IP-10 is a promising candidate for further evaluation as an immunotherapeutic agent to treat HCC patients.

P6.06.103
Rapid and massive localization of multiple lymphocyte subsets to specific tissues following administration of Interleukin-15

***E. Lugli**[1], H. Welles[2], K. Song[2], B. R. Bryant[3], C. K. Goldman[3], S. Rao[2], K. C. Conlon[3], T. A. Waldmann[3], M. Roederer[2];*
[1]Humanitas Clinical and Research Institute, Rozzano, Italy, [2]Vaccine Research Center, NIAID, NIH, Bethesda, MD, United States, [3]Metabolism Branch, NCI, NIH, Bethesda, MD, United States.

The cytokine Interleukin (IL)-15 has potential applications in cancer immunotherapy and in vaccination as it expands anti-tumor T and Natural Killer (NK) cells and promotes long-lived T cell memory, respectively. While studying the immunological impact of intravenous IL-15 administration in a Phase I clinical trial in patients with cancer, we observed that lymphopenia preceded target cell expansion. Polychromatic flow cytometry of lymphocyte subpopulations in the peripheral blood of humans and, subsequently, rhesus macaques revealed that NK and memory T cells completely disappeared from the blood within minutes upon administration, thus suggesting localization to tissues. Among memory T cells, effector memory/terminal effector cells responded the fastest, followed by central memory, stem cell memory and naïve cells. Overall, the cytokine affected CD8+ more than CD4+ T cells. Animals sacrificed at 6 hours post administration indicated a massive increase in the proportion of memory CD8+ T cells in the proximal (jejunum) and distal (rectum) intestine. Conversely, naïve T cell proportion preferentially increased in the lymphnodes. The absence of proliferation (Ki-67) and activation (CD38, HLA-DR) markers indicates redistribution rather than expansion of resident cells. NK and CD8+ T cells returned in the circulation ~24 hours post treatment and were highly proliferating and activated. These data indicate the potential of IL-15 not only to expand discrete immune subsets but also to induce their localization in specific sites of the body, including mucosal

tissues. Vaccination strategies aimed at inducing mucosal immunity should exploit this novel function of IL-15.

P6.06.104
Enhancing the effector functions of tumor-infiltrating lymphocytes with a combination of new genetic adjuvants

A. Margalit[1,2], *A. Pato*[1,3], *H. Weinstein-Marom*[1,3], *N. Levin*[1,3], *T. Peretz*[3], *A. Machlenkin*[3], *M. Lotem*[3], *G. Gross*[1,2];
[1]*MIGAL Galilee Research Institute, Kiryat Shmona, Israel,* [2]*Tel-Hai College, Upper Galilee, Israel,* [3]*Sharett Institute of Oncology, Hadassah Hebrew University Hospital, Jerusalem, Israel.*

Adoptive cell therapy (ACT) using ex-vivo expanded and activated tumor-infiltrating lymphocytes (TILs) is currently the most effective treatment of metastatic melanoma and is extensively explored in other cancers. Yet, severe hurdles still limit its clinical outcome and broader application. These include full T cell differentiation and T cell exhaustion following lengthy ex-vivo propagation, the presence of inhibitory cells in heterogeneous TIL populations, the need to overcome immunosuppression at the tumor microenvironment and the dependence of T cell survivability on the systemic administration to patients of high-dose IL-2, which is often intolerably toxic.
For solving at least some these problems we have recently generated a set of new genetic adjuvants comprising constitutively active (ca) TLR4, caCD40 and a membrane-attached derivative of IL-2. The electroporation of polyclonal human CD4 and CD8 T cells and anti-melanoma TILs with in-vitro-transcribed mRNA encoding these adjuvants greatly enhanced their effector functions, while combinations of these adjuvants exerted a synergistic effect. Anti-melanoma TILs transfected with adjuvant mRNA, but not with irrelevant mRNA, exhibited markedly enhanced reactivity against autologous melanoma but not against HLA-mismatched tumor. Moreover, the combination of these mRNAs further improved the magnitude of this enhancement.
Our findings suggest that this new set of genetic adjuvants can improve the anti-tumor reactivity of TILs and offer a new tool for cancer ACT.

Transgenic expression of soluble human CD5 enhances experimentally-induced autoimmune and anti-tumoral immune responses

V. G. Martinez[1], *R. Fenutría*[1], *I. Simões*[1], *V. Gil*[2], *J. Sintes*[3], *C. Raman*[4], *P. Engel*[3], *M. Ramos-Casals*[2], *G. Soldevila*[5], *F. Lozano*[1,3,6];
[1]*IDIBAPS (Institut d'Investigacions Biomèdicas August Pi i Sunyer), Barcelona, Spain,* [2]*Servei de malalties autoimmunes sistémiques, Hospital Clínic de Barcelona, Barcelona, Spain,* [3]*Departament de Biologia Cellular, Immunologia i Neurociències, Universitat de Barcelona, Barcelona, Spain,* [4]*Department of Medicine, University of Alabama at Birmingham, Birmingham, AL, United States,* [5]*Departamento de Inmunología, Instituto de Investigaciones Biomédicas, Universidad Nacional Autónoma de México, México D.F., Mexico,* [6]*Servei d'Immunologia, Hospital Clínic de Barcelona, Barcelona, Spain.*

CD5 is a type I glycoprotein constitutively expressed in thymocytes, T lymphocytes and a subtype of B cells, called B1a; current data support the view that CD5 is a negative regulator of antigen-specific receptor-mediated signalling in T and B1a lymphocytes, and that this would be achieved through interaction with CD5 ligand/s (CD5L) of still undefined nature expressed on antigen-presenting cells. To explore the functional relevance of the CD5/CD5L interactions *in vivo* we report here the generation and characterization of transgenic mice expressing elevated circulating levels of a human soluble form of CD5 (shCD5) in sera. We hypothesized that shCD5 would be able to bind its natural ligand/s in the mouse and, as a result, impair intracellular signalling mediated by CD5. Interestingly, analysis of the shCD5 transgenic mice showed a significantly reduced proportion of Treg cells (CD4+CD25+FoxP3+), as well as decreased numbers of peritoneal IL-10-producing B1a (CD5+) lymphocytes. Moreover, NKT cells were increased in the spleen and peritoneum of transgenic mice. The observed reduction in these regulatory cell subpopulations, coupled with the increase in effector subpopulations, resulted in an enhancement of the immune reponse, as shown by the more severe forms of experimental autoimmune disease observed in these mice, as well as an increased anti-tumoral response in *in vivo* cancer models. These data reveal the relevant role played by CD5/CD5L interactions on the homeostasis of some functionally relevant lymphocyte subpopulations resulting in the enhancement of immune responses to autologous antigens.

Agonist anti-CD137(4-1BB) mAbs enhance CD8-mediated antitumor immunity. Agonist anti-human CD137 mAbs covering four distinct epitopes on the CD137 glycoprotein co-stimulated T cell activation irrespective of the engaged epitope or its interference with CD137L binding. CD137 perturbation with all these agonist mAbs resulted in antigen and antibody internalization towards an endosomal vesicular compartment. Internalization was observed in activated T lymphocytes from humans and mice, not only in culture but also in antibody-injected living animals. These in vivo experiments were carried out upon systemic intravenous injections with anti-CD137 mAbs and showed internalization in tumor-infiltrating lymphocytes and in activated human T cells transferred to immunodefficient mice. Efficient CD137-internalization required K63-polyubiquitination and endocytosed CD137-containing vesicles were decorated with K63-polyubiquitins. CD137 stimulation activates NF-κB through a K63-linked polyubiquitination-dependent route and CD137-associated TRAF2 becomes K63-polyubiquitinated. Consistent with a role for TRAF2 in CD137 signalling, transgenic mice functionally deficient in TRAF2 showed a delayed immunotherapeutic activity of anti-CD137 mAbs. As a whole, these findings advance our knowledge of the mechanisms of action of anti-CD137 immunostimulatory mAbs such as those currently undergoing clinical trials in cancer patients.

Chemokine-receptor modified Adoptive T cell Therapy (ACT)

S. Garetto, A. Trovato, ***E. Martini****, R. Angioni, C. Soldani, M. Kallikourdis;*
Istituto Clinico Humanitas, Rozzano, Italy.

Adoptive Cell Therapy (ACT), using expanded ex vivo cancer patient T cells, has developed into a promising strategy for tumor therapy. The local immunosuppression of the tumor and the insufficient homing of transferred lymphocytes to the tumor site limit the efficacy of this technique.
Taking advantage of tumor chemokine production, we hypothesized that adoptively transferred CD8+ T cells, transduced with chemokine receptors matching the chemokines expressed at the primary tumor or the metastatic sites, would preferentially be attracted to their required sites of action. Performing chemokine expression analysis at the primary tumor and metastatic sites, we found that CCL2 in the primary tumor and CXCL12 in the lymph node metastasis are the predominant chemokines. To formally demonstrate that we can induce preferential homing of modified CD8+ T cells to the metastasis, we are using as the TRAMP tumor system that has similarities with the human disease. Our preliminary results show that CD8+ T cells transduced with the matching chemokine receptor preferentially reach the draining lymph nodes of the tumor, where the metastasis occurs. To investigate the benefit in survival following ACT, we are now performing experiments using an induced tumor model, based on injection of the TRAMP-C2 cell line.

Background: In spite of large advances in using dendritic cell (DC) vaccine for treatment of malignancies, the optimal maturation cocktail for producing efficient mature DCs have not yet been established. The aim of this study was to determine the best combination of TLR agonists with the synergistic effect on maturation of human monocyte-derived DCs for immunotherapy of malignancies especially acute myeloid leukemia.
Methods: DCs were generated in vitro from CD14+ monocytes from healthy donors. Different TLR ligand cocktails were used for DCs maturation. Subsequently, matured DCs were assessed phenotypically. IL-12p70 production and allostimulatory capacity of DCs also were analyzed. Ultimately, the ability of DCs in CTL induction against Leukemia blasts was determined.
Results: Results demonstrated that combination of particular agonists resulted in generation of mature DCs with high expression of CD83 and IL-12p70. Among different agonists, combination of TLR7/8, 4 and TLR3 or 2/6 showed prominent effect on DCs. Such potent DCs showed higher capacity to stimulate allogeneic T cells and autologous cytotoxic T cells than immature counterparts. Moreover increased killing capacity of induced CTLs against leukemic targets was shown.
Conclusion: Synergistic TLR stimulation could be efficient approach in generation of ex vivo produced DCs for immunotherapy of cancer in clinical setting.

P6.06.109
Therapeutic effect of anti- pan HLA-class II mAb 4713 on human lymphoma cells, including Hodgkin lymphoma and Adult T cell leukemia cell lines

S. Matsuoka[1], *Y. Ishii*[2], *A. Nakao*[3], *H. Yagita*[4], *M. Abe*[1], *N. Mizutani*[1], *O. Naomi*[1], *K. Terashima*[5], *O. Hino*[1];
[1]*Derartment of Pathology and Oncology Juntendo University School of Medicine, Tokyo, Japan,* [2]*RIKEN Reseach Center for Allergy and Immunology, Yokohama, Japan,* [3]*Dept. of Immunology, Univ. of Yamanashi Faculty of Medicine, Yamanashi, Japan,* [4]*Derartment of Immunology Juntendo University School of Medicine, Tokyo, Japan,* [5]*Derartment of Comprehensive Pathology, Tokyo Medical Dental University, Tokyo, Japan.*

To develop a new therapeutic device for Hodgkin lymphoma, we immunized BALB/c mouse with living cells of 2 Hodgkin lymphoma cell lines alternately. We hybridized spleen cells from this immunized mouse with myeloma cells, P3U1. And we screened hybridoma clones by the direct cytotoxicity for the Hodgkin lymphoma cell line not used for immunization. Newly established mouse anti-human monoclonal antibody, raised by this strategy, rapidly induced serum complement independent cell death on not only Hodgikin cell lines but also Burkit lymphoma cell lines. Intriguingly IL-2 dependent not advanced Adult T cell Leukemia cell lines were not sensitive but aggressive IL-2-independent cell lines were sensitive for 4713 induced cytotoxicity. Consequently, this mAb named 4713 revealed to be mouse anti-human pan HLA class II specific monoclonal antibody, for recognizing HLA-DP, DQ, DR transfected cells but not non-transfected cells. Based on their cytolytic activity, it appears that anti-pan HLA class II monoclonal antibody may be most likely to contribute to the therapy of some types of lymphoma/leukemia including Hodgkin Disease, Burkit lymphoma and advanced ATL.
Treatment of this mAb induced large pore formation on target lymphoma cells. This fact suggests that cell death induced by anti-pan HLA class II mAb may share same death signals induced by cytolytic anti-pan MHC class I mAb, which we reported previously to induce large pore formation on target cell surface.

P6.06.110
Identification of unique colorectal cancer T-cell antigens by next generation sequencing of somatically mutated genes

D. Mennonna, *C. Maccalli, M. Romano, R. Bordoni, G. De Bellis, E. Orsenigo, L. Albarello, G. Casorati, G. Parmiani, P. Dellabona; San Raffaele Scientific Institute, Milan, Italy.*

Immunotherapy holds promise for cancer treatment. Unique TAAs, encoded by somatically mutated cancer genes, may generate strongly immunogenic epitopes that induce tumor control by the host's immune system. We are using massive DNA sequencing of somatic mutations in colorectal cancer cells (CRC), and possibly also in their Cancer Stem Cells (CSCs), to identify patient-specific unique TAAs. We established 8 tumor cells lines from CRC patients, two of which also cultured as CSCs. Pools of mRNAs encoding 20 CAN-genes were subjected to high throughput sequencing, confirming the presence of somatic mutations in some of these genes. Synthetic peptides spanning the mutated proteins expressed by each CRC cell line are tested for their ability to elicit an in vitro immune response. Results obtained in one CRC sample show that the frameshift mutation occurring in the APC gene generates a neo-epitope that is presented by HLA-DR molecules in tumor cells and it is recognized by specific CD4+ T cells. Peptides corresponding to the point mutations in TP53 and SMAD4 gene products elicit CD8+ and CD4+ T cells that specifically react against the same CRC cells. Conversely, an autologous T cell line induced by this CRC cell line recognize the mutated SMAD4 peptide. These preliminary results would support the feasibility of the approach to identify unique TAAs in CRC by massive sequencing and reverse immunology.

Examination of an immunoregulator in a syngeneic animal model

G. Merchand-Reyes[1], *M. A. Becerril-García*[1], *I. Gracia-Mora*[2], *S. Estrada-Parra*[1], *I. Estrada-Garcia*[1], *S. M. Perez-Tapia*[1], *C. Sandoval-Montes*[1];
[1]*Escuela Nacional de Ciencias Biologicas, Instituto Politecnico Nacional, Mexico City, Mexico,* [2]*Universidad Nacional Autonoma de Mexico, Mexico City, Mexico.*

Dialyzable leukocyte extracts (DLE), described by Lawrence in the mid-20th century, have been used widely as an adjuvant therapy for various diseases due to their immunoregulatory activity. Clinical studies on DLE in combination with conventional therapy against cancer have demonstrated that they are beneficial, reducing metastases and the side effects of chemotherapy and increasing life span. Nevertheless, their mechanism of action in cancer remains poorly understood.
Diffuse large B-cell lymphoma is a highly aggressive neoplasm that is resistant to many therapies, prompting the development of new therapies, particularly those that increase the immune response. This study examined the effects of DLE in A20 cell lymphoma in a syngeneic murine model. In vitro, the proliferation and cell cycle progression of A20 cells were unaltered on incubation with DLE of human origin. In vivo, treatment with various doses of DLE in mice that were subcutaneously isotransplanted with B cell lymphoma effected less tumor growth than in untreated mice but was insufficient to control the tumor. Mice that received combination therapy of cyclophosphamide and DLE experienced less tumor growth than those that were treated with either agent alone. Further, combination therapy delayed tumor recurrence resulted in fewer cases of recurrence than cyclophosphamide. In conclusion, DLE enhance the response to conventional treatment in a syngeneic murine tumor model.

P6.06.112
Evaluation of anti-proliferative activity of ruthenium (III) compounds on human cancer cell lines using RTCA - xCELLigence System

M. A. Mihaila[1], *M. Bostan*[1], *G. G. Matei*[1], *V. Uivarosi*[2], *L. I. Brasoveanu*[1];
[1]*"Stefan S. Nicolau" Institute of Virology, Center of Immunology, Bucharest, Romania,* [2]*"Carol Davila" University of Medicine and Pharmacy, Faculty of Pharmacy, Inorganic Chemistry, Bucharest, Romania.*

The clinical use of Cisplatin and its analogues might be limited by tumour drug resistance and adverse effects, therefore other transition-metal agents that possess anti-tumour and anti-metastatic activities such as ruthenium (III) compounds could be considered as alternative drugs. In order to evaluate the anti-proliferative activity of several ruthenium compounds with anti-tumour activity and find the optimal time points and concentrations for high throughput predictive toxicological assessment, we have used the xCELLigence system comparing to other cytotoxicity assays (MTT, XTT). The xCELLigence system is a real-time cell analyzer based on label-free platform technology that continuously monitor cellular responses to a given treatment using the inherent morphological and adhesive characteristics of cells, and combine them with cellular endpoint assays such as flow-cytometry. Our complex interdisciplinary approach aims to develop pharmaceutical product models with significant anti-tumour action and minimal side effects. The study focused of evaluation of anti-proliferative activity of ruthenium (III) compounds compared to Cisplatin on various cancer cell lines (breast MDA-MB-231; colon LoVo; cervix HeLa; ovarian Sk-Ov-3; tongue PE/CA-PJ49 cells) using different co-solvents systems. In addition, percentages of apoptotic cells were evaluated using Annexin V/FITC and propidium iodide (PI) double staining (BD Annexin V-FITC Apoptosis Detection Kit), while DNA progression through cell cycle phases was estimated using PI staining (BD Cycletest Plus/DNA Reagent kit), followed by flow-cytometry. Extension of the research toward the solubilization of ruthenium compounds in order to improve their pharmacokinetics and testing their anticancer activity in soluble forms might improve their potential therapeutic use as anticancer agents.

P6.06.113
Competent maturation of human dendritic cells by protein fractions of listeria monocytogenes

R. Mirzaei[1], *A. Saei*[1], *R. Boghozian*[1], *B. Vaziri*[2], *J. Hadjati*[1];
[1]*Tehran University Medical Sciences, Tehran, Iran,* [2]*Pasteur Institute of Iran, Tehran, Iran.*

Objective: Dendritic cells (DCs) are sentinels of the immune system that instruct the activation of T and B lymphocytes. DCs are responsible for initiating immune responses against tumor antigens. DCs Maturation is essential for induction of appropriate anti-tumor responses. Until know, a potent activator for DCs maturation has not been introduced. Therefore, in this study, the ability of protein fractions of listeria monocytogenes in human monocyte-derived DCs maturation was analyzed.
Material and Methods: The listeria monocytogenes suspension was prepared. Subsequently, Bacteria were spun down by centrifugation, and were sonicated in the presence of protease inhibitors cocktail. Protein extract was fractionated firstly by stepwise precipitation with increasing amounts of ammonium sulfate and secondly by Ion-Exchange chromatography. The ability of achieved fractions in inducing DCs maturation was determined by different immunological assessments. Ultimately, the proteome of matured DCs was compared between different matured DCs.
Results: The result showed that one protein fraction of listeria monocytogenes is more potent in inducing DCs maturation. The protein components of selected fraction were characterized by SDS-PAGE and Mass-spectrometry. Proteomics analysis clarified that there are significant differences between DCs cytoplasmic proteome.
Conclusions: We conclude that some proteins of intracellular bacteria such as listeria monocytogenes can be considered as potent activators of human DCs in order to instruct immune responses against tumor antigens.

P6.06.114
Cloning and expression of human L- Asparaginase and study of its anti growth effect on leukemia cell lines

L. Mohammadnejad[1], *B. Baradaran*[2], *D. Shanehbandi*[2], *M. Pourhassan Moghaddam*[3], *S. Sadreddini*[2];
[1]*Immunology research center, Tabriz University of Medical Science, Tabriz, Iran,* [2]*Immunology Research Center, Tabriz University of Medical Science, Tabriz, Iran,* [3]*Faculty of advanced Medical Sciences, Tabriz University of Medical Sciences, Tabriz University of medical science, Tabriz, Iran.*

Objectives: L-Asparaginase catalyzes the hydrolysis of L-asparagine to L-aspartate and ammonia. L-Asparaginase has an antineoplastic activity selectively reduces the level of L-asparagine in blood and decreases the proliferation of cancerous cells. Consequently, it have been widely used as a therapeutic agent in the treatment of acute lymphoblastic leukemia. In the present study, we aim to produce of human L-Asparaginase enzyme and investigate of its antineoplastic effect on leukemia cell line.
Method: Total RNA was extracted from PC3 cell line and converted to cDNA. L-Asparaginase gene was amplified by RT-PCR and cloned into the PGEM- T vector. The positive clones were digested and finally confirmed by sequencing. The product was expressed in E. coli using pET-22b expression vector. Recombinant protein contained hexahistidine tag was purified using nickel-nitrilotriacetic acid chromatography. C105 cell line were treated by different concentration of purified enzyme. The cytotoxic effect of enzyme were measured by MTT assay.
Result: The sequence of cloned L-Asparaginase gene consisted of 937 bp showed 100% identity with previously reported sequence of this gene. Expression of L-Asparaginase gene in E. coli resulted in high levels of protein with molecular weight of 32 kDa in SDS-PAGE. The result of MTT assay showed that the C105 cell line is considerably sensitive to deduced protein.
Conclusion: In this study the recombinant L-Asparaginase was expressed and the anti proliferative effect of this product on a leukemia cell line was confirmed. Hence, it would be of interest to employ this recombinant protein as anti leucemic drug.

P6.06.115
Exosomes displaying high expression of CD24 and HSP90 induced cellular and humoral immune response "in vivo"

C. Mongini[1], *J. De Toro*[2], *P. Di Sciullo*[1], *F. Menay*[1], *M. Gravisaco*[3], *A. Vendrell*[4], *C. Waldner*[5], *L. Hershlik*[2];
[1]*National Research Council of Argentina (CONICET), Buenos Aires, Argentina,* [2]*National Research Council of Argentina (CEFYBO-CONICET), Buenos Aires, Argentina,* [3]*Instituto Nacional de Tecnología Agropecuaria, Castelar, Buenos Aires, Argentina,* [4]*National Research Council of Argentina (CONICET), Buenos Aires, Argentina,* [5]*National Research Council of Argentina (CONICET), Buenos Aires, Argentina.*

Exosomes have emerged as a new approach for the diagnosis and therapy of cancer. The use of these nano-vesicles as modulators of the immune system is being studied presenting them as readily available and stable tumor antigens. The objective of this work was to characterize exosomes derived from the murine T-cell lymphoma LBC and their immunogenic properties. The expression of proteins of immunological relevance, such as MHC I, CD8, CD24 and Hsp90 on exosomes membrane was demonstrated. We demonstrated surface expression of Hsp90 and intralumen Hsp70, indicative of a different protein expression pattern with the cells from which they derive. An over-expression of tumor associated antigens on LBC exosomes when compared to LBC cell lysates or even to intact LBC cells, corresponding to proteins of 51 kDa on LBC-derived exosomes that could not be detected in LBC cells, was found. These tumor antigens were recognized not only by memory lymphocytes but also induced a primary immune response in vitro and a humoral and cellular immune response in vivo, as INF gamma secreted LBC-sensitized splenocytes and specific antibodies were identified in the sera of mice immunized with LBC exosomes. In conclusion, the association of tumor-associated antigens and other molecules of immunologic interest such as MHC, Hsp or costimulatory molecules on tumor exosomes might determine the their immune properties. All these findings confirm exosomes as promising defined acellular tumor

antigens for the development of an antitumor vaccine for the immunotherapy of cancer.

P6.06.116
Imiquimod enhances anti-lymphoma response in a tumor cell lysate vaccine and inhibits tumor cells growth

***C. Mongini**, J. De Toro, L. Hershlik, M. Gravisaco, C. Waldner, P. Di Sciullo;*
National Council Research of Argentina (CONICET), Buenos Aires, Argentina.

Our aim was to study the immunomodulating and proapoptotic properties of the TLR7 agonist Imiquimod to be used as adjuvant in a tumor vaccine. Imiquimod showed an antiproliferative effect on LBC T-cell lymphoma in vitro at 48 and 72 h with doses between 0.5 and 200 µg/ml, inducing apoptosis in a dose dependent manner. BALB/c mice inoculated intraperitoneally twice with LBC cells lysates with or without 100 µg/mouse of Imiquimod and challenged one week later with LBC cells intraperitoneally, showed a significant increase in survival compared to un-immunized controls (LBC-lysate<0.05, LBC-lysate + IMQ<0.0005) and to mice receiving Imiquimod (p<0.0002; Logrank).Tumor incidence was only 5±5% in LBC-lysate+IMQ group whereas in LBC-lysate group was 52.5±2.5%. Although the percentages of specific cytotoxicity were above normal in both immunized groups (p<0.05, ANOVA), LBC-lysate+IMQ immunization induced the highest levels. A significant enhance in peritoneal cavity CD8+, CD4+ T and B cells (p<0.0001, ANOVA) with an increase IFNγ in supernatant from peritoneal cavity cells and splenocytes was demonstrated in all vaccinated groups compared to normal (p<0.001, ANOVA). Our vaccine also generated circulating antibodies in all immunized mice that rejected the tumor up to 75 days after challenge. Finally, mice that rejected the first tumor challenge were re-challenged with LBC tumor with an increased in survival in all immunized groups over the control (p<0.01, Logrank) with rejection rates close to 100%. We demonstrated that Imiquimod not only modulates immune response efficiently to reject tumor generating a long-lasting memory, but also is capable of inducing tumor apoptosis.

P6.06.117
Therapeutic activity of a combination of immunostimulatory monoclonal antibodies (anti-B7-H1, CD137 and OX40) on a c-myc-driven spontaneous transgenic model of hepatocellular carcinoma

***A. Morales-Kastresana**[1], M. F. Sanmamed[1], I. Rodriguez[1], A. Palazon[1], I. Martinez-Forero[1], S. Labiano[1], S. Hervas-Stubbs[1], B. Sangro[2], C. Ochoa[1], A. Azpilikueta[1];*
[1]CIMA, Pamplona/Iruña, Spain, [2]CUN, Pamplona/Iruña, Spain.

Several immunostimulatory monoclonal antibodies (ISmAbs) that derepress and unleash antitumor immune responses are showing efficacy in cancer clinical trials. MAbs anti-B7-H1 (PD-L1) block a critical inhibitory pathway for T cells, while antibodies anti-CD137 and OX40 provide intense T cell costimulation. Documenting efficacy of immunotherapies on spontaneous tumors arising in oncogene transgenic mice is considered more predictive than experiments on transplanted tumors. A combination of these ISmAbs has been tested on a transgenic mouse model of spontaneous primary liver cancer in which c-myc drives transformation and the tumor cells express ovalbumin as a surrogate transgenic antigen. The induced tumor lymphocyte infiltrates and immune mechanisms of action were studied. The triple combination of mAbs clearly extended survival of mice bearing hepatocellular carcinomas (HCC) and synergized with adoptive T cell therapy with activated TCR-transgenic T cells that recognize OVA. Mice undergoing therapy showed a clear increase in the tumor tissue infiltration by activated and blastic CD8 T lymphocytes expressing the ISmAb-targeted receptors. The triple combination of ISmAbs did not result in enhanced OVA-specific CTL activity but other antigens in cell lines derived from such HCC were recognized by the elicited tumor infiltrating T lymphocytes. Indeed adoptive transfer of OT-1 cells to tumor bearing mice resulted in their tolerization, unless the triple mAb therapy was instigated. Our results emphasize the role of combinational immunotherapy approaches including ISmAbs to impact on agressive and highly T cell-tolerizing hepatocellular carcinomas.

P6.06.118
Establishment of human cancer stem-like cell targeting immunotherapy

***R. Morita**[1], Y. Hirohashi[1], T. Torigoe[1], A. Takahashi[1], T. Terui[2], Y. Tamura[1], S. Hashino[3], A. Taketomi[4], S. Todo[4], N. Sato[1];*
[1]Department of Pathology, Sapporo Medical University School of Medicine, Sapporo, Japan, [2]Higashisapporo Hospital, Sapporo, Japan, [3]Hokkkaido University Health care center, Sapporo, Japan, [4]Department of General surgery, Hokkaido Univ. Graduate School of Medicine, Sapporo, Japan.

Cancer stem-like cells (CSCs) have been reported to be resistant to chemotherapy and radiotherapy. However, it is still not clear whether if CSCs are sensitive to immune cells. In the present study, we analyzed gene expression profiles of human colon CSCs and evaluated the sensitivities to immunotherapy. RT-PCR and microarray analysis revealed that tumor-associated antigens can be classified into three groups according to expression in CSCs and non-CSCs. 'Shared antigens' are expressed in both CSCs and non-CSCs, 'CSC antigens' are preferentially expressed in CSCs and 'non-CSC antigens' are preferentially expressed in non-CSCs. The potencies of CSC antigens and shared antigens were compared by using cytotoxic T lymphocyte (CTL) clones specific for a CSC antigen (OR7C1) and a shared antigen (CEP55). The CEP55-specific CTL clone and OR7C1-specific CTL clone showed almost the same level of cytotoxicity *in vitro.* On the other hand, the OR7C1-specific CTL clone showed a greater anti-tumor effect than that of the CEP55-specific CTL clone *in vivo*. These results raised the possibility that treatment-resistant CSCs are sensitive to CTLs and that CSC-targeting immunotherapy using CSC antigens is feasible.

P6.06.119
Schedule-dependent anticancer therapy by targeting TNF-alpha to tumor vessels in combination with melphalan and gemcitabine

***L. Mortara**[1], P. Orecchia[2], P. Castellani[3], L. Borsi[3], B. Carnemolla[4], E. Balza[3];*
[1]Department of Biotechnology and Life Sciences, Univ. of Insubria, Varese, Italy, [2]Department of Experimental Medicine, Univ. of Genova, Genova, Italy, [3]Lab of Cell Biology, Department of Translational Oncology, IRCSS AOU San Martino-IST, Genova, Genova, Italy, [4]Lab of Immunology, Department of Translational Oncology, IRCSS AOU San Martino-IST, Genova, Genova, Italy.

L19-tumor necrosis factor-alpha (L19mTNF-a, L), a fusion protein consisting of mouse TNF-a and the human antibody fragment L19 directed to the ED-B of fibronectin, is able to selectively target tumor vasculature, and act synergistically with melphalan (M) in syngeneic mouse tumor models. We have studied the antitumor activity of single L treatment in combination with M and gemcitabine (G) using different administration protocols in two different murine tumor models: WEHI-164 fibrosarcoma and K7M2 osteosarcoma. Single L/M therapy and two injections of G alone exerted similar therapeutic effect curing 80-90% of WEHI-164 tumor, respectively, and 20% of K7M2 tumor-bearing mice. Combination studies of the three drugs showed that when 2 injections of G were administered after L/M the percentage of cured mice was unchanged in WEHI-164 tumor treated mice (80%), whereas in K7M2 tumor mice greatly improved (from 20% up to 80%). On the contrary, when G was administered before L/M, a strong antagonist effect was induced with reduction of tumor cure rate. All responding mice showed significant reduction of CD11b+Gr-1+ MDSC and an increase of CD4+ and CD8+ T cells in tumor infiltrates, as well as significant reduction of CD4+CD25+ Treg cells at the level of draining lymph nodes. What is important, is that all cured mice rejected tumor challenge up to one year after therapy. Targeted delivery of L19mTNF-a synergistically increases the antitumor activity of melphalan and gemcitabine, but optimal administration schedules are required. This investigation provides information for designing clinical studies using L19mTNF-a in combination with chemotherapeutic drugs.

P6.06.120
High-level expression of IGFBP-3 by recombinant vaccinia virus leads to its incorporation into IMV and affects virus replication and immunogenicity

***J. Musil**, L. Kutinova, K. Zurkova, P. Hainz, K. Babiarova, J. Krystofova;*
Institute of Hematology and Blood Transfusion, Prague, Czech Republic.

The aim of this study was to investigate, whether the tumor-suppressive properties of Insulin-like growth factor-binding protein-3 (IGFBP-3) can be used to enhance the efficiency of therapeutic immunization against the HPV16 E7 oncogene associated with cervical cancer. We constructed recombinant vaccinia viruses (rVACV) co-expressing the immunogen SigE7Lamp and IGFBP-3. The expression of IGFBP-3 was controlled either by the early promoter H5 or by the synthetic early-late (E/L) promoter. Our results show that IGFBP-3 expression under the H5 promoter (P13-SigE7Lamp-H5-IGFBP-3) is significantly higher than under E/L promoter(P13-SigE7Lamp-E/L-IGFBP-3) (***p<0.001). The mice bearing TC-1 tumors treated with P13-SigE7Lamp-H5-IGFBP-3 had significantly smaller tumors than PBS-treated mice by day 11 (*p<0.05), whereas mice treated with P13-SigE7Lamp-E/L-IGFBP-3 or the control virus P13-SigE7Lamp-TK$^-$ had significantly smaller tumors by day 18 (***p<0.001). Co-expression of IGFBP-3 increased T cel l response against VACV antigen but not against HPV16 E7 antigen as determined by ELISPOT IFN-γ. *In vitro* analysis of virus multiplication has shown that P13-SigE7Lamp-H5-IGFBP-3 has significantly higher replication rate than P13-SigE7Lamp-TK$^-$ or P13-SigE7Lamp-E/L-IGFBP-3 (***p<0.001) and that adding an IGFBP-3 neutralizing antibody significantly decreased yields of P13-SigE7Lamp-H5-IGFBP-3 (**p<0.01). Furthermore, using Western-blot analysis we detected insertion of IGFBP-3 into virions of P13-SigE7Lamp-H5-IGFBP-3. We therefore hypothesize that incorporation of IGFBP-3 into intracellular mature virus helps virus replication. Indeed, our results show that cell absorption rate of P13-SigE7Lamp-H5-IGFBP-3 is significantly higher than P13-SigE7Lamp-TK$^-$ (*p<0.05). Summarized, higher cell absorption leads to overall better replication and thus resulting in prolonged and enhanced antigen stimulation during immunization.

P6.06.121
Syntesis of matrix and matrix metalloproteases in 2D and 3D cultures of pancreatic cells

***E. V. Myrsikova**, E. N. Kaliberda, E. V. Svirshchevskaya;*
Shemyakin and Ovchinnikov Institute of Bioorganic Chemistry RAS, Moscow, Russian Federation.

Degradation of tissue matrix and vessel formation is essential for tumor growth. Matrix metalloproteases (MMPs) constantly degrade surrounding matrix and form new niches for growth. Models possessing ability to study cell interactions with matrix are essential. The aim of this work was to study synthesis of matrix and MMPs in 3D cultures of pancreatic cell lines. Supernatants of 3D cultures of AsPC-2, Colo 357, BxPC-3, and Su86.86 pancreatic cell lines, obtained on poly-HEMA films, were collected at 24, 48 and 72 hrs and subjected to casein and gelatin zymography to identify enzymatic activity. Matrix formation was studied by confocal microscopy in 3D cultures stained with cumarin. We demonstrated that different cells secrete different sets of MMPs however bands with MW 20; 40; 88; 95; 118 kDa were present in all gelatin zymorgams; while 40 kDa band varied in casein gels. Maximum production for all type of cells was observed at 24 hrs. Both active and latent forms of MMP 7 and 9 were identified. Higher secretion was found in 2D cultures, possibly due to the easier MMPs secretion. Secretion of MMPs decreased in a row: BxPC-3>AsPC-1>Colo-375>Su86.86=PANC-1. MCTS formed acellular matrix around spheroids which also differed for different cells. The depth of matrix decreased in a row: BxPC-3>AsPC-1>Colo 357. We were unable to register matrix shell around Su86.86 and PANC-1. There results show a good correlation between MMP and matrix synthesis.
This work was facilitated by funding from the European Union Framework Program 7 (SaveMe) project.

P6.06.122
Selective killing of activated B-cells and inhibition of antibody production with bispecific CD20 x CD95 antibodies

***K. Nalivaiko**[1], M. Hofmann[1], L. Grosse-Hovest[2], P. H. Krammer[3], H. Rammensee[1], G. Jung[1];*
[1]Interfaculty Institute for Cell Biology, Department of Immunology, Tübingen, Germany, [2]Synimmune GmbH, Tübingen, Germany, [3]Division of Immunogenetics, Tumor Immunology Program, German Cancer Research Center, Heidelberg, Germany.

Multimeric monoclonal antibodies directed to the death receptor (CD95/APO-1/Fas) are capable of inducing apoptosis in CD95 expressing and -sensitive cells. However, clinical application of such agonistic antibodies, e.g. to achieve killing of CD95 expressing human cells is precarious, due to expression of CD95 on normal tissue, such as liver.
In 2001 we reported that CD95 antibodies, hybridized to a second antibody directed against a different target antigen on the same cell, such as CD20 and CD40, induce apoptosis of the cells if the expression of the target antigen exceeds a certain threshold level. This concept seeks to refine CD95 targeting by developing bispecific reagents which restricts CD95 agonistic activity to cells carrying a second target antigen.
While this principle was originally applied to malignant cells the data we present here demonstrate that CD20 X CD95 bispecific antibodies kill activated CD95 expressing human B-cells and that antibody production by pokeweed mitogen (PWM) stimulated B cells is markedly reduced. The bispecific antibodies are significantly more effective in mediating these effects than monospecific CD20 antibodies. Our results confirm that normal B-cells acquire sensitivity to CD95 mediated apoptosis and that bispecific CD20 X CD95 antibodies may be used to effectively suppress antibody production not only in vitro but also in patients with antibody mediated autoimmune diseases. Compared to monospecific CD20 antibodies those reagents offer a new effector principle and specificity for activated rather than resting B cells.

P6.06.123
Modulating effects of different doses of 5-flurouracil (5-FU) on the maturation and function of dendritic cells (DC) in vitro

***A. Namdar**[1], M. Hafezi[2], N. Khosravianfar[2], A. Rezaei[1], J. Hadjati[2];*
[1]Immunology department, School of Medicine, Isfahan University of Medical Sciences, Isfahan, Iran, [2]Immunology department, School of Medicine, Tehran University of Medical Sciences, Tehran, Iran.

Backgound: Cancer chemotherapy drugs are detrimental to immune cells due to their generalized cytotoxic effects. However, accumulating evidences demonstrate that suboptimal doses of some of these drugs, are not only cytotoxic, but also can augment tumor immunity by various mechanisms, especially by affecting tumor suppressive cells such as myeloid derived suppressor cells (MDSC). Moreover, in recent years, combination of chemotherapeutic agents and dendritic cell therapy has shown promising results in cancer immunotherapy. In this research, we evaluated effects of different non-cytotoxic doses of 5-Fluorouracil (5-FU) on the maturation and functional characteristics of bone marrow derived dendritic cells (BM-DC) of mouse.
Methods: DCs were generated from C57BL/6 bone marrow cells by standard protocol in the presence of different concentrations of 5-FU. Production of IL-10 and IL-12 by DCs were evaluated using ELISA and maturation markers for DCs by flowcytometry.
Results: The results showed that different doses of 5-FU have modulating effects on the maturation and functional characteristics of DCs.The effect of 5-FU on DCs was dose dependent.
Conclusion: According to the findings of the current study suboptimal doses of 5-FU have different effects on DCs function, which should be considered in combination therapy of cancer in clinical setting.

P6.06.124
Outer membrane proteins and vesicle proteins targeted as new vaccine strategies for pathogenic gram negative bacteria through particulate delivery system

***B. Nayak**, P. R. Rauta;*
National Institute of Technology Rourkela, Rourkela, India.

Virulence-related outer membrane proteins (OMPs) are expressed in pathogenic Gram-negative bacteria such as *Aeromonas hydrophila and Vibrio cholerae* and are essential to bacterial survival within macrophages and for eukaryotic cell invasion. The outer membrane proteins of enteric pathogens are one of several factors involved in the interaction between the bacterium and the epithelial cell surface, and confer bacterial resistance to bile salts and to host defense factors such as lysozyme and leukocyte proteins. OMVs (Outer membrane vesicles) also function in transport of virulence factors, adherence to and entry into host cells, or modulation of the host response. So the undertaken work is important in predicting PLA/Chitosan conjugated Omp/Omv microparticles (MPs) as a better delivery system and may offer an enhanced optimal immune response against Omp, so that Omp and Omv can be established as successful vaccine candidates both in lower and higher vertebrates against respective gram negative bacteria. Outer membrane proteins (Omps) from *A. hydrophila*, one of the bacterial pathogens causing aquatic diseases has been isolated and characterized by SDS PAGE. PLA based microparticles encapsulating Omps/Omvs antigens from *A. hydrophila* have been formulated using a double emulsion-solvent (W/O/W) evaporation technique. Preparation of Chitosan based antigen loaded microparticles and Chitosan coated PLA microparticles encapsulating antigens are under progress. Various encapsulation studies, interaction studies with the microparticles have been performed. We are continuing with stabilization experiments of Omp and Omv proteins from *A. hydrophila*.

P6.06.125
Down-regulation of pro-angiogenic and pro-metastatic genes in scFvs treated breast cancer cells

***F. Nejatollahi**[1,2], V. Younesi[2], M. Asgharpour[2];*
[1]Shiraz HIV/AIDS Research Center, Shiraz University of Medical Sciences, Shiraz, Iran, [2]Human Recombinant Antibody Laboratory, Department of Immunology, School of Advanced Medical Sciences and Technologies, Shiraz University of Medical Sciences, Shiraz, Iran.

Introduction: Intra-tumoral angiogenic and metastatic genes expression seem to be closely linked to HER2 expression level on breast cancer cell. Tumor cells secrete chemokines and matrix metalloproteinases (MMPs) in the tumor microenvironment. The expression levels of CXCL10, CXCL10L (CXCR3) and MMP-2 are closely related to each other and play critical roles in tumor cell proliferation, angiogenesis, and metastasis. In this study the effects of single chain antibodies (scFvs) against HER2 on the expression of pro-angiogenic and pro-metastatic genes were investigated.
Methodology: Following 48 hours treatment of scFvs (three human anti-HER2 scFvs had been previously isolated against HER2 epitopes in our laboratory) with SKBR3 cell line, total RNA was extracted and used for cDNA synthesis. Quantitative real-time PCR was done in triplicate using specific primers to measure CXCL10, CXCL10L (CXCR3) and MMP-2 transcripts.
Results: After 48 h treatments of SKBR3 cells with scFvs, down-regulation of CXCR3, CXCL10 and MMP2 gene transcripts were observed.
Conclusions: Studies have revealed a role for endogenous CXCL10/CXCR3 axis in the cell proliferation and invasion of breast cancer. MMPs are associated with tumor cell metastasis and angiogenesis, by clearing a path for migrating tumor cells and activating pro-angiogenic molecules. In the present study, gene expression of pro-angiogenic and pro-metastatic factors were investigated in scFvs treated breast tumor cells. Anti-HER2 scFvs, down-regulated the CXCR3 , CXCL10, and MMP2 transcripts in breast cancer cells. The results suggest that anti-HER2 scFvs are able to inhibit breast cancer cell line invasion via signaling pathways involving MMP-2 and CXCR3/CXCL10 axis.

P6.06.126
Down-regulation of Epidermal Growth Factor in a breast cancer cell line treated with anti-HER2 single chain antibodies

***F. Nejatollahi**[1,2], M. Asgharpour[3], V. Younesi[4];*
[1]Shiraz HIV/AIDS Research Center, Shiraz University of Medical Sciences, Shiraz, Iran, [2]Human Recombinant Antibody Laboratory, Department of Immunology, School of Advanced Medical Sciences and Technologies,Shiraz University of Medical Sciences, Shiraz, Iran, [3]Human Recombinant Antibody Laboratory, Department of Immunology, School of Advanced Medical Sciences and Technologies, Shiraz University of Medical Sciences, Shiraz, Iran, [4]Human Recombinant Antibody Laboratory, Department of Immunology, School of Advanced Medical Sciences and Technologies,, Shiraz University of Medical Sciences, Shiraz, Iran.

Introduction: Epidermal growth factor receptor 2 (HER2) is over-expressed in certain different carcinomas such as breast cancer. Homo- and hetero-dimerization of HER2 with other members of HER family induce phosphorylation of tyrosine residues within the intracellular domain of receptor. These residues provide docking sites for adaptor proteins and link the HER2 to downstream survival, growth and angiogenic networks. In the current study the effect of specific scFvs against HER2 epitopes on the Epidermal Growth Factor (EGF) expression in cancer cells were investigated
Methodology: Three human anti-HER2 scFvs previously isolated against HER2 extracellular domains in our laboratory were used to treat SKBR3 breast cancer cell line individually and in combination. After 48 hours the expression of Epidermal Growth Factor was measured using real time PCR.
Results: Significant downregulation of EGF was observed when a cocktail containing the three scFvs were used.
Conclusions: Expression profile of HER family members on tumor cells, growth and survival of breast tumor cells may be affected by an autocrine loop between the HER family members and their ligands; like Epidermal growth factor (EGF). This loop could be disrupted by down-regulation of EGF expression in breast cancer cell line following treatment by anti-HER2 scFvs cocktail. However, individual scFvs were not able to inhibit EGF gene expression.This offers that the scFvs cocktail containing three specific scFvs against HER2, could be more useful for inhibition of tumor growth and proliferation.

P6.06.127
IL-12 immunotherapy: characterization of a CD4+ effector population

***M. E. Nelles**[1], C. L. Furlonger[1], J. A. Medin[1,2,3], C. J. Paige[1,2,4];*
[1]Ontario Cancer Institute, University Health Network, Toronto, ON, Canada, [2]Department of Medical Biophysics, University of Toronto, Toronto, ON, Canada, [3]Institute of Medical Sciences, University of Toronto, Toronto, ON, Canada, [4]Department of Immunology, University of Toronto, Toronto, ON, Canada.

The ability of interleukin-12 (IL-12) to initiate anti-cancer immune responses is well established, and this cytokine was recently ranked 3rd on a list of agents rated for their potential to treat cancer during the NCI Immunotherapy Agent Workshop. We have therefore used a murine leukaemia model to characterize the immune response initiated by a cell-based immunotherapy approach employing IL-12. This approach leads to protective immunity, but initial rejection is surprisingly dependent primarily on a CD4+ cellular subset. In contrast, injection of recombinant IL-12 leads to CD8+ T cell-mediated rejection. This highlights that the mode of IL-12 delivery has a distinct impact on the immune response initiated.
To further characterize this CD4+ effector population, as well as derive mechanistic information, in vitro assays have been established. We have demonstrated that NKT cells play a critical role in activating a DC population that subsequently drives the maturation of these cytotoxic CD4+ T cells, eventually leading to clearance of the leukaemia cells. Though CD4+ T cells are known to possess cytotoxic capacity, little is understood about the physiological role that a CD4+ CTL might play. Description of such a population that arises naturally, without targeted manipulation of the experimental system, is of great interest. Our work begins to address what stimuli are responsible for activation of this CD4+ effector population and the mechanisms they use to mediate cancer eradication.

P6.06.128
EBV-transformed Lymphoblastoid Cell Lines as Vaccines against Cancer Testis Antigen-positive Tumors

F. Neumann[1], *D. Kaddu-Mulindwa*[1], *T. Widmann*[1,2], *K. D. Preuss*[1], *G. Held*[1], *C. Zwick*[1], *K. Roemer*[1], *M. Pfreundschuh*[1], *B. Kubuschok*[1];
[1]*José Carreras Center for Immuno- and Genetherapy, Department of Internal Medicine I, Saarland University Medical School, Homburg, Germany,* [2]*ACURA Waldklinik Dobel, Dep. of Internal Medicine/Oncology, 75335 Dobel, Germany.*

EBV-transformed lymphoblastoid cell lines (LCL) are potent antigen-presenting cells. To investigate their potential use as cancer testis antigen (CTA) vaccines, we studied the expression of 12 CT genes in 20 LCL by RT-PCR. The most frequently expressed CT genes were SSX4 (50 %), followed by GAGE (45 %), SSX1 (40 %), MAGE-A3 and SSX2 (25 %), SCP1, HOM-TES-85, MAGE-C1, and MAGE-C2 (15 %). NY-ESO-1 and MAGE-A4 were found in 1/20 LCL and BORIS was not detected at all. Fifteen of 20 LCL expressed at least one antigen; 9 LCL expressed ≥2 CT genes, and 7 of the 20 LCL expressed ≥4 CT genes. The expression of CT genes did not correlate with the length of *in vitro* culture, telomerase activity, aneuploidy or proliferation state. While spontaneous expression of CT genes determined by real time PCR and Western Blot was rather weak in most LCL, treatment with DNA methyltransferase 1 inhibitor alone or in combination with histone deacetylase inhibitors increased CTA expression considerably thus enabling LCL to induce CTA-specific T-cell responses. The stability of the CT gene expression over prolonged culture periods makes LCL attractive candidates for CT vaccines both in hematological neoplasias and solid tumors.

P6.06.129
ENO1-specific Tregs frustrate Th1/Th17 effector cells isolated from pancreatic cancer patients

E. Niccolai[1,1], *P. Cappello*[2], *C. della Bella*[1], *M. Benagiano*[1], *F. Cianchi*[1], *L. Bencini*[1], *F. Novelli*[2], *M. D'Elios*[1], *A. Amedei*[1,3];
[1]*University of Florence, Florence, Italy,* [2]*University of Turin, Turin, Italy,* [3]*Department of Experimental and Clinical medicine, Florence, Italy.*

Pancreatic cancer (PC) is an aggressive disease with dismal prognosis. Surgical resection is the recommended treatment for long-term survival, but patients with resectable PC are the minority (with a 5-year survival rate of 20%). Therefore, development of novel therapeutic strategies, such as anti-PC immunotherapy, is crucial. α-Enolase (ENO1) is an enzyme expressed on the surface of pancreatic cancer cells, and it is able to promote cell migration and cancer metastasis. The capacity of ENO1 to induce an immune response in PC patients renders it a true tumor-associated antigen. In this study we characterized the effector functions of ENO1-specific T-cells, isolated from PC patients and we specifically evaluated the successful role of intra-tumoral Th17 (T helper 17 cells) and the inhibitory role of Tregs (regulatory T cells) in promoting or reducing respectively the cancer-specific immune response. In this ex-vivo study, we have demonstrated, for the first time, that in PC patients, ENO1-specific Th17 cells have a specific anti-cancer effector function, and that there are decreased levels of these cells in cancer compared to healthy mucosa. In PC patients, there are elevated levels of ENO1-specific Tregs which leads to inhibition of the antigen-specific effector T cells, thus highlighting a possible role in promoting PC progression. These results might be relevant for the design of novel immunotherapeutic strategies in pancreatic cancer.

P6.06.130
IgE as a new player in tumor surveillance

E. Nigro[1], *V. Yenagi*[2], *E. Soprana*[1], *A. T. Brini*[2], *A. G. Siccardi*[1], *L. Vangelista*[1];
[1]*San Raffaele Scientific Institute, Milan, Italy,* [2]*Dipartimento di Scienze Biomediche, Chirurgiche ed Odontoiatriche, Università degli Studi di Milano, Milan, Italy.*

IgE is a key player in anti-parasitic immunity and allergies. Several research groups found that IgE may exert powerful anti-tumor potency *in vivo*, opening a new field of investigation named AllergoOncology. In our approach, mouse and human IgE have been employed as vaccine adjuvants, highlighting the importance of the IgE-FcepsilonRI interaction in the establishment of a strong allergy-like inflammatory response at the tumor site, with the induction of an adaptive anti-tumor immune response and memory. These results and epidemiological studies suggesting an inverse association between allergy and malignancies, directed our attention towards a possible role played by endogenous IgE in tumor surveillance. Strikingly, transgenic (high IgE-producing) mice immunized with irradiated TS/A-LACK mammary tumor cells are completely resistant to tumor growth after challenge with living TS/A-LACK cells. Using N2C cells, a HER2/*neu*-expressing tumor model, absence of tumor development occurs even without immunization. In order to definitely prove the involvement of endogenous IgE in the anti-tumor protection observed in this *in vivo* system, we generated a double mutant (high IgE-producing/FcepsilonRIalpha knock out) mouse. As expected, this new transgenic mouse develops the N2C tumor due to the inability of IgE to exert its effect in the absence of FcepsilonRI. Furthermore, sera from high IgE-producing mice challenged with N2C cells contain tumor-specific IgE, as evinced from a cell-based mediator release assay.
Among the future directions, a relevant effort is being spent in the detection and isolation of tumor-specific IgE mAbs from challenged high IgE-producing mice, opening new perspectives in cancer treatment.

P6.06.131
First exploration of clinical value of telomerase expression in triple-negative breast cancer tissues

M. Nikolay[1], *E. Gross*[1], *R. Napieralski*[1], *H. Jansen*[1], *F. Yang*[1], *M. Kiechle*[1], *M. Aubele*[2], *M. Schmitt*[1];
[1]*Frauenklinik, Klinikum rechts der Isar, Munich, Germany,* [2]*Helmholtz Zentrum, Munich, Germany.*

The human telomerase is an enzyme which is involved in cell senescence and division, providing DNA-protective functions during replication. It is suppressed in most of normal somatic cells but becomes active in malignant tumors. The goal of this project was to evaluate expression of human telomerase reverse transcriptase (hTERT), which is a catalytic subunit of telomerase, in triple-negative breast cancer tissue samples and the breast cancer cell line MDA-MB-435.
For evaluation of hTERT protein expression, immunohistochemistry (IHC) with a polyclonal antibody (600-401-252S, Rockland) against hTERT was performed; for gene expression qRT-PCR was employed. For IHC, 178 triple-negative breast cancer cases were assessed on tissue microarrays (TMA), for qRT-PCR the cell line MDA-MB-435. Since active telomerase associates with the nucleus, evaluation of hTERT by IHC was judged on the absence or presence of nuclear staining. Cases with nuclear staining were considered as positive. Staining results were statistically compared with clinicopathological data of the patients and their 5-year overall and disease-free survival (n=146).
Nuclear staining was observed in 29% (43 out of 146 patients) of the cases. Presence of nuclear staining was statistically significantly correlated with low-grade (G1) tumors (p=0.008). Patients with nuclear expression of hTERT had a tendency for better 5-year overall survival (p=0.068). In the MDA-MB-435 cell line, expression of hTERT gene was very low in comparison with the expression of the house-keeping gene HMBS.
Expression analyses of hTERT provided interesting results, but larger collectives of triple-negative breast cancer are needed for further investigation.

P6.06.132

Tumor-associated antigen-specific CD4$^+$ T-cell immunity augmented by CTL-epitopes vaccination in patients with malignant tumor

*Y. Tomita[1], A. Yuno[1], H. Tsukamoto[1], Y. Yoshitake[1], T. Tsunoda[2,3], Y. Nakamura[3], M. Shinohara[1], **Y. Nishimura**[1];*
[1]Graduate School of Medical Sciences, Kumamoto University, kumamoto, Japan, [2]OncoTherapy Science Incorporation, Research and Development Division, Kanagawa, Japan, [3]Laboratory of Molecular Medicine, Human Genome Center, Institute of Medical Science, the University of Tokyo, Tokyo, Japan.

We identified novel tumor associated antigens (TAAs) including CDCA1, LY6K and KIF20A that are overexpressed in lung cancer, head and neck malignant tumor (HNMT), pancreatic cancer, and other various malignancies, but not expressed in many adult normal tissues except for testis and fetal organs by using cDNA microarray analyses. Recently,
we identified TAAs-derived CTL-epitopes that can activate tumor-reactive and HLA-A2 or -A24-restricted CTLs in both *in vitro* preclinical and *in vivo* peptide vaccine clinical studies. In this study, we identified these TAAs-derived promiscuous 20~26-mer long peptides (LPs) bearing CTL-epitopes that can induce Th1 cells restricted by several frequent HLA class II and tumor-specific CTLs restricted by HLA-A2 or -A24. The LPs were naturally processed and presented by dendritic cells. In addition, these LPs induced propagation of TAA-specific CTLs by cross-presentation in both human *in vitro* and HLA-class I transgenic mice *in vivo*. Furthermore, these LPs and Th1 cell clone enhanced induction of TAA-specific CTLs of HNMT patients. Significant frequencies of TAA-specific Th1 cells were detected after short-term *in vitro* stimulation with LPs in HNMT patients vaccinated with TAA-derived CTL-epitope peptides and patients before vaccination, but not in healthy donors; responses were augmented by repeated vaccinations. These results show for the first time the presence of novel TAA-specific Th1 cell responses in HNMT patients and underline the potential utility of these LPs for propagation of both antigen-specific Th1 cells and CTLs.

P6.06.133

Effect of mature dendritic cells primed with autologous tumor antigens, patients with epithelial ovarian cancer to stimulate the cytotoxic activity of mononuclear cells in vitro

***I. Obleuhova**[1], V. Kurilin[1], M. Goncharov[2], A. Tarkhov[2], S. Krasilnikov[3], S. Sennikov[1];*
[1]Institute for Clinical Immunology, Novosibirsk, Russian Federation, [2]Municipal Hospital № 1, Novosibirsk, Russian Federation, [3]Cancer dispantser, Novosibirsk, Russian Federation.

Along with conservative treatment of epithelial ovarian carcinoma, which has the highest frequency of occurrence of gynecological cancers, specific immunotherapy is a modern and advanced way of treating the disease. Special role in the immunotherapy vaccine therapy is based on dendritic cells (DC). Therefore, the purpose of this study was to assess the effectiveness of the modulation of cytotoxic activity in vitro (in a culture of mononuclear cells) using autologous dendritic cells and tumor antigens patients with epithelial ovarian cancer.
We used peripheral venous blood and tumor biopsy samples obtained during surgery for removal in 23 patients with ovarian epithelial carcinoma at the age of 41-80 years. Dendritic cells were obtained by adhesion on plastic. To obtain antigen-loaded DCs after 48 hours of culture was added to immature DCs tumor antigen (autologous tumor lysate). As the factor of maturation after 24 hours was introduced rhTNF-α. A day later, received dendritic cells were cultured for five days with a non-adherent fraction of MNCs in the ratio of 1:10 with the addition rhIL-18 and rhIL-12. Modulation efficiency was assessed by cytotoxic activity MNCs against autologous tumor cells, production of IFN-γ and the number of perforin-containing lymphocytes. Demonstrated the ability of DCs primed lysate antigens of tumor cells to stimulate the cytotoxic activity of MNCs in more than 2-fold compared with the DC, untreated lysate, increase the number of perforin-containing lymphocytes and increased production of IFN-γ).Addition of IL-12 and IL-18 contributed to the strengthening of the effects obtained in co-culture with DCs.

P6.06.134

Immunotherapeutic and toxic effects of a triple fusion protein encompassing apolipoprotein A-I, interleukin-15 and the interleukin-15 receptor α sushi domain

***M. C. Ochoa**[1], J. Fioravanti[1], R. Inmaculada[1], S. Hervas-Stubbs[1], A. Azpilicueta[1], G. Mazzolini[2], A. Gurpide[3], J. Prieto[1], P. Berraondo[1], I. Melero[1,3];*
[1]FIMA, Pamplona, Spain, [2]Austral University, Buenos Aires, Argentina, [3]Clinica Universidad de Navarra, Pamplona, Spain.

Interleukin 15 (IL-15) effects on CD8 T and NK lymphocytes hold promise to treat cancer. Fusion proteins have been engineered to provide IL-15 receptor alpha (IL-15Rα) mediated trans-presentation to lymphocytes and extend the plasma half-life of the cytokine. In this study, we report on a triple fusion protein combining apolipoprotein A-I, IL-15 and IL-15Rα's sushi domain. Apolipoprotein A-I conveys IL-15 to high-density lipoproteins (HDL), from which the cytokine is trans-presented by the IL-15Rα´s sushi domain. Such a construction was tested by hydrodynamic gene transfer to the liver of mice. Lethal toxicity was observed upon injection of 10µg of the expression plasmid. Mice died from an acute lymphocytic pneumonitis in which T and NK cells dominate a severe inflammatory infiltrate. Importantly, mice devoid of NK cells were not susceptible to such toxicity and mice lacking granzymes A and B also survived the otherwise lethal gene transfer. Lower plasmid doses (<2.5µg) were tolerated and dramatically increased the numbers of NK and memory CD8 T lymphocytes in the liver, spleen and lungs, to the point of rescuing the deficiency of such lymphocyte subsets in IL-15Rα$^{-/-}$ mice. Doses of plasmid within the therapeutic window successfully treated metastatic tumor models, including B16OVA lung metastasis of melanoma and MC38 colon cancer liver metastasis. Sushi-IL15-Apo as a recombinant protein was also bioactive *in vivo*, became conjugated to HDL and displayed immuno-therapeutic effects against metastatic disease.

P6.06.135

Cytotoxic effect of methanolic fractions of Scrophularia oxysepala on MCF-7 human breast cancer cell line

***M. Orangi**[1], B. Baradaran[1], T. Kazemi[1], A. Pasdaran[2], J. Majidi Zolbanin[1], B. Hosseini[1], L. Mohammadnejad[1];*
[1]Immunology Research Center, Tabriz University of Medical Sciences, Tabriz, Iran, [2]Department of Pharmacognosy, Faculty of Pharmacy, Guilan University of Medical Sciences, Rasht, Iran.

Background: Cancer is a major public health problem in both developed and developing countries. It is the second largest common disease spread world-wide. Drug toxicity and resistance to chemotherapeutic agents make a struggle to treat cancer. For this reason, initial research focuses on traditional medicines or herbal formulations. As we know, breast cancer is the most commonly occurring cancer among women (about 25%). So, the cytotoxic effect of methanolic fractions of Scrophularia oxysepala was investigated in human breast cancer MCF-7. Scrophularia oxysepala plant was collected from Eastern Azarbaijan province, Iran. This is the first time that cytotoxic effect of Scrophularia oxysepala fractions and cell death mechanism of it, is studied.
Methods: The MCF-7 and L929 cells were seeded in 96-well culture plates in the presence of different concentrations (30, 50, 100, 200, 300 µg/µl) at 12, 24, 36 hours and then results were followed to determine cytotoxic effects on viability and apoptosis by MTT, TUNEL and DNA fragmentation.
Result: The obtained results declared that certain concentrations have cytotoxic effect on MCF-7 cell line and induce apoptosis while L929 cells, as normal cell line, remained intact.
Conclusion: Increased concentration of the fractions and treating time reduced cell viability. Our data showed that methanolic fractions of Scrophularia oxysepala have an apoptotic effect on MCF-7 cells and it might be an effective agent in cancer treatment.

[1]*Dipartimento di Medicina Interna e Specialità Mediche, "Sapienza" University of Rome, Rome, Italy,* [2]*Dipartimento di Medicina Interna e Specialità Mediche,, Rome, Italy,* [3]*Dipartimento di Medicina Interna e Specialità Mediche, "Sapienza" University of Rome, Italy, Rome, Italy.*

Immunogenic cell death has been defined in mice by the ability of inducing a protective CD8 mediated immune response in tumor challenge experiments. To prove this hypothesis in human we took advantage of a reverse immunology approach by which apoptotic immunogenic antigens have been identified in ovarian cancer patients. Proteins induced ex-vivo in primary tumors by chemotherapy treatment were isolated and ranked according to immunological properties as indicated by IFNγ ELISPOT. A small number of proteins turned out to be immunogenic and were further analyzed by FACS analysis. Both memory CD4 and CD8 responses were observed upon overnight stimulation with selected proteins showing either a Th1 or a Th17 phenotype. Interestingly immune responses showed a statistical significant increase in patients who respond to chemotherapy than in non-responders. Immunogenic proteins isolated from 2D gel were therefore identified by mass spectrometry. Analysis of protein annotations showed an enrichment of anti apoptotic pathways suggesting a potential biological role of the immune correlates. The immunogenic properties of a subset of proteins were further confirmed using recombinant proteins opening the possibility of developing a predictive assay based on the immune responses. The T cell interrogation system represents a new strategy of reverse tumor immunology that proposes to identify chemotherapy induced tumor-associated antigens, which may then be validated as possible diagnostic tumor biomarkers or included in the design of neoadjuvant tumor vaccines.

P6.06.137
G1-4A, a polysaccharide from T. Cordifolia induces killer phenotype and increases dendritic cell immunogenicity in murine lymphoma model

V. K. Pandey*, B. Shankar, K. B. Sainis;
Bhabha Atomic Research Center, Mumbai, India.*

Dendritic cells (DC) play a central role in the development of adaptive immune response against tumor. DC are the only professional antigen presenting cells which generate a specific T cell response against tumor cell by the process of cross-presentation. In addition to activating cytotoxic T cells, DC also possess direct killer activity against tumor cells. In this study, we have investigated the effect of TLR4 agonist G1-4A, an arabinogalactan derived from *T. Cordifolia* to induce killer activity as well as maturation of DC. Immature bone marrow derived dendritic cells (BMDC) were treated with G1-4A for 48 hr. We observed increased expression of co-stimulatory molecules CD40/80/86 and MHC II which also serve as DC maturation markers. Augmentation of IL-12 and TNF-α production was also seen. Functional maturation of G1-4A treated DC was assessed by mixed leucocyte reaction. In addition to activating cytotoxic T cells, G1-4A treated DC co-cultured with tumor cells (E:T- 25:1) showed 35% increase in direct cytotoxicity as assessed by flow cytometry. This increased killer activity was associated with an increase in iNOS expression and nitric oxide production. DC can acquire tumor antigens through uptake of soluble antigens released from dying tumor cells or phagocytosis of apoptotic tumor bodies and this process could be expedited by direct killing of tumor cells. Tumor cell lysate pulsed mature BMDC (G1-4A) significantly decreased the tumor burden in a murine lymphoma model. The implication of differential efficacy of lysate pulsing and direct tumor cell killing to DC based tumor immunotherapy will be discussed.

P6.06.138
Bivalent CD28 agonistic aptamer: a novel adjuvant-vaccine for lymphoma

F. Pastor*, M. M. Soldevilla, H. Villanueva, S. Inoges, A. L. de Cerio, M. Bendandi;
CIMA, Pamplona, Spain.*

Tumor vaccination is one of the main cancer immunotherapy strategies. It aims at stimulating a systemic immune response targeted to antigens expressed in the tumor lesions. One of the main challenges in developing effective vaccination protocols are the identification of expressed tumor-specific antigens and effective adjuvants which can stimulate a robust and durable immune response. Among the very few tumor-specific antigens described so far, probably the only one that can be identified in all patients with B-cell lymphoma is the idiotype, which is contained in the variable region of the tumor immunoglobulin. In this work, we have selected by SELEX a CD28 aptamer. As previously described, the agonistic capacity of an aptamer is achieved by dimerization. Two different dimeric forms were tested. Even though both dimeric forms preserved similar affinity for CD28, the costimulatory capacity was considerably improved, with a shorter and more flexible linker, surpassing the costimulatory capacity of agonistic anti-CD28 antibodies. In order to study the adjuvant effects of the CD28 dimeric agonistic RNA aptamer, A20 lymphoma-bearing mice were vaccinated with the lymphoma-idiotype complex with the CD28 agonistic aptamer. Mice treated with this vaccine formulation showed a significant increase in the overall survival compared to control groups. Mice vaccinated with A20 idiotype complex with the CD28 agonistic aptamer showed a more potent immune response, measured by IL-2 and INF-g production, and higher titers of anti-idiotype antibodies.

P6.06.139
Abrogation of tumor-associated immunosuppression by targeting tumor-infiltrating regulatory T-cell function can restore impaired T cell responses in patients with liver cancer

A. Pedroza Gonzalez[1], *J. Kwekkeboom*[1], *S. P. Singh*[1], *E. Tjwa*[1], *W. G. Polak*[1], *D. J. Grünhagen*[1], *K. Biermann*[1], *J. N. M. Ijzermans*[1], *H. L. A. Janssen*[1], *D. Sprengers*[2];
[1]*Erasmus MC, Rotterdam, Netherlands,* [2]*Academic Medical Center, Amsterdam, Netherlands.*

Growing evidence shows that regulatory T cells (Treg) hamper the development of effective anti-tumor immunity in patients with cancer, and present a major hurdle for tumor immunotherapy. We recently described accumulation of activated CD4+FoxP3+ Treg at the tumor site in patients with liver cancer (hepatocellular carcinoma or metastasized colorectal cancer). These tumor-infiltrating Treg are potent suppressors of the local anti-tumor T cell responses, and they are characterized by the expression of higher levels of CTLA-4 and GITR than Treg in normal liver tissue or blood from the same patients. Now we show that treatment with a soluble form of the natural ligand of GITR (GITRL), or with blocking antibodies to CTLA-4, reduces the suppression mediated by tumor-derived Treg in *ex vivo* assays, restoring proliferation and cytokine production by effector T cells. These results suggest that modulation of intra-tumoral Treg function by either GITR-ligation or blocking CTLA-4 may be a promising strategy for alleviation of intra-tumoral immunosuppression, thereby contributing to immunotherapy induced effective immune responses in liver cancer patients.

P6.06.140
Cancer from hell: Devil Facial Tumour Disease

T. Pinfold*, G. Brown, A. Kreiss, G. Woods;
Menzies Research Institute Tasmania, Hobart, Australia.*

Devil Facial Tumour Disease (DFTD) is a rare form of cancer that spreads like a contagious disease. It is a parasitic clonal cell line transmitted between hosts through biting. The disease is limited to Tasmanian devils, which are carnivorous marsupials endemic to Tasmania, an island state of Australia. It has a 100% mortality rate,

has reduced the population by 80% and may cause extinction of the Tasmanian devil in the wild within the next 30 years.
The lack of immunogenicity may be one possible mechanism used by DFTD cells to escape the host's immune system. Because of the lack of molecular tools and limited access to Tasmanian devils we developed a mouse model of DFTD. The tumour cells are immunogenic as immunocompetent BALB/c and C57BL/6 mice rejected xenograft implantation of 10^6 DFTD cells while immunocompromised NOD/SCID mice accepted the xenograft and developed DFTD tumours. Evidence for the immunological basis of the rejection was demonstrated with adoptive protection by splenocytes transferred from BALB/c to NOD/SCID mice.
In vitro stimulation of devil lymphocytes induced cytotoxic anti-DFTD activity. To determine if this could be effective in vivo, two NOD/SCID mice were co-injected with 5 x 10^5 DFTD cells and 5 x 10^6 stimulated devil lymphocytes. Seven weeks later the tumour growth was less than 10% compared to the control. Replication of this work with 10^4 DFTD cells plus lymphocytes failed to engraft the tumour providing insight into possible immunotherapy approaches for the disease.

P6.06.141
Expression patterns of cancer/testis antigens constitute a stable patient-specific fingerprint in multiple recurrent lesions of evolving metastatic melanoma

Z. Pos[1], *J. R. Wunderlich*[2], *D. F. Stroncek*[3], *J. A. Malek*[4], *P. F. Robbins*[2], *L. Rivoltini*[5], *M. Maio*[6], *L. Chouchane*[7], *E. Wang*[8], *F. M. Marincola*[8];
[1]*MTA-SE "Lendület" Experimental and Translational Immunomics Research Group, Budapest, Hungary,* [2]*Surgery Branch, National Cancer Institute, National Institutes of Health, Bethesda, MD, United States,* [3]*Cell Processing Section, Department of Transfusion Medicine, Clinical Center, National Institutes of Health, Bethesda, MD, United States,* [4]*Department of Genetic Medicine, Weill Cornell Medical College in Qatar, Doha, Qatar,* [5]*Unit of Immunotherapy of Human Tumors, Fondazione IRCCS, Istituto Nazionale Tumori, Milan, Italy,* [6]*Cancer Bioimmunotherapy Unit, Centro di Riferimento Oncologico, Aviano, Italy,* [7]*Weill Cornell Medical College in Qatar, Doha, Qatar,* [8]*Infectious Disease and Immunogenetics Section, Department of Transfusion Medicine, Clinical Center, National Institutes of Health, Bethesda, MD, United States.*

Rare cases of metastatic melanoma with multiple, timely well-separated recurrences provide a unique opportunity to directly analyze the sequence of events during late stage disease progression, and identify conserved aspects of each patient's cancer that remain stable throughout multiple recurrences.
Here we present results of a study following 8 metastatic melanoma patients with an unusually protracted disease course, who developed a total of 26 recurrences over several years. Melanoma cells isolated from subsequent metastatic lesions were investigated by comparative genomic hybridization and global transcript analysis. We observed that subsequent recurrences did not display orderly trends toward a more aggressive phenotype in individual patients. Case-specific characteristics dominate late-stage cancer evolution, as differences among patients clearly exceed within-patient lesion variability, both at DNA copy number ($p<0.001$) and RNA gene expression level ($p<0.001$). Interestingly, tumor immunity-related melanoma genes were enriched among stable patient-specific traits, exemplified by several cancer-testis antigens (MAGE-A4, -B2, -C2, and BAGE-2) and antigen presentation-related transcripts (MHC I and II cluster, CIITA).
These results suggest that the late evolution of metastatic melanoma, which dramatically turns an indolent disease into a lethal phase, occurs through a series of random events that do not follow a consistent step-wise process. Within this random drift, however, key aspects of the immunologic profile of metastatic melanoma remain conserved even after years of progression, making advanced melanoma ideally targetable by personalized cancer immunotherapies. This study was supported by the Associazione Italiana per la Ricerca sul Cancro, IG 11746 and the Hungarian Academy of Sciences "Lendület" grant LP2012-49/2012.

Targeting Th17-associated cytokines with a bi-specific antibody improves anti-myeloma responses

R. H. Prabhala[1,2], *M. Fulciniti*[1], *J. Bae*[1], *A. Nigroiu*[3], *S. Lee*[2], *J. F. Daley*[1], *M. Marelli*[4], *K. Grabstein*[4], *K. C. Anderson*[1], *N. C. Munshi*[1,2];
[1]*Dan-Farber Cancer Institute, Boston, MA, United States,* [2]*VABHS/Harvard Medical School, West Roxbury, MA, United States,* [3]*BU Medical Center, Boston, MA, United States,* [4]*Allozyne, Seattle, WA, United States.*

Elevated levels of cytokines (interleukin-6, transforming growth factor-beta, and IL-1) in bone marrow (BM) micro-environment play an important role in both sustaining multiple myeloma (MM) cell growth and immune dysfunction in MM. We have previously demonstrated that interleukin-17 (IL-17) producing Th17 cells and associated cytokines, particularly, IL-23, are significantly elevated in blood and BM in MM and IL-17 promotes MM cell growth in vitro and in vivo (*Blood*. 2010; 115:5385-5392) making it an important therapeutic target for MM. Therefore, we pre-clinically evaluated a bi-specific antibody (AZ17) that targets both IL-23 and IL-6, the 2 cytokines with both direct and indirect effects on the initial differentiation of Th17 cells and the activation of effector Th17 cells in MM. We observe significant inhibition of MM cell growth (N=9) by AZ17 in the presence of BM stromal cells (BMSC). In addition AZ17 bi-specific antibody significantly reduced MM cell-colony size and number in MethoCult agar media. AZ17 significantly down-regulated IL-6 production in MM-BMSC co-culture (N=3). Moreover, we evaluated impact of AZ17 on CD8+ cytotoxic T lymphocytes (CTLs), generated from HLA-A2+ MM patient PBMCs using MM-specific peptides (derived from XBP1, CD138 and CS1), and cultured with or without HLA-A2+ MM cells and intra-cellular granzyme B was analyzed as an indicator of cytotoxicity. AZ17 bi-specific antibody significantly enhanced expression of granzyme B in MM-specific CTLs (N=5). These in vitro observations suggest efficacy of AZ17 in myeloma and provide the rationale for its in vivo and subsequently clinical evaluation both for anti-myeloma effects.

Neuroblastoma (NB) is the most common extracranial solid tumor in children. High-risk NB patients still have poor clinical outcome despite aggressive chemotherapy. Low to absent expression of surface major histocompatibility complex (MHC) class I molecules and defects in antigen processing machinery make human NB cells appropriate targets for MHC unrestricted immunotherapeutic approaches. Human Vγ9Vδ2 lymphocytes exert MHC-unrestricted anti-tumor activity and are activated by phosphoantigens whose expression in cancer cells is increased by aminobisphosphonates. These compounds are well established in the clinic as inhibitors of osteoclastic activity and possess antiangiogenic and proapoptotic properties for different human tumors. We have investigated the in vivo anti-NB activity of human Vγ9Vδ2 T cells and zoledronic acid (ZOL).
SH-SY-5Y human NB cells were injected in the adrenal gland of immunodeficient mice. After three days, mice received ZOL or human Vγ9Vδ2 T cells or both agents by intravenous administration once a week for 4 weeks.
A significantly improved survival was observed in mice receiving the combined treatment. Inhibition of tumor cell proliferation, angiogenesis and lymphangiogenesis, and increased tumor cell apoptosis were detected. Human Vγ9Vδ2 T lymphocytes were attracted to NB-tumor masses of mice receiving ZOL where they interfered with tumor microenvironment by expressing the cytotoxic molecule TIA-1 and by secreting IFN-γ that in turn induced CXCL10 expression in NB cells.
This study shows that human Vγ9Vδ2 T cells and ZOL in combination can inhibit NB growth in vivo and may provide the rationale for a phase I clinical trial in high-risk NB patients.

P6.06.144
Analysis of IL-10 serum levels in epithelial ovarian carcinoma in comparison to Ovarian benign Cyst

*S. Rezaeifard, **S. Rahimifar**, M. Razmkhah;*
Shiraz Institute for Cancer Research, Shiraz, Iran.

Background: Tumor cells are influenced by the components of tumor milieu for instance; cytokine expression in tumor microenvironment can affect both anti-tumor immune response and tumor cell survival. Interleukin-10 (IL-10) is an immunosuppressive cytokine and several studies suggest that this cytokine could suppress anti-tumor immune response and might have key role in tumor progression.
Method: We aim to evaluate IL-10 content in serum of malignant ovarian cancer, benign cyst patients and normal individuals by ELISA.
Result: Serum level of IL-10 in ovarian cancer patients was higher than in benign cyst patients and normal individuals (P >0.05). In addition, IL-10 was significantly elevated in serum of normal individuals compared to benign cyst patients (P = 0.02).
Conclusion: These data support that Th2 cytokines such as IL-10 may be important in the tumor microenvironment and might play pivotal role in tumor progression by suppressing anti-tumor immune response. So, this cytokine can be used in the molecular targeting of ovarian cancer.

P6.06.145
Equipotent antagonism towards both ligands and excellent anti-tumor efficacy with a peptide inhibitor of PD-1 immune check point pathway

*P. G. Sasikumar, R. K. Shrimali, L. K. Satyam, S. Adurthi, R. Ramachandra, S. Vadlamani, K. A. Reddy, D. S. Samiulla, K. Sunilkumar, **M. Ramachandra**;*
Aurigene Discovery Technologies, Bangalore, India.

Pioneering success of anti-CTLA4 antibody and the impressive clinical data on agents that target PD-1 or its ligands have opened novel avenues in the area for caner immunotherapy. However, along with impressive clinical activity, immune-related toxicities have also been observed in significant (25-30% with anti-CTLA4 and up to 15% with anti-PD1) patient population. Sustained inhibition of PD-1 signaling as a result of a long half-life (>15-20 days) is likely contributing to severe adverse effects observed in clinical trials with antibodies targeting PD-1 signaling. In the present study, we sought to characterize in detail a peptide antagonist of the PD1 signaling providing desired anti-tumor efficacy with shorter exposure for effective management of severe adverse effects.
A novel peptide AUR-012 (29-mer) constructed with elements from PD-1 displayed equipotent antagonism towards PD-L1 and PD-L2, and potent activity in rescue of proliferation and effector functions of lymphocytes. Sustained changes in circulatory immune cells and ability to secrete IFN-γ indicated that pharmacodynamic effects persist even after the clearance of AUNP-12 in animal models. In models of melanoma, breast, kidney and colon cancers, AUR-012 showed excellent efficacy in inhibition of primary tumour growth and metastasis. AUR-012 showed additive anti-tumor activity when combined with vaccination or a chemotherapeutic agent known to induce “immunological cell death”. In 14 days repeated dose toxicity studies, AUR -012 was well tolerated at 100x efficacious doses.
The findings demonstrating equipotent antagonism of both PD-L1 and PD-L2 signaling along with impressive efficacy in preclinical models support further development of AUR-012 for clinical use.

P6.06.146
Development of a monoclonal antibody against the canine CCR2 as a new targeted anticancer therapy in the scope of comparative oncology

***T. P. Raposo**[1], D. J. Argyle[2], B. C. B. Beirao[2], I. Pires[1], F. L. Queiroga[1];*
[1]UTAD - CECAV, Vila Real, Portugal, [2]The Royal (Dick) School of Veterinary Studies and The Roslin Institute, University of Edinburgh, Edinburgh, United Kingdom.

Introduction: In this project, it is proposed that the clinical application of a monoclonal antibody against the receptor of the Monocyte Chemotactic Protein-1 (MAb anti-CCR2), would hinder cancer progression, inhibiting macrophages recruitment. Canine mammary tumours (CMT) will be used as a model of human breast cancer, in face of molecular, histologic and clinical similarities of the disease in both species. Herein, the initial stages of the production of a MAb anti-CCR2 are described, aiming the future clinical application.
Material and Methods: RNA was extracted from canine bone marrow, CCR2 cDNA was synthesized by RT-PCR, cloned into a plasmid vector, and then confirmed through DNA sequencing. Transformed BL21 DE3 *E.coli* were used as a system of bacterial expression. The bacterial lysates were purified through an affinity chromatography column, to isolate the CCR2 protein which was subsequently verified through mass spectrometry.
Results: The purity of the isolated protein was confirmed by mass spectrometry analysis and it is now suitable for the mice immunisation. Throughout the purification process, the inclusion of urea in the lysis, wash and elution buffers was crucial to withdraw the most of the protein from the bacterial lysates.
Conclusion: Hitherto, the antigen production stage was concluded, obtaining a pure form of CCR2, ready for the immunisation of mice. Hence, it is now possible to progress to the following phases in the development of a Mab anti-CCR2 using hybridoma technology. Afterwards, an experimental therapy delivering anti-CCR2 monoclonal antibody to the tumour site will be applied to dogs with advanced CMT.

P6.06.147
Anti EGFR monoclonal antibody inhibits prostate cancer PC3 cells growth

***A. Rezaiemanesh**[1], J. Majidi[2], B. Baradaran[2], A. Movasaghpour[2], A. Nakhlband[2], J. Barar[2], Y. Omidi[2];*
[1]Tehran University of Medical Sciences, Tehran, Iran, [2]Tabriz University of Medical Sciences, Tabriz, Iran.

Epidermal growth factor receptor (EGFR) network appears to be a rich target for prostate cancer. Thus, in this current investigation, to pursue our newly developed anti EGFR monoclonal antibody (mAb) in prostate cancer, its inhibitory effect was investigated in PC3 cells. The binding specificity of antibody was examined by flow cytometry and immunofluorescence staining. Cultured cells were treated with various doses of the anti-EGFR mAb at different time points and the cellular and/or molecular impacts were assessed. MTT assay was utilized to examine the cytotoxic effects. Semi-quantitative RT PCR was used to evaluate the expression of EGFR and some important apoptosis signaling molecules (e.g., MAPK1, STAT5, Akt1 kinase). Flow cytometric and immunofluorescence staining analyses showed that the anti-EGFR mAb can bind to EGFR with high specificity. The results revealed that the anti-EGFR mAb can inhibit cell growth in a dose and time dependent manner. RT PCR analysis revealed that the binding of anti-EGFR mAb to its receptors can eventually result in down regulation of Akt1 kinase gene, but not MAPK1, STAT5 and EGFR genes. Based on our findings, it can be concluded that Akt1 is the most important downstream signaling molecules affected by anti-EGFR mAbs.

P6.06.148
Characterization of a genetic mouse model of lung cancer: a promise to identify oncoantigens associated with different stages of NSCLC progression

F. Riccardo[1], *M. Arigoni*[1], *M. Iezzi*[2], *D. L. Longo*[1], *M. Carrara*[1], *A. Fiore*[1], *G. Forni*[1], *R. A. Calogero*[1], *E. Quaglino*[1], *F. Cavallo*[1];
[1]*University of Turin, Torino, Italy,* [2]*University of Chieti, Chieti, Italy.*

Non-small cell lung cancer (NSCLC) accounts for 81% of all cases of lung cancer and they are often fatal because 60% of the patients are diagnosed at an advanced stage. Besides the need for earlier diagnosis, there is a great need for additional effective therapies. Lung cancer progression in $p53^{R172H\Delta g}$/$Kras^{G12D}$ mice that develop aggressive NSCLC, mimicking features of human lung cancer, was characterized by using non-invasive magnetic resonance imaging (MRI) and immunohistochemical analysis. To identify new NSCLC associated oncoantigens against which addressing the immune system, we performed gene expression and RNA seq profiling from total RNA extracted from lungs of 10, 20 and 30 week-old $p53^{R172H\Delta g}$/$Kras^{G12D}$ and wild type mice. Transcription profiling was performed taking in account the relationship between murine and human lung tumor progression. 282 genes were found significantly differentially expressed during the increment of tumor mass. Interestingly, 10 transcripts related to inflammatory response and 44 transcripts associated to inflammation disorder class were identified as up-regulated and down-regulated genes respectively, agreeing with the link existing between chronic immune activation and tumorigenesis in human NSCLC. RNA-seq library constructions was performed in order to identify novel oncoantigens and fusion transcripts associated with NSCLC, potentially useful as therapeutic targets. The receptor tyrosine kinase ROS1 was identified as the most promising candidate for vaccination against NSCLC since its overexpression correlates with poor prognosis for overall survival in human stage I NSCLC and increases in recurred NSCLC. A DNA vaccine against ROS1 has been generated and is now under investigation in $p53^{R172H\Delta g}$/$Kras^{G12D}$ mice.

P6.06.149
Tumour vaccine for oral cancer: prospects and challenges

G. Rodrigues*;*
Kasturba Medical College, Manipal University, Manipal, India.

Oral cancer is one of the major reasons for morbidity and mortality worldwide. Despite significant advances in radiation, surgery and chemotherapy, substantial gap remains in its effective control. Even with all recent advances, the overall five-year survival rate for oral cancer has remained status quo at around 55% and hence, a need for effective vaccine has been felt for long that could confer long-term immunity and have a huge impact in control of this deadly disease. We did a retrospective literature search with key terms “Tumors Vaccines” AND “Oral Cancers” AND “Dentistry” through Pub Med, MEDSCAPE, MICROMEDEX, relevant immunology, dental and medicine journals and this was done independently by the authors. Majority of tumor vaccine research in dentistry is limited to Human Papilloma Virus (HPV) vaccines. However these are more focused on cervical cancer, with oral malignancy as only one of the secondary outcomes. It has been observed that HPV has a definitive role in oral cancers and these vaccines could have a positive impact in prevention of its ever-increasing incidence, though gray areas in research like optimal dosing schedule, efficacy in men, duration of protection and oral cancer specific studies remain unanswered. Emergence of second generation tumor vaccines against oral cancer does seem promising. There is a need to sensitize dental professionals with the latest advancement in tumor vaccines. A subtle shift from bench side research to bed side availability of an effective tumor vaccine in dentistry armamentarium does not seem to be a distant dream.

P6.06.150
Multifaceted immunotherapeutic effects of vitamin D-binding protein-derived macrophage activating factor (GcMAF) on human breast cancer and neuroblastoma cells

M. Ruggiero[1], *S. Pacini*[2], *G. Morucci*[2], *J. J. V. Branca*[2], *E. Ward*[3], *R. J. Smith*[3], *L. Thyer*[3], *M. Gulisano*[2];
[1]*Department of Experimental Biomedical and Clinical Sciences, Firenze, Italy,* [2]*Department of Experimental Medicine, Firenze, Italy,* [3]*Macro Innovations, Cambridge, United Kingdom.*

The vitamin D axis includes vitamin D, its receptor (VDR) and vitamin D-binding protein (or Gc-globulin) that is the precursor of the Gc-globulin-derived Macrophage Activating Factor (GcMAF), a protein that has been proposed as an immunotherapeutic agent in the treatment a variety of conditions ranging from cancer to neurological disorders. Here we demonstrate that GcMAF (Immuno Biotech Ltd) added to human breast cancer cells (MCF-7, HPA Culture Collection) inhibited their proliferation, induced morphological changes, reduced vimentin expression and inhibited cancer cell-induced angiogenesis. We also describe the effects of GcMAF on the activation of macrophages added to MCF-7 cells. Macrophages (Raw 264.7, HPA Culture Collection) were activated by culturing them in the presence of 100 ng/ml GcMAF for 72 h prior to addition to the MCF-7 cells. The macrophages were added at a ratio of 1:1 to the MCF-7 cells. Photography was taken over a 60 h period using an Olympus CK2 microscope and a GXCAM-3 with NCH Debut capture software. After about 60 h, the irregular growth of the breast carcinoma cells was arrested and carcinoma cells were phagocytised by the activated macrophages. Finally, we demonstrate the GcMAF inhibited proliferation of human brain neuroblastoma cells (SH-SY5Y, ATCC) and induced morphological changes consistent with induction of apoptosis. Taken together, these results support the hypothesis that GcMAF has multiple biological effects: it inhibits cancer cell proliferation and metastatic potential; it reverts the neoplastic phenotype; it inhibits cancer cell-induced angiogenesis; and it stimulates tumoricidal macrophages that phagocytise cancer cells.

P6.06.151
In vitro cytotoxic effects of dichloromethane extract of Scrophularia atropatana on WEHI-164 cells

E. Safarzadeh[1], *B. Baradaran*[1], *A. Delazar*[2], *T. Kazemi*[1], *M. Orangi*[1], *D. Shanehbandi*[1], *S. Esnaashari*[3];
[1]*Immunology Research Center,Tabriz University of Medical Sciences, Tabriz, Iran,* [2]*Drug Applied Research Center,Department of Pharmacognosy, Faculty of Pharmacy, Tabriz, Iran,* [3]*Drug Applied Research Center, Tabriz, Iran.*

Background: Cancer is one of the most prevalent diseases worldwide which is a major public health issue in both developed and developing countries. Recent studies have shown that medicinal plants are potential agents for cancer therapy .The present study was designed to explore the cytotoxic effects and the cell death mechanism of dichloromethane extract of Scrophularia atropatana on fibrosarcoma cell line (WEHI -164) compared to non-malignant (L929) cells.
Materials and Methods: WEHI -164 and L929 cells cultured in RPMI 1640 were exposed to a range of concentrations (100, 150, 200, 300, 400, 500, 600 µg/ml) of the extract and then incubated for 24, 36 and 48 h under specific condition (37 °C, 5% CO2). Cytotoxic effects were measured using 3-(4,5-Dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay. To detect apoptosis, cell death assays, TUNEL test and DNA fragmentation assay were performed.
Results: In the present study, the dichloromethane extract of Scrophularia atropatana exhibited considerable cytotoxic effects in WEHI-164 cells in a dose and time-dependent manner without cytotoxic effect on L929 cells. TUNEL, cell death and DNA fragmentation assays showed that the dichloromethane extract of Scrophularia atropatana induces apoptosis in WEHI-164 cells.
Conclusion: The data obtained demonstrate that dichloromethane extract of Scrophularia atropatana has a proapoptotic effects on WEHI-164 cell line and it may be effective agent in treatment of cancer.

P6.06.152
Tumour cell lysate loaded-Dendritic Cell vaccine induces biochemical and memory immune response in castration-resistant prostate cancer patients

*D. Reyes[1], C. Pereda[1], E. Castellón[1], R. Valdenevito[2], M. López[1], **F. Salazar-Onfray**[1];*
[1]Institute of Biomedical Sciences, Faculty of Medicine, University of Chile, Santiago, Chile, Santiago, Chile, [2]Service of Urology, University of Chile, Clinical Hospital., Santiago, Chile.

Purpose: Previously, we described a method to produce ex vivo antigen presenting cells (APCs)loaded with a melanoma cell lysate named TRIMEL as antigen source and activation factor. Tumour-antigen presenting cells (TAPCells)-vaccine constituted a safe therapy for melanoma patients, inducing immunological responses and increasing survival. Herein, we investigate prostate cancer cell lysate (PCCL)/TRIMEL-loadedTAPCellseffect in castration-resistant prostate cancer (CRPC) patients, co-injected with the *Concholepas concholepas* Haemocyanin (CCH) as an adjuvant. **Experimental Design:**Cell lysate capacity for inducing APCs maturation and T cell activation was analysed by flowcytometry and Elispot. Delayed-type hypersensitivity (DTH) reaction against PCCL and frequency of blood circulating $CD8^+$ memory T cells (Tm) were measured after treatment of twenty CRPC patients. Biochemical responses were analysed by measuring the prostate specific antigen (PSA) in serum. **Results:** The lysate mix induced phenotypic and functional mature DCs capable to activate PCCL-specific T cells. No relevant adverse reactions were observed. Six out of 14 patients showed a significantly decrease of PSA levels in serum. DTH+ patients showed a prolonged PSA doubling-time after treatment. An expansion of both central and effector $CD8^+$ Tm capable to produce IFN-γ, Granzyme B and Perforin was detected. All biochemical-responders showed a DTH reaction against prostate tumour lysate. **Conclusions:** Treatment of CRPC patients with PCCL/TRIMEL-loaded TAPCells,co-injected with CCH as adjuvant, is a safe procedure. Biochemical and memory immune responses were detected, although the limited number of cases makes necessary the confirmation of results in a phase II clinical trial.

P6.06.153
Evaluation of anti-FoxP3 vaccine efficacy following DNA-protein prime-boost immunization in mice

***M. Samadi**[1], A. Memarnejadian[2], R. Vahabpour[2], S. Sadat[2], M. Aghasadeghi[2], J. Hadjati[3];*
[1]Immunology Department, Faculty of Medicine, Shahid Sadoughi University of Medical Sciences, Yazd, Iran, [2]Department of Hepatitis and AIDS, Pasteur Institute of Iran, Tehran, Iran, Tehran, Iran, [3]Department of Immunology, School of Medicine, Tehran University of Medical Sciences, Tehran, Iran.

FoxP3+Regulatory T cells (Tregs) are main obstacle against anti tumor immune responses and depletion of these cells is purpose of many studies in the field of cancer research. In this study we evaluated the breakdown of tolerance against FoxP3 by targeting FoxP3 as most specific marker for Tregs in comparison to CD25 using DNA-protein prime-boost vaccination.
C57/BL16 mice were primed against FoxP3 by one subcutaneously injection of DNA vaccine coding FoxP3 and boosted by two subcutaneously injections of FoxP3 recombinant protein. Three weeks after last injection, splenocytes separated, IFN-γ ELISPOT assay and proliferation assay were done to compare FoxP3 specific T cells in vaccinated and control groups. Serum of mice was evaluated for detecting anti-FoxP3 total IgG and IgG subclasses including IgG1, IgG2a, IgG2b and IgG3 by ELISA.
Our results indicated that IFN-γ producing cells and FoxP3 specific T cells significantly increased in vaccinated group. Serum levels of anti -FoxP3 total IgG in vaccinated group was significantly higher than control group. The analysis of anti-FoxP3 IgG subclasses showed a significant increase in IgG2a and IgG2b levels.
In conclusion, this study demonstrates that anti-FoxP3 DNA-protein prime-boost vaccination is possible to breakdown of T-cell and B-cell tolerance against FoxP3. Increased number of anti -FoxP3 IFN-γ producing cells and elevated levels of IgG2a and IgG2b can be considered as a consequence of a type 1- immune response that is proper for the purpose of this vaccination.

P6.06.154
The relevance of heat shock protein 90 and its role in cancer treatment

***A. Santos**[1], B. Campostrini[2], M. Geller[1], A. Abrahão[3], L. Oliveira[4], K. Cunha[3], A. Fonseca[4], M. Ribeiro[5], M. Romero[3], E. Naliato[5];*
[1]Instituto Carlos Chagas, Rio de Janeiro, Brazil, [2]Faculdade de Medicina de Jundiaí, Jundiaí, Brazil, [3]Universidade Federal Fluminense, Rio de Janeiro, Brazil, [4]UNIFESO, Teresópolis, Brazil, [5]Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil.

Heat Shock Proteins (HSP) constitute a family of chaperones. These proteins are very important for cytoprotection and tolerance build-up against ischemia, hypoxia, high temperatures, infection, among others. They can be classified by their molecular masses. In this study, we deal with HSP90. Hematological malignancies and solid tumors have increased levels of HSP90. This overexpression accounts for the ability of cancer cells to maintain homeostasis in a hostile environment. HSP90 also allows the cancer cells to tolerate genetic alterations that would be fatal otherwise. The purpose of this study is to review the literature concerning HSP90, its functions, its role in immunology and the advances in the clinical development of HSP90 inhibitors on different kinds of cancer.

P6.06.155
Pseudo-exhaustion of CD8+ T cells in acute myeloid leukemia (AML)

***F. M. Schnorfeil**[1,2], K. Emmerig[1,2], J. Neitz[1,2], F. S. Lichtenegger[3,2], R. Draenert[4], W. Hiddemann[2], M. Subklewe[1,5];*
[1]Clinical Cooperation Group Immunotherapy, Helmholtz Zentrum München, German Research Center for Environmental Health, Munich, Germany, [2]Department of Internal Medicine III, Klinikum der Universität München, Munich, Germany, [3]Division of Clinical Pharmacology, Klinikum der Universität München, Munich, Germany, [4]Division of Infectious Diseases, Klinikum der Universität München, Munich, Germany, [5]Department of Internal Medicine III, Klinikum der Universität München, Munich, Germany, Munich, Germany.

The prognosis of acute myeloid leukemia (AML) is poor due to high relapse rates after induction chemotherapy. Dendritic cell (DC)-based immunotherapy is a promising strategy to stimulate AML-specific immunity, particularly T cells. However, the functionality of T cells in AML patients is not well described. T cell exhaustion, characterized by an increased expression of inhibitory molecules and funtional deficits, has been suggested to contribute to immune evasion in various solid and hematological malignancies.
To characterize T cell exhaustion in AML, CD8+ T cell surface expression of CD244, CD160, PD-1 and TIM-3 as well as proliferation and cytokine production were measured. Results were compared to healthy controls (HCs) and untreated HIV-infected patients. To specify the stimulatory effect of DCs on AML patient-derived T cells, we cocultured DCs with autologous T cells.
We detected increased frequencies of CD244+, CD160+ and PD-1+ CD8+ T cells in HIV patients, while AML patients at time of diagnosis and relapse or during refractory disease had higher frequencies of CD244+ and TIM-3+ or PD-1+ CD8+ T cells, respectively. However, no functional impairment of AML patient-derived T cells was observed. DC stimulation resulted in upregulation of PD-1 and TIM-3, accompanied by high IFNγ secretion, that could be enhanced by PD-1 blockade.
Thus, we found elevated levels of exhaustion-associated inhibitory molecules on CD8+ T cells of AML patients, which were further upregulated upon DC stimulation. Our data suggest that immunotherapeutic strategies combining DC vaccination and immunomodulatory antibodies directed against T cell inhibitory molecules are particularly suited for AML treatment.

Functionalized polyethyleneimine-based nanoparticles improve antigen cross-presentation of murine bone marrow derived macrophages and dendritic cells depending on size and zeta potential

M. Schröder[1]*, A. Schallon*[2]*, M. Wagner*[2]*, M. Gottschaldt*[2]*, U. Schubert*[2]*, P. Knolle*[1]*;*
[1]*Friedrich-Wilhelms-Universität, Bonn, Germany,* [2]*Friedrich-Schiller-Universität, Jena, Germany.*

Nanoparticles (NP) have recently been used in several different applications in the field of nanomedicine. In most cases they are used as carriers for drug delivery, to increase solubility or to reduce drug toxicity, especially in cancer therapy. The activation of $CD8^+$ cytotoxic T cells, which thus are able to specifically attack and kill cancer cells is another promising application for NPs. Antigen presenting cells (APCs), like dendritic cells (DCs) and macrophages, play a key role in effectively inducing such a $CD8^+$ T cell immune response. They have the capability to take up antigens and present them on MHCII or cross-present them on MHCI, thereby inducing subsequent immunological processes.
We used NPs based on linear or branched poly(ethylene imine) of differently molar masses and varying concentrations of the murine model antigen ovalbumin (Ova). After incubation of bone-marrow-derived macrophages or dendritic cells with different NP concentrations, we coincubated $CD8^+$ OTI T cells and measured the expression of activation markers (CD69, CD80, MHCI, MHCII) as well as inflammation-related cytokines (IL-2, IFNgamma, IL-12, TNFalpha) with FACS and ELISA respectively.
For several NP combinations, the $CD8^+$ T cell and APC activation was significantly increased by more than tenfold compared to free Ova. In addition, this increase was most prominent in positively charged NP with a PEI:Ova relation of 0.04, independent of the polymerization architecture (linear or branched).
These PEI-Ova-NP are a promising tool as further conjugation with TLR-Ligands or other functionalizations might increase their immunogenicity.

Immunopharmacodynamic response to blinatumomab in patients with relapsed/refractory B-precursor acute lymphoblastic leukaemia (ALL)

A. Schub[1]*, V. Nägele*[1]*, G. Zugmaier*[1]*, C. Brandl*[1]*, Y. Hijazi*[1]*, M. S. Topp*[2]*, P. Kufer*[1]*, A. Wolf*[1]*, M. Klinger*[1]*;*
[1]*Amgen Research (Munich) GmbH, Munich, Germany,* [2]*University of Würzburg, Würzburg, Germany.*

Background: Blinatumomab is an anti-CD19/anti-CD3 bispecific T cell engager (BiTE®) that induces target cell-dependent, polyclonal T cell activation and proliferation, resulting in redirected lysis of $CD19^+$ target cells.
Methods: In a phase 2 study, adult patients (N=36) with relapsed/refractory B-precursor ALL received continuous blinatumomab IV infusion for 28 days ≤5 treatment/consolidation cycles.
Results: Lymphocytes in all patients responded in a similar fashion. After infusion start, peripheral B cell counts dropped to ≤1 B cell/µL in <1 week and remained undetectable throughout treatment. Peripheral T cell redistribution was characterized by swift disappearance within the first 2-6 hrs and subsequent recovery to baseline within several days. Otherwise, T cell counts remained at least stable in most patients. In some patients expansion of the T cell compartments was observed, likely due to specific proliferation of activated T cells. During the first infusion days, a significant proportion of T cells newly expressed the activation marker CD69, and granzyme B was detectable in serum. Additionally, a transient cytokine release dominated by IL-10, IL-6 and IFN-γ was observed in most patients shortly after infusion start, which was alleviated or absent in subsequent cycles. Consistent with previous studies, blinatumomab serum steady state concentrations (mean±SD) were 198±61 pg/mL and 694±236 pg/mL at doses of 5 and 15 µg/m²/d, respectively.
Conclusions: Immunopharmacodynamic response to blinatumomab was characterized by B cell depletion, T cell activation and redistribution, and release of granzyme B and cytokines, suggesting T cell engagement according to the expected BiTE® mode of action.

P6.06.158

Role of the transcription factor forkhead box P3 in breast cancer and metastasis

L. Sfondrini[1]*, A. Cataldo*[1]*, V. Uva*[1]*, T. Triulzi*[2]*, P. Casalini*[2]*, E. Tagliabue*[2]*, A. Balsari*[1,2]*;*
[1]*Dep. of Biomedical Science for Health-University of Milan, Milan, Italy,* [2]*Molecular Targeting Unit- Dep. of Exp. Oncology National Cancer Institute Foundation IRCCS, Milan, Italy.*

Background: The transcription factor forkhead box P3 (FOXP3), known for its critical role in regulating the development and function of regulatory T cells, can be also expressed in cancer cells. We have previously shown that FOXP3 expression in breast cancer represents a strong prognostic negative factor for distant metastases-free survival. Thus, we investigated the role and molecular mechanism of action of FOXP3 in the metastatic process using breast cancer models. **Methods and results:** MDA-MB-231 human breast cancer cells, expressing low levels of FOXP3, was used to establish a tet-off inducible expression system, in which full-length (WT) FOXP3 or splice variant form (Δ2) were induced upon doxycycline removal. Real Time PCR and Western Blot analysis confirmed that in this condition FOXP3 mRNA and protein levels were significantly increased in both WT and Δ2 FOXP3-tet-off MDA-MB-231 clones. *In vitro*, an up-regulation of WT and Δ2 FOXP3 inhibited cell proliferation, but resulted in an increased migration and invasion. *In vivo* experiments, initially performed using Δ2 FOXP3-tet-off clones, revealed a significant increase in the number of spontaneous and experimental lung metastases, obtained by mammary fatpad and intravenous injections, respectively, when Δ2 FOX3 expression was induced *in vivo* by doxycycline removal. Accordingly, a significant modulation of the expression of genes relevant for dissemination and/or control of the immune response has been observed in Δ2 FOXP3-induced when compared to not-induced ones by gene microarrays analysis. **Conclusions**: These findings indicate that in breast tumor FOXP3 expression inhibits tumor growth while promotes metastatic capability.

Production of lacZ inducible T cell hybridoma specific for human and mouse gp10025-33 peptides

A. Sharbi-Yunger*;*
Weizmann Institute of Science, Rehovot, Israel.

The key event in T cell activation is the recognition of a peptide bound to major histocompatibility complex (MHC) molecules on the surface of antigen presenting cells (APCs). The enormous pool of peptides displayed on MHC makes it almost impossible to detect a given peptide-MHC complex on the surface of APCs by using conventional indirect methods. On the other hand, direct recognition of a selected peptide by the TCR results in generation of intracellular signals leading to initiation of the primary stages of T cell activation. To facilitate measurement of T cell activation and to enable identification of individual clones, β-galactosidase (*lacZ*) inducible $CD4^+$ and $CD8^+$ T cell hybrids were developed. Previous studies showed that heterologous *Escherichia coli* β-galactosidase (*lacZ*) gene, under control of the IL-2 entire enhancer region or the nuclear factor in activated T cells (NFAT) element alone, is specifically induced in transfected and activated T cells. Thus, activation of transfected T cells, results in synthesis of both IL-2 and *lacZ* gene products. Moreover, since the *lacZ* remains sequestered within the activated cells, chromogenic or fluorogenic substrate enables measurement of an activating event in a single T cell. Generation of the hybrids is relatively easy and allows maintenance in culture and the *lacZ* assay provides a rapid, sensitive and non-radioactive method for measuring T cell activation. In this study we isolated T cells from Pmel-1 mice and generated a *lacZ* inducible $CD8^+$ T cell hybridoma.

[2]*Municipal Clinical Hospital №1, Novosibirsk, Russian Federation,*
[3]*Avaxis Bio Co.Ltd, Novosibirsk, Russian Federation.*

Breast cancer (BC) has the highest frequency of women's cancers. We investigated the efficacy of DC transfected polyepitope constructs containing HLA-A0201-associated peptide CTL epitopes of different tumor-associated antigens for breast cancer to stimulate the cytotoxic response in culture mononuclear cells of patients with BC.
Monocytes from mononuclear cells (MNCs) of peripheral blood from BC-patients were cultured in the presence of rhIL-4, rhGM-CSF and rhTNF-a for generation of mature DC. Delivery of DNA-construct containing HLA-A0201-associated peptide CTL epitopes, in mature DCs was performed using magnetic transfection. To stimulate the cytotoxic activity was carried co-culture of DC and MNCs in several parallel cultures at meeting the same culture conditions - the ratio of DC: MNC 1:10 and stimulate Th1-polarized by rhIL-12 and rhIL-18. Autologous tumor cells and cell lines MCF-7 we used as target cells. DNA-transfected mature DC stimulate the cytotoxic potential of MNCs against autologous tumor cells, and against MCF-7. Addition of IL-12 and IL-18 at cocultivation MNCs and transfected DC is an effective method of stimulation the specific cytotoxic response against tumor cells. The use of autologous tumor cells as a target cell results in a more pronounced cytotoxic response, compared with the cell line MCF-7.
Thus, the use polyepitope DNA constructs for antigenic load of DC and stimulation of MNCs culture with transfected DC leads to the stimulation of cytotoxic response directed at tumor cell lysis.

P6.06.161
Supportive involvement of tumor-associated myeloid cells in RNA adjuvant therapy for cancer

H. Shime*, M. Matsumoto, T. Seya;*
Department of Microbiology and Immunology, Hokkaido University Graduate School of Medicine, Sapporo, Japan.

Tumor-associated myeloid cells including tumor-associated macrophages (TAMs) and myeloid-derived suppressor cells (MDSCs) contribute to tumor growth by inducing smoldering inflammation and immune suppression. On the other hand, acute phase inflammation elicited by the activation of pattern recognition receptors leads to tumor regression. PolyI:C, a synthetic analog of double-stranded (ds) RNA,induces retardation of tumor growth in mice by inducing Th1-type immune response. PolyI:C stimulates dendritic cells and macrophages to mature and produce proinflammatory cytokines through TLR3 and MDA5 receptors, which activates the adaptor molecules TICAM-1 (TRIF) and MAVS, respectively. The effect of polyI:C on tumor-associated myeloid cells has not been fully understood. Here, we show that polyI:C treatment induces phenotype switch of TAMs and MDSCs from tumor-supportive to tumor-suppressive in tumor-bearing mice. PolyI:C administration provoked TNF-α-dependent hemorrhagic necrosis and retardation of 3LL tumor growth. TAMs were the main producers of TNF-α and exerted cytotoxic activity. Furthermore, MDSCs as well as TAMs in polyI:C-treated mice exhibited the increase in the expression of Th1-inducing genes. PolyI:C-stimulated TAMs and MDSCs induced NK cell activation, which required the type-I IFN signaling. Both TICAM-1 and MAVS were involved in the activation of TAMs and MDSCs in vivo. These data suggest that tumor-associated myeloid cells contribute to tumor regression by directly inhibiting tumor growth and enhancing antitumor immune response by turning an NK activator in dsRNA treatment. Adjuvant immunotherapy using dsRNA will be a promising treatment for not only activating the innate array of immunity but also converting tumor-associated myeloid cells to antitumor effectors.

P6.06.162
The cross-talk between plasmacytoid DC and conventional DCs shapes the anti-tumor memory CD8$^+$T cells

K. Shimizu*, S. Fujii;*
RIKEN, IMS, Yokohama, Japan.

A key goal of vaccine immunotherapy is the generation of long-term memory CD8$^+$ T cells capable of mediating immune surveillance. The path from naïve precursor to effector and memory CD8+T cell development begins with interactions between mature dendritic cells and naïve T cells. However, the developmental program of generating memory T cells at DC level has not been established in detail.
We previously demonstrated that an iNKT cell-triggered DCs in vivo, linked innate and adaptive immunity by an administration of iNKT ligand-loaded tumor cells. In the current study, we have further elucidated a novel intercellular pathway governing the development of potent memory CD8$^+$ T cell responses against tumor antigens that is mediated through cross-presentation by CD8$^+$ DCs. Generation of CD8$^+$ memory T cells against tumor cells loaded with iNKT ligand depended on cross-talk between CD8$^+$ DCs and pDCs that was regulated by IFNalpha/IFNalphaR signals. The IFN-alpha production by pDCs was stimulated by OX40 signal from the iNKT cells, and HMGB1 signal from the dying tumor cells. Thus, integrating some key parameters on DCs can program the ensuing CD8$^+$ memory T cell response. These findings reveal an integrative pathway of intercellular collaboration on DCs for the generation of tumor-specific CD8$^+$ memory T cells that can be exploited for strategic vaccination in the setting of tumor immunotherapy.

Immunization against tumor-associated macrophages - enhancement of DNA vaccine potency against legumain

M. Smahel*, M. Duskova, I. Polakova, J. Musil, M. Petrackova;*
Institute of Hematology and Blood Transfusion, Prague, Czech Republic.

Tumor-associated macrophages (TAMs) are one of tumor-stroma components that are most important for tumor progression. Asparaginyl endopeptidase legumain that is overexpressed in M2-polarized TAMs have been identified as a suitable target for elimination of these cells. To enhance the efficacy of DNA immunization against legumain, we performed several modifications in legumain that could improve induction of immune responses. First, we mutated the RGD motif into GGD or RGG sequences. This alteration resulted in diminished maturation of legumain and impaired cellular localization into the Golgi apparatus. Then, as tolerance to self-antigens can be broken by activation of CD4$^+$ T cell help, we tried to enhance the immunogenicity of legumain by insertion of a foreign helper epitope, namely the p30 epitope from the tetanus toxin (aa 947-967). Finally, both modifications of legumain were combined. After DNA immunization of C57BL/6 mice with these constructs via a gene gun, we identified the CD8$^+$ T cell epitope $Lgmn_{111-119}$ that binds to H-2D^b molecules. Furthermore, we showed that mutagenesis in the RGD motif significantly enhanced the immune response against legumain. The addition of the p30 helper epitope induced the specific production of IFN-γ by T cells, but did not further increase legumain-specific immunity which might be caused by simultaneous activation of a Th2 response demonstrated by the production of IL-4. However, the beneficial effect of the helper epitope was proved after the depletion of regulatory T cells with antibody against CD25.
This project was supported by grants NT11541-4/2010 and NT13862-4/2012 from the Czech Ministry of Health.

P6.06.164
New role for Toll-like receptor 9 agonists, CpG-ODN as cancer cell "chemosensitizer"

M. Sommariva[1], *L. Sfondrini*[1], *L. De Cecco*[2], *E. Wang*[3], *E. Tagliabue*[2], *A. Balsari*[1];
[1]*University of Milan, Milan, Italy,* [2]*Fondazione IRCCS - Istituto Nazionale dei Tumori, Milan, Italy,* [3]*National Institutes of Health, Bethesda, MD, United States.*

Synthetic oligodeoxynucleotides expressing CpG motifs (CpG-ODN) are TLR9 agonists that have shown antitumor activity in preclinical models and in humans based on their unique ability to stimulate both the innate and adaptive arm of the immune system. Here, we investigated the efficacy of CpG-ODN alone or in combination with different therapeutic agents (bevacizumab, Poly(I):Poly(C), gefitinib, cetuximab and cisplatin) in human ovarian carcinoma xenografts. We found that only the combinations CpG-ODN/cetuximab and CpG-ODN/Cisplatin increased the Median Survival Time (MST) vs. CpG-ODN alone. For a more advanced stage of ovarian cancer, the triple combination, CpG-ODN/cetuximab plus cisplatin strongly increased survival (MST=105.5; P=0.001 vs CpG-ODN/cetuximab group) as compared with other treatment groups. We demonstrated that the synergism between peritumorally administered CpG-ODN and cisplatin, a DNA-damaging chemotherapy agent, is due to the ability of CpG-ODN to induce down-modulation of the expression of DNA repair genes directly and/or by modulation of microRNAs expression (i.e. hsa-miR-302b). In contrast to tumor cells, analyses conducted on immune cells revealed an upmodulation of DNA repair genes. This suggests that, upon detection of an infectious agent via TLR9, immune cells might regulate DNA repair genes to decrease their susceptibility to possible pro-apoptotic signals during infections and induce down-modulation of DNA repair gene expression in infected (or transformed) cells to facilitate their elimination. Since experiments were performed using athymic mice which lack T lymphocytes, our findings highlight the importance of innate immune cells present in the tumor microenvironment in sensitizing cancer cells to DNA-damaging chemotherapy and, in general, during TLRs immunotherapy.

Study of the anti-tumor effect of X- radiation in combination with DC vaccine

S. Song[1], *L. Chang*[2], *L. Wei*[2];
[1]*Hebei Medical University, Shijiazhuang, China,* [2]*Hebei Medical University, shijiazhuang, China.*

Radiotherapy is one of the most important methods against cancer. By means of modifying the tissue structure and activity of the tumor, X-ray can enhance the immunogenicity of tumor cells, which release "danger signals", such as HMGB-1and hsp70, and up-regulates the expression of adhesion molecules, such as VCAM-1, MHC-I and ICAM-1. In our study, the aim is to observe the synergy effect between X-ray and DC vaccine against tumor. X-ray at a dose of 10Gy for sequential 3 times interval of 24 hours could induce 4T1 cells apoptosis as well as necrosis. The expression level of HMGB-1 indicated a increasing trend, while TGF-β with a decreasing trend. Compared with the control group, DCs loaded with protein from X-irradiated 4T1 could obviously induce the expression of ICAM-1,MHC II and CD86, and could powerfully stimulate the proliferation of allogeneic T lymphocytes.X-ray combined with DC vaccine significantly inhibit tumor cells growth *in vivo,* the production of IFN-γ of spleen lymphocytes and CTL activity enhanced. The combination of X-ray and DC vaccine up-regulated the number of $CD8^+$T cells, and had no obvious regulatory role for the T- Reg cells, but raising the ratio of $CD8^+$T/T-Reg. Moreover, the expression of IL -6 and IL -10 significantly decreased whereas the CXCL16/CXCR6 markedly up-regulated. Conclusion, X-ray could work in coordination with DC vaccine on anti-tumor by significantly improving the tumor microenvironmen.

Dual targeting by TCR-redirected T cells enables remission from autochthonous mouse prostate cancer and long-term disease-free survival

T. Manzo[1,2], ***T. Sturmheit***[1,2], *V. Basso*[1], *R. Hess Michelini*[1], *I. Olvera Gomez*[1], *T. Schumacher*[3], *M. Bellone*[1], *A. Mondino*[1];
[1]*San Raffaele Scientific Institute, Milan, Italy,* [2]*Università Vita-Salute San Raffaele, Milan, Italy,* [3]*The Netherlands Cancer Institute, Amsterdam, Netherlands.*

Hematopoietic cell transplantation and adoptive cell therapy can overcome mechanisms of central and peripheral tolerance, which limit protective immunity in tumor-bearing patients. In clinical trials, the infusion of tumor-derived lymphocytes, or of autologous PBMCs genetically engineered to express a tumor-specific TCR, has demonstrated some therapeutic efficacy in several solid tumors. We now report that the infusion of TRAMP (TRansgenic Adenocarcinoma of the Mouse Prostate)-derived autologous TCR transduced mouse T cells with specificity for an epitope from a tumor-associated antigen (the large T antigen) is per se insufficient for tumor remission. When tumor redirected T cells are however co-infused with autologous T cells engineered to recognize a minor histocompatibility antigen (HY-encoded Uty), therapeutic Graft versus Tumor Responses are observed and mice survival is significantly prolonged. Of note, Graft Versus Tumor Responses are not accompanied by Graft versus Host Disease in spite of ubiquitous HY expression, which may best be explained by alloreactive T cells remaining responsive only at the tumor-site. We hypothesize that the synergy of tumor and minor H antigen redirected T cells results from dual targeting of the transformed epithelium and/or the tumor associated stroma, among which HY-expressing fibroblast-like cells and endothelial cells can readily be identified. Current studies are aimed at characterizing the tumor-associated stroma, at visualizing the dynamics of T cell infiltration into the tumor by non-invasive in vivo imaging, and at testing various combinations of TCR engineered T cells.

P6.06.167
Targeting the self-antigen nucleolin for antibody immunotherapy of breast and other cancers

N. Sutkowski[1,2], *W. Sun*[1], *D. Fernandes*[1,2], *S. Rubinchik*[1];
[1]*Medical University of South Carolina, Charleston, SC, United States,* [2]*Hollings Cancer Center, Charleston, SC, United States.*

Not all autoreactive antibodies are harmful, despite their role in autoimmune disease. Autoantibodies targeting tumor antigens, growth factors and their receptors are currently used therapeutically for treatment of cancer and autoimmunity. Ordinarily, healthy subjects do not exhibit strong secondary antibody responses to self-proteins, because most autoreactive B cells do not receive sufficient T cell help required for the germinal center reaction and for differentiation into IgG secreting cells. Our data demonstrate that rare, potentially therapeutic autoreactive B cells can be efficiently rescued from tonsil with EBV immortalization, and manipulated *in vitro* to secrete IgG, by supplying factors that mimic antigen stimulation and T cell help. Because this process is performed wholly *in vitro*, it constitutes a rapid and cost effective technology, resulting in the isolation of fully human antibodies. In addition, antibodies can be generated against highly toxic antigens, since immunization is unnecessary. As proof of concept, we have developed a panel of human monoclonal antibodies targeting the self-tumor antigen nucleolin for use in cancer immunotherapy. Nucleolin is normally expressed in the nucleus of all cells, but it is over-expressed in both the cytoplasm and on the cell surface of tumor cells in the most common forms of breast cancer, making nucleolin a new type of tumor antigen. The nucleolin specific antibodies elicit complement and ADCC-independent cytotoxicity of breast tumors, without affecting normal breast tissue. This is an important attribute for treatment of immunosuppressed cancer patients. The antibodies are currently undergoing pre-clinical testing against breast cancer.

P6.06.168
Low dose radiation-mediated enhanced effector function regulated by the ERK1/2 pathway in human T cells

Z. Tabi[1], *L. K. Spary*[1], *S. Al-Taei*[2], *J. Salimu*[1], *A. Clayton*[1], *J. Staffurth*[1], *M. D. Mason*[1];
[1]*Institute of Cancer and Genetics, Cardiff University, Cardiff, United Kingdom,* [2]*Velindre NHS Trust, Cardiff, United Kingdom.*

Radiation therapy (RT) is a primary treatment in many haematological and solid cancers, causing irreparable damage to tumour cell DNA. However, immune cells are also exposed to radiation during RT. We previously reported that T cell responses to recall antigens were enhanced by low dose radiation in vitro. Here we study the characteristics and mechanism of low dose radiation-induced enhancement of T cell function. We used PBMC from healthy donors or prostate cancer patients, T cells purified from PBMC and peptide-specific CD8+ T cell lines. Irradiation was carried out using a 137Cs-source (0.637Gy/min). Low dose radiation (0.6-2.4Gy) enhanced both peptide- and TCR cross linking-induced T cell proliferation and IFNg production. Irradiated T cells responded to 10-fold lower concentration of peptide with a broader Th1 cytokine profile. Cytotoxic activity of tumour antigen-specific T cells was also elevated in a dose-dependent and antigen-specific manner. T cells remained “primed” to give enhanced responses to stimulation even 24h after radiation. Similar results were observed with T cells from prostate cancer patients who received 2.0-2.4Gy localised (pelvic) radiation, as TCR cross-linking resulted in significantly elevated IFNg and TNFa production 24h after RT. Significantly increased ERK1/2 phosphorylation was observed in the irradiated plus stimulated T cells. The role of this pathway in enhancing T cell responses was subsequently confirmed in blocking experiments. We report here a direct effect of low dose radiation on T cells resulting in a significant enhancement of T cell function. This effect maybe exploited to boost T cell responses in immunotherapeutic settings.

P6.06.169
Enhancement of antigen-specific CTL inducing ability in the leukemic plasmacytoid dendritic cell line (PMDC11) by lentiviral vector-mediated transduction of caTLR4 gene

M. Takahashi[1], *M. Iwafuchi*[1], *A. Yamahira*[1], *N. Satoh*[1], *T. Uchiyama*[1], *S. Hashimoto*[2], *A. Bonehill*[3], *E. Faure-Kumar*[4], *N. Kasahara*[4], *M. Narita*[1];
[1]*Niigata University, Niigata, Japan,* [2]*Nagaoka Red Cross Hospital, Nagaoka, Japan,* [3]*Medical School of the Free University Brussels, Brussel, Belgium,* [4]*CURE Vector Core & JCCC Vector Shared Resource Facility University of California, Los Angeles, CA, United States.*

A leukemic plasmacytoid dendritic cell (pDC) line with HLA-A*02:01/24:02, PMDC05, which was established in our laboratory, acquired a higher expression of CD80 after transduction with lentiviruses encoding the CD80 gene. CD80-expressing PMDC05 was named PMDC11. In order to establish a more potent antigen presenting cells for cellular immunotherapy in tumors or severe infections, PMDC11 cells were transduced with a constitutively active (ca) TLR4 gene by using the Tet-On system (caTLR4-PMDC11). CD8+ T cells from healthy donors with HLA-A*02:01 were co-cultured with mutant WT1 peptide-pulsed PMDC11 or caTLR4-PMDC11 cells. IL-2 (50 IU/ml) and IL-7 (10 ng/ml) were added on day 3 of culture. Priming with mutant WT1 peptide-pulsed PMDC11 or caTLR4-PMDC11 was performed every week and two thirds of the IL-2/IL-7 containing medium was replenished every 3-4 days. Immediately before the priming with PMDC11 or caTLR4-PMDC11 cells, cultured cells were analyzed for the percentage and number of CD8+/WT1 tetramer+ T cells. CD8 T cells positive for both wild and mutant WT1 tetramer were generated after 2-3 weeks of culture and CD8+/WT1 tetramer+ T cells were much increased in caTLR4-PMDC11-primed CD8+ T cell culture compared with PMDC11-primed CD8+ T cell culture. These CD8+ T cells co-cultured with caTLR4-PMDC11 cells were demonstrated to be cytotoxic to WT1-expressing target cells. These data revealed that the antigen-specific CTL inducing ability of PMDC11 is enhanced by transducing caTLR4 gene, and that caTLR4-PMDC11 cells could be applied as potent antigen presenting cells for generating antigen-specific CTLs in adoptive cellular immunotherapy against tumors and severe viral infections.

[1]*Faculty of Medicine, Institute of Biomedical Sciences, University of Chile, Santiago, Chile,* [2]*Millennium Institute on Immunology and Immunotherapy, Santiago, Chile,* [3]*Millennium Institute on Immunology and Immunotherapy, Chile, Chile,* [4]*Cell Therapy Laboratory, Blood Bank Service, University of Chile Clinical Hospital, Santiago, Chile.*

Introduction: Malignant melanoma is a highly aggressive skin cancer with increasing incidence worldwide. Though its epidemiological importance, few effective therapies have been developed. Our dendritic cells based immunization (TAPCells) is a interesting approach that, in our hands, improved median survival rate over three times on patients that developed a DTH reaction to a melanoma lysate (TRIMEL). NY-ESO1 is a highly immunogenic tumor associated antigen (TAA) that seems relevant in melanoma and has been used in other protocols of immunotherapies.
Materials and Methods: Sera from 20 healthy donors and 40 TAPCells immunizated advanced stage melanoma. Anti NY-ESO1 specific antibodies were tested by ELISA. All experiments were approved by the Bioethical Committee for Human Research of University of Chile, Faculty of Medicine.
Results: Melanoma patients have higher anti NY-ESO1 titers than controls. Even more, TAPCells immunization induce an increase in these titers in both responding and non responding melanoma patients. Survival rates according to the anti NY-ESO1 levels are currently under analysis.
Conclusion: Beside inducing cellular immunity, TAPCells based immunotherapy induce humoral response anti tumoral associated antigens in melanoma patients.

P6.06.171
HSV-1 activated plasmacytoid dendritic cells inhibit melanoma cell growth

S. Thomann[1], *J. B. Boscheinen*[1], *B. Schuler-Thurner*[2], *S. Groß*[2], *B. Schmidt*[3];
[1]*Institute of Clinical and Molecular Virology, University of Erlangen-Nürnberg, Erlangen, Germany,* [2]*Department of Dermatology, University of Erlangen-Nürnberg, Erlangen, Germany,* [3]*Institute of Medical Microbiology and Hygiene, University of Regensburg, Regensburg, Germany.*

Malignant melanoma is an aggressive tumor with increasing incidence, frequent metastasis, and poor prognosis. On the other hand, melanoma is a very immunogenic type of cancer with repeatedly reported spontaneous regression. To date, the success of immunotherapies using tumor antigen-pulsed monocyte-derived dendritic cells for advanced stages of melanoma has been limited, although significantly correlated with the induction of tumor-specific cytotoxic T lymphocytes.
Our aim is to improve these tumor-vaccination approaches using virus-activated plasmacytoid dendritic cells (PDC). PDC can engulf, process, and present tumor antigens; have cytotoxic activity; are recruited into the skin to melanoma lesions; and are the main producers of type I interferons, which contribute to activation of the adaptive immune system. INF alpha is currently used as adjuvant therapy in melanoma patients. Our hypothesis is that upon appropriate vaccine stimulation, PDC are able to induce immune responses against melanoma cells. Therefore, we activated PDC with a replication-deficient herpes simplex virus type 1 and cocultured them with five melanoma cell lines and six patients’ primary isolates. Cell-free PDC supernatants reduced the melanoma cell growth only to a minor extent, whereas cocultures with virus-activated PDC effectively killed nearly all melanoma cell lines. To better define the underlying mechanism, we used a neutralizing antibody against the IFN-a receptor (IFNaR Ab). The effects of soluble components were mainly due to IFN-a, whereas effects of activated PDC could not be neutralized by the IFNaR Ab. Taken together, our results suggest that virus-stimulated PDC inhibit melanoma cell growth via a cell-contact dependent mechanism.

P6.06.172
Polysaccharide nanocomplexes harboring split vaccine and TLR ligands are potent vaccine carriers against influenza

G. Tincer[1], *C. Coban*[2], *K. Ishii*[3,4], *I. Gursel*[1];
[1]*Biotherapeutic ODN Res Lab, Department of Molecular Biology and Genetics, Bilkent University, Ankara, Turkey,* [2]*Laboratory of Malaria Immunology, WPI Immunology Frontier Research Center, Osaka University, Osaka, Japan,* [3]*Laboratory of Adjuvant Innovation, National Institute of Biomedical Innovation, Osaka, Japan,* [4]*Laboratory of Vaccine Science, WPI Immunology Frontier Research Center, Osaka University, Osaka, Japan.*

Nucleic acid based TLR ligands are widely used in the vaccine formulations as potent adjuvants against pathogens. Yet, elimination of these labile ligands either by nucleases or by adsorption onto serum proteins restricts their *in vivo* therapeutic applications. Delivering these labile agents within proper depot carrier systems can provide increased *in vivo* stability and efficient targeting/internalization to relevant immune cells. We recently demonstrated that β-glucan polysaccharide (PS) is recognized by TLR2 and initiates proinflammatory signaling cascade. Moreover, nanocomplexes of PS with pIC (TLR3L), R848 (TLR7L) and CpG ODN (TLR9L) induce synergistic and more pronounced immune activation *in vivo*. Here, nanocomplexes with SV (split vaccine of influenza virus) along with different TLRL were used as a candidate vaccine against flu. C57BL/6 mice either i.n. or i.d. immunized with the mixtures of TLRL+SV, and their PS nanocomplexes. Sera of nanocomplex treated animals` induced robust IgG and Th1-dependent antibody production after booster i.n. injection. Additionally, significantly higher IgA titers were detected from both nasal wash and sera of PS(pIC+SV) treated mice. Spleen T-cells from i.n. immunized mice with PS(TLRL+SV) nanocomplexes strongly responded against both MHC-I and MHC-II influenza-specific peptides as-evidenced by IL-2 and IFN-γ productions. However, after i.d. immunization of PS/TLRL+SV vaccine formulations, IgG2c levels at all investigated titers after booster injection were lower than the levels of IgG1 suggesting a Th2-biased response. Taken together, our results implicated that i.n. injection of PS(TLRL) nanocomplexes led to a more pronounced mucosal as well as humoral responses against H1N1 Ag along with efficient CTL response.

P6.06.173
Protein chimera of IL-2-S4B6 mAb exerts similar or even higher biological activity as IL-2/S4B6 mAb immunocomplexes in vivo

J. Tomala*, J. Kovarova, M. Kabesova, P. Votavova, H. Chmelova, B. Dvorakova, B. Rihova, M. Kovar;*
Institute of Microbiology, v.v.i., Academy of Sciences of the Czech Republic, Prague 4, Czech Republic.

In vivo biological activity of IL-2 can be dramatically increased by complexing IL-2 with certain anti-IL-2 mAbs. The immunocomplexes of IL-2 and anti-IL-2 S4B6 mAb (henceforth IL-2/S4B6) are highly stimulatory for recently activated naïve $CD8^+$ T cells, memory $CD8^+$ T and NK cells ($CD122^{high}$ populations), and moderately stimulatory for T_{reg} cells. Moreover, they were reported to have potent anti-tumor effects.
We designed and produced protein chimera consisting of IL-2 linked to light chain of anti-IL-2 mAb S4B6 through flexible oligopeptide spacer $(Gly_4Ser)_3$ and characterized it in terms of structure that proved to be similar to IL-2/S4B6 immunocomplexes. Moreover, *in vitro* and *in vivo* experiments showed that the protein chimera mimics IL-2/S4B6 immunocomplexes not only structurally, but also functionally as it was able to stimulate proliferation of purified and activated OT-I $CD8^+$ T cells *in vitro* and induce vigorous expansion of purified CFSE-labeled OT-I $CD8^+$ T cells activated by injection of low dose of SIINFEKL peptide *in vivo*. This *in vivo* expansion was even higher than that seen after administration of IL-2/S4B6 immunocomplexes.
In conclusion, IL-2-S4B6 mAb protein chimera mimics IL-2/S4B6 immunocomplexes structurally as well as functionally, and it is probably even more potent than its immunocomplex counterpart.

Colorectal cancer (CRC) is one of the most common malignancies throughout the world. Several risk factors, both genetic and environmental, have been linked with colorectal carcinogenesis. Recent reports suggested an association of some viruses, especially JCV and human papilloma virus (HPV) with CRC. In the present study, we looked for the presence of JCV DNA and T-Ag expression in fresh colorectal tumor biopsies and in paired adjacent normal mucosa collected from forty seven Tunisian patients. DNA was extracted from fresh tissues using the Invitrogen Purelink Genomic DNA mini Kit. Two PCR methods were used to amplify a region of the T gene: a simple PCR with the JCTs/JCTas primer pair specifiying a 154 bp sequence, and a nested PCR using JCTs/JCTas as external and the pair 4129/4209 specifiying a 98 bp sequence, as internal primers. T-Ag expression was determined by immunohistochemical staining using a mouse monoclonal antibody (clone PAb416) directed against SV40 T-Ag that cross reacts with JCV T-Ag. PCR data indicated that 10 of 47 (22%) CRC tumors were positive for JCV DNA whereas all paired adjacent normal mucosa biopsies were negative. On the other hand, immunohistochemical staining showed nuclear T-Ag expression in all ten JCV DNA- positive samples and in 3 additional tumor samples which appeared DNA-negative by PCR. In conclusion, our data are in line with an association of JCV with at least a subpopulation of colorectal tumors.

Chemotherapy can enhance trastuzumab-mediated ADCC

T. Triulzi[1], *L. Sfondrini*[2,1], *S. Varchetta*[3], *V. Regondi*[1], *M. Sasso*[1], *P. Casalini*[1], *G. Bianchi*[4], *G. Mariani*[4], *A. Balsari*[2,1], *E. Tagliabue*[1];
[1]*Dept. of Experimental Oncology and Molecular Medicine, Fondazione IRCCS, Istituto Nazionale dei Tumori, Milan, Italy,* [2]*Department of Biomedical Science for Health, University of Milan, Milan, Italy,* [3]*Department of Infectious Diseases, Istituto di Ricovero e Cura a Carattere Scientifico Policlinico San Matteo, Pavia, Italy,* [4]*Department of Medical Oncology, Fondazione IRCCS, Istituto Nazionale dei Tumori, Milan, Italy.*

Recent clinical data indicated a synergistic therapeutic effect between trastuzumab and taxanes in neoadjuvant setting in HER2-positive breast cancer patients. We hypothesized that the mechanism by which trastuzumab synergizes with taxanes might be mainly through ADCC and that it might depend on the ability of drug-induced stress to improve NK cell effectiveness.
A rapid and dynamic surface expression upmodulation of NK activator ligands was observed in HER2-positive BT474 and MDAMB361 breast carcinoma cell lines treated with taxotere both *in vitro* and *in vivo*, accompanied by about a 15-40% increase in *in vitro* trastuzumab-mediated ADCC. Consistently, antibodies blocking NK receptors (NKG2D and CD226) specific for these ligands significantly reduced this enhancement. We obtained PBMC from 8 HER2-positive breast carcinoma patients isolated at different time points during the neoadjuvant treatment protocol with taxanes followed by trastuzumab. Analysis of NK cells showed that even if their amount among PBMC decreased, their overall activation status increased after chemotherapy, resulting in *in vitro* ADCC levels on BT474 similar to those obtained with PBMC isolated before treatment. Notably NKG2D receptor on NK cells was significantly enhanced by chemotherapy treatment.
Altogether, our results indicate that taxanes can increase tumor susceptibility to ADCC acting on both tumor and NK cells, raising the possibility of identifying optimal chemotherapy administration schedules and new potential strategy to maximize trastuzumab-mediated ADCC.

Osteosarcoma antigen PBF-derived peptides could elicit immunological response in patients with refractory osteosarcoma

T. Tsukahara[1], *M. Emori*[1], *A. Takahashi*[1], *T. Torigoe*[1], *T. Yamashita*[2], *N. Sato*[1], *T. Wada*[2];
[1]*Dept Pathology, Sapporo Medica University, Sapporo, Japan,* [2]*Dept Orthopaedic Surgery, Sapporo Medica University, Sapporo, Japan.*

Osteosarcoma is the high-grade malignant tumor of bone and occur mainly in the 1st and 2nd decades. Although the introduction of neo-adjuvant chemotherapy increased 5-year survival rate to 70%, the prognosis of non-responders to chemotherapy is still poor. Towards the development of peptide vaccination therapy for osteosarcoma, we previously identified autologous CTL-defined osteosarcoma antigen PBF and CTL epitope in the context of HLA-B55 using cDNA library expression cloning. Next, we identified and characterized HLA-A24 and HLA-A2-restricted PBF-derived peptides (PBF A24.2 and PBF A2.2) using limiting dilution/MLPC/tetramer procedure. On the basis of these results, we started clinical phase I trial of vaccination of PBF-derived peptides in HLA-A24+ or HLA-A2+ patients with refractory PBF+ osteosarcoma. Each PBF A24.2 (1mg or 10mg) and PBF A2.2 (1mg) was vaccinated with IFA in five and three cases, respectively. Six-time vaccination schedule was completed in two. After vaccinations, peptide-specific immunological response was observed in four of five HLA-A24+ and two of three HLA-A2 patients using tetramer or ELISPOT. All patients were evaluated as PD under RECIST criteria. In one HLA-A2+ patient, however, necrotic change and infiltration of CD8+ cells in metastatic cutaneous lesion was observed and suggested the effect of peptide vaccination. CPA was occurred in one patient after 5th vaccination of PBF A24.2. In this case, the cause was conceived as adriamycin cardiomyopathy. No other severe adverse events were observed. For further characterization of the effect of vaccination, the clinical trial is still continued.

P6.06.177
Tattoo delivery of Semliki Forest virus-based immunization strategies against cervical cancer

S. van de Wall*, T. Daemen;*
UMCG, Groningen, Netherlands.

Cervical cancer is the second most prevalent cancer among women worldwide. The disease develops as a result of infection with high-risk human papillomavirus (HPV) through persistent expression of early proteins E6 and E7 with transforming capacities in cervical epithelial cells. Numerous immunotherapeutic strategies have been described to induce both cellular and humoral immune responses against the early proteins. Our group pioneered the application of a replication-defective recombinant viral vector system based on Semliki Forest virus (SFV) for vaccination against cervical cancer. In preclinical studies, we demonstrated that a replicon vaccine, based on recombinant SFV encoding HPV E6 and E7 (rSFVeE6,7), induces robust HPV-specific cellular immune and memory responses resulting in excellent therapeutic anti-tumor efficacy. DNA vaccine administration by tattooing can induce potent immune responses. Yet little is known about the efficacy of viral vectors delivered by tattooing.
In this project, the efficacy of tattoo injection with rSFVeE6,7 and SFV-based DNA vaccines was explored.
Our results showed that intramuscular (i.m.) injection of a SFV-based DNA vaccine and rSFVeE6,7 resulted in lower antigen expression in contrast to tattoo injection. Despite the lower antigen expression, tattoo injection was associated with a higher immune response with both vaccine strategies. rSFVeE6,7 also elicited a more potent immune response in contrast to our SFV-based DNA vaccine.
This preliminary study suggests that tattoo immunization has a higher intrinsic immune potentiating activity compared to i.m. immunization. The explanation for this enhanced efficacy will be further studied to unravel the immune mechanisms behind this effect.

A new identified CD20-spliced protein as potential target for T cell-based immunotherapy in B-cell lymphoma/leukemia patients

C. Vauchy[1,2], *C. Gamonet*[1,2], *E. Daguindau*[3], *C. Henry*[1], *P. Rohrlich*[1,3], *O. Adotevi*[1,3], *C. Borg*[1,3], *C. Ferrand*[1,4], *Y. Godet*[1,2];
[1]*Inserm UMR1098, Besançon, France,* [2]*Université de Franche-Comté, Besançon, France,* [3]*CHRU Jean Minjoz, Besançon, France,* [4]*EFS Bourgogne Franche-Comté, Besançon, France.*

CD20 is an antigen expressed on the cell surface of B lymphocytes. It is targeted by therapeutic monoclonal antibodies such as Rituximab in various B cell lymphomas and leukemias. We have identified an alternative transcript variant (ΔCD20) of the human MS4A1 lacking most of the transmembrane segments (Henry et al., Blood 2010). Whereas it was not detected in quiescent B lymphocytes from healthy donors, its expression is detectable in activated EBV infected B cells and in various B cell pathologies such as follicular lymphoma, chronic lymphocytic leukemia, diffuse large B-cell lymphoma and mantle cell lymphoma.
In the present study we show that the Rituximab treatment of normal B lymphocytes or B-cell lymphomas induces the expression or overexpresses the ΔCD20 protein respectively. Thereby ΔCD20 could be an attractive target for T cell immunotherapy in association with Rituximab treatment. Thus, with a reverse immunology approach we sought to identify MHC-I and -II restricted epitopes derived from the ΔCD20 specific sequence. The HLA-A2/DRB1*0101 mouse model was used to identified a ΔCD20 specific epitope presented in the HLA-A*0201 context, and HLA-DR epitopes. ΔCD20 specific CD4+ T cell producing IFN-γ were also observed in lymphoma patients with various HLA class II contexts. Finally, isolated ΔCD20 specific CD4+ T cells clones are capable to induce autologous lymphoma B cell apoptosis after in vitro co-culture.
These results identify ΔCD20 as an attractive target for T cell-based immunotherapy and Rituximab combination treatment for B cell lymphomas and leukemias.

P6.06.179
Immunotherapy for the liver metastases prevention with a vaccine strain of an attenuated *Salmonella* Typhi

A. Vendrell[1], *A. Tesone*[1], *J. De Toro*[1], *L. Herschlik*[1], *M. Gravisaco*[2], *J. Goin*[1], *G. Larotonda*[3], *C. Mongini*[1], *C. Waldner*[1];
[1]*Centro de Estudios Farmacológicos y Botánicos, Buenos Aires, Argentina,* [2]*Instituto de Biotecnología, CICVyA INTA, Buenos Aires, Argentina,* [3]*LAVET Lab Argentina, Buenos Aires, Argentina.*

In previous studies we demonstrated that an attenuated *Salmonella* Typhi vaccine strain (CVD 915) induces tumor-specific immune and therapeutic responses, following intratumoral and subcutaneous inoculations, in mice bearing a subcutaneous mammary adenocarcinoma (LM3). The aim of this work was to study whether orogastric (og) administration of CVD 915 can prevent tumor cell implantation in liver, in a mouse model of liver metastases. Each BALB/c mouse received og $5x10^9$UFC of CVD 915 or PBS (control group). After 24 hours, mice were subjected to surgery and 50,000 LM3 cells were injected into their spleens. Then, a splenectomy was performed. After 24 h of bacterial treatment, CVD 915-treated mice exhibited elevated IFN-γ serum levels. Seven days later, *Salmonella* treatment stimulated the proinflammatory Th1 cytokines production (enhanced IFN-γ level in serum, $p<0.001$, and detectable serum TNF-α and IL-12 levels). The prophylactic treatment with *Salmonella* significantly decreased the occurrence of liver metastases as well as their average volume (1.9 vs. 6.2 mm^3) 21 days after surgery, as compared with control mice ($p<0.05$). Moreover, at that time, an increased frequency of $CD4^+$ lymphocytes but a decreased proportion of B cells ($B220^+$) in both liver and peripheral blood were observed in CVD 915-treated animals ($p<0.05$). These results indicate that a CVD 915-based immunotherapy used preventively via og route induces an antitumor immunity and prevents the implantation of metastasis in a vital organ. The use of this vaccine as an adjunct therapy to conventional cancer treatments, such as surgery, should be assessed in the future.

Antitumor activity of a *Salmonella* Typhi vaccine strain in a mouse model of T-cell lymphoma

A. Vendrell[1], *A. Tesone*[1], *J. De Toro*[1], *L. Herschlik*[1], *M. J. Gravisaco*[2], *J. C. Goin*[1], *G. Larotonda*[3], *C. Mongini*[1], *C. I. Waldner*[1];
[1]*Centro de Estudios Farmacológicos y Botánicos CONICET-UBA, Buenos Aires, Argentina,* [2]*Instituto de Biotecnología, CICVyA, INTA, Buenos Aires, Argentina,* [3]*Lavet Lab Argentina, Buenos Aires, Argentina.*

Previously we demonstrated the therapeutic efficacy of an attenuated vaccine strain of *Salmonella* Typhi as a cancer immunotherapy in a mouse model of subcutaneous T cell lymphoma. EL4 tumor-bearing mice treated with *Salmonella* Typhi CVD 915, by injection into the tumor and in the area of the draining lymph nodes, showed reduced tumor growth and increased survival. In this work, we further studied the therapeutic efficacy and the antitumor effector mechanisms promoted by this bacterium. Our results indicate that the treatment with *Salmonella* promoted a reduction in the mitotic index of the tumors (p <0.05) and delayed the development of palpable metastases in the lymph nodes (p <0.001). Furthermore, the administration of *Salmonella* in tumor-bearing mice promoted leukocyte infiltration, mainly neutrophils (p <0.01) and decreased IL-10 levels in the tumor microenvironment (p <0.05), and also reduced LTreg frequency in tumor draining lymph nodes. Under these conditions, *Salmonella* remained viable within the tumor, and tumor-infiltrating neutrophils released TNF-α and expressed bacterial antigens. Finally, *Salmonella* was found to bind to tumor cells and exert oncolytic activity upon direct contact with the tumor cell. These results demonstrate the efficacy of a vaccine strain of *Salmonella* Typhi as an oncolytic and immunotherapeutic agent against a highly malignant tumor.

P6.06.181
Lcn2 secreted from DCs induces CD8+ T-cell apoptosis, it is involved in T-cell priming, and upon DCs vaccination trigger a Th1 phenotype

M. Floderer[1], *M. Prchal*[2], *J. Warszawska*[3], *S. Knapp*[3], *T. Felzmann*[4], ***C. Vizzardelli***[5];
[1]*St. Anna Children's Cancer Research Institute,, Vienna, Austria,* [2]*Institute of Pharmacology and Toxicology, Dept for Biomedical Science University of Veterinary Medicine, Vienna, Austria,* [3]*Dept. of Medicine 1, Div. of Infectious Diseases & Tropical Medicine, Medical University Vienna, and Ce-M-M- Center for Molecular Medicine of the Austrian Academy of Sciences, Vienna, Austria,* [4]*Activartis Biotech GmbH, Vienna, Austria,* [5]*St. Anna Children's Cancer Research Institute, Vienna, Austria.*

Lipocalin 2 is expressed from dendritic cells during the late phases of Dex and LPS maturation. DCs are professional antigen presenting cells capable of regulating immunity. Besides the classical understanding concerning mouse DC subsets, new studies are suggesting that DCs follow a multi-stage differentiation programme after encountering danger signals, which facilitates the fine-tuning of the immune responses. Tolerance maintenance, immune-stimulation and immune-suppression are time dependent functions of the DCs. Lcn2 is active in defence against bacteria via capturing of iron, and it is involved in autocrine apoptosis of T-cells. In order to understand the function of Lcn2 in the DC/T-cell interaction, we stimulated mouse bone marrow Lcn2-/- or wild type DCs with Dex and LPS and co-cultured with T-cells from OT-I or OT-II transgenic mice. The induction of apoptosis in T-cells was highly reduced using the Lcn2-/- compared to WT DCs. An in vivo Cytotoxic T-Lymphocyte killing assay using LPS treated Lcn2-/-- or WT-DCs as vaccine showed that the specific killing ability was diminished in mice that had received Lcn2-/--DCs (in WT-DCs 96,18 ± 0,5057, in Lcn2-/--DCs 87,12 ± 2,034, p<0.01). We conclude that Lcn2 is involved in the priming of CD8+ and CD4+ T-cells in a dose dependant manner, and induces a TH1 microenvironment. In DCs treated with Dex and LPS high expression of Lcn2 is involved in CD8+ T-cell apoptosis. This study aims to contribute to better understand the DCs' biology and to improve their use in cancer vaccination.

P6.06.182
Allogeneic dendritic cells induce potent antitumor immunity by activating KLRG1$^+$CD8 T cells

C. Wang, *Z. Zhu, Y. Wu, X. Liu, Y. Wang, Z. Li, D. Peng, Z. Chang, X. Cao, M. Zhang;*
School of Medicine, Tsinghua University, Beijing, China.

There is increasing evidence that strong antitumor effects can be elicited by allogeneic vaccines, although the underlying mechanisms remain undefined. In this context, first, we observed that allogeneic DC (alloDC) vaccination could significantly inhibit tumor progression in C57BL/6 mice, as well as in immunodeficient $\beta_2m^{-/-}$ mice. Then, we found that alloDC immunization could result in a predominant increase in a subpopulation of CD8 T cells co-expressing T cell–activated markers and NK receptors, among which the most representative is KLRG1. Subsequently, we revealed the positive correlation between the amount of KLRG1$^+$CD8 T cells and antitumor efficacy in alloDC-vaccinated mice, followed by a further exploration demonstrating the involvement of KLRG1$^+$CD8 T cells in tumor rejection, as they showed more efficient migration to tumor sites and more potent antitumor effects when adoptively transferred into naïve mice. Finally, alloDC-activated KLRG1$^+$CD8 T cells were shown to exert direct cytotoxicity on tumor cells by the granule exocytosis pathway. The data we present in this study suggest that the small KLRG1$^+$CD8 T cell subset, which was thoroughly ignored in normal mice, represents an important allo-stimulated antitumor effector subset. Based on the high antitumor efficiency of these KLRG1$^+$CD8 T cells, a therapeutic vaccination using allogenic APCs might be a potential anti-tumor approach.

P6.06.183
Expression of cancer testis antigens (CTAs) and its correlation with clinical parameters in Chinese hepatocellular carcinoma

M. Wang[1], *J. Li*[2], *Y. Zhao*[3], *D. Li*[4], *Z. Fan*[4], *Y. Sun*[4], *Z. Tang*[4], *Z. Li*[5], *S. Wu*[5], *Y. Zhang*[6];

Background: Many therapies such as surgery, chemical or physical approaches have been used for treatment of HCC; however, the outcome is still poor. Cancer immunotherapy is considered to be one of the promising strategies in recent years. We aim to evaluate the expression of cancer testis antigens (CTAs) in Chinese hepatocellular carcinoma and its correlation with clinical parameters. Methods: Expression levels of CTAs including MAGE-A3, MAGE-A4, MAGE-C2 and NY-ESO-1 mRNA were detected with reverse transcription polymerase chain reaction (RT-PCR) in HCC tissues and corresponding adjacent non-cancerous tissues from 54 HCC patients. Genes of five samples with positive PCR results were sequenced. Results: 87.0% of HCC tumor tissue samples expressed at least 1 CTA. HCC adjacent non-cancerous tissues did not express CTA. 77.8% tumor tissue samples expressed MAGE-A3 mRNA, 35.2% samples expressed MAGE-A4 mRNA, 68.5% samples expressed MAGE-C2 mRNA and 13.0% samples expressed NY-ESO-1 mRNA. The expression of CTA showed correlation with Ki67(r=0.35, P0.05). The expression of MAGE-A3 showed correlation with the high expressions of AFP in serum (r=0.42, P<0.01) and lymph node metastases (r=0.31, P=0.02). The expressions of NY-ESO-1 showed no correlation with the expressions of AFP and lymph node metastases (P>0.05). Conclusion: Our findings demonstrate the tumor-specific expression of CTAs genes show correlations with

tumor stages and proliferation and may represent useful targets for tumor specific immunotherapy in HCC patients.

P6.06.184
Cell surface delivery of TRAIL strongly augments the tumoricidal activity of T-cells

***V. R. Wiersma**, M. de Bruyn, D. F. Samplonius, W. Helfrich, E. Bremer;*
University Medical Center Groningen, Groningen, Netherlands.

Adoptive T-cell therapy has the potential to enhance antitumor immunity, although it is generally ineffective in patients with solid tumors. This is mainly caused by resistance of malignant cells to cytotoxic defense mechanisms of the immune system. During normal tumor immune surveillance, natural killer (NK)-cells use surface expressed TNF-related apoptosis-inducing ligand (TRAIL) to kill transformed cells. In contrast, the expression of TRAIL on T-cells is typically low. In order to enhance the tumoricidal activity of T-cells, we designed a strategy to specifically deliver TRAIL to the T-cell surface. Hereto, we constructed two TRAIL-fusion-proteins directed to T-cell antigens CD3 and CD7, designated anti-CD3:TRAIL and K12:TRAIL, respectively. Both anti-CD3:TRAIL and K12:TRAIL selectively bound to T-cells and accreted TRAIL at the T-cell surface. This potently enhanced the tumoricidal activity of T-cells toward cancer cell lines and primary patient-derived malignant ovarian carcinoma. Furthermore, T-cell surface delivery of TRAIL inhibited tumor growth and increased survival time of xenografted mice more than 6-fold. Interestingly, both fusion proteins had a distinct mode of action, as anti-CD3:TRAIL mainly induced granzyme/perforin-mediated cell lysis, whereas K12:TRAIL activated initiator caspase-8/-9 and effector caspases. In addition, anti-CD3:TRAIL also activated resting T-cells by triggering CD3 signaling. In conclusion, cell surface delivery of TRAIL to T-cells potently augments the tumoricidal activity of T-cells *in vitro* and *in vivo*, and could be easily integrated in current T-cell-based anti-cancer therapies.

P6.06.185
NK depletion enhances the rejection of established melanoma by tumor-specific CD4+ T cells

***K. A. Wilson**[1], S. R. Goding[1], K. M. Harris[1,2], H. R. Neeley[1], P. A. Antony[1];*
[1]University of Maryland, School of Medicine, Baltimore, MD, United States, [2]Immune Tolerance Network, Bethesda, MD, United States.

Five-year survival rates for patients diagnosed with metastatic melanoma are less than 5%. Adoptive cell transfer (ACT) has achieved an objective response of 50% by Response Evaluation Criteria in Solid Tumors (RECIST) in this patient population. For ACT to be maximally effective, the host must first be lymphodepleted. The lymphodepletion procedure is often accompanied by myelotoxic, nephrotoxic, and pulmono-toxic adverse effects. It is hypothesized that lymphodepletion may remove regulatory elements and cytokine sinks, or increase that activation and availability of antigen presenting cells (APCs). We are using an *in vivo* model of ACT of tumor-specific CD4+ T cells (TRP1 cells) to study the interaction between natural killer (NK) cells and CD4+ T cells during malignancy. We found that depletion of natural killer (NK) cells enhances therapy. NK depletion increases the number of tumor-specific $CD4^+$ T cells and APCs, and the serum concentration of pro-inflammatory cytokines. Additionally, we observe increased autoimmune vitiligo and fewer tumor relapses after ACT when combined with NK cell depletion. Our data suggests that NK depletion removes a cytokine sink. Understanding this mechanism may help develop new therapies that would obviate the need for toxic lymphodepletion prior to ACT.

P6.06.186
IL-17A promotes immune cell recruitment in human esophageal cancers

***J. Xia**, L. Lv, K. Pan;*
Sun Yat-sen University Cancer Center, Guangzhou, China.

We previously reported that tumor-infiltrating IL-17A-producing cells play a protective role in human esophageal squamous cell carcinoma (ESCC). However, the potential mechanisms involved remain unclear. In the present study, we investigated the effects of IL-17A on immune cell recruitment and function in ESCC. In vitro chemotaxis assays using the ESCC cell lines EC109 and KYSE30 demonstrated that while IL-17A showed no significant direct effects on the migration of T cells, NK cells as well as DCs, it could induce ESCC tumor cells to produce inflammatory chemokines, e.g. CXCL9, CXCL10 and CCL2, CCL20, which are associated with the migration of T cells, NK cells and DCs respectively. In addition, IL-17A enhanced the cytotoxic effects of NK cells against tumor cells by augmenting the expression of cytotoxic molecules, e.g. TNF-α, IFN-γ, perforin and granzyme B and activation receptors, e.g. NKp46, NKp44, NTB-A and NKG2D on NK cells. Furthermore, immunohistochemical analysis revealed that the density of IL-17A-producing cells was positively and significantly associated with the density of CD1a+ dendritic cells (DCs) in tumor tissues. With the analyses of 181 ESCC patients, we found a correlation of higher number of tumor infiltrating CD1a+ DCs with significantly improved overall survival of patients with ESCC. This study provides further understanding of the roles of Th17 cells in ESCC, which may contribute to the development of novel cancer immunotherapy strategies.

P6.06.187
The effects of esomeprazole combined with classical cancer drugs on lung cancer cells and peripheral blood mononuclear cells

***A. Yılmaztepe Oral**[1], &. Korkmaz[1], F. Budak[2], G. Özkaya[3], E. Ulukaya[1], H. Oral[2];*
[1]Uludag University Faculty of Medicine, Department of Medical Biochemistry, Bursa, Turkey, [2]Uludag University Faculty of Medicine, Department of Immunology, Bursa, Turkey, [3]Uludag University Faculty of Medicine, Department of Biostatistics, Bursa, Turkey.

Ascidity of tumour microenviroment is one of the important factors in resistance to chemotherapeutics. Proton pumps play a critical role by transfering H^+ ion from cell cytoplasm into extracellular compartment. In this study, to examine if esomeprazole, a proton pump inhibitor, increases the sensitivity of A-549 cells to classical drugs used for lung cancer treatment. For this aim, the combination of classical drugs used for lung cancer treatment with esomeprazole were applied onto A-549 cells, and then, their cytotoxic effects were evaluated with Methyl Thiazol Tetrazolium (MTT) Assay, ATP-TCA and M30 ELISA. It was demonstrated that combinations of esomeprazole only with cisplatin and carboplatin lead to significant increase in cytotoxicity. Additionally, M30 levels were measured in order to determine the cell death mechanism. The increase of M30 levels in carboplatin alone and in combination with esomeprazole exhibit that carboplatin causes cell death by apoptosis. The fact that no increase was observed with ciplatin alone and in combination with esomeprazole suggested that cisplatin, unlike carboplatin, leads to cell death by necrosis. Furthermore, the cytotoxic effect of esomeprazole alone and in combination with cancer drugs on lymphocytes were investigated with MTT and flow cytmetric cell cycle analysis. When compared with control group apoptotic cell ratio was dose-dependently increased with both esomeprazole alone and in combination with cisplatin or carboplatin. Our study suggests that espomeprazole augments the sensitivity of tumour cells to chemotherapeutics, and also, may protect the host from side effects caused by high doses of cancer drugs.

Infection of normal B cells by Epstein Barr Virus (EBV) induces activation and subsequent transformation of B cells to lymphoblastoid cell lines (LCLs). Chronic lymphocytic leukemia (CLL) cells can be infected by EBV in vitro, however, they are refractory to transformation. We describe establishment of a LCL line with B1 characteristics following in vitro EBV infection and costimulation with CpG and CD40 ligand from a mutated CLL patient. Infection with EBV alone did not result in establishment of growing LCLs. The growing LCL was found to co-express CD5 and CD19 implying its possible leukemic origin, however, immunoglobulin heavy chain variable gene (IGHV) analysis revealed disparity in VH rearrangement pattern of the LCL (VH3) and the corresponding CLL B cells (VH6). Further flow cytometry revealed expression of CD5, 43, 27, 20 and CD23 and dim expression of activation markers CD38 and CD25, suggesting derivation from the normal B1 circulating pool. Sequencing of IGVH gene demonstrated expression of IGHV3-23*01 and IGHJ4*02 gene which belong to the skewed human B1 BCR repertoire. The LCL cells secrete secreted IgM, as determined by ELISA.
Our results indicate that despite employment of an improved EBV transformation method which enhanced the B cells transformation efficiency, the leukemic CLL B cells are refractory to EBV transformation.

Identification of surface molecules with enzymatic and signaling proprieties as targets for mAb-immunotherapy of human prostate cancers

G. Zaccarello[1], *A. Zitella*[2], *V. Quarona*[1], *L. Daniele*[3], *G. Chiorino*[4], *M. Bellò*[5], *A. Tizzani*[2], *A. L. Horenstein*[1,6], *G. Bisi*[5], *F. Malavasi*[1];
[1]*Lab of Immunogenetics, Department of Medical Sciences, University of Torino, Torino, Italy,* [2]*Department of Urology, Città della Salute e della Scienza Hospital, University of Torino, Torino, Italy,* [3]*Department of Biomedical Sciences & Oncology, University of Torino, Città della Salute e della Scienza Hospital, Torino, Italy,* [4]*Cancer Genomics Lab, Fondo Edo Tempia, Biella, Italy,* [5]*Department of Nuclear Medicine, Città della Salute e della Scienza Hospital, Torino, Italy,* [6]*Research Center on Experimental Medicine (CeRMS), Torino, Italy.*

We developed a panel of murine monoclonal antibodies (mAb) for diagnosis and therapy of human prostate cancers by selecting targets with enzymatic and/or signaling proprieties. mAb selection was made by exploiting different approaches on fresh and prostate cells). The selection grid lead to the selection of mAbs tested for their ability to modulate the transcriptome of the LNCaP line. Out of these, one was characterized as an anti-PSMA, a glycoprotein provided with enzymatic activities of N-acetylated α-linked acidic dipeptidase (NAALADase) and also of pteroyl poly-γ-glutamyl carboxypeptitdase (i.e., folate hydrolase). The molecule is homologous with the transferrin 1 and 2 receptors. The anti-PSMA mAb was efficiently used for radio-immumoscintigraphy in mice bearing a human prostate tumor. *In vitro* mAb ligation did not induce significant variations in the transcriptome on LNCaP, as tested by microarray.
Other reagents selected were agonistic mAb regulating gene activation. GF/3E8 modulates the expression of genes involved in carcinogenesis, metastatic spreading and transcription of cancer biomarkers.
GF/3D3 and C5 mAbs bind a 60 kDa heat-shock protein.
This study has enriched the armamentarium of mAbs specific for human prostate. The ongoing efforts are to use the regents non giving activatory signals as carriers of radioactive tracers (or toxins), ideal tools to trace primary and secondary lesions. Next step of the project is to use of the enzymatic characteristic of PSMA to convert pro-drug in to activate *in situ* anti-cancer drugs. Ambitious goal will be to use agonistic mAb for differentiation therapies or to induce cell death.

P6.06.190
Modulation of tumor microenvironment associated with tumor regression in melanoma patients receiving adoptive cell transfer therapy

J. Zhou[1], *B. Xiao*[1], *J. Sun*[1], *Z. Liu*[1], *Y. Zhong*[2], *G. Zhang*[1], *X. Chi*[1], *Q. Huang*[1];
[1]*Ludong University, Yantai, China,* [2]*University of South Carolina School of Medicine, Columbia, SC, United States.*

Mechanisms of tumor regression in melanoma patients after adoptive T cell transfer have not been fully understood. In this report, the interaction between the tumor microenvironment and adoptively transferred T cells in melanoma patients was examined. The gene expression of gp100 and MART-1 decreased dramatically in the fine needle aspiration biopsies from patients with objective responses after adoptive immunotherapy, suggesting that analysis of gp100 and MART-1 expression represents a surrogate marker for clinical responses in melanoma patients. Following T cell transfer, significant increases in the expression of CD8, IFNγ, TGFβ1, TNFα and ARG1 were observed in tumor deposits. Responders demonstrated significantly increased ratio of CD8 to CD4 and higher level of TNFα expression in tumors than non-responders, suggesting that expression of this inflammatory cytokine may be associated with tumor regression. In contrast, non-responders demonstrated higher levels of CTLA-4, IDO and IL-10 expression in tumors than responders, implying that they may impede tumor regression. Moreover, the expression levels of CD8, CD25, IL-2 and GM-CSF in tumors one week after adoptive cell transfer significantly correlated with clinical response duration. Specific clonotypes derived from the transferred T cells selectively accumulated in tumors one month after adoptive cell transfer, indicating that they may play a role in tumor microenvironment modulation and tumor regression. The results indicate that clinical response may be associated with relatively high levels of expression of T cell activation markers and stimulatory cytokines and relatively low levels of expression of inhibitory molecules modulated by adoptive cell transfer immunotherapy.

P6.06.191
A tumor vaccine against chronic lymphocytic leukemia

F. Zhu, *R. Gorczynski, D. E. Spaner;*
University of Toronto, Toronto, ON, Canada.

Chronic lymphocytic leukemia (CLL) is incurable with conventional therapies. Malignant B cells in CLL are able to be antigen-presenting cells (APC) themselves and are ideal targets of immunotherapy. However, various immune-based therapeutic approaches that were tried haven't improved the survival of patients significantly. In this study, CLL cells were treated with PMA, IL-2, Imiquinod (TLR-7 agonist) which are all B cell activators for 48 hours. The treated cells developed branched projections and had an elevated expression of CD54, CD83, CD80 and CD86 on cell membrane, which are all characteristics of mature dendritic cells (DC). Moreover, these treated cells are more immunogenic in cytotoxic T lymphocyte assay (CTL) with peripheral blood mononuclear cells (PBMC) from healthy donors than original CLL cells. CLL animal models (NOD.SCIDIL-$2^{\gamma-/-}$ mice), which had CLL cells engrafted in peritoneal cavity (PC) and spleen (SP), were infused with treated autologous CLL cells twice as tumor vaccine. Then CFSE-labeled autologous CLL cells were given to the mice to test if engrafted T cells were activated by the vaccination in vivo. Cells in PC and SP were collected for counting and CTL assay *ex vivo*. The vaccinated mice had less CLL cells engrafted both in PC and SP, especially those mice that are treated with anti-CD200 antibody and anti-CD20 antibody in advance. The CTL assay confirmed that cells from vaccinated mice were able to kill more CLL cells and anti-CD200/anti-CD20 treatment augmented the ability. Our

data suggest an effective immunotherapeutic strategy for CLL which may be used clinically.

P6.06.192
Construction and functional activity of shRNA targeting Wnt-1 gene hyperexpressed by Wnt-1 breast tumors in mice

D. A. Zubkov[1]*, A. A. Lysenko*[2]*, E. V. Smirnova*[1]*, A. A. Zubareva*[3]*, E. V. Svirshchevskaya*[1]*;*
[1]*Shemyakin and Ovchinnikov Institute of Bioorganic Chemistry RAS, Moscow, Russian Federation,* [2]*Gamaleya Research Institute of Epidemiology and Microbiology, Moscow, Russian Federation,* [3]*Bioengineering Center RAS, Moscow, Russian Federation.*

RNA interference is used to down regulate key genes involved in tumor progression. For biomedical applications, expression of short hair-pin interfering RNA (shRNA) in viruses possesses the advantage of safe gene delivery to tumors by intravenous injections. The aim of this work was to construct shRNA interfering Wnt-1 gene involved in breast tumor formation in mice. Five Wnt-1 shRNA, coding different regions of Wnt-1 gene, were obtained in HEK-293T cells in the form of non-replicating lentivirus particles (LVP) using pLV-neo system. LVP were concentrated and purified using PEG and the titers were estimated on 3T3 fibroblast monolayers. Functional activity was verified in vitro using primary Wnt-1 cells obtained from tumors. Incubation with LVP2, 5 and their mixtures suppressed in a dose-dependent manner Wnt-1 expression as was determined by flow cytometry using antibodies to Wnt-1. LVP1, 3 and 4 did not affect Wnt-1 expression. LVP2 and LVP5 were injected intravenously into mice with Wnt-1 tumors three times a week during 3 weeks. Control mice were treated with chitosan nanoparticles loaded with doxorubicin (Chi-DOX) or doxorubicin alone. Both DOX and Chi-DOX effectively inhibited while LVPs significantly stimulated the growth of tumors. These results are rather unexpected and require further study.
This work was supported by Federal targeted program “Scientific and educational innovations for 2009-2013”, grant # 14.512.11.0001.

Repeated intra-muscular injections of allogeneic mesenchymal stem cells (MSC) promote donor-specific T-cell hypo-responsiveness but also induce allo-antibody

S. Alagesan*, M. Creane, T. O’Brien, R. Ceredig, T. Ritter, M. D. Griffin;*
Regenerative Medicine Institute, School of Medicine, National University of Ireland, Galway, Galway, Ireland.

MSC from allogeneic donors (allo-MSC) have therapeutic potential for immune-mediated diseases and may be immune-privileged. For clinical translational, however, clearer understanding of allo-MSC immunogenicity is needed. In this study, anti-donor T-cell and B-cell responses following single or repeated intra-muscular injections of allo-MSC were examined in mice.
BALB/c mice received 10^6 allo(B6)-MSC, allo(B6)-splenocytes, syngeneic(BALB/c)-MSC or vehicle once or on two occasions 2 weeks apart. One week later, anti-donor T-cell and antibody responses were assessed. In T-cell “re-call” assays stimulated by donor(B6) or third-party(FvB) DCs, increased donor-specific $CD4^+$ and $CD8^+$ T-cell proliferative responses occurred following single or repeated allo-splenocyte injections and single allo-MSC injections compared to vehicle and syngeneic MSC. In contrast, repeated allo-MSC injection was associated with donor-specific T-cell hypo-responsiveness. Key results: B6-DC-induced $CD4^+$ T-cell proliferation (%-divided, mean±SD): Vehicle injections: 67.8±7.9%; Repeated allo-splenocyte injections: 85.1±4.1%; Repeated allo-MSC injections: 37.4±12.8%. $CD8^+$ T-cell proliferation: Vehicle: 68.2±9.6%; Repeated allo-splenocyte: 88.6±0.5%; Repeated allo-MSC: 47.3±12.4%. FvB-DC-induced T-cell proliferation did not differ between the groups.
Flow cytometry-based assays indicated similar titres of donor-specific (anti-B6) IgG among recipients of single and repeated allo-splenocytes as well as single and repeated allo-MSC. However, IgG isotype-specific assays indicated that IgG1:IgG2a ratio was higher in serum of repeated allo-MSC recipients compared to repeated allosplenocyte recipients (2.6±0.25 vs 0.6±0.22; p=0.000004). Nonetheless, sera from recipients of multiple allo-MSC injections were associated with complement-mediated lysis of B6 target cells *in vitro*.
Thus, repeated intra-muscular inoculations of allo-MSC induce distinctive donor-specific immune responses that include T-cell hypo-responsiveness and IgG1-dominant allo-antibody production.

P6.07.02
Generation of tolerogenic monocyte-derived dendritic cells from patients with primary Sjögren’s syndrome that suppress Ro/La specific T cell responses

R. Volchenkov[1]*, J. G. Brun*[2]*, R. Jonsson*[1]*,* ***S. Appel***[1]*;*
[1]*Broegelmann Research Laboratory, Gade Institute, University of Bergen, Bergen, Norway,* [2]*Department of Rheumatology, Haukeland University Hospital, Bergen, Norway.*

Primary Sjögren’s syndrome is a chronic autoimmune disease, characterized by mononuclear cell infiltrations preferentially in salivary and lacrimal glands that lead to dryness of mouth and eyes. In a majority of the patients, autoantibodies against SSA (Ro52 and Ro60) or SSB (La) are present. There exists no cure, and current therapies rely mostly on alleviating the symptoms. Therapeutic vaccination with antigen specific tolerogenic dendritic cells (DC) might become a future option of individualized therapy for patients with autoimme diseases like Sjögren’s syndrome. Here we generated monocyte-derived tolerogenic DC from patients with primary Sjögren’s syndrome using dexamethasone, vitamin D3 and LPS (DexVD3 DC). The phenotype was analyzed by flow cytometry and cytokine profile was investigated using 25-plex Luminex assay and ELISA. The capacity to induce Ro/La specific T cells was evaluated by an autologous MLR. Furthermore, the suppressive capacity of the induced T cells was analyzed in a suppression assay. DexVD3 DC generated from patients with primary Sjögren’s syndrome had an increased expression of CD83 compared to DexVD3 DC from healthy controls. They induced little antigen specific T cell proliferation, but the induced T cells successfully suppressed Ro/La specific T cell proliferation. Therefore, DexVD3 DC presenting Ro/La antigens might be a promising new therapeutic option for patients with primary Sjögren’s syndrome.

P6.07.03
Mesenchymal stem cells (MSC) modulate the expression of adhesion molecules involved in activated T-lymphocyte extravasation into the central nervous system (CNS): contribution to the therapeutic effect of MSC in inflammatory CNS diseases?

F. Benvenuto[1]*, L. Vergani*[1]*, F. Gualandi*[2]*, N. Kerlero De Rosbo*[1]*, A. Uccelli*[1]*;*
[1]*University of Genoa, Genoa, Italy,* [2]*IRCCS "IST -San Martino2, Genoa, Italy.*

Multiple Sclerosis (MS) is an autoimmune disorder associated with an abnormal leucocyte migration into the CNS through a multistep process characterized by the interaction between activated leucocytes and endothelial cells of the brain blood barrier (BBB) and choroid plexus. This interaction is mediated through several molecules expressed on activated leukocytes like α4β1 integrin and LFA-1, which bind to VCAM1 and ICAM-1, respectively, therefore blocking of receptors and/or ligands implicated in this interaction results in amelioration of the disease. Furthermore the majority of T cells in the cerebrospinal fluid (CSF) express CXCR3, suggesting its fundamental role in T cell extravasation into the CNS. Mesenchymal stem cells (MSC), potent immunoregulators that modulate effector functions of cells of innate and adaptive immune system through juxtacrine and paracrine mechanisms, are being investigated for therapy to MS. Accordingly, we have studied the effect of MSC in vitro on the expression of the receptors and their ligands on T cells and endothelial cells. We show that MSC decrease the expression of α4β1 integrin and ICAM-1 both at $_m$RNA and plasma membrane levels. The expression of CXCR3 on T cells was also decreased by

MSC together with the CXCR3-mediated migratory activity. MSC decreased the expression of ALCAM and ICAM-1 which become up-regulated on the plasma membrane of endothelial cells and are crucial for extravasation of T lymphocytes into the CNS. Our transwell experiments indicate that the dual mode of action of MSC on T lymphocytes and on endothelial cells is likely to be through paracrine mechanisms.

P6.07.04
Umbilical cord blood T cells cultured with IL-7 in addition to IL-2 exhibit a higher degree of polyfunctionality and superior proliferation potential

***S. Berglund**, J. Gertow, I. Magalhaes, J. Mattsson, M. Uhlin;*
Karolinska Institute, Stockholm, Sweden.

BACKGROUND: Umbilical cord blood transplantation (UCBT) is an increasingly used stem cell source for allogeneic stem cell transplantation. One disadvantage to UCBT is that treatment with donor lymphocyte infusion (DLI) is not possible. We wanted to explore if cultured T cells from the UCB graft could offer an alternative to DLI in this setting. METHODS: T cells were positively selected with CD3+/CD28+ magnetic beads and cultured with IL-2 at escalating concentrations. In addition, IL-7 (20 ng/ml) was added to half of the cultures. After 7 days of expansion the T cells were analyzed by flow cytometry to determine phenotype, and cytokine production.
RESULTS: There was significantly greater proliferation in cultures to which IL-7 had been added. Phenotypical differeces such as a higher CD4+/CD8+, a lower percentage of central memory T cells (CD45RO+ CCR7+) and a higher percentage of effector memory T cells (CD45RO+ CCR7-) was seen with IL-7. We assessed the intracellular production of IL-2, TNF-alpha, IFN-gamma and CD107a, and found that a higher percentage of polyfunctional T cells (positive for three or four factors) was seen in cells cultured with IL-7 in CD3+ and CD3+CD8+ cells, with a trend towards the same association also in CD3+CD4+ cells.
CONCLUSION: There seem to be a proliferation advantage in adding IL-7 to a lower dose of IL-2. Addition of IL-7 also seems to have an impact on the differentiation status of the cells. T cells cultured in IL-7 had more polyfunctional traits, possibly increasing the activity of a putative future DLI.

P6.07.05
A simple and quick method for isolation of mononuclear cells from peripheral blood and buffy coat

***S. Bhatia**;*
Genekam Biotechnology AG, Duisburg, Germany.

Isolated mononuclear cells (MNC) are fundamental requirement for a number of immunological experiments. At present, density gradient centrifugation is the method of choice to isolate MNC from human peripheral blood and buffy coat, but it is cumbersome, unsuitable for small volumes e.g. 50 ul, needs 90 minutes to be performed and there is a loss of a number of cells during this process.
We developed a new method based on solution called Genekam MNC Isolater containing different inorganic chemicals. This solution can be mixed with peripheral blood or buffy coat at ration of 1:3 or 1:10 and kept at room temperature for 10 minutes. Subsequently it is washed two times with phosphate buffer to get a clean pellet containing MNC. We used it successfully on 50 ul to 1 ml samples to get the sufficient number of MNC within 25 minutes for culturing. Cultured cells remain vital upto 30 days. Number of cells produced in our method are much higher than density gradient centrifugation, hence it makes it more stable for applications, where large number of MNC from small volume of blood and huge number of MNC from large volume of blood or buffy coat are needed. The cells are examined microscopically for their morphology and through flowcytometry for different biomarkers of lymphocytes e.g.CD3, CD4, CD19, C20 etc.
We developed simple, quick and economical method to isolate MNC, which may accelerate the research work in immunology. Now we are applying it to perform different other immunological experiments in our laboratory.

P6.07.06
Altered B cell development and fuctions in Adenosine Deaminase deficient patients

***I. Brigida**[1], A. V. Sauer[1], F. Ferrua[2], S. Giannelli[1], S. Scaramuzza[1], M. P. Cicalese[2], M. Casiraghi[2], E. Traggiai[3], M. Van der Burg[4], A. Aiuti[1,5];*
[1]San Raffaele Telethon Institute for Gene Therapy (HSR-TIGET), Milan, Italy, [2]Pediatric Immunohematology and Bone Marrow Transplantation Unit, San Raffaele Scientific Institute, Milan, Italy, [3]Novartis Institute for Research in Biomedicine, Basel, Switzerland, [4]Department of Immunology, Erasmus MC, University Medical Center, Rotterdam, Netherlands, [5]Department of Systems Medicine, Tor Vergata University, Rome, Italy.

Adenosine deaminase (ADA) deficiency causes severe cellular and humoral immune deficiency and dysregulation due to metabolic toxicity. Alterations in B cell development and function have been poorly studied in these patients. Enzyme replacement therapy (ERT) and hematopoietic stem cell gene therapy (GT) are therapeutic options in patients lacking a suitable bone marrow transplant donor. We studied bone marrow (BM) of ADA-deficient patients and investigate the ability of ERT and GT to restore normal B cell differentiation and functions in BM and PB. We found that BM B cells from untreated ADA-deficient patients show an increased proportion of pre-B1 B-cells and a progressive decrease in later stage of maturation. This is in agreement with observation that the strongest selective advantage for ADA-transduced cells is observed at the transition from immature to naïve cells. BM alterations were overcome in patients treated with GT or ERT, but in the latter group immature B cells were expanded. In the periphery, transitional B cells accumulate under ERT and persist long-term, while after GT, transitional B cell frequency progressively normalized. Down regulation of BAFF-R and higher BAFF plasma levels were observed both in ERT and GT patients. B cell proliferative responses after BCR/TLR triggering were severely impaired in ERT patients but improved after GT. Our findings confirm that transfer of ADA gene into autologous hematopoietic stem cells restores B-cell development and functions.

P6.07.07
The effector function of antiviral T cells in stem cell donors is strongly impaired by G-CSF mobilization

***C. Bunse**, S. Borchers, S. Tischer, N. Moraw, C. Figueiredo, U. Köhl, A. Ganser, R. Blasczyk, E. Mischak-Weissinger, B. Eiz-Vesper;*
Hannover Medical School, Hannover, Germany.

Cellular therapies have become a powerful tool to complement impaired immune reconstitution in patients after hematopoietic stem cell transplantation (HSCT). Recent publications suggest that G-CSF-mobilized donors might be a source for antiviral T cells for adoptive therapy. As information on number and functionality of antiviral T cells is scarce, we aimed to (1) identify the immunomodulatory effects of G-CSF on antiviral T-cells, (2) detect influence of the apheresis procedure and (3) discuss optimal time points to collect antiviral T cells for transfer.
We assessed (1) numbers of CMV-, EBV- and ADV-specific T cells using 14 HLA-matched multimers, (2) functionality by IFN-γ ELISpot in response to overlapping peptide pools, (3) immunophenotyping using bio-plex, Granzyme B ELISA and multicolour flow cytometry for T-effector and -memory cell subsets in order to characterize the influence of G-CSF and enrichment procedure.
Absolute numbers of antiviral T cells detected after G-CSF stimulation and compared to G-CSF-untreated samples and *in vitro* expansion rate upon antigenic stimulation was not influenced. However, functionality as expressed by mean reduction in IFN-γ (75% *in vivo*, 40% *in vitro*) and Granzyme B secretion (32% *in vitro*) was significantly impaired in response to all tested antigens tested.
Our results suggest that antiviral T cells from mobilized stem cell grafts might not be the optimal source for adoptive therapies due to their functional impairment. For patients with early viral complications whose donors is still under the influence of G-CSF or those with seronegative donors, third party T cells might be an attractive alternative.

P6.07.08
Tie2 monocyte-mediated delivery of interferon-alpha to the liver as a novel treatment for colorectal carcinoma liver metastases

M. Catarinella[1], *G. Escobar*[1], *R. Aiolfi*[1], *A. Fiocchi*[1], *M. De Palma*[2], *A. Esposito*[1], *L. Naldini*[1], *L. G. Guidotti*[1], *G. Sitia*[1];
[1]*San Raffaele Scientific Institute, Milan, Italy,* [2]*École Polytechnique Fédérale de Lausanne, Lausanne, Switzerland.*

Colorectal carcinoma (CRC) is the third most frequent and the fourth leading cause of cancer-related mortality worldwide. The liver is the most common site of CRC metastases, which constitute the major cause of CRC-related deaths also due to the partial efficacy of the available treatments.
Tie2-expressing monocytes (TEMs) are a subset of circulating monocytes recruited at the tumor site in response to pro-angiogenic stimuli.
In this study we investigate the possibility to utilize engineered TEMs to treat CRC liver metastases by delivering low amounts of interferon-alpha (IFN-α) specifically at the tumor site *in vivo*.
Briefly, we established a model of CRC liver metastases by injecting CT26 mouse colon cancer cells in the spleen of immunocompetent inbred CB6 mice (Balb/c x C57B6 F1). 7 weeks prior to injection, mice were transplanted with syngenic bone marrow where hematopoietic stem/progenitor cells were transduced *in vitro* in order to express IFN-α under the control of the Tie2 regulatory elements. After bone marrow reconstitution we assessed the ability of TEMs-IFN-α to repress tumor growth. Notably, our results indicate that when compared to controls, mice bearing TEMs-IFN-α display reduced tumor burden, delay in tumor appearance and tumor regression. Initial evidence suggests that IFN-α can act directly by reducing tumor cells proliferation and indirectly by enhancing both innate and adaptive immune responses. Moreover, no side effects related to the administration of type I interferon molecules were observed. Taken together our results suggest that TEMs-IFN-α might represent a valuable tool for the treatment of CRC liver metastases.

P6.07.09
Overexpression of galectin-9 in islets prolongs grafts survival via downregulation of Th1 responses

F. Chou[1], *C. Kuo*[2], *Y. Wang*[3], *H. Sytwu*[1];
[1]*Department and Graduate Institute of Microbiology and Immunology, National Defense Medical Center, Taipei, Taiwan,* [2]*Graduate Institute of Medical Sciences, National Defense Medical Center, Taipei, Taiwan,* [3]*Center for Vascularized Composite Allotransplantation, Chang Gung Memorial Hospital, Taipei, Taiwan.*

The differential activation of T helper (Th) cells and production of cytokines contribute to graft rejection or tolerance. In general, the Th1-type cytokines and cytotoxic T cells are detected consistently in host undergoing rejection, whereas Th2 responses are linked to a tolerance condition. Galectin-9 modulates Th1 cell immunity by binding to the T-cell immunoglobulin mucin-3 (Tim-3) molecule expressed on the Th1 cells. We investigate whether overexpression of galectin-9 in islets prolongs grafts survival in diabetic recipients. Islets were transduced with lentiviruses carrying galectin-9 and were then transplanted to streptozotocin-induced diabetic NOD/SCID recipients. The normoglycemic recipients then received splenocytes from diabetic NOD mice. Blood glucose concentration was monitored daily after adoptive transfer. The histology of the islet grafts and flow cytometric analyses were assessed at the end of the study. Overexpression of galectin-9 in islets prolonged grafts survival in NOD/SCID mice after challenge with diabetogenic splenocytes (mean graft survival, 38.5 vs 26.0 days, n = 10, respectively; P = 0.0096). The galectin-9-overexpressed grafts showed decreased infiltration of IFN-γ-producing $CD4^+$ and $CD8^+$ T cells, but not of IL-17-producing $CD4^+$ T cells. Strikingly, this islet-specific genetic manipulation did not affect the systemic lymphocyte composition, indicating that galectin-9 may regulate T cell-mediated inflammation *in situ*. We demonstrate that galectin-9 protects grafts from Th1- and Tc1-cell-mediated rejections, suggesting that galectin-9 has preventive and/or therapeutic benefit in transplant therapy for autoimmune diabetes and may be applied further to the transplantation of other organs or tissues.

P6.07.10
T and B cell restricted MOG expression through retroviral transduction of bone marrow stem cells mediates protection against EAE induction

J. Y. Chung, *Z. Nasa, A. Joglekar, F. Mackay, F. Alderuccio;*
Department of Immunology, Monash University, Melbourne, Australia.

Irradiated mice transplanted with bone marrow stem cells (BMSC) transduced with the autoantigen myelin oligodendrocyte glycoprotein (MOG) are tolerant upon MOG35-55 peptide immunisation and do not develop the clinical symptoms associated with experimental autoimmune encephalomyelitis (EAE). However due to the large number of cell lineages that derive from bone marrow stem cells it is difficult to attribute the induced tolerance to a specific cell lineage. To address this, I have established a novel method of generating cell lineage specific gene expression following retroviral transduction of bone marrow stem cells. This strategy utilises the Cre lox system to mediate a single DNA inversion event within the encoded provirus DNA that aligns the encoded gene of interest with the retroviral promoter, thus allowing gene expression only in Cre expressing cell lineages. Utilising this novel strategy we have restricted MOG expression to T or B cells utilising lck-cre and CD19-cre transgenic BMSCs. Upon challenge with MOG35-55 peptide immunisation, we have found a 50% reduction in the incidence of EAE in both lck-creMOG and CD19-creMOG BM recipient mice compared to non-manipulated lck-cre or CD19-cre BM recipient or normal C57BL/6 mice. Furthermore, of the CD19-creMOG mice that did develop EAE, we found EAE onset was significantly delayed. This work provides evidence that following transfer of transduce BM, MOG autoantigen delivery through T or B cells can play a part in mediating protection against EAE induction. Further studies are currently underway to determine the mechanism by which immune tolerance to MOG is mediated in both settings.

P6.07.11
Intrathecal transplantation of neural stem/precursor cells hampers the CNS-confined immune response of experimental autoimmune encephalomyelitis

D. De Feo[1], *A. Merlini*[1], *C. Laterza*[1], *B. Elena*[2], *F. Ruffini*[2], *G. Martino*[2];
[1]*Università Vita-Salute San Raffaele, Milan, Italy,* [2]*Ospedale San Raffaele, Milan, Italy.*

Transplantation of neural stem/progenitor cells (NPCs) in experimental autoimmune encephalomyelitis (EAE) has consistently shown that NPCs promote neuroprotection through pleiotropic mechanisms, including a strong, but only partially characterized immunomodulatory effect. We investigated if and how the intrathecal transplantation of NPCs could modulate the CNS-restricted effector phase of EAE, the key event in disease initiation and maintenance.
We found that intrathecal transplantation of NPCs in MOG-immunized C57BL/6 EAE mice induced a significant and persistent amelioration of clinical disability when compared to sham treatment. At the end of follow-up, 80 days post immunization (dpi), neuropathology of NPC-transplanted mice showed lower demyelination and axonal loss. Flow cytometry analysis of CNS inflammatory infiltrate at 40 dpi revealed that these findings were preceded by a significant reduction of infiltrating myeloid cells as well as of encephalitogenic T helper cells.
Transplanted NPCs localized strategically in the meningeal perivascular spaces, in close contact with local antigen presenting cells, such as myeloid dendritic cells (DCs) and perivascular macrophages, suggesting that NPCs might interfere with the antigen-recall of autoreactive T cells within the CNS.
Indeed, in vitro co-culture of NPCs with bone marrow-derived DCs showed that NPCs inhibit, trough secreted factors, the maturation and the capability of reactivating myelin-specific T cells of DCs.
Our work confirms the efficacy of intrathecally transplanted NPCs in ameliorating EAE and suggests that NPCs can impair the antigen recall and terminal polarization of encephalitogenic T cells within the subarachnoid perivascular spaces, thus preventing CNS accumulation of infiltrating inflammatory cells responsible for disease progression.

P6.07.12
Exploring the immunogenicity and efficacy of bone marrow-derived allogeneic cell therapy in vivo using a humanised mouse model

G. Feng[1], *S. Menzies*[1], *A. Boyers*[1], *M. Rigby*[1], *A. Gutteridge*[1], *H. Fox*[1], *V. Owenson*[1], *O. Stevens*[1], *R. Deans*[2], *P. Whiting*[1];
[1]*Pfizer Neusentis, Cambridge UK, United Kingdom,* [2]*Athersys, Cleveland, OH, United States.*

Allogeneic stem cell therapies offer great potential as off-the-shelf therapeutic agents to a wide range of degenerative and autoimmune diseases. The immunogenicity of stem cell products may have an impact on the safety and efficacy of allogeneic cell therapies. There is currently no reliable experimental model to monitor T cell responses against stem cell products in vivo. Using a fluorescent immunosorbent spot (FluoroSpot) assay, we found mice that received human bone marrow-derived mesenchymal stem cell (MSC) infusions have increased frequency of IFN-gamma producing cells against human antigen. This effect is mediated through both the direct and indirect pathway of antigen recognition. In the same xenogeneic setting, MultiStem®, another human bone marrow-derived stem cell product (Multipotent Adult Progenitor Cell) shows very limited long term engraftment after infusion. To investigate human T cell responses against stem cells in an allogeneic setting, a humanised mouse model was established using NOD-scid gamma (NSG) mice, reconstituted with peripheral blood mononuclear cells (PBMCs) from prescreened naïve human donors. We demonstrated that MultiStem did not sensitise naïve human responders through the direct pathway of alloantigen recognition. In addition, MultiStem treatment maintained body weight in a graft versus host disease (GVHD) model in NSG mice humanised with HLA mismatched allogeneic immune cells. Taken together, MultiStem demonstrates low immunogenicity and anti-inflammatory efficacy, therefore showing potential for treating human autoimmune diseases.

Performance characterization of a novel cell processing sorter: microchip sorting without aerosols in a closed system

J. Lee, L. Pietrzyk, E. Rodriguez-Mesa, ***J. Foster****;*
Owl Biomedical, Santa Barbara, CA, United States.

Owl biomedical has developed a cell sorting platform with a closed, single -use fluidics path capable of safe, high-specificity, high-purity, and high-volume sorting. Cell samples are driven with low, positive pressure through a sorting microchip where cells are laser interrogated and sorted by a high-speed mechanical valve based on a user defined fluorescent phenotype. We developed a cell-based longitudinal stability assay (a "gage") using 1% CFSE+ labeled K562 cells spiked in a 2M/mL background of K562s to quantify the Nanosorter® sort performance and reliability. The data show the Nanosorter achieves highly repeatable sort results using a traditional purity metric and two metrics for yield; depletion yield measures the ability of the valve to sort target cells and absolute yield characterizes the target cell recovery from the entire closed fluidic system. In addition to sort performance data, the gage quantifies the Nanosorter mechanical and optical stability over time by trending metrics such as sample flow rate, detected events, dead volume, and missing counts. Over nine gage runs sorting at 2,200 cells per second, the Nanosorter enriched from 1% input to 91% ±3% pure target cells, with 88% ±6% depletion yield, and 55% ±10% absolute yield. A richer biological gage is in development using a 1:4 dilute whole blood (1B cells/mL) labeled with CD4-PE and CD45-APC.Cy7 with a no lyse no wash protocol. Preliminary data from this gage also shows high CD4+ cell enrichment and yield. The closed, single-use nature of the fluidics will be uniquely valuable for cell therapy manufacturing.

P6.07.14
Purifying Tregs with a new closed sorter

L. Pietrzyk, J. Dunne, ***J. Foster****;*
Owl Biomedical, Santa Barbara, CA, United States.

Therapeutic use of regulatory T cells is of broad interest, and current purification strategies have limitations. We are developing a new sorting platform which achieves the multidimensional selection capabilities of droplet sorters and the single-use, closed fluid path typical of magnetic enrichment systems. We have characterized a first generation commercial device by sorting CD4+CD25hiCD127dim cells from human PBMCs. Performance metrics include assessments of the purity and recovery of the selected cells, and were found to vary as expected according to instrument settings, sample cell density and input Treg starting frequency. We find consistent enrichment between 10 and 20 fold, with 70-80% of the Tregs selected appropriately when sorting in the range of 2e7 PBMCs over 2.5 hours, without the need for operator intervention using a standard sort protocol. Design features of the device facilitate workflows typical in a cell therapy manufacturing environment and routine research applications. A second generation device is currently in development.

Quality controls of Cell-Based therapies: Assessment of conditioned Dendritic Cells phenotypes by Global Gene Expression Profiles

M. Foti[1,2], *C. Ripamonti*[1], *S. Baldassarri*[1], *J. Michalek*[3];
[1]*University of Milano-Bicocca, Milano, Italy,* [2]*Genopolis Consortium, University of Milano-Bicocca, Milano, Italy,* [3]*Masaryk University, Brno, Czech Republic.*

Whole-cell immunotherapies have shown promising results in clinical trials. Nevertheless, the complex nature of the cellular product and the individual variability associated to their preparation makes cellular immunotherapies less well characterized. Therefore, one major challenge in the development of whole cell therapies is the ability to demonstrate a clear comparability of the cellular product obtained after the application of different differentiation settings and conditioning protocols in the manufacturing process.
Research in our lab is focused towards the development of novel molecular assays that can be used as quality controls in cell-based therapies. Using a functional genomics approach we have been able to select a genetic signature of activation of DCs *in vitro*. We selected lists composed of 44 genes able to discriminate different DCs phenotypes. We validated the signature *in vivo* in DCs derived from a mouse model of inflammation. The selected signature has been further validated in human derived DCs in order to develop a quality control molecular assay for DCs-based therapies. Therefore, the basic methods to select a genetic signature of DCs that may predict *in vivo* functional activity and its applications in cellular immunotherapies are presented.

P6.07.16
Improved monitoring and generation of HAdV-specific T cells by a newly identified A*02 MHC class I multimer and short-term *in vitro* expansion

R. Geyeregger*;*
CCRI, Vienna, Austria.

Adenoviral infections are a major cause of morbidity and mortality after allogeneic hematopoietic stem cell transplantation (HSCT) in pediatric patients. Adoptive transfer of donor-derived human adenovirus (HAdV)-specific T-cells represents a promising treatment option. However, the difficulty in identifying and selecting rare HAdV-specific T-cells, and the short time span between patients at high risk for invasive infection and viremia are major limitations. We therefore developed an IL-15-driven 6 to 12 day short-term protocol for *in vitro* detection of HAdV-specific T cells and identified a new adenoviral CD8 T-cell epitope derived from the E1A protein for the frequent HLA-type A*02:01. Using this novel and improved diagnostic approach we observed a correlation between adenoviral load and reconstitution of $CD8^+$ and $CD4^+$ HAdV-specific T-cells including central memory cells

in HSCT-patients. Adaption of the 12-day protocol to good manufacturing practice conditions resulted in a 2.6-log (mean) expansion of HAdV-specific T-cells displaying high cytolytic activity (4-fold) compared to controls and low or absent alloreactivity. Similar protocols successfully identified and rapidly expanded CMV-, EBV-, and BKV-specific T-cells. Our approach provides a powerful clinical-grade convertible tool for rapid and cost-effective detection and enrichment of multiple virus-specific T-cells that may facilitate broad clinical application.

Effect of myeloid-derived suppressor cells on dendritic cells maturation and function

N. Khosravianfar[1], *A. Namdar*[2], *M. Hafezi*[3], *A. Razavi*[1], *J. Hadjati*[4]; [1]*Department of pathobiology,school of public health,Tehran university of Medical Sciences, Tehran, Iran,* [2]*Department of immunology,school of medicine,Isfahan university of Medical Sciences, Isfahan, Iran,* [3]*Depatrment of pathobiology,school of public health,Tehran university of Medical Sciences, Tehran, Iran,* [4]*Department of immunology,school of medicine ,Tehran university of Medical Sciences, Tehran, Iran.*

Background: Myeloid-derived suppressor cells (MDSCs) are major regulators of the immune system that accumulate in tumors and are an important hindrance to cancer immunotherapy. Dendritic cells (DCs) are professional antigen-presenting cells in immune system. These cells have critical role in anti-tumor immunity. As it has been well documented that MDSCs interface with DCs maturation and function, therefore in this study the effect of MDSCs on DCs maturation and function was investigated.
Methods: Bone marrow derived DCs were generated in the RPMI1640 with 5% fetal serum supplemented with recombinant mouse GM-CSF and IL-4. Simultaneously, MDSCs were isolated from spleen of tumor bearing mice, and were cocultured with DCs in the presence of 5-fluorouracil and/or LPS for 48 and 36 hours respectively. Afterwards DCs were harvested and their activity to produce IL-12 was measured by standard ELISA. Besides, expression of DCs surface markers (CD40 and CD11c) was evaluated by flow cytometery.
Results: Our results showed that IL-12 production was significantly reduced by DCs co-cultivated with MDSCs. DCs also expressed lower surface costimulatory molecules.
Conclusion: Based on our experiments, MDSCs may interfere with anti tumor immunity through inhibition of DC's function. This finding should be considered in designing DC based vaccines for treatment of cancer.

P6.07.18
Cloning of human antigen-specific TCRs can confer the candidates for cancer gene therapy

E. Kobayashi[1], *E. Mizukoshi*[2], *H. Kishi*[1], *H. Hamana*[1], *T. Nagai*[1], *T. Ozawa*[1], *H. Nakagawa*[2], *A. Jin*[1], *S. Kaneko*[2], *A. Muraguchi*[1]; [1]*University of Toyama, Toyama-shi, Japan,* [2]*University of Kanazawa, kanazawa-shi, Japan.*

[Introduction] Antigen (Ag)-specific T-cell therapy or T-cell receptor (TCR) gene therapy is a promising immunotherapy for infectious diseases as well as cancers. Either TCR beta chain or alpha chain repertoire is currently analyzed; however, the availability of a suitable screening system for analyzing both Ag-specific TCR alpha/beta pairs from single T cell is limited. Here, we report an efficient cloning and functional evaluation system of TCR cDNA derived from a single Ag-specific human T cell by which we can obtain TCR cDNAs and determine their antigen specificity within 10 days. We designated this system the hTEC10 system (human TCR efficient cloning within 10 days)
[Method] In hTEC10 system, human antigen-specific T cells are detected by staining with antigen-specific MHC tetramers and single cells are obtained by FACS. TCR cDNA is amplified from single cells, cloned into an expression vector, and transduced into the TCR-negative T cell line TG40. The antigen specificity of the TCR is then assessed by staining the transduced TG40s with MHC tetramers. This entire process can be performed within 10 days.
[Results and Discussion] To evaluate this system, we first cloned and analyzed 379 Epstein-Barr virus-specific TCRs from 10 latent healthy donors. We then applied this system to clone tumor antigen-specific TCRs from cancer patients who had been treated with peptide vaccination. We obtained 199 α-fetoprotein (AFP)-specific TCRs and showed their cytotoxic activities toward AFP peptide-bearing cells. This system may provide a faster and powerful approach for TCR gene therapy for infectious diseases and cancers.

P6.07.19
A novel methodology of immune regulation using pluripotent stem cells

H. Kudo[1], *H. Sasaki*[2], *H. Wada*[2], *S. Kojo*[2], *T. Chikaraishi*[1], ***K. Seino***[2]; [1]*St.Marianna School of Medicine, Kawasaki Kanagawa, Japan,* [2]*Hokkaido University, Sapporo Hokkaido, Japan.*

In several decades in the last century, tissue or organ transplantation therapy has been developed for curing patients with end-stage organ dysfunction. However, shortage of donated tissue or organ has been one of the biggest problems to perform the therapy. Recently, a promise of regenerative medicine using pluripotent stem cells such as embryonic stem cells (ESCs) or induced pluripotent stem cells (iPSCs) as donor source has been increased. However, particularly when ES cells were used, immune-suppressive therapy should be required because the donor-recipient combination would be allogeneic. We successfully induced immunosuppressive cells in a differentiation process with granulocyte-macrophage colony-stimulating factor (GM-CSF) from mouse ESCs. The immunosuppressive cells were similar to so-called regulatory macrophages in the meaning of cell surface molecule and gene expressions. They efficiently suppressed allogeneic T cell proliferative responses, at least in part, in nitric oxide dependent manner. We applied these cells to in vivo allogeneic transplantation and found that they substantially prolonged ESCs-derived graft survival. These results open a new insight for development of a novel immune-regulatory strategy in the age of regenerative medicine based on the use of pluripotent stem cells.

P6.07.20
The application of in vitro expanded CD4 Th1 cells in adoptive cell therapies

K. Li[1], *F. Ronchese*[2], *M. Thorn*[3], *C. Jackson*[4], *S. Young*[1]; [1]*Pathology Department, Dunedin School of Medicine, University of Otago, Dunedin, New Zealand,* [2]*Malaghan Institute of Medical Research, Wellington, New Zealand,* [3]*Department of Medical and Surgical Science, Dunedin School of Medicine, University of Otago, Dunedin, New Zealand,* [4]*Oncology Department, Dunedin public Hospital, University of Otago, Dunedin, New Zealand.*

Adoptive cell therapies (ACT) have been used as an immunotherapy for cancer treatment; with most ACT focusing on tumor-reactive CD8 T cells. However, both clinical and animal studies suggest that therapeutic strategies that only focus on the use of CD8 T cells are not effective in eliminating tumor cells. In this study, we sought to investigate the therapeutic efficacy of mono-cellular therapy and combination therapies of CD4 and CD8 T cells. Methods for CD8 T cell expansion have been well established, while ex vivo/in vitro expansion of CD4 T cells has not yet been optimized. By using OT-II cells as a model, we have achieved more than 5,000 CD4 T cell expansions in 24 days. The majority of these in vitro expanded cells express early effector cell phenotypes as CD27+/CD28+/CD127+/PD-1-/CTLA-4-; and they were able to express multiple cytokines after short duration of antigen re-stimulation. These cytokines were predominantly IL-2, IFN-g, and TNF-a, and low level of IL-4, IL-17 and granzyme B, suggesting a Th1 cell phenotype. Preliminary in vitro cytotoxic assays showed both direct killing of target cells by these CD4 T cells; and also enhanced CD8 T cells cytotoxicity. The in vivo efficacy of ACT with CD4 T cells and/or CD8 T cells is currently under investigation.

P6.07.21
Chondrogenic differentiation of mesenchymal stem cells alters cellular immunogenicity in vitro and in vivo

*A. E. Ryan, **P. Lohan**, L. O'Flynn, O. Treacy, C. Coleman, G. Shaw, M. Murphy, R. Ceredig, M. D. Griffin, T. Ritter;*
National University of Ireland, Galway, Galway, Ireland.

Osteoarthritis (OA) is characterized by articular cartilage degradation and joint inflammation. Allogeneic mesenchymal stem cells (MSCs) have potent regenerative and immunosuppressive potential and are being investigated as a therapy for OA, however little is known about the immunological changes that occur in allogeneic MSCs after induced or trans-differentiation. A fully allogeneic rat model was used for this study. Chondrogenic differentiation was induced in alginate layers. After 18 days, rat MSCs up-regulated Collagen 2 (>50 fold), Aggrecan and Sox-9 (> 4 fold). Allogeneic differentiated MSCs lose the ability to inhibit T-cell proliferation in co-cultures *in vitro*, which was associated with significantly reduced nitric oxide & prostaglandin E_2 ($p<0.001$) in co-culture supernatants. Differentiation altered immunogenicity as evidenced by up-regulation of MHC-I, MHC-II, CD86, induced proliferation of allogeneic $CD4^+$and $CD8^+$ cells ($p<0.01$), and increased susceptibility to cytotoxic lysis by allo-specific T cells. 10^6 undifferentiated or differentiated allogeneic MSCs were injected or implanted in alginate subcutaneously. *Ex vivo* recall analysis 6 weeks later, confirmed increased memory T-cell response in draining lymph nodes of animals injected with undifferentiated (>4-fold) and differentiated MSCs (>5-fold), however only differentiated MSCs induced systemic memory T-cell responses ($p<0.05$). Implantation of undifferentiated MSCs in alginate reduced local T-cell responses by 75%; however alginate-encapsulated differentiated allogeneic T cells induced detectable memory T-cell responses both locally and systemically ($p< 0.05$). H & E analysis of mononuclear cells at the implantation site confirmed this finding. Systemic allo-immune responses to differentiated MSCs indicate that they become immunogenic and will require immunosuppressive therapy to be used therapeutically.

P6.07.22
Migration of human mesenchymal stem cells towards inflammatory lesions after transfection with CD29 specific siRNA

***L. Marusciac**, C. Panaitescu, F. Bojin, V. Paunescu;*
University of Medicine and Pharmacy Victor Babes Timisoara, Timisoara, Romania.

Background and aims: Mesenchymal stem cells (MSCs) are a population of non-hematopoietic stem cells with differentiation potential, which have the capacity to migrate towards inflammatory lesions. Several adhesion molecules, chemokines, and integrins are involved in the MSC response to inflammation. The aim of this study was to investigate the specific role of integrin beta1 (CD29) in MSC migration towards inflammatory skin lesions, in order to increase the MSC efficiency in wound healing.
Method: A GFP-expressing human MSC line (hMSCs) was purchased. The cell expression of CD29 was inhibited specifically by transfection with siRNA duplexes. An inflammatory skin lesion was produced in CD1 Nu/Nu mice, and the transfected hMSCs were injected subcutaneously. hMSC migration in vivo was evaluated macroscopically by a fluorescence imaging system and microscopically by immunofluorescence for CD29, vimentin, cytokeratin and Ki67.
Results: The intracellular and surface expression of CD29 was abundant, as shown by immunohistochemistry and flow cytometry (74.22±2.3% positive cells), respectively. CD29 was successfully inhibited, its expression being reduced by 76% in transfected hMSCs (18.02% positive cells). Transfected hMSCs also exhibited decreased expression of CD90 and CD105. When compared with control hMSCs, transfected hMSCs migrated more slowly to the skin inflammatory lesion site, but their proliferation rate was higher, as shown by their expression of Ki67. However, there were no significant differences between overall healing times.
Conclusion: CD29 inhibition has downstream effects by affecting the expression of MSC specific markers and MSC proliferation. It may offer a novel approach to the treatment of inflammatory skin lesions.

P6.07.23
Treatment with EBV-Cytotoxic T-Lymphocytes of pediatric liver transplant recipients affected by EBV-related Post-transplantation lymphoproliferative disease in early phase

***M. Miele**[1], M. Sciveres[2], M. Di Bella[1], S. Riva[2], G. Amico[1], R. Liotta[2], A. Sonzogni[3], P. Grossi[2], P. Conaldi[1,2];*
[1]Fondazione RIMED, Palermo, Italy, [2]ISMETT, Palermo, Italy, [3]Ospedale Riuniti, Bergamo, Italy.

The Epstein-Barr virus (EBV) associated post-transplantation lymphoproliferative disorder (PTLD) is a severe complication of transplantation due to immunosuppressive regimen. The disease results in immortalization and transformation of infected B-cells and it is highly frequent in pediatric transplanted patients since it is related to the virus primary infection in EBV-seronegative recipients.
Aim of our study is to control disease progression by infusion of autologous EBV-specific T lymphocytes (CTL), expanded and activated in vitro, in order to provide persistent cytotoxic activity against infected B-cells in vivo.
Seven liver transplanted children, with a diagnosis of polyclonal EBV-related PTLD (3 polymorphic, 4 “early lesions”, median age at diagnosis 4 years-old), have been enrolled in our Institution. All patients showed adenotonsillar and gastrointestinal PTLD with positive EBV-encoded small RNA (EBER) staining; the IFN-γ secreting EBV specific lymphocytes measurement at ELISPOT assay resulted low (median value: 0,49±0.5 lymphocytes/µl of blood). EBV-CTLs, before infusion, are examined for sterility, immunophenotype, potency and EBV specificity. Treatment protocol consisted in 2 blocks of 3 monthly infusions (average dose 1.5x106CTL/Kg) followed by complete histological reassessment.
Infusions have been well tolerated and no adverse reactions have been recorded. Results of histological assessment after 6 infusions document downgrading of polymorphic PTLD to “Early Lesions” or to normal tissue in 5/7 patients (two complete regression); overall decrease in EBER positive lymphocytes is found in histological sections. These preliminary results are encouraging and confirm that CTLs, generated in our facility, are a reliable tool for cell therapy to mediate regression of low grade disease

P6.07.24
Immune system modulation during cytokine induced killer cells adoptive therapy in hematologic patients

*S. Coin[1], I. Cavattoni[2], V. Artusi[3], A. Pievani[4], I. Pusceddu[2], E. Tagliafico[3], S. Cortelazzo[2], A. Rambaldi[4], M. Introna[4], **V. Monsurro**[1];*
[1]University of Verona Medical School, Verona, Italy, [2]General Hospital of Bolzano, Bolzano, Italy, [3]University of Modena and Reggio Emilia, Modena, Italy, [4]Ospedali Riuniti di Bergamo, Bergamo, Italy.

Adoptive therapy of cytokine-induced killer cells (CIK) have shown anti-leukemic activity. In a phase II study of allogeneic CIK cells, in patients relapsing after allogeneic hematopoietic stem cell transplantation, we performed a longitudinal immune monitoring based on gene expression profiling in adittion to phenotypic and functional characterisation of PBMCs. We isolated PBMCs from 4 patients before and 5 hours after each CIK infusion. Gene expression profiling was executed with HG-U219 array strips (Affymetrix, USA). Time course analysis was performed applying a regression model to estimate the effect of the interaction between time and classes of complete responders (CR) versus partial responders (PR) patients. We identified 23 probes corresponding to 17 genes whose variation of expression over time was different between classes. Based on the kinetic of gene modulation we were able to discriminate two different subgroups: one enriched in genes associated to inflammation and blood cell motility with similar co-regulation and a second characterised by genes associated to developmental disorder, embryonic development, hereditary disorder. Almost all the genes selected were up-regulated only in the PR at time zero while they were up-regulated after the first CIK infusion and down-modulated in the late time points analysed in CR. According to our data the infusion of allogeneic CIK cells induces a transient up-regulation of specific inflammatory cytokines in CR but after the second infusion it leads to a generalized anergic status of PBMCs, probably caused by the parallel over-expression of the G0S2 gene, known to inhibit hematopoietic cells proliferation.

P6.07.25
Toxicity evaluation of CD44v6-specific T cells in a xenograft model that fully recapitulates human hematopoietic development

M. Norelli[1,2], *M. Casucci*[1], *B. Camisa*[1], *L. Falcone*[1], *G. Oliveira*[1,2], *A. Saudemont*[3], *C. Bordignon*[1,4], *F. Ciceri*[1], *C. Bonini*[1], *A. Bondanza*[1];
[1]*San Raffaele Scientific Institute, Milano, Italy,* [2]*Universitá Vita-Salute San Raffaele, Milano, Italy,* [3]*Anthony Nolan Research Institute, London, United Kingdom,* [4]*Molmed S.p.A, Milano, Italy.*

Introduction. Antitumor efficacy of genetically modified T cells (GMTs) in humans often associates with toxicity. In particular, off-tumor expression of the targeted antigen raises concerns when using GMTs expressing natural or chimeric receptors. We have developed a strategy for multiple-tumor eradication with GMTs expressing a CD44v6-specific chimeric receptor. Since CD44v6 is expressed at certain stages of hematopoietic development, it is mandatory to preclinically demonstrate that our strategy will not cause unbearable hematopoietic toxicity.
Aim. To develop a xenograft mouse model for predicting the spectrum of hematopoietic toxicities by CD44v6-specifc GMTs
Results. The immundeficient mouse strain NOD.Cg-Prkdc-Scid IL2rg-tmWjl/Sz (NSG) completely lacks T, B and NK cells. Human cord-blood derived CD34+ hematopoietic stem cells (HSCs) readily engrafted in irradiated NSG mice, but mainly reconstituted CD19+ B cells. Conversely, NSG mice transgenic for human IL-3, SCF and GM-CSF (3GS-NSG) also reconstituted T cells and myeloid cells. Reconstituted T cells were single positive for CD4 or CD8 and had a CD45RA+/CD62L+/CD95- naïve phenotype. When stimulated ex vivo with a clinical-level protocol for GMT generation, reconstituted T cells expanded and differentiated into CD45RA-/CD62L+ central memory T cells. Reconstituted myeloid cells were enriched for CD14+ monocytes. Importantly, when analyzed on all populations, CD44v6 expression was absent on HSCs and progenitors cells, but present on CD14+ monocytes, which is in accordance with the human situation.
Conclusions. We have developed a xenograft mouse model that fully recapitulates human hematopoietic development and that is suited for preclinically evaluating the potential hematopoietic toxicities of CD44v6-specifc GMTs and rescue approaches.

TLR7/8 Ligand Is Necessary to Generate Potent Blast-Derived Dendritic Cells in Acute Myeloid Leukemia

M. Nourizadeh[1,2], *F. Masoumi*[2], *A. Memarian*[2], *K. Alimoghaddam*[3], *S. Moazzeni*[4], *J. Hadjati*[2];
[1]*Immunology, Asthma and Allergy Research Institute, Tehran University of Medical Sciences, Tehran, Iran,* [2]*Immunology Department, School of Medicine, Tehran University of Medical Sciences, Tehran, Iran,* [3]*Hematology, Oncology and Stem Cell Transplantation Research Center, Tehran University of Medical Sciences, Dr. Shariati Hospital, Tehran, Iran,* [4]*Immunology Department, School of Medicine, Tarbiat Modares University, Tehran, Iran.*

Active dendritic cell (DC) immunization protocols are quickly obtaining interest as an alternative therapeutic approach in patients with acute myeloid leukemia (AML). Despite progress in DC-based immunotherapy, some discrepancies were reported in generating potent DCs. Regarding the differentiation ability of leukemic blasts to DCs, here we generated DCs from various subtypes of AML blasts. For DC maturation, a combination of TLR agonists was used. Leukemic Blasts from 15 patients were differentiated and 6-day immature AML-DCs were cultured in the presence of TLR agonists for 24 hrs. The morphology, expression of surface molecules, allostimulatory activity, cytokine production and phagocytic function of resultant DCs were compared with immature DCs and primary blasts. To induce cytotoxic T cells in vitro, auotologous T cells of patients after remission were co-cultured with matured DCs for 21 days. Cytotoxicity of CTLs was assessed by CFSE staining of targets. Our results showed that although Poly(I:C) has a synergistic effect on LPS, the addition of TLR7/8 agonist (R848) is necessary to reinforce the effect of LPS or LPS+Poly (I:C) to produce highly efficient DCs with increased IL-12 production and substantial capacity to activate allogeneic T cells. Compared to immature DCs or blasts, AML-DCs matured with TLR4 plus TLR7/8 agonists with or without TLR3 agonist were able to induce CTLs with greater cytotoxicity against relevant targets. Therefore, a combination of TLR4 and TLR7/8 agonists (with or without TLR3 agonist) could be regarded as an appropriate maturation cocktail for AML-DC production, and have potential use for immunotherapy of AML patients.

P6.07.27
Mannose-α(1→2)-Mannose derivative for dendritic cell targeted delivery

J. S. Pappalardo[1,2], *T. S. Levchenko*[2], *S. Salmaso*[2], *C. A. Langellotti*[3], *M. Vermeulen*[3], *M. Toniutti*[2], *T. Musacchio*[2], *V. P. Torchilin*[2];
[1]*INTA - Virology Institute - Bionanotech Lab., Hurlingham, BA, Argentina,* [2]*Northeastern University - CPBN, Boston, MA, United States,* [3]*CONICET, Autonomous City of Buenos Aires, Argentina.*

Dendritic Cells (DCs) are professional antigen presenting cells (APC) since they have the unique ability to activate naïve T lymphocytes (TL), initiating the adaptative immune response. To modulate it, many options have been developed including vaccines, immune gene therapies and specific targeting to DCs. DC-targeted vaccination is a promising alternative against certain infectious diseases and cancer. The use of DCs for this purpose is attractive because of their ability to present epitopes through the MHC class I and activate cytotoxic CD8+ T responses.
Mannose is a glucid that belongs to many pathogen-associated molecular patterns (PAMPs) which can be used anchored to nanovehicles such as liposomes to target their cargo to DCs. This is possible since PAMPs will bind to the pattern-recognition receptors on the DCs surface. C-Type membrane lectins, such as DC-SIGN and the mannose receptor, present on the DCs surface, recognize oligosaccharides containing mannose and/or fucose and mediate their specific endocytosis.
To target DCs we have used rhodamine-labeled Mannose-α(1→2)-Mannose-liposomes (Manα1-2Man-L) and uptake was observed with bone marrow-derived mouse DCs and monocyte derived human DCs in a specific manner. We showed by fluorescent microscopy and flow cytometry that fluorescent-labeled liposomes containing Manα1-2Man were taken up by DC in a specific manner: more than 65% and 53% of targeting respectively.
These results show that the Manα1-2Man-L are a good tool to load DC in vitro. We also showed that he liposomes are stable and negatively charged suggesting that binding specificity is due to the decoration and not the net charge.

P6.07.28
Therapeutic effect of bone marrow-derived clonal mesenchymal stem cells in DSS-induced colitis model

J. Park[1], *J. Kim*[1], *T. Yi*[2], *S. Song*[2], ***S. Park***[1];
[1]*Sungkyunkwan University, Suwoan, Republic of Korea,* [2]*Inha University College of Medicine, Incheon, Republic of Korea.*

Bone marrow-derived clonal mesenchyaml stem cells (BM-cMSCs), isolated by a subfractionation culturing method, are derived from single cell, highly homogeneous and show multilineage differentiation potential. Although recent studies indicate that BM-cMSCs have been recognized as cell therapy sources against certain diseases, it still remains unknown whether BM-cMSCs are therapeutically effective in ulcerative colitis. In this study we provide further evidences that mouse BM-cMSCs are used as cell therapy sources by examining the effects of mouse BM-cMSCs injection on the dextran sulfate sodium (DSS)-induced colitis model. BM-cMSCs, which were injected intravenously injected, relieved the pathological phenotypes of DSS-induced colitis mice, regarding loss of body weight, stool scores, the reductions of colon length and hematochezia scores. The *iv* injected BM-cMSCs were considerably distributed on inflammatory regions of colons in DSS-induced colitis. Furthermore, H/E staining showed significantly restored intestinal tissue damages induced by DSS and reduced inflammations. These findings strongly suggests that BM-cMSCs are therapeutically applicable in inflammatory diseases such as colitis.

P6.07.29
Update on IPEX syndrome: new diagnostic biomarkers and therapeutic perspectives

L. Passerini[1], *F. Barzaghi*[1], *E. Rossi Mel*[1,2], *C. Sartirana*[1], *V. Lampasona*[3], *E. Bosi*[4,5,6], *G. Fousteri*[4], *L. Naldini*[1,6], *M. G. Roncarolo*[1,6], *R. Bacchetta*[1];
[1]*San Raffaele Telethon Institute for Gene Therapy, Division of Regenerative Medicine, Stem Cells and Gene Therapy, San Raffaele Scientific Institute, Milan, Italy,* [2]*University of Rome Tor Vergata, Rome, Italy,* [3]*Center for Genomics, Bioinformatics and Biostatistics, San Raffaele Scientific Institute, Milan, Italy,* [4]*Diabetes Research Institute, Division of Immunology, Transplantation and Infectious Diseases, San Raffaele Scientific Institute, Milan, Italy,* [5]*Laboraf, Autoimmunity Laboratory, San Raffaele Scientific Institute, Milan, Italy,* [6]*Vita-Salute San Raffaele University, Milan, Italy.*

Immune dysregulation, Polyendocrinopathy, Enteropathy, X-linked (IPEX) syndrome is a life-threatening autoimmune disease due to mutations in *Forkhead box P3* (*FOXP3*), a transcription factor crucial for $CD4^+CD25^+$ regulatory T cell (Treg) function. In IPEX autoimmunity results from the dysfunction and instability of Tregs, devoted to control immune responses to foreign and auto-antigens. Patients with similar symptoms but wild-type *FOXP3* (IPEX-like), or patients with atypical milder IPEX forms are not easily diagnosed.
We previously reported that quantification of Tregs by analysis of the demethylation status of the *FOXP3* locus characterizes a subset of IPEX-like patients. We show here that anti-harmonin, the 75kDa USH1C protein and, to a minor extent, anti-villin-autoantibodies, measured by LIPS assays, are detectable in the sera of all IPEX patients but not in IPEX-like patients, thus providing specific markers of IPEX, that also prove to be reliable markers to monitor response to therapy.
At present, therapies for IPEX are limited to immunosuppression, with only partial efficacy, and haematopoietic stem cell transplantation, which is not always available. We investigated whether lentivirus-mediated gene transfer of wild-type FOXP3 in IPEX $CD4^+$ T cells could convert effector T cells into Tregs ($CD4^{FOXP3}$). Patients-derived $CD4^{FOXP3}$ cells expressed Treg markers, were anergic, and displayed potent suppressive activity, both in vitro and in vivo, in a model of xenogeneic graft-versus-host-disease. Furthermore, ectopic expression of FOXP3 stably suppressed cytokine production, also in inflammatory conditions.
Overall, these findings pave the way for adoptive therapy with $CD4^{FOXP3}$ T cells and for more expert diagnosis and follow-up of IPEX patients.

P6.07.30
Investigation of mouse bone marrow Lin^- cells regenerative properties in vitro and in vivo

G. Ramanauskaite*, D. Zalalyte, A. Vaitkuviene, V. Kaseta, G. Biziuleviciene;*
SRI Center for Innovative Medicine, Vilnius, Lithuania.

The objective of our study was to determine the influence of skin tissue-specific microenvironment on mouse bone marrow-derived Lin^- cell proliferation and migration *in vitro* and *in vivo*. Female BALB/c mice were used. Cells were analyzed for the expression of CD117, CD34, Sca-1, CD90 and CD133 by flow cytometry. Lin^- cells exhibited a 2- to 13-fold higher expression of stem/progenitor cell surface markers compared with unpurified bone marrow cells. Proliferation of MACS-purified cells in 3D cultures was investigated by WST-8 assay. Lin^- cell migration was evaluated by *in vitro* scratch assay. The results obtained show that basement membrane matrix is more effective for Lin^- cell proliferation *in vitro*. However, type I collagen matrix better enhances the re-epitelization process, that depends on the cell migratory properties. Lin^- cells were administered subcutaneously to mice, in which skin lesion were created with the use of an 6-mm punch biopsy instrument. The most significant effect in full-thickness skin wound model *in vivo* was detected after treatment with Lin^- cells, integrated in type I collagen matrix.

P6.07.31
Promotion of corneal graft survival by donor bone marrow derived dendritic cells is mediated by creating an intragraft immunoregulatory milieu

L. O'Flynn[1], *O. Treacy*[1], *A. E. Ryan*[1], *M. Morcos*[1], *L. Joshi*[2], *J. Gerlach*[2], *M. Cregg*[1], *M. Nosov*[1], ***T. Ritter***[1];
[1]*College of Medicine, Nursing and Health Sciences, Regenerative Medicine Institute, National University of Ireland, Galway, Ireland,* [2]*Glycoscience Group, National Centre for Biomedical Engineering Science, National University of Ireland, Galway, Ireland.*

The *ex-vivo* generation of donor bone marrow derived rat dendritic cells (BMDCs) and glucocorticoid treated BMDCs with potent immunomodulatory properties for application in cornea transplantation is described.
BMDCs were generated via culturing BM precursor cells with rat GMCSF and IL-4 containing medium supplemented with dexamethasone (Dexa) to induce an immature, maturation resistant phenotype. BMDC and Dexa BMDC phenotype, antigen presenting cell function and their immunomodulatory properties were examined and characterised in detail. Both BMDC and Dexa BMDCs displayed significant immunomodulatory properties relative to freshly isolated OX62+ DCs, including but not limited to, a significant increase in mRNA expression of programmed death-ligand 1 and indoleamine 2,3-dioxygenase. Also, both BMDCs and Dexa BMDCs displayed a profound impairment in their capacity to stimulate allogeneic lymphocytes. Moreover, in a fully MHC I/II mismatched rat corneal transplantation model (Dark Agouti (DA) to Lewis (LEW)), injection of donor (DA) derived BMDC or Dexa BMDCs ($1x10^6$cells/animal, day -7) significantly prolonged corneal allograft survival. With both cell therapies, we observed a significant reduction in the level of allograft cellular infiltration and a significant increase in the ratio of intragraft FoxP3 expressing regulatory cells.
Taken together, our results demonstrate a detailed analysis of the significant therapeutic effect of donor derived BMDCs with and without glucocorticoid treatment in corneal allograft survival by modulation of the allo-immune response at the level of both the allograft and the draining lymph nodes. Without the need of additional immunosuppression, our study represents a novel therapeutic approach for the prevention of corneal allograft rejection.

P6.07.32
Ex vivo generation and expansion of polyclonal human Treg

E. Candia[1], *C. Covian*[2], *F. Rodriguez*[2], *J. Morales*[1], ***M. Rosemblatt***[3,4,5], *J. Fierro*[1];
[1]*Clinica Las Condes, Santiago, Chile,* [2]*Universidad Andres Bello, Santiago, Chile,* [3]*Fundacion Ciencia Vida, Santiago, Chile,* [4]*Facultad de Ciencias Biologicas, Universidad Andres Bello, Santiago, Chile,* [5]*Facultad de Ciencias, Universidad de Chile, Santiago, Chile.*

Administration of regulatory T cells (Treg) appears as a suitable strategy to modulate bone marrow and organ transplantation. Previous work performed in mice has shown the feasibility of generating and expanding ex vivo Treg from naive T cells (Tn). In the present study we aimed to generate polyclonal human Treg ex vivo as a first step to modulate the immune response.
Peripheral blood mononuclear cells were obtained from healthy volunteers, Tn isolated by negative immune-selection were polyclonally stimulated and cultivated in media supplemented with IL-2, TGFβ, all-trans retinoic acid (ATRA) and rapamycin at different concentrations. The number and proportion of Treg generated was determined after 6 days by flow cytometry through the expression of CD4, CD25 and Foxp3.
Results show that TGFβ is a key cytokine to generate Treg in vitro, however a contaminating population of non Treg was also observed. ATRA in conjunction with IL-2 and TGFβ increased marginally the number of Treg, whereas Rapamycin showed no additional effect. We also show that the expression of CCR9 and β7 is augmented by TGFβ while the expression of β7 is further increased by the addition of ATRA. Addition of Rapamycin increased the expression of CXCR4.
Our results show the feasibility of generating human Treg from Tn in the setting of polyclonal activation in cultures supplemented with IL-2 and TGF-beta. Addition of ATRA and Rapamycin contribute to the differential expression of homing receptors.
Supported by Fondecyt 1120731 and Clinica Las Condes.

P6.07.33
Generation of highly effective and stable murine alloreactive Tregs by combined anti-CD4 mAb, TGF-β and RA treatment

U. Schliesser[1]*, M. Chopra*[2]*, A. Beilhack*[2]*, S. Vogel*[1]*, J. Schumann*[1]*, K. Wood*[3]*, H. Volk*[1,4]*, B. Sawitzki*[1,4]*;*
[1]Charite, Institute for Medical Immunology, Berlin, Germany, [2]IZKF Research Group, Department of Medicine II and Pediatrics, University of Würzburg Medical School, Würzburg, Germany, [3]Nuffield Department of Surgical Sciences, University of Oxford, John Radcliffe Hospital, Oxford, United Kingdom, [4]Berlin Brandenburg Center for Regenerative Therapies, BCRT, Berlin, Germany.

Transfer of alloreactive Tregs (aTregs) into transplant recipients represents an attractive treatment option to improve long-term graft acceptance. We recently described a protocol for the generation of aTregs using a non-depleting anti-CD4 antibody (anti-CD4 mAb). Here we investigated whether adding TGF-β and Retinoic Acid (RA) or Rapamycin (Rapa) can further enhance their stability and in vivo function.
Methods: CD4+ T cells were cultured with allogeneic B cells in the presence of anti-CD4 mAb alone, anti-CD4 mAb+TGF-β+RA or anti-CD4 mAb+Rapamycin. CD4+CD25+ T cells obtained were analysed for Foxp3, Helios, t-bet and RORγt expression and cytokine production. Cells were restimulated with allogeneic B cells and cytokine release and stability of Foxp3 expression determined. aTregs were tested for their in vivo function by studying their ability to inhibit the rejection potential of co-transferred effector T cells.
Results: Addition of TGF-β+RA or Rapamycin resulted in a relative and absolute increase of CD25+Foxp3+ expressing T cells. However, production of inflammatory cytokines (IFN-γ, IL-17) was completely abolished in aTregs obtained from anti-CD4 mAb+TGF-β+RA treated cultures. Although CD25+Foxp3+ cells from all culture conditions displayed complete demethylation of TSDR region, only anti-CD4 mAb+TGF-β+RA Tregs showed stable Foxp3 expression upon restimulation. Consequently, anti-CD4 mAb+TGF+RA aTregs could more effectively inhibit acute graft versus host disease (aGvHD) and skin transplant rejection mediated by effector T cells in comparison to aTregs harvested from anti-CD4 mAb only or anti-CD4 mAb+Rapamycin cultures.

P6.07.34
Generation and Characterization of WT1-specific T cells derived from healthy donors for adoptive tumor therapy

S. Schmied, ***A. Richter****, M. Assenmacher;*
Miltenyi Biotec GmbH, Bergisch-Gladbach, Germany.

The Wilms tumor antigen 1 (WT1) is highly expressed on leukemic cells, but not on healthy tissue. WT1, therefore, is a favorable target antigen for allogeneic T cell therapy to prevent or treat leukemic relapse after stem cell transplantation.
Although, WT1-specific T cells have been detected in healthy individuals in low frequencies, the efficient expansion of these T cells for clinical use has remained a major challenge.
To date, generation of WT1-specific T cells has mostly been restricted to priming and expansion of either CTL or T helper cell clones. Although, the generation of a $CD4^+/CD8^+$-mixed T cell line using a time-consuming priming approach was reported recently, the T cell cultures displayed low frequencies of WT1-specific T cells; moreover, broad characterization of the expanded T cells was omitted.
In this study we aim to develop an improved method for the generation of functionally potent, polyclonal WT1-specific T cells from peripheral blood of healthy donors.
WT1-specific, reactive T cells are enriched directly from peripheral blood mononuclear lymphocytes (PBMC) by magnetic separation of T cells that upregulate the activation marker CD137 on the cell surface after an antigen-specific stimulation. After a 9-day expansion phase those T cell cultures show specific reactivity against WT1-presenting autologous cells, as detected by cytokine production after antigen-specific restimulation. Comprehensive phenotypic and functional characterization of those polyclonal WT1-specific T cell cultures reveals a potent T cell product.
In the future, our approach should be implemented for GMP-conform, highly automated generation of WT1-specific T cells for potential clinical use.

P6.07.35
Constitutively CD40-activated B cells regulate CD8 T cell inflammatory response by IL-10 induction

M. Shimoda[1]*, A. Bolduc*[1]*, M. Takezaki*[1]*, Y. Ametani*[1]*, A. L. Mellor*[1]*, M. Kamanaka*[2]*, R. A. Flavell*[2]*, T. Tsubata*[3]*, P. A. Koni*[1]*;*
[1]Georgia Regents University, Augusta, GA, United States, [2]Yale University School of Medicine, New Haven, CT, United States, [3]Tokyo Medical and Dental University, Tokyo, Japan.

B cells are exposed to high levels of CD40 ligand (CD40L, CD154) in chronic inflammatory diseases. In addition, B cells expressing both CD40 and CD40L have been identified in human diseases such as autoimmune diseases and lymphoma. However, how such constitutively CD40-activated B cells under inflammation may impact on T cell response remains unknown. Using a mouse model in which B cells express a CD40 ligand transgene (CD40LTg) and receive autocrine CD40/CD40L signaling, we show that CD40LTg B cells not only over produced IL-10 but also stimulated memory-like CD4 and CD8 T cells to express IL-10. This IL-10 expression by CD8 T cells was dependent on IFN-I and Programmed cell death protein 1, and was critical for CD8 T cells to counter-regulate their over activation. Furthermore, adoptive transfer of naïve CD8 T cells in RAG-1-/- mice normally induces colitis in association with IL-17 and IFNγ cytokine production. Using this model, we show that adoptive co-transfer of CD40LTg B cells, but not wild type B cells, significantly reduced IL-17 response and regulated colitis in association with IL-10 induction in CD8 T cells. Thus, B cells expressing CD40L can be a therapeutic goal to regulate inflammatory CD8 T cell response by IL-10 induction

P6.07.36
Cell therapy of cancer with alloreactive intentionally mismatched IL-2 activated donor lymphocytes targeting anti-cancer killer NK & T cells using monoclonal and bispecific antibodies

S. Slavin[1]*, C. Brodie*[2,3]*;*
[1]The International Center for Cell Therapy & Cancer Immunotherapy (CTCI), Tel Aviv, Israel, [2]Faculty of Life Sciences, Bar Ilan University, Ramat Gan, Israel, [3]Hermelin Brain Tumor Center, Department of Neurosurgery, Henry Ford Hospital, Detroit, MI, United States.

Graft-vs.-leukemia or solid tumors effects following allogeneic stem cell transplantation (SCT) are well established, however, use of SCT may be hazardous and associated with unavoidble graft-vs-host disease (GVHD). We investigated whether short-term immunotherapy could be induced by intentionally mismatched alloreactive killer NK and T cells (IMAK), maximally activated with interleukin 2 with no SCT. Monoclonal and trifunctional bispecific antibodies (BSA) were used for targeting IMAK against antigens over-expressed on malignant cells confirmed efficacy of eradication of otherwise lethal inoculum of B16 melanoma while avoiding GVHD in mice. Successfully treated mice could also resist fresh tumor challenge, suggesting development of anti-cancer immunity by Fc binding of malignant cells to host dendritic cells and presentation to T cells cells. Commercially available monoclonal and BSA against target antigens (EGFR, VEGF, Her-2/neu, CD20, EpCAM) using Erbitux, Avastin, Herceptin, MabThera & Catumaxomab, respectively were used in a pilot clinical trial. We have confirmed that treatment of patients with hematologic malignancies and solid tumors with IMAK with (n=16) or without (n=40) targetting antibody is safe and potentially effective with no GVHD in patients with hematological malignancies and metastatic solid tumors. We are now investigating whether targeting of IMAK may be further improved using low energy acoustic shockwave therapy (AST) that may increase the perfusion of malignant tissue as well as increase binding of killer lymphocytes to cancer cells. Based on our cumulative experience we conclude that treatment with short-lived targeted IMAK may represent an effective future approach for personalized targeted cancer immunotherapy.

P6.07.37
Distribution of the lymphoid cells of various functional activity after transplantation

A. O. Solovieva[1], *A. F. Poveshchenko*[2], *K. E. Zubareva*[1], *O. V. Poveshchenko*[2], *V. I. Konenkov*[1];
[1]*Federal State Budgetary Institution "Scientific Institution of Clinical and Experimental Lymphology" of the Siberian Branch under the Russian Academy of Medical Sciences, Novosibirsk, Russian Federation,* [2]*Federal State Budgetary Institution, Novosibirsk, Russian Federation.*

Collective cell migration is an important process that determines cell reorganization in a number of biological events such as development, regeneration and immune responses. Bone marrow - the most important organ of the hematopoietic system and is also a key component of the lymphatic system. The spleen plays important roles in regard to the immune system. Bone marrow contains undifferentiated lymphoid cells, whereas more mature cells are located of spleen. Cells migration is necessary step of the immune response. Therefore the study of the this lymphoid cells function of varying degrees of differentiation is an important problem. Distribution of intravenously injected or implanted male mise bone marrow-derived cells or splenocytes inside female sibling host animals was traced using Y-chromosome-sensitive PCR. When injected via the tail vein, Y-chromosome-positive cells were found in all studied organs: heart muscle, skin, muscles, lungs, liver, spleen, lymph nodes, brain and bone marrow. Transplanted cells derived bone marrow and spleen migrated in all organs at all times after transplantation. The dynamics of the distribution is similar, but more intense splenocytes migrated to the lymphoid organs, such as lymph nodes and spleen.

P6.07.38
Tumor associated fibroblasts are endowed with increased ability to support tumor development

M. Toma, *R. A. Lazarovicz, O. Gavriliuc, C. A. Tatu, A. Gruia, C. Tatu, G. Tanasie, C. Panaitescu, F. Bojin, V. Paunescu;*
University of Medicine and Pharmacy Victor Babes, Timisoara, Romania.

Tumor associated fibroblasts (TAFs) from solid human tumors provide structural and functional support to tumor development and progression. The main purpose of this study was to investigate TAF phenotype and functions comparative to bone marrow-derived mesencymal stem cells (MSCs) and to evaluate the role of these cells in tumorigenesis. TAFs were isolated using enzymatic digestion from surgical removed breast tumor pieces and were cultured for several passages in standard cultivation conditions, similar to MSCs. Cellular analysis included transmission electron microscopy (TEM), immunophenotyping (HLA-DR, CD29, CD44, CD73, CD90, CD106, and CD117), cytoskeleton and matrix proteins expression based on immunohistochemistry, and tri-lineage differentiation potential towards adipocytes, osteoblasts, and chondrocytes. ELISA assay was used for determining cells secretory profile, and we found that TAFs secrete significantly increased amounts of VEGF, TGF-β1, IL-4, IL-10, and TNF-α. Tumor cell lines SK-BR3, MDA-MB231 and MDA-MB468 were used for flowchamber adherence studies, under progressively increasing shear stress from 0.35 to 15 dyne/cm2, on MSCs or TAFs cellular substrate. The results showed that tumor cells have increased adherence to TAFs, for all values of shear stress, mainly because VEGF and IL-4 secretion, so that we may conclude that even though MSCs and TAFs share functional and structural characteristics, TAFs represent a more specialized cellular type, able to provide support for tumor growth and development, and can be a target for further anti-tumor therapies.

P6.07.39
Mesenchymal stromal cell therapy prolongs corneal allograft survival in rats

O. Treacy, *L. O'Flynn, A. Ryan, M. Morcos, M. Wilk, S. Schu, M. Cregg, M. Griffin, M. Nosov, T. Ritter;*
Regenerative Medicine Institute, College of Medicine, Nursing and Health Sciences, National University of Ireland, Galway, Galway, Ireland.

Mesenchymal stromal cells (MSCs) have potent immunomodulatory potential and are being investigated clinically to prolong allograft survival. Here, we investigated the ability of MSCs to prolong allograft survival in a rat corneal transplant model.
Syngeneic (syn), allogeneic (allo) or 3rd party MSCs were isolated from bone marrow of Lewis (LEW), Dark Agouti (DA) or Wistar-Furth rats, respectively. A fully allogeneic rat cornea transplant model (DA to LEW) was used for *in vivo* studies. Recipient (LEW) rats received one dose of 1x10^{6} MSCs (syn, allo or 3rd party) i.v. on day -7 and a second dose on the day of transplantation (day 0). Graft survival was monitored. Histology and flow cytometry was used to analyze cellular infiltration.
Untreated allografts were uniformly rejected (MST 16.6±1.5d, n=9) and, while syn-MSC treatment showed some evidence of attenuation of rejection (MST 18.3±4d, n=9), no clear pattern emerged following this treatment. In contrast, corneal allograft rejection was significantly delayed in approximately 90% of allo-MSC treated and 80% of 3rd party MSC treated allograft recipients. Flow cytometric analysis showed lower percentages of infiltrating NKT cells in corneas of both allo- and 3rd party MSC treated animals, coupled with a significantly higher frequency of splenic CD4+Foxp3+ regulatory T cells (Tregs), compared to controls.
Systemic administration of both allo- and 3rd party MSCs prolongs allograft survival with between 80 and 90% of allografts surviving for ≥ 30 days. This can be in part explained by the presence of fewer intragraft NKT cells and a higher frequency of splenic Tregs.

P6.07.40
TLR5 signaling enhances the proliferation of human allogeneic CD40-activated-B-cell-induced regulatory CD4 T cells

P. Chan, J. Zheng, Y. Liu, Z. Xiang, ***W. Tu****;*
The University of Hong Kong, Hong Kong, Hong Kong.

Although diverse functions of different toll-like receptors (TLR) on human natural regulatory T cells have been demonstrated recently, roles of TLR-related signals on human induced regulatory T cells remains exclusive. Previously our group developed an *ex vivo* high-efficient system in generating human alloantigen-specific CD4^{hi}CD25^{+} regulatory T cells from naïve CD4^{+}CD25^{-} T cells using allogeneic CD40-activated B cells as stimulators. In this study, we investigated the role of TLR5-related signals on the generation and function of these novel CD4^{hi}CD25^{+} regulatory T cells. It was found that induced CD4^{hi}CD25^{+} regulatory T cells expressed an up-regulated level of TLR5 compared to their precursors. The blockade of TLR5 using anti-TLR5 antibodies during the co-culture decreased CD4^{hi}CD25^{+} regulatory T cells proliferation by induction of S phase arrest. The S phase arrest was associated with reduced ERK1/2 phosphorylation. However, TLR5 blockade did not decrease CTLA-4, GITR, and FOXP3 expressions and suppressive function of CD4^{hi}CD25^{+} regulatory T cells. In conclusion, TLR5 signaling enhances the proliferation of CD4^{hi}CD25^{+} regulatory T cells by promoting S phase progress through ERK1/2 signaling but is not involved in the suppressive function of human CD40-activated B cell-induced CD4^{hi}CD25^{+} regulatory T cells.

P6.07.41
Adoptive T cell therapy in patients with prostate cancer

K. Vavrova[1]*, K. Zurkova*[2]*, R. Horvath*[1]*, J. Bartunkova*[1]*;*
[1]2nd Medical School of Charles University & University Hospital Motol, Prague, Czech Republic, [2]Inst. of Hematology and Blood Transfusion, Prague, Czech Republic.

Prostate cancer is one of the most common malignant diseases in men over 50 years of age. Current therapeutic approaches are highly effective in the early stages; however, treatment of the metastatic disease is more complicated and associated with poor prognosis. Epidemiological data encourage intense research of innovative experimental methods that would improve the quality of life and prolong the survival of cancer patients. Among the treatment strategies, immunotherapy seems to be the most promising method.
The Department of Immunology 2nd Medical School and University Hospital Motol has been focusing on tumor immunology and antitumor immunotherapy for over ten years. We have developed a DC-based vaccine that proved the ability to induce antigen-specific T cells that recognize and eliminate transformed tumor cells. Due to low frequencies of induced tumor-specific T cells we try to find approaches that might increase the numbers of specific effectors. Therefore the aim of the project is to develop and optimize a large scale *ex vivo* expansion protocol for adoptive T cell transfer, using autologous tumor-specific T-lymphocytes induced by the DC-based vaccine. For clinical use, the aim is to adjust protocol settings to Good Clinical Practice (GMP) conditions. The combination of therapeutic vaccine and adoptive transfer offers a promising approach for the treatment of tumor diseases.

P6.07.42
Changes in T lymphocyte subsets accompany the clinical response to Mesenchymal Stem Cell (MSC) therapy - first experience in irradiation-induced colitis

J. Voswinkel[1]*, J. Lataillade*[2]*, S. Francois*[3]*, M. Mohty*[1]*, N. Gorin*[1]*, M. Benderitter*[3]*, A. Chapel*[3]*;*
[1]Hopital Saint Antoine, APHP, Dpt of Haematology and Cell Therapy, Paris, France, [2]Burn Treatment Center, Percy Military Hospital, Clamart, France, [3]Institute of Radiological Protection and Nuclear Safety, Fontenay-aux-Roses, France.

Background: Therapy by Mesenchymal Stem Cells (MSC) facilitates functional recovery and dampens the systemic inflammatory response in radiation-induced colitis. Bone marrow-derived MSC from the patients´ children were injected to four patients.
Patients and Methods: MSC were obtained by culture from bone marrow aspirates. A quantity of $2x10^6$ - $6x10^6$ MSC /kg were infused intravenously to the patients. Pain, hemorrhage, frequency of diarrheas and fistulisation as well as the lymphocyte subsets in peripheral blood were evaluated before MSC therapy and during the follow-up.
Results: Two patients revealed a substantiated clinical response for pain and hemorrhage after MSC therapy. In one patient pain reappeared after 6 months and again substantially responded on a second MSC infusion. A beginning fistulisation process could be stopped in one patient resulting in a stable remission for more than 3 years of follow-up. The frequency of painful diarrhea diminished from an average of 6/d to 3/d after the first and 2/d after the 2nd MSC injection in one patient. A decline of CD4+ and CD8+ T lymphocytes and an increase of potentially regulatory CD25+ T cells accompanied the clinical response in this patient after the MSC injections. In all patients prostate cancer remained in stable complete remission. No toxicity occurred.
Conclusion: A modulation of the lymphocyte subsets towards a regulatory pattern and diminution of activated T cells accompanies the clinical response in refractory irradiation-induced colitis. For patients with refractory chronic inflammatory and fistulising bowel diseases, systemic MSC injections represent a safe and effective option for salvage therapy.

Genetically modified T cells expressing an affinity enhanced NYESO-1 T Cell Receptor in cancer therapy

D. D. Williams[1]*, A. P. Rapoport*[2]*, E. A. Stadtmauer*[3]*, G. K. Binder-Scholl*[4]*, J. E. Brewer*[1]*, A. D. Bennett*[1]*, M. Kalos*[5]*, B. L. Levine*[6]*, C. H. June*[3]*, B. K. Jakobsen*[1]*;*
[1]Adaptimmune Ltd., Abingdon, United Kingdom, [2]Greenebaum Cancer Center, University of Maryland,, Baltimore, MD, United States, [3]Abramson Cancer Center, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA, United States, [4]Adaptimmune LLC, Philadelphia, PA, United States, [5]Translational and Correlative Studies Laboratory, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA, United States, [6]Department of Pathology and Laboratory Medicine, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA, United States.

Thymic selection of T cell receptors (TCRs) ensures the low affinity of natural TCRs targeted to self-antigens, including those associated with tumours, such that they cannot recognize the level of self-antigens presented on most cancer cells. We have developed an approach that uses adoptive transfer of T cells genetically engineered to express optimised affinity TCRs that specifically target an epitope shared by the Cancer Testes (CT) antigens NYESO-1 and LAGE-1 (SLLMWITQC) in the context of HLA-A201. This approach has been evaluated pre-clinically and is currently being evaluated in a Phase I/IIa clinical study in multiple myeloma. To date 13 patients have reached the day 100 assessment and a CR/nCR response rate of 76% has been observed. An analysis of patient samples to determine bioactivity, trafficking, durable persistence and anti-tumour activity of the enhanced affinity TCR modified T cells has provided an insight into the mechanism and efficacy of the therapy. Data indicate T cell persistence in the responding patients is directly correlated with decreased NY-ESO-1/LAGE-1 antigen levels and decreases in the myeloma marker CD138. These observations indicate that incorporation of the affinity optimised tumour antigen specific TCRs into autologous T cells can overcome the limitations of thymic restrictions to the repertoire of TCRs able to target low levels of antigen on cancer cells.

P6.07.44
Exploring leukemia- and virus-reactive CD8+ T lymphocytes with stem-cell-like and central memory properties for effective immunotherapy in humanized mice

Y. Xu*, A. Mades, S. A. Khan, M. Theobald, U. F. Hartwig;*
University Medical Center of Johannes Gutenberg-University Mainz, Dept. of Hematology, Internal Oncology & Pneumology, Mainz, Germany.

Adoptive transfer of antiviral and tumor-reactive T cells has become a powerful therapy to treat cancer and virus-associated malignancies such as EBV-mediated lymphoproliferative disorders. However, terminally differentiated, high avidity effector T cells exhibit limited homing and self-renewal capacity to establish sustained memory. In this study we thus explored the modulation of the canonical Wnt-signaling pathway shown to affect T cell differentiation to generate HLA-A*0201 restricted, EBV- and Wilms Tumor1 (WT1) antigen-specific cytolytic T lymphocytes (CTL) from naïve human CD8+ cells with stem-cell-like memory (TSCM) and central-memory (TCM) properties.
Following repetitive stimulation with autologous DCs or PBMCs loaded with EBV- or WT1-peptide mix or EBV-transformed B cells (B-LCL) in the presence of IL-12, -7, -15, -21 and the glycogen synthase kinase-3β inhibitor TWS119 for 28-33 days we obtained strong expansion of EBV- and WT1-specific CD45RA+CD62L+CCR7+ TSCM and CD45RO+CD62L+CCR7+ TCM as compared to unmodulated control CTL. Additional studies revealed elevated ß-catenin levels and higher expression of eomesdermin supporting our phenotypic T cell differentiation analyses. Whereas both TWS119 treated and control CTL populations elicited comparable reactivity in vitro, EBV- and WT1-reactive TSCM and TCM showed prolonged persistence following adoptive transfer into human IL-15 supplemented NSG mice. Moreover, so far we observed superior killing of B-LCL engrafted into NSG mice as compared to control CTL in both preemptive and therapeutic situations.

We conclude that stem-cell-like and central memory type EBV- and WT1-reactive CTLs with increased homing capability and sustained effector functions can be generated from naïve T cells by modulating Wnt-signaling for improved immunotherapy.

P6.07.45
Intrapancreatic transplantation of allogeneic mesenchymal stromal cells (MSCs) decreases blood glucose levels in experimental type 1 diabetes

***J. N. U. Yaochite**, L. S. Neto, C. Caliári-Oliveira, M. M. da Matta, K. C. Malmegrin, C. C. B. O. Menezes, D. T. Covas, J. C. Voltarelli, E. A. Donadi;*
School of Medicine of Ribeirão Preto, University of Sao Paulo, Ribeirão Preto, Brazil.

Introduction: Mesenchymal stromal cells (MSCs) transplantation has been proposed to be one possible therapeutic alternative in type 1 diabetes (T1D). However, one challenge associated with MSCs transplantation is the route of administration for efficient cell delivery. Aim: Evaluating the therapeutic potential of intrapancreatic transplantation of allogeneic MSCs in experimental T1D. Methods**:** Diabetes was induced in C57BL/6 mice by streptozotocin. MSCs were isolated from adipose tissue of Balb/c mice. $1x10^6$ MSCs were administrated by intrapancreatic injection in hyperglycemic mice twelve days after diabetes induction. The control group was injected with PBS. The glycemia was monitored periodically. The glucose tolerance test (GTT) was performed 57 days after MSCs/PBS injection. The frequency of $Foxp3^+$ cells in spleen and pancreatic lymph nodes was evaluated at day 70^{th} post-treatment. Results: We observed that the intrapancreatic administration of MSCs could recover the hyperglycemia in 60% of diabetic animals. During GTT, the treated group showed a significant improvement of the peripheral response to glucose in all time points evaluated. The area under the curve of MSCs-treated group was lower when compared with the control (45.560 *versus* 71.884; p=0.003). At day 70^{th}, the fasting /non fasting glycemia of responders treated-mice were lower compared with the control (166.42/183.6 mg/dL *versus* 302.2/382.9 mg/dL, p<0.001). We did not observe differences in the frequency of $Foxp3^+$ cells. Conclusion: The intrapancreatic transplantation of allogeneic MSCs was effective in improving glucose control in diabetic mice. The intrapancreatic route represents a new approach to avoid MSCs pulmonary entrapment with promising results in T1D. Acknowledgment: FAPESP/CNPq.

P6.07.46
Generation of gene engineered mesenchymal stem cells and its efficacy against human breast cancer

***F. Yap**[1], S. Cheong[2], R. Ammu[1], C. Leong[3];*
[1]International Medical University, Bukit Jalil, Kuala Lumpur, Malaysia, [2]Universiti Tunku Abdul Rahman, Sungai Long, Malaysia, [3]National University Malaysia, Cheras, Kuala Lumpur, Malaysia.

Breast cancer has become an escalating disease that has highly significant ramifications for future global health. In Malaysia, breast cancer is the number one cancer killer and affects the health of Malaysian women from all walks of life. Novel approaches on treatment of breast cancer are urgently needed to improve the clinical outcome of these patients. Recent studies have suggested that mesenchymal stem cells (MSCs) can home to and incorporate within the tumor tissues. This finding offers a novel way to deliver therapeutic agents to the tumor sites. In the study, we propose to generate genetically engineered MSCs (GE-MSCs) that express IL-12 and IL-18. The efficacy of these GE-MSCs will then be tested on a panel of breast cancer cell lines (MCF-7, MDA-MB-231 and T-47D). Bone marrow derived MSCs were characterized by immunophenotyping and differentiation studies. MSCs were found to selectively migrate towards breast cancer cells in a dose dependent manner. GE-MSCs were successfully generated by transfection with recombinant plasmids encoding IL-12 and IL-18 and the cytokines secreted by GE-MSCs were able to induce IFN-γ production by peripheral blood mononuclear cells. A marked increase of IFN-γ was observed when both cytokines were used, demonstrating their synergistic effects. Apart from that, these GE-MSCs retained properties of MSCs such as differential plasticity and migration abilities. The GE-MSCs appear to possess potent anti-proliferative and cytotoxic effects against breast cancer cells. The GE-MSCs also capable of activating unprimed T lymphocytes by up-regulated CD69 which may in part enhance the treatment efficacy.

P6.07.47
Endothelial cells: new targets for MSCs-mediated immunomodulation in mouse

***L. Zanotti**[1], C. Soldani[1], C. Ploia[1], F. Moalli[2], E. Dander[3], G. D'Amico[3], A. Sarukhan[1], A. Viola[1];*
[1]Humanitas Clinical and Research Center, Rozzano, Milano, Italy, [2]2Theodor Kocher Institute, University of Bern, Bern, Switzerland, [3]3Centro Ricerca "M. Tettamanti," Clinica Pediatrica Università degli Studi di Milano Bicocca, Monza, Italy.

Chronic inflammation is involved in the pathogenesis of several human diseases, such as atherosclerosis, allergy and autoimmune diseases. Several anti-inflammatory pharmacological drugs are currently available but with limited efficacy and deleterious long-term consequences.
Long lasting tolerance induction may represent an effective resolution for these diseases and scientists have become interested in therapies based on cells with immunomodulatory activity. It has been demonstrated that Mesenchymal Stem Cells (MSCs) exert potent immunosuppressive effect both *in vitro* and *in vivo*, although the results of clinical trials are still disappointing and the biological mechanisms responsible for MSC effect remain poorly defined.
The aim of our study is to obtain a deeper understanding on MSC immunomodulatory mechanisms *in vivo*.
By transplanting alginate-encapsulated MSCs, we have recently shown that their therapeutic effect is completely independent of migration capacity or cell to cell contacts. Using TCR transgenic mice, we have found that encapsulated MSCs hamper recruitment of leukocytes and dendritic cells into inflamed lymph nodes. We speculated that this could be due to a direct effect on endothelial activation. Here we show that, *in vivo*, MSC hamper the up-regulation of VCAM and the increase in the number of CD31 positive vessels in inflamed lymph nodes. Furthermore, MSC-conditioned medium is able to down regulate the expression of VCAM1 and ICAM1 on endothelial cell lines in vitro. Altogether, these data strongly suggest that soluble factors secreted by MSC can modulate immune responses by directly inhibiting endothelial cell activation. The precise molecules involved in this process are currently under investigation.

P6.07.48
Treatment of autoimmune hepatitis by inhibiting CD8+T cells using hepatic stroma-induced regulatory DCs

*Q. Wang[1], D. Chen[2], H. He[1], H. Tang[1], W. Song[1], **M. Zhang**[2];*
[1]Taishan Medical University, Taian, China, [2]Tsinghua University, Beijing, China.

Dendritic cells(DCs) play a key role in triggering protected immune response against microorganisms or suppressing autoimmune inflammatory responses. We thus presumed that regulatory DCs (DCreg) may protect liver from $CD8^+$T cell-mediated liver damage. Autoimmune hepatitis(AIH) were induced in mice by transferring HBV-specific CTL into HBV transgenic mice. Liver significantly displayed damage from day1 to day3 after transfer of specific HBV-CTL, and gradually restored at day 6. During AIH, injection of liver stroma-induced DCreg significantly reduced the level of aspartate aminotransferase (AST), indicating a protective effect on liver. Liver DCreg were characterized by a longer life span, reduced expression of CD11c, Ia, CD80, CD86, CD40 along with increased expression of CD11b. They stimulated OT-1 $CD8^+$T cell to express CD25 and CD69 but inhibited mature DC-triggered $CD8^+$T cell proliferation. Compared with mature DCs, DCreg produced much higher nitric oxide (NO). Addition of NO synthase inhibitor PBIT remarkably reversed the DCreg inhibition of the proliferation of $CD8^+$T cells. These data provides a new idea for the treatment of autoimmune hepatitis by using regulatory DC in the future.

P6.07.49
Spatial distribution of transplanted bone marrow-derived mesenchymal stem cells in recipient's organs in the B16 melanoma model

K. E. Zubareva[1], *A. O. Solovieva*[1], *A. F. Poveshchenko*[2], *O. B. Gritsyk*[1], *E. A. Nechaeva*[1], *V. I. Konenkov*[1];
[1]*Federal State Budgetary Institution "Scientific Institution of Clinical and Experimental Lymphology" of the Siberian Branch under the Russian Academy of Medical Sciences, Novosibirsk, Russian Federation,* [2]*Federal State Budgetary Institution, Novosibirsk, Russian Federation.*

Introdaction. It is believed that the intratumoral integration of exogenously delivered bone marrow-derived mesenchymal stem cells (MSCs) may contribute to the stroma of tumors. MSCs were suggested as delivery vehicles for anticancer agents into tumors. However, the spatial distribution of MSC in recipient organisms during tumorogenesis has not yet been fully investigated.
Methods. We isolated MSCs from bone marrow of mice, fluorescently labeled the cells, and injected them into tail vein of mice bearing B16 melanoma. The recipient's organs (tumor, skin, lymph nodes, lung, liver, spleen, brain, the bone marrow) were harvested at different times after MSC transplantation: one hour, 3, 7 and 14 days. We detected MSCs in organs by histological analysis and real time polymerase reaction.
Results. After 1 hour donors MSCs were identified in all organs, with maximal donor cell markers in the lung, liver and spleen. In histological sections, cells were mainly observed in the blood vessels of organs.
After 3 days, highest levels of donor cell markers were observed in lymph nodes, bone marrow and lung. Analysis of distribution transplanted MSCs on day 7 showed accumulation of cells into the tumor and organs that are metastasized: lung, liver and spleen. Migration activity of MSCs into tumor and organs that are metastasized increased from 1h to 7 day after cells transplantation, when the tumors were visualized macroscopically. Overall, we believe that the concept that MSCs can be used as delivery vehicles for anticancer agents into tumors, is valid and worthy of further investigation.

P6.08 Stem cells in immunity

P6.08.01
Comparison of immunoregulatory properties of stem cells from human exfoliated deciduous teeth and bone marrow-derived mesenchymal stem cells

K. Adib*, R. Alipour, B. Hashemi Beni;*
Medical School Isfahan University of Medical Sciences., Isfahan, Iran.

Mesenchymal stem cells (MSCs) have remarkable capacities (stemness properties, unique immunoregulatory features and etc.) that suggest the application of them in various new therapeutic disciplines. Stem cells from human exfoliated deciduous teeth (SHED) are introduced recently. Because of their convenient accessibility, safety of harvest(despite BMMSC),and being ethically uncontroversial**,** SHED can be a preferable source for the ever-increasing MSCs' applications. While they are new, compared to other MSC populations, their immunoproperties have not been studied as much as necessary. In this study, we explored the effect of SHED on proliferation of T lymphocytes and compared to BMMSCs**.** With this aim, at first the isolated T lymphocytes were activated both specifically (by allogenic PBMCs) and nonspecifically (by phytohemagglutinin, PHA) in vitro and cocultured with SHED or BMMSCs under same conditions, subsequently their proliferation and cytokine secretion were measured.
In our experiment, BMMSCs and also SHED could inhibit the proliferation and cytokine production of both PHA and alloantigen stimulated T lymphocytes in a dose-dependent manner. Although the inhibition decreased by the separation of lymphocytes and MSCs by a semipermeable membrane, but it was not abolished.
This study showed that SHED can suppress the activation of human T lymphocytes in vitro. However, compared to BMMSCs, this suppression was distinctly alleviated. Moreover, in the equal condition the pattern of immune-modulation of BMMSCs and SHED was different, suggesting that SHED do not exert the exact mechanisms of BMMSCs' immunosuppression.

P6.08.02
Production and characterization of murine monoclonal antibodies against human synthetic peptide of CD_{34}

L. Aghebati Maleki*, J. Majidi, B. Baradaran, J. Abdolalizadeh, A. Movassaghpour;*
Immunology Research Center, Tabriz, Iran.

The treatment of hematologic malignancies, solid tumors, and some non-malignant diseases like immunodeficiency diseases is offered by hematopoietic stem cells (HSCs) as a unique self-renewal and differentiation source which most commonly is selected by CD_{34} surface marker for HSC. By the advent of hybridoma technology, monoclonal antibodies applications exert extensive changes in medical fields such as diagnosis, treatment and purification. Antibodies are highly specific and functional in applications such as ELISA, Flowcytometry, Immunocytochemistry, and Western blot assays. In this study, splenocytes from Balb/c mice immunized with two 14-mer synthetic peptide were fused with SP2/0 murine myeloma cells. Fused cells were grown in hypoxanthine, aminopterine and thymidine (HAT) selective medium. Supernatant of hybridoma cells were screened by enzyme-linked immunosorbent assay (ELISA) for antibody production and the desired clones were selected and cloned by limiting dilution (L.D) assay. Eventually, the specificity and cross reactivity of secreted mAbs were further studied by ELISA and western blot analysis (WB). Isotype of this mAb was identified as γ heavy chain and k light chain. Reactivity of these antibodies was then evaluated in different immunological assays including ELISA, Immunofluorescence (IF), Western blot (WB) and Flowcytometry. Monoclonal antibody was purified by affinity chromatography on protein A-Sepharose and then confirmed by SDS-PAGE. These results indicate that peptide-based antibody against CD_{34} surface marker of HSC can be used for research, diagnosis and purification.

P6.08.03
The effect of TNF-α in differential gene expression pattern of CXCR4 on human marrow-derived mesenchymal stem cells

M. Ayatollahi*, R. Ziaei, R. Yaghobi, Z. Sahraeian, B. Geramizadeh;*
Transplant Research Center, Shiraz, Iran.

Introduction: Cell therapy and tissue repair are used in a variety of diseases including tissue and organ transplantation, autoimmune diseases and cancers. Now mesenchymal stem cells (MSCs) are an attractive and promising source for cell-based therapy according to their individual characteristics. Soluble factors which are able to induce MSCs migration have a vital role in cell engraftment and tissue regeneration. Tumor necrosis factor α (TNF-α) is a major cytokine present in damaged tissues. Methods: We have investigated the pattern of gene expression of chemokine receptor CXCR4 in nine groups of human bone marrow-derived MSCs stimulated with TNF-α in different dose and time manner. Results: Comparison of TNF-α treated with untreated MSCs revealed the highest expression level of CXCR4 after treatment with 1 ng/ml, and 10 ng/ml of TNF-α in 24 hours, and the production of CXCR4 mRNA was regulated up to 216 and 512 fold, respectively. Our results demonstrated the differential gene expression pattern of chemokine receptor CXCR4 in human marrow-derived MSCs stimulated with inflammatory cytokine TNF-α. Conclusion: These findings suggest that in vitro control of both dose and time factors may be important in stem cell migration capacity, and perhaps in future-stem cell transplantation therapies.

P6.08.04
Association between T Reg marker polymorphism and tuberculosis

E. Beiranvand[1], *S. Abediankenari*[2], *B. Beiranvand*[3];
[1]*Pasteur Institute of Iran,Tehran iran, Member of Research Committee, Mazandaran University of Medical Sciences. Sari, Iran., Tehran, Iran,* [2]*Immunogenetics Research Center, Faculty of Medicine, Mazandaran University of Medical Sciences, Sari, Iran., Sari, Iran,* [3]*Jundishapur University of Medical Sciences, Ahvaz, Iran.*

Introduction: The FOXP3 gene encodes a transcription factor thought to be essential for the development and function of regulatory T cells(Treg), which are play a key role in balancing immune responses to maintain peripheral tolerance against antigens .The Studies have found an association between common polymorphisms in FOXP3 and some of infection diseases. However, data about FOXP3 gene in TB is limited. The aim of present study was to analyze the association between FOXP3 gene polymorphism and susceptibility to TB in the North of IRAN.
Methods: In a case–control study, 183 TB patients and 183 controls were recruited according to age and gender. We investigated one FOXP3 promoter single nucleotide polymorphism (SNP), -3279 A>C (rs3761548) by using PCR sequence-specific primer (PCR-SSP) technique.
Results: We found that there was no evidence of an increased risk associated with the FOXP3 and rs3761548 (-3279 AC) genotype (P > 0.05).
Conclusion: In this study, we showed that there were no differences between TB patients in comparison with controls. It is concluded that relationship between TB and Foxp3 gene needs to more experiments in difference population.

P6.08.05
Developmental endothelial locus-1 (Del-1) is a negative regulator of GCSF-dependent hematopoietic stem cell mobilization

L. Chen[1,2], *I. Mitroulis*[1,3], *N. Mende*[4], *G. Siegert*[3], *C. Waskow*[4], *G. Hajishengallis*[5], *T. Chavakis*[1,2];
[1]*Division of Vascular Inflammation, Diabetes and Kidney, Department of Internal Medicine III, University Dresden, Dresden, Germany,* [2]*Institute of Physiology, University Dresden, Dresden, Germany,* [3]*Institute for Clinical Chemistry and Laboratory Medicine, University Dresden,, Dresden, Germany,* [4]*Center for Regenerative Therapies Dresden, Dresden, Germany,* [5]*Department of Microbiology, School of Dental Medicine, University of Pennsylvania, Philadelphia, PA, United States.*

Hematopoietic stem cell (HSC) mobilization from the bone marrow to the peripheral blood is important in the course of bone marrow transplantation. HSC mobilization can be stimulated by granulocyte colony-stimulating factor (G-CSF) and CXCR4 antagonism (by AMD3100), which are broadly used in the clinical setting. Adhesive interactions, like VLA-4/VCAM-1 and LFA-1/ICAM-1 between the HSCs and bone marrow stromal cells regulate HSC retention in the bone marrow and thus modulate HSC mobilization. Del-1 is an endothelial-derived endogenous inhibitor of inflammatory cell recruitment by antagonizing LFA-1-dependent leukocyte adhesion to endothelial ICAM-1 (Choi et al., Science, 2008; Eskan et al., Nat Immunol, 2012). Here we found that Del-1 is expressed in the bone marrow, in both mesenchymal stem cells and endothelial cells. Interestingly, Del-1 KO mice showed higher numbers of HSC in the peripheral blood after G-CSF but not after AMD3100 stimulation. Upon G-CSF administration, the level of Del-1 in the endosteal bone is decreased, which is reminiscent of the reduced GCSF-mediated expression of CXCL12, Kit ligand and osteopontin, which are important factors for HSC retention. Moreover, bone marrow mononuclear cells (BMMNC) from Del-1-proficient mice can bind to immobilized Del-1 through LFA-1 in vitro, indicating that Del-1 could contribute to HSC retention directly. Our results suggest that Del-1 in the bone marrow is a negative regulator of HSC mobilization, and further studies are required to reveal the underlying mechanism.

P6.08.06
Differential efficacy of human mesenchymal stem cells on disease in murine lupus based on source of origin

E. L. Collins[1], *F. Gu*[2], *O. Naga*[1], ***G. Gilkeson***[1];
[1]*Medical University of South Carolina, Charleston, SC, United States,* [2]*The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing Jiangsu, China.*

Systemic lupus erythematosus (SLE) is a devastating autoimmune disease that targets multiple organ systems. A population of non-hematopoetic stem cells, mesenchymal stem cells (MSC), are of increasing interest as a therapeutic option for autoimmune diseases such as SLE. MSCs can be derived from various sources such as bone marrow or umbilical cords. In this study we examine the efficacy of human MSCs with varying origin on disease in murine based lupus. Human MSCs were harvested from umbilical cords, healthy donor bone marrow, and lupus patient bone marrow. We showed that in MRL/lpr mice, MSCs from all sources improved survival, increased body weight, and decreased proteinuria. Glomerular IgG, but not C3, deposition is significantly decreased in mice receiving umbilical cord and healthy donor MSCs. However, MSC from lupus patients caused a significant increase in glomerular C3 and IgG. Although no differences were seen in the percentage of CD4+ or CD8+ T, mice receiving lupus MSCs experienced a 2-fold increase in the percentage of Foxp3+ cells in the spleen. These mice also experienced this percentage increase in TCRβ+, B220+, and CD138+ cells in the bone marrow. Human MSC from various origins all made an impact on the disease severity of lupus prone mice. However, these results suggest that MSCs from healthy donors or umbilical cords appear to me more effective in murine lupus than the MSCs derived from lupus patients.

P6.08.07
LT-beta receptor signaling promotes progression of chronic myeloid leukemia in mice

S. Hoepner[1], *C. Riether*[1], *C. Schürch*[1,2], *A. F. Ochsenbein*[1,3];
[1]*Tumorimmunology, Department Clinical Research, University of Bern, Switzerland,* [2]*Institute of Pathology, University of Bern, Switzerland,* [3]*Department of Medical Oncology, University Hospital of Bern, Inselspital, Switzerland.*

Despite promising progress in long-term treatment of Leukemia, the removal of leukemic stem cells (LSCs) and therefore cure of the disease remains an unmet need. Numerous studies indicate that LScs are resistant to conventional treatment such as radiotherapy or chemotherapy. Tumor necrosis factors (TNF) and their receptors (TNFR) regulate cell survival, growth, apoptosis and differentiation. TNFR signaling is of importance in anti-tumor immunity but also contributes to chronic inflammation. Lymphotoxin-beta receptor (LTbR) is shown to play a role in regulating developmental programs and formation of lymphoid organs, but is also critically involved in the regulation of immune responses. In this study, we now show that LTbR is expressed on normal hematopoietic stem cells and on LSCs. Hematopoiesis in naïve LTbR-KO mice is comparable to naïve BL/6 mice. To investigate the role of LTbR signaling in leukemia, we induced chronic myelogenous leukemia (CML) in mice by retroviral transduction of bone marrow (BM) progenitor cells with BCR/ABL. Surprisingly, LTbR signaling on leukemia stem and progenitor cells significantly promotes CML development compared to LTbR-KO CML. Analysis of homing capacity of LSCs to BM revealed impairment of LTbR-KO LSCs to home into BM compared to control. In conclusion, LTbR signaling seems to positively affect leukemic development. Therefore, blocking LTbR signaling may be a strategy to target leukemia stem and progenitor cells directly.

P6.08.08
In vivo imaging approach for continuous monitoring of transplanted cells

***Z. Karabekian**, A. Popratiloff, N. Sarvazyan;*
The George Washington University, Washington, DC, United States.

With significant developments in tissue engineering, the concern of immunogenicity of transplanted cells or tissue constructs becomes critical. Yet, current methods for assessment of cell survival are often limited to a single time point at the end of the engraftment period. To circumvent this limitation we developed an imaging protocol that allows continues tracking of transplanted cells within the same animal as well as simultaneously assessment of general inflammatory reaction caused by the same cells. To illustrate this technique we employed mouse fibroblasts of the H-2b haplotype obtained from C57Bl/6 mice and immortalized by transformation with Simian Virus-40 T large antigen. Immunogenicity of aforementioned cells was diminished by stable transduction with lentivirus encoding anti-beta2-microgobulin shRNA. Parental and modified cells were loaded with cell tracker of different colors and injected in the pinna of either right or left ear of syngeneic (C57Bl/6) mice. Parallel experiments were conducted using allogeneic (Balb/C) mice. Grafted cells were visualized by confocal microscopy while degree of general inflammation was assessed by ear thickness measurements. In vivo visualization experiments were conducted on daily basis under general anesthesia and allowed live monitoring of the engraftment process. Evans Blue was used to simultaneously measure blood flow to the graft area. The developed approach offers a convenient and easily adaptable way to evaluate survivability of grafted cells or tissue engineered cell constructs in syngeneic or xenogeneic environments (Supported by AHA/SDG5680036, NSF/CBET1231549 & NIH/1S10OD010710 awards)

P6.08.09
Preparation of a high affinity monoclonal antibody against morphine showing no cross reactivity with heroin

***S. Kashanian**;*
Tehran University of Medical Sciences, Tehran, Iran.

Morphine (7, 8-didehydro-4, 5-epoxy-17-methylmorphinan-3, 6-diol) is obtained from opium, derived from the milky exudate of the incised unripe seed capsules of the poppy plant, Papaver somniferum. This compound is a potent narcotic analgesic with substantial potential for abuse and constitutes a significant health problem for human society. Drug testing is a rising demand to restrict the spread of substances of abuse and to provide more protection to the members of society.
Monoclonal antibody (MAb) with a high affinity towards morphine can be considered as a great tool for its detection. In this study we prepared a MAb specific for morphine with no cross reactivity with heroin.
To prepare the immunogen, a morphine derivative (6-hemisuccinate) was conjugated to cationized BSA. Mice were immunized for 4 months. ELISA technique was used to screen the presence of antibody in the serum and culture media. Beatty method was used to calculate antibody affinity.
Results indicate that prepared antibody has a high affinity (5.9×108 M-1) towards morphine and less than 0.001% cross reactivity with heroin.

P6.08.10
Recombinant human Cyclophilin A supports differentiation of granulocytes

***L. M. Khromykh**[1], N. L. Kulikova[2], L. Y. Grivtsova[1], M. A. Frenkel[1], N. N. . Tupitsyn[1], A. A. Kalinina[1], D. B. Kazansky[1];*
[1]Federal State Budgetary Institution "N.N. Blokhin Russian Cancer Research Center" under the Russian, Moscow, Russian Federation, [2]Institute of Engineering Immunology, 142380 Lyubuchany, Chekchov District, Moscow Region, Russia, Moscow Region, Russian Federation.

Cyclophpilin A (CypA) is an18 kDa protein is found in all mammalian tissues and have a wide spectrum of functions. As a secreted form, CypA is present in the plasma of healthy individuals and in human breast milk. CypA is a chemokine for stem cells and various types of bone marrow precursors (dendritic cells, granulocytes, T- and B-lymphocytes). Although CypA was shown to promote differentiating of stem cells into dendritic cells, whether CypA can support development of other hematopoietic cells has not been investigated.
The goal of our study was to evaluate the effects of a recombinant human cyclophilin A (rhCypA) on differentiation of hematopoietic stem cells in vivo in mice and in vitro in human cells. Administration of rhCypA to sub-lethally irradiated mice increased the numbers of stem cell colonies in the spleen. In cyclophosphamide (CTX) treated mice, administration of rhCypA induced a significant increase in leukocytes and differentiated granulocytes in the blood. RhCypA restored $CD31^+GR1^+$ granulocytes and $CD11b^+CD11c^+$ dendritic cells in the bone marrow of CXT-treated mice. The restoration of granulocytes by rhCypA was due to its effect on $SCA\text{-}1^+$ stem cells in the mouse bone marrow. Studies using human leukapheretic product and bone marrow showed that rhCypA supported differentiation of $CD33^+CD14^+$, $CD33^+CD64^+$, and $CD13^+CD14^+$ myelomonocytes in vitro. Morphological analysis of these cells revealed a significant accumulation of young granulocytes. Thus our data demonstrated the activity of rhCypA as a differentiating factor for granulocytes.

P6.08.11
Susceptibility of human cardiac progenitor cells to natural killer cell lysis

***I. lauden**[1], W. Boukouaci[1], N. Dam[1], N. Jabrane-Ferrat[2], D. Charron[1], R. Tamouza[1], R. Al-Daccak[1];*
[1]Inserm UMRS 940, Paris, France, [2]Inserm UMRS 1043- CNRS UMR5282, Toulouse, France.

Stem cells therapies as alternative cure for heart failure has been strengthened by findings showing the existence of human cardiac stem/progenitor cells (hCPC). The use of autologous hCPC is hindered by the state of patients and calls upon the use of allogeneic hCPC. However, their immunological risk should be fully understood for their clinical application. Natural killer (NK) cells could eliminate allogeneic cells expressing low levels of MHC class I molecules or high levels of ligands for NK activating receptors. The cytolytic activity of NK cells is triggered after integration of signals transmitted from their activating and inhibitory receptors. In this work, hCPC were characterized for the expression of ligands for activating and inhibitory NK cells receptors under inflammatory conditions or not. Then their susceptibility to NK cell-mediated lysis as well as their capacity to modulate NK cell activities in allogeneic settings was evaluated. hCPC express similar levels of ligands for activating NK receptors under inflammatory and non-inflammatory conditions and were lyzed by activated NK cells. However, the expression of ligands for inhibitory receptors was increased/induced under inflammatory conditions, which led to a drastic decrease in their susceptibility to NK killing. hCPC were also able to modulate the NK cytolytic activity towards target cells, and this was accompanied by a decrease in the expression of NK activating receptors. Collectively, these data indicate that allogeneic hCPC display low immunological risk, in particular in an inflammatory context, supporting thus, their applicability after myocardial infarction.

P6.08.12
Properties of TiCaPCON-based nanostructured coating as bioimplant constituent

*A. N. Kopilov[1], N. Y. Anisimova[1], **O. V. Lebedinskaya**[2], D. V. Shtansky[3], M. V. Kiselevsky[1];*
[1]State Institution N.N. Blokhin Russian Research Cancer Centre, RAMS, Moscow, Russian Federation, [2]Acad. E.A. Wagner Perm State Medical Academy, Perm, Russian Federation, [3]National University of Science and Technology "MISIS", Moscow, Russian Federation.

Biocompatibility of TiCaPCON-based nanostructured coating with multi-potent mesenchymal stromal cells (MMSC) isolated from mice red bone marrow that possessed high level of CD271 expression and with human dendritic cells (DC) generated from peripheral blood monocytes was analyzed.

The aim of work was to explore the possibilities of this material application as a bioimplant constituent to replace bone tissue defects. MMSC and DC were introduced in suspension to TiCaPCON-coated slide surface (NRTU «MISIS» films, Moscow). Coating-free slides served as control. Microphotography was performed using inverted microscope (Leica, Germany) daily for 7 days of incubation at 37°C. Studies conducted on 200 slides demonstrated that TiCaPCON appeared to be both biocompatible as did not render cytopathogenic action on mice MMSC and human DC and bioactive material as it favored adhesion, proliferation and colonization of cells under study.
Thus, TiCaPCON-coated and MMSC-colonized implant possessed the properties of accelerated fixation and biointegration in damaged tissue/organ site. Therefore, TiCaPCON appears to be promising as a composite bioimplant (material of natural or synthetic origin) constituent being able to provide reliable supporting and/or structure-forming function.

P6.08.13
Mass-production and characterization of anti-human CD_{34} monoclonal antibody in peritoneum of BALB/c mice

***J. Majidi**, B. Baradaran, l. Aghebati Maleki, J. Abdolalizadeh, A. Movassaghpour;*
Immunology Research Center, Tabriz, Iran.

Monoclonal antibodies or specific antibodies are now an essential tool of biomedical research and are of great commercial and medical value. The purpose of this study was to produce large scale of monoclonal antibody against CD_{34} in order to diagnostic application in leukemia and purification of human hematopoietic stem/progenitor cells. For large scale production of monoclonal antibody, hybridoma cells that produce monoclonal antibody against human CD_{34} were injected into the peritoneum of the Balb/c mice which have previously been primed with 0.5 ml pristane. Approximately, 5 ml ascitic fluid was harvested from each mouse. Evaluation of mAb titration was assessed by ELISA method. MAb was purified from ascitic fluid by affinity chromatography on protein A-Sepharose and then, the purity of mAb was assessed by SDS-PAGE and conjugated with FITC. Specific binding of conjugated mAb with CD_{34} marker of human hematopoietic stem/progenitor cells was evaluated using flowcytometry and immunofloresance techniques. This mAb showed appropriate reactivity in the following assays as if ELISA, Flowcytometry, Immunofluorescence staining and Western blot (WB). The results of immunological assays clearly showed that our antibody strongly reacts with CD_{34} antigen. The conjugated monoclonal antibody could be a useful tool for isolation, purification of human hematopoietic stem cells.

P6.08.14
Cell Cycle Analysis of Human Colorectal Cancer Stem Cells Reveals their Quiescent Nature

***H. R. Mirzaei**[1], H. Mirzaei[2], J. Jalili[1], M. Eghbali[3], N. Bagherpour[4];*
[1]Tehran University of Medical Sciences, Tehran, Iran, [2]Mashhad University of Medical Sciences, Mashhad, Iran, [3]Isfahan University of Medical Sciences, Isfahan, Iran, [4]Science & Research Branch, Islamic Azad University, Tehran, Iran.

Aim: The CD133 antigen has been identified as a putative stem cell marker in colorectal cancer tissues. The aim of this study was to investigate the cell cycle state of CD133 + and CD133 - cells, isolated from primary and metastatic human colorectal tumors. Materials and Methods: After mechanical and enzymatic dissociation of the tumor samples, CD133 + and CD133 - subsets were identified and separated by magnetic cell sorting. Flow cytometric analysis was performed to compare the cell cycle of both CD133 + and CD133 - cells isolated from primary and liver metastatic cancer cells. Results: The results indicated that CD133 + cells isolated from both primary and liver metastatic colorectal cancers were found in higher percentage in the G0/G1 phases. However, the CD133 - cells isolated from primary colorectal cancers were predominantly found in the S and G2/M phases. Surprisingly, the CD133 - cells isolated from liver metastatic colorectal cancers were mostly found in the G0/G1 phase. Conclusion: The present study provides evidence that CD133 + cells are in a quiescent state in colorectal cancer, representing a mechanism that would at least partially explain chemotherapy resistance and tumor recurrence in post-therapy patients.

P6.08.15
NF-kB *rela*-deficient macrophages fail to support bone formation and maintain the microenvironment for hematopoiesis after X-ray irradiation and HSC transplanatation

***S. Mise-Omata**, T. Fukazawa, Y. Obata, T. S. Doi;*
RIKEN Bioresource Center, Tsukuba, Japan.

In bone, cells derived from HSCs and MSCs are interacted each other. Bone is remodeled by osteoblasts derived from MSCs and osteoclasts from HSCs. The maintenance and differentiation of HSCs are supported by niche cells derived from MSCs. NF-κB is an important transcription factor for hematopoiesis, bone remodeling, and inflammation. *rela-/-* fetal liver chimeric mice, which are prepared by transferring fetal liver cells into lethally irradiated host mice, are known to have reduced lymphopoiesis, although their hematopoietic activity of HSCs is intact. We found that they also developed osteoporosis. In *rela-/-* chimeric mice, bone formation was declined, but differentiation of osteoclasts was not enhanced. The most severe osteoporotic *rela-/-* chimeric mice possessed enhanced mobilization of HPCs in the peripheral, implying an impairment of microenvironment for hematopoiesis in *rela-/-* chimeric mice. Recently, macrophages in bone marrow are known to be important to maintain the microenvironment and to support bone formation. In order to assess the ability of F4/80+ macrophages to support bone formation, we co-transferred wild type F4/80+ macrophages with fetal liver cells into the host mice. As a result, the bone formation was rescued, indicating that a defect of *rela-/-* macrophages caused reduced bone formation. *rela-/-* macrophages more express NOS2, a typical M1 type inflammatory gene, but less express PGE2, important for wound healing and bone formation. The failure of wound healing after X-ray irradiation caused by a defect of macrophage function may occur, resulting in reduced bone formation and impairment of microenvironment for hematopoiesis in *rela-/-* chimeric mice.

P6.08.16
The effect of the Immunomodulatory functions of adipose derived mesenchymal stem cells on the expression of major transcription factors in CD4 T cell subsets

***A. Mohammadzadeh**[1,2], A. Pourfatolah[1], M. Soleymani[2], S. Moradi[3];*
[1]Tarbiat modares university, Tehran, Iran, [2]Bonyakhteh research center, Tehran, Iran, [3]Bonyakhteh Research Center, Tehran, Iran.

The potential and promising role of cultured adipose-derived mesenchymal stem cells (AD-MSCs) in regenerative medicine and new cell therapeutic concepts has been shown recently by many investigations. On the basis of the immunomodulatory functions of mesenchymal stem cells which have been indicated, It has been proposed that this function of MSCs play a pivotal role in establishment and leading of T lymphocytes, especially CD4 T cells, toward different functional subsets. In this context,
To detect the impact of AD-MSCs immunomodulatory and regulatory functions on the immune system in in vitro co-culture conditions at the gene expression level, we used Real Time-PCR as a sensitive method to investigate this effect on C57BL/6 spleen cells. Then, we analyzed the effects of AD-MSCs on master regulators and related major cytokine genes and on cell differentiation potential. Expression of c well-known CD4 effector T cell-related transcription factors, i.e. t-bet, GATA-3, Ror-gt and Foxp3 and cytokines, i.e. IFN-g, IFN-b and IL-b for Th1 cells, IL-4 for Th2 cells, IL-17 and STAT-3 for Th17 cells and IL-10 and TGF-b for regulatory T cells respectively, were evaluated by real time - polymerase chain reaction (RT-PCR).
In conclusion, the findings of this study confirm previous studies on MSCs and provide important implications for the role of immunomodulatory MSC effects in the differentiation fate of CD4-Tcell subsets.

P6.08.17
The effect of DiD on the immunosuppressive function and differentiation potency of Mesenchymal stem cells

M. S. Mohtasebi[1], *F. Nasri*[1], *E. Kamali Sarvestani*[1,2];
[1]*Department of Immunology, Shiraz University of Medical Sciences, Shiraz, Iran,* [2]*Autoimmune Diseases Research Center, Shiraz University of Medical Sciences, Shiraz, Iran.*

MSCs with immunomodulatory function and differentiation into various cell types can be used for treatment of autoimmune diseases. The fate of MSCs after injection helps the researchers to improve this therapy. In this regard, lipophilic carbocyanin fluorescent dyes with high emission spectra, such as DiD, avoid interference with background fluorescence and are suitable for in vivo imaging studies. In this study, in vitro and in vivo function of DiD labeled MSCs were examined. More than 99% of the MSCs were tagged with high intensity DiD. No significant change was observed in the Mitochondria Membrane Potential (MMP), Reactive Oxygen Species (ROS) production, proliferative capacity of the MSCs, and the morphology of adipocytes, osteoblasts, and Neural Progenitor Cells (NPCs), under proper differentiation media after labeling. DiD did not affect the expression of Nestin mRNA in NPCs derived from labeled and intact MSCs (p=0.7). No significant change was observed in production of PGE2 and IL-10 from the MSCs and NPCs after labeling. DiD labeled as well as intact MSCs significantly suppressed the proliferation of activated T cell in MLR by PGE2, reduced IFN-g and IL-17. Moreover, allogeneic MSCs with or without DiD similarly (p=0.63) improved the clinical score of the EAE mice. In comparison to the untreated EAE mice, a significant decrease in the levels of circulating IFN-γ and interleukin-17 and an increase in the IL-10 levels were observed in the EAE mice treated with labeled MSCs. This results revealed DiD is suitable for labeling of MSCs in neuronal autoimmune diseases.

P6.08.18
Human mesenchymal stem cells modulation of alveolar macrophage polarization in vivo and in vitro

A. D. Krasnodembskaya[1], ***T. Morrison***[1], *D. McAuley*[1], *M. A. Matthay*[2];
[1]*Queens University of Belfast, Belfast, United Kingdom,* [2]*University California San Francisco, San-Francisco, CA, United States.*

Rationale: We have previously reported that bone marrow-derived mesenchymal stem cell (MSC) treatment is protective in several models of ALI and sepsis. To effectively translate MSC into the clinical practice better understanding of the mechanisms mediating their effect is needed. ALI is a serious clinical syndrome characterized by dysregulated and excessive pulmonary inflammation. Key cellular mediators of the lung innate immunity are macrophages and neutrophils. It is recognized that macrophages can be polarized towards M1 (implicated in the development of ALI) or M2 (responsible for the resolution of inflammation). The current studies were undertaken to test 1) relative importance of macrophages vs. neutrophils to the MSC protective effect in vivo and 2) if human MSCs have a role in polarizing alveolar macrophages towards M2 phenotype in vivo and in vitro.
Results: In the in vivo model of E.coli pneumonia, when given to the neutrophil depleted mice, hMSC treatment demonstrated strong trend toward reduction of the severity of lung injury, improved bacterial clearance and reduced TNF-α levels in the BAL 24 h after infection, compare to PBS-treated animals, suggesting the central role of lung macrophages as cellular mediators of MSC effect. Both in vivo and in vitro hMSC administration was associated with significant up-regulation of CD206 (mannose receptor, widely accepted to be a marker for M2 activation) on AM and reduced TNF-alpha secretion.
Conclusions: Bone marrow-derived hMSCs have the capacity to change the phenotype and functional properties of alveolar macrophages, resulting in driving their polarization towards less inflammatory state.

The characteristic of minor cell populations in multiple sclerosis patients after cell therapy

D. Nizheharodava[1], *A. Borisov*[2], *E. Nazarova*[3], *E. Rudakovskaya*[1], *M. Zafranskaya*[1];
[1]*Immunology Department, Belarusian Medical Academy of Post-Graduate Education, Minsk, Belarus,* [2]*Neurology Department, Belarusian State Medical University, Minsk, Belarus,* [3]*Transplantology Department, Minsk City Hospital N9, Minsk, Belarus.*

Introduction. Minor cell populations demonstrate functional diversity, from effector action to immunoregulation, depending on pathological conditions. Our previous results showed significant differences in numbers and functions of minor cell populations including γδT-cells, $CD8_{low}$T-cells, NK-cells and TNK-cells in multiple sclerosis (MS) patients compared with donors.
Objective. To estimate the influence of cell therapy upon minor cell populations' quantity in peripheral blood of MS patients.
Materials and methods. Peripheral blood mononuclear cells (PBMC) were obtained from relapse-remitting MS patients (n=15) with expanded disability status scale (EDSS) score median of 2,5 before and after intravenous infusion of autologous bone marrow-derived mesenchymal stem cells. PBMC were harvested at baseline and during 1 year after cell therapy and monitored with flow cytometer FC500 using appropriate antibodies.
Results. γδT-cells, which are able to regulate myelin-specific T-cell response, increased in peripheral blood of MS patients on day 10 after cell therapy ($p<0,01$) and continued elevation during 1 year of treatment ($p<0,05$) without any significant changes in $CD8^+$γδT-cells population with potential cytotoxic activity. The percent of $CD8_{low}$T-cells reduced after 1 month of cell infusion ($p<0,01$) and the decrease of $CD8_{low}CD45RO^+$T-cells and $CD8_{low}CD119^+$T-cells populations was observed during 9 months after treatment ($p<0,01$). The last one correlated with activated $CD3^+CD25^+$T-cells' percent ($R=0,59$, $p<0,05$). The number of NK-cells correlated with EDSS before treatment ($R=0,54$, $p<0,01$) and decreased after 1 month of cell therapy ($p<0,05$) without significant differences in TNK-cells percentage.
Conclusion. Cell therapy established immunoregulatory profile of minor cell populations in peripheral blood of MS patients following 1 year after treatment.

P6.08.20
Immunoregulatory activity of Decidual/Endometrial Stromal Cells in humans

C. Reyes-Perdomo[1], *K. Torres*[2], *M. López*[2], *P. Silva*[3], *E. García-Olivares*[4], *O. Blanco Muñoz*[2];
[1]*Fundación Cardiovascular de Colombia - Pontificia Universidad Javeriana, Floridablanca, Colombia,* [2]*Fundación Cardiovascular de Colombia, Floridablanca, Colombia,* [3]*Universidad de Santander (UDES). Facultad de Salud, programa de Medicina., Bucaramanga, Colombia,* [4]*Instituto de Biopatología y Medicina Regenerativa (IBIMER). Universidad de Granada., Granada, Spain.*

Decidua is the maternal tissue that is in close contact with the fetal trophoblast cells. During normal pregnancy tolerance mechanisms develop at the level of the decidua. In the case of abortion or pre-eclampsia caused by antiphospholipid antibodies or autoimmune diseases, an immunologic activation develops against trophoblast. Human decidual cells (DCS) from the uterus and parent cells, the endometrial cells (ESC), are closely related to the mesenchymal stem cells (MSC), and like the latter, can survive during xenotransplants, and probably during semiallogeneic transplants as well. DCS/ESC show advantages over bone marrow MSC in terms of collection. Additionally, they have surface antigen markers in common like HLA-G, due to their immunomodulatory activity. In our present work it has been proved that the expression of HLA-G from the DSC/ESC might be the responsible for the immunomodulatory effects of the DSC as well as for the effects o their equivalents, the ESC.
Methodology. DSC were collected from termed placenta and ESC were isolated from menstruation. Samples were purified and cultured. To study T cells proliferation and diferentation, T cells were isolated from peripheral blood from healthy donors and co-cultured with DSC/ESC. Immunomodulatory effects of the DSC/ESC were determined through monoclonal antibodies by flow cytometry, RT-PCR and Western Blotting.

Results. HLA-G expressed by the DSC/ESC was proved to contribute to T cells modulation.
Conclusion. HLA-G expressed by the DSC/ESC might be responsible for the immunomodulatory effects of DSC/ESC, proving its importance as immunosuppressive, useful for clinical therapies or gynecological-obstetrician immunological problems.

P6.08.21
Adipose Derived Stem Cells Isolated from Omentum: a Novel Source of Chemokines for Ovarian Cancer Growth

S. Rezaeifard[1], *M. Razmkhah*[2], *M. Robati*[3], *M. Momtahan*[3], *A. Ghaderi*[4];
[1]*Shiraz Institute for Cancer Research, Department of Immunology, Shiraz, Iran,* [2]*Shiraz Institute for Cancer Research, Shiraz, Iran,* [3]*Department of Gynecology, Shiraz University of Medical Sciences, shiraz, Iran,* [4]*Shiraz Institute for cancer research, Department of Immunology, shiraz, Iran.*

The main site of ovarian cancer metastasis is the omentum. Omental adipose tissue is known for contribution to the tumor growth and metastasis through different mechanisms.
Objective: In the present study, adipose derived stem cells (ASCs) were isolated from the omentum of patients with ovarian cancer and those with ovarian cysts and the expression of SDF-1/CXCR4, IP-10/CXCR3, RANTES/CCR5, IL-4 and IL-10 were analyzed.
Methods: ASCs were isolated from 10 ovarian cancer and 25 ovarian benign cyst patients. Our investigations were done by quantitative Real Time PCR (qRT-PCR), flowcytometry, Western blot and also ELISA.
Result: Expression of IP-10 and CCR5 showed statistically significant difference between omentum derived ASCs of ovarian cancer patients compared to those with benign cysts ($p<0.05$). Expression of IL-10 also detected in the supernatant of cultured malignant ASCs.
Conclusion: Omental adipose tissue may play crucial roles for tumor promotion through the expression of tumor promoting chemokines. Accordingly, tumor-surrounding adipose tissue may be a novel target for immunotherapy of cancer.

P6.08.22
Isolation and Characterization of Mesanchaymal Stem Cells from Mouse Decidua

B. Sadighimoghadam[1,2], *S. Moazzeni*[1];
[1]*Tarbiat Modares, Tehran, Iran,* [2]*Semnan University of Medical Sciences, Dept. of Immunology, Iran.*

Background: Mesanchymal stem cells (MSCs) have been isolated from different sources. These cells expand in vitro rapidly and under defined condition differentiate to other cells and tissues. Due to their immunomodulatory and tissue repairing potential MSCs are under intensive studies as therapeutic cells.
In this investigation we tried to purify cells with MSCs-like potency from pregnant mouse deciduas for the first time.
Methods: After scarifying femal Balb/c mouse in 13.5 days of pregnancy, the uterus was opened from antimesometrial side, all embryos and placenta were separated and the deciduas were chopped and digested with collagenase D and collagenase type I. The cell suspension was passed through the cell mesh and after washing the pellet was re-suspended and cultured in DMEM medium. After 4 days of culturing, the adherent cells were isolated and examined for morphological properties, surface markers, and differentiation markers.
Results: The isolated cells expressed several stem cell markers and showed the potency to differentiate to bone and cartilage tissues. In addition the isolated cells proliferate significantly faster and easier than BM-MSC and adipose derived MSC.
Conclusions: We conclude that deciduas are a useful source of MSCs and our protocol provides an efficient isolation method for MSCs separation from mouse decidua.

P6.08.23
The role of p15Paf oncogene in hematopoiesis

M. Savic, *L. K. Denzin;*
Child Health Institute of New Jersey, New Brunswick, NJ, United States.

The mechanisms that regulate hematopoietic stem cell (HSC) self-renewal and differentiation into multipotent progenitor populations remain unclear despite being an active and clinically relevant area of research. We have recently showed that the highly conserved proliferating cell nuclear antigen (PCNA) associated factor (Paf), an oncogene over-expressed in most malignancies, is one of the molecular switches that controls hematopoiesis. Mice carrying a targeted deletion of the Paf gene are leukopenic due to a disruption of the regulated proliferation of HSCs that resulted in their functional impairment. Both ubiqitylation and interaction with PCNA are important for Paf to promote cell survival upon the introduction of replication blocks. Data support that Paf association with PCNA regulates DNA polymerase switching during translesion synthesis (TLS). Whether Paf function in HSCs, potentially by regulating DNA replication and repair, is entirely PCNA dependent is still unknown. Therefore, to analyze the molecular mechanisms by which Paf mediates HSCs self-renewal and differentiation, transgenic mice were created that expressed a mutant PAF that does not interact with PCNA. The ability of the PAF PCNA binding mutant to reconstitute hematopoiesis when expressed in Paf-/- mice was determined using a series of phenotypic and functional assays to measure HSCs function and development. In the light of recent findings that Paf likely mediates TLS DNA polymerase switching, the results of our studies will be relevant not only for understanding the function of Paf in hematopoiesis, but will also provide information relevant to Paf function in cancer development.

P6.08.24
Cytotoxic CD8+ T cells regulate myelopoiesis by cytokine signals to bone marrow stromal cells

C. Schürch[1,2], *C. Riether*[1], *A. F. Ochsenbein*[3];
[1]*Department of Clinical Research, University of Bern, Bern, Switzerland,* [2]*Institute of Pathology, University of Bern, Bern, Switzerland,* [3]*Department of Medical Oncology, University Hospital and University of Bern, Bern, Switzerland.*

Cytotoxic CD8+ T cells (CTLs) play a major role in host defense against intracellular pathogens. However, complete clearance of pathogens and return to homeostasis requires a regulated interplay of innate and acquired immunity. In contrast to T cells that have high proliferative potential, innate immune cells have to be continuously replenished from bone marrow (BM) hematopoietic stem- (HSCs) and progenitor cells. Inflammation-induced hematopoiesis, also known as emergency hematopoiesis, is critical for the control of systemic bacterial infections and may also be important in viral infections. Here, we show that interferon-gamma (IFNg) secreted by effector CTLs regulates hematopoiesis and induces myeloid differentiation resulting in an accumulation of myeloid cells. IFNg did not primarily affect hematopoietic stem or progenitor cells directly, but stimulated BM mesenchymal stromal cells (BMSCs) of the HSC niche to produce hematopoietic cytokines including interleukin-6. This reduced the expression of the transcription factors Runx-1 and Cebpa in hematopoietic progenitor cells resulting in increased myeloid differentiation. Our study indicates that during an acute viral infection, CTLs exert an indirect positive feedback on myelopoiesis via BMSCs.

P6.08.25
Large zinc finger transcrition factor Schnurri-3 functions in the osteochondroprogenitor cell to regulate bone mass

A. Singh[1], *C. Lester*[2], *L. H. Glimcher*[3], *D. Jones*[4];
[1]*NCATS-NIH, Rockville, MD, United States,* [2]*Brigham and Women's Hospital, Boston, MA, United States,* [3]*Weill Cornell Medical College, New York, NY, United States,* [4]*Merck Pharmaceuticals, Boston, MA, United States.*

The large zinc finger transcription factor Schnurri-3 (Shn3) was originally identified as a DNA binding protein of the heptameric recombination signal sequence for V(D)J recombination of immunoglobulin genes. Previous studies from our group have

revealed an unexpected role for Shn3 in the skeletal system and have identified Shn3 as a central regulator of postnatal bone mass. Mice lacking Shn3 display severe osteosclerosis primarily due to enhanced osteoblast activity. In this study we have characterized a specific cell population in which Shn3 functions to regulate bone mass. Based on analysis of mice lacking Shn3 in osterix or collagen II expressing cells, we hypothesized that Shn3 must be functioning in the common progenitor cell for osteoblasts and chondrocytes-the osteochondroprogenitor cell. However, characterization of this cell population has been limited due to lack of definitive cell surface markers to phenotype these cells. We established a flow cytometry based high throughput screen to identify a panel of unique cell surface molecules that can be used to identify and isolate osteochondroprogenitor cells. These osteochondroprogenitor cells not only formed bone and cartilage in vitro but also in vivo when transplanted under the kidney capsule of recipient donors. Lastly, we were able to demonstrate that Shn3 functions intrinsically in the osteochondroprogenitor cells to control bone mass.

P6.08.26
The advent of mucosal-associated invariant T (MAIT) cells from iPSCs opens a novel avenue for immunology

H. Wakao[1], *K. Yoshikiyo*[2], *U. Koshimizu*[2], *K. Enomoto*[2], *T. Tanaka*[2], *Y. Yasutomi*[2], *H. Fujita*[1];
[1]*HOKKAIDO UNIVERSITY School of Medicine, Kita-ku Sapporo-shi, Japan,* [2]*Asubio Pharma, Kobe, Japan.*

Mucosal-associated invariant T (MAIT) cells belong to the innate type immune cells, play an important physiological role in host pathogen defense and may also be involved in inflammatory disorders and multiple sclerosis. The rarity and inefficient expansion of these cells have hampered detailed analysis and application. Here we report an iPSC-based reprogramming approach for the expansion of functional MAIT cells. We found that human MAIT cells can be reprogrammed into iPSCs using a Sendai virus harboring standard reprogramming factors without cell cycle stimulation. Under T-cell permissive conditions, these iPSCs efficiently redifferentiate into MAIT-like lymphocytes expressing the T cell receptor (TCR) Vα7.2, CD161, and interleukin-18Rα. Upon incubation with bacteria-fed monocytes, the derived MAIT cells show enhanced production of a broad range of cytokines including interferon gamma and tumor necrosis factor alpha. Following adoptive transfer into immunocompromised mice, these cells migrate to the bone marrow, liver, spleen, and intestine and protect against Mycobacteria abscessus, most likely via granulysin release. Our findings pave the way for further functional analysis of MAIT cells and determination of therapeutic potential. The work has been published in Cell Stem Cell (May 2013).

Commensal bacteria-derived membrane vesicles supress Th-1 dominated immune responses in vaccinated and tumor-bearing mice

E. Alpdundar[1], *S. Yildiz*[1], *B. Bayyurt*[2], *M. Ozcan*[1], *G. Gucluler*[2], *D. Bayik*[2], *B. Gungor*[1], *I. Gursel*[2], *M. Gursel*[1];
[1]*Middle East Technical University, Ankara, Turkey,* [2]*Bilkent University, Ankara, Turkey.*

Constitutive secretion of extracellular membrane vesicles is a common feature of cells from all domains of life including Archaea, Bacteria, and Eukarya. Although the contribution of gram negative bacterial outer membrane vesicles in disease pathogenesis has been extensively studied, whether commensal bacteria constitutively secrete such vesicles is still unknown. Given the importance of microbiota as regulators of immune homeostasis, we aimed to assess the immunomodulatory properties of extracellular vesicles secreted by 3 different human commensal lactobacilli isolates in comparison to E.coli derived outer membrane vesicles. AFM microscopy, dynamic light scattering and zeta potential measurements revealed that commensal-derived membrane vesicles (MVs) were nearly 250 nm in diameter and had high negative charge densities (-40 mV). Mice immunized with an inactivated viral vaccine against the foot an mouth disease virus showed suppressed FMD-specific IgG2a response when the vaccine contained MVs derived from commensals but not from E.coli. Similarly, commensal MVs suppressed anti-OVA antibody responses in OVA immunized mice and exacerbated tumor progression following challenge with EG.7 tumor cells, suggesting that commensal-derived MVs ameliorate Th-1 dominated inflammatory responses. In contrast, encapsulation of cyclic-di-GMP in commensal-derived MVs enhanced the immunostimulatory properties of this cyclic di-nucleotide and reversed the tolerogenic potential of the MVs. These results indicate that human commensal bacteria-derived membrane vesicles can have powerful immunomodulatory effects and can have potential therapeutic applications as novel anti-inflammatory agents.

P6.09.02
Immunomodulatory cytokine gene expression profiles and lymphoprolifration response in hamsters vaccinated by leptospiral vaccine with several adjuvants

R. Banihashemi[1,2], *M. Tebianian*[2], *J. Majidi*[3], *B. Baradaran*[3], *A. Jabbari*[2], *K. Tadayyon*[2], *S. Jalali*[4], *M. Sekhavati*[2], *R. Ghaderi*[2], *G. Shokri*[2];
[1]*Tarbiat Modares University, Tehran, Iran,* [2]*Razi Vaccine and Serum research Institute, Karaj, Iran,* [3]*Tabriz Medical University, Tabriz, Iran,* [4]*Tehran Medical University, Tehran, Iran.*

Introduction: Leptospirosis is an acute infectious disease caused by *Leptospira spp*. that produces a broad range of health problems mainly in the developing world. The present work aimed to quantify the mRNAs from cytokines ex vivo and its relationship with the lymphoproliferative response of vaccine-sensitized splenocytes as major elements in the protection against leptospirosis.
Materials and Methods: 64 four-week-old male hamsters separated in eight equal groups were subcutaneously inoculated with four-leptospiral vaccine and four-control adjuvant through a triple-injection regiment at fortnightly intervals. Animals in group one only received the plain vaccine preparation with no adjuvant while other groups were immunized with the same vaccine preparation but different adjuvants. Two weeks after the last injections, all animals were euthanized and subjected to splenectomy. After preparation of splenocytes, cytokine profiles and lymphoproliferative response has been evaluated against the recall antigen.
Results: Vaccination of hamsters led to significant lymphoproliferative response in all of the animals although differences were noticed in reaction levels between groups. The induction of Th1 ($IL12p_{40}$, IFNγ and TNFα), Th2 (IL4, IL10) and Treg (TGFβ) type cytokine were evaluated from tested animals lymphocyte stimulated by ex vivo antigen utilizing real time PCR
Conclusion: We have demonstrated that adjuvant plays a fundamental role in the type and extent of the immune responses raised by leptospiral vaccination. In our hands, alum triggered both type 1 and type 2 immune reactions. Giving the fact that both Th1 and Th2 responses were stimulated, we strongly recommend selection of alum in any formulation of leptospiral vaccine.

P6.09.03
Intradermal and subcutaneous adjuvant effects of type I enterotoxigenic *Escherichia coli* (ETEC) heat-labile toxin derivatives

C. J. M. Braga, *J. F. Rodrigues, S. B. Boscardin, L. C. S. Ferreira; University of São Paulo, São Paulo, Brazil.*

Type I heat-labile toxins (LT), produced by enterotoxigenic *Escherichia coli* (ETEC) strains have remarkable immunological properties but clinical trials raised concerns on the use of these toxins as vaccine adjuvants regarding both safety (when administered thorough the intra-nasal route) and effectiveness (after transcutaneous immunization). Nonetheless, the recent discovery of natural LT variants with altered biological features and the use alternative parenteral routes may unveil more rational approaches for the use of LT-based vaccine formulations. In the present study we determined the intradermal and subcutaneous adjuvant effects of three LT derivatives including the reference type I LT (LT1), a non-

toxic derivative (LTK63), and a natural polymorphic LT variant (LT2), frequently encoded by wild type LT^+ ETEC strains, using as a model antigen a recombinant HIV-1 p24 protein. In particular, we evaluated the differential activation of antigen-specific cytotoxic $CD8^+$ T lymphocytes (CTL), required for the control of intracellular pathogens such as HIV. Similar antigen-specific humoral (serum IgG) and T helper adjuvant effects were observed in BALB/c mice immunized with the tested LT derivatives. However, LTK63 showed reduced in vivo activation and induction of migratory behavior of dendritic cells when compared to the natural LT forms. In addition, mice immunized with LT1 or LT2 showed significantly higher in vivo activation of $CD8^+$ T cell-dependent cytotoxic responses when compared to mice immunized with the non-toxic LT derivative. Collectively, these results support the use of natural LT derivatives as parenterally delivered vaccine adjuvants particularly for the induction of strong CTL responses by protein-based vaccine formulations.

P6.09.04
Investigating Layered Double Hydroxides (LDHs) as Designer Inorganic Vaccine Adjuvants

H. C. Buckley[1], *S. Preston*[2], *G. Williams*[3], *O. Rysnik*[4], *D. Lunn*[5], *B. Lambrecht*[6], *D. O'Hare*[1], *J. Austyn*[4];
[1]*Department of Chemistry, University of Oxford, Oxford, United Kingdom,* [2]*Department of Zoology, University of Oxford, Oxford, United Kingdom,* [3]*Department of Pharmacology, University College London, London, United Kingdom,* [4]*Nuffield Department of Surgical Sciences, University of Oxford, Oxford, United Kingdom,* [5]*Department of Statistics, University of Oxford, Oxford, United Kingdom,* [6]*Faculty of Medicine and Health Sciences, Department of Internal Medicine, University of Ghent, Ghent, Belgium.*

Despite its extensive use for decades, the vaccine adjuvant 'alum' consists of a heterogeneous mixture of poorly characterised compounds and has a limited ability to promote cellular (Th1-type) immune responses. The application of solid-state inorganic chemistry could lead to many potential new metal-based particulate adjuvants; layered double hydroxides (LDHs) are chemically homogeneous, crystalline materials that can be synthesised in a variety of chemical compositions and particle sizes. Previously, we found that LDHs of different chemical compositions can stimulate human dendritic cell (DC) responses *in vitro* and mouse antigen-specific antibody responses *in vivo*, and that some responses were significantly different from those induced by alum. Statistical analysis revealed direct correlations between the chemical and physical properties of the LDH and the immune response elicited, allowing accurate prediction of the immune response based on the material's properties. We have now synthesised LDHs of different chemical compositions with controlled particle sizes in the range 10 nm to 10 μm and tested their capacity to stimulate DCs. For a given chemical composition, we find that the particle size markedly alters the ability of the LDH to stimulate DC maturation, assessed using a variety of markers including co-stimulatory molecule expression and cytokine secretion. Our findings demonstrate that immunity can be driven purely by chemistry, and open the possibility of rational manipulation of immunity for therapeutic purposes.

P6.09.05
A novel allergen-adjuvant conjugate suitable for allergen-specific Th2 redirection

E. Cardilicchia, ***L. Filì****, A. Casini, L. Maggi, C. Manuelli, E. Occhiato, F. Boscaro, S. Romagnani, E. Maggi, P. Parronchi;*
University of Florence, Florence, Italy.

Background: As the new TLR7-ligand 8-hydroxy substituted adenine SA-2 was found by our group to revert allergen-specific T_H2 responses both in vitro and in vivo, we studied a new compound (SA-26E) which was chemically conjugated to the purified natural allergen Derp2 (nDer p2-Conj) as a potential new adjuvant for possible application in allergen-specific immunotherapy (SIT).
Method: nDer p2-Conj was characterized by MALDI-TOF analysis and evaluated for induction of NF-κB in CD14+ cells, TLR-triggering in transfected HEK293 cell lines, cytokine production in BDCA4+ and CD14+ cells, Th-skewing effects in allergen-specific human T cell lines and T cell clones and allergenicity in BASOTEST assays.
Results: nDer p2-Conj induced innate cells to produce IFN-α and IL-12 via TLR7 triggering. As a consequence, the conjugate reverted T_H2-prone allergen T cell lines into IFN-γ-producing cells (T_H1/T_H0 phenotype) as assessed by cytokine production in the supernatants, intracellular cytokine expression and T_H-related transcription factor expression. nDer p2-Conj was also able to revert the phenotype of T_H2 established cells. The T_H1 differentiation induced by allergen conjugate could be reverted by the addition of neutralizing antibodies against T_H1 citokines. In addition, Derp2 specific T cell clones derived from the T cell lines cultured in the presence of Derp2 conjugate showed a T_H1/T_H0 profile. Finally, the nDer p2-Conj reduced basophils activation in comparison with uncoupled allergen protein.
Conclusion: A system of chemical conjugation to relevant proteins as allergens has been set up with maintenance of modulatory effects of these complexes, thus allowing the development of new vaccine strategies.

P6.09.06
Helix pomatia Hc (HpH) hemocyanin as protein-carrier and bio-adjuvant of bacterial and viral proteins

S. Chausheva[1], *V. Gesheva*[1], *N. Mihaylova*[1], *K. Idakieva*[2], *L. Doumanova*[1], *A. Tchorbanov*[1];
[1]*Institute of Microbiology, Bulgarian Academy of Sciences, Sofia, Bulgaria,* [2]*Institute of Organic Chemistry, Bulgarian Academy of Sciences, Sofia, Bulgaria.*

Objectives. Killed viral vaccines and bacterial toxoids are weakly immunogenic. The hemocyanins are widely used as immune modulators. In the present study we promote the hemocyanin, isolated from the terrestrial gastropod Helix pomatia (HpH) as protein-carrier as well as bio-adjuvant. The purified HpH was combined with standard antigens and a construct of HpH with influenza virus hemagglutinin intersubunit peptide (IP) or HpH - tetanus toxoid were used for immunization.
Methods. HpH was isolated and purified from hemolymph by ultracentrifugation and chromatography.
Immunization: Balb/c mice were immunized i.p. with HpH-IP, or HpH combined with tetanus toxoid (TT). As controls commercial anti-flu and tetanus vaccines were used. The mice were bled and collected sera were kept frozen. ELISA: determination of anti-TT and anti-IP antibodies. Cytokine detection: IL4 and IFN-γ levels were measured by ELISA. Cytotoxic assay: We examined the CTL activity of isolated spleen cells to influenza virus-infected cells.
Results. An immunization of mice with Influenza peptide conjugated to Helix pomatia hemocyanin induced a strong anti-influenza cytotoxic response. The IgG antibody response to the TT combined with HpH was comparable to the response of the toxoid in CFA. Immunization of experimental animals with HpH combined with IP or TT led to generation of enhanced levels of key cytokines for development of Th1 or Th2 - related immune response.
Conclusions. The vaccination of mice demonstrates that the HpH is acceptable as a potential bio-adjuvant for subunit vaccines and it could be used as natural adjuvant or protein-carrier.

P6.09.07
Novel vaccine adjuvant for induction of cellular and humoral immunity

S. Crabe*, J. Nitcheu, V. Serra;*
Wittycell, Evry, France.

Wittycell S.A.S. is a privately owned company pioneering a new approach in the development of vaccine adjuvants based on the stimulation of innate immune responses through iNKT cells and the amplification of adaptive immune responses through iNKT-dendritic cell interactions.
The most unique feature of WTCc is its ability to induce strong antigen-specific cytotoxic T-cell responses in classical preclinical models also used for benchmark adjuvant study, e.g. CpG. Immunization with WTCc/antigen induces the activation of iNKT as well as the generation of specific cytotoxic T cells. We demonstrate that engendered immune response can be protective in case of

infectious disease but also in tumor model. A statistic time to relaps is observed during tumor therapeutic vaccination with an endogenous antigen after one injection. This delay is associated with activated NK and tumor specific T cells detected not only in spleen but also into the tumor. His distinct characteristic, combined with a good toxicity profile and clear industrial manufacturing feasibility makes WTCc an attractive candidate for many applications, including mass vaccination.
After successful demonstration of the NTK activity and adjuvant effect of WTCc in mice and monkey using different indications and further confirmation of the NTK activity induced by WTCc in humans, Wittycell nominated WTCc as the first clinical candidate. Wittycell had finished a full GMP and GLP preclinical package and started end of 2011 an HBV clinical Phase I/IIa in normal volunteers to evaluate clinical and laboratory safety, tolerability profiles and determine efficacy based on Ab and T cell induction.

P6.09.08
Designing small molecules as optimal vaccine adjuvants

*T. Y. H. Wu[1], M. Singh[2], **U. D'Oro**[3], A. T. Miller[1], S. Valentini[3], E. De Gregorio[3], M. L. Mbow[2], D. T. O'Hagan[2], M. P. Cooke[1], N. M. Valiante[2];*
[1]Genomics Institute of Novartis Foundation, San Diego, CA, United States, [2]Novartis Vaccines, Cambridge, MA, United States, [3]Novartis Vaccines, Siena, Italy.

Adjuvants increase vaccine potency largely by activating innate immunity and promoting inflammation. These processes may result in side effects, which constitute a major hurdle for adjuvant use in humans. Traditional adjuvants are complex poorly characterized molecules or mixtures that provide little opportunity for rational improvements in terms of potency and safety. They are also difficult to manufacture, purify and formulate. Here we describe new principles for engineering small molecule immune potentiators (SMIPs) as adjuvants with increased therapeutic indices.
First, we used medicinal chemistry to identify and optimize a novel class of TLR7 SMIPs, benzonaphthryridines (BZN). We then postulated that limiting the biodistribution of the SMIP adjuvant could increase vaccine efficacy and minimize side effects associated with systemic and generalized inflammation. To test this hypothesis, BZN analogs were designed to be less soluble than traditional LMW drugs to facilitate retention at the injection site. These lipophilic compounds were more potent in vivo than soluble compounds as adjuvants although they were less potent TLR7 agonists and exhibited minimal systemic exposure and no systemic immune activation. However, low solubility renders industrial develop of these first generation SMIPs difficult. This drawback was overcome by designing soluble SMIPs with linkered phosphonates that could be adsorbed to aluminum hydroxide (AlOH) via ligand exchange. Through novel medicinal and formulation chemistry and extensive immuno-pharmacology we show that remarkable potency can be achieved with little to no systemic exposure, localized innate immune activation and short in vivo residence times of SMIP-based adjuvants.

Long-term antigen-specific antibody responses against RSV glycoprotein by an osmotic active nanocarrier via enhanced phagocytosis

***J. Firdous**[1], M. A. Islam[1], S. Park[1], B. Shim[2], M. Song[2], J. Chang[3], D. Boraschi[4], S. Han[5], C. Cho[1], C. Yun[1];*
[1]Department of Agricultural Biotechnology and Research Institute for Agriculture and Life Sciences, Seoul National University, Seoul, Republic of Korea, [2]Laboratory Science Division, International Vaccine Institute, Seoul, Republic of Korea, [3]Division of Life and Pharmaceutical Sciences, Center for Cell Signaling and Drug Discovery Research, Ewha Womans University, Seoul, Republic of Korea, [4]Dipartimento di Scienze Farmaceutiche, University of Modena, via Campi 183, 41100, Modena, Italy, [5]Department of Oral Microbiology & Immunology and Dental Research Institute, School of Dentistry, Seoul National University, Seoul, Republic of Korea.

Recently, subunit vaccines are becoming favorable choice for effective immunization. However, systemic degradation often hampers their immunogenicity. To achieve the best efficacy without drawback, adequate delivery of subunit vaccine is a critical issue. Recently, we developed a polysorbitol-based osmotically active transporter showing high efficacy as a nanocarrier for gene delivery. Here, we report this polysorbitol-mediated transporter (PSMT) for effective delivery of respiratory syncytial virus glycoprotein (R-Gp) as a subunit vaccine candidate. The physicochemical properties of PSMT and PSMT/R-Gp nanoparticles were found suitable; the structural integrity and biological effectiveness (in vitro indexes of immune stimulation) of R-Gp was well protected when complexed by PSMT. Osmotic PSMT was found entirely non-toxic both in vitro and in vivo. A routine intranasal administration of PSMT/R-Gp nanoparticles elicited strong antigen-specific antibody (IgG1, IgG2c, IgA and IgM) responses which was significantly higher compared to that of naked R-Gp and well comparable to cholera toxin (CT)/R-Gp used as controls. The enhanced antibody response was likely due to the osmotic property of PSMT and effective transportation of R-Gp. A long-term antibody persistency was found up to six months after primary immunization. The mechanism study elucidated that macrophage exhibited finger-like projections as a sign of activation upon PSMT/R-Gp treatment and showed internalization through phagocytosis by the osmotic transporter followed by intracellular release from phagosome via proton sponge effect. Furthermore, the precise mechanism of PSMT/R-Gp nanoparticles during the phagocytosis was confirmed by inhibition assay. This study suggests that PSMT could be a safe and potent adjuvant system for subunit vaccines.

Autologous hsp70 enhances the expression of adhesion, fusion receptors, HLA and costimulatory molecules on murine peritoneal macrophages in a T cell lymphoma

***P. K. Gautam**, P. Deepak, S. Kumar, A. Acharya;*
Banaras Hindu University, Varanasi, India.

Tumor microenvironment has been known to suppress the function of macrophages and induce the polarization into tumor-associated macrophages that ultimately support tumor growth and progression. However, various biological response modifiers such as LPS, Interferon, various types of colony-stimulating factors are able to activate macrophage and potentiate the immune system against various immunopathologies. Heat shock protein 70 is one of the natural substances that have been reported to activate macrophages and therefore by virtue, it has been suggested as an effective immunotherapeutic approach against a variety of tumors. However, effect of hsp70 on the expression of adhesion molecules, fusion receptors, costimulatory molecules and HLA molecule have not yet been done. Therefore, in this study, an attempt has been made understand the exogenous application of hsp70 on the expression CD54, Mac-1, CD172a, CD47, CD80, CD86 and HLA-H2d(b) on the macrophages of tumor-bearing host. Macrophages were harvested from normal healthy and Dalton's lymphoma-bearing mice, adherent purified, characterized and single cell monolayer was prepared. Peritoneal macrophages were treated with 10µg/ml of autologous hsp70 purified from DL cells and further experiments were performed. It has been observed that tumor progression suppresses the expression of receptor molecules that are CD54, MCP-1, CD172a (SIRP-α), CD47, CD80, CD86 and HLA-H2d(b) while treatment of autologous hsp70 resulted in significant increase. Therefore, it can be concluded that exogenous application of tumor-derived autologous hsp70 enhances the expression of those molecules that are important for adhesion, fusion, antigen presentation and costimulation on normal as well as tumor-associated macrophages.

[2]INSERM U955, University of Paris East Creteil, Creteil, France,
[3]CNRS, UMR 8147, Paris, France, [4]CNRS, UMR 8113, Cachan, France.

Administration of mast cell (MC) activators with vaccine antigens induces protective antigen-specific immune responses. The mediators secreted by activated-MCs may act by modulating the balance between effector (LTeffec) and regulatory (LTreg) T lymphocytes. Yet, we demonstrated that the tolerant- or immunogenic-priming of T cells by dendritic cells (DCs) partly depends on GILZ (Glucocorticoid-induced leucine zipper) protein. DCs expressing high GILZ levels acquire a tolerant phenotype and induce LTreg, while they must downregulate GILZ expression to induce LTeffec. We thus hypothesized that MC mediators decrease GILZ expression in resting DCs and thereby direct their phenotype away from tolerance and towards immunogenicity.
We first demonstrated that circulating resting pDCs and mDCs freshly isolated from healthy donors express high GILZ levels. GILZ expression in DCs is under the control of endogenous steroids, IL-10 and TGFβ, and therefore dramatically drops after blood DCs isolation. Thus, GILZ is never detected in IL-4-Monocyte-derived DC (IL4Mo-DCs), but its expression is restored to similar levels as in freshly isolated DCs by treatment with exogenous steroids. Using such GILZ-expressing "resting-IL4Mo-DCs", we showed that activated-MC culture supernatants and histamine significantly reduced GILZ expression in resting-IL-4Mo-DCs through an ERK signaling pathway. This decline of GILZ results in a loss of ability to activate antigen-specific LTreg.
Collectively, these data reveal that MC mediators act as adjuvants by decreasing GILZ expression in DCs and thus their regulatory potential. These novel insights on MC activity highlight new potential pathways in adjuvant therapy. Moreover, they highlight GILZ as a new target to modulate DC functions.

P6.09.12
Adjuvant potential of QS-21 on protective efficacy of DPT vaccine

***C. Goyal**[1,2], S. Mishra[3], M. Gautam[4], S. Gairola[4], B. Patwardhan[5];*
[1]Panacea Biotec Limited, India, Lalru, India, [2]Department of Pharmaceutical Biotechnology, Bharati Vidyapeeth University, Pune, India, [3]Symbiosis International University, Pune, India, [4]Serum Institute of India Ltd.,, Pune, India, [5]Interdisciplinary School of Health Sciences, University of Pune, Pune, India.

Background: Combined use of vaccines and adjuvants is emerging as one of the innovative approaches in adjuvant development. Various immunomodulators such as QS-21, MDP and MF-59 are currently under consideration for possible inclusion in alum-containing vaccines.
Methods: Guinea pig model was used for the study. Host challenge procedure was used wherein diluted doses of DPT vaccine (1:80 & 1:160) and diphtheria toxin ($10LD_{50}$) were used as antigen and challenge respectively. Antitoxin levels, IFN-γ/IL-4 level ratios, sera cortisol and survival rate were used as markers of immune efficacy. Vero cell assay and ELISA techniques were used to determine antitoxin and cytokine levels respectively.
Results: Co-administration of QS-21 (250 µg/Kg) with DPT vaccine resulted in significant increase ($p<0.05$) of after-challenge diphtheria antitoxin levels (0.219 ± 0.060 IU/ml) as compared to same and double dose of control (0.076±0.045 & 0.160±0.064 IU/ml respectively). Moreover, IFN-γ/IL-4 ratios were significantly ($p<0.05$) raised (0.80 vs 0.51), suggesting a mixed Th1/Th2 response of QS-21 as compared to more limited responses of alum alone. Serological findings were supported by decreased morbidity and mortality (100% survival in QS-21 treated group vs 57% & 80% in control groups.
Conclusion: Study establishes adjuvant potential of QS-21 with DPT vaccine as indicated by significantly enhanced protective efficacy (Kaplan-Meier survival analysis), significantly higher antitoxin and cytokine levels (Mann-Whitney test) even at higher dilution (1:160) of vaccine, suggesting antigen sparing effect. Such approaches will be helpful in further reduction of antigenic requirements for obtaining protective immunity, thus increasing production capacity and decreasing cost.

P6.09.13
An adjuvant, fungal immunomodulatory protein (FIP)-*fve*, potentiates the immune response by engaging the co-stimulatory molecules, CD27 and CD134 (OX-40)

***O. Haris**, K. I-Chun, H. Chiung-Hui;*
National University of Singapore, Singapore, Singapore.

Fungal immunomodulatory protein (FIP)-*fve* has been shown to be an immunomodulator in tumor immunology and allergy. However, the molecular mechanism by which FIP-*fve* modulates the immune response to exert its adjuvant effect is yet to be elucidated. Our *in vitro* results demonstrated that FIP-*fve* required the interaction between mouse T cells and bone marrow-derived dendritic cells (BM-DCs) to induce the optimal T cell proliferation and secretion of several pro-inflammatory cytokines and chemokines, such as IFN-γ, MIG, MIP-1α, MIP-1β, and IP-10. In addition, we found that FIP-*fve* could directly activate T cells in a dose- and time- dependent manner, shown by the up-regulation of CD69, CD25, CD134 (OX-40), CD137 (4-1BB) on both gated $CD4^+$T and $CD8^+$T cells as well as CD27, CD28 on gated $CD8^+$T cells mostly. Interestingly, blocking of the interaction between CD134 (OX-40), CD27 and their corresponding ligands significantly reduced the FIP-*fve*-induced T cell proliferation and cytokine/chemokine secretion. Furthermore, when FIP-*fve* was injected into the mouse footpad, we observed that the absolute cell number of $CD4^+$T cells, $CD8^+$T cells, and B cells were increased tremendously in the draining lymph node. However, our *in vivo* bromodeoxyuridine (BrdU)-incorporation assay suggested that the proliferating cells upon FIP-*fve* injection were mostly $CD8^+$T cells and $CD4^+$ T cells. To confirm the T cell activation in draining lymph node, FIP-*fve* was also shown to up-regulate the expression of CD69 and the co-stimulatory molecules, CD27 and CD28, on the gated T cells. Thus, FIP-*fve* may function as an adjuvant via activation and modulation of immune system.

P6.09.14
SCE 350ET: A plant derived adjuvant inducing Th1 and Th2 type immune response

***B. Jayashankar**[1], K. P. Mishra[1], D. Singh[1], S. Murthy[1], R. K. Tulswani[1], K. Udayasankar[2], K. Mishra[1], L. Ganju[1], S. B. Singh[1];*
[1]Defence Institute of Physiology and Allied Sciences, Delhi, India,
[2]Central Food Technological Research Institute, Mysore, India.

Adjuvants are the vaccine additives that efficiently induce antigen specific immune response. In the present study, we have evaluated the adjuvanticity of the supercritical CO2 extract of Seabuckthorn leaves (SCE350ET) in Balb/C mice. The efficacy of SCE350ET as adjuvant was determined using diphtheria toxoid (DT) antigen. The dynamic changes in the immune response were measured in terms of humoral and cell-mediated immune response (CMI). The results indicated that the levels of DT specific immunoglobulins IgG and its isotypes IgG1, IgG2a and IgG2b were significantly enhanced by SCE350ET. In addition, mitogenic stimulation of splenocytes isolated from SCE350ET and DT immunized group of mice showed significant lymphocyte proliferation and production of Th1 and Th2 cytokines interferon (IFN)-γ and interleukin-4 (IL-4) respectively. Furthermore, increased expression of CD25, MHCII and effector memory markers (CD44hi CD62Llow) by SCE350ET, confirmed its potential to generate strong CMI. The increased antibody response may be due to the increased expression of Oct-2, which skewed B cells to antibody producing plasma cells. In conclusion, this study suggests that SCE350ET has potent immunostimulatory activity and hence, seems to be a promising balanced Th1 and Th2 directing immunological adjuvant.

P6.09.15
Oligomannose-coated liposome as a novel antigen-delivery vehicle and an adjuvant for induction of cellular immune responses

***N. Kokima**, M. Ishii, Y. Kawauchi;*
Tokai University, Hiratsuka, Japan.

Antigen-delivery systems are important for inducing and modifying immune responses. A key to development of vaccines is the ability to deliver antigens to antigen-presenting cells (APCs) and to activate APCs more efficiently for induction of adoptive immunity. Thus, strategies that target APCs and modulate APC functions in vivo have significant implications for vaccine design.
We have demonstrated that oligomannose-coated liposomes (OMLs), which consist of phosphatidylcholine, cholesterol, a mannotriose-containing neoglycolipid, can induce strong cellular immunity. In this study, we summarize OMLs as novel antigen-delivery vehicles that have a strong adjuvant effect on induction of Th1 immune responses and CTLs specific for the encased antigen. This property of OMLs is due to their ability to assist selective cellular uptake by APCs in vivo and to promote subsequent APC maturation, effective presentation of the encased antigens on both MHC class I and class II molecules, preferential secretion of IL-12 from APCs, and migration of APCs into lymphoid tissues from peripheral tissues, where both naïve CD4+ and CD8+ T cells are activated.
Administration of OML-based vaccines can eliminate an established tumor, inhibit elevation of the serum level of IgE against an allergen, and prevent progression of some protozoan infections in mouse models. OMLs with an encased antigen are also able to induce antigen-specific CTLs in PBMCs obtained from patients. These feasibility studies have revealed potential of OML-based vaccines for clinical use in vaccination for diseases in which CTLs and/or Th1 cells act as effector cells.

P6.09.16
Fucoidan effect on mononuclear leukocyte immunophenotype and lymphoid organ morphology in mice

***O. V. Lebedinskaya**[1], E. A. Lebedinskaya[1], N. K. Akhmatova[2], I. D. Makarenkova[2];*
[1]Acad. E.A. Wagner Perm State Medical Academy, Perm, Russian Federation, [2]I.I. Mechnikov Institute for Vaccines and Sera, RAMS, Moscow, Russian Federation.

The aim of investigation was to study the fucoidan effect on immunophenotype characteristics of spleen mononuclear leukocytes (ML) and on structure and cell composition of mice lymphoid organs. Fucoidan was administrated to CBA mice in a dose of 200 mg/kg of body weight. Subset structure of lymphocytes isolated from spleen was examined with flow cytometry. ML immunophenotype assay was carried out under the administration of two types of preparation - fucoidan japonica and cidcorideus to splenocyte cultures in a dose of 10 μg/ml. Paraffin sections of lymphoid organs were stained by histological and histochemical methods. Intraperitoneal fucoidan injection evoked 1,5-2-fold increment in natural killers-T cells, by 2-6-fold - the amount of T- and B-lymphocytes, and by 1,5-fold - the number of cytotoxic lymphocytes. Morphological analysis revealed the expansion of thymus lobe cortex, enlargement of periarterial muffs area, lymphoid nodes frequently merging in conglomerates in spleen. Following the introduction each of two fucoidan preparations to ML mice spleen cultures there were observed similar changes in splenocyte: statistically significant increase in amount of NK, NKT-cells, activated T-helpers, B-lymphocytes, and decrease in $CD3^+$ and $CD8^+$ cells. Pronounced TLR expression by cell surface was noted. It was demonstrated that fucoidan modulated the effector activity of innate and adaptive immunity and resulted in lymphoid cell proliferation in primary and secondary lymphoid organs. Its ability to promote Toll-like receptor expression by ML surface seems to be promising for its use in immunotherapy. This work was supported by RFBR grant №11-04-96037r_ural_a and administrative body of Perm Region.

P6.09.17
Chitosan effect on the inactivated influenza vaccine immunogenicity

*N. K. Akhmatova[1], S. S. Markushin[1], E. A. Akhmatov[1], L. A. Geiderova[1], E. V. Sorokina[1], N. P. Utkina[2], E. A. Ilinykh[2], **O. V. Lebedinskaya**[2];*
[1]I.I. Metchnikov Research Institute for Vaccines and Serum, RAMS, Moscow, Russian Federation, [2]Acad. E.A. Wagner Perm State Medical Academy, Perm, Russian Federation.

Inactivated influenza vaccines are one of the most effective means of preventing influenza. This type of vaccine reduces the protective properties in the elderly and poorly protected against drift variants of influenza virus.
Given the lack of immunogenicity of inactivated influenza vaccine, we investigated the effect of chitosan on the activation of immune effector mechanisms under the combined administration with inactivated influenza vaccine.
As adjuvant for influenza vaccines the chitosan glutamate solution (MW 200 kD) was taken, deacylated by 85%, to a final concentration of 0.5%. Mice were vaccinated intramuscularly with 0.2 ml of a formulation containing the vaccine and 0.5% chitosan glutamate.Mice were vaccinated intramuscularly injecting 0.2 ml of a formulation containing 3 mg for each component of the vaccine, and 0.5% of the preparation of chitosan (final concentration) or buffer.
It is shown that parenterally administered chitosan derivatives in combination with inactivated influenza split vaccine strengthened the activation of innate and adaptive immunity in mice, which was manifested in the expression of Toll-like receptors on the spleen(-s) (TLR2, TLR9), induction of cytokine synthesis in blood (IL -12, INF-γ, IL-17, IL-1β and IL-5), increasing the number of T (CD3, CD4, CD8, γδT), B lymphocytes (CD19, CD5), NK (CD16/32), NKT (CD3 / NK), T-reg (CD4/CD25/Foxp3) cells.
The expediency of chitosan glutamate application to enhance the immunogenicity and protective efficacy of inactivated influenza vaccines that activate the mucosal and systemic immunity by parenteral immunization is demonstrated.
This work was supported by RFBR grant №11-04-96037r_ural_a and administrative body of Perm Region.

P6.09.18
Functional and immunophenotype characteristics of peripheral blood mononuclear leukocytes from healthy donors under sodium nucleinate effect

***O. V. Lebedinskaya**[1], E. A. Lebedinskaya[1], N. K. Akhmatova[2];*
[1]Acad. E.A. Wagner Perm State Medical Academy, Perm, Russian Federation, [2]I.I. Mechnikov Institute for Vaccines and Sera, RAMS, Moscow, Russian Federation.

Aim: investigation of sodium nucleinate (SN) - sodium salt of low-molecular weight RNA produced from baker's yeast - against functional activity and immunophenotype of cells-effectors of immunity from healthy donor peripheral blood.
There were analyzed killer activity relatively to K-562 cell line, proliferative activity and immunophenotype of mononuclear leukocytes isolated from healthy donor blood and cultivated for 48 h with the addition of sodium nucleinate.
Investigation demonstrated that lymphocytes obtained from peripheral blood mononuclear leukocytes (PBML) as a result of extracorporal activation with sodium nucleinate were characterized by significantly greater functional activity as compared with the initial cells. Cytotoxic properties of activated cells increased from 49,5% (control) to 69,7-74,7% at SN concentration of 1-100 μg/ml. Proliferative activity increased from 16,1% (control) to 56,3-61,3% after 1-10 μg/ml of SN addition in cultures. Smears made from cultural cell suspension demonstrated large amount of pro-lymphocytes and immunoblasts, some cells in mitotic division that reflected the lymphoid cell blasttransformation as a result of their SN-induced activation. While studying the immunophenotype of SN-activated PBML from donors it was revealed that those expressed activation molecules CD38, CD25, molecules of II-type major histocompatibility complex (HLA-DR), adhesion molecules (CD57, CD58) on their membranes.
Thus sodium nucleinate renders promoting effect on natural killers of donors and results in formation of lymphocytes similar to lymphokine-activated killers by their immunophenotype. SN ability to activate PBML evidences for its promising use for immune disease prevention

and as nonspecific stimulator of immunity effectors in therapy of oncological patients.

Studies with novel synthetic immunogens as a tool for efficient antibody generation

*J. Malik, G. Dunau, G. Casi, C. Cattaneo, C. Fessele, M. Soukupova, S. Dziadek, **V. Lifke**;*
Roche Diagnostics GmbH, Penzberg, Germany.

With the aim to develop efficient and highly defined immunogens for a robust induction of anti-peptide antibody responses we investigated Three-Component Immunogens that only incorporate the minimally required components: a B cell epitope; a specific, highly effective promiscuous T_H cell epitope; and covalently attached synthetic immunostimulatory adjuvant such as muramyl dipeptide (MDP). In this study the Three-Component-Immunogen PTH-Polio-MDP was analyzed for its potential in the production of monoclonal antibodies compared to a conventional immunogen incorporating the carrier protein KLH as well as a Three-Component-Immunogen containing a cationic peptide. Balb/c mice were immunized with the different immunogens - with or without additional adjuvant (such as CFA/IFA) - and subsequently hybridoma cells were prepared and analyzed regarding the produced antibodies. Furthermore the potential of MDP to activate bone marrow-derived dendritic cells was examined. We found that the Three-Component-Immunogen with MDP (PTH-Polio-MDP) exhibits a clear immunostimulatory effect even without the use of an additional adjuvant. In contrast, the standard immunogen with a carrier protein required the use of adjuvant to induce a sufficient humoral immune response.

P6.09.20
EDA-streptavidin fusion protein conjugated to biotinylated HCV-NS3 protein for the induction of T cell immune responses against NS3

***T. Lozano**, L. Arribillaga, L. Villanueva, M. Gorraiz, M. Durantez, N. Casares, F. Borras-Cuesta, P. Sarobe, J. Prieto, J. Lasarte;*
FIMA, Pamplona, Spain.

Aims: Recombinant proteins are poor immunogens and do not induce strong T cell responses if they are not combined with appropriate adjuvants, or modified to improve their capture by dendritic cells (DCs). In previous works we have shown that fusion of an antigen to the extra domain A from fibronectin (EDA) targets the antigen to dendritic cells via TLR4 and improves its immunogenicity. In this work we have prepared a fusion protein between EDA and streptavidin (EDAvidin) to allow its interaction with biotinylated antigens. We have tested the immunogenicity of biotinylated NS3 combined with EDAvidin to induce strong anti-NS3 immune responses as a potential vaccination strategy against HCV infection. Methods: Recombinant EDAvidin, EDA-NS3 fusion protein and NS3 were produced and purified by affinity chromatography. NS3 was biotinylated using Sulfo-NHS-biotin reagent. The capacity of EDAvidin to bind to biotinilated proteins was tested by surface Plasmon resonance, western blot and ELISA. Immunogenicity of the recombinant proteins was tested in HHD transgenic mice (expressing human HLA-A2) by ELISPOT and in vivo killing assays. Results: Recombinant EDAvidin tetramerizes and binds very efficiently to biotynilated proteins. EDAvidin retains the proinflammatory properties of EDA, activating TLR4 signaling pathway. Immunization of mice with EDAvidin combined with biotinylated NS3 induce a strong anti-NS3 immune responses similar to that induced by the fusion protein EDA-NS3. Conclusions: EDAvidin can bind biotinylated proteins and improve their immunogenicity in vivo. EDAvidin combined with biotinylated NS3 can be considered as a vaccination strategy against hepatitis C virus infection.

P6.09.21
Development of a new microparticle vaccine adjuvant with the ability to deliver peptides to dendritic cells

***F. Mainini**[1], S. Young[1], D. Larsen[1], G. Webster[2], M. Eccles[1];*
[1]University of Otago, Dunedin, New Zealand, [2]Innate Therapeutics, Auckland, New Zealand.

MIS416 is a novel vaccine adjuvant generated from propionibacterium acnes cell wall skeletons comprising naturally occurring NOD-2 and TR9 ligands with the ability to induce effective adaptive Th1 immunity (1). In this research project we aim to enhance the therapeutic potential of MS416-adjuvanted vaccines by directly conjugating specific peptides derived from Tumors Associated antigens (TAA), achieving co-delivery of antigen and adjuvant. We hypothesized this will enhance the quality and quantity of ensuing adaptive immunity. Using the high-affintiy streptavidin-biotin complex as a conjugation strategy for peptide attachment, we were able to irreversibly couple different fluorescent molecules to the surface of MIS416 as proof of principle. The OVA-derived peptide SIINFEKL, was then coupled to MIS416 and this MIS416-peptide conjugate was pulsed onto BMDC (c57bl6 mice) showing that DC were activated by the conjugate. Flowcytometry, analysis showed that levels of MHCII,CD40,CD80 and CD86 were upregulated by our novel vaccine conjugate. Proliferations assays have been carried out to prove that DC pulsed with MIS416-SIINFEKL are able to activate OT1 T cell and upregulate activation markers such as CD69. Future work will test MIS416-TAA conjugates in therapeutic transplanted tumor models.

PolyICLC increases the immunogenicity and efficacy of the filovirus virus-like particle (VLP) vaccine

***K. O. Martins**, T. K. Warren, J. Wells, A. Bergeron, J. Steffens, S. van Tongeren, S. Bavari;*
USAMRIID, Frederick, MD, United States.

The filoviruses Marburg and Ebola have reported mortality rates of as high as 90% and occur naturally in Africa and the Philippines. We examined the efficacy of a promising dsRNA mimic, polyICLC (Hiltonol), in combination with the filovirus virus-like particle (VLP) vaccine. VLP vaccination of cynomolgous macaques resulted in 100% protection from Ebola Sudan challenge at low VLP dose levels, when vaccination was in combination with 100ug of polyICLC. To further understand the efficacy of the adjuvant, we used progressively decreasing doses of polyICLC with a non-protective dose of vaccine in mice. We show that at dose levels as low as 100ng, polyICLC increases survival after Ebola challenge from 10% to 100% and increases anti-glycoprotein IgG titers. To further elucidate the impact of the adjuvant on the immune response, we compared the anti-glycoprotein T cell response in mice vaccinated with a protective dose of VLP, with and without polyICLC. PolyICLC increased the antigen-specific T cell response, resulting in a detectable, polyfunctional, and predominantly CD4+T cell response. Finally, we explored the relationship between adjuvant efficacy and serum cytokine levels as a measure of potential toxicity. We collected serum 1 hour, 5 hours, and 24 hours after vaccination, and we examined serum levels of type I interferon as well as a panel of chemokines and cytokines. These data demonstrate that polyICLC is a highly efficacious adjuvant at dose levels far lower than those previously explored, and it increases the immunogenicity and efficacy of the VLP vaccine.

P6.09.23
Physicochemical and immunological parameters of the anti-allergic adjuvanted vaccine PROLINEM-DS

***A. Más Quintero**, W. Ramírez, A. Labrada, Y. Oliva, M. Mateo, V. Bourg, D. Torralba, J. Llama;*
National Center of bioproducts, Mayabeque, Cuba.

Introduction: Th1 promoting adjuvants, as the Proteoliposome from Neisseria meningitides (PL) seemed to be helpful for designing new anti-allergic vaccines. The novel anti-allergic vaccine candidate comprising allergens from Dermatophagoides siboney mite and PL

adsorbed onto alum, showed a protective anti-allergic response in Balb/c mice. The objective of this work was to test the physics-chemical and immunological parameters for stability to real time of the new vaccine. Methods: Following the ICH methodology, samples of three pilot scale GMP batches were stored at 4°C and assayed at 0,3,6,9,12,18 and 24 months. Possible desorption from alum gel was monitored, testing the supernatant for allergenic activity (IgE-inhibition ELISA), Der s1 content (MAb-ELISA) and total protein content. Preservation of antigen's integrity was checked by SDS-PAGE and Western-Blotting after forced desorption. Other tests were applied for measuring preservative content, pH stability, and sterility. Since, a potency test is not yet established for this new vaccine, allergen-specific immunogenicity in Balb/C mice was determined at the beginning and end of the study. Results: After 24 months no deviations of quality specifications were detected in any parameter. Although a slight tendency toward increasing the allergen activity and Der s 1 content in the supernatant was noted, it was not statistically significant (regression analysis, $p<0.05$). The immunogenicity test showed the expected outcome regarding induction of allergen-specific IgG, IgG1 and IgG2a antibodies (is PL adjuvant effect dependent), similarly to initial results. Conclusion: This study proved the vaccine stability during 24 months as a basis for approval of a reliable expiration period.

P6.09.24
Immunogenic and adjuvant properties of OmpS1 and OmpS2 porins

M. A. Moreno-Eutimio[1], *R. Pastelin-Palacios*[2], *C. Perez-Shibayama*[3], *C. Gil-Cruz*[3], *M. Fernández-Mora*[4], *A. Isibasi*[3], *E. Calva*[4], *C. Lopez-Macias*[3];
[1]*Hospital Juárez de México, Mexico City, Mexico,* [2]*Facultad de Química. Universidad Nacional Autónoma de México (UNAM), Mexico City, Mexico,* [3]*Medical Research Unit on Immunochemistry, Specialties Hospital. IMSS, Mexico City, Mexico,* [4]*Departamento de Microbiología Molecular, Instituto de Biotecnología, UNAM, Cuernavaca, Mexico., Mexico.*

Salmonella enterica serovar Typhi (*S*. Typhi) is the causal agent of typhoid fever, a disease that primarily affects developing countries. Various antigens from this bacterium have been reported to be targets of the immune response, with the highly abundant OmpC and OmpF porins being of particular importance. Recently, the S. Typhi genome has been shown to encode two porins - OmpS1 and OmpS2 - that are expressed at low levels under in vitro culture conditions; however, the immunogenic properties of these proteins and their contributions to the bacterial immune response have not been investigated. In this study, we demonstrate that immunising mice with either OmpS1 or OmpS2 induced production of specific, long-term antibody titres and conferred protection against *S*. Typhi challenge. We also found that OmpS1 is a Toll-like receptor (TLR) 4 agonist, whereas OmpS2 is a TLR2 and TLR4 agonist. Both porins induced the production of TNF and IL-6, and OmpS2 was also able to induce IL-10 production. Co-immunisation of OmpS1 or OmpS2 with ovalbumin (OVA) increased anti-OVA antibody titres, the duration and isotype diversity of the OVA-specific antibody response, and the proliferation of T-lymphocytes. These porins also had adjuvant effects on the antibody response when co-immunised with either the Vi capsular antigen from *S.* Typhi or inactivated 2009 pandemic influenza A(H1N1) virus (A(H1N1)pdm09). Taken together, the data indicate that OmpS1 and OmpS2, despite being expressed at low levels under in vitro culture conditions, are potent protective immunogens with intrinsic adjuvant properties.

P6.09.25
The role of alum-induced host DNA release in antigen-presenting cell activation and T cell priming

L. E. Noges[1,2], *A. S. McKee*[1,2], *J. Kappler*[1], *P. Marrack*[1];
[1]*National Jewish Health, Denver, CO, United States,* [2]*University of Colorado Anschutz Medical Campus, Aurora, CO, United States.*

Aluminum salts (alum) are widely used as adjuvants in human vaccines even though their mechanism of action remains unclear. It is known that host DNA rapidly coats injected alum and may be responsible for immune cell stimulation. Intramuscular immunization with alum plus influenza A nucleoprotein stimulates robust CD4+ T cell responses. We have confirmed that this response is attenuated if DNAse is co-injected with alum and nucleoprotein. Our experiments suggest that host DNA, induced by alum, increases the interaction time between antigen specific T cells and antigen presenting cells (APCs). Following alum immunization, at least three distinct populations of antigen-loaded cells appear in the draining lymph nodes: monocytes, migratory dendritic cells, and B cells. We therefore hypothesize that host DNA, released upon immunization with alum, contributes to alum's adjuvanticity by activating one or more of these sets of APCs. DNAse treatment does not prevent any of these cell populations from taking up antigen or migrating to draining lymph nodes, but it may alter the stimulatory qualities of these cells. Therefore, we are currently assessing how DNAse co-injection alters the activation profiles of antigen-loaded APCs and their ability to prime CD4+ T cells. We expect that one or more subsets of APCs depend on host DNA stimulus to effectively prime T cells upon alum immunization. These studies contribute to our understanding of the role of host DNA release in alum's adjuvant effect.

P6.09.26
Salmonella typhi porins are adjuvants on the specific immune responses to co-inmunized antigens

M. Pérez-Toledo[1,2], *R. Pastelin-Palacios*[3], *C. Gil-Cruz*[4], *C. Pérez-Shibayama*[5], *M. Moreno-Eutimio*[6], *A. Cunningham*[7], *M. Pérez-Tapia*[8], *L. Bonifaz*[2], *A. Isibasi*[2], *C. López-Macías*[2];

TLR agonists as CpG and flagellin have been used as adjuvants on a variety of antigens. We have previously shown that Salmonella typhi porins are highly immunogenic proteins which antibody responses are modulated by TLRs and that induce diverse and long lasting antibody responses against themselves. Here, we evaluated the adjuvant effect of S. typhi porins on antibody and cellular immune responses over a model antigen, as ovalbumin, and an inactivated pandemic influenza virus. We found that S. typhi porins exert adjuvant effect on the antibody responses elicited against ovalbumin, that were characterized by the diversification of isotypes and avidity maturation of antibodies. The adjuvant effect elicited by porins was also observed on T cell responses, as we found augmented proliferation of CD4 specific T cells and cytokine secretion, mainly IFN-γ and IL-2. Finally, we evaluated if S. typhi porins could also exert and adjuvant effect on immune responses against an immunogen, as an inactivated pandemic influenza virus. We found that porins augment the magnitude and persistence of antibody responses against influenza virus, and that this response was isotype diversified and displayed characteristics of avidity maturation. All together, these results suggest that Salmonella typhi porins could be used as adjuvants because of the immunostimulatory properties on the antibody and cellular immune responses that can elicit.

P6.09.27
Therapeutical effects of a novel nDer p2-conjugated TLR7 in a mouse model of lung inflammation

***S. Pratesi**, F. Nencini, G. Petroni, P. Parronchi, E. Maggi, A. Vultaggio;*
Centre for Research, Transfer and High Education DENOTHE and Departments of Internal Medicine, Univ, Florence, Italy.

There is a growing interest in the use of Toll-like receptor 7 ligands for the new therapeutical strategy of allergic diseases. Modified adenines (MA) which trigger TLR7 represent a new group of adjuvants. We investigated the ability of a synthetic MA, called SA26E, chemically conjugated to nDer p2 to trigger murine TLR7. We analyzed the therapeutical effect of SA26E conjugated in a murine model of lung inflammation.
C57Bl/6 mice were intraperitoneal immunized with nDer p2 at d0 and d7. At d14 mice were intratracheally challenged with nDer p2, while at d21 and d28 mice were intraperitoneal treated with an administration of nDer p2-conjugate or nDer p2 alone. At d49 and d53 mice were challenged with nDer p2 and sacrified at d56 for the analysis.
SA26E mantained the ability to trigger HEK293 cell line transfected with murine TLR7 after conjugation. Moreover MA-nDer p2 conjugate reduced eosinophils in bronchoalveolar lavage of mice treated but not of control mice. This effect was associated with a shift in the antibody profile from a type 2- (IgE and IgG1) to a type 1-associated (IgG2a). A reduction of IL-13 and an increase of IFN-γ was observed in the supernatants of mononuclear cells from lung in vitro stimulated. A concomitant significant increase of IL-10 levels was found in the supernatants of nDer p2-stimulated cells of spleen and draining lymph nodes.
Data suggest that the nDer p2-SA26E conjugate regulates and redirects the immune response in a therapeutical fashion and may constitute an approach for immunotherapy of allergic diseases.

P6.09.28
Inhibitory effects of silibinin on invasive properties of human breast cancer cell line, MDA-MB-231, through suppression of the proteolytic cascade of cathepsin B/ urokinase-type plasminogen activator

***S. Rahimifar**[1], M. Yousefi[2], M. Momeny[1], A. Emami[1];*
[1]Tehran University Medical of Sciences, Tehran, Iran, [2]Tabriz University Medical of Sciences, Tabriz, Iran.

Tumor cell dissemination to distant organs is thought to be the main reason for death in patients with advanced breast cancer. Although new treatments including multiple new cytotoxic drugs has been developed for metastatic breast cancer these therapeutics exert a minor impact on outcome of disease. So, establishment of more effective preventive and curative regimens with a low cytotoxicity profile against MBC seems crucial.
This study aimed to study the effects of silibinin, a natural non-toxic anti-cancer drug, on metastatic breast cancer cell line, MDA-MB-231. Herein, MTT metabolic activity assay, bromodeoxyuridine cell proliferation assay, cell-based ERK 1/2 activation assessment, cathepsin B activity assay and quantitative real-time PCR were performed to appraise the effects of silibinin on breast cells.
Silibinin inhibited metabolic activity, cell proliferation, ERK 1/2 activation, cathepsin B enzymatic levels in MDA-MB-231 cells. In addition, an expressive decrease in mRNA levels of cathepsin B, urokinase plasminogen activator receptor and hyaluronidase-2 were observed.
Altogether, silibinin inhibits proliferation of breast tumor cells. Moreover, our data revealed that silibinin could inhibit invasive features of a invasive breast cell line, through suppression of the proteolytic cascade of cathepsin B/urokinase-type plasminogen activator. Furthermore, silibinin might disrupt the activation of ERK 1/2 through suppression of uPAR. silibinin might control the transcriptional levels of uPAR through induction of programmed cell death 4 (PDCD4).

P6.09.29
Effective mucosal protection against sexually-transmitted viral infections is provided by MEC/CCL28

***V. Rainone**[1], G. Dubois[2], L. Gissmann[3], V. Temchura[4], K. Uberla[4], M. Nebuloni[1], D. Trabattoni[1], F. Veas[2], M. Clerici[1,5];*
[1]University of Milan, Milan, Italy, [2]University of Montpellier, Montpellier, France, [3]German Cancer Research Center, Heidelbergh, Germany, [4]Ruhr-University Bochum, Bochum, Germany, [5]Don C. Gnocchi Foundation, Milan, Italy.

Background: MEC/CCL28 binds to CCR3 and CCR10 and recruits IgA-secreting plasma cells (IgA-ASCs) in the mucosa. The suitability of CCL28 as an adjuvant for the elicitation of optimal innate and acquired immunity was assessed in mice using HIV-1, Influenza A and HPV-16 Virus-like Particle models.
Materials and methods: Balb/c mice were immunized intramuscularly with a prime-boost regime based on HIV1IIIB-, H7N1- or HPV16-VLPs in the presence/absence of CCL28 and of the control CCL19. Flow citometry evaluation of CCR3 and CCR10 was performed on splenocytes. Th1 and Th2 cytokine production was performed on splenocytes and mucosal biopsies, whereas IgG and IgA antibodies were evaluated in sera and mucosal secretions. Immune sera and mucosal secretions were tested for ex vivo neutralization of either HIV-1 subtype B and C strains, H7N1 strain or HPV-16. IgA-ASC recruitment at the mucosal level was verified with immune-histochemistry analyses.
Results: The following immune parameters were significantly augmented in VLP-CCL28 mice compared to all other groups in all three animal models: 1) the percentage and the surface density of CCR3 and CCR10 on CD19+ splenocytes; 2) antigen-specific IFN-γ, IL-4 and IL-5 production in splenocytes and mucosal specimens; 3) total and antigen-specific IgG and IgA titers in sera and mucosal secretions; 4) serum and mucosal secretion, mostly IgA-dependent, neutralizing activity; 5) IgA-ASCs in either rectum, lungs or uterine cervix.
Conclusions: CCL28 has a robust immunomodulatory effect on both systemic and mucosal immunity and could play a useful role in increasing the efficacy of preventive vaccines for mucosal viral infections.

P6.09.30
Adjuvants as possible solution to polysaccharide unconjugated vaccines

*B. Romeu, M. Lastre, M. Cuello, O. Cabrera, E. González, D. González, A. Mandariote, L. García, D. Cardoso, **O. Pérez**;*
Finlay Institute, Havana, Cuba.

Background. Plain polysaccharide (Ps) vaccines were the first meningococcal vaccines developed. Nevertheless, they neither function in new born / infant nor induce memory response and could induce antibody hyporesponsiveness. Therefore, covalent conjugated vaccines offer a particular type of adjuvation where the carrier gives the T cell help. However, adjuvants in the restricted sense never were considered as an alternative solution. Therefore, we developed a proprietary adjuvant Finlay platform derived from Neisseria meningitidis. Aims. To determine if adjuvants could be use as an alternative solution to covalent conjugated Ps vaccines. Results. The Ps used were: PsVi from Salmonella Typhi and PsA from N. meningitidis serogroup A respectively. The adjuvants used were: Outer membrane vesicles (Proteoliposome, AFPL™, Adjuvant Finlay PL) from N. meningitidis serogroups B, A, W135 and AFCo (Cochleate) 1 derived from PL. MenAfricVac™ as well as unconjugated plain Ps were use as controls. Anti Ps IgG class and IgG1, IgG2a, IgG2c and IgG3 subclasses were evaluated after two parenteral or three mucosal doses. The conventional memory response was evaluated after a booster dose. Non-conventional T and B memory response was also evaluated. AFPL™ overcomes the thymus-independence of Ps inducing a Th1 typical pattern. AFPL™ induces similar anti Ps responses than covalent conjugated vaccines. They induce memory response at B and T cell levels. Conclusion. Adjuvants could be an alternative to covalent conjugated vaccines. The mechanism of T cell memory induction needs to be fully explored.

P6.09.31
Influence of phosphate salts and alum content on to the immunogenicity and stability of a *Dermatophagoides siboney* adjuvanted vaccine

R. Samalea[1], *W. Ramírez*[1], *B. Tamargo*[2], *D. Torralba*[1], *A. Morejón*[1], *D. Martínez*[1], *A. Más*[1], *J. F. Infante*[3], *V. Bourg*[1], *A. Labrada*[1];
[1]*National Center of Bioproducts (BioCen), Mayabeque, Cuba,* [2]*Institute of Pharmacy and Food (IFAL), La Habana, Cuba,* [3]*Finlay Institute, La Habana, Cuba.*

Background: AFPL1 is a novel combination adjuvant containing alum-adsorbed Outer Membrane Proteoliposomes from Neisseria meningitidis. Phosphate ions interfere with adsorption of Dermatophagoides allergens to Al(OH)3. In addition, alum is associated to the development of granulomas in the injection site, so its content should be minimized.
Aim: To evaluate the immunogenicity and stability of formulation variants of a novel Dermatophagoidessiboney AFPL1-adjuvanted vaccine, using different content of phosphate salts and Al(OH)3.
Methods: A 23 experimental design was used for evaluating the effect of phosphate (0-8.5mmol/L) and alum content (0.5-2mg/mL) on to adsorption of Der s1. Stability during storage was assessed following standard ICH guidelines. Four formulation variants were selected for immunogenicity testing in Balb/C mice, using three weekly injections (2 µg Der s 1). Allergen-specific antibodies IgG, IgG1, IgG2a, and IgE were measured in serum by ELISA; IL-13, IL-5, IL-10 and INF-γ cytokines were measured in cell culture supernatants by ELISA.
Results: Best variants regarding Der s1 adsorption were in the range 0-4.26mmol/L of HPO4and0-2.5mmol/L of H2PO4, achieving values up to 99.9%. All variants were able to maintain Der s1 and protein adsorption levels during storage. Regarding immunogenicity, all tested variants induced a mixed response of IgG1 and IgG2a antibodies in a similar extent, as well as, a moderate increase of IFN-γ, and decrease of Th2 cytokines and lung tissue inflammation as compared to allergic control.
Conclusions: Reduction of alum and phosphate content could be considered as pharmaceutical improvements with no disadvantages regarding immunogenicity and safety of this experimental allergy vaccine.

P6.09.32
GM-CSF enhances the cellular immune response elicited by a DNA vaccine against HIV even in a low dose approach.

V. C. Santana[1], *R. R. Almeida*[1], *S. P. Ribeiro*[1,2], *D. S. Rosa*[3,1,2], *J. Kalil*[1,4,2], *E. Cunha-Neto*[1,2,4];
[1]*Laboratory of Clinical Immunology and Allergy-LIM60, Division of Clinical Immunology and Allergy, Department of Medicine, University of São Paulo, School of Medicine., São Paulo, Brazil,* [2]*Institute for Investigation in Immunology-INCT, São Paulo, Brazil,* [3]*Division of Immunology - Federal University of São Paulo-UNIFESP, São Paulo, Brazil,* [4]*Heart Institute (InCor), University of São Paulo School of Medicine, São Paulo, Brazil.*

The cytokine GM-CSF has been used in several clinical trials with vaccines and have shown great adjuvant efficacy when combined with vaccine formulations that aimed induction of cellular immune response. This property is mainly due to GM-CSF ability to attract and stimulate antigen-presenting cells to the immunization site. Here we demonstrate that GM-CSF co-administration can enhance the magnitude and quality of the immune response induced by a HIV-specific DNA vaccine. The DNA vaccine HIVBr18, which encodes 18 conserved, multiple HLA-DR-binding peptides from the HIV-1 subtype B consensus sequence, was mixed with a plasmid encoding murine GM-CSF. Balb/c mice were immunized with 100 µg of HIVBr18 plasmid alone, or in combination with 100 µg of the GM-CSF plasmid. After three doses we observed that the group of animals that received the combination of plasmids developed a cellular immune response with higher magnitude and better quality, as demonstrated by a higher number of cells producing simultaneously IFN-g, IL-2 and TNF-a. We also observed that reducing the amount of HIVBr18 to 25 µg, in association with GM-CSF, led to a cellular immune response with similar magnitude to that found with 100 µg of the HIVBr18 plasmid administered alone antigen administrated alone. Our data corroborate the adjuvant properties of GM-CSF on DNA vaccines observed in different models. DNA vaccines that are more immunogenic and generate higher quality immune responses could be instrumental in the development of a new formulation for a HIV vaccine.

P6.09.33
Proteus mirabilis flagellin, neither a good adjuvant nor a protective antigen against urinary tract infection

P. Scavone[1], *A. Umpiérrez*[1], *A. Rial*[2], *J. A. Chabalgoity*[2], *P. Zunino*[1];
[1]*Instituto de Investigaciones Biológicas Clemente Estable, Montevideo, Uruguay,* [2]*Instituto de Higiene, Facultad de Medicina, Montevideo, Uruguay.*

P. mirabilis, a gram negative bacterium associated with complicated urinary tract infections (UTI), expresses several virulence factors including MR/P fimbriae and flagella. Flagellin from certain bacteria has shown interesting adjuvant and protective properties but *P. mirabilis* flagellin has not been analyzed so far.
Here, we evaluated the role of *P. mirabilis* flagellin as protective antigen in a mouse UTI model, and its adjuvant capacity for the protective antigen MrpA (MR/P fimbriae structural subunit).
Four groups of mice were intranasally immunised at days 0, 3, 10, 17 and 24 with either MrpA, flagellin, both proteins and PBS only. Before and after immunisation urine and blood samples were collected to evaluate antibodies induction. Cytokine production was analysed on day 30 in splenocytes. At day 31 mice were challenged using an ascending *P. mirabilis* UTI model, being sacrificed 7 days after for bacteria quantification in kidneys and bladders.
MrpA-immunised mice showed a significant increase in serum and urine specific IgG and IgA while mice immunised with MrpA-flagellin or flagellin did not. Animals did not show significant anti-flagellin antibodies induction. MrpA-immunised showed a significant decrease in bacteria recovered from bladders and kidneys compared with any other group of mice. Instead, infection levels in flagellin, MrpA-flagellin and PBS-immunised mice showed no significant differences between them. Remarkably, IL-10 was significantly induced in the mice receiving flagellin or MrpA-flagellin.
These results showed that *P. mirabilis* flagellin is not a good adjuvant and did not protect mice against UTI, and suggested that it may have an immunomodulatory role.

P6.09.34
Circulating influenza-specific $CD4^+$ $ICOS1^+$ $IL\text{-}21^+$ expand after vaccination, exert helper function and predict antibody responses in humans

F. Spensieri, *E. Borgogni, L. Zedda, M. Bardelli, F. Buricchi, G. Volpini, S. Tavarini, O. Finco, G. Del Giudice, F. Castellino;*
Novartis Vaccines & Diagnostics, Siena, Italy.

Protection against influenza is mediated by neutralizing antibodies, and their induction at high and sustained titers is key for successful vaccination. We searched for early immunological parameters that associates in a predictive manner with the rise in neutralizing antibody after influenza vaccination. T follicular helper cells (Tfh) have been identified, in lymph-nodes and tonsils, as the T cell subset specialized in helping B lymphocytes with IL-21 and ICOS1 playing a central role in this function. We searched for antigen specific $IL\text{-}21^+$ $CD4^+$ T cells in peripheral blood. We show that influenza-specific $ICOS1^+$ $IL\text{-}21^+$ $CD4^+$ T cells can be measured in human blood upon *in vitro* stimulation, expand after MF59-adjuvanted influenza vaccination and their expansion associates and predicts the rise of functional antibodies. We also show that blood derived $CXCR5^-$ $ICOS1^+$ $CD4^+$ T cells are enriched in T cells able to help influenza-specific B cell differentiation into antibody-secreting cells
in vitro in an IL-21- and ICOS1-dependent manner. We suggest that the expansion of an antigen-specific $IL\text{-}21^+$ $CD4^+$ T cell sub-population in peripheral blood is an early predictor of the ability of a vaccine to prime the immune system and could become a useful parameter to test vaccine immunogenicity in humans.

P6.09.35
Immunological characterization of M13 phage vaccine

***K. Sugimura**, T. Osako, S. Kawabata, R. Miyahara, T. Tsurumaru, R. Oda, D. Tomari, R. Shioya, S. Hashiguchi;*
Graduate School of Science and Engineering, Kagoshima University, Kagoshima, Japan.

We have recently shown the immunological basis of M13 phage vaccine that is dependent on MyD88-signaling. Mice can be immunized by administrating phosphate-buffered solution containing M13 phage without any adjuvant materials. M13 phage evokes strong IgG response as early as 14 days after primary immunization and lasts its immunological memory for long term (BBRC 402: 19-22, 2010).
We have also demonstrated that M13 phage displaying less than a few copies of amyloid β 42 (Aβ42)-mimotope peptide at the N-terminus of g3p induces a significant level of Aβ42 fibril-specific IgG antibody in mice (J. Neuroimmunol. 236: 27-38, 2011). These results suggest promising features of M13 phage displaying a given epitope-inserted g8p in place of g3p for vaccine vehicle because a phage bears 2700 copies of g8p in contrast to 5 copies of g3p. We demonstrate the immunological features of motif-integrated g8p-phage in murine models of Alzheimer disease and cedar pollinosis, respectively.
Safety issues and the potential significance of bacteriophages for therapeutic agents have been demonstrated (EMBO reports 13: 20-21, 2012).
Thus, peptide-displaying filamentous bacteriophage induces strong immune responses to displayed peptides, suggesting a novel application of phage-display library as bacteriophage vaccine.

P6.09.36
New proteoliposomevaccineformulation from N. meningitidisserogroup B, without aluminum hydroxide, retains its antimeningococcalprotectogenic potential as well as Th-1 adjuvant capacity

***B. Tamargo**;*
Institute for Pharmacy and Foods.UH, Habana, Cuba.

Proteoliposomes purified from the Outer Membrane of *Neisseria meningitidis* B, have been successfully used as core for adjuvants and vaccine formulations .We have tried to increase their structural definition and to conserve their efficacy and stability avoiding the addition of the aluminum hydroxide to the final formulation.Liposomal particle systems were prepared from components of defined molecular structure, such as a *Neisseria meningitidis* B protein complex, extracted and purified without forming vesicle structures.Liposomes were prepared from a mixture of dioleoylphosphatidyl serine and cholesterol, using the classical dehydration-rehydration method.Transmission Electron Microscopy (TEM) was used to characterize the liposomes.BALB/c mice were used for animal testing procedures.Analysis of specific IgG response, serum bactericidal activityas well as DTH reaction was carried out. Isolation and purification of mRNA and real-time PCR, was performed to determine the dominating Thlymphokine pattern.The new antimeningococcal formulation without aluminum hydroxide prepared with components of defined molecular structure assembled itself into Neoproteoliposomes(NPL) ranging from 50 to 70 nm in diameter. (PD-Tp),as well as the NPL-formulation favors a Th1 response pattern, suggested by the higher percentages of DTH, increased expression of proinflamatory lymphokine mRNAs when administered by intramuscular and intranasal routes.It stimulates systemic bactericidalantibody response against *Neisseria meningitidis* B and immunologic memory similar to VA-MENGOC-BC® vaccine, even at lower dosages and is less reactogenic in comparison with the formulation with aluminum hydroxide.This new adjuvant formulation could be applicable to the development of new and improved vaccines against meningococcal disease, and eventually as modulators of the immune response against other diseases.

P6.09.37
Evaluation of the Adjuvant properties for Chitosan-Polyvinylpyrrolidone-based Nanoparticles.

*I. Y. Izaguirre-Hernández[1], A. Y. Tenorio-Barajas[2], V. M. Altuzar-Aguilar[2], C. O. Mendoza-Barrera[2], **H. Vivanco-Cid**[1];*
[1]Universidad Veracruzana, Instituto de Investigaciones Medico-Biológicas, Veracruz, Veracruz, Mexico, [2]Universidad Veracruzana, Centro de Investigaciones en Micro y Nanotecnología, Veracruz, Veracruz, Mexico.

Polymeric Nanoparticles (NPs) have recently been shown to possess significant potential as drug or antigen delivery systems. In addition to the carrier function, the adjuvant capacity is also an important and desirable property in the context of vaccination. Here, we evaluated the adjuvant properties for a new NPs formulation based on two-polymer combination: Chitosan and Polyvinylpyrrolidone (CS-PVP). The NPs were synthesized by ionic gelation and characterized by transmission electron microscopy (TEM), Dinamyc Light Scattering (DLS) and Fourier Transform Infrared Spectroscopy (FTIR). Moreover, biological properties of NPs were addressed in vitro by studying their effect on cell viability and Dendritic Cells (DCs) maturation. 500,000 bone marrow DCs were stimulated with CS-PVP NPs at different concentrations for 24 hours. At the end of the time, we analyzed the surface expression for costimulatory molecules by flow cytometry. Our results showed an enhanced surface expression of CD40, CD80, CD86 and MHC II on NPs stimulated-DCs at two different concentrations: 250 y 500 µg/mL, confirming the maturation phenotype. Using Human Monocyte-derived Dendritic Cells, we evaluated by ELISA the production of TNF-α and IL-6. 200000 Human DCs were stimulated for 24 hours with 300 µg/mL of CS-PVP NPs. Intermediate levels of both TNF-α (260 pg/ml) and IL-6 (75 pg/mL) were detected comparing against LPS. These results clearly indicate that CS-PVP NPs formulation active both murine and human DCs, opening the possibility for using such as a potential adjuvant in vaccination.

P6.09.38
A Non-lytic form of Listeriolysin O induces Human Dendritic Cells to produce IL-12 and IL-23

*K. Hernandez-Flores[1], P. Thomas-Dupont[1], F. Mijangos-Zamudio[1], Y. Paterson[2], **H. Vivanco-Cid**[1];*
[1]Universidad Veracruzana, Instituto De Investigaciones Medico-Biologicas, Veracruz, Veracruz, Mexico, [2]University of Pennsylvania, Department of Microbiology, Philadelphia, PA, United States.

Introduction. LLO, a pore-forming citolysin is a key virulence factor of Listeria monocytogenes (LM). LLO induces a wide range of biological effects during the infection by LM or by itself as recombinant antigen. Here we studied the effects of a non hemolytic form of LLO on the production of two key cytokines for coordinating innate and adaptive immune responses against intracellular pathogens such as IL-12 and IL-23. Objective. We aimed to test the innate immune response of Human Monocyte-derived Dendritic cells (hDCs) to a non-hemolytic form of LLO named as DetoxLLO (mutated at C484A, W491A, W492A positions). Materials and methods. Human Monocyte-derived DCs were stimulated with DetoxLLO (0.5 or 1µg/mL). DCs were stimulated with DetoxLLO in the presence or absence of 50 µg/mL of polymyxin B; 24 hours after stimulation, sups were tested to measure the concentration of TNF-α, IL-6, IL-12 and IL-23 by ELISA technique. Results: DetoxLLO induced the production of IL-6 (1,615.66 pg/mL), TNF α (2,739.15 pg/mL), IL-12 (2,471.53 pg/mL) and IL-23 (269.60 pg/mL). Cytotoxic effects were undetected after 24 hours stimulation with DetoxLLO. Conclusion: We have identified a very potent innate immune response when DetoxLLO is used as an exogenous antigen on human DCs. The production of IL-12 and IL-23 by human DCs after the recognition of LLO could be very important for the immune response during the human infection by Listeria. As a potential adjuvant for human vaccination purpose, DetoxLLO could be use to polarized the immune responses toward a Th1 or Th17 responses.

Vaccines are the most effective agents to control infections. In addition to the pathogen antigens, vaccines contain adjuvants that are used to enhance protective immune responses. However, the molecular mechanism of action of most adjuvants is ill known, and a better understanding of adjuvanticity is needed to develop novel adjuvants based on molecular targets that further improve vaccine efficacy. This is particularly important for tuberculosis, malaria, AIDS and other diseases for which protective vaccines do not exist. Release of endogenous danger signals has been linked to adjuvanticity, however the role of extracellular ATP during vaccination has never been explored. Here, we tested whether ATP release is involved in the immune boosting effect of four common adjuvants: aluminium hydroxide, calcium phosphate, incomplete Freund's adjuvant and MF59. We found that only MF59 induced a rapid and transient release of ATP at the injection site. Immunization of mice with an MF59-adjuvanted influenza vaccine and apyrase, an ATP-hydrolyzing enzyme, strongly inhibited the recruitment of immune cells within the muscle and reduced antigen-specific T cell responses and antibody titers. This demonstrates that a transient ATP release is required for innate and adaptive immune responses induced by MF59 and link for the first time extracellular ATP to an enhanced response to vaccination.

P6.09.40
Effect of monogalactosyldiacylglycerol from different marine macrophytes on conformation and immunogenicity of hemagglutinin of Influenza A virus H1/N1 A/California/07/2009

V. N. Vorontsov[1], *N. M. Sanina*[1], *E. Y. Kostetsky*[1], *A. V. Tsybulsky*[1], *L. A. Davydova*[1], *A. N. Mazeika*[1], *N. S. Vorobieva*[1], *V. L. Shnyrov*[2];
[1]*Far Eastern Federal University, Vladivostok, Russian Federation,* [2]*University of Salamanca, Salamanca, Spain.*

Tubular immunostimulating complexes (TI-complexes) consisting of cucumarioside A2-2, cholesterol and monogalactosyldiacylglycerol (MGDG) from marine macrophytes are a most promising antigen delivery system, providing much higher adjuvant effect than classic ISCOMs or Freund's complete adjuvant. Earlier, we have shown that conformation and immunogenicity of porin, incorporated in TI-complexes, depend on physicochemical properties of MGDG. In order to check the universality of this approach for optimization of TI-complex, we used recombinant monomeric hemagglutinin (HA) of Influenza A virus H1/N1 A/California/07/2009. MGDG samples with different physicochemical properties were isolated from Sargassum, Ulva and Zostera. In spite of different effect of MGDGs on conformation of HA the level of anti-HA antibodies, induced by respective TI-complexes, similarly increased by 2 times compared with HA alone. The absence of the expected effect is probably due to the absence of conformational antigenic determinants in the selected antigen.

Cyclic-di-GMP based immune stimulatory formulations as novel vaccine adjuvants and anti-cancer agents

S. Yildiz[1], *E. Alpdundar*[1], *B. Bayyurt*[2], *M. Ozcan*[1], *G. Gucluler*[2], *D. Bayik*[2], *B. Gungor*[1], *I. Gursel*[2], *M. Gursel*[1];
[1]*Middle East Technical University, Ankara, Turkey,* [2]*Bilkent University, Ankara, Turkey.*

3´,5´-Cyclic diguanylic acid (c-di-GMP) is a bacterial derived small cyclic dinucleotide that functions as the universal bacterial secondary messenger. To date, studies concerning its immunostimulatory effects revealed that cytosolic sensing of c-di-GMP by the innate immune receptor STING, induces a robust type-I interferon production in antigen presenting cells, leading to their maturation. However, the chemical structure and the anionic nature of c-di-GMP limit its efficient entry through cellular membranes, requiring its transfection to cytosol. Here, we present a simple molecular complexation strategy that improves the intracellular delivery and boosts the immunostimulatory activity of c-di-GMP. Moreover, we also show that bacteria derived membrane vesicles (MV) can be utilized as vesicular carriers of this cyclic dinucleotide. Vaccination of mice using model antigen OVA adjuvanted with c-di-GMP/nonaarginine peptide complexes or c-di-GMP encapsulated in bacterial MVs, induced significantly higher levels of antigen-specific total IgG when compared to OVA or OVA+free c-di-GMP immunized groups. In contrast to OVA immunized mice, OVA+c-di-GMP/nonaarginine and OVA+c-di-GMP/bacterial MV adjuvanted groups showed complete protection from EG.7 tumor challenge. Consistent with the ability of these formulations to induce anti-tumorimmunity, ex-vivo re-stimulation of spleen cells harvested from immunized mice with the SIINFEKL peptide resulted in 8 to 10 fold increase in IFN-γ production. These findings suggest that c-di-GMP/nonarginine complexes or c-di-GMP/bacterial MVs are effective vaccine adjuvants and can generate tumor-specific CD8 T cell responses.

Determinants of immune responses to mucosal delivery of a malaria parasite protein on Lactococcus lactis cell walls and co-administration of an inducer strain

S. Anavarathavinayagamoorthy[1], *R. Ramasamy*[2];
[1]*National Science Foundation, Colombo 07, Sri Lanka,* [2]*University Brunei Darussalam, Jalan Tungku Link, Gadong, Brunei Darussalam.*

Lactococcus lactis are potentially useful vectors for mucosal delivery of vaccines. We report on oronasal immunisation of different mouse strains with the *Plasmodium falciparum* merozoite surface antigen (PfMSA2), magnitude of immune response by co-administration of recombinant vector and nisin inducer *L. lactis* strain and related histopathological changes.
PfMSA2 was covalently attached to cell walls of live *Lactococcus lactis* (MSA2cP) and non-covalently attached to *L. lactis* cell wall ghosts (MSA2cA), and used for immunisation. Immune responses and effect of co-administration on immune responses in mice and histopathological changes in gut associated lymphoid tissue were investigated.
Serum IgG antibodies to MSA2 were elicited by both immunogens in strain-dependent manner. The IgG isotype antibodies of these mice reflected the influence of Th1 and Th2 cells. Serum and faecal IgA anti-MSA2 antibodies were also detected. Antigen specific IFN-γ producing T cells were detectable in spleens of all inbred mouse strains immunised with MSA2cA and in C57 mice immunised with MSA2cP. Co-inoculation of inducer *L. lactis* significantly improved antibody response to MSA2. Enlargement of mesenteric lymph nodes, increased lymphatic infiltration of the lamina propria as well as germinal centre formation in the spleen were noted in mice fed with *L. lactis*.
Results suggests that mucosal immunization of *Pf* MSA2 is able to generate protective levels of systemic antibodies and cellular immunity in mice dependent on strain and anchoring method and co-administration of an inducer strain elicited better immune responses. These findings are relevant for developing better vaccine delivery systems for human use.

P6.10.02
Mucosal delivery of ACNPV baculovirus driving expression of the Gal-lectin LC3 fragment confers protection against amoebic liver abscess in hamster

J. C. Carrero[1]*, D. M. Meneses-Ruiz*[1]*, J. H. Aguilar-Diaz*[1]*, J. Hernandez-Ruiz*[2]*, A. Luz-Madrigal*[3]*, L. Vaca*[3]*, J. P. Laclette*[1]*;*
[1]Instituto de Investigaciones Biomédicas, Ciudad de México, Mexico, [2]Hospital General de la Ciudad de México, Ciudad de México, Mexico, [3]Instituto de Fisiología Celular, Ciudad de México, Mexico.

Mucosal vaccination against amoebiasis using the Gal-lectin of E. histolytica has been proposed as one of the leading strategies for controlling this human disease. However, most mucosal adjuvants used are toxic and the identification of safe delivery systems is necessary. Here, we evaluate the potential of a recombinant Autographa californica baculovirus driving the ex-pression of the LC3 fragment of the Gal-lectin to confer protection against amoebic liver abscess (ALA) in hamsters following oral or nasal immunization. Hamsters immunized by oral route showed complete absence (57.9%) or partial development (21%) of ALA, resulting in some protection in 78.9% of animals when compared with the wild type baculovirus and sham control groups. In contrast, nasal immunization conferred only 21% of protection efficacy. Levels of ALA protection showed lineal correlation with the development of an anti-amoebic cellular immune response evaluated in spleens, but not with the induction of seric IgG an-ti-amoeba antibodies. These results suggest that baculovirus driving the expression of E. histolytica vaccine candidate antigens is useful for inducing protective cellular and humoral immune responses following oral immunization, and therefore it could be used as a system for mucosal delivery of an anti-amoebic vaccine.

P6.10.03
Mucosal influenza vaccine comprising of M2e-HSP70 formulated with N-Trimethyl chitosan(TMC) particles induces strong M2e specific immune responses

M. Dabaghian[1]*, S. Ebrahimi*[2]*, M. Tebianian*[2]*, G. Nikbakht Brujeni*[1]*;*
[1]University of Tehran, Tehran, Iran, [2]Razi Vaccine and Serum Research Institiute, karaj, Iran.

Nasal vaccines can induce systemic IgG and mucosal IgA antibody responses, which establish two layers of immune defense against infectious pathogens like influenza.
Mucosal vaccines have to overcome several limitations, including mucociliary clearance and the inefficient uptake of soluble antigens. Therefore, nasal vaccines require potent adjuvants and delivery systems to enhance their immunogenicity and to protect their antigens.
In this study, ectodomain of the conserved influenza matrix protein 2 (M2e) which has been found to induce heterosubtypic immunity was fused to C-terminus of Mycobacterium tuberculosis (MBT) HSP70 and a derivative of chitosan, N-trimethyl chitosan (TMC), was used as a carrier for this fusion protein.
Ionically crosslinked nanoparticles were formulated with M2e-HSP70 protein using the ionic gelation technique with pentasodium tripolyphospate (TPP) as a crosslinking agent. Particles had a size in the range of 200-250nm and positive surface charge. Intranasal immunization with M2e-HSP70/TMC in BALB/c mice induced significantly higher M2e specific antibody, IgG in serum, than those induced in control groups (M2e-HSP70, TMC and HSP70). The anti-M2e IgG subtype induced was mainly IgG2a. Cellular immune response was evaluated by cytokine production assay of splenocytes after in vitro stimulation.
M2e-HSP70/TMC-immunized mice were fully protected against lethal challenge (MLD90) of influenza A infection (PR/8) compared to control groups of mice with survival rates of 20% to 30%.
This data confirmed that M2e-HSP70 fusion protein formulated with TMC nanoparticles could be an effective construct to induce strong immunogenicity and obtain full protection as a promising candidate mucosal influenza vaccine.

P6.10.04
Beta-glucan particles as novel antigen delivery systems: towards oral vaccination

R. De Smet[1]*, S. Verschuere*[1]*, T. Demoor*[2]*, L. Allais*[1]*, M. Dierendonck*[3]*, B. G. De Geest*[3]*, C. Pilette*[4]*, C. Cuvelier*[1]*;*
[1]Department Pathology, University of Ghent, Ghent, Belgium, [2]Department Pathology, University of Michigan, Michigan, Ann Arbor, MI, United States, [3]Department of Pharmaceutics, University of Ghent, Ghent, Belgium, [4]Department of Pneumology, Cliniques Universitaires St. Luc,, Université Catholique de Louvain, Belgium.

Gastro-intestinal infections are still a main cause of enteric diseases and mortality among humans and animals. Oral vaccination is crucial in generating an adequate local mucosal immune response, however the hostile environment of the intestinal tract and oral tolerance remain huge obstacles that inhibit the ability to successfully develop new mucosal vaccines. A promising strategy for vaccination with safe, biodegradable non-replicating antigen delivery systems has gained increased interest for eliciting cellular and humoral immune responses. The current study evaluates the potential of β-glucan (BGP) and calcium carbonate (CaCO3)- and mannitol-templated polyelectrolyte particles as mucosal antigen delivery systems and their adjuvant characteristics. All microparticle types are efficiently internalized by Caco-2 and HT-29 cell lines and in particular the BGP triggered the expression of pro-inflammatory cytokines IL-23p19, IL-8 and beta-glucan receptors in activated Caco-2 cells and CCL20 in HT-29 cells. In contrast, the expression level of TGF-b, an important mediator of the active component of oral tolerance, was significantly downregulated in HT-29 cells. Oral administration of BGP induced intestinal adaptive immune responses characterized by an increased sIgA and secretory component production. Interestingly, adoptive transfer experiments pointed out the proliferation of naïve OVA-specific CD4+ OT-II cells and increased IL-17 production in spleens of BGP-fed mice upon antigen restimulation. These results demonstrate that BGP enhances MHC-II-presentation and promotes mucosal immune responses preferably steered towards a Th17 response and represents a promising strategy for oral vaccination.

P6.10.05
Hsp65-producing Lactococcus lactis prevents experimental colitis by IL-10- and TLR2-dependent pathways

A. M. C. Faria*;*
Universidade Federal de Minas Gerais, Belo Horizonte, Brazil.

Disruption of the delicate balance between tolerance and immunity in the gut mucosa can cause inflammatory bowel diseases (IBD) in genetically susceptible hosts. Heat shock proteins (Hsp) are conserved proteins that are highly expressed in inflammation. Thus, they are good therapeutic antigenic targets for oral tolerance in IBD. Herein, we investigated the effects of administration of Lactococcus lactis genetically engineered to secrete Hsp65 in murine colitis. Mice received Hsp65-L. lactis orally during four days. Ten days thereafter, colitis was induced by 1.5% dextran sodium sulfate (DSS). Hsp65-L.lactis administration completely prevented colitis with diminished levels of TNF-α, IL-6 and IL-4 and enhanced IL-10 levels in the colonic mucosa. In IL-10 deficient mice, Hsp65-L.lactis fail to prevent intestinal inflammation. The same was observed in TLR2-/- but not in TLR4-/- mice. Interestingly, frequency of lamina propria IL-10+ B cells enhanced in mice treated with Hsp65-L. lactis. In conclusion, Hsp65 delivered by Lactococcus lactis prevents intestinal inflammation via IL-10 and TLR2 pathways.

Prime-boost strategies in mucosal immunization affect local IgA production and the type of Th response

F. Fiorino*, E. Pettini, G. Pozzi, D. Medaglini, A. Ciabattini;*
Università di Siena, Siena, Italy.

Combination of different delivery routes for priming and boosting represents a vaccination strategy that can modulate magnitude,

quality, and localization of the immune response. A murine model was used to study T-cell clonal expansion following nasal and subcutaneous priming, and secondary immune responses after boosting by either homologous or heterologous route. Antigen-specific T-cell priming studies, performed by using the adoptive transfer model of OVA-specific transgenic T cells, showed that both nasal and subcutaneous immunizations efficiently elicited primary antigen-specific CD4+ T cells clonal expansion in the respective draining lymph nodes, that disseminated towards distal lymph nodes and spleen. After boosting, a very high serum IgG response was induced in all groups, while significant levels of local IgA were detected only in mice boosted by the nasal route. Mucosal priming drove a stronger Th1 polarization than the systemic route, as shown by serum IgG subclass analysis. IFN-γ production was observed in splenocytes of all groups, while prime-boost vaccine combinations including the mucosal route yielded higher levels of IL-17 production. Memory lymphocytes were identified in both spleen and draining lymph nodes in all immunized mice, with the highest number of IL-2 producing cells detected in mice primed and boosted by the nasal route. Studies of priming of pathogen-specific T cells are ongoing using multimeric MHC-peptide complex technology.
These data provide relevant insights for the design of optimal prime-boost strategy.

Nanogel-based PspA nasal vaccine induces S. pneumoniae - specific neutralizing antibody immune responses in nonhuman primates

Y. Fukuyama[1], *Y. Yuki*[1], *Y. Katakai*[2], *H. Takahashi*[3], *S. Sawada*[3], *H. Shibata*[2], *M. Mejima*[1], *S. Kurokawa*[1], *K. Akiyoshi*[3], *H. Kiyono*[1];
[1]*Institute of Medical Science, The University of Tokyo, Tokyo, Japan,* [2]*Tsukuba Primate Research Center, National Institute of Biomedical Inovation, Tsukuba, Japan,* [3]*Kyoto University Graduate School of Engineering, Kyoto, Japan.*

We previously developed an affective vaccine delivery system with self-assembled nanosize hydrogel (nanogel), which composed of a cationic type of cholesteryl group-bearing pullulan (cCHP). In our recent study, we demonstrated that intranasally immunized pneumococcal surface protein A (PspA) with cCHP vaccine (PspA-nanogel) induced strong antigen-specific systemic and mucosal antibody (Ab) immune responses with protective immunity in mice. In this study, we examined whether PspA-nanogel nasal vaccine could induce PspA-specific Ab responses in nonhuman primates. The cynomolgus macaques nasally immunized with 25 μg of PspA-nanogel five times at two weeks intervals showed significantly increased levels of PspA-specific serum and broncho alveolar lavage fluid (BALF) IgG, and nasal wash (NW) S-IgA Ab responses when compared with control macaques nasally immunized with 25 μg of PspA alone or PBS. Further, increased levels of IFN-γ, IL-4 and IL-17 production were found in PspA-nanogel immunized macaques but not control macaques. When the Balb/c mice were challenged with the mixture of 7.5 x 103 CFUs of S. pneumoniae strain A66.1 (Xen10) and the serum from macaques given nasal PspA-nanogel vaccine, they showed a full protection. However, the other mice, which were challenged with the mixture of the same level of S. pneumoniae and the serum from 25 μg of PspA alone or PBS as control macaques, were died within 2 days after challenge. These results show that nasal PspA-nanogel vaccine can effectively induce PspA-specific serum IgG with neutralizing activity and S-IgA Ab immune responses in nonhuman primates.

P6.10.08
Immunisation using a sustained release vaccine generates functional CD8 T cell memory

A. J. Highton[1], *S. Hook*[2], *R. Kemp*[1];
[1]*Department of Microbiology and Immunology, University of Otago, Dunedin, New Zealand,* [2]*School of Pharmacy, University of Otago, Dunedin, New Zealand.*

Generating an effective memory population of quantity, quality and in the correct biological location is key in having a good vaccination method. Although humoural immune responses conferred through current vaccination methods are effective, in many cases there is a need for vaccination that will confer a cytotoxic CD8 T cell response. We investigated the generation of murine memory CD8+ T cells using a sustained antigen release vaccine vehicle (chitosan gel) containing ovalbumin protein or conventional vaccination using dendritic cells loaded with protein. The aims of this work were to evaluate the efficacy of sustained release vaccines and to compare their ability to generate peripheral versus mucosal CD8 T cell memory.
Mice were euthanised at memory time points following subcutaneous vaccination and cell populations were assessed in peripheral and gut associated lymphoid tissues using flow cytometry and ex vivo cytotoxicity assays. In vivo cytotoxicity was also assessed. We could detect CD8 T cell memory populations in both peripheral and gut associated lymphoid organs specific for the ovalbumin protein vaccine and a cytotoxic response was seen in vivo up to 60 days following this. These results indicate that subcutaneous vaccination with a sustained release vaccine can generate a population of functional CD8 memory cells in gut associated lymphoid tissues. We have established an orthotopic mouse model of colorectal cancer and are testing the efficacy of this vaccine in protective tumour immunity. This form of vaccination could be used to induce immunity in sites that are not easily accessible such as the gut.

P6.10.09
In vitro Inhibition of Staphylococcus aureus Isolates by Anti-Anti-Idiotypic Antibodies to Staphylococcal Protein A (SpA)

A. A. Justiz Vaillant[1], *P. Akpaka*[1], *M. Smikle*[2], *N. McFarlane-Anderson*[3];
[1]*Departments of Paraclinical Sciences, Faculty of Medical Sciences. University of the West Indies, Saint Augustine, Trinidad and Tobago,* [2]*Department of Microbiology, Faculty of Medical Sciences. University of the West Indies. Mona Campus, Kingston, Jamaica,* [3]*Department of Basic Clinical Sciences. Faculty of Medical Sciences. University of the West Indies. Mona campus, Kingston, Jamaica.*

This study investigates the ability of antibodies to SpA (a protein produced by the bacterium *Staphylococcus aureus*) to inhibit the growth of the bacteria. Chickens immunised with SpA produced anti - SpA antibodies in their eggs (primarily the yolk). These anti-SpA antibodies were used to feed chicks, which produce antibodies that recognise the original antigen. When these antibodies were purified from their sera and included in the growth medium of the *Staphylococcus aureus*, there was inhibition of the bacterial growth. This indicates that these antibodies had specifically bound to the cell surface of the bacteria and prevented growth of the bacteria, i.e. the antibodies could protect against bacterial infection. The potential of such antibody in the hyper-immune egg to act as oral therapeutic agents is discussed.
The anti-SpA hyperimmune egg may be considered as an oral mucosal vaccine that estimulated the production of antibodies that recognised the original antigen on the surface of *Staphylococcus aureus.*

To establish a safer and more effective vaccine against pneumococcal respiratory infections, current knowledge regarding the antigens common among pneumococcal strains and improvements to

the system for delivering these antigens across the mucosal barrier must be integrated. We developed a pneumococcal vaccine that combines the advantages of pneumococcal surface protein A (PspA) with a nontoxic intranasal vaccine-delivery system based on a nanometer-sized hydrogel (nanogel) bearing a cationic cholesteryl-group-bearing pullulan (cCHP). The efficacy of the nanogel-based PspA nasal vaccine (cCHP-PspA) was tested in murine pneumococcal airway infection models. Intranasal vaccination with cCHP-PspA provided cross-protective immunity against lethal challenge with Streptococcus pneumoniae, reduced colonization and invasion by the bacteria in the upper and lower respiratory tracts, and induced systemic and nasal mucosal Th17 responses, high levels of PspA-specific serum immunoglobulin G (IgG), and nasal and bronchial IgA antibody responses. Importantly, there was no sign of PspA delivery by nanogel to either the olfactory bulbs or the central nervous system after intranasal administration. Moreover, in vivo blocking of CCL28 during cCHP-PspA immunization suppressed the induction of IgA-positive plasmablasts in the nasal passages and consequent nasal PspA-specific IgA production showing CCL28 was required for the recruitment of IgA+B220+CD138+ plasmablasts. These results demonstrate the effectiveness and safety of the nanogel-based PspA nasal vaccine system as a universal mucosal vaccine against pneumococcal respiratory infection and provide the mechanistic evidence for effective induction of nasal mucosal IgA immune responses by nasal vaccination using cCHP nanogel vaccination system.

P6.10.11
The protective activity of the bacterial antigens in mucosal route of immunization in mice

O. V. Lebedinskaya[1], *N. P. Utkina*[1], *N. K. Akhmatova*[2];
[1]*Acad. E.A. Wagner Perm State Medical Academy, Perm, Russian Federation,* [2]*I.I. Metchnikov Research Institute for Vaccines and Serum RAMS, Moscow, Russian Federation.*

The antigens of the opportunistic bacteria are active stimulators of the mucosal innate immune system effectors. The purpose: to investigate the ability of bacterial antigens (multicomponent vaccine Immunovac-VP-4) administered orally to stimulate adaptive immunity in mice against *K.pneumoniae, P.vulgaris, S.pneumoniae.* Mice were immunized orally twice with vaccine at a dose of 2000 mg, then mice were challenged with lethal doses of bacteria. When mice were immunized with vaccine Immunovac we observed a protective effect against *K.pneumoniae* with the index of efficiency (IE) of 2.3 to 5.7. If the mice were challenged of *P.vulgaris*, the IE was 2.7. It is interesting the data on the extent of mice protection, immunized against *S.pneumoniae* type 3, which antigens are not included in the vaccine. In this case, EI ranged from 12 to 16. Perhaps an important role in the protection of mice against Salmonella infection is the presence of common *K.pneumoniae* and pneumococcal antigens, included in the vaccine. *S.pneumoniae* is important etiologically significant factor in chronic inflammatory diseases of the respiratory system. The activation of the mucosal immunity effector cells and generalization of this process in the lymphoid organs, distant from the route of vaccine administration is a highlight, providing protection against pneumococcus. Therefore, mucosal vaccine constructs based on antigens of opportunistic microorganisms, provide the activation of innate as well as adaptive immunity. This work was supported by RFBR grant №11-04-96037r_ural_a and administrative body of Perm Region.

P6.10.13
T-cell priming characterisation through a systems biology approach

E. Pettini, ***G. Prota****, A. Ciabattini, A. Boianelli, F. Fiorino, G. Pozzi, A. Vicino, D. Medaglini;*
Università di Siena, Siena, Italy.

T-cell priming at mucosal sites is a key event in the development of vaccination strategies. T-cell priming after vaginal and nasal immunization was studied in vivo analyzing CFSE proliferation data through a multi-type branching process. Immunization studies were conducted using a model vaccine formulation constituted by ovalbumin (OVA) plus the mucosal adjuvant CpG ODN 1826. Primary activation and dissemination of Ag-specific T cells was analysed in vivo after adoptive transfer of OVA-specific transgenic T-cells. Antigen-loaded dendritic cells were detected only within the respective draining lymph nodes where a rapid recruitment of activated antigen-specific T cells was observed. The enhanced number of T-cell within draining lymph nodes suggested an antigen-specific T-cell recall from distal lymph nodes and spleen. T cells were activated by the antigen encounter and acquired homing molecules essential to disseminate towards distal lymphoid organs as confirmed by the modulation of the expression of CD45RB, CD69, CD44 and CD62L molecules. A multi-type Galton Watson branching process was used to model in vivo CFSE proliferation data, in order to calculate the probabilistic decisions of a cell to enter in division, rest in quiescence or migrate/dye. This mathematical model, previously used for in vitro analysis of T-cell proliferation, has been here successfully applied to study in vivo T-cell clonal expansion following mucosal immunization.

P6.10.14
Evaluation of the potential of dry thermostable Hepatitis-B mucosal vaccine as a global strategy for cold-chain and needle free vaccination

R. Sharma[1,2], *B. Malik*[2], *G. Rath*[2], *A. K. Goyal*[2];
[1]*Vaccine R & D, Panacea Biotec Ltd., Mohali, India,* [2]*ISF College of Pharmacy, Moga, India.*

Introduction: Thermostable mucosal vaccines will reduce needle borne infection, deprived mucosal immunity, dependency on cold chain facilities while facilitating easy distribution, cost reduction and stockpiling of vaccines, confirming immediate availability in routine and pandemic immunization.
Methods: In present study Hepatitis-B surface antigen loaded chitosan particulates were prepared by ionic gelation method and dried (spray drying and lyophilization) using bland of stabilizers. Formulations were characterized in-vitro on basis of morphology, structural integrity, crystallanity, in process stability and change in Tg. Optimized formulations were assayed for their in-vivo immunogenicity in female Balb/c mice to evaluate protective humoral and cellular immune responses.
Results & Discussion: Developed vaccines were found more stable revealed by in-vitro immunogenicity testing, SDS-PAGE and CD spectra. Aerodynamic diameter of 2.5 and 1.4 µ for lyophilized and sprays dried formulation respectively, was suitable for pulmonary immunization. Developed formulations were later assayed for their in-vivo immunogenicity in female Balb/c mice and found to elicit protective humoral and cellular immune responses revealed by serum IgG, IgG2a, IgG1. IgM and mucosal IgA levels in different body fluids.
Conclusion: An ideal vaccine candidate should elicit both cellular and humoral responses. It should provide protective mucosal immunity to clear infection at site of entry. Developed vaccines were found to elicit protective immune responses and were also stable for sufficient time at normal storage temperature thus confirming an immediate availability and simple distribution of vaccines in routine and pandemic immunization in future. However the work still needs a deep research to be employed at commercial scale.

P6.10.15
Encapsulation of antigens in whole plant cells functions as a combined production and delivery platform for oral vaccines

R. P. Shepherd*, A. M. Walmsley;*
Monash University, Clayton, Australia.

Oral delivery of transgenic plant material was heralded as a safe, rapidly produced, and economical platform for the development of vaccines. However, as with conventionally produced oral vaccines, proteolytic degradation during digestion and the subsequent heterogeneous immune response limits what should be a synergistic match of production platform and delivery method. We are currently investigating the effect of sub-cellular localisation of antigenic proteins on the rate of release and immunogenicity following oral administration. Using genetic fusions of plant-cell trafficking signal sequences and the B-subunit of the heat-labile toxin (LTB) from

enterotoxigenic E.coli, we have successfully shown LTB is sequestered to different sub-cellular compartments of the Nicotiana benthamiana leaf cell. Correctly folded LTB is localised to the apoplast, endoplastic reticulum, non-lytic vacuole, and protein bodies. An in vitro simulated gastric fluid assay shows LTB is released at different rates depending on the sub-cellular encapsulation. An in vivo feeding trial in C57Blk6 mice provides evidence that sequestering LTB within non-lytic vacuoles improves the IgG1-domiant humoral, and sIgA mucosal response. Optimisation of release kinetics during digestion may facilitate improved delivery of antigenic proteins and other orally delivered biologics, and may harness the intrinsic capacity of plant cells as both production and delivery vehicles.

P6.10.16
Establishment of murine norovirus S7 infection system for vaccine development

N. Takeyama[1,2], *Y. Chen*[2], *Y. Tohya*[3], *K. Oroku*[1], *H. Kiyono*[2], *Y. Yuki*[2]; [1]*Nippon Institute for Biological Science, Ome, Tokyo, Japan,* [2]*Institute of Medical Science, The University of Tokyo, Tokyo, Japan,* [3]*College of Bioresource Sciences, Nihon University, Fujisawa, Japan.*

Norovirus (NV) belongs to the Caliciviridae family with non-enveloped, positive-strand RNA. Over 60% of non-bacterial gastroenteritis outbreaks are due to human NV (HNV), which is a major public health concern. The lack of HNV cell culture system and animal infection model hampers the studies in HNV vaccine development. The discovery of murine NV (MNV) has provided a great volume of biological information of NV. In this study, we aimed to establish the MNV infection mouse model by using MNV-S7 isolated in Japan, as an alternative approach for HNV vaccine development. When Balb/cA and C57BL/6J were orally inoculated with 7.5log10 TCID50/dose of MNV-S7, MNV-RNA and the viral titers could be detected in fecal samples from 1 day post infection (dpi). The excretion of MNV-S7 in feces persisted for at least 2 weeks, with peaks between 1 to 5 dpi. After 14 dpi, MNV-RNA and viral titers decreased, which might be attributed to antigen-specific host immune responses. Using newly established MNV-S7 infection model, we vaccinated Balb/cA nasally with MVN-S7 recombinant VP1 P-domain [rVP1(P)], together with or without cholera toxin. VP1 specific antibodies in both systemic and mucosal compartments, particularly with high levels of serum IgG, were induced in both groups. After MNV-S7 challenge, vaccinated mice showed a slight decrease in MNV-RNA and the viral titers at 5 and 7 dpi, indicating that rVP1(P) exhibited a limited protection. These results will be a support in improving the researches in host infection and immunity on NV and the vaccine development of NV.

P6.10.17
Maternal antibodies enhance systemic and local immune responses after early mucosal immunization in a porcine model

M. A. Vega-Lopez[1], *E. R. Guzman-Bautista*[1], *C. E. Garcia-Ruiz*[2], *A. L. Gama*[2], *C. Ramirez-Estudillo*[1], *O. I. Rojas*[1]; [1]*CINVESTAV-IPN/MEXICO, Mexico, D.F., Mexico,* [2]*FES-Cuautitlan-UNAM, Mexico, D.F., Mexico.*

In newborn mammals, maternal antibodies (MatAb) confer protection against antigenic challenges, although it has been also reported a suppressive effect on neonatal immunization. We evaluated the immune response to ovoalbumin (OVA) after mucosal immunization on 7 and 14 days (7d, 14d) old, SPF Vietnamese minipigs, from negative (OVA-) or previously immunized (OVA+) sows. Sows were intramuscularly immunized to OVA 30 days before farrowing. Maternal anti-OVA IgG and IgA were detected in colostrum and serum and were intestinally absorbed by the offspring during the first three days of life. These antibodies were detected in piglets' serum, but not in mucosal secretions (saliva, nasal secretion). The systemic (serum) anti-OVA IgG and IgA responses were significantly higher in piglets immunized at 7d of life, from OVA+ sows, compared with piglets from OVA- sows and similar to piglets immunized at 14d of age. Also the anti-OVA IgA in nasal secretion was higher in OVA+ 7d piglets and in saliva of OVA+ 14d piglets. In our hands, the suppressive effect of MatAb, reported by others at early immunization, was not detected. On the contrary, a stimulating effect was found with MatAb in one week old piglets and this effect disappeared in 14d old piglets. These results may open the possibility to induce effective early systemic and mucosal immune responses in the young through early immunization, even in the presence of MatAb. Supported by grants from CONACyT (234097) and ICyTDF (323/09). Thanks to DVM Manuel Flores and Daniel Cortes for technical assistance.

P6.10.18
M-cell targeting strategy improved the immunogenicity of viral myocarditis-specific mucosal DNA vaccine

Y. Yue, *S. Xiong, W. Xu;*
Institutes of Biology and Medical Sciences, Soochow University, Suzhou, Jiangsu Province, China.

Induction of mucosal T cell immune responses is a priority of many vaccine strategies against mucosal invaded pathogens such as coxsakievirus B3 type (CVB3). We previously developed a chitosan-pVP1 vaccine and intranasal immunization could induce both systemic and mucosal immunity which provided a moderate prevention of CVB3-myocarditis. How to further improve its immunogenicity and immunoprotection becomes the center of our focus. Considering that M (microfold) cells are specialized epithelial cells responsible for mucosal antigen sampling, targeting M-cells will be an attractive way to elicit a strong immune response toward mucosal antigens. In the present work, we showed that an efficient mucosal vaccination against CVB3-induced myocarditis could be accomplished by incorporating the chitosan-pVP1 vaccine with an M-cell targeting CPE30 peptide. Following chemical conjugation with CPE30, chitosan was coacervated with pVP1 to form vaccine particles. Mice were intranasally vaccinated with CPE30 conjugated chitosan-pVP1 at 2-weeks interval for 4 times. 2 weeks following the last immunization, CVB3-specific T cell immune responses in spleen and mesenteric lymph node (MLN) were carefully determined. We found that compared with chitosan-pVP1, CPE30 conjugated chitosan-pVP1 significantly promoted systemic and mucosal T cell proliferation, increased the percentages of specific IFN-γ+ T cells and robustly enhanced CTL immune responses. Accordingly, less severe myocarditis with limited immune cell infiltration was evidenced in the heart tissues following CVB3 challenge, indicating the enhanced resistance to CVB3 induced myocarditis. These data suggests that M cell-targeting CPE-30-chitosan-pVP1 vaccine might represent a promising vaccine candidate to protect against CVB3 infection.

Induction of the activation of innate and adaptive immunity by lipidated peptide vaccine: robust and enduring protective memory Th17 cells against Mycobacterium tuberculosis

J. N. Agrewala[1], *U. Gowthaman*[1], *W. Zeng*[2], *D. C. Jackson*[2]; [1]*CSIR-Institute of Microbial Technology, Chandigarh, India,* [2]*The University of Melbourne, Melbourne, Australia.*

In tuberculosis-endemic population, the main reason for the failure of BCG vaccine is the obstacle caused by non-tuberculous mycobacteria and helminths in its processing and presentation. Usually, peptides do not require extensive antigen processing since they can bind to major histocompatibility complex molecules and therefore can be directly presented to T cells. As a result, peptide vaccines can surmount the problems associated with BCG failure. It is well-established fact that not only adaptive but also innate immunity plays a crucial role in protection against tuberculosis. Hence we have constructed a novel lipopeptide vaccine by linking promiscuous CD4 and CD8 epitopes of Mycobacterium tuberculosis to Pam2Cys, a Toll Like Receptor-2 agonist. This lipopeptide has unique property of self-adjuvanting and concurrently activating both innate and adaptive immunity. The vaccine binds directly to MHC I and MHC II molecules and TLR-2. It stimulates dendritic cells to secrete cytokines, upregulates the expression of costimulatory molecules and significantly augments their ability to present antigen to T cells.

Further, the vaccinated animals impart robust and enduring memory Th1 and Th17 response. The protection observed is significantly better than BCG. This lipidated-peptide vaccine is unique since it overcomes MHC barriers and evokes immune response irrespective of HLA polymorphism in human. This vaccine has enough potential to induce long-lasting protection against Mycobacterium tuberculosis. Therefore can be a potent future vaccine candidate for controlling tuberculosis.

P6.11.02

Pre-clinical isolation and expansion of CMV specific T-cells for adoptive immunotherapy based either on IFN-γ production or activation-dependent expression of CD154

E. Albiero[1,2]*, K. Chieregato*[1]*, M. A. Cassatella*[3]*, F. Rodeghiero*[1,2]*, G. Astori*[1]*;*
[1]*Advanced Cellular Therapy Laboratory - Department of Cellular Therapy and Hematology, San Bortolo Hospital, Vicenza, Italy,* [2]*Hematology Project Foundation Research Laboratories, Vicenza, Italy,* [3]*Section of General Pathology, Department of Pathology and Diagnostics, University of Verona, Verona, Italy.*

Introduction. Cytomegalovirus (CMV) reactivation after allogeneic hematopoietic stem cell transplantation (HSCT) counts for up to 30% of deaths. In 2012, in the Hematology of Vicenza Hospital 53% of patients underwent HSCT experienced CMV reactivation. The capture of T-cells secreting cytokines (γ-catch) or expressing activation markers after viral antigens stimulation allows isolation of CMV-specific T-cells (CMV-T) to be used in Adoptive Cellular Therapy.
Aim. We explored the T-cell response of the CMV-T obtained with either γ-catch or CD154 selection upon stimulation with pp65, IE1 or both CMV peptides.
Methods. PBMC were isolated from CMV(+) donors and cultured in standard conditions. For the isolation of CMV-T, cells were either magnetically enriched by the γ-catch or by CD154-microbeads. CMV-T were cultured in the presence of feeder cells for three weeks and then stained for immunophenotyping (IF), intracellular cytokine staining (ICC), CFSE-based proliferation assay by FACS.
Results. Purity and enrichment of CMV-T resulted comparable between CD154+ and IFN-γ+ cells and virus epitopes. The IFN-γ secreting CD4+ T cells have been enriched up to 66%. Although isolation of CD154+ CMV-T cells greatly favours enrichment of CD4+ T cells, a number of CD8+ T cells was expanded depending on the type of peptide and of the simultaneous use of them. CFSE staining on day 21 evidenced that isolated and expanded CMV-T underwent division after stimulation.
Conclusions. Both methods and epitopes elicited CD3+ CMV-T responses but resulting in different T-cell populations, potentially leading to divergent in-vivo T-cell responses.

P6.11.03

Broad and cross-clade CD4+ T-cell responses elicited by a DNA vaccine encoding highly conserved and promiscuous HIV-1 M-group consensus peptides

R. R. Almeida[1]*, D. S. Rosa*[2]*, S. P. Ribeiro*[1]*, V. C. Santana*[1]*, E. G. Kallás*[1]*, J. Sidney*[3]*, A. Sette*[3]*, J. Kalil*[1,4]*, E. Cunha-Neto*[1,4]*;*
[1]*University of São Paulo School of Medicine, São Paulo, Brazil,* [2]*Federal University of São Paulo, São Paulo, Brazil,* [3]*La Jolla Institute for Allergy and Immunology, La Jolla, CA, United States,* [4]*Heart Institute, São Paulo, Brazil.*

Broad, polyfunctional and cytotoxic $CD4^+$ T-cell responses have been associated with control of HIV-1 replication and may represent a beneficial component of an efficacious HIV vaccine. Also, strategies to cope with virus and host genetic diversity are urgently needed. We rationally designed a multiepitopic DNA vaccine in order to elicit broad and cross-clade $CD4^+$ T-cell responses against highly conserved and promiscuous peptides from the HIV-1 M-group consensus sequence. We identified 27 conserved, multiple HLA-DR-binding peptides in the HIV-1 M-group consensus sequences of Gag, Pol, Nef, Vif, Vpr, Rev and Vpu using the TEPITOPE algorithm. The peptides bound *in vitro* to an average of 12 out of the 17 tested HLA-DR molecules and also to HLA-DP, -DQ and murine IA^b and IA^d molecules. Sixteen out of the 27 peptides were recognized by PBMC from HIV-1-infected patients and 72% of such patients recognized at least 1 peptide. Immunization with a DNA vaccine (HIVBr27) encoding the identified peptides elicited IFN-γ secretion against 11 out of the 27 peptides in BALB/c mice; $CD4^+$ and $CD8^+$ T-cell proliferation was observed against 8 and 6 peptides, respectively. HIVBr27 immunization elicited cross-clade T-cell responses against several HIV-1 peptide variants and polyfunctional $CD4^+$ and $CD8^+$ T cells against the pool of HIVBr27 peptides. In addition, HIVBr27 immunization led to lower viral load in mice challenge with recombinant Vaccinia virus encoding HIV-1 Gag and Pol. We believe that our concept may cope with HIV-1 genetic diversity, provide increased population coverage and elicit protective T-cell immunity against HIV-1/AIDS.

P6.11.04

Long-term expression of interferon alpha fused to apolipoprotein A-I allows the development of vaccine-induced adaptive immune responses

F. Aranda*, M. Vasquez, N. Ardaiz, J. Fioravanti, I. Echeverria, P. Sarobe, M. Di Scala, G. González-Aseguinolaza, J. Prieto, P. Berraondo;*
Center for Applied Medical Research, Pamplona, Spain.

Interferon alpha (IFNα) is a key cytokine for the development of adoptive immune response due to its role as signal 3 in $CD8^+$ activation. However, the high and frequent doses used for the treatment of chronic viral hepatitis and cancer subvert the immunomodulatory capacity of IFNα, boosting the NK cell activities and abrogating the $CD8^+$-mediated immune responses.
In this work, we modeled the long-term treatment with IFNα expressing in the liver of mice this cytokine by a recombinant adenoassociated virus.
The sustained production of IFNα exerted a potent antiviral effect in hepatitis B transgenic mice and in mice infected by a lethal dose of encephalomyocarditis virus. However, these antiviral effects were associated with a profound hematological toxicity, and with a chronically activated immune system that presented an exhausted phenotype. In this setting, the efficacy of vaccines designed to boost the adaptive immune responses were hampered.
Interestingly, the long term expression of IFNα fused to apolipoprotein A-I exerted a similar antiviral effect but minimized the hematological toxicity and the exhaustion of the immune system. In this case, the activity of vaccines was preserved.
In conclusion, IFNα fused to apolipoprotein A-I maintains the potent antiviral activity of IFNα and the capacity of the adaptive immune system to respond to other immunotherapies designed to boost cytotoxic T cell responses able to eradicate established tumors or chronic viral infections.

P6.11.05

HLA-G5 expression in isolated adipose derived stem cells (ASCs) from breast cancer patients compared to normal breast tissues

B. Bahrami[1]*, M. Razmkhah*[2]*, A. Ghaderi*[3]*;*
[1]*Shiraz Institute for cancer research, Department of Immunology, Shiraz, Iran,* [2]*Shiraz Institute for cancer research, shiraz, Iran,* [3]*Shiraz Institute for cancer research, Department of Immunology, shiraz, Iran.*

Background: Adipose derived stem cells (ASCs) are detected in tumor microenvironment which play an immunomodulatory effects on both innate and adaptive immune responses. ASC-mediated immunesuppression mainly induced through the secretion of soluble molecules such as IDO, NO, PGE2 and HLA-G5.
Aim: to assess the expression of HLA-G5 in adipose derived stem cells isolated from breast cancer patients compared to those isolated from normal breast tissue after cosmetic mamoplasty.
Methods: ASCs were isolated from 15 breast cancer patients and 10 normal adipose tissues using collagenase digestion. HLA-G5 was assessed by q-RT- PCR method.
Result: There was no significant difference in the expression of HLA-G5 in ASCs of breast cancer patients in comparison with those isolated from normal individuals.

Conclusion: Although recent studies showed an immunomodulatory effect for HLA-G5 associated on ASC in cancer tissues, in the current study expression of HLA-G5 was not significantly different between breast cancer and normal breast tissue.

P6.11.06
Immunogenicity of a Clostridium-difficile DNA based anti-toxin vaccine in an aging mouse model

***M. E. Bernui**, S. Baliban, J. Jacobson, S. Wells, M. Kutzler;*
Drexel University College of Medicine, Phladelphia, PA, United States.

Clostridium difficile infection (CDI) is a major source of morbidity and mortality in the United States, costing over $1.1 billion/year. More than 90% of CDI-related deaths occur in individuals >85yrs. Protection against C. difficile-associated disease is mediated by host antibody responses against C. difficile toxins. Our goal is to determine the immunogenicity of a DNA based anti-toxin vaccine in an aging mouse model. Thus, young (4 mo.) and old (>18mo.) mice were immunized with our optimized DNA vaccine encoding toxin A and toxin B receptor-binding domain (A-RBD; B-RBD). Day 12 post-first immunization the younger mice had significantly higher IgG titers against A-RBD, with 25 ug/ul versus 5 ug/ul anti-toxin serum IgG. However 10 days post-second immunization the old and young mice had comparable IgG titers (~500 ug/ul IgG against A-RBD). Interestingly, anti B-RBD IgG responses in older mice remained lower (1000 ug/ul vs 2000 ug/ul). Differences in anti-toxin IgG and IgA in fecal extracts between aged and young mice were also observed. Therefore, our DNA vaccine platform generated an antibody response against C. difficile toxin-based DNA vaccines in older mice but defects in vaccine priming occur leading to lower titers. Two weeks post-second immunization higher frequencies of CD4+/CD44+ (activated) T cells were detected in older mice but not in younger cohorts. We also observed a higher frequency of toxin-specific CD4+ T cells that secrete pro-inflammatory cytokines (IFN-g, IL2) and Th2 cytokines (IL4, IL10) in older mice, supporting the notion of a deleterious “inflamm-aging” response.

P6.11.07
Targeting the non-structural protein 1 from dengue virus to a dendritic cell population confers partial protective immunity to lethal virus challenge

H. R. Henriques[1], E. V. Rampazo[1], A. J. S. Gonçalves[2], J. H. Amorim[1], R. H. Panatieri[1], K. N. S. Amorim[1], M. M. Yamamoto[1], L. C. S. Ferreira[1], A. M. B. Alves[2], ***S. B. Boscardin**[1];*
[1]University of Sao Paulo, Sao Paulo, Brazil, [2]Oswaldo Cruz Foundation, Rio de Janeiro, Brazil.

Dengue is the most prevalent arboviral infection and the development of a vaccine is a World Health Organization priority. Among the vaccine candidates being tested in preclinical settings is the nonstructural protein 1 (NS1). In the present study, we tested the immune responses generated by targeting the NS1 protein to two different dendritic cell (DCs) populations. DCs are important antigen presenting cells and targeting proteins to maturing DCs has proved to be an efficient means of immunization. Antigen targeting is accomplished by the use of a monoclonal antibody (mAb) directed against a DC cell surface receptor fused to the protein of interest. We used two mAbs (αDEC205 and αDCIR2) to target two distinct DC populations, expressing either DEC205 or DCIR2 endocytic receptors, respectively, in mice. The fusion mAbs were used to immunize BALB/c mice in the presence of the Toll-like receptor (TLR) 3 ligand poly (I:C), as a DC maturation stimulus. We observed induction of strong anti-NS1 antibody responses in both groups. When we tested the induction of cellular immune responses, the number of IFN-γ producing cells was higher in αDEC-NS1 immunized animals. Also, mice immunized with the αDEC-NS1 mAb were significantly protected from a lethal intracranial challenge with the DENV2 NGC strain when compared to mice immunized with αDCIR2-NS1 mAb. We conclude that targeting the NS1 protein to the $DEC205^{+}$ DC population together with poly (I:C) is a promising approach to induce protective immunity to dengue virus infection.

P6.11.08
Expression and biological characterization of a recombinant monoclonal antibody, scFv, against BaP1, a P-I metalloproteinase from *Bothrops asper* snake venom

***J. Castro**[1], A. Ohashi[1], M. Caporrino[1], T. S. Oliveira[1], J. Gutiérrez[2], A. Rucavado[2], O. H. P. Ramos[3], G. S. Magalhães[1], I. Fernandes[1], E. L. Faquim-Mauro[1];*
[1]Laboratory of Immunopathology-Butantan Institute, São Paulo, Brazil, [2]Clodomiro Picado Institute, San José, Costa Rica, [3]Institut de Biologie et de Technologies de Saclay (iBiTec-S), Paris, France.

BaP1 is a metalloproteinase relevant in the local tissue damage associated with envenomations by *Bothrops asper*. Our aim is to express a recombinant scFv antibody against BaP1 with neutralizing ability. For this, the construct was cloned into pMST3 vector in fusion with SUMO protein and expressed in cytoplasm of C43 (DE3) bacteria. Both scFv and SUMO (control) were analyzed by SDS-PAGE to confirm their purity. The ability of monoclonal antibody (MaBaP1) and the scFv to recognize total *B.asper* venom and BaP1 was assessed by ELISA. The capacity of scFv to neutralize fibrin degradation induced by BaP1 was evaluated using agarose gel substrate containing fibrin. The hemorrhage neutralization in skin mice and gastrocnemius muscle necrosis were estimated by incubating BaP1:scFv at 10:1 molar ratio. Purified scFv and SUMO presented bands of 38.9 and 13.6 kDa, respectively. ELISA showed that scFv was able to recognize BaP1 as well as whole venom, but not SUMO. Fibrinolysis induced by BaP1 was significantly neutralized (73.8% and 46.7%) in a concentration-dependent manner by scFv but not by SUMO. ScFv, as well as MaBaP1 completely neutralized hemorrhage and muscle necrosis induced by BaP1. Moreover, the production of inflammatory mediators induced by BaP1 in peritoneal cavity was neutralized by scFv. Our data showed that scFv specifically recognized and neutralized biological effects of BaP1, suggesting its potential use for snake poisoning therapy. Financial support: FAPESP, PRODOC-CAPES, CNPq and INCT-TOX program of CNPq and FAPESP.

P6.11.09
Leishmania major large Rab GTPase (LmlRab) protects BALB/c mice against a L. major challenge and is highly immunogenic in individuals immune to cutaneous and visceral leishmaniasis

***R. Chamakh**, A. Garnaoui, K. Aoun, M. Chenik;*
Institut Pasteur de Tunis, Tunis, Tunisia.

Leishmania major large Rab GTPase (LmlRab) is a new atypical RAB protein displaying a high homologies with the Rab GTPase protein family and highly conserved in leishmania species, it plays a key role in intracellular transport. In order to identify leishmania vaccine candidates, we analysed the protective effect of the recombinant LmRab in the BALB/c mouse model. The cellular immune responses induced by LmRab and it divergent carboxy-terminal part LmRabC, were also evaluated in individuals with healed CL (n= 33) or with asymptomatic infection to L. major (n= 18) (HCLm and AsCLm) and asymptomatic to L. infantum (n=26) for visceral leishmaniasis (AsVLi).
LmRab with CpG were able to confer a strong protection in vaccinated mice against a virulent L. major challenge (2 10^{6} metacyclics), this protection were observed up to 20 weeks post challenge. In immune individuals, LmRab and LmRabC proteins were able to induce a specific significant levels of IFNγ in CL and VL immune groups compared to control group ($p<0,05$). Both proteins induced significant amounts of IL-10 in all groups with no significant difference. Granzyme B, the known cytotoxic mediator of CD8+ T cells, was also observed in individuals with immunity to L. major and controls, with no significant difference. Our results showed that the LmRab protein was able to induce a dominant Th1 immune response in individuals with immunity to L. major or L. infantum infection. These results indicate that LmRab may constitute a potential vaccine candidate against cutaneous and visceral leishmaniasis.

P6.11.10
Recombinant lipidated dengue-2 envelope protein domain III induces durable neutralizing antibodies and reduces the risk of antibody-dependent enhancement

***H. Chen**, C. Chiang, C. Pan, C. Hsieh, J. Tsai, M. Chen, H. Liu, S. Liu, P. Chong, C. Leng;*
National Health Research Institutes, Miaoli, Taiwan.

Vaccines are considered a cost-effective way to control infectious diseases. To rationally design vaccines, antigens and, frequently, adjuvants must be selected to trigger appropriate immune responses against a specific pathogen. We selected dengue-2 envelope protein domain III as a dengue vaccine candidate and expressed this candidate in the lipidated form in an *Escherichia coli*-based system. Dengue envelope protein domain III mediates binding of the dengue virus to the host cellular receptor. The lipid moiety of the bacterial-derived lipoprotein can activate the innate immune system to elicit an appropriate adaptive immune response. We demonstrated that lipidated dengue-2 envelope protein domain III is more immunogenic than nonlipidated dengue-2 envelope protein domain III. Most importantly, the lipidated dengue-2 envelope protein domain III alone triggered a durable neutralizing antibody response with a low risk of severe side effects. The safety profile of the lipidated subunit vaccine is superior to that of live attenuated vaccines because it lacks infectious RNA. In addition, lipidated subunit vaccines are non-replicating and thus may be less susceptible to replication interference than live attenuated vaccines. Our study suggests that the lipidated subunit vaccine approach could be applied to other serotypes of dengue virus as well as other pathogens.

P6.11.11
Human monoclonal ScFv that blocks sodium ion activity of tetrodotoxin

***M. Chulanetra**[1], K. Bangphoomi[2], N. Sookrung[3], J. Thanongsaksrikul[4], P. Srimanote[4], H. Kurasano[5], K. Choowongkomon[2], W. Chaicumpa[6];*
[1]Graduate Program in Immunology, Faculty of Medicine Siriraj hospital, Mahidol University, Bangkok, Thailand, [2]Department of Biochemistry, Faculty of Sciences, Kasetsart University, Bangkok, Thailand, [3]Department of Research and Development, Faculty of Medicine Siriraj hospital, Mahidol University, Bangkok, Thailand, [4]Graduate Program in Biomedical Sciences, Faculty of Allied Health Sciences, Thammasat University, Pathumthani, Thailand, [5]Department of Applied Veterinary Medicine and Public Health, Obihiro University of Agriculture and Veterinary Medicine, Inada-cho, Obihiro, Hokkaido, Japan, [6]Department of Parasitology, Faculty of Medicine Siriraj hospital, Mahidol University, Bangkok, Thailand.

Tetrodotoxin (TTX) intoxication is commonly found in Asia-Pacific regions mainly from eating seafood containing the toxin, such as puffer fish, eggs of horseshoe crabs. TTX blocks sodium ion channel of nerve cell membrane causing paresthesia, paralysis, respiratory failure and rapid death, if not treated promptly and properly. Currently, there is no specific anti-dote and the TTX intoxicated patients received only palliative treatment. In this study, human monoclonal single chain antibody fragments (HuScFv) that block the TTX activity for treatment of the TTX intoxication was invented. Phage clones displaying HuScFv that bound specifically to the TTX was selected from a human ScFv phage display library; using TTX as the phage bio-panning antigen. TTX specific HuScFv were produced and purified from the phage transfected E. coli. HuScFv from two E. coli transformants: s16 and s35 could neutralize the TTX toxicity to neuroblastoma cells ex vivo as well as in the TTX intoxicated mice. Computer homology modeling and molecular docking enlightened the molecular mechanisms of the HuScFv in neutralization of the TTX activity. The HuScFv invented in this study have high potential for developing further for treatment of human TTX intoxication.

Broadly neutralizing human monoclonal antibodies: a novel resource against influenza viruses

***E. Criscuolo**, F. Cappelletti, N. Clementi, N. Mancini, G. A. Sautto, R. A. Diotti, M. Clementi, R. Burioni;*
Università Vita-Salute San Raffaele - Laboratorio di Microbiologia e Virologia, Milano, Italy.

Influenza virus still represents a serious threat for human health, causing pandemics and annual epidemics. From 1918, four influenza A pandemics occurred, caused by H1N1, H2N2, H3N2 and vH1N1 subtypes. Moreover, the recurrent concerns deriving from the possible adaptation to humans of influenza viral isolates circulating in animal reservoirs, the potential arising of resistance to the currently available anti-viral drugs and the lack of an effective prevention make influenza virus a relevant menace for the world population. In this scenario, the identification of human monoclonal antibodies endowed with strong neutralizing activity and directed against viral isolates belonging to different influenza subtypes can raise hope for the development of monoclonal antibody-based immunotherapy. Even more interestingly, they can play a pivotal role in the development of new vaccines. Here, we describe two human mAbs directed against influenza haemagglutinin (HA), named PN-SIA28 and PN-SIA49, featuring such characteristics. They can be effectively considered as suitable candidates for antibody-based immunotherapy due to their low IC50 (half maximal (50%) inhibitory concentration) and to the protection of animal models against lethal influenza virus challenges conferred by PN-SIA49. At the same time, the fine characterization of the conserved structural motifs on the HA, recognized by these mAbs, can be the key to success in the development of new epitope-based vaccines.

P6.11.13
Use of Rodent Models to Identify Components of the Immune Response Compromised by Prior Exposure to Adenovirus: Filling in the Missing Pieces with Formulation Development for an Ebola Vaccine

***M. A. Croyle**[1], J. Choi[1], S. C. Schafer[1], A. N. Freiberg[2];*
[1]The University of Texas at Austin, Austin, TX, United States, [2]The University of Texas Medical Branch, Galveston, TX, United States.

Development of a rapidly acting vaccine against Ebola is needed for natural outbreaks or those that result from bioterrorist activity. Recombinant adenovirus serotype 5 (rAd5) an advanced vector system to deliver Ebola antigens for immunization. However, Ad is common in the environment and many have anti-Ad antibodies that may compromise its efficacy as a vaccine.
Early studies established pre-existing immunity (PEI) to Ad by intramuscular (IM) injection of Ad 30d prior to immunization. Since Ad is a respiratory pathogen, IM injection does not accurately reflect natural infection. To address this issue, we test the hypothesis that the manner by which PEI is induced will significantly impact the type of immune response generated by an Ad-based vaccine and that this will vary with immunization route.
Multiparameter flow cytometry analysis revealed that, when PEI is induced by the same route as immunization, antigen-specific CD8+ IFN-γ producing T cells and polyfunctional antigen-specific cells producing IFN-γ, IL-2 and TNF-α are significantly reduced. The antigen-specific effector/effector memory CD8+ T cell proliferative response followed the same trend. Th2-type antigen-specific antibody responses were significantly reduced 28d after vaccination. This correlated with poor survival after lethal challenge.
Several novel formulations improved transduction efficiency in the presence of neutralizing antibodies. Formulations that improved multi-functional $CD8^+$ T cell and Th2 type responses increased survival. Unlike current strategies to improve T cell quality in vaccines, we use pharmaceutically acceptable excipients that do not target TLRs or other PPRRs, eliminating unwanted side effects from over-activation of the immune system.

P6.11.14
Recombinant Vesicular Stomatitis Virus-based Vaccine Protects Mice against Viral Myocarditis

C. Dong;
Institutes of Biology and Medical Sciences,Soochow University, Suzhou, China.

Objective: Coxsakievirus B3 type (CVB3) is a major cause of viral myocarditis and currently there is still no effective vaccine available in clinic. To develop a mucosal vaccine against CVB3 infection, we generated a recombinant vesicular stomatitis virus (VSV) -based vaccine and its protection role against viral myocarditis was examined in Balb/c mice infected with CVB3.
Material and methods: We constructed a recombinant VSV expressing CVB3 capsid protein VP1 using VSV reverse genetic system. Western blot and Immuno-fluorescence staining indicated that the VP1 was successfully expressed upon VSV infection. Mice were intranasally vaccinated with 10^5~10^6 PFU recombinant VSV at single does. A DNA mucosal vaccine (Chitosan-pVP1) previously developed in our lab was used as a control and intranasally immunized at 2-weeks interval for 4 times. Two months later, mice were challenged with $3X10^5$ TCID50 lethal dose of CVB3. Additionally, CVB3-specific T cell mediated and humoral immune responses were carefully determined.
Results: Recombinant VSV-based vaccine elicited robust cellular immune response as well as humoral immune response as evidenced by enhanced T cell proliferation, increased specific IFN-γ^+ T cells, better CTL immune response and elevated sIgA secretion comparing with chitason-VP1. Meanwhile, we noticed that the survival rate increased with less severe myocarditis in heart tissues upon viral challenge.
Conclusion: The VSV-based vaccine expressing CVB3 VP1 might be a promising candidate that protect against CVB3 infection.

P6.11.15
Cell penetrable human ScFv specific to influenza A virus matrix protein, M1, mitigates influenza severity

F. Dongdinon;
Kasetsart University, Naknon Pathom, Thailand.

Matrix protein-1 (M1) is highly conserved across type A influenza viruses. This protein has many important functions in the viral replication cycle; thus it is one of the targets of novel anti-influenza.To study therapeutic efficacy of M1 specific, cell penetrable human single chain antibody (HuScFv) in mitigating severity of influenza in infected mice.E. coli derived-human single chain antibody fragments (HuScFv) specific to recombinant M1 of influenza A virus H5N1 (clade 1) was produced using a human antibody phage display library. HuScFv from selected huscfv-phagemid transformed E. coli clones were linked molecularly to a cell penetrating peptide, penetratin (PEN) and PEN-HuScFv were produced and purified. BALB/c mice were infected intranasally with mouse adapted-avian H5N1 virus (clade 2.3). They were then treated with M1 specific-PEN-HuScFv. Control infected mice received PBS treatment. Internal organs (lung, brain, spleen, liver and kidney) were collected. Tissue viral loads were determined by real time RT-PCR. Histopathology of the tissues was also examined. Infected BALB/c mice that received M1 specific-PEN-HuScFv had reduced viral loads and histopathological features in tissues compared to the controls.M1 specific-PEN-HuScFv could mitigate severity of influenza in mice infected with A H5N1 of the heterologous clade. Cross therapeutic efficacy of the transbodies on influenza caused by different virus subtypes remains to be evaluated.

P6.11.16
Phylogenetic study of BTV in Morocco since 2004 : determination of new reassortants

K. Drif[1], *O. Fassi Fihri*[1], *G. Sebbar*[2], *N. Chafiai*[2], *C. Loutfi*[2], *M. Ennaji*[3], *M. Elharrak*[2];
[1]*IAV Hassan II, Rabat, Morocco,* [2]*Biopharma, Rabat, Morocco,* [3]*FST, Mohammadia, Morocco.*

The bluetongue (BT) is a non-contagious disease transmitted by blood-sucking arthropods of the genus Culicoides. The disease affects small ruminants, especially sheep which are very sensitive.
Since 2004 two serotypes circulating in Morocco BTV-1 and 4, several samples were collected during different epidemics, the strains were isolated but no thorough phylogenetic study has been established to characterize and reveal different reassortants have been able to generate from parental strains.
The first year of our study involved a serological survey of sheep and cattle to define the epidemiological situation with respect to this arbovirus, also reveal the rate of coinfection by differents serotypes.
Out of the 429 sera that were collected, 216 are from the cattle of the Gharb region, 109 were collected in 2009 from different regions of Morocco, and the rest was collected in 2012 from sheep of other regions of the country. All the sera collected were tested by neutralization using reference viruses of serotype 1 and 4 and the result is that the rate of co infection was high especially among cattle. Hence the results prove the importance of a molecular study involving BTV isolates that represents different regions of Morocco and different years since the first outbreak.
The next step is mainly based on the sequencing of BTV isolates to better understand the evolution of this virus through the years, then a study of the pathogenesis and immune response of animals would also assess whose goal is to classify different reassortants in Morocco.

P6.11.17
IFN-α improves TAPCells-based immunotherapy by inducing a highly activated dendritic cells in vitro

F. Falcon-Beas[1,2], *C. Falcon-Beas*[1,2], *F. Tempio*[1,2], *C. Perez*[1,2,3], *I. Flores*[1,2], *C. Pereda*[1,2], *F. Salazar-Onfray*[1,2], *M. N. Lopez*[1,2,3];

Introduction: IFN-α allows a cross-talk between the innate and adaptive immunity, promoting TH1 differentiation and inducing the generation and activation of CTLs. On monocytes, induces differentiation into highly activated DCs. We set to evaluate the effect of IFN-α on our already clinical effective TAPCell immunotherapy on both prostate and melanoma patients.
Materials and Methods: Monocytes were incubated with rhIL-4 and rhGM-CSF, stimulated at day 2 with a melanoma, prostate tumor lysate (TRIMEL and TRIPRO respectively) or lipopolysaccharide and harvested at day 3. Maturation markers were tested by flow cytometry. Cytokine determination was performed by ELISA and by FlowCytomix® Technology. DCs were cultured with allogeneic CD4+ T cells and proliferation, effector and regulatory T cells profiles were determined by flow cytometry. Delayed type hypersensitivity reaction (DTH) of a prostate cancer patient treated with this modified vaccine was evaluated and compared with a prior immunization with the standard DC-based vaccine.
Results and Discussion: IFN-α increased DCs maturation markers. Also, IFN-α treated DCs secrete more IL-12 while secreting lower levels of IL-10. Despite we found no difference on the induction of effector T helper profiles, the amounts of IL-10 secreted by those T cells was significantly lower. We observed that the DTH reaction was significantly larger than observed previously with our standard vaccine.
Conclusion: The use of IFN-α ex vivo on DCs used in cancer immunotherapy could avoid the high rate of adverse reactions of the systemic treatment while delivering the adequate signals to the proper cell types, conferring improved anti tumour immunity.

P6.11.18

Directed evolution of human single-chain Fv antibody fragment (scFv) anti-crotoxin, the main toxin of Crotalus durissus terrificus snake venom

*T. S. Oliveira[1], J. A. Castro[1], M. Caporrino[1], O. H. P. Ramos[2], E. L. Faquim-Mauro[1], G. S. Magalhães[1], **I. Fernandes**[1];*
[1]Laboratory of Immunopathology-Butantan Institute, São Paulo, Brazil, [2]Institut de Biologie et de Technologies de Saclay (iBiTec-S), Paris, France.

The WHO incorporated, in 2009, snakebite envenoming in its list of neglected tropical diseases. Single chain (scFv) antibodies consist of variable heavy and light domains joined by short flexible linker and can be used as therapeutic agents. In a previous work, crotoxin (CTX), the main component of *C. d. terrificus* snake venom was used to select human neutralizing recombinant scFvs by phage display technology from a naive library of more than 10^{10} scFvs. Among all ScFvs isolated one of them, named ScFv6, showed the best perfomance. Our aim is to enhance ScFv6 affinity by site-directed mutagenesis viewing a possible therapeutic alternative for envenoming. In order to clarify the mechanisms of neutralization, docking and energy minimization calculations of the antibody-CTX were also conducted. From these simulations, three single changes were chosen to be mutated. Mutants S30A and Y31F had aminoacid changes in CDR H1 while R103H in CDR H3. The mutants were codon optimized, cloned into pET20b+ vector for bacteria expression. Protein expression was induced with IPTG and periplasmic fractions were isolated through osmotic shock. Purification by immobilized metal affinity chromatography and SDS-PAGE analysis showed that all scFvs were expressed in soluble form. Circular dichroism revealed that scFvs had preserved secondary structure. Sequencing confirmed the desired mutations. Preliminary results show that all mutants presented similar expression levels. ScFvs will be now analysed regarding their affinity to CTX by surface plasmon resonance assay.

Data-driven approach reveals molecular and physiological events underlying synergistic effects of DNAhsp65 immunotherapy associated to conventional chemotherapy in experimental tuberculosis

***R. Ferracine Rodrigues**[1], C. R. Zárate-Bladés[2], W. Martin Rios[1], L. da Silva Soares[1], P. Rodrigues Marques de Souza[3], I. Tincani Brandão[1], A. P. Masson[1], S. Gusmão Ramos[1], G. Chiocchia[4], C. Lopes Silva[1];*
[1]University of Sao Paulo, Ribeirao Preto, Brazil, [2]National Institutes of Health; NIH, Bethesda, MD, United States, [3]Federal University of Sergipe, Aracaju, Brazil, [4]Cochin Institute, Paris, France.

Tuberculosis was declared a global emergency by WHO. New strategies to treat the disease are urgently needed. Immunotherapy, as adjunct of chemotherapy, kills the pathogen and boosts the immune system, shortening the conventional treatment.
We applied a data-driven approach to understand the molecular events underlying the combined effects of chemotherapy plus DNAhsp65 immunotherapy against tuberculosis and to define the real value of this strategy, envisioning their evaluation in clinical trials.
Infected BALB/c mice were treated with DNAhsp65, or isonizid and rifampicin or both. Microarray assay, covering the whole mice genome, was performed from RNA lung samples. The combination of therapies specifically changed the expression of 867 genes ($p<0.05$, fold change>1.5), indicating it produces synergistic and not just addictive effects.
Functional analysis showed that these genes belong to important physiological functions to overcome an infection. Pathways related to drugs side effects had their scores reduced by the combined therapies. Together, these observations indicated infection and inflammation controls and fibrosis reduction. Real-time PCR, ELISA, ELISPOT, CFU assay, histological analysis and collagen deposition measurements validated microarray data and functional analysis.
So, by using a data-driven approach, we showed for first time that the association of chemotherapy and DNAhsp65 immunotherapy in tuberculosis has synergistic effects that ultimately are reflected in the host immune response improvement and lung preservation. Next steps include identify short biosignatures allowing robustly discriminate all groups and translate the therapeutic efficacy.
This strategy has major implications regarding to application of Systems Immunology in therapeutic strategies development as gene based medicines.

P6.11.20

Efficient neutralization of Respiratory Syncytial Virus activity via novel anti-F/G bispecific antibodies concepts: treatment paradigm for severe RSV infections

*P. Kern[1], Y. Nie[2], H. Duerr[1], K. Kaluza[1], S. Bohini[2], S. Offner[1], G. Tiefenthaler[1], I. Thorey[1], C. Jie[2], **J. A. A. Fischer**[1];*
[1]Roche Large Molecule Research, pRED Penzberg, Penzberg, Germany, [2]Hoffmann-La Roche Inc., Nutley, NJ, United States.

Respiratory syncytial virus (RSV) is a highly contagious virus which primarily affects young children and individuals who have underling lung or heart diseases or are immunocompromised. RSV accounts for about 70-90% of all viral bronchiolitis and pneumonia and 2.8-4.3 million hospitalizations annually in children younger than 5 years old. Currently there is no vaccine or effective treatment for RSV infections. The only prophylactic drug available, Palivizumab, is a neutralizing antibody targeting RSV F protein. Severe RSV infections are usually associated with overwhelming inflammation in the lung characteristic of massive immune cell infiltration. RSV G protein has been suggested to be involved in this pathogenesis, and monoclonal antibodies targeting G protein demonstrated potent anti-inflammatory and antiviral effects in cultures and in animal models. In the current study, we generated a bi-specific antibody (Bs-Ab) with high affinity to RSV G and F envelope proteins, aiming for better therapeutic efficacy through blocking both RSV infection and RSV G protein-mediated inflammation. These tetravalent Bs-Abs retained binding specificity and high affinity to their respective antigens. In the plaque and cytopathic effect assays, the Bs-Abs demonstrated more potent antiviral activity than the parental F and G mAbs alone or in combination. In the cotton rat RSV challenge experiment, the Bs-Abs also exhibited better antiviral efficacy than the individual mAbs or combinations. Further studies using appropriate RSV disease models are needed to determine the therapeutic potential of these anti-F/G bs-Abs for severe RSV infections.

P6.11.21

A mucin-like peptide induces protection against Fasciola hepatica infection.

***T. Freire**[1], V. Noya[1], N. Brossard[1], E. Rodriguez[1], D. Mazal[1], P. Berasain[2], C. Carmona[2];*
[1]Facultad de Medicina, Universidad de la Republica, Montevideo, Uruguay, [2]Facultad de Ciencias, Universidad de la Republica, Montevideo, Uruguay.

Fasciola hepatica is a worldwide distributed helminth pathogen that causes great economic losses in sheep and cattle. The appearance of *F. hepatica* populations that are resistant to common flukicidal drugs, along with the fact that these drugs do not avoid the hepatic damage in animals, means that new methods of treatment are required. The future prospect for the development of anti-liver fluke vaccines is optimistic and given their consumer acceptability and environmental friendliness, offer the best way forward.
Our group has recently identified a putative mucin-like protein, Fhmuc, expressed in the invasive newly excysted juvenile (NEJ). Mucins are highly O-Glycosylated proteins that are associated with evasion of immune response and adhesion of parasite and hence important for parasite survival in harmful host environment. Thus, this mucin might be a good vaccine candidate against fasciolosis
In this work we present data regarding the immune response induced by the mucin-like peptide Fhmuc. We observed that Fhmuc has pro-inflammatory properties both *in vitro* and *in vivo*, leading to the production of high levels of pro-inflammatory cytokines. When tested in a model of fasciolosis in mice, Fhmuc has proven to protect from infection, especially when administrated together with dendritic cells. These results open new horizons in the development of vaccines against *Fasciola hepatica* infection.

P6.11.22
Immunological characterization of non-responsiveness to routine vaccination - role for regulatory immune cells and IL10

E. Garner-Spitzer[1], *A. Wagner*[1], *M. Paulke-Korinek*[1], *H. Kollaritsch*[1], *F. X. Heinz*[2], *M. Redlberger-Fritz*[2], *K. Stiasny*[2], *G. F. Fischer*[3], *M. Kundi*[4], *U. Wiedermann*[1];
[1]Medical University Vienna, Institute for Specific Prophylaxis and Tropical Medicine, Vienna, Austria, [2]Medical University Vienna, Institute of Virology, Vienna, Austria, [3]Medical University Vienna, Department of Blood Group Serology, Vienna, Austria, [4]Medical University Vienna, Institute of Environmental Health, Vienna, Austria.

Non-responders (NR) lack a sufficient protective immune-response after vaccination, yet underlying immunological mechanisms remain widely unknown. Thus we performed a study with NR to tick-borne encephalitis (TBE) or Hepatitis-B and compared their immune-responsiveness after TBE and Influenza vaccination at humoral and cellular level.
In TBE-NR TBE titers remained low but vaccinees mounted protective Influenza titers. Hepatitis-B-NR reacted with adequate titers to both vaccines as did controls, i.e. TBE high-responders. Cellular immune-response (cytokines) correlated with ab-titers in both TBE groups and flow-cytometric analysis of PBMC revealed that in TBE-NR compensatory mechanisms on T-cell level seem to be present. In Hepatitis-B-NR cellular immune-responses to TBE and Influenza were diminished despite protective ab-titers; low IFNy and IL-2 production was accompanied by high IL-10 levels already present in un-stimulated PBMC. Certain Hepatitis-B associated HLA class II subtypes were over-represented and high IL-10 levels seem linked to these subtypes.
To identify the source of IL-10, regulatory immune cell populations were characterized in selected donors. This revealed that FOXP3+ T-regs (and their IL-10 production) increased post booster in both NR groups yet decreased in high-responder vaccinees. Similarly CD19/24+/38+ immature transitional B-cells (B-regs) were highest in Hepatitis-B-NR, increased from lower pre-booster numbers in TBE-NR and decreased in TBE high-responders. In contrast, CD19/24+/27+ B10 B-cells, FOXP3- Tr1 cells and tolerogenic DCs (DC10) were not present in a conclusive manner in the three groups.
Our data indicate that different types of NR are governed by different immunological mechanisms which involve IL-10 production and regulatory T- and B-cell populations.

P6.11.23
Epitope mapping of the human antibody response to filamentous hemagglutinin of Bordetella pertussis

M. Golara[1], *S. Abdolmaleki*[1], *H. Asgarian-Omran*[1], *J. Khoshnoodi*[1], *A. Hemmati*[2], *M. Jeddi-Tehrani*[2], *F. Shokri*[1,2];
[1]Department of Immunology, School of Public Health, Tehran University of Medical Sciences, Tehran, Iran, [2]Monoclonal Antibody Research Center, Avicenna Research Institute, ACECR, Tehran, Iran.

Filamentous hemagglutinin (FHA) is an important immunogenic antigen of Bordetella pertussis and a major component of acellular pertussis vaccines. To study the immunodominant epitopes of this antigen we investigated the human antibody response to FHA using four overlapping recombinant fragments spanning the whole sequence of FHA. The recombinant FHA fragments were expressed in Ecoli and purified through His-tag. The antibody response to these fragments was assessed in serum samples collected from healthy adults vaccinated with an acellular pertussis vaccine. Serum antibody levels were measured by an indirect ELISA.The highest levels of antibody were directed against a fragment of FHA (FHA3) spanning amino acid residues 1877-2250 of the FHA molecule in all samples tested. No or little antibody was detected against the other recombinant fragments of FHA. Our results suggest that the human antibody response to FHA is restricted to immunodominant epitopes located within residues 1877-2250 of the FHA molecule. This recombinant fragment of FHA might be employed to replace the native FHA molecule in acellular pertussis vaccines.

P6.11.24
StreptInCor a S. pyogenes candidate vaccine increases the number of natural regulatory T cells in peripheral blood from rheumatic fever patients

K. F. Köhler[1,2], *C. F. Freitas*[1], *J. Kalil*[1,2,3], ***L. Guilherme***[1,2];
[1]Heart Institute (InCor), School of Medicine, University of São Paulo, São Paulo, Brazil, [2]Immunology Investigation Institute, National Institute for Science and Technology, University of São Paulo, São Paulo, Brazil, [3]Clinical Immunology and Allergy Division, School of Medicine, University of São Paulo, São Paulo, Brazil.

Group A Streptococci (GAS) diseases remain as a major public health problem in development countries, reaching 600 million registered cases with 233,000 deaths for year. If not treated properly can lead to autoimmune post-streptococcal sequels, such as Rheumatic Fever (RF) that affects mainly children and teenagers. Rheumatic heart disease (RHD) is the most serious sequel of RF, leading to progressive and permanent valvular lesions. We are developing a vaccine model against S.pyogenes. After identified protective epitopes of C-terminal portion of the M protein, a peptide with 52 aminoacids named StreptInCor (medical identity) was designed. The vaccine epitope induced systemic protective immune response in murine models. Here, we evaluated the capacity of regulatory T cells induction by StreptInCor, through identification of specific cellular markers (CD3, CD4, CD25, CD127 and Foxp3) for this subset of T cell by gene expression and flow citometry. Peripheral blood mononuclear cells (PBMC) of RHD and controls were stimulated with 10µg/ml of StreptInCor synthetic peptide. We observed that StreptInCor induced the increase of natural T regulatory cells (nTreg) in PBMC in both groups (P=0.0043 and 0.0006, respectively). The number of nTreg cells in PBMC from DRC patients before the stimulus is lower than that observed in PBMC from controls (P=0.0341). These results are very important and indicated that the vaccine peptide may have therapeutic potential to control both inflammatory and autoimmune response in RF/RHD patients.

P6.11.25
The monovalent pandemic influenza A/H1N1vaccine induces a significant CD8+T cells and antibodies response did not reach the threshold necessary for successful vaccination in Mexican hospital employees.

M. T. Herrera, *Y. González, E. Juárez, F. Hernández, C. Carranza, M. Sarabia, M. Manjarrez, S. Guzmán, E. Sada, M. Torres;
Instituto Nacional de Enfermedades Respiratorias, México, Mexico.*

After the pandemic influenza registered in 2009, the development of a new pandemic influenza vaccine to provide protection to high-risk groups is necessary. With the aim of evaluating the immune responses elicited by the monovalent pandemic influenza A/H1N1vaccine, we investigated employees of a Mexican hospital for respiratory diseases. Methods. A paired blood samples were obtained before and one month post-vaccination (n=60). Antibodies anti-A/H1N1 pandemic influenza virus were determined by hemagglutinin inhibition and microneutralization. The frequency of IFN-[[Unsupported Character - Symbol Font γ]] producing T cells and $CD4^+$ and $CD8^+$ T cells proliferation in response to specific peptides of pandemic A/H1N1, seasonal H1N1 or seasonal H3N2 were determined by ELISPOT and flow cytometry respectively. Results. We observed a significant increase of the geometric mean titers (GMT) of antibodies against pandemic A/H1N1 post-vaccination, with a seroconversion rate of 48.3% and seroprotection rate of 66.7%. Nearly half of our study population had basal levels of IFN-[[Unsupported Character - Symbol Font γ]]-producing T cells and proliferation of $CD4^+$ in response to peptides of pandemic A/H1N1 virus that did not change after vaccination. The proliferation of $CD8^+$ T cells was significantly increased post-vaccination. Conclusions. The monovalent pandemic influenza A/H1N1 vaccine elicited a humoral response that did not reach the threshold necessary for successful vaccination but induces a significant increase of $CD8^+$ T cells proliferation, which could be used as a parameter of protective immunity induced by vaccination.

P6.11.26
Viral vector-based vaccines encoding multiple epitopes of Hepatitis C virus induce robust and protective T cells responses

***P. Ip**, A. Boerma, H. W. Nijman, J. Wilschut, T. Daemen;*
University Medical Center Groningen, Groningen, Netherlands.

Hepatitis C virus infection contributes to approximately one third of liver cirrhosis and hepatocellular carcinoma cases worldwide. Most cases cannot be cured by standard treatment with pegylated interferon-α and ribavirin and no vaccine is available yet. An absolute prerequisite for a therapeutic vaccine against HCV infection is the potency to induce vigorous and broad spectrum CD8 and CD4 T cells responses. Vaccines based on viral vectors are ideal candidates for therapeutic HCV vaccines as they elicit robust humoral and cellular immune responses. We generated HCV vaccines based on Semliki Forest virus (rSFV) expressing all- or parts of the non-structural (NS) proteins of HCV. Immunizations of mice with rSFV expressing all NS proteins induced strong and long-lasting NS3-specific CD8 T cell responses. The strength of the responses was similar to those induced with rSFV expressing only two NS proteins. Immunizations furthermore resulted in a significant delay of tumor-growth of HCV-expressing EL4 tumor cell. To our knowledge, this is the first study showing that the size of transgene does not affect the activity of rSFV particles even when a transgene as large as 6 kb is inserted. As broad spectrum T cell responses in general are only seen in patients that clear an HCV infection, vaccines based on rSFV, allowing expression of all NS proteins, and inducing robust T cell activity as well as the essential broad spectrum T cell response have a high potential for the treatment of HCV infections.

P6.11.27
DNA vaccine encoding Hantavirus glycoprotein N-terminal, targeted to the major histocompatibility complex II compartment by lysosome-associated membrane protein, significantly elicits both specific humoral and cellular immune responses and induces immune protection against Hantavirus challenge in Balb/c mice

***D. Jiang**[1,2], Y. Sun[1], L. Cheng[3], C. Dong[1,4], K. Yan[1,2], F. Zhang*[3], K. Yang*[1];*
[1]Department of Immunology, The Fourth Military Medical University, Xi'an, China, [2]Brigade of Cadet, The Fourth Military Medical University, Xi'an, China, [3]Department of Microbiology, The Fourth Military Medical University, Xi'an, China, [4]Department of Biotechnology Lochus, School of Pharmacy, The Fourth Military Medical University, Xi'an, China.

Lysosome-associated membrane protein (LAMP) can target and bind the endosome/lysosome, the most important components of the MHC class II-processing compartment (MIIC) in the exogenous antigen-processing pathway. LAMP-targeting could greatly enhance the immune response against a number of antigens and DNA plasmids encoding endogenous antigen could take advantage of LAMP and be carried directly into MIIC. Hantavirus glycoprotein N-terminal, named Gn, could induce neutralizing antibody production, though a low serum titer as natural infection. To analyze the influence of LAMP on Hantaan virus (HTNV) Gn vaccine
potency and develop a novel effective vaccine against HTNV, we constructed three eukaryotic vectors as naked DNA vaccine named pVAX-Gn, pVAX-LAMP and pVAX-LAMP/Gn, respectively. Balb/c mice were immunized with those plasmids, and the specific humoral and cellular responses elicited against Gn were measured by ELISA, cytotoxicity assays and ELISpot assay. To measure the protective efficacy, virus challenging in vivo and neutralizing antibody valence were conducted by viral load detection (qRT-PCR and sandwich ELISA) and the cell microculture neutralization test. We found that HTNV Gn showed a strong immunogenicity to elicit both humoral and cellular responses with LAMP as a chimera. Results of protection assay in vivo indicated the immune response established was HTNV specific and protective. These findings not only demonstrate that the LAMP as a trafficking molecule can introduce Gn to MHCII-presenting pathway and significantly enhance HTNV specific immune response, but also suggest that the pVAX-LAMP/Gn as DNA vaccine has potential application on clinic for HTNV infection immunoprophylaxis.

P6.11.28
Antibody-driven vaccine design: a human cytomegalovirus pentameric vaccine selectively eliciting potent neutralizing antibodies

***A. Kabanova**[1], D. Lilleri[2], S. Becattini[3], G. Agatic[3], G. Gerna[2], D. Corti[3], A. Lanzavecchia[3];*
[1]University of Siena, Siena, Italy, [2]Fondazione IRCCS Policlinico San Matteo, Pavia, Italy, [3]Institute for Research in Biomedicine, Bellinzona, Switzerland.

The use of neutralizing antibodies to identify novel target antigens has been proposed as an effective strategy to identify candidate vaccines capable of eliciting protective B cell immunity. We previously showed that human neutralizing human cytomegalovirus (HCMV)-specific antibodies can be divided in two groups: (a) antibodies recognizing glycoproteins B (gB) and H (gH) able to neutralize viral infection at nanomolar concentrations, and (b) antibodies recognizing the viral gH/gL/UL128-131 complex able to neutralize viral infection at picomolar concentrations. In this study, we produced a recombinant gH/gL/UL128-131 pentameric complex which preserved all the functional antigenic sites targeted by human neutralizing antibodies and when formulated with a non-denaturing polyanionic carbomer adjuvant was found to induce strong neutralizing antibody response in mice. The pentamer was superior to gB, which represents a candidate vaccine in ongoing clinical trials, both in terms of neutralizing antibody titers and protection of different cellular targets. Through a clonal analysis of the response in vaccinated mice and infected humans, we found that most of the antibodies elicited by the pentamer were neutralizing and effective in the picomolar range, while most antibodies elicited by gB were not neutralizing. These results illustrate how potent neutralizing antibodies can be used to identify, within a complex pathogen, the most effective antigens capable of eliciting a protective response.
Our research project was supported by a grant from Cariplo Foundation, Italy.

P6.11.29
Human alpha-1-antitrypsin therapy blocks multiple organ dysfunction syndrome and diminishes bacterial load in a mouse bacterial sepsis model

***Z. Kaner**, D. E. Ochayon, G. Shahaf, B. M. Baranovski, M. Mizrahi, E. C. Lewis;*
Ben-Gurion University of the Negev, Beer-Sheva, Israel.

Background: Severe bacterial infection can cause sepsis, multiple organ dysfunction syndrome (MODS) and death. Human alpha-1-antitrypsin (hAAT) is a circulating serine-protease inhibitor that rises during acute phase responses and possesses anti-inflammatory, immune-modulating and tissue-protective properties. Evidence suggests that hAAT may also have the potential to block microbial activity. hAAT is clinically available and currently evaluated for individuals that are not genetically-deficient in hAAT. Aim: Examine whether hAAT improves prognosis in bacterial infection and sepsis model. Methods: Mice transgenic for hAAT (hAAT+/+) and hAAT-injected wild-type mice were compared to untreated wild-type mice in a cecal ligation and puncture (CLP) model. Animal survival, bacterial load and liver and pancreas function were determined, lungs were examined by histology and cytokine and immune cell profiles were obtained. Results: hAAT significantly reduced mortality, as well as liver and pancreas injury, and diminished apoptosis in lung cells. Stimulated circulating IL-1β levels were reduced 358.9±185-fold. Immune cells exhibited a phenotype of reduced activation; surface CD86, CD40 and MHC II on peritoneal cells were 10.05±1.801-fold, 16.50±1.371-fold and 6.925±4.739-fold lower in hAAT+/+ mice compared to wild-type mice. Surprisingly, bacterial load in peritoneal lavages was markedly lower in the hAAT group. Conclusions: hAAT therapy affords a significant reduction in bacterial burden after live bacterial infection. Its ability to reduce organ damage and death rates render it an attractive approach for individuals prone to infections. Since bacteria can readily proliferate in hAAT-containing media, the mechanism of action appears to be host-dependent, suggesting a lower risk for the emergence of bacterial resistance.

P6.11.30

In silico prediction of promiscuous Leishmania infantum KMP-11, H1, LeIF, CPA, CPB peptides and experimental validation of eliciting CD4+ and CD8+ T-cell specific responses

*M. Agallou, O. Koutsoni, E. Dotsika, **E. Karagouni**;*
Hellenic Pasteur Institute, Athens, Greece.

Previous studies on leishmaniasis have demonstrated that both IFNγ-producing $CD4^+$ and $CD8^+$ T lymphocytes are significant players in protection mechanisms against visceral disease. Recent trend on vaccine designing has been shifted to peptide vaccines based on computational prediction of immunodominant T-cell epitopes that are more specific, safe, and easy to produce. *Leishmania infantum* KMP-11, H1, LeIF, CPA and CPB were screened for antigenic epitopes by using online bioinformatics tools (BIMAS, NetCTL, NetMHCII, SYFPEITHI, EpiJen) on their ability to bind promiscuously to mice and human MHC class I and II molecules. Peptides were selected only if were selected by the most of programs used according to their predicitive scores. From the predicted epitopes, 10 peptides were synthesized that contained both MHC class I and II specific epitopes for each protein, characterized as “polyepitope” peptides. To validate polyepitope peptides immunogenicity experimentally, BALB/c mice were immunized subcutaneously 3 times with two different peptide pools. Cellular responses were detected by proliferation assays, flow cytometry and ELISA. Six out of ten (60%) induced proliferative responses in lymph nodes, whereas only three peptides (30%) induced spleen cells proliferation. These peptides were also potent inducers of $CD4^+IFN\gamma^+$ and/or $CD8^+IFN\gamma^+$ T cells as confirmed by flow cytometry. Finally, four peptides were selected for further vaccination experiments against visceral leishmaniasis, CPA_2, H1_1, LeIF_6 and CPB_1, based on their ability to induce strong T cell responses, suggesting that promiscuous T-cell epitopes can be identified using reverse vaccinology.

P6.11.31

Recombinant polyepitop-forming chimera protein derived from Borrelia burgdorferi OspC variants induces specific antibodies recognizing wide spectrum of antigenic variants of pathogenic Borreliae

***M. Krupka**[1], J. Masek[2], R. Cahlikova[1], B. Knoppova[1], E. Weigl[1], M. Sebela[3], J. Turanek[2], M. Raska[1];*
[1]Department of Immunology, Faculty of Medicine, Palacky University in Olomouc, Olomouc, Czech Republic, [2]Veterinary Research Institute, Brno, Czech Republic, [3]Department of Biochemistry, Faculty of Science, Palacky University in Olomouc, Olomouc, Czech Republic.

Lyme disease is the most frequent zoonosis in Europe and in the United States. It may progress into a chronic form and could lead to nervous or cardiovascular system, joints, skin or eyes affections. Outer surface protein C (OspC) is 23 kDa, lipoprotein antigen of spirochete Borrelia burgdorferi species complex - causative agent of Lyme disease. OspC is one of the most promising candidates for vaccine design. Due to high sequence variability of OspC it is not possible to induce protective immunity to broader range of Borrelia strains by single variant of OspC protein.
In this study, we created a fusion chimera recombinant protein (chOspC) composed of OspC immunodominant domains from most frequent infective strains of B. burgdorferi. Protein was expressed in E. coli in fusion with His-tag allowing metalloaffinity chromatography purification. Identity of protein was confirmed by MALDI-TOF.
Recombinant chOspC was used for the immunization of experimental mice. Hyperimmune sera were tested to evaluate their reactivity with several OspCs using Western blot and human diagnostic line-blot stripes. Mice immunized with B31 variant of OspC served as a control.
Sera of chOspC-vaccinated mice reacted specifically and strongly with whole B. burgdorferi bacteria lysates on Western blot forming single band at position corresponding to OspC as well as with all three OspCs from selected pathogenic subspecies on line blot. In contrast, control sera reacted to only subspecies-specific OspC. Described properties are promising for further testing of chOspC protein as potential Lyme disease vaccine component.
Supported by grants LF_2013_13, TA01011165 and GAP304/10/1951.

Antigen-presenting cells (APCs) are responsible for presenting foreign antigens to, and activating T cells to fight off infection. Manipulation of APCs to modulate immune responses to immunization has been a focus in vaccinology. Due to high frequencies of APCs in the skin, we are interested in the skin as a site for immunization. Keratinocytes and skin-resident plasmacytoid dendritic cells can be activated via binding of their Toll-like receptor 9 to CpG oligodeoxynucleotides (ODN) – synthetic DNA that mimic unmethylated CpG bacterial DNA. Here, we encapsulated the ovalbumin (OVA) antigen in polylactide co-glycolide microparticles (PLG-OVA) and show that mice immunized subcutaneously in a prime-boost regime with PLG-OVA generate antigen-specific cytotoxic T cells when CpG ODN is used as an adjuvant. Using flow cytometric analysis, 2.3% antigen-specific cells are detected within the $CD8^+$ T cell population in the blood when CpG ODN is administered topically ($P<0.05$ compared to PLG-OVA alone). In addition, 0.8% of $CD8^+$ splenocytes produce interferon-gamma when re-stimulated with OVA peptide (SIINFEKL) *in vitro* ($P<0.001$). The microparticles show a triphasic release of OVA which simulates two doses of antigen injected separately. Using this release property and a second topical application of adjuvant, we enhance the generation of antigen-specific cytotoxic T cells in the blood from 0.4 to 0.9% ($P<0.05$) and OVA-specific total IgG and IgG2c production, effectively generating a single-injection vaccine with split topical adjuvant administration that induces robust cytotoxic T cell and antibody responses. Generating single-injection vaccines may enhance vaccination compliance and may also decrease the cost of administration.

P6.11.33

An animal model serum cytokine profile (Th1 & Th2) for new formulation of Leishmania major post challenging

***A. Latifynia**[1], A. , Khamesipour[2], S. , Bokaie[3], M. Gharagozlou[4], M. Vojgani[1], N. Khansari[1];*
[1]Tehran University of Medical Sciences, Tehran, Iran, [2]Leprosy and Dermal disease Center, Tehran University of Medical Sciences, Tehran, Iran, [3],Department of Epidemiology, Faculty of Veterinary Medicine, University of Tehran, Tehran, Iran, [4]2Department of Pathobiology, Veterinary Medicine, University of Tehran, Tehran, Iran.

Leishmania is diffused worldwide, resulting in estimated 12 million new cases each year. In the case of cutaneous leishmaniasis effective protection against infection has been largely attributed to the development of potent CD4+ Th1 type immune response, characterized by the production of IL-12 and IFNγ, which subsequently mediates macrophage activation, nitric oxide production and parasite killing. The effect of BCG on the course of established Murine leishmaniasis was examined before. Although to date there is no vaccine against leishmania; several of the vaccine preparations spend their advanced stages of clinical testing. Up to know, several different methods of vaccine preparation have been used which is plus or without adjutant. We had prepared crude antigen combinations by five different methods using antigens from L.major parasites with five injection doses, before. Also, its safety, toxicity, efficacy and immunogenicity evaluated pre challenge in animal models. In this study examined both BCG and new adjuvant (Teucrium polium (T.P), three injection groups Λ(LT, LB, LBT) and two injection doses (100, 200 µg/.0.1ml) in Balb/c mice post challenge.In six injected groups Th1 (IFN-γ, IL-12) and Th2 cytokines (IL-4, IL-10) were measured. Our results showed that in three injection groups (LB, LT and LBT) that obtained one of two adjutants; BCG/TP and or both of them and 100, 200µg/0.1ml with two booster doses: LBT group has lowest IFNγ and highest IL-12 value, LT and LB groups have equal IL-12, but LB have more IFNγ and IL-10 but less than IL-4 in LT group

P6.11.34
HIV infected individuals demonstrate significantly reduced polysaccharide-specific B cell response to T-cell independent vaccination compared to non-infected individuals

***D. J. Leggat**, A. S. Iyer, N. M. Khaskhely, M. Westerink;*
University of Toledo-Health Science Campus, Toledo, OH, United States.

The peripheral blood of newly diagnosed HIV infected individuals is subjected to high uncontrolled viral titers. The decimation of both T and B cells thus leaves these individuals highly susceptible to opportunistic infections, including Streptococcus pneumoniae, despite the availability of vaccines. We have previously shown using directly labeled fluorescent pneumococcal polysaccharides that the majority of pneumococcal polysaccharide-specific B cells in healthy individuals were IgM+ memory B cells. Using this method, we identified specific deficiencies in B cell populations responding to pneumococcal polysaccharide vaccination in HIV infected individuals. Namely, a significant decrease in the pneumococcal polysaccharide-specific IgM+CD27+CD43+CD5+/-CD70- B cell population compared to healthy individuals. This population has recently been described as human B1 cells. Consequently, HIV infected individuals showed reduced polysaccharide specific antibody responses and opsonophagocytic titers compared to healthy individuals. Furthermore, we correlated changes in pneumococcal polysaccharide-specific B cell populations post-vaccination with individual CD4+ T cell counts. We observed a decreasing trend in pneumococcal polysaccharide-specific IgM+ memory B cells with lower CD4+ T cell counts despite the T-independent type II nature of the polysaccharide vaccine antigens. These data indicate that the loss of pneumococcal polysaccharide-specific IgM+CD27+CD43+CD5+/-CD70- B cells in HIV infected individuals correlates with their CD4+ T cell counts and results in poor responsiveness to pneumococcal vaccination.

P6.11.35
Characterization of CMV-specific T-cell receptors for clinical application

***X. Liang**[1], S. Ameres[1], S. Krebs[2], L. Schirrmann[1], H. Blum[2], A. Moosmann[1];*
[1]Clinical Cooperation Group Immunooncology, Helmholtz center Munich and University of Munich, Munich, Germany, [2]Laboratory of Functional Genome Analysis, Gene Center, University of Munich, Munich, Germany.

Adoptive therapy with specific T cells can control cytomegalovirus (CMV) reactivation and disease in immunocompromised patients. However, many donors of an allogeneic stem cell transplantation are CMV-negative and thus cannot provide CMV-specific T memory cells. Such T cells can be artificially produced for therapy by T-cell receptor gene transfer. Important criteria for selection of suitable TCRs for therapy include (1) absence of alloreactivity and (2) efficient recognition of infected cells.
It was previously found that many CMV-specific T cells exhibit alloreactivity. We determined the TCR sequences of various CMV-specific T cell clones specific for two pp65-derived epitopes (YSE, HLA-A*0101 and NLV, HLA-A*0201), and have analyzed their reactivity against a panel of B-cell lines that cover 41 of the most frequent HLA allotypes. We identified three NLV-specific and eight YSE-specific TCRs without alloreactivity against frequent HLA allotypes, including allotypes that are cross-recognized by other NLV-specific T cells.
T cells specific for the CMV antigen IE-1 are associated with control of CMV reactivation in immunocompromised patients, but IE-1 appeared to be poorly presented by infected cells. We recently identified IE-1- specific CD8 T cells that overcome these immunoevasive effects. They recognize a novel immunodominant HLA-C-restricted epitope (CRV, HLA-C*0702). We show that these T cells express a multitude of different TCRs, some of which are shared between different donors. Widely shared ("public") TCRs may be preferable for therapy because of their compatibility with various HLA allotypes. We currently analyze the CRV-specific TCR repertoire at high resolution to identify public TCRs for therapy.

P6.11.36
Long-term follow-up study to the Fiji Pneumococcal Project: Investigation of immune hyporesponsiveness following a 12-month pneumococcal polysaccharide booster

***P. V. Licciardi**[1,2], E. Clutterbuck[3], A. Balloch[4], Z. Toh[4], K. Bright[1], F. M. Russell[1,5], M. L. K. Tang[6,2,7], A. Pollard[3,8], E. K. Mulholland[1,9];*
[1]Pneumococcal Research, Murdoch Childrens Research Institute, Melbourne, Australia, [2]Department of Paediatrics, University of Melbourne, Melbourne, Australia, [3]Centre for Clinical Vaccinology and Tropical Medicine, University of Oxford, Oxford, United Kingdom, [4]Pneumococcal Laboratory, Murdoch Childrens Research Institute, Melbourne, Australia, [5]Centre for International Child Health, Murdoch Childrens Research Institute, Melbourne, Australia, [6]Allergy and Immune Disorders, Murdoch Childrens Research Institute, Melbourne, Australia, [7]Allergy and Immunology, Royal Children's Hospital, Melbourne, Australia, [8]Department of Paediatrics, University of Oxford, Oxford, United Kingdom, [9]London School of Hygiene and Tropical Medicine, London, United Kingdom.

Background & Aim: The Fiji Pneumococcal Project (FiPP) examined the immunogenicity of reduced dose schedules comprising pneumococcal conjugate (PCV) and polysaccharide (PPS) vaccines. Following a micro-PPS (20%) challenge dose at 17 months, children that received the PPS at 12 months age exhibited immune hyporesponsiveness in terms of serotype-specific IgG and opsonophagocytic (OPA) levels. The 12-month PPS dose also had no impact on vaccine-type carriage.
Methods: This was a follow-up study to examine the long-term immunological impact of the 12-month PPS booster. Blood samples were taken pre- and 28-days post-PCV13 immunisation from the first 101 children (now 4-6 years old) re-consented into this study. To date, analysis includes specific IgG measurement to all 23 serotypes in PPS as well enumeration of the memory B cell response to serotypes 1, 3, 4, 6B, 14, 19F and 23F.
Results: Significantly lower pre-PCV13 IgG levels for 6B (p=0.003), 22F (p=0.024) and 23F (borderline p=0.053) were detected in children that received the 12-month PPS; after PCV13, only serotype 22F IgG was lower in PPS-vaccinated children compared to those that weren't (p=0.009). Memory B cell responses were not different before PCV13, however a significantly lower number of 23F-specific B cells (p=0.021) post-PCV13 were found in children given PPS at 12 months of age.
Conclusion: With the exception of a few serotype, immune hyporesponsiveness was no longer observed before or after PCV13 vaccination. Analysis is ongoing to evaluate the impact of the PPS booster in this study.

P6.11.37
Improvement in clinical signs and cellular immunity of dogs with visceral leishmaniasis using the immunomodulator P-MAPA

***V. M. Lima**[1,2], M. B. Santiago[1], L. S. Neto[1], M. A. Somenzari[1], P. C. Ciarlini[1];*
[1]UNESP, Araçatuba, Brazil, [2]Universidade Estadual Paulista, Araçatuba, Brazil.

This study investigated the immunotherapeutic potential of the protein aggregate magnesium-ammonium phospholinoleate-palmitoleate anhydride immuno-modulator (P-MAPA) on canine visceral leishmaniasis. Twenty mongrel dogs presenting clinical symptoms compatible with leishmaniasis and diagnosis confirmed by the detection of anti-Leishmania antibodies were studied. Ten dogs received 15 doses of the immunomodulator (2.0 mg/kg) intramuscularly, and 10 received saline as a placebo. Skin and peripheral blood samples were collected following administration of the immunomodulator. The groups were followed to observe for clinical signals of remission; parasite load in the skin biopsies using real-time PCR, the cytokines IL-2, IL-10 and IFN-γ in the supernatant of peripheral blood mononuclear cells stimulated in vitro with either total promastigote antigen or phytohemagglutinin measured by capture ELISA, and changes in CD4+ and CD8+ T cell subpopulations evaluated by flow cytometry. Comparison between the groups showed that treatment with the immunomodulator promoted improvement in clinical signs and a significant reduction in parasite load in the skin. In peripheral blood mononuclear cell cultures, supernatants showed a decrease in IL-10 levels and an increase in IL-2 and IFN-γ. An increase in CD8+ T cells was observed

in peripheral blood. In addition, the in vitro leishmanicidal action of P-MAPA was investigated using 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) and no leishmanicidal activity was detected. These findings suggest that P-MAPA has potential as an immunotherapeutic drug in canine visceral leishmaniasis, since it assists in reestablishing partial immunocompetence of infected dogs.

P6.11.38
A novel tool for induction of specific T-cell immune responses: Complexes of streptavidin-fused antigens with biotinylated antibodies targeting receptors on dendritic cell surface

*O. Stanek[1,2], **I. Linhartova**[1], L. Majlessi[3,4], P. Jinoch[5], F. Skrob[5], C. Leclerc[3,6], P. Sebo[1];*
[1]Institute of Microbiology, Czech Academy of Sciences, Prague, Czech Republic, [2]Department of Biochemistry and Microbiology, ICT Prague, 166 28 Prague 6, Czech Republic, Prague, Czech Republic, [3]Unité de Régulation Immunitaire et Vaccinologie, Paris, France, [4]dInstitut National de la Santé et de la Recherche Médicale U883, 75724 Paris Cedex 15, France, Paris, France, [5]EXBIO Praha, a.s., Nad Safinou II 341, 252 42 Vestec, Czech Republic, Prague, Czech Republic, [6]Institut National de la Santé et de la Recherche Médicale U883, 75724 Paris Cedex 15, France, Paris, France.

For various diagnostic and vaccinal applications, it is important to stimulate antigen-specific immune responses of T lymphocytes. This remains a technical challenge, as it depends on targeted delivery of antigens into cytosol or endosomes of professional antigen presenting cells (APCs), such as dendritic cells, which process antigens and present them to T cells in complex with MHC class I and II molecules, respectively.
Here we describe a novel system for antigen delivery into APCs that offers high flexibility of targeting of various endocytic receptors. The system is based on genetic fusion of the antigen of choice with streptavidin that in its tetrameric form binds a biotinylated targeting antibody recognizing an endocytic receptor on the surface of APC.
As a proof of principle, chicken ovalbumin or the mycobacterial antigens CFP-10 and ESAT-6, as well as antigen pp65 of cytomegalovirus were used as model antigens that were genetically linked to N- or C-terminal ends of the streptavidin core protein. Purified tetrameric antigen-streptavidin (Ag-SA) complexes with antibodies against surface receptors CD11b, CD11c, MHC II and DEC 206 (manose receptor) were formed and used for antigen delivery into mouse dendritic cells or human PBMC *in vitro,* injected or administered intranasally into mice for induction of systemic and mucosal immune responses *in vivo*. Analysis of the capacity of such-treated APCs to stimulate specific T cell response revealed that efficient epitope presentation on MHC class I and II molecules can be achieved *in vitro* already at antigen concentrations of 0.1 - 1 nM.

P6.11.39
Vaccine-mediated B cells responses to *S. aureus* hemolysin, and effect of different boosting intervals on functional humoral responses

***G. Lofano**[1], F. Mancini[2], M. Fiorillo[1], S. Bertholet[3];*
[1]University of Rome "La Sapienza", Rome, Italy, [2]University of Padova, Padova, Italy, [3]Novartis V&D, Siena, Italy.

Although antibody titers are usually considered the best readout for vaccine efficacy, the importance of memory B-cell responses in conferring protection has remained controversial. Primary exposure to an antigen generates, along with antibody-secreting cells (ASCs), a heterogeneous B-cell memory compartment that changes over time and that may respond in different ways when re-encountering the cognate antigen. The goal of this study is to characterize B-cell responses after priming and the effect of different boosting intervals on the differentiation and function of ASCs and memory B cells. We used a vaccine model based on the alpha-Hemolysin (Hla) protein from *Staphylococcus aureus*, adjuvanted with Alum. This vaccine induced high antibody titers and was protective in sepsis and pneumonia animal infection models. We performed a time course analysis following one or two immunizations, two weeks apart: mice immunized twice had higher anti-Hla IgG titers compared to mice immunized once. ASCs measured by Elispot were increased in spleen 10 days after boosting and remained elevated in bone-marrow for at least 4 months. A similar trend was observed between the two groups when looking at the frequencies of Hla-specific memory B cells. Next steps will address the phenotypic and functional characterization of Hla-specific memory B cells to define a correlation between different boosting intervals and the protective humoral response. This work aims at providing new insights in the memory B-cell compartment that might benefit the design of new vaccination strategies.

P6.11.40
Efficacy of Flu SAM (HA) vaccine against Influenza infection in mice

*M. Brazzoli[1], **D. Magini**[2], S. Buccato[1], A. Bonci[1], D. Casini[1], S. Mangiavacchi[1], L. Brito[3], D. Maione[1], A. Geall[3], S. Bertholet[1];*
[1]Novartis, Siena, Italy, [2]Università di Siena, Siena, Italy, [3]Novartis, Cambridge, MA, United States.

Influenza (Flu) is a vaccine preventable disease but remains a major problem worldwide and vaccine production remains suboptimal. SAM vaccines, developed from self-amplifying RNA encoding an antigen and delivered with a non-viral delivery system, could potentially address current vaccine production limitations during a new pandemic influenza outbreak.
In this study, we demonstrated that a pandemic H1-SAM vaccine induced humoral immune responses comparable to non-adjuvanted subunit vaccine, both in terms of total antibody titers and functionality in mice. Antibodies induced by immunization with a SAM (HA) vaccine were able to neutralize virus infectivity and inhibit HA activity. In conclusion, if the SAM vaccine platform proves safe, potent, well-tolerated and effective in humans, fully synthetic vaccine technologies could provide a rapid response platform to influenza outbreaks.

P6.11.41
CXCL10 is critical for the generation of protective CD8 T cell response induced by antigen pulsed CpG-ODN activated dendritic cells

***S. Majumder**, S. Bhattacharjee, B. Paul Chowdhury, S. Majumdar;*
Bose Institute, Kolkata, India.

The visceral form of leishmaniasis is the most severe form of the disease and of particular concern due to the emerging problem of HIV/visceral leishmaniasis (VL) co-infection in the tropics. Till date miltefosine, amphotericin B and pentavalent antimony compounds remain the main treatment regimens for leishmaniasis. However, because of severe side effects, there is an urgent need for alternative improved therapies to combat this dreaded disease. In the present study, we have used the murine model of leishmaniasis to evaluate the potential role played by soluble leishmanial-antigen-pulsed-CpG-ODN stimulated dendritic cells in restricting the intracellular leishmanial growth. We found that mice vaccinated with a single dose of SLA-pulsed DC stimulated by CpG-ODN were protected against a subsequent leishmanial challenge and had a dramatic reduction in parasite burden along with the generation of parasite specific cytotoxic T lymphocytes. Moreover, we demonstrate that the induction of protective immunity conferred by SLA-CpG-DCs depends entirely on the CXC chemokine IFN-c-inducible protein 10(CXCL10). CXCL10 is directly involved in the generation of a parasite specific CD8+ T cell-mediated immune response. We observed significant reduction of CD8+ T cells in mice depleted of CXCL10 suggesting a direct role of CXCL10 in the generation of CD8+ T cells in SLA-CpG-DCs vaccinated mice. CXCL10 also contributed towards the generation of perforin and granzyme B, two important cytolytic mediators of CD8+ T cells, following SLA-CpG-DCs vaccination. Together, these findings strongly demonstrate that CXCL10 is critical for rendering a protective cellular immunity during SLA-CpG-DC vaccination that confers protection against Leishmania donovani infection.

P6.11.42

DNA vaccine encoding hepatitis C virus proteins NS3-NS5B induces more effective immune response in comparison with DNAs expressing individual nonstructural genes

O. V. Masalova[1], *E. I. Lesnova*[1], *A. V. Ivanov*[2], *A. Pichugin*[3], *K. Y. Permyakova*[1], *R. I. Ataullakhanov*[3], *A. A. Kushch*[1];
[1]*D.I.Ivanovsky Institute of Virology, Moscow, Russian Federation,* [2]*Engelhardt Institute of Molecular Biology, Moscow, Russian Federation,* [3]*Institute of Immunology, Moscow, Russian Federation.*

Currently, there are several DNA vaccines against hepatitis C virus (HCV) being tested, but the optimal composition of HCV genes is not yet defined. The goal of study was to evaluate the effectiveness of genetic immunization of mice with DNA pcNS3-NS5B encoding five hepatitis C virus (HCV) nonstructural proteins: NS3, NS4A, NS4B, NS5A and NS5B in comparison with plasmids containing genes of the same individual nonstructural proteins. The HCV DNA constructions with gene GM-CSF as adjuvant were injected intramuscularly in DBA mice three times. Humoral immune response was assessed with ELISA; cellular immune response - in blast transformation reaction, by quantitation of CD4+ and CD8+ T cell proliferation using flow cytofluorimetry, by intracellular synthesis and secretion of IFN-γ and IL-2 in ELISpot and ELISA. It was found that the functionally active T cell response was achieved to antigens presenting NS3, NS4, NS5A and NS5B epitopes of different HCV genotypes in response to pcNS3-NS5B plasmid and was stronger than that to plasmids carrying individual genes. Injection of pcNS3-NS5B induced high CD4+ T cells proliferation, IL-2 and IFN-γ secretion, anti-NS3 and anti-NS5B IgG2a production. These findings indicate that genetic immunization with pcNS3-NS5B is promising approach for development of hepatitis C vaccine.

P6.11.43

Vaccination with recombinant empty capsids of foot-and-mouth disease virus triggered an immune response that surpassed the viral challenge in a mice model

A. C. Mignaqui[1,2], *V. Ruiz*[1,2], *V. Gnazzo*[1,2], *A. Sammarruco*[1], *S. Perret*[3], *G. St-Laurent*[3], *Y. Durocher*[3], *A. Wigdorovitz*[1,2];
[1]*Virology Institute, INTA, Hurlingham, Argentina,* [2]*CONICET, Buenos Aires, Argentina,* [3]*Biotechnology Research Institute, NRC, Montreal, QC, Canada.*

The use of recombinant empty capsids against foot-and-mouth disease virus (FMDV) has been reported to be a promising alternative to the current inactivated vaccine.
The encoding sequences of the capsid precursor P12A and the protease 3C were used to generate the expression vectors pTT5-P12A3C and pTT5-P12A. When cells were transfected with pTT5-P12A3C, the protease 3C cleaved the capsid precursor P12A into the structural proteins VP0, VP1 and VP3 that assembled into empty capsids.
To evaluate the immunogenicity of the recombinant proteins, mice were immunized with a low amount of virus that elicits an immune response in all animals and the equal amount of recombinant proteins.
Mice inoculated with the lysates of cells transfected with pTT5-P12A3C and with inactivated FMDV induced high antibody serum titers at 14 days post vaccination that increased after booster immunization and were protected against viral challenge. Mice inoculated with the lysates of cells transfected with pTT5-P12A induced low antibody serum titers that did not increase after booster immunization.
A significant difference was observed in the immune response elicited in the animals vaccinated with P12A3C or P12A recombinant proteins, confirming that the correct cleavage of P12A by protease 3C and assembly of the structural proteins is critical to achieve a protective immunity. Furthermore, the structures produced by transient gene expression in mammalian cells with pTT5-P12A3C induced high levels of antibody and protection against viral challenge in mice suggesting that the strategy is a suitable alternative for vaccine production.

P6.11.44

A novel HPV-16 L1 based chimeric virus-like particle containing HPV 16 E6 and E7 epitopes elicits a persistent specific antibody immune response and tumor regression

A. Monroy-García[1,2], *M. A. Gómez-Lim*[3], *J. Hernández-Montes*[4], *B. Weiss-Steider*[4], *R. García-Rocha*[1], *M. Mora-García*[4];
[1]*CMN SXXI IMSS, Mexico D.F, Mexico,* [2]*FES-ZARAGOZA UNAM, Mexico d.f, Mexico,* [3]*CINVESTAV, Irapuato, Guanajuato, Mexico,* [4]*FES-ZARAGOZA UNAM, Mexico D.F, Mexico.*

HPV L1-based virus like particles vaccines (VLPs) are efficient to induce temporary prophylactic activity through the induction of neutralizing antibodies. However VLPs that can provide prophylactic as well as therapeutic properties for a long time are necessary. We generated a novel HPV 16 L1-based chimeric virus like particle (cVLP) that was produced in plants and that contains a string of T-cell epitopes from HPV 16 E6 and E7 fused to its C-terminus. In the present study we analyzed the persistence of specific IgG antibodies with neutralizing activity induced by the immunization with cVLPs, as well as their therapeutic potential in a tumor model of C57BL/6 mice strain. Interestingly, we obtained that these cVLPs induced persistent IgG antibodies for over 12 months, with cross-reactivity and cross-neutralizing activity for VLPs composed of HPV-16 L1 protein. Efficient prevention and rejection of tumors induced by TC-1 tumor cells expressing HPV-16 E6/E7 oncoproteins was observed in mice immunized with these cVLPs. In addition, in mice bearing tumors, important tumor regression (57%) was observed after immunization with cVLPs. The chimeric particles of the type described in this work may potentially be the basis for developing HPV prophylactic and therapeutic vaccines with high efficacy. Support: CONACYT (82827 and 8373); FIS-IMSS/PROT (60 and 617 and 876) grants.

TELL ME project for an effective communication during infectious outbreaks

E. Mordini[1], *M. Green*[2], *D. Greco*[1], *B. De Mei*[3], *R. Satolli*[4], *N. Gilbert*[5];
[1]*Centre for Science, Society and Citizenship, CSSC, Rome, Italy,* [2]*School of Public Health at the University of Haifa, Haifa, Israel,* [3]*National Centre for Epidemiology, Surveillance and Health Promotion, CNESPS, Rome, Italy,* [4]*Zadig ltd, Rome, Italy,* [5]*Centre for Research in social simulation, CRESS, Guildford, United Kingdom.*

During infection outbreaks, one of the major problems has always been to communicate with the population in order to influence behaviors, reduce the spread of disease and avoid panic. TELL ME (Transparent communication in Epidemics: Learning Lessons from experience, delivering effective Messages, providing Evidence) is a 36 month Collaborative Project, funded by the European Commission (FP7), which aims to provide evidence and to develop models for improved risk communication during infectious disease crises. TELL ME combines public health, social sciences, behavioral scie nces, political sciences, law, ethics, communication and media, in order to develop original communication strategies regarding complicated messages and advice based on uncertainties, also addressing the issue of vaccine-resistant groups.
TELL ME aims to identify the most appropriate tools to raise awareness about pandemic risk and to deal with complexity, uncertainty and misinformation on this topic. Amongst the project's main focuses there are also the new opportunities offered by social media for monitoring and epidemiologic surveillance; the narratives underlying the different reactions from different groups; the big issue of stigmatization and discrimination caused by communication mistakes; the cases of resistance to vaccines and the best strategies to support vaccinations.
Since communication is a multifaceted framework, such an effort is directed to all the stakeholders involved, from healthcare professionals to representatives of public health institutions, from researchers to local authorities, from journalists to the general population.
The research leading to these results has received funding from the European Union Seventh Framework Programme ([FP7/2007-2013] [FP7/2007-2011]) under grant agreement n° [278723].

P6.11.46
Selection of neutralizing scFv antibodies against glycoprotein B of Herpes simplex virus type1

F. Nejatollahi[1,2]*, V. Bagheri*[2]*, M. Motamedifar*[3]*;*
[1]Recombinant Antibody Laboratory, Dept. of Immunology, School of Advanced Medical Sciences and Technologies, Shiraz University of Medical Sciences, Shiraz, Iran, [2]Shiraz HIV/AIDS Research Center, Shiraz University of Medical Sciences, Shiraz, Iran, [3]Departments of Bacteriology- Virology, Shiraz University of Medical Sciences, Shiraz, Iran, Shiraz, Iran.

Introduction: Herpes simplex virus type 1 (HSV-1) is responsible for a wide range of human diseases from the localized infection such as orolabial or corneal lesions to lifethreatening encephalitis, neonatal disease and pneumonia in the immunocompromised individuals. Glycoprotein B (gB) play a critical role in the entry of the virus into target cells. Isolation of specific single chain antibodies (scFv) by antibody phage display has become a popular method in recent years. In this study, a phage display library was used to isolate specific neutralizing scFvs against gB of HSV-1.
Materials and Methods: Panning was performed by using human phage display library against the immunodominant epitope of gB. Fingerprinting was carried out on PCR-amplified scFvs. The reactivity of isolated clones to the peptide was determined by phage ELISA. The neutralising activities of scFvs were evaluated using plaque reduction assay.
Results: After four rounds of panning, PCR and DNA fingerprinting of clones, two specific clones for epitope of gB were selected. The frequencies of clones were 45% and 20% which showed neutralizing effects 59% and 55%, respectively.
Conclusions: There are some reports of identification of the neutralizing epitopes of gB by monoclonal antibodies. In this study, we selected two specific neutralizing scFvs against gB of HSV-1 which can be used as a promising immunotherapeutic tool for preventing neonatal herpes infection whenever passive immunization against HSV-1 is needed. Further investigations in vivo is needed to show the effects of soluble forms of the selected scFvs

P6.11.47
Vaccination with MenAfriVac, a serogroup A conjugate meningococcal vaccine, induces salivary antibodies that could prevent pharyngeal colonization

P. A. Kristiansen[1], L. Nome[1], K. Sinnadurai[1], R. Ouédraogo[2], F. Diomandé[3], D. Caugant[1,4], ***L. M. Ness***[1]*;*
[1]Norwegian Institute of Public Health (NIPH), Oslo, Norway, [2]Centre Hospitalier Universitaire Pédiatrique Charles de Gaulle, Ouagadougou, Burkina Faso, [3]WHO Inter country Support Team, Ouagadougou, Burkina Faso, [4]Faculty of Medicine, University of Oslo, Oslo, Norway.

Background. MenAfrivac, a conjugate vaccine to combat the devastating serogroup A meningococcal disease in sub-Saharan Africa, was first introduced in Burkina Faso in 2010. We have previously shown that the vaccine can eradicate meningococcal colonization. We therefore investigated if the vaccine could stimulate mucosal antibodies that prevent colonization.
Methods. A longitudinal study was conducted in 198 school children aged 10-14 years in Burkina Faso. Saliva was collected using OraSure collection device®, before vaccination with MenAfriVac and 9 weeks after. The concentrations of specific IgA and IgG (specific for serogroup A meningococcal capsular polysaccharide, PsA) and total IgG were determined by in-house bead-based multiplex assays (Bio-Plex) and ELISA. Total IgA was determined by a Bio-Plex kit (Bio-Rad).
Results. Specific IgG and IgA concentrations were significantly higher after vaccination (P<0.0001, paired t-test) while total IgG was lower and IgA concentrations remained stable. The proportion of individuals with detectable anti-PsA IgG increased from 22% (Geometric Mean Titer, GMT=1.5 ng/mL) before vaccination to 60% (GMT=18.1 ng/mL) after vaccination. This increase was likely due to IgG leaking from serum onto the mucosa. PsA-specific IgA was found in higher concentration than specific IgG and was detected in 99% of participants before vaccination (GMT=158 ng/mL). An increase in specific IgA titers was seen in 69% of vaccinees (GMT=255 ng/mL).
Conclusions. Immunization with MenAfriVac induced a significant increase of salivary IgG and IgA antibodies against serogroup A polysaccharide that could act as a first-line defence against meningococci and be a possible mechanism for the observed eradication of colonization.

P6.11.48
Interferon- and immunotherapy in immunocompromised children with associated viral-viral infections: recurrent acute respiratory viral infections (ARVI) and various herpesviral infections

I. V. Nesterova[1]*, S. V. Kovaleva*[2]*, O. Shinkareva*[2]*, L. N. Kokova*[2]*;*
[1]Russian University of Friendship of People, Moscow, Kuban State Medical University, Krasnodar, Russian Federation, [2]Kuban State Medical University, Krasnodar, Russian Federation.

The treatment of immunocompromised children with high-frequency of recurrent associated viral infections is very difficult. We had examined 27 children 5-8 years suffering from recurrent ARVI with a frequency of 17,2±1,01 episodes per year. The mono-and mixed infections (HSVI/II types, EBV, CMV, HHV6) were identified in 100% of cases. The control group included 20 healthy children. Functions of neutrophilic granulocytes (NG) and interferon (IFN) system were tested. Significant defects of phagocytic activity, killing and microbicidal (NADPH-oxidase) function of NG ($p<0.001$; $p<0.05$; $p<0.05$), the deficit of serum IFNα ($p<0.05$) and IFNγ ($p<0.05$) were present in all children. Patients were randomized into 2 groups. The group 1 received: a) basic systemic and local therapy viferon (recombinant IFNα2) with gradual reduction of doses,-2.5 months; b) for elimination herpes infections - izoprinozin, - three 10-days break courses. The group 2 received the same course of drugs as group 1: viferon, izoprinozin and additionally for the correction of NG - licopid - two 10-days break courses. In both groups clinical efficacy of the therapy during the study and in catamnesis were tested. We saw significant reduction in the frequency of ARVI to 2-3 times a year, prolongation of clinically successful period from 7-10 to 100-150 days. Adequate doses of recombinant IFNα2 had promoted significant growth of serum levels of IFNα ($p<0.001$) and IFNγ ($p<0.05$). Application of licopid had restored disturbed functions of NG in the group 2 ($p<0.001$; $p<0.05$; $p<0.05$), but not in the group 1. Interferon- and immunotherapy had a high clinical-immunological effectiveness, more pronounced in the group 2.

P6.11.49
Influence DNA-vaccines encoding antigens of CCHFV on immune system in mice

O. V. Nosareva*, T. A. Panova, A. E. Nesterov, S. V. Seregin, V. S. Petrov;*
State Research Center Virology and Biotechnology Vector, Koltsovo, Russian Federation.

Crimean-Congo hemorrhagic fever virus (CCHFV) - a tick-borne virus that is transmitted to humans through infected tick bites or by direct contact with viremic humans and animals. This is a nairovirus in the family Bunyaviridae causes, highly-contagious hemorrhagic disease with a fatality rate of approximately 30%, it distributed widely in many parts of World. The number of reported cases has increased in recent years, climatic change and human perturbations of biocenoses may have led to the migration of tick. There is currently no commercially available vaccine for CCHF.
The aim of this work was to evaluate efficiency as well as the type of immune response induced by candidate DNA-vaccines (pV3N and pV3GN) carrying the genes of structural proteins CCHFV in mice.
Various parameters including antibody and cytokine responses (INF-g, IL-2 and IL-10), proliferation assay were used to evaluate the type of immune response. To evaluate nonspecific influence the DNA-vaccines on immune system of mice lymphoproliferation in responses on T- and B-cell mitogens were measured. Our results have confirmed the immunogenicity of both individual plasmid pV3N and pV3GN in eliciting cellular Th1-immune response characterized by dominance of IgG2a, high level of INF-g. Moreover immunization with a mixture of these plasmids can enhance responses compared with the individual plasmid, so decreased the effect of immunosuppression.
Our results suggest that recombinant plasmids pV3N, pV3GN may be a candidate DNA vaccine, so they induce both cellular and humoral

immune responses, and the use of a mixture of plasmids is the most promising variant.

Adeno-associated virus (AAV) based Mycobacterium tuberculosis (MTB) vaccine induces humoral and cellular immune response in mice

A. Nowag[1], *J. Rybniker*[1], *K. Demant*[1], *S. Winter*[1], *H. Janicki*[2], *H. Büning*[2,3], *P. Hartmann*[1,4];
[1]*Infectious Diseases Laboratory; Department I of Internal Medicine; University Hospital of Cologne, Cologne, Germany,* [2]*Laboratory for AAV Vector Development; Department I of Internal Medicine; University Hospital of Cologne, Cologne, Germany,* [3]*Center for Molecular Medicine Cologne, University of Cologne, Cologne, Germany,* [4]*Institute for Medical Microbiology, Immunology and Hygiene; University Hospital of Cologne, Cologne, Germany.*

The current tuberculosis epidemic continues to call for the development of new and effective vaccines. Prompted by the recent findings that viral vector based vaccines are effective in boosting immune activation and protection by *bacillus Calmette-Guérin* (BCG) vaccination, we designed recombinant adeno-associated viral vectors encoding the mycobacterial antigen Ag85a. The presence of different serotypes allows various vaccination and booster strategies. Two serotypes were tested for both, humoral and cellular immune responses in Balb/c mice: rAAV2:Ag85a and rAAV5:Ag85a. A single intramuscular injection in Balb/c mice was well tolerated and lead to a strong and sustained humoral immune response towards Ag85a for both constructs under investigation. Furthermore, an intramuscular injection with AAV2:Ag85a followed by a booster injection with AAV5:Ag85a at week 4, induced a specific anti-Ag85a cellular immune response in isolated and cultivated splenocytes of vaccinated mice upon stimulation with Ag85a at week 8. To further enhance immunogenicity, capsid modifications were introduced. The AAV2 capsid was engineered as scaffold for Ag85a display providing a prime contact to the immune system, while the genome served as template for antigen expression thereby boosting the initial response (Ag85a-AAV2:Ag85a). Mice vaccinated with this single shot prime-boost vaccine developed antigen-specific immune responses significantly faster and at higher levels than mice treated with protein-based or conventional gene-based vaccines therefore offering earlier protection. Furthermore antigen-VP2 fusion is conceivable for a variety of applications such as vaccination with multiple antigens using a single construct. These findings demonstrate the potency of capsid modified AAV vectors in vaccine development.

P6.11.51
Evaluation of E. coli DNA vaccine expressing OmpT and Ag43 gene in BALB/c mice

A. A. Oñate[1], *P. Fernández*[1], *A. Retamal*[1], *R. Vidal*[2];
[1]*Universidad de Concepción, Concepción, Chile,* [2]*Universidad de Chile, Santiago, Chile.*

E. coli is part of the normal microbiota of the gastrointestinal tract of birds and mammals, however, some strains have been associated with gastrointestinal infections that affect humans and animals. Of these, exist a subset of Shiga toxin-producing E. coli (STEC), are capable of producing severe infections in humans as hemorrhagic colitis and hemolytic uremic syndrome (HUS). STEC infections can vary from asymptomatic infection, watery diarrhea to severe illness with bloody diarrhea or hemorrhagic colitis (HC) and hemolytic uremic syndrome (HUS). The HUS primarily affects children. This study aimed to evaluate two DNA vaccines carry the gene coding for an outer membrane protease T (OmpT), fundamental to the degradation of antimicrobial peptides produced by the host, and the gene for Ag43, outer membrane proteins of highly conserved in STEC. Genes were cloned in an expression vectors pVAX1 and pVAX-Flag, which were used to immunize animals and purification of recombinant proteins respectively. Animals inoculated with DNA vaccine pVAX-OmpT and pVAX-Ag43 developed post-immunization antibodies specific to systemic and mucosal level. In vitro stimulation of splenocytes from vaccinated mice with either recombinant proteins or total Coli protein extracts resulted in a T-cell proliferative response. These findings indicate that whith the DNA vaccine immunization carrying the OmpT and Ag43 gene from E. coli have potential for use as a vaccine to induce protection against infections.
This work was support by grant FONDECYT 1110260

P6.11.52
An unbiased genome-wide *Mycobacterium tuberculosis* gene-expression approach to discover new antigens for human T cells that are expressed during pulmonary infection

T. Ottenhoff;
Leiden University Medical Center, Leiden, Netherlands.

Mycobacterium tuberculosis (*Mtb*) causes almost 2 million deaths annually. BCG, the only vaccine available against tuberculosis (TB), induces highly variable protection and better TB vaccines are urgently needed. A prerequisite for vaccine-targeted antigens is that they are expressed during *Mtb* infection in the lungs of susceptible individuals. In search for new TB-vaccine antigens, we followed a genome-wide unbiased discovery approach to investigate the *in vivo* expression of 2170 *Mtb* genes (all first genes of all predicted Mtb operons) during *Mtb* infection in the lungs of mice. Four genetically related mouse strains were studied, representing a spectrum of TB susceptibility controlled by the super-susceptibility to tuberculosis 1 locus. We selected the most upregulated sets of *in vivo* expressed *Mtb* (IVE-TB) genes, and analyzed their expression patterns in distinct disease phenotypes such as necrosis and granuloma formation. While a significant subset (44%) were known as environmental stress response genes, the majority of the *Mtb* genes identified has been largely unstudied so far.
To validate their immunogenicity we analyzed antigen induced immune responses in the blood of tuberculin skin test positive (TST+) individuals. Several *Mtb* IVE-TB proteins were recognized by TST^+ESAT6/CFP10-responsive individuals, indicating that these antigens are presented during natural *Mtb* infection. IVE-TB antigens induced strong IFN-γ^+/TNF-α^+ $CD8^+$ and TNF-α^+/IL-$2^+$$CD154^+$/$CD4^+$ T-cell responses in long-term latently *Mtb* infected individuals. In conclusion, these IVE-TB antigens are expressed during pulmonary infection *in vivo*, are immunogenic, induce strong T-cell responses in long-term latently *Mtb* infected individuals and represent attractive antigens for new TB vaccines.

P6.11.53
Cationic Poly-D, L-lactide-co-glycolide (PLG) Microparticles Enhance the T Cell Response to Naked DNA and Protect Mice from Tumor Challenge

C. Pan, *H. Chung, H. Hu, S. Wu, Y. Hsiao;*
NHRI, Zhunan Town, Miaoli County, Taiwan.

Cationic poly-D, L-lactide-co-glycolide (PLG) microparticles have shown to target to antigen presenting cells efficiently and become an attractive vaccine delivery system. In this study, a DNA plasmid expressing ovalbumin (pOVA) in the presence of the cationic surfactant CTAB could bind onto the surface of PLG microparticles and form PLG/pOVA DNA vaccine. To evaluate the potential of PLG formulated DNA vaccine in vaccine development, we tested the immune stimulating effect of PLG/pOVA and pOVA DNA vaccine in vitro and in vivo. An increase of CD86 expression in a mouse leukemia macrophage RAW.264 was observed after PLG/pOVA stimulation. In addition, mice immunized with PLG/pOVA elicited a higher IFN-γ production than pOVA alone, especially in CD8+ T cells. Polyfunctional T cell responses were also measured and found the percentage of OT-1 specific polyfunctional T cells was higher in PLG/pOVA immunized mice than pOVA alone (8.24% vs. 6.55%). To test the protection of PLG/pOVA, we challenged immunized mice with OVA-expressing EG7 tumor cells. PLG/pOVA and pOVA immunized mice but not control group showed an inhibition in tumor cell growth. In summary, cationic PLG formulated DNA vaccine could be a powerful tool to enhance T cell response and protect from tumor challenge. Furthermore, this PLG microparticle delivery system can carry both plasmid DNA and protein in the same PLG microparticle that might improve the weak antibody production of formulation with DNA alone.

P6.11.54
Production of human monoclonal ScFv that bind to different functional domains of M2 and inhibit H5N1 influenza virus replication

T. -. Pissawong[1], *S. Maneewatch*[1], *P. Srimanote*[2], *F. Dong-din-on*[3], *T. Songserm*[3], *K. Bangphoomi*[4], *W. Chaicumpa*[1];
[1]*Mahidol university, Bangkok, Thailand,* [2]*Thammasat University, Pathumthani, Thailand,* [3]*Kasetsart University, Nakhopathom, Thailand,* [4]*Kasetsart university, Bangkok, Thailand.*

Novel effective anti-influenza agent that tolerates influenza virus antigenic variation is needed. Highly conserved influenza virus M2 protein has multiple pivotal functions including ion channel activity for vRNP uncoating, anti-autophagy and virus assembly, morphogenesis and release. In this study, fully human monoclonal single chain antibodies (HuScFv) specific to recombinant and native M2 proteins of A/H5N1 viruses (both adamantane sentivie and resistant) were produced from four *huscfv*-phagemid transformed *E. coli* clones (no. 2, 19, 23 and 27) selected from a HuScFv phage display library. HuScFv of all clones show different amino acid sequences particularly at the CDRs. Influenza virus infected cells exposed to the HuScFv had reduced virus release and intracellular virus. Phage peptide mimotope searching revealed that conformational epitopes of HuScFv2 located at the residues important for ion channel activity, anti-autophagy and M1 binding; epitope of HuScFv19 located at the M2 amphipathic helix and cytoplasmic tail important for anti-autophagy, virus assembly, morphogenesis and release; epitope of HuScFv23 involved residues important for the M2 activities similar to HuScFv2 and also amphipathic helix residues for viral budding and release while HuScFv27 epitope spanned ectodomain, ion channel and anti-autophagy residues. Molecular docking results conformed to the epitope identification by phages. While the molecular mechanisms of the HuScFv await experimental confirmation, the small human antibody fragments have high potential for developing further as a safe, novel and mutation tolerable anti-influenza agent especially against drug resistant variants.

P6.11.55
Vaccination using recombinants influenza and adenoviruses encoding amastigote surface protein-2 are highly effective on protection against Trypanosoma cruzi infection

R. Polidoro[1], *B. Galvão-Filho*[1], *L. I. dos Santos*[1], *P. Sales-Junior*[2], *O. Bruna-Romero*[3], *M. M. Rodrigues*[4], *R. T. Gazzinelli*[1,2,5], *A. Vieira-Machado*[2];
[1]*Departamento de Bioquímica e Imunologia - UFMG, Belo Horizonte, Brazil,* [2]*Centro de Pesquisas René Rachou - Fiocruz, Belo Horizonte, Brazil,* [3]*Universidade Federal de Santa Catarina, Belo Horizonte, Brazil,* [4]*CTCMol - Unifesp, Belo Horizonte, Brazil,* [5]*University of Massachusetts Medical School, Worcester, MA, United States.*

There is no human vaccine for Chagas' disease and its treatment presents some adversities. ASP2 protein from the agent *Trypanosoma cruzi* is a conserved immunogenic protein that reaches high protection levels in susceptible mice by specific $CD8^+$T cells stimulation being an interesting candidate for vaccine antigen. Recombinant viruses emerge as promising tools for testing heterologous prime-boost vaccination protocols. In the present study, we generated and evaluated recombinant influenza viruses carrying sequences coding for polypeptides corresponding to medial and carboxi-terminal portions of *Trypanosoma cruzi*'s ASP2. Those recombinant viruses were used in vaccination of C57BL/6 and C3H/He mice in sequential immunization with recombinant adenovirus encoding the complete sequence of ASP2 (Ad-ASP2; heterologous prime-boost protocol). This immunization protocol was able to elicit strong specific anti-ASP2 cellular immune response in vaccinated animals. Also, on susceptible mice strain C3H/He, a higher degree of protection could be found in mice primed with recombinant influenza virus and boosted with Ad-ASP2. By intracellular staining of CD8+ T cells obtained from spleen of vaccinated C3H/He mice, we observed that heterologous prime-boost protocol elicited more CD8+ T cells specific for the immunodominant epitope as well as higher number of specific $CD8^+$ T TNF-alfa and IFN-gamma producers that mobilized CD107a protein. Our results suggest that immunodominant specific CD8+ T cells elicited after immunization could be directly related to degree of protection achieved by different immunization protocols using different viral vectors and the usefulness of recombinant influenza viruses as vaccine vectors against infectious diseases.

P6.11.56
Designing and modeling super evolutionary polytopic constructs as minor and complement vaccine for Human Immunodeficiency Virus (HIV) based vaccines

M. R. Ranjbar*;*
Tehran University, Tehran, Iran.

Introduction: Feline Immunodeficiency Virus (FIV), Bovine Immunodeficiency Virus (BIV) and Simian Immunodeficiency Virus (SIV), except some differences, are closely similar to the Human Immunodeficiency Virus (HIV) in genomic organization, morphology, physical and biochemical features and manifestation of disease. Evolutionary patterns and different compatibility of this virus to its host, help designing vaccine and stimulate of immune system more effectively.
Method: In this study twofold approaches include experimental known epitopes and modeling by computer were adopted for designing. After basic study, protein sequences of SIV, FIV and BIV retrieved from Genbank. Then sequences were aligned, analyzed by wide array of bioinformatics software and online servers. Then, all sequences tested for prediction of epitopes that have immunogenicity for T cell and B cell epitopes and potency to attachment to some alleles in HLA. Selected epitopes attached to each other in different patterns and evaluated for best statuses of proteasomal cleavage sites and then Codon optimization was done for compatibility with different expression systems.
Results: Ten unique polytopic constructs (3 SIV, 2 FIV, 1 BIV and 4 mixtures of HIV SIV FIV and BIV) with different patterns of attachment were obtained. So many details were considered in process of designing effective vaccine.
Conclusion: Our designed constructs could be used as both Protective and Therapeutic (boost the immune system of an already-infected person). Specially, as minor and complement vaccine beside Human Immunodeficiency Virus (HIV) based vaccines. Although these constructs are designed for humans, they may be used as Feline vaccine .

P6.11.57
The TB vaccine recombinant BCG-LTA-K63 induces higher Th1 immune responses in mice

D. Rodriguez*, I. P. Nascimento, L. C. C. Leite;*
Instituto Butantan, São Paulo, Brazil.

Mycobacterium bovis BCG has been widely used as a tuberculosis vaccine, despite waning efficacy in adults. It is considered that BCG is poor in inducing Th1 immune responses for efficient protection against TB. Adjuvant properties have been described for the Escherichia coli heat-labile toxin (LT), composed of an enzymatically active A and nontoxic B subunits. rBCG expressing a nontoxic mutant subunit A (rBCG-LTA-K63) induced protection against TB challenge in BALB/c mice. In the present work we analyzed the cellular immune responses induced by this construct. Groups of mice were immunized s.c. with 106 cfu of BCG or rBCG-LTA-K63 and after 60 days the spleens were placed in culture and stimulated with PDS. After incubation, the cells were collected for intracellular cytokine staining with FITC-, PE-, and PE-Cy7-conjugated monoclonal antibodies against: CD4, CD8a, IFN-γ, IL-4, IL-17, TNF-α and IL-2. The cytokine secretion was also evaluated in the supernatant of splenocyte culture. A proportion of CD4 T cells produced IFN-γ and TNF-α (47.1 and 34.6% respectively), significantly higher in mice immunized with rBCG-LTA-K63 than with BCG (21.4 and 18.9%) or saline controls (13.0 and 8.4%). IFN-γ production was significantly higher in rBCG-LTA-K63 cells (1231+/- 120 pg/mL) when compared with BCG (862+/- 259 pg/mL). IL-17 and IL-2 production was comparable in immunized groups and IL-4 was not detected. In conclusion, we demonstrated that immunization of mice with rBCG-LTA-K63 induces a Th1-shifted immune response characterized by increased production of IFN-γ and TNF-α, significantly higher than BCG, correlating with a higher protection against TB.

P6.11.58
Influence of different adjuvant formulations in humoral responses after immunization with a HIV envelope glycoprotein trimer

*J. S. Apostólico[1,2], S. B. Boscardin[3], M. M. Yamamoto[3], J. Kalil[4,5], E. Cunha-Neto[2,5], **D. S. Rosa**[1,2];*
[1]Division of Immunology, Federal University of São Paulo (UNIFESP), São Paulo, Brazil, [2]Laboratory of Clinical Immunology and Allergy-LIM60, University of São Paulo School of Medicine, São Paulo, Brazil, [3]Department of Parasitology, University of São Paulo, São Paulo, Brazil, [4]University of São Paulo School of Medicine, São Paulo, Brazil, [5]Heart Institute (InCor), University of São Paulo School of Medicine, São Paulo, Brazil.

An effective HIV vaccine is urgently needed and is still a scientific challenge. It is widely accepted that robust humoral and T cell responses are required for the control of virus transmission and disease progression. However, the induction of broadly neutralizing antibodies against the virus has proven hard to achieve. One of the most promising antigens is the envelope glycoprotein, but vaccine candidates based on the monomeric envelope protein gp120 failed to induce protection in efficacy trials. One strategy to overcome this caveat is the use of the stable envelope protein trimer gp140 that contains both gp120 and gp41 ectodomains.
Adjuvants are known to improve the immunogenicity of subunit vaccines, and in the last years several TLR and NOD ligands have entered clinical trials and proved their efficacy. They can also modulate the type of immune response induced by the antigen towards a specific profile (Th1, Th2, etc). For the present work, we used different adjuvant formulations (Poly I:C, CpG ODN, MPL, MDP, Imiquimod, Resiquimod) and analyzed their influence on the anti-gp140 antibody titers, IgG isotypes and germinal center formation after immunization in the presence of the gp140 trimer. Robust Env-specific antibody titers and germinal center formation developed after three doses of gp140 in the presence of different adjuvant formulations. The adjuvants MPL, Poly I:C and CpG ODN induced the highest humoral immune response. These observations have implications for gp140 subunit vaccine design and may be relevant for optimal responses in nonhuman and human primates.

P6.11.59
Immunogenic properties of the lettuce-derived C4(V3)6 multiepitopic HIV protein

*D. Govea-Alonso[1], N. Rubio-Infante[1], A. Garcia Hernandez[2], J. Varona Santos[2], S. Korban[3], L. Moreno Fierros[2], **S. Rosales Mendoza**[1];*
[1]Universidad Autonoma de San Luis Potosi, San Luis Potosi, Mexico, [2]FES Iztacala, Universidad Nacional Autonoma de Mexico, Tlalnepantla, Mexico, [3]University of Illinois, Urbana, IL, United States.

Elicitation of broad humoral immune responses is a critical factor in the development of effective HIV vaccines. As an effort to advance in the development of a candidate vaccine based in a multiepitope recombinant protein, this study describes the immunogenic properties of a previously reported C4(V3)6 multiepitopic protein containing V3 loops corresponding to five different HIV isolates MN, IIIB, RF, CC, RU, using *E. coli* as conventional expression host and lettuce cells as a convenient production and delivery platform. Both *E. coli*- and lettuce-derived C4(V3)6 elicited local and systemic immune responses when orally administered to Balb/c mice. Importantly, the lettuce-derived C4(V3)6 showed a higher immunogenic potential than the *E. coli*-derived one. Broad responses were evidenced when compared the reactivity of sera from mice immunized with C4(V3)6 with those elicited by a chimeric protein carrying a single V3 sequence. The lettuce-derived C4(V3)6 elicited antibodies with positive reactivity against V3 loops from isolates MN, RF and CC. In addition, splenocyte proliferation assays indicated that significant T helper responses are induced by the C4(V3)6 immunogen. Taken together, these findings accounts for the concept of eliciting broader humoral responses trough the C4(V3)6 multiepitopic protein and encourage on the production of multiepitopic vaccines produced in plant cells which serve not only as low cost expression host but also as an effective delivery vehicle for oral administered immunogens.

P6.11.60
Efficacy and safety of a nanoproteoliposomic vaccine candidate against epidemic serovars of Leptospira spp

***L. Rosario Fernandez**;*
University of Havana, Havana, Cuba.

Leptospirosis constitutes the zoonosis with highest impact in veterinary and human health. The vaccines available are fundamentally made of inactivated whole cells and most of them for veterinary use. These formulations although effective have multiple limitations, among them the narrow margin of crossed protection against serovars included in the same formulation, low immunologic memory, absence of cellular response and several safety issues. The present study evaluated in the Golden/Syrian hamster the efficacy and safety profile of a new nanoparticulated vaccine formulation. This new vaccine candidate protected up to 100% of the immunized animals (schedule of two doses with a three week interval of) against the homologous and heterologous lethal challenge with 100 000 DL50 of the serovars: Canicola, Ballum, Mozdok and Cophenagen. In all the cases the elimination of carrier state was also verified in kidneys, liver and lung. The immunization generated high levels of IgM and IgG (IgG1 and IgG2a) after the first and second dose, respectively. Also, high levels of IFNγ and IL-1 were observed, and in all the groups the animals survived the lethal challenge up to a year after immunization, with high expression of CD45+ memory marker. Toxicity assays demonstrated absence of damage at immunological and vital organs. These results demonstrate the effectiveness of this new vaccine formulation, it is recommended in future studies to enlarge the evaluation of heterologous protection to other strains of epidemic interest.

P6.11.61
The effect of papilloma virus vaccine in the Th17 differentiation

***M. Salgado-Bustamante**, Y. Cataño-Canizalez, D. Portales-Pérez, R. González-Amaro;*
Universidad Autónoma de San Luis Potosi, San Luis Potosi, Mexico.

The cervical cancer had been associated with the persistent infection of certain genotypes of human papillomavirus (HPV). Actually, there are two commercial vaccines against oncogenic genotypes infection of HPV: the bivalent vaccine Cervarix® (GarsoSmithKline) and the quadrivalent vaccine Gardasil® (Merck). The Th17 cells are a subpopulation of lymphocytes important in the elimination of certain pathogens. However, the increase in their expansion cause different pathological conditions and is associated with the development of cancer. The importance as part of the protective response generated after the vaccination against HPV has not been determined. In this work, we evaluated if change in the response of differentiation T CD4+ lymphocytes is promoting due Gardasil® vaccine. 23 young healthy women were vaccine and blood samples were collected at three times: before vaccination and two weeks after the second and third doses. The Th17 differentiation was induced *in vitro* using the vaccine as stimulus and percentage positive cells and IL-17 production were evaluated. In this study, we show that the cells of women which have been vaccinated with Gardasil® have less response to Th17 differentiation in culture. Hence, the results suggest that vaccine protection is probably given to mediate by other type of response like Th1 and Th2.

P6.11.62
Engraftment of plasma membrane vesicles into liposomes: A new method for designing of liposome-based vaccines

***A. Samiei**, S. Kamali Sarvestani;*
Department of Immunology, Autoimmune diseases research center, Shiraz, Iran.

Immunization with plasma membrane vesicles (PMVs) engrafted into liposomes not only preserves the real biological structure of plasma membrane constituents, but also can potentiate the immune responses against a wide range of antigens present in the PMVs. Therefore, in the present study five different techniques have been investigated to engraft the PMVs derived from a characterized

leishmania parasite into liposomes. The percentage of engraftment was determined by two-color flow cytometry. Among the investigated techniques, freeze-drying method with 91 ± 2% of engraftment is preferred over other methods due to its simplicity and stability of particles during storage. In addition, the immunogenicity of leishmania-derived fused particles obtained by this method was checked *in vivo*. The results showed that the serum levels of anti-leishmania IgG2a antibodies (an indicator of Th1 responses) were significantly higher in mice vaccinated with fused particles than mice injected with PMVs alone (0.5 ± 0.02 OD and 0.2 ± 0.02 OD, respectively; p=0.05), while the total anti-leishmania IgG levels did not show significant difference. Therefore, freeze-drying method is an efficient technique for preparation of liposome-based artificial cell like particles with the ability to maintain the native conformation of proteins as well as the induction of Th1-deviated immune responses.

P6.11.63

Protective activity of antibodies generated by the immunization of the mixture of LPPG from E. histolytica with the OmpC porin from S. typhi, as a bivalent vaccine against amebic liver abscess by E. histolytica and infection by S. typhi

I. Sánchez-González[1]*, B. Cocom-Chan*[1]*, I. Wong-Baeza*[2]*, A. Isibasi*[1]*;*
[1]Specialty Hospital, National Medical Center Century XXI, IMSS, Mexico City, Mexico, [2]*National Polytechnic Institute (IPN), Mexico City, Mexico.*

Entamoeba histolytica and Salmonella typhi are high prevalence pathogens in undeveloped countries, causing every year more than 300,000 deaths around the world. Currently, there is no vaccine against E. histolytica and the vaccines against S. typhi, the Germanier and the Vi polysaccharide do not generate long-term immunity and there has being S. typhi outbreaks without antigen Vi. Therefore, a more effective vaccine that can provide protection against both pathogens must be developed. In the Unit of Medical Research in Immunochemistry, we have isolated and characterized key molecules for both pathogens, the lipopeptidophosphoglycan (LPPG) from E. histolytica and the OmpC porin from S. typhi. In this study, we evaluated the protective activity of antibodies generated by the immunization of the mixture of LPPG with the OmpC porin against amebic liver abscess (ALA) by E. histolytica and infection by S. typhi. Our results showed, that two immunizations of LPPG with OmpC porin induced high-titer long-lived of IgG and IgM specific antibodies to both antigens and also had high affinity. The antibodies binded to trophozoites membranes of E. histolytica and had opsonophagocytic activity against S. typhi. Furthermore, the passive transference of only 100µL of immune serum protected mice in 60% against the development of ALA and also in 100% and 60% against 5 and 20 LD50 of S.typhi respectively.These findings demostrate that the administration of LPPG with OmpC porine, generate protective antibodies against ALA development by E. histolyica and infection by S. typhi.

P6.11.64

Broadly anti-hepatitis C virus (HCV) cross-neutralizing monoclonal antibodies (mAbs) directed against the HCV/E2 glycoprotein and not subjected to Ab-mediated interference

G. A. Sautto*, N. Mancini, G. Gorini, R. A. Diotti, N. Clementi, E. Criscuolo, M. Castelli, F. Cappelletti, M. Clementi, R. Burioni;*
Università Vita-Salute San Raffaele - Laboratorio di Microbiologia e Virologia, Milano, Italy.

Hepatitis C virus (HCV) is one of the major cause of chronic liver disease worldwide. There is evidence that neutralizing anti-HCV monoclonal antibodies (mAbs) may find potential applications in novel prophylactic and therapeutic strategies against this infection. However, several HCV escape mechanisms from the immune response have been described. One of them consists in the elicitation of Ab subpopulations interfering with the neutralizing activity of other Abs. In particular, it was reported that Abs directed against the 436-447 region (epitope II) of HCV/E2 glycoprotein may interfere with the neutralizing activity of Abs directed against the 412-423 region (epitope I). Here we describe the potent neutralizing activity and the unique biological features of two broadly cross-reactive and cross-neutralizing anti-HCV/E2 human mAbs (e20 and e137). In particular, we investigated on the molecular features of the interference phenomenon describing an anti-HCV/E2 mAb (e509), whose epitope is centred on epitope II. Interestingly, e509 influenced the potent neutralizing activity of one of the best characterized anti-HCV/E2 murine mAb (AP33), whose epitope encompasses epitope I. On the other hand, e509 did not show any interfering activity against e20 and e137, whose epitopes partially overlap with that of e509 and which possibly displace it from the antigen.
These data give a possible clue to interpret the conflicting studies published to date on the mechanism of Ab-mediated neutralization interference and contribute to the comprehension of this phenomenon that may be of importance in the set up of novel mAb-based anti-HCV therapeutic strategies as well as in immunogen design.

P6.11.65

Severity of Epstein-Barr Virus (EBV)-induced infectious mononucleosis (IM) correlates with the frequency of crossreactive influenza A virus-M1 and EBV-BMLF-1-specific CD8 T cells

L. K. Selin*, L. B. Watkin, K. Luzuriaga, N. Aslan;*
Univ of Massachusetts Medical School, Worcester, MA, United States.

During EBV-associated IM influenza A-specific crossreactive memory T cells are activated and play a role in disease severity. In HLA-A2+ IM patients, influenza M158 (IAV-M1)-specific CD8 memory T cell responses cross-reacted with two different EBV lytic epitopes, BMLF-1280 (17/29) and BRLF-1190 (19/20). Furthermore, 11/22 IM patients demonstrated some intra-viral cross-reactivity between EBV-BRLF1 and -BMLF1 responses. Disease severity of IM did not correlate with viral load, but instead directly correlated with significantly increased frequencies of crossreactive IAV-M1/EBV-BMLF-1-specific CD8 cells, as well as IAV-M1, EBV-BMLF-1 specific CD8 cells, but not BRLF1 responses. When severity of IM was scored and patients were assigned to either mild or severe groups, disease severity correlated with specific TCR Vb usage in all three tetramer-positive populations suggesting that TcR selection is driving disease outcome. Consistent with IAV-M1 and EBV-BMLF1 responses driving increased immunopathology was the observation that patients with severe disease had significantly more IAV-M1 and EBV-BMLF1 cells producing IFNg/MIP1-b in response to antigen as compared to patients with mild disease. These results suggest that T cell crossreactivity can impact T cell selection and function and ultimately disease outcome. Insights on these issues are important for the intelligent design of vaccines and to develop effect therapeutic interventions for virally induced disease.

Differential proteomics approach to identify putative protective antigens of Mycobacterium tuberculosis presented during early stages of macrophage infection

S. Sharma[1]*, A. Kumar*[2]*, P. Sharma*[2,3]*, A. Bhaskar*[2]*, A. Singh*[2]*, A. K. Tyagi*[1]*, K. V. S. Rao*[2]*, V. Manivel*[2]*;*
[1]Department of Biochemistry, University of Delhi South Campus, New Delhi, India, [2]*International Centre for Genetic Engineering and Biotechnology, New Delhi, India,* [3]*North Eastern Region-Biotechnology Programme Management Cell (NER-BPMC), Department of Biotechnology, Government of India, New Delhi, India.*

There is an urgent need for an effective vaccine against tuberculosis as the currently available BCG vaccine has failed to accomplish its target of controlling the TB epidemic. Waning of BCG efficacy over time and poor induction of MHC class I restricted responses have prompted research for an alternative that can tide over these shortcomings. In this study we employed differential proteomics to obtain a list of potential vaccine candidate antigens. Bacterial epitopes being presented at early stages on MHC class I and class II molecules of macrophages infected with *Mycobacterium tuberculosis* (*M.tb*) were identified using iTRAQ labeling and reverse phase LC-MS/MS. The putative vaccine candidates thus identified were tested as plasmid DNA vaccines in mice to ascertain their protective efficacy

against a challenge of aerosolized *M.tb*. The protection was evaluated as the ability of the vaccine candidates to reduce the bacterial CFU counts compared to empty vector control in the lungs of infected mice at 8 weeks post challenge. Of the seventeen DNA vaccine constructs we evaluated, two vaccine candidates Rv0143c (chloride channel gene) and Rv1384 (carbamoyl phosphate synthase), both presented in context of MHC class I, induced levels of protection comparable to those observed with BCG. This proof of concept study demonstrates the rationale of our strategy to find novel T-cell epitope based TB vaccine candidates and shortlist the promising ones for further, more stringent evaluation in the guinea pig model.

Skewing of SAG mediated therapy for a predominant Th1 during Visceral Leishmaniasis on triggering CD2 epitope

S. Sinha[1]*, S. Bimal*[2]*, S. Sundaram*[1]*;*
[1]*Centre for Biotechnology, University of Allahabad, Allahabad, India,* [2]*Rajendra Memorial Research Institute of Medical Sciences, Patna, India.*

We have evaluated the effect of combining CD2 with conventional antimonial (sb) therapy in protection in BALB/c mice infected with either drug sensitive or resistant strain of Leishmania donovani with $3x10^7$ parasites via-intra-cardiac route. Mice were treated with anti CD2 adjunct SAG sub-cutaneously twice a week for 4 weeks. Assessment for measurement of weight, spleen size, anti-Leishmania antibody titer, T cell and anti-leishmanial macrophage function was carried out day 0, 10, 22 and 34 post treatments. The combination therapy was shown boosting significant proportion of T cells to express CD25 compared to SAG monotherapy. However, the level of IFN-γ was not statistically different between combination vs. monotherapy ($p = 0.298$) but CD2 treatment even alone significantly influenced IFN-γ production than either SAG treatment ($p = 0.045$) or with CD2 adjunct SAG treatment ($p = 0.005$) in Ld-S strain as well as in Ld-R strain. The super-oxide generation began enhancing very early on day 10 after SAG treatment with CD2 during which SAG action was at minimum. Unlike SAG treatment, treatment of SAG with CD2 also led to production of nitric oxide and TNF-α, resulting in most effective clearance of L. donovani from infected macrophages. Our results indicate that CD2, which can boost up a protective Th1 response, might also be beneficial to enable SAG to induce macrophages to produce leishmanicidal molecules and hence control the infection in clinical situation like Kala-azar along with overcoming drug resistance.

P6.11.68

Analysis of Brucella abortus mutant strains Δbmfp and Δomp19 as potential live vaccines against brucellosis

J. A. Souza Fh[1]*, V. P. Martins*[2]*, F. O. Oliveira*[3]*, P. C. Campos*[1]*, S. L. Cravero*[4]*, S. C. Oliveira*[1]*;*
[1]*Universidade Federal de Minas Gerais, Belo Horizonte, Brazil,* [2]*Universidade Federal de Brasília, Brasília, Brazil,* [3]*Universidade Federal de Juiz de Fora, Governador Valadares, Brazil,* [4]*CICVyA-INTA, Buenos Aires, Argentina.*

Brucella abortus, a facultative intracellular bacterium, is the etiological agent of a zoonotic disease termed brucellosis, which causes serious economic losses in livestock and represent a public health threat. Current commercial vaccines strains against brucellosis have several drawbacks, as residual virulence and variable efficacy. Therefore, research efforts have focused on developing improved vaccines that combine safety and efficacy. Herein, we evaluated the role in pathogenesis of the *Brucella* Outer Membrane Protein 19 (OMP19) and *Brucella* Membrane Fusogenic Protein (BMFP). Additionally, we also tested the vaccine potential of the *Brucella* mutant strains Δ*omp19* and Δ*bmfp*. In this study, we showed that the B. abortus Δ*omp19* and Δ*bmfp* mutant strains have reduced persistence in mice and defective intracellular multiplication in bone marrow derived macrophage. The mutant strains are attenuated and confer protection after challenge with *B. abortus* virulent strain in immunocompromised IRF-$1^{-/-}$ mice as follows: Δ*bmfp* (100%), S19 (87,5%), RB51 (63,5%), Δ*omp19* (59,2%). In immunocompetent C57Bl/6 mice, the Δ*bmfp* mutant strain induces superior protection than that conferred by commercial strain RB51 and similar to vaccine S19, while the Δ*omp19* mutant strain induced lower protective immunity than vaccine S19, but similar to vaccine RB51. In conclusion, *B. abortus* OMP19 and BMFP are critical for full bacterial virulence and the Δ*bmfp* mutant strain is a potential vaccine candidate. Moreover, the absence of the protein BMFP in *Brucella* Δ*bmfp* mutant strain may serve as a molecular marker useful as a diagnostic tool to differentiate infected from vaccinated animals.

P6.11.69

Inhibition of the entry of *Streptococcus pyogenes* in epithelial and endothelial cells by disintegrins

Y. F. SU*, W. J. Chuang;*
Department of Biochemistry and Molecular Biology, Tainan, Taiwan.

Group A *Streptococcus* (GAS, *Streptococcus pyogenes*) is an important human pathogen that cases acute pharyngitis, superficial skin infections, sepsis and necrotizing fasciitis in humans. This bacterium uses adhesins (ex. M protein and streptococcal fibronectin binding proteins) to enter mammalian cells by using fibronectin (Fn) as bridge to interact with integrins. This may help GAS to evade antibiotics killing and host immune responses. Snake venom disintegrins are the nature antagonists against integrins. We hypothesized that disintegrin may disrupt the entry process of GAS into mammalian cells to enhance the elimination of GAS by antibiotics. GAS could be internalized into epithelial and endothelial cells in the presence of FBS or Fn. Disintegrin rhodostomin (Rho) and its mutants (ARLDDL and KG) did not influence the growth and viability of GAS and mammalian cells. Further, we use the Rho, ARLDDL and KG to treat cells while NZ131 infecting epithelial and endothelial cells in the presences of FBS or Fn. Rho and KG reduce GAS invasion into epithelial and endothelial cells under both FBS and Fn conditions. In addition, both Rho and KG also influence the adhesion of GAS onto epithelial and endothelial cells under Fn condition while almost no effects on adhesion under FBS condition. However, ARLDDL had no effects on adhesion or invasion of NZ131 in both epithelial and endothelial cells. These results suggest that disintegrins (Rho and KG) may enhance the efficiency of antibiotics in treatment of GAS infections and potentially agent to inhibit GAS infection.

P6.11.70

Immunophenotypic features of peripheral blood in case of severe adverse event associated to yellow fever vaccination

A. Teixeira-Carvalho[1,2]*, M. Luiza-Silva*[2]*, A. Campi-Azevedo*[2]*, R. M. Martins*[3]*, R. Galler*[3]*, M. d. Maia*[3]*, M. d. Freire*[3]*, S. M. Eloi-Santos*[4]*, O. A. Martins-Filho*[2]*;*
[1]*Food and Drug Administration, Bethesda, MD, United States,* [2]*Oswaldo Cruz Foundation, Belo Horizonte, Brazil,* [3]*Oswaldo Cruz Foundation, Rio de Janeiro, Brazil,* [4]*Federal University of Minas Gerais, Belo Horizonte, Brazil.*

Introduction and aim: Yellow fever (YF) infection remains an important public health problem. The vaccination constitutes the most effective means to control the disease. Although YF-17D vaccine has proven to be very safe, cases of serious adverse events (YF-SAE) associated to the vaccine have been reported. Herein, we report immunological features in case of severe adverse event, 15 days after yellow fever vaccination.
Material and Methods: Ex vivo analysis of leukocyte subsets was performed by flow cytometry. Data from 10 healthy volunteers, 15 days after YF-17DD vaccination were considered as reference values (RV).
Results: Our data revealed that the impact of YF antigens on monocytes induced a deficient expression of CD32 (117.3/215.0±47.0). In addition, on the adaptive immunity compartment, this YEL-SAE case were characterized by activation events in T and B cells demonstrated by increased frequency of CD4+CD69+(7.2/3.0±1.8), CD4+HLA-DR+(12.7/4.0±2.0), CD8+HLA-DR+(40.5/5.0±2.4), and CD69/CD19+(49.1/12.0±3.6) cells, as well as an increased expression of CD54 in CD4+ and CD8+ cells (28.4/4.0±2.2; 74.4/6.0±4.0, respectively). On the other hand, it was

observed a decreased expression of CD32 in B-cells (75.0/160.0±32.0), CXCR3 in T-cells (11.6/26.68±4.7;16.6/32.73 ± 6.50), besides lower frequency of CD62L+CD8+ cells (5.8/48.0±6.4).
Conclusion: Analysis of this YF-SAE demonstrated a deficiency innate immune response characterized by down modulation of Fc-receptors in monocytes. On the other hand, in adaptive microenvironment we observed a specific induction of T and B cell responses in peripheral blood, 15 days after vaccination. These results corroborate data of YF-SAE case reported previously by our group.

E2 multimeric scaffolds displaying HIV-1 Envelope regions elicit V3 and MPER-specific neutralizing antibody and T cell responses when combined with gp160 plasmid DNA

M. Trovato[1], *S. J. Krebs*[2], *S. McBurney*[2], *C. Smith*[2], *P. J. Jaworski*[2], *W. F. Sutton*[2], *R. Sartorius*[1], *L. D'Apice*[1], *P. De Berardinis*[1], *N. L. Haigwood*[2];
[1]*Institute of Protein Biochemistry, C.N.R., Naples, Italy,* [2]*Division of Pathobiology and Immunology, Oregon National Primate Research Center, Oregon Health and Sciences University, Beaverton, OR, United States.*

It is widely believed that induction of both broadly neutralizing antibodies (bNAbs) and T cells are crucial for a successful HIV-1 vaccine. To elicit immune responses against HIV-1 we generated multimeric scaffolds, based on the E2 component of the pyruvate dehydrogenase complex from Geobacillus stearothermophilus, displaying antigens from the HIV Envelope (Env) glycoproteins gp120 and gp41. E2 self-assembles into a 60-mer particle with 60 copies of an antigen on each scaffold. The HIV-SF162 V3 and MPER regions were expressed as N-terminal fusions to the E2 core. To increase solubility, Env-E2 scaffolds were refolded from inclusion bodies with equimolar amounts of E2wt and purified by size exclusion chromatography. Purified Env-E2 multimers were tested alone or in combination with HIV-SF162 Env(gp160) plasmid DNA in rabbits and mice. We also tested DNA expressing Envelope gp160 with deletions in variable regions V2, V3, and V1-V3. Immunization with V3-E2 co-administered with DNA elicited strong V3-specific NAb response after two immunizations in 6 weeks in rabbits and V3-dextramer specific CD8+ T cells producing IFN-gamma in mice. Rabbits immunized with DNA plus MPER-E2 rapidly generated NAbs targeting the broadly neutralizing 2F5 as well as the 4E10 epitopes, confirmed using HIV-2/MPER chimeric viruses. CD4+ T-cell response and cytokine polarization were also investigated. Rabbits immunized with MPER-E2 had NAbs against both Tier 1 and Tier 2 HIV-viruses. Our results indicate that this novel strategy of co-immunization with E2 scaffolds and DNA could represent an efficient platform by which to direct immune responses, including bNAbs, toward HIV-1 conserved regions.

***A S. agalactiae* protein of heterologous expression, an interesting alternative for vaccine development**

A. E. Vasquez[1,2], *J. Soto*[1], *M. Barrientos*[1], *D. Soto*[1], *V. Valenzuela*[1], *S. E. Illanes*[3];
[1]*Instituto de Sald Publica de Chile, Santiago, Chile,* [2]*Millennium Institute on Immunology and Immunotherapy, P. Universidad Católica de Chile, Chile., Santiago, Chile,* [3]*Department of Obstetrics & Gynaecology and Laboratory of Reproductive Biology, Faculty of Medicine, Universidad de Los Andes, Chile., Santiago, Chile.*

Streptococcus agalactiae, also known as Group B streptococcus or GBS, is a β-hemolytic Gram-positive streptococcus which is one of the leading causes of neonatal sepsis and postpartum infection. Genitourinary tract colonization reaches 20% of pregnant women and is considered a sexual transmission disease.
In the world there is no vaccine against GBS, only a phase 2 study based on conjugated polysaccharides. An interesting alternative is to use proteins as the basis for vaccine development. In our laboratory, we obtained the SIP protein (rSIP) by the recombinant DNA techniques and formulated as a prototype vaccine with AbISCO 100 ® adjuvant. Protective immunity in murine model was evaluated against a challenge with GBS; bacterial infection and then genitourinary tract washings was also tested. High levels of antibodies type IgA, IgG and IgG2a were observed, an increased secretion of cytokines IL-2 and INF-γ was detected in the immunized experimental groups with rSIP. Besides, there was a decrease in the colony forming unit (CFU). These observations increased when the protein was formulated with the adjuvant AbISCO 100 ®.
Moreover, a passive immunity transfer was analyzed, detecting that infused animals with a mixture of CD8/CD4 cells purified from rSIP/AbISCO-100 immunized animals showed a decreased of CFU count in animals infected with GBS.
The strategy of using conserved immunodominant proteins is an interesting alternative for the development of vaccines against GBS

P6.11.73
Passive immunotherapy with modified intravenous immunoglobulins (IVIg) improves survival in experimental sepsis by attenuating inflammatory and coagulation pathways

T. Vassilev[1], *I. Djoumerska-Alexieva*[1], *J. Dimitrov*[2], *L. Roumenina*[2], *E. Voynova*[1], *I. Nina*[1], *K. Srini*[2];
[1]*Stefan Angelov Institute of Microbiology, Sofia, Bulgaria,* [2]*INSERM Unit 872, Paris, France.*

The exposure of some IgG antibodies to ferrous ions is known to enhance their polyspecificity that includes the ability to bind at least one pro-inflammatory cytokine (J.Biol.Chem.2006:281,439). Sepsis is a medical disaster that responds poorly to available drugs including intravenous immunoglobulin (IVIg) preparations. IVIg, pre-exposed *in vitro* to Fe(II) ions was used for passive immunotherapy of mice with sepsis induced by the injection of LPS, of live *E.coli*, of zymosan or by the CLP technique. A single dose of 50 to 250 mg/kg of the modified immunoglobulin preparation, but not of the native, commercially available IVIg significantly increased survival in all sepsis models.
The mechanisms of the protective activity of modified IVIg were studied in LPS sepsis. Its therapeutic effect was not due to a more efficient LPS neutralization and was still present when administered 6 hours after LPS. In the treated animals the serum levels of pro-inflammatory cytokines were decreased, IL10 levels were increased, the coagulation abnormality was overcome and the complement exhaustion was prevented. The exposure to Fe(II) ions induced structural changes in the IgG molecules as demonstrated by fluorescent spectroscopy, kinetic and thermodynamic analyses. These changes did not result in their denaturation as the modified preparations still met the strict Pharmacopoeia requirements for IVIg. We suggest that modified IVIg with additionally enhanced polyspecificity, induced by a brief exposure to pro-oxidative ferrous ions, has a clinical potential in sepsis and other variants of the SIRS syndrome (post-traumatic, in avian flu, etc.).

P6.11.74
Protection in mice by administrating antibodies against C-terminal modified nonstructural protein 1 in dengue virus infection

S. Wan[1,2], *Y. Lin*[1,2];
[1]*Center of Infectious Disease and Signaling Research, National Cheng Kung University Medical College, Tainan, Taiwan,*
[2]*Department of Microbiology and Immunology, National Cheng Kung University Medical College, Tainan, Taiwan.*

Thrombocytopenia and plasma leakage are important symptoms in severe dengue patients, which are related with dysfunction of platelets and endothelial cells. Previous studies in our laboratory showed that antibodies (Abs) against dengue virus (DENV) nonstructural proteins 1 (NS1) cross-react with human platelets and endothelial cells leading to their dysfunction. Based on sequence homology analysis, the C-terminal region of DENV NS1 protein contains cross-reactive epitopes. For safety in vaccine development, the cross-reactive epitopes of DENV NS1 protein should be deletion or modified. In this study, we tested the protective effects of Abs against full-length DENV NS1, NS1 lacking the C-terminal aa 271-352 (designated delta C NS1) and chimeric DJ NS1 consisting of N-terminus of DENV NS1 (aa 1-270) and C-terminus of JEV NS1 (aa

271-352). DENV NS1 immunization caused a prolonged bleeding time in mice, but delta C NS1 and DJ NS1 immunization did not. The anti-delta C NS1 and DJ NS1 Abs showed lower binding activity to endothelial cells and platelets than that of anti-DENV NS1 Abs. Using a DENV-induced hemorrhage mouse model, anti-delta C NS1 and DJ NS1 Abs reduced DENV-induced mouse tail prolonged bleeding time, MCP-1 production, and macrophage infiltration. Treatment with anti-delta C NS1 and DJ NS1 Abs controlled the viral load of DENV2 infection in vivo and synergized with complement to inhibit viral replication in vitro. According to these findings, modified NS1 proteins, delta C NS1 and DJ NS1, may provide a safer strategy for vaccine development against DENV infection.

P6.11.75
Single cell cloning of antigen specific monoclonal antibodies from macaque plasmablasts

*E. Silveira, Y. Kovalenkov, **J. Wrammert**;*
Emory University, Atlanta, GA, United States.

In spite of a renewed interest in the induction of neutralizing antibody responses in the field of HIV research over the last few years, the majority of our knowledge about these responses is limited to the analysis of serum antibodies or monoclonal antibodies generated from memory B cells during chronic infection. Relatively little is known about the early cellular responses that eventually will give rise to the long lived plasma cells and memory B cells both in a chronic infection as well as in a vaccine setting. We and others have found that the vast majority of the plasmablasts appearing in blood after acute viral infection or vaccination are specific for the inducing pathogen and thus represent an excellent source for generating recombinant monoclonal antibodies from single cells. Using this approach we can interrogate the epitope specificity and the repertoire breadth of the individual responding B cells. Herein we have adapted these strategies for use in ongoing SIV and HIV studies in macaques and thus established a novel and very useful tool to analyze antibody responses in macaques at a single cell level, and also generate a large panel of virus specific monoclonal antibodies. A thorough understanding of plasmablast responses induced by vaccination or infectious challenge, how they are modified by the use of different adjuvants and finally how they correlate with protection after SIV challenge will be important in designing better HIV vaccine candidates for use in humans.

P6.11.76
A clinical trial on anti-HBV-DC vaccine combined with thymosin-α1 in the HBeAg negative patients of chronic hepatitis B virus infection

***B. Wu**[1,2], J. Yang[2], Y. Liu[1], X. Wang[1], X. Huang[1], Z. Xiao[1], X. Li[1], M. Yang[1], Y. Zhou[2], H. Huang[1];*
[1]Southern Medical University Renkang Hospital, Dongguan, China,
[2]Guangzhou Pubang Bio-Immunological Tech Research Institute, Guangzhou, China.

Aims: To observe the clinical efficacy of anti-HBV-DC vaccine, the dendritic cells originating from peripheral blood mononuclear cells(PBMC) sensitized by HBsAg, in combination with thymosin-α1, in the HBeAg negative patients of chronic hepatitis B virus(HBV) infection.
Methods: 24 inactive HBsAg carriers and 25 chronic hepatitis B(CHB) patients were recruited in the trial. PBMCs obtained from 50ml of heparinized peripheral blood through density gradient centrifuge and adherence method were proliferated under the induction by GM-CSF and IL-4, and sensitized with the 50μg HBsAg. Anti-HBV-DC vaccine was harvested on day 7 and injected, half hypodermically and half intravenously, to the patient once every two weeks for 12 practices applications totally. Thymosin-α1 1.6mg was injected hypodermically twice a week. Quantitative HBVM(TRFIA) and HBVDNA and hepatic functions were evaluated at week 0, 4, 12, and 24.
Results: At week 4, 12 and 24, The HBsAg negative conversion rate were 8.00%(2/25), 12.00(3/25) and 20.00%(5/25) respectively, the HBVDNA negative conversion rate were 63.64%(7/11), 72.73%(8/11) and 72.73%(8/11) in HBeAg negative CHB patients.
The HBsAg negative conversion rate were 12.50%(3/24), 25.00%(6/24) and 37.50%(9/24) respectively in inactive HBsAg carriers.
Conclusions: anti-HBV-DC vaccine in combination with thymosin-α1 can be considered as a safe approach with high efficacy for HBeAg negative patients of chronic HBV infection, which can effectively inhibit the viral replication, decrease rapidly and eliminate the HBsAg, and may eliminate the HBsAg for partial patients.

P6.11.77
A clinical study on anti-HBV-DC-MTL in the HBeAg negative chronic hepatitis B virus infection

***B. Wu**[1,2], J. Yang[2], Y. Liu[1], X. Wang[1], X. Huang[1], Z. Xiao[1], X. Li[1], M. Yang[1], Y. Zhou[2], Q. Qiu[1];*
[1]Southern Medical University Renkang Hospital, Dongguan, China,
[2]Guangzhou Pubang Bio-Immunological Tech Research Institute, Guangzhou, China.

Aims: To observe the clinical efficacy of anti-HBV-DC-MTL, the dendritic cells(DC) and mixed T lymphocyte(MTL) originating from PBMC sensitized by HBsAg, in HBeAg negative chronic hepatitis B virus(HBV) infection.
Methods: 19 inactive HBsAg carriers and 19 chronic hepatitis B(CHB) patients were recruited in the study.PBMCs were obtained from 50ml peripheral blood. Anti-HBV-DC was proliferated from adherence PBMCs under the induction by GM-CSF and IL-4, and sensitized with 50μg HBsAg. Anti-HBV-MTL was proliferated from no-adherence PBMCs under the induction by IL-2, IL-12 and anti-HBV-DC. Anti-HBV-DC was harvested on day 7 and injected, half hypodermically and half intravenously, to patient once every two weeks for 12 times totally. Anti-HBV-MTL was harvested on day 14 and injected intravenously to patient once every two weeks for 12 times totally. Telbivudine was taken 600mg daily for 10 CHB patients those HBVDNA>10000 copy/ml. Quantitative HBVM(TRFIA) and HBVDNA were evaluated at week 0, 4, 12, and 24.
Results: Mean of HBsAg and HBVDNA decreased significantly at week 4, 12 and 24, HBsAg negative conversion rate were 10.53%(2/19), 15.79(3/19) and 21.05%(4/19) respectively, HBVDNA negative conversion rate were 69.23%(9/13), 76.92%(10/13) and 92.31%(12/13) in HBeAg negative CHB patients.
Mean of HBsAg decreased gradually along the time from week 4, 12 to 24,in inactive HBsAg carriers. At week 4, 12 and 24, HBsAg negative conversion rate were 15.79%(3/19), 26.32%(5/19) and 36.84%(7/19) respectively.
Conclusions: Anti-HBV-DC-MTL can effectively inhibit the viral replication, decrease rapidly and eliminate the HBsAg, and may eliminate the HBsAg for partial patients.

P6.11.78
A clinical study on hepatitisi B vaccine triple-therapy in chronic hepatitis B virus infection

***B. Wu**[1,2], J. Yang[2], Y. Liu[1], X. Wang[1], X. Huang[1], Z. Xiao[1], X. Li[1], M. Yang[1], H. Huang[1];*
[1]Southern Medical University Renkang Hospital, Dongguan, China,
[2]Guangzhou Pubang Bio-Immunological Tech Research Institute, Guangzhou, China.

Aims: To observe the clinical efficacy of the admixture of hepatitis B vaccine, rhGM-CSF and BCG polysaccharide ucleic acid(for short: hepatitis B vaccine triple-therapy) combined with adefovir dipivoxil in the patients of chronic hepatitis B virus(HBV) infection.
Methods: 18 HBeAg positive chronic hepatitis B(CHB) patients, 11 HBeAg positive chronic HBV carriers, 5 HBeAg negative CHB patients, 2 HBeAg negative chronic HBV carriers and 12 inactive HBsAg carriers were recruited in the study. Hepatitis B vaccine containing 20μg HBsAg, rhGM-CSF 100μg and BCG polysaccharide nucleic acid 2ml were mixed. And then the admixture injected hypodermically to the patient once every two weeks for 12 practices applications totally. Adefovir dipivoxil was taken 10mg daily for 33 patients those HBVDNA>10000 copy/ml. Quantitative HBVM(TRFIA) and HBVDNA were evaluated at week 0, 12, and 24.
Results: At week 12 and 24, HBeAg seroconversion rate were 13.79%(4/29) and 27.59%(8/29) respectively, HBVDNA negative

conversion rate were 37.14%(13/35), and 60.00%(21/35), HBsAg negative conversion rate were 2.08%(1/48) and 6.25%(3/48), HBsAb positive conversion rate were 16.67%(8/48) and 37.50%(18/48), HBsAg seroconversion rate were 2.08%(1/48) and 6.25%(3/48).
The rate of adverse effect was 50.17%. The adverse effect include fever, headache, ache all over, bellyache, urticaria and hives, dyspnea, and tumefaction ache in the injection site after injected the admixture.
Conclusions: The hepatitis B vaccine triple-therapy in combination with adefovir dipivoxil can be considered as a efficient approach for patients of chronic HBV infection, which may effectively inhibit the viral replication, improve the production of HBsAb and HBeAb, and increase HBeAg seroconversion rate.

Currently, there is a need of new anti-influenza agents that target influenza virus proteins other than ion channel M2 and neuraminidase. Non-structural protein-1 (NS1) is a highly conserved multifunctional protein which is indispensable for the virus replication cycle. In this study, fully human single chain antibody fragments (HuScFv) that bound specifically to recombinant as well as native NS1 proteins were produced from three different huscfv-phagemid transformed E. coli clones selected from a human ScFv phage display library. Results of Western blot analysis, mimotope searching/epitope identification, homology modeling and molecular docking and phage mimotope ELISA inhibition indicated that HuScFv of one E. coli clone reacted with NS1 R domain important for host innate immunity suppression while HuScFv of the other two clones bound to E domain at the sites necessary for NS1 binding to the host eIF4GI and CPSF30, respectively. The HuScFv could enter the influenza virus infected cells and interfered with the NS1 activities leading to replication inhibition of viruses belonging to various heterologous A subtypes and type B. HuScFv treated influenza virus infected cells had up-expression of IRF3 and IFN-beta genes in comparison with the controls, indicating that the antibodies could restore the host innate immune response. The fully human single chain antibodies have high potential for developing further as a safe (adjunctive) therapeutic agent for mitigating, if not abrogating, severe symptoms of influenza.

P6.11.80
3-dimensional laser structured Si scaffolds improve macrophage adherence and antigen-specific response

I. Zerva[1], *C. Simitzi*[1], *A. Ranella*[2], *E. Stratakis*[2], *C. Fotakis*[2], *I. Athanassakis*[1];
[1]*Department of Biology, University of Crete, Heraklion, Greece,*
[2]*Institute of Electronic Structure and Laser (IESL), Heraklion, Greece.*

Aim: The aim of the present study was to investigate whether 3D micro and submicron laser textured transplantable Si scaffolds with tunable morphology and chemistry could support macrophage adherence, antigen presentation and specific antibody production.
Methods: Differences of the morphological features of Si substrates were advantageously achieved by tuning the laser structuring parameters resulting in scaffolds of gradient micro-geometries, 3D porosity and hydrophilicity. Macrophages were isolated from BALB/c mice and cultured on 3D substrates seeded with Human Serum Albumin (HSA) and subsequently syngeneic T and B lymphocytes. . The adherence of macrophages and their interaction with T_H cells on the 3D substrates was revealed using SEM and Confocal Microscopy analysis. Functional assays included the measurement of interleukins IL-2, IL-4 and specific antibody production in cell culture supernatants by ELISA.
Results: SEM and confocal microscopy analysis showed that less rough 3D hydrophilic scaffolds were more favorable to macrophage adherence as compared to flat or high roughness scaffolds. T cell activation was demonstrated by detecting IL-2 and IL-4 in culture supernatants, while the development of antigen specific response was proved by detection of HSA-specific antibody production.
Conclusions:
The 3D scaffolds displaying the capacity to exquisitely control pore size, microtopography and surface chemistry support development of humoral immune response more effectively as compared to conventional flat surfaces and could therefore provide useful materials for *in vitro* and *in vivo* applications.

P6.12.01
The effect of atorvastatin on skin allograft survival and growth of B16F10 melanoma cells in mice

N. Zeidan, F. El-Rami, ***A. Abdelnoor****;*
American University of Beirut, Beirut, Lebanon.

Earlier we reported that atorvastatin (Lipitor) suppressed IL-4, interferon-γ and antibody levels in mice immunized with egg albumin. It was also observed that acute rejection episodes were less, and duration of graft survival was longer in kidney transplant patients at the American University of Beirut Medical Center who received a statin in addition to their immunosuppressive regimen. The aim of this study was to evaluate the immunomodulatory effect of atorvastatin on skin allograft survival and on tumor growth in mice.
BALB/c mice were transplanted with skin allografts from C57BL/6 mice and given either atorvastatin alone or in combination with immunosuppressive agents. Average survival days of skin allografts was recorded and serum levels of interleukin-1β and interferon-γ were quantified. BALB/c mice and C57BL/6 mice were challenged intraperitoneally with B16F10 melanoma cancer cells and were then treated with atorvastatin. They were observed regularly for tumor growth.
The results indicated that in transplanted mice, atorvastatin given alone or in combination with immunosuppressive agents prolonged allograft survival time in spite of a non-significant change in serum cytokine levels. Furthermore, atorvastatin treatment enhanced tumor growth in C57BL/6 mice and promoted tumor growth in BALB/C mice. The results obtained are supportive of atorvastatin being an immunosuppressive agent.
It is hypothesized that the immunosuppressive effect of atorvastatin could be related to its effect on membrane cholesterol of antigen presenting cells (APC) resulting in hindering the ability of APCs to present antigen to T-lymphocytes.

P6.12.02
The -318C/T, -1722T/C and +49A/G polymorphisms at the CTLA-4 gene in kidney allograft tolerance

D. C. C. Alves[1], *F. C. Dias*[1], *J. C. O. Crispim*[2], *G. E. B. Silva*[1], *R. S. Costa*[1], *L. T. Saber*[1], *E. A. Donadi*[1];
[1]*Faculdade de Medicina da Universidade Estadual de São Paulo, Ribeirão Preto, Brazil,* [2]*Faculdade de Ciencias Farmacêuticas do Rio Grande do Norte, Natal, Brazil.*

Kidney rejection remains as a major cause of morbidity associated with successful engraftment. The CTLA-4 molecule is expressed on activated T cells and binds to B7 molecules on antigen-presenting cells, delivering negative signals to T lymphocytes. We investigated whether single nucleotide polymorphism (SNP) -318C/T, -1722T/C and +49C/G of the CTLA-4 gene were associated with susceptibility to acute or chronic kidney allograft rejection. DNAs were extracted from peripheral blood cells of 114 kidney transplant patients (acute rejection n=17, chronic rejection n=51 and no rejection n=46) and 196 healthy controls and the CTLA-4 polymorphisms were successfully genotyped using allelic discrimination method on the StepOnePlus instrument (Applied Biosystems). No statistically significant association was found between the groups at the -318C/T CTLA-4 polymorphism. When compared to healthy controls, the frequency of the CTLA-4 -1722TT genotype, responsible for increased transcription of the CTLA-4, was marginally decreased in the rejection group (acute + chronic) (p=0.0609) and the CTLA-4 -1722CT genotype was increased in the chronic rejection group (p=0.0158) and in the whole rejection group (acute + chronic) (p=0.0066). The CTLA-4 +49AG genotype was underrepresented in chronic rejection group when compared to no rejection (p=0.0018) and to healthy controls (p=0.0022) and also in rejection group (acute + chronic) when compared to no rejection (p=0.0111) and to healthy controls (p=0.0153). In conclusion, the CTLA-4 -1722TT and CTLA-4 +49AG genotypes were associated with protection against development of kidney allograft rejection, while CTLA-4 -1722TC genotype was associated with susceptibility to kidney allograft rejection.

P6.12.03
KIR & their HLA ligand and aGVHD incidence post HSC TX

A. Amirzargar, *s. Hosseinian, M. Mahmoudi, M. Ostadali, K. Alimoghadam, A. Masoud;*
Tehran university of medical sciences, Tehran, Iran.

Introduction: Killer Ig-like receptor (KIR) play an important role in the outcome of HSC Tx and GVHD incidence .**Material and methods:**The study population was comprised of 86 donor and recipient siblings transplanted with hematopoietic cells during March 2010 to June 20111. The patient group consisted of: 29 patient with ALL, 27 patients with AML and 30 with Thalassemia. All the patients and donors were examined for KIR and KIR HLA Ligand by multiplex PCR-SSP method using commercial Olerup KIR and HLA ligand genotyping KIT.**Results:**The results of this study showed that the presence of 2DL2 in donors is related to aGVHD incidence with a Hazard ratio is 4.21 (P.value =0.001.) by contrast, presence of 2DS4 (o.125 Hazard ratio and 0.000 P.value) and 3DS1 (Hazard ratio= o.248 and P.value=0.000) is associated with reduction of aGVHD incidence. **Inconclusion:**Accordingly donor NK cells can destroy their alloreactive targets. If malignant cells remained after chemotherapy targeted by NK cells and prevent relapsing the disease. The result of this study is in accordance with Ruggeri`s study which found that alloreactivity prevents aGVHD. Therefore, Nk cells alloreactivity by destroying APC prevent recipient antigen from presenting to T cells which are the most important cells in aGVHD and consequently preventing disease occurance .

P6.12.04
Clinical Relevance of HLA and MICA Antibodies in Live Related Renal Transplantation

D. K. Bhat, *J. A. Siddiqui, S. Goswami, A. Baranwal, G. Kaur, S. Agarwal, N. Mehra;*
All India Institute of Medical Sciences, New Delhi, India.

The presence of HLA and non-HLA antibodies has been associated with rejection and poor allograft outcome following renal transplantation. The present study was undertaken to evaluate the clinical role of HLA and MICA antibodies in live related renal transplantation. Sera from 64 renal transplant patients before and after 7-14 days post transplantation were taken and analysed by Luminex XY platform for the presence of HLA and MICA antibodies. Presence of both of these antibodies correlated with poor graft survival. A comparison of well functioning grafts (WFG) with the rejection cases in the presence/ absence of all the three types of antibodies was done. The 30% of the acute rejection cases had all the three types (HLA Class I, II and MICA) of antibodies present at the pre-transplant stage. However, none of the well functioning graft showed the presence of all the three types (*P<0.001*). 10% of the acute rejection cases showed *de novo* development of HLA antibodies. On the other hand 50% of the ATN cases showed the presence of all the three types of antibodies (*P<0.0001*). Interestingly, 33% of the cases which developed ATN were detected to have no HLA class I or HLA class II antibodies but anti-MICA antibodies in both pre and post transplant serum samples. Although 5% of the patients with WFG showed the presence of HLA class I and class II antibodies none were detected to have the pre-transplant or post-transplant MICA antibodies. The study highlights the relevance of MICA antibodies in poor graft survival.

P6.12.05
Kidney donor MICA antigens and MICA antibody specificities detected in renal transplant recipients

M. Buc[1], *J. Tirpáková*[2], *Z. □ilinská*[3], *S. Chreňová*[4], *V. Ďurmanová*[1], *D. Kuba*[2], *M. Sapák*[1];
[1]*Department of Immunology, Comenius University School of Medicine, Bratislava, Slovakia,* [2]*Slovak Centre of Organ Transplantations, Bratislava, Slovakia,* [3]*Urology Clinic of University Hospital Bratislava, Bratislava, Slovakia,* [4]*Slovak Centre of Organ Transplantations,, Bratislava, Slovakia.*

Purpose/Objective: Despite recent advances in solid organ transplantations, an antibody mediated rejection caused by donor specific antibodies represents still a major problem in kidney graft survival. Besides HLA-induced humoral response, anti-MICA antibodies have recently attracted attention because of their possible role in a graft rejection.
Patients, material and Methods
The aim of our study was to establish if MICA antibodies are induced following the kidney transplantation and if are specific for MICA antigens of their donors. 20 patients were enrolled to the study and anti-MICA antibodies were detected by a multiplex technology. MICA alleles were typed by a sequence analysis.
Results: Anti-MICA positive sera from renal transplant patients evaluated for antigen specificities showed mostly more complex reactivity patterns as 20% of the tested sera reacted with a single MICA antigen only. The spectrum of anti-MICA antibodies gradually enlarged: six months after the transplantation, antibodies specific for other than original MICA antigens were identified. Evaluation if the recipient′s anti-MICA antibodies are donor′s MICA antigens specific has disclosed that it is not the case. Most of patient′s sera (65%) recognised not only the donor MICA antigens, however also others. The match between antibody specificities and MICA antigens was observed in 35% of patients only.
Summary: We didn't find a correlation between the specificities of the kidney recipient′s MICA antibodies and MICA antigens of the donor.
This work was supported by Ministry of Health of the Slovak Republic under the project No- 2007/41-UK-09.

P6.12.06

Detection of lymphocyte subsets in kidney transplant patients receiving induction with basiliximab or thymoglobulin: impact on kidney function

A. Caballero[1], *P. Ruiz-Esteban*[2], *M. Leon*[3], *E. Palma-Merida*[2], *D. Burgos*[2], *M. Cabello*[2], *M. Gonzalez-Molina*[2], *A. Torres*[2], *D. Hernandez*[2];
[1]*Department of Inmunology. Hospital Carlos Haya., Malaga, Spain,* [2]*Department of Nephrology. Hospital Carlos Haya., Malaga, Spain,* [3]*Department of Anatomic Pathology. Hospital Carlos Haya., Malaga, Spain.*

Induction therapy with basiliximab or thymoglobulin after kidney transplantation modifies the expression of lymphocyte subsets, including the Treg cells (CD127lowCD25high).Though this may influence the renal graft function, it has barely been studied using fine needle aspiration cytology (FNAC). In a cross-sectional study of 27 kidney transplant recipients(aged 53.5±15 year; 19men) with no acute rejection we studied by flow cytometry the expression of the receptors CXCR3 and CCR4 in CD127highCD25low and Treg cells of the graft obtained six months post-transplant. Overall, the patients who received basiliximab (as compared with thymoglobulin) had a greater percentage of CD4 T cells (31.4±10.3% vs. 19.5±12.3%; *P*=0.033) and a lower proportion of CD8 T cells (22.7±12.5 vs. 43.1±23.7%; *P*=0.020) in the FNAC and peripheral blood samples. As previously reported, thymoglobulin was associated with an increased percentage of Treg cells as compared with basiliximab (13.2±10.7 vs. 9.5±6%), though this trend was not seen in the FNAC samples (9.1±6.7 vs. 9.5±7%).The patients with post-transplant delayed graft function had increased CD8 T cells (39.5±21 vs. 19.6±14.5%; *P*=0.029) and expression of the receptor CCR4 on the Treg cells (14±22.4 vs. 9.6±17%) as compared with those who had immediate graft function. Likewise, a worse renal function (Crs≥2 mg/dL) was associated with a similar result after the FNAC (CD8: 44.6±14.6 vs. 24.5±20, *P*=0.06 and CCR4:24±27 vs. 7.6±14.7%; *P*=0.09). In summary, monitoring the expression of the chemokine receptors CCR4 and CXCR3 by flow cytometry in the conventional CD4 Tcell and Treg subsets obtained by FNAC may be a useful tool to study the course of the immune response in transplant patients with delayed graft function and worsening graft function.

P6.12.07

Evolution in kidney transplant recipients of the expression of skin-homing receptors in the different CD4+ T cell subsets

A. Caballero[1], *P. Ruiz-Esteban*[2], *M. Leon*[3], *E. Palma-Merida*[2], *D. Burgos*[2], *M. Cabello*[2], *M. Gonzalez-Molina*[2], *A. Torres*[2], *D. Hernandez*[2], *D. Hernandez*[2];
[1]*Department of Inmunology. Hospital Carlos Haya., Malaga, Spain,* [2]*Department of Nephrology. Hospital Carlos Haya., Malaga, Spain,* [3]*Department of Anatomic Pathology. Hospital Carlos Haya., Malaga, Spain.*

Monitoring the CD4+Tcell subsets, including the Treg cells(CD4 CD25highCD127low)and the conventional CD4+Tcells (CD127highCD25low), may help optimize the management of kidney transplant recipients. The expression of the chemokine receptors CXCR3 and CCR4 in these cells may provide valuable information about the functionality of these cells in the kidney graft. In a prospective study of 27 kidney transplant recipients (aged 53.5±15years;19 men) with no acute rejection we measured by flow cytometry the expression of the receptors CXCR3 and CCR4 in Treg cells and conventional CD4+T cells in samples obtained from both fine needle aspiration cytology (FNAC) of the graft and from the peripheral blood at 1 and 6 months posttransplantation. Whereas in peripheral blood samples we detected a significant increase in Treg cells from the first to the sixth month post-transplant (5.8±10versus11.6±6.6%;*P*=0.040),this increase was more obvious in the Treg using the FNAC samples(3.3±4versus12.3±7%; *P*=0.002).Likewise, at 6 months post-transplant we noted an increase in the percentage of Treg with a high expression of the skin-homing CCR4 in peripheral blood (1.6±2.5 versus 4.4±6.6%).This receptor (binding CCL2) is related with chemokines involved in inflammatory processes unrelated to rejection. This finding was more notable in the kidney graft samples obtained by FNAC (CCR4 1 month: 0 versus 6 months:9.7±16.4%;*P*=0.055). No significant changes were seen in the expression of the chemokine receptor CXCR3 or in theTreg cells or the conventional CD4+T cells. In summary, post-transplant monitoring of Treg cells and the chemokine expression (CXCR3 and CCR4) by FNAC may be a useful tool for following up the immunological response in kidney transplant patients.

P6.12.08

Pretransplant interferon-gamma secretion by CMV-specific CD8+ T cells informs the risk of cytomegalovirus replication after transplantation

S. Cantisán[1], *J. Torre-Cisneros*[1], *R. Lara*[1], *J. Redel*[2], *A. Rodríguez-Benot*[3], *J. Gutiérrez-Aroca*[4], *M. Montejo*[5], *L. Bueno*[6], *A. Rivero*[1], *R. Solana*[1];
[1]*IMIBIC-Reina Sofia Hospital, Cordoba, Spain,* [2]*Reina Sofia Hospital, Department of Neumology, Cordoba, Spain,* [3]*Reina Sofia Hospital, Department of Nephrology, Cordoba, Spain,* [4]*Reina Sofia Hospital, Department of Microbiology, Cordoba, Spain,* [5]*Cruces Hospital, Infectious Diseases Unit, Bilbao, Spain,* [6]*Cruces Hospital, Department of Nephrology, Bilbao, Spain.*

OBJECTIVES: We analyzed pretransplant CMV-specific CD8+ T cells secreting IFNγ by CMV-specific CD8+ T cells to determine whether this assessment provides prognostic value of CMV replication after transplantation.
MATERIALS AND METHODS: This longitudinal study was carried out in two centers of the REIPI network (Reina Sofia Hospital, Cordoba, and Cruces Hospital, Bilbao, Spain). Fifty-five adult patients awaiting lung or kidney transplantation were evaluable for the study. IFNγ production by CMV-specific CD8+ T-cells was assessed pretransplant using the QuantiFERON®-CMV (QF-CMV) assay. A result was considered "reactive" when the CMV antigen response minus the negative control response was greater than 0.2 IU/mL of IFNγ. CMV load was monitored for 24 months after transplantation.
RESULTS: All CMV-seronegative recipients were QF-CMV "non-reactive", QF-CMVNR, (11/11). However, in CMV-seropositive recipients, R(+), 30/44 (68.2%) were QF-CMV "reactive" (QF-CMVR) and 14/44 (31.8%) were QF-CMVNR. Within R(+) recipients 7/14 (50%) of R(+)QF-CMVNR recipients developed CMV replication after transplantation, whereas the virus replicated only in 4/30 (13.3%) of R(+)QF-CMVR patients. In kidney transplant recipients, CMV replicated earlier post-transplant, reached a higher peak CMV load, replication episodes were longer and the frequency of CMV disease was higher in R(+)QF-CMVNR patients than in R(+)QF-CMVR recipients.
CONCLUSIONS: One third of R(+) transplant candidates are QuantiFERON-CMV "non-reactive" and they are at higher risk for CMV replication after transplantation. Thus, determining pretransplant IFNg production by CMV-specific CD8+ T cells may be useful in predicting the risk of post-transplant CMV replication in solid-organ transplantation and it might aid in reclassifying transplant candidates.

P6.12.09

Role of toll like receptors in sensing endogenous danger signals released during hepatocyte cold storage or upon warming-up

C. Chebrolu[1], *U. Rauen*[2], *J. Buer*[1], *T. Scholtysik*[1], *S. Schimanski*[1], *C. Kirschning*[1];
[1]*Institute for medical microbiology, Essen, Germany,* [2]*institute for Physiological Chemistry, Essen, Germany.*

Cell death such as upon tissue injury precipitates release or exposure of intracellular molecules some of which are immune stimulatory damage-associated molecular patterns (DAMPs). They bind to specific pattern recognition receptors (PRRs) - the same receptors that detect pathogen-associated molecular patterns - of the innate immune system. Therefore, pathogen induced and non-infectious inflammatory responses do not differ principally and a distinction between self and non-self is not operative at this level. Specific PRRs such as toll like receptors (TLRs) have been implicated as sensors of specific DAMPs released from damaged tissue such as extracellular matrix components. Ischemia/reperfusion injury elicits inflammatory response while not involving microbial products but nonetheless posing a potentially fatal threat to organ allograft hosts profoundly influencing acute as well as medium and long-term graft function. Both hypothermic storage as well as heat shock (such as upon

reperfusion) induced cell death are being considered as triggers of immune activation and primary graft non-function upon transplantation. We evaluated the stimulatory potential of homogenates of cold stored or/and heat shocked primary hepatocytes by challenging macrophages of various genotypes. We observed that neither overnight hypothermic (4°C) preservation nor rewarming of the hepatocytes induced a measurable stimulatory capacity in our experimental system. In contrast, 45°C heat shock (HS) followed by incubation at regular cell culture conditions (cult) resulted in profound cell stimulation upon hepatocyte homogenate challenge. Moreover, lack of activation of Myd88/Trif / macrophages in response to HS-cult treated hepatocytes suggested an involvement of TLRs. We will report our work in progress.

Relationship between human leukocyte antigen genotypes and cytomegalovirus infection in kidney transplantation

L. Dican[1]*, L. Loga*[2]*, R. Stan*[1]*;*
[1]*University of Medicine and Pharmacology, Cluj-Napoca, Romania,*
[2]*Clinical Institute of Urology and Renal Transplantation, Cluj-Napoca, Romania.*

The aim of our study was to analyze the association of HLA alleles and the occurrence of CMV antigenemia in kidney transplantation Romanian recipients. The HLA types were performed in 115 patients by polymerase chain reaction with the sequence specific primer method by low resolution Olerup SSP KIT. DNA was extracted from whole blood using innuPREP Blood DNAMini kit. The CMV antigenemia test was performed by immunofluorescence assay for detection of CMV pp65 antigen in circulating peripherial blood leukocytes. The HLA type were compared between the patients who had undergone and those who had not undergone antigenemia. 24 Recipients were CMV antigenic positive. As a result, the frequency of HLA-32 was high in patients with antigenemia, the OR value was 5.24 ($P<0.05$). Also, in our study, the HLA-DQ8 might was more frequent in patients with antigenemia compared to patients compared to patient without CMV antigenemia ($p=0.046$, OR=4.25, CI=1.21-18.47). In conclusion HLA-A32 and DQ8 might represent a potential risk for CMV infections after kidney transplantation.

P6.12.11
Mesenchymal stem cell (MSC) therapy to improve nerve function in a rat limb transplant model

E. Fitzpatrick*, M. DeHart, J. Tercero, T. Brown, S. Salgar;*
Madigan Army Medical Center, Tacoma, WA, United States.

Introduction: Optimizing nerve regeneration and preventing immune rejection are vital to successful outcomes in hand and limb transplantation (Tx). As a first step, our objective was to investigate whether MSC can improve nerve regeneration and function. **Methods:** We performed orthotopic syngeneic right hind-limb transplants in Lewis ($RT1.A^l$) rats. Following Tx rats received syngeneic MSC (5×10^6; passage ≤7) or vehicle locally around nerve, bone and vascular anastamoses sites, and 5×10^6 MSC intravenously on the day of surgery; MSC injections (i.v.) were repeated at weekly intervals for four weeks. **Results:** Rat MSC expanded *ex vivo* were $CD29^+$, $CD90^+$, $CD34^-$, $CD31^-$, $CD45^{low}$, MHC Class I^+, Class II^-, $CD80^{low}$, and $CD86^-$. MSC were pluripotent and differentiated in to adipocytes, osteocytes and chondrocytes in *ex vivo* cultures under specific conditions. At 4 weeks post-Tx sensory nerve function as determined by cutaneous pain reaction test was <0.6 on a scale of Grade 0-3 (0=No function; 3= Normal function). However, by 8 weeks in vehicle treated animals (n=7) it was 2.2±0.7 (tibial), 1.1±0.5 (peroneal) and 1.5±0.9 (sural), and in MSC treated animals (n=6) it was 2.6±0.5 (tibial), 1.9±0.5 (peroneal) and 1.9±0.7 (sural); peroneal ($p<0.05$), tibial ($p>0.05$) and sural ($p>0.05$) nerve function was higher in stem cell treated group compared to vehicle group. Walking track analysis did not produce clear foot prints to calculate Sciatic Function Index (SFI). Laser doppler analysis revealed normal vascularization and limb transplant survival was >90%. **Conclusion:** The limb transplant procedure was highly successful, and MSC therapy appears to promote nerve function recovery.

P6.12.12
Monoclonal Antibody Therapy does not Abrogate Rejection Risk in Renal Transplant Recipients

S. Goswami*, N. Mehra;*
All India Institute of Medical Sciences, New Delhi, India.

Monoclonal antibodies are being increasingly used as therapeutic agents in medicine. Rituximab (anti-CD20) and Daclizumab (anti-IL2Rα) are two such monoclonal antibodies used to prevent organ rejection, but are not fail-safe. We have analyzed the pre and post-transplant antibody profile in serum of renal transplant recipients receiving Rituximab and /or Daclizumab.
Study Group: Kidney recipients with acute rejection and having PRA ≥ 10% pre-transplant were selected for the study (n=11). Those with well-functioning grafts served as the control group (n=15). Serum from these recipients was analyzed retrospectively by LABScreen kits for anti-HLA class-I, class-II and anti-MICA antibodies.
Results: Patients undergoing graft dysfunction showed the presence of either anti-HLA or anti-MICA antibodies or both. Acute antibody-mediated rejection was preferentially associated with the presence of pre-transplant anti-HLA and/or anti-MICA antibodies (9/11 cases, $p \leq 0.05$). Pre-transplant anti-MICA antibodies alone led to hyperacute rejection in two cases and pre-transplant DSA led to hyperacute rejection in one case. Two cases that had acute rejection within 10 days post-transplant revealed anti-HLA and anti-MICA antibodies in the pre-transplant serum.
Conclusion: A negative CDC cross-match following rituximab/daclizumab therapy does not imply absence of anti-HLA or anti-MICA antibodies in the recipient. Antibodies may still be detectable by more sensitive methods like Luminex and presence of pre-transplant anti-HLA and/or anti-MICA antibodies correlates with poor graft outcome in renal transplant. Further analysis on Luminex has shown that de-novo antibodies post-transplant, to HLA class-I/II or MICA indicate poor prognosis and may lead to accelerated graft rejection in such cases.

P6.12.13
Related organ transplantation - how voluntary is the act?

I. C. Gubert*, C. S. Rocco, M. G. Bicalho, C. Cunico;*
Universidade Federal do Parana, Curitiba, Brazil.

In spite of the significant advances in transplantation technology and immunossupression procedures for a successful grafting, a few issues concerning emotions and feelings projected over the potential live donor still demand considerations. It is the purpose of this essay to approach the conflicts and dilemmas inherent to related donor organ donation. The methodology consisted on a search on current literature on the subject of organ donation and bioethics. Live donation brings an inherent internal conflict once it is consensus that donor safety is important which means that, for him or her, the best choice is not donating. However, there is a continuous tension between personal autonomy and the expectation in the family environment that wishes the well being of all its members, in special of those in vulnerability, the sick member in need of an organ and the potential donor, seen as the ultimate chance of restoring the equilibrium in the family environment and bringing back one´s health. In biomedical area knowledge and new technologies incorporated to transplant procedures follow international safety criteria; however, under bioethics and family optics, a few gaps demand reflections. In the approach by the doctor and his staff, the technical, legal and bioethical issues must be present and equally valued during the dialogue with the family. In this scenario, in which so many individualities prevail, the challenge relies on how to minimize the conflicts and dilemmas in order to reach a harmonious and balanced decision reducing coercion to a negligible issue.

P6.12.14
Dysregulated innate immunity is associated with Post-Transplantational Diabetes Mellitus in renal transplantation

***K. Jeong**, J. Moon, Y. Kim, T. Lee, C. Ihm;*
Kyunghee University, Seoul, Republic of Korea.

Toll-like receptors (TLRs) are key innate immune receptors that mediate the inflammatory responses in transplantation and are related to the pathogenesis of insulin resistance. Post-transplantation diabetes mellitus (PTDM) is an important metabolic complication after renal transplantation. In this study, we ascertained whether single nucleotide polymorphisms (SNPs) in TLRs have any association with PTDM in Korea population.
A total of 305 patients who had received kidney transplants were included. We analyzed the association between the PTDM development and the 6 SNPs (TLR1 rs 4833095, TLR1 rs 5743557, TLR2 rs 3804099, TLR6 rs3775073, TLR6 rs3821985, TLR6 rs1039559).
The overall incidence of PTDM in this study population was 16.7% (51 of 305 patients). The percentage of steroid-treated acute rejection episodes were no significant different between the two groups. In PTDM groups, there were more patients using tacrolimus, but the difference was also not statistically significant. The patients with PTDM had significantly higher allele frequency compared to those without PTDM for the TLR2 rs3804099*T, TLR6 rs3775073*A, TLR6 rs3821985*C, TLR6 rs1039559*C alleles. The TLR6 rs 1039559 were significantly associated with the development of PTDM after adjust with age. Then we tested whether any particular TLRs' halpotype was associated with PTDM. The frequency of the GGT haplotype of TLR6 was significantly higher in the non-PTDM group compared to the PTDM group.
Our study demonstrates a significant association between SNPs of TLR6 and PTDM, and this suggests that activation of the innate immune system via TLR activation might have an essential role in the pathogenesis of PTDM.

P6.12.15
Mechanisms of HLA class I antibody in inducing endothelium inflammation

***F. M. A. Naemi**[1], V. Carter[2], A. Mulder[3], F. H. J. Claas[3], J. A. Kirby[1], S. Ali[1];*
[1]Newcastly University, Newcastle, United Kingdom, [2]NHSBT, Newcastle, United Kingdom, [3]Leiden University Medical Center, Leiden, Netherlands.

The formation of donor-specific HLA antibodies post-transplantation is associated with acute and chronic allograft rejection episodes in most types of solid organ transplantation. In this study we examined the pathways responsible for the expression of adhesion molecules and chemokines by endothelial cells in response to HLA class I antibodies. The potential of locus specific HLA antibodies to induce endothelial cell activation was also studied.
Stimulation of human microvascular endothelial cells (HMEC-1) with mouse HLA class I antibody (W6/32) induced significant expression of adhesion molecules; VCAM-1 andICAM-1 by a mechanism sensitive to PI3K/Akt inhibition (P<0.001). W6/32 antibody significantly induced the expression of CXCL8 which was reduced by 50% and 35% in the presence of Akt and PKA pathway-specific inhibitors, respectively. Silencing of CREB using siRNA induced 50% reduction in the expression of CXCL8 compared to control, p<0.001. W6/32-treated endothelial cells induced a significant monocyte adhesion and migration compared to control, p<0.001. Allospecific antibodies from sensitized kidney patients significantly enhanced the phosphorylation of CREB and expression of VCAM-1, ICAM-1 and CXCL8. Monoclonal human antibodies targeting specific HLA-A68 or HLA-B58 antigens also induced CREB phosphorylation. Down-regulation of HLA-B locus antigens using siRNA significantly reduced CREB phosphorylation in response to HLA-B58 antibodies.These data show that antibodies formed against HLA class I antigens are able to induce activation of microvascular endothelial cells. Monoclonal antibodies targeting only HLA-A or -B antigens also induced endothelial activation, demonstrating that antibodies to either locus can act independently to activate cells.

P6.12.16
Dynamic changes of T-regulatory/dendritic cell subsets and IL-17/TGF-β gene expression in stable kidney transplanted patients

***H. Nikoueinejad**[1,2], A. Amirzargar[1], M. Nafar[3], B. Einollahi[2];*
[1]Tehran University of Medical Sciences, Tehran, Iran, [2]Baqiyatallah university of medical sciences, Tehran, Iran, [3]Shahid Beheshti university of medical sciences, Tehran, Iran.

Introduction: We aimed to identify some cellular and molecular biomarkers that would allow clinicians to assess the graft acceptance. Patients and Methods: This prospective study considered 57 consecutive stable graft patients during one year after transplantation. Flow-cytometric frequencies of circulatory Tregs ($CD4^+CD25^+FoxP3^+$ and $CD8^+CD28^-$), myeloid Dendritic cells (mDC type 1, mDC type 2), plasmacytoid DCs (pDC) and real-time PCR-evaluated gene expression of IL-17 and TGF-β of peripheral blood mononuclear cells were investigated before transplantation, 2 weeks, 1, 3, 6 months, and one year after transplantation.
Results: The mean number of Tregs and PDCs decreased 2 weeks after transplantation (P<0.001) and then increased till the end of follow up as they reached their values before transplantation within one month in the case of pDCs (P=0.16) and 6 months in the case of $CD4^+CD25^+FoxP3^+$ Tregs (P=0.338). The mean number of mDC1s and the gene expression of TGF-β increased 2 weeks after transplantation (P=0.002) and then decreased till the end of follow up as they reached their values before transplantation within 6 months in the case of mDC1s (P=0.714) and 3 months in the case of TGF-β gene expression (P=0.18). There were no significant changes in the mean number of mDC2s till the 6^{th} month (P=0.041). Despite the expression of internal control of IL-17, there was not any expression of IL-17.Conclusion: There may be a clinical utility for Treg/DC and IL-17/TGF-β gene expression monitoring as predictors of stable grafts.

P6.12.17
Crosstalk between inflammation, ADAM10 proteolytic activity and Notch signaling in antibody-mediated rejection and endothelial dysfunction

*A. Pabois[1], C. Toquet[2], N. Gérard[1], S. Pattier[3], C. Laboisse[2], B. Charreau[1], **T. Simon**[4];*
[1]INSERM, ITUN, UMR 1064, Nantes, France, [2]Service d'Anatomie pathologique, Centre Hospitalier Universitaire (CHU), Nantes, France, [3]Service de Cardiologie, CHU, Nantes, France, [4]INSERM UMR1064, Nantes, France.

A Disintegrin And Metalloproteinases (ADAMs) regulate key proteolytic events involved in inflammatory cytokine and chemokine release and in Notch signaling. ADAM10 is constitutively and preferentially expressed in endothelial cells (EC) whereas ADAM17 is usually induced by inflammation. This study investigates the contribution of ADAMs and Notch signaling to vascular injury associated with donor-specific antibody-mediated rejection (AMR) in cardiac allografts. Regulation of ADAM10, -15, -17, Notch receptors (Notch1, 2, 3, 4) and ligands (Jagged1, Dll4), and VCAM1 was analyzed by quantitative PCR and by immunohistochemistry in cardiac biopsies from patients with stable graft (n=4) or with AMR (n=9), non failing heart (n=8) and dilated cardiomyopathy (n=9). Crosstalk between inflammation, ADAM10 proteolytic activity and Notch pathway was further investigated in cultured EC from donor transplants. We found that AMR induced by donor-specific anti-HLA is characterized by an upregulation of both ADAM10 and ADAM17 mRNAs (respectively 4.3 and 3.4-fold increase *versus* controls, p<0.01) without any change in ADAM15 mRNA. ADAM10 is located in graft EC and in infiltrating CD68+ macrophages and some CD3+ T cells. AMR is also associated with a significant increase in Notch ligands Jagged1 and Dll4 and drastic downregulation of the endothelial Notch4. In cultured EC, TNF recapitulates ADAM10-dependent Dll4/Notch4 imbalance. ADAM10 blockade also efficiently decreases the production of the pro-inflammatory cytokines and chemokines IL6, IL8, MCP1, CXCL16 and CX3CL1. To conclude, our findings suggest that ADAM10 is a major metalloproteinase driving proteolytic events involved in inflammatory responses and immune cell recruitment during AMR through the Notch pathway.

P6.12.18
Calculated Panel-Reactive Antibody: comparison of different approaches to calculate it

E. Rigol-Monzó[1]*, E. A. González*[2]*, C. Serra-Pagès*[2]*, G. Ercilla*[2]*, J. Martorell*[2]*;*
[1]*IDIBAPS, Barcelona, Spain,* [2]*Servei d'Immunologia. Hospital Clínic i Provincial de Barcelona, Barcelona, Spain.*

Background: Solid Phase Immunoassays, as Single Antigen Luminex (SA), enable to identify antibody specificity with high sensitivity and therefore increase the detection of unacceptable antigens for patients who have antibodies against HLA antigens. The Calculated Panel-Reactive Antibody (cPRA) is a parameter that estimates the percentage of donors who would be non acceptable for a recipient that have donor specific antibodies (DSA).
Methods: A cPRA calculator tool has been developed with a spreadsheet application based in HLA genotypes from 2260 deceased donors and 543 receptors of hematopoietic progenitor transplantation and the direct upload of the SA software output. Different ways to approach the algorithm (cut-off values, inclusion of HLA loci C* and DQB1* and resolution) have been compared. 85 subjects were selected from the renal transplantation (TX) waiting list according to Complement Dependent Cytotoxicity PRA (PRA-CDC) reactivity (>50%).
Results: The modification cutoff values (MFI>1500, MFI>3000, MFI>6000) produce no relevant changes in cPRA results (less than 12%). Inclusion of DQB1 confers a mean increase of 20% in the cPRA value while C* only 1%. There is no relevance between the results calculated using either high resolution typing or low resolution. A group of patients (47%) with PRA-CDC between 40% and 80% but cPRA>80% is identified.
Conclusion: Low resolution typing of deceased donors is adequate to calculate cPRA and the inclusion of DQB1 typing should be considered. cPRA based on local population can be helpful to mathematically asses the difficulties of sensitized patients to be transplanted if DSA negativity is required.

P6.12.19
Antibody Mediated Rejection with a Negative C1Q Assay

A. J. Savage*, W. Uber, J. Crumbley, A. Burnette, S. Hawkins, O. Moussa;*
Medical University of South Carolina, Charleston, SC, United States.

We present a 20-year-old female with orthotopic heart transplant secondary to congenital heart disease who developed late antibody mediated rejection with negative C1q staining. At the time of the transplant she was highly presensitized. She underwent a series of desensitization measurements. She had a negative retrospective crossmatch. She did well over the first 10 years of her transplant. At her 10 year mark, steroids were discontinued secondary to low bone density. The following year, she developed a low-level Class I HLA antibody. She continued to do well until 6 months later when she presented in antibody mediated rejection with hemodynamic compromise (endothelial activation with 1+C3d and 2+C4d staining). She had developed multiple new Class I and Class II donor specific antibodies. C1Q testing was negative for both Class I and Class II antibodies. She was hospitalized for over a month for aggressive treatment for antibody-mediated rejection which included plasmapheresis, IVIG and bortezomib. She improved clinically with significant reduction in her DSA levels. One year later she presented with a rise in antibody titers and trace focal C3d but negative C4d. Again her C1q staining was negative. She was started on cyclophosmadie and DSA levels regressed. Six months later she presented in AMR with hemodynamic compromise for a second time with patchy diffuse C4d and negative C3d with endothelial activation. Again, her C1q staining was negative.
Conclusion: We present a case where AMR with hemodynamic compromise presented twice in the same patient with multiple negative simultaneous C1q assays.

P6.12.20
Relationship between the number of NK cell subsets and Chronic Allograft Nephropathy (CAN)

A. Sepanjnia*, S. Asadi, A. Amirzargar, P. Ahmadpour, F. Purrezagholi;*
Tehran University of Medical Science, Tehran, Iran.

Background: NK cells have two key effector functions, which are the cytotoxic lysis of target cells and the release of inflammatory cytokines that amplify the immune response. Around 90% of human peripheral blood NK cells are $CD56^{dim}$ and display a high level of cytotoxicity, while the remaining 10% are $CD56^{bright}$ and display greater cytokine secretion. It has been reported that expression of the NK cell activating receptor NKG2D is increased with acute and chronic nephropathy after human kidney transplantation. In this study we have shown that the number of NK cells is not different between biopsy proven CAN patients and healthy controls, particularly at early time-points. **Methods** A case-control study was carried out on 25 patients with CAN and 25 matched healthy controls. NK cell numeration was determined by flow cytometry of PBMC, and NK cells that were $CD56^{bright}$ discerned with anti-CD127 from NK $CD56^{dim}$ cells that don't have CD127. **Results** No significant difference was observed in NK cells numeration between controls and patients (P value>.05); although, the number of NK $CD56^{dim}$ cells was higher than NK $CD56^{bright}$ cells in CAN patients and controls. **Conclusion** We have evaluated the effect of natural killer cells frequency and stage of maturity among CAN patients. Our results revealed that there is no difference between the number of NK cells of CAN patients and healthy controls.

P6.12.21
Cardiomyocyte and P19 embryonic stem cell

R. Setorg*, S. Abediankenari, M. Malekzadeh, N. Rezaei, M. Alipour; Mazandaran University of Medical Sciences, Sari, Iran.*

Introduction: Three types of pluripotential stem cell lines have been established from mammalian embryos: embryonic stem (ES), embryonic germ (EG), embryonic carcinoma (EC) cells. P19 cells are a line of pluripotent embryonal carcinoma cells. They are feeder cell independent and can differentiate into cells of all three germ layers. The purpose of this study is differentiation of these cells to cardiac cells in culture medium.
Material and Methods: In this research, we used dimethylsulfoxide(DMSO) (Sigma) for inducing P19 cells into cardiac cells. Undifferentiated P19 cells were cultured under adherent condition in growth medium, Dulbecco Modified Eagles Medium (DMEM) (Gibco) supplemented with 10% fetal bovine serum (Gibco), penicillin (100 U/ml) and streptomycin (100µgr/ml) (Gibco). The cultures were maintained in 5% CO2 atmosphere at 37˚C.
Results: We treated P19 cells with 2 concentrations of DMSO and formed Embryoid Bodies (EBs) via liquid suspension culture in bacterial- grade dishes method. 5×104 cells/ml was aggregated for 4 days in 60 mm non adhesive bacteriological-grade Petri dishes containing 5 ml of the growth medium, in the presence of 0.5% and 1% DMSO.
Discussion: Optimization of DMSO concentration is necessary for differentiation to cardiac cells. It is concluded that P19 line cells are sensitive to dilution and concentration of inducing medium supplements.

P6.12.22
Clinical relevance of cytokine gene polymorphism on the development of acute rejection episodes and chronic allograft nephropathy following live donor renal transplantation

J. A. Siddiqui*, G. Kaur, D. Bhowmik, S. Guleria, N. Mehra;*
All India Institute of Medical Sciences, New Delhi, India.

Genetic variability in cytokines, which results in a shift of the cytokine milieu, could significantly impact the outcome of immune response, and thus the incidence of rejection and graft survival. In this study, 22 single nucleotide polymorphisms (SNPs) in 13 cytokine genes namely interleukin (IL) 1-alpha (T/C -889), IL1-beta (C/T -511, T/C +3962),

IL12 (C/A -1188), interferon-gamma (A/T UTR 5644), transforming growth factor-beta (C/T codon 10, G/C codon 25), tumor necrosis factor-alpha (G/A -308, G/A -238), IL2 (T/G -330, G/T +160), IL4 (T/G -1098, T/C -590, T/C -33), IL6 (G/C -174, G/A nt 565), IL10 (G/A -1082, C/T -819, C/A -592), IL1R (C/T pst1 1970), IL1RA (T/C mspa1 11100) and IL4RA (G/A +1902) in182 patients undergoing renal transplantation from their live related and unrelated donors. Of these, 50 patients experienced acute rejection episodes (ARE), 42 experienced chronic allograft nephropathy (CAN) (25 patients who had previous ARE and 17 without any ARE), while the remaining 115 patients had well functioning grafts (WFG). The high producer genotype TT of IFN- showed a strong association with development of ARE; while the AA genotype conferred protection from ARE (p=0.000) and CAN (p=0.007). Similarly, genotype GG at codon 25 of TGF-, was associated with ARE (p<0.05) and CAN (p<0.05). Further, TT genotype of IL-1 -511 and IL1RA mspa1 11100 was also associated with AR episodes (p<0.001 and p<0.01). The study highlights the clinical relevance of CGP as an important biomarker to predict acute rejection episodes and chronic allograft nephropathy following kidney transplantation.

P6.12.23
Short term survival of the related alive donor's renal implant and the compatibility HLA

*Y. Trujillo Alvarez[1], A. Brito Garcia[1], E. Noris Garcia[1], N. Diaz Baez[1], N. Peña Fresneda[1], D. Barberia Torres[1], R. Viguera Lopez[2], S. Arce Bustabad[1], **G. Penton Rol**[3];*

Introduction: The separation of the lymphocytes T and B for magnetic pearls are a highly effective technique (compared with the technique of Fiber of Nylon) for the serological typing and the different modalities of tests crusades for the transplant. Objective: The magnetic pearls are covered with specific antibodies that recognize specific markers in the surface of the membrane of the lymphocytes T and B. When the lymphocytes have been separated, HLA typing is doing and later on the couple's donor-receiver selection**.** Results: To all they the protocol of the related alive donor's donating selection was applied settled down in the department of Immunology of the Institute of Nephrology: cross-match and auto reaction of lymphocytes to 4 °C, 22 °C and 37 °C, study of sensitization and the HLA typing class I and class II by means of the microlymphocitotoxicity test. The final cross-match carries out 48 hours before the transplant with the selected donor. It uses little quantity of blood, quick, a viability of a 98% of alive cells, without contamination and the concentration of cells required is obtained to carry out the HLA typing and other histocompatibility tests. Conclusion: With this technique we are able to introduce the typing HLA DR and HLA DQ for serology in the Donating couple's selection Lives Related in the Renal Transplant. Of the 100 studied receivers, 9 were identical HLA with their donor (siblings) with a survival of 100% and the rest HLA haploidentical (siblings and parents) with a survival of 96%.

P6.12.24
Relationship of Serum Soluble Interleukin-2 Receptor (IL-2) & CD 30 with the Renal Allograft Rejection- A Hospital Based Experience in Renal Transplant Patients of Kashmir Valley

***R. Wani**;*
SKIMS, Srinagar, India.

Background: Renal allograft rejection is mediated by T lymphocytes, expressing interleukin-2 receptors and their concentrations have been suggested as a marker of acute rejection episodes. Soluble CD30 released following T cell activation can be used also as biomarkers for the prediction of allograft rejections. Thus, irreversible damage caused by rejection could be relieved and avoided by early diagnosis and treatment.
Objective: The purpose of this study was to investigate the relationship between serum sIL-2R & sCD30 levels with the rejection episodes in recipients.
Methods: Serum soluble IL-2R & CD 30 levels were measured with ELISA in recipients and in controls using the IL-2R &s CD 30 ELISA kits.
Results: Serum sIL-2R levels in patients with the rejection group were evidently higher (Mean ±SD: 329.85±59.22 pgs/ml) as compared to the Non- rejection group (Mean ±SD: 18.12±11.22 pgs/ml P<0.05). The higher values of sIL-2R were markedly reduced by adequate antirejection therapy. The healthy control group showed lower sIL-2R concentrations (Mean ±SD: 14.67±7.53 pgs/ml).
Our study demonstrate that the sCD30 levels in patients before transplantation was higher to that of healthy controls (Mean ± SD: 25.63±13.84 ng/ml vs Mean± SD: 13.44± 5.01 ng/ml; P=0.0001), 95%CI (6.96-17.41). On comparing pre and their corresponding post transplant samples, sCD30 values were not found to be significant, P= 0.89, 95%CI (-19.1-16.8).
Conclusion: Our results suggest that the serum sIL-2R concentrations showed significant correlation with the acute rejection episodes. The data does not support the idea of sCD30 being used as a potential marker for allograft rejection.

P6.12.25
Frequencies of CTLA4^{+}, FoxP3^{+} and CD127^{low} T cells within the CD4^{+}CD25^{high} population early after lung transplantation predict the incidence of chronic rejection after two years

***G. Warnecke**, J. Salman, A. Knoefel, W. Sommer, C. Kuehn, I. Tudorache, M. Avsar, T. Fuehner, J. Gottlieb, T. Welte;*
Hannover Medical School, Hannover, Germany.

Regulatory T cells (Treg) regulate alloantigens and thus may counteract the development of chronic rejection (i.e. bronchiolitis obliterans syndrome, BOS) in lung transplantation. BOS affects over 60% of lung transplant recipients within five years. Here, we analyzed Tregs in peripheral blood of 120 lung recipients prospectively during the first 2 years and correlated with the onset of BOS.
In consecutive lung transplant recipients, the number of circulating Treg was detected by flow cytometry before transplantation and 3 weeks, 3, 6, 12, 18 and 24 months after transplantation. Treg were defined as CD4^{+}CD25^{high} T cells and were further analyzed for relevant markers such as, amongst others, CTLA4, CD127, FoxP3 and IL-2. Lung function and protocol biopsy results at the time points 3 weeks, 3, 6, 12, 18 and 24 months after transplantation were analyzed. We defined two groups by the development of BOS stage 1 or higher versus BOS stage 0. Repeated measures ANOVA were performed to compare differences of Treg sub-populations between the groups.
38/120 patients developed a BOS stage 1 or higher at 2 years after lung transplantation. The other 82/120 patients showed a course with stable lung function. A significant positive correlation was detected between the frequencies of CD4^{+}CD25^{high}CD127^{low}, CD4^{+}CD25^{high}CTLA-4^{+}, CD4^{+}CD25^{high}FoxP3+ and CD4+CD25highIL-2+ T cells and the absence of BOS 2 years after lung transplantation (p<0.05).Higher frequencies of CD4+CD25highCD127low, CD4+CD25highCTLA-4+, CD4+CD25highFoxP3+ and CD4+CD25highIL-2+ T cells as early as 3 weeks after transplantation are associated with protection against BOS during the initial 2 years after lung transplantation.

Correlation between reconstitution of differentiated effector, effector memory and regulatory T cells populations and insulin independence in type 1 diabetes patients after autologous hematopoietic stem cell transplantation

***L. C. M. Arruda**[1,2], J. T. C. Azevedo[1,2], R. M. Bolzoni[1], D. T. Covas[1,3], J. C. Voltarelli[1,3], K. C. R. Malmegrim[1,3];*
[1]National Institute of Science and Technology in Stem Cells and Cell Therapy, Regional Hemotherapy Center of the School of Medicine of Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil, [2]Department of Biochemistry and Immunology, School of Medicine of

Ribeirão Preto, University of São Paulo, RIbeirão Preto, Brazil, [3]Department of Clinical Medicine, School of Medicine of Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil.

Introduction: High dose immunossuppression (HDI) followed by autologous hematopoietic stem cell transplantation (AHSCT) has emerged in last past years as a therapeutic alternative for newly diagnosed type 1 diabetes mellitus (T1D) patients, however the mechanisms involved in this setting remained unclear. Objective: To address the correlation between immune reconstitution and insulin independence in two clinical groups, based in duration of insulin independence and time of remission (less or more than 3 years insulin-free), after HDI/AHSCT. To evaluated the reconstitution of effector, effector memory and regulatory T cells after treatment. Methods: Peripheral blood was collected from 21 T1D patients (group A: 11 insulin-free for at least 3 years; group B: 10 insulin-free less than 3 years), at pre-transplantation and different time points after transplantation. Peripheral blood mononuclear cells were immunophenotyped by flow cytometry analysis. Results: We found significant increased numbers of $CD4^+CD27^-CD45RO^-$ differentiated effector T cells at months +24 and +54 post-AHSCT in group B when compared with the group A in the same periods. We also detected significant increase of $CD4^+CD27^-CD45RO^+$ effector memory T cells at months +2, +3, +6, +9 and +30 post-AHSCT in group B when compared with the group A in the same periods. The $CD4^+CD25^{hi}FoxP3^+$ regulatory T cell numbers only increased in group A at months +18, +30 and +60 after transplantation when compared with pre-transplantation period. Conclusions**:** Our results suggest an improvement of the peripheral immunoregulatory mechanisms after HDI/AHSCT, which may contribute to reestablishment of self-tolerance and control of autoimmunity on these T1D patients.

P6.13.02
Immunotherapy of xeno-graft versus host disease with ICOS monoclonal antibodies in immunodeficient mice

***A. Burlion**[1], N. Y. Petit[1], G. Fourcade[1], M. Mattei[2], O. Brégerie[2], S. Pastor[3], D. Olive[3], G. Marodon[1];*
[1]INSERM U959, Paris, France, [2]CEF UPMC, Paris, France, [3]INSERM UMR1068, Marseille, France.

ICOS (CD278), which belongs to the CD28 superfamily, is a powerful co-stimulatory molecule for T cells and is highly expressed on effector/activated T cells. Thus, targeting ICOS could dampen an unwanted immune response. To address this question using human cells, we determined the impact of a novel anti-human ICOS monoclonal antibody on the xeno-Graft vs Host Disease (GVHD) that develop after transfer of human PBMC into immunodeficient $NOD.SCID.\gamma c^{-/-}$ mice. Sixty-five percent of the mice injected with the anti-ICOS mAb (n=12) survived GVHD compared to controls, which all died by day 50 (n=12; median survival of 19 days). Injected mice were analyzed for numbers and phenotype of human cells in the blood, and in lymphoid and non-lymphoid organs by flow cytometry and histology. Expansion of human T cells in the blood of xenografted aniamls was greatly diminished by the antibody. Moreover, a significant reduction in mononuclear cell infiltrates was observed in the peripheral organs of treated animals. However, protection from GVHD did not correlate with lower activation of effector T cells, nor with increased numbers of regulatory T cells. In anti-ICOS treated animals, human $ICOS^+$ T cells were observed 3 months after treatment with no or moderate signs of GVHD. Protection from GVHD by the antibody might be due to a defect in T cell survival/expansion, related to blockade of ICOS-LICOS co-stimulatory signal. Thus, targeting ICOS may represent a new therapeutic strategy to treat GVHD.

P6.13.03
Identification of hematopoietic minor H antigens using leukemia reactive T cells and genetic linkage analysis

***B. Chung-Ueck**[1], J. Castle[2], J. Albrecht[1], M. Frey[1], R. Voss[2], E. Distler[1], W. Herr[1];*
[1]University Medical Center - 3rd Medical Department -Hematology, Mainz, Germany, [2]University Medical Center - Institute of Translational Oncology (TRON), Mainz, Germany.

A successful effective treatment of leukemia patients by allogeneic hematopoietic stem cell transplantation depends on graft-versus-leukemia effect mainly mediated by donor T cells. GvL is frequently associated with alloreactivity of T cells to epithelial organs, graft-versus-host disease, and can be sometimes too weak resulting in leukemia relapse after transplantation. Overcoming these limitations adoptive transfer of donor T cells specifically recognizing leukemia cells as targets is a promising strategy. Minor histocompatibility antigens play a crucial role as targets for GvL/GvHD reactive donor T cells. Knowledge of mHag with specific or preferential expression in hematopoietic tissue may therapeutically induce selective GvL responses in the absence of GvHD.
For identification of human hematopoiesis-specific mHag recognized by cytotoxic T lymphocytes, genetic linkage analysis can be used. Leukemia-reactive CTL were isolated by in vitro stimulation of naïve CD8+ T cells from healthy individuals with fully HLA class I-matched primary acute myeloid leukemia blasts. The recognition pattern of two CTL to a panel of previously genotyped B-LCL were analyzed by IFN-γ-ELISPOT assay. B-LCL originated from three large pedigrees from the CEPH reference family collection (Corielle Institute/New Jersey/USA). Based on the recognition patterns all individuals were divided into either mHag-positive or mHag-negative, respectively. Genetic linkage analysis using genotypes of these individuals, which are online available at the CEPH database, was performed to identify linked regions and to narrow down the region for final gene identification coding the mHag peptides. Of particular interest for future immunotherapy trials are those mHag expressed specifically or at least preferentially in hematopoiesis.

P6.13.04
Monitoring early CMV-specific CD8+ T-cell responses after allogeneic stem cell transplantation by HLA-multimers

***M. Ciaurriz**[1], L. Beloki[1], N. Ramirez[1], C. Mansilla[1], A. Zabalza[2], E. Bandres[2], M. Rodriguez[2], E. Olavarria[1,2];*
[1]Biomedical Research Center NavarraBiomed, Pamplona, Spain, [2]Complejo Hospitalario de Navarra, Pamplona, Spain.

We present the results of a pilot study using pentamer (PM) and streptamer (ST) multimer complexes for monitoring CMV-specific CD8+ T-cells (CTLs). We analysed 14 patients that underwent allogeneic Stem Cell Transplantation (allo-SCT). All patients and donors were positive for the HLA-A*02:01 allele. PM and ST were directed against the epitope NLVPMVATV (495-503) of the CMV phosphoprotein 65 (pp65). Samples were obtained at 15-day intervals until day +90 and monthly thereafter.
Three patterns were observed. In 2 patients (14%) no CMV-specific-CTLs could be detected despite several CMV reactivations, requiring prolonged cumulative antiviral therapy (67 and 136 days each).
In 6 patients (43%) CMV reactivation occurred at a mean of 36 days (10-74) and triggered a rapid increase of CMV-specific-CTLs with a median of 6.9×10^5/L (range 0.02-279.7). The CMV-PCR became immediately negative and antiviral therapy was stopped promptly after a median of 15.3 days (8.7-23).
Finally, 6 patients (43%) showed an early immune reconstitution with CMV-specific-CTLs detected with a median of 1.53×10^5/L (range 0.2-54.72) in the absence of CMV-PCR reactivation at a median of 20.5 days (10-34) post-SCT. No CMV-PCR reactivation was observed in this group with a median follow-up of 8 months (3-14).
Monitoring CMV-specific-T-cells might be able to distinguish patients at higher risk of recurrent virus reactivation and in need of prolonged antiviral therapy. Patients with increasing CMV-specific-CTLs detectable at the time of CMV-PCR reactivation may only need a short course of antiviral therapy, while those with early CMV-specific-CTLs may be protected from CMV reactivation.

P6.13.05

Mesenchymal Stem Cells as an Immunotherapy for Chronic graft-versus-host disease

C. De la Mata[1], *C. Olmedo*[1], *L. Moratalla*[1], *E. Lopez*[1], *A. Hernandez*[1], *S. Gomez*[1], *S. Garzón*[2], *R. Saldaña*[2], *C. Solano*[3], *M. Jurado*[1]; [1]*Hospital Universitario Virgen de las Nieves, Granada, Spain,* [2]*Hospital de Jerez, Jerez, Spain,* [3]*Hospital Clínico de Valencia, Valencia, Spain.*

Background and Aims
Mesenchymal Stem Cells (MSCs) have immunomodulatory properties in vitro and in vivo. Chronic graft-versus-host disease (cGVHD) is an important problem in long-term survivors of allogeneic stem cell transplantation, it increases mortality and morbidity, and causes impaired functional status. cGVHD is a TH-2 mediated disease. In this study, TH1 and TH2 cytokines and lymphocytes subsets were analysed in cGVDH patients after MSC infusion .
Methods
Patients with cGVHD newly diagnosed, were treated with intravenous infusion of MSC, obtained from adipose tissue. We evaluated lymphocyte subsets and cytokines after 7, 20, 42 and 56 weeks using Flow Cytometer.
Results
Differences were observed on cytokines evaluated, especially on IL-10, IL-2 and TNFa. Also we found difference between control and MSC patients in the lymphocyte subsets, especially on week 20 after therapy.
Conclusions
MSC have an impact on cytokines and lymphocytes population. MSC infusion may be an effective therapy for patients with cGVDH.

P6.13.06

Acute myeloid leukemia (AML)-reactive CD4+ T-cell clones isolated from 10/10 HLA match donors recognize HLA-DP mismatch antigens and eliminate leukemia blasts in NSG mice in vivo

Y. Eichinger*, E. Distler, M. Frey, S. Khan, U. Hartwig, W. Herr; University Medical Center, 3rd Dept. of Medicine, Hematology, Mainz, Germany.*

In allogeneic hematopoietic stem-cell transplantation, donor-derived T cells mediate beneficial graft-versus-leukemia (GvL) effects but also graft-versus-host disease (GvHD). As $CD4^+$ T cells recognize peptides presented by HLA-class-II molecules that are not expressed on non-hematopoietic cells under non-inflammatory conditions, they might have a more favourable safety profile than $CD8^+$ T cells in terms of avoiding GvHD. In this project we have developed a reliable protocol for the *in vitro* generation of AML-reactive donor $CD4^+$ T cells that could be used for adoptive transfer experiments in AML-engrafted NOD/SCID-IL2Rγ(null) (NSG) mice.
Naive $CD4^+$ T cells were sorted from healthy donor PBMC. They were stimulated in 96-well mini-mixed lymphocyte-leukemia cultures (mini-MLLC) with irradiated primary AML blasts with complete HLA-A/B/C/DR/DQ match. AML-reactive mini-MLLCs were expanded in six different donor-patient pairs. They showed strong IFN-γ and TNF-α production as well as lysis (up to 60% at E:T = 20:1) upon incubation with AML blasts or patient-derived EBV-B lines in ELISpot and ^{51}Cr-release assays. Several $CD4^+$ CTLs were of clonal origin according to TCR-Vβ chain analysis. Nearly all of them recognized patient-derived mismatched HLA-DP, as determined by using HLA-DP transfectants as targets. NSG mice engrafted with AML blasts and then infused with AML-reactive $CD4^+$ CTL showed complete disappearance of AML blasts in bone marrow, spleen and blood. Homing of T cells was confirmed as they could still be detected in these organs one week after transfer. Our data suggest to further investigate $CD4^+$ T cells as potent cytolytic effector cells in adoptive immunotherapy of leukemias.

P6.13.07

Fetal membrane cells promote regulatory T cells and suppress alloreactivity in a cell contact dependent manner

T. Erkers*, S. Nava, J. Yosef, O. Ringdén, H. Kaipe; Karolinska Institutet, Stockholm, Sweden.*

We introduced the use of stromal cells from term fetal membrane (FMCs) in patients with steroid refractory Graft-versus-Host Disease. FMCs have many advantages compared to bone marrow-derived mesenchymal stromal cells (BM-MSCs), including an increased allosuppression, unlimited supply, great expansion potential and high expression of integrins. In this study, we are elucidating factors of importance in the reduction of alloreactivity by FMCs. We found that FMCs require cell-cell contact in order to mediate suppression in mixed lymphocyte reactions (MLR) (p=0.01, n=11). The frequency of CD4+CD25highFOXP3+ regulatory T-cells (Tregs) was increased (median 2.3-fold), whereas the proportion of total CD25+ T-cells was decreased (median 1.4-fold) when the FMCs were added to the MLR cultures (p=0.03, n=10 and p=0.03, n=6, respectively). This was only observed when cell-cell contact was allowed between the MLR and FMCs. Blocking activity of indoleamine-2,3-dioxygenase (IDO) (median 2.6-fold increase in proliferation compared to MLR+FMC-control, p=0.01, n=8), IFN-gamma (median 2.0-fold increase, p<0.01, n=11), Prostaglandin E2 (median 1.26-fold increase, p=0.01, n=12) and PD-L1 (median 1.23-fold increase, p=0.03, n=7), significantly impaired the anti-proliferative ability of the FMCs in MLRs. Inactivation of IDO reduced the frequency of Tregs. In contrast to BM-MSC, pre-treatment of the FMCs with IFN-gamma (100 U/ml) decreased suppression of alloreactivity (p<0.01, n=16), but stimulation of FMCs with MLR supernatants containing low levels of IFN-gamma had no effect on the suppressive capacity in the MLR.
To conclude, FMCs differs in several aspects from MSCs and needs proximity to allo-reactive lymphocytes to mediate a suppressive effect and increase the frequency of Tregs.

P6.13.08

Circulating human Thymic Seeding Progenitors expand after allogeneic HSCT in parallel with a decrease of CXCR4 expression

S. Glauzy[1,2,3], *I. André-Schmutz*[4,5], *J. Larghero*[1,2,6], *S. Ezine*[7], *R. Peffault de Latour*[2,8], *S. Servais*[8], *G. Socié*[1,2,8], *E. Clave*[1,2,3], *A. Toubert*[1,2,3]; [1]*INSERM U940, Paris, France,* [2]*Univ Paris Diderot, Sorbonne Paris Cité, Institut Universitaire d'Hématologie, Paris, France,* [3]*Laboratoire d'Immunologie et d'Histocompatibilité, Hôpital Saint-Louis, AP-HP, Paris, France,* [4]*INSERM U768, Paris, France,* [5]*Univ Paris Descartes, Sorbonne Paris Cité, Hôpital Necker, Paris, France,* [6]*Unité de Thérapie Cellulaire et CIC de Biothérapies, Hôpital Saint Louis, AP-HP, Paris, France,* [7]*INSERM U1020, Paris, France,* [8]*Service d'Hématologie-Greffe de Moelle, Hôpital Saint-Louis, AP-HP, Paris, France.*

Long term T-cell reconstitution after allogeneic hematopoietic stem cell transplantation (HSCT) is dependent on patient thymic function and affected by acute graft-versus-host disease (aGVHD). T-lineage reconstitution after HSCT is limited by progenitor supply to the thymus. In humans, a subset of circulating Thymic Seeding Progenitors (TSP) with a CD34+lin-CD10+CD24- phenotype, exhibits a very low myeloid but a B, T and NK lymphoid potential. We analysed by flow cytometry this population in the peripheral blood of 39 patients, 3 months after HSCT, in comparison to 15 healthy donors (HD). Patients without aGVHD (n=11) and patients with a grade I aGVHD (n=7) had significantly (p=0,005) more TSP than patients with severe aGVHD (grade II, III and IV (n=21)) or HD. TSP from patients and HD both generated mature T cells in vitro using limiting dilution assay on OP9/DL1 cells. Moreover, patients and HD cell-sorted TSP displayed a similar global expression by quantitative RT-PCR of 22 genes involved in progenitor T cell differentiation and homing.
Noteworthy, we observed an important reduction of CXCR4 expression in TSP from patients without aGvHD compared to HD (p=0.002), consistent with an enhanced exit from the bone marrow. CXCL12, the CXCR4 ligand, was decreased in patient's plasma, especially in case of aGVHD. In conclusion, at 3 months after HSCT, we observed in patients without severe aGVHD, a rebound of circulating functional TSP associated with a modulation of the CXCR4/CXCL12 axis. These data identify TSP as a novel therapeutic target to enhance immune reconstitution after HSCT in humans.

P6.13.09

In vivo rapamycin-induced Tregs do not traffic to the bone marrow: preservation of the GVL effect after T-cell replete HLA-haploidentical HSCT

F. Gullotta[1], *J. Peccatori*[2], *M. Carbone*[1], *M. Noviello*[1], *M. Battaglia*[1], *M. Bernardo*[3], *F. Locatelli*[3], *F. Ciceri*[2], *C. Bonini*[1], *A. Bondanza*[1];
[1]*Fondazione Centro San Raffaele, Milan, Italy,* [2]*Ospedale San Raffaele, Milan, Italy,* [3]*IRCCS Bambin Gesù Hospital, Rome, Italy.*

Introduction: we have recently completed a Phase I/II study of T-cell replete hematopoietc stem cell transplantation (HSCT) from an HLA-haploidentical donor in 113 pts with hematological malignancies followed by GVHD prophylaxis with rapamycin. Incidences of grade III-IV acute GVHD and chronic extensive GVHD were 21% and 35%, respectively. There was expansion of circulating CD4+/CD25+/FoxP3+/IL-7Rα- Tregs (median 6.5% range 0.2-37.2, P<0.01 compared with controls), which were suppressive ex vivo. Tregs frequencies correlated with GVHD severity. One-year PFS was 44% in pts with early disease (n=18) and 30% in pts with advanced disease (n=95).
Aim: A long-standing question is whether Tregs-based strategies may interfere with the GVL effect. We thus aimed at verifying if rapamycin-induced Tregs traffic to the bone marrow (BM) suppressing effector T cells locally.
Results: The BM of rapamycin-treated pts was depleted of Tregs (at day 30, BM Tregs frequencies: median 0.3% range 0.0-2.2, P<0.01 compared with PB Tregs). High-level CXCR4 expression on circulating Tregs suggested a specific antimigratory effect of rapamycin. On the contrary, the BM was heavily infiltrated by CD45RA-/CD62L- effector memory CD8+ T cells that expressed VEGFR-2. Circulating T cells co-cultured with VEGF-producing BM-resident stromal cells promptly up-regulated VEGFR-2, resulting in a dose-dependent suppression of proliferation. Interestingly, VEGFR antagonists, such as sorafenib and sunitinib, but not dasatinib, partially reverted the antiproliferative effects of stromal cells.
Conclusions: While protecting from GVHD, rapamycin-induced Tregs do not traffic to the BM, thus leaving the GVL effect unharmed. The potential immunosuppressive effect of BM-resident stromal cells merits further investigation.

P6.13.10

Basophils as regulators of CD4 T cells in graft versus host disease

F. Hermann*, Y. Talke, M. Rodriguez Gomez, I. Ketelsen, K. Renner, M. Mack;*
Universitätsklinikum Regensburg, Regensburg, Germany.

Until recently basophils were considered mainly as effector cells of an innate immune response linked to allergy and parasite infection. Only in the past years they were recognized as important regulators of adaptive immunity.
T cell proliferation is an important part of immune regulation, as well as in malignant disease.
We have found that non-activated, as well as activated basophils are able to inhibit T cell proliferation in vitro. This effect is independent of Fas and MHCII, but dependent on the soluble factors IL 4 and IL-6.
Based on these findings we analysed the role of basophils in the model of acute graft-versus-host-disease (GvHD) and found a significant increase in the GvHD score of mice after depletion of basophils. Adoptive transfer of basophils leads to a significant reduction in the GvHD score compared to control. Mice depleted of basophils showed an increased CD4+ T cell count in spleen and mesenteric lymph nodes as well as an increase in total CD45+ cells in the GvHD model. Depletion of basophils also led to more IL-17+ CD4+ T cells in the mesenteric lymph nodes but not in the spleen compared to controls.
To analyse the in vivo effects of IL-4 and IL-6 in the GvHD model we administered the cytokines or PBS. IL-4 led to a significant lower GvHD score und better survival compared to controls and the IL-6 treated group. Injections with IL-6 on the other hand significantly increased the GvHD score and reduced the survival compared to IL-4 and controls.

P6.13.11

Innate memory CD4 T cells suppress autoimmune graft-versus-host disease

W. Huang[1,2], *Q. Qi*[1,2], *J. Hu*[1,2], *F. Huang*[1,2], *T. M. Laufer*[3], *A. August*[1,2];
[1]*Department of Microbiology & Immunology and Infection & Pathology Program, Cornell University, Ithaca, NY, United States,* [2]*Huck Institutes of Life Sciences and Center for Molecular Immunology and Infectious Disease, The Pennsylvania State University, University Park, PA, United States,* [3]*Department of Medicine, University of Pennsylvania School of Medicine, Philadelphia, PA, United States.*

Chronic graft-versus-host disease (cGVHD) is the major complication post hematopoietic cell transplantation. Major histocompatibility complex class II (MHCII) mediated $CD4^+$ T cell differentiation and function plays a critical role in cGVHD, and the lack of hematopoietic MHCII (H-MHCII) causes cGVHD in syngeneic irradiated murine recipients. We have studied this process using murine bone marrow transplant of MHCII deficient or sufficient donors. We find that irradiated WT recipients that received $MHCII^{-/-}$ bone marrow exhibited a systemic decrease in IL-10 and increase in TNF-α production, and defective development of H-MHCII dependent innate memory phenotype (IMP, $CD44^{hi}/CD62L^{lo}$) $CD4^+$ T cells. Transfer of IMP $CD4^+$ T cells, but not conventional regulatory T cells, abrogate the pathogenesis and suppress the activation of pro-inflammatory intraepithelial lymphocytes. The presence of MHCII on dendritic cells (DCs) is sufficient to rescue IMP $CD4^+$ T cell development and reverse subsequent pathogenesis. Furthermore, the absence of the Tec kinase ITK rescues the development of IMP $CD4^+$ T cells independent of MHCII expression on donor bone marrow, and resultant $Itk^{-/-}$ IMP $CD4^+$ cells can partially prevent the pathogenesis. We conclude that IMP $CD4^+$ T cells can act as a suppressive population during cGVHD, and that DC expression of MHCII is critical for the development of such IMP $CD4^+$ T cells. In addition, ITK regulates the development of IMP $CD4^+$ T cells partially independent of DC expression of MHCII. This work provides a mechanism for the development of cGVHD, and suggests an approach of suppressing such responses in syngeneic bone marrow graft.

P6.13.12

Establishment of a protocol for evaluating human mesenchymal stem cell efficacy on GvHD treatment

M. Jeon[1], *H. Yoo*[1], *K. Na*[1], *T. Yi*[2], *Y. Cho*[3], *S. Kim*[3], *W. Kim*[4], *S. Song*[1];

Ltd., Incheon, Republic of Korea,* [4]*Department of Radiology, INHA University School of Medicine, Incheon, Republic of Korea.*

Mesenchymal stem cells (MSCs) exist in almost all adult tissues and organs. MSCs are multi-potent and can differentiate into distinct cell types such as chondrocytes, osteocytes, and adipocytes. Since the discovery of the immunomodulation property of MSCs about a decade ago, it has been actively investigated whether MSCs can be used for the treatment of immune related diseases such as graft-versus-host disease (GvHD). However, how to evaluate the MSC efficacy for the clinical trial is still unclear since MSC showed controversial results between in vitro and in vivo. Therefore, we established a protocol for evaluating the human MSC efficacy on GvHD treatment using a mouse MHC-unmatched B6 -> BALB/c GvHD model system. Human clonal MSCs (hcMSCs) were isolated from human bone marrow according to our subfractionation culturing method. To establish a mouse model, we administrated two different mouse clonal MSCs. One of them showed significantly reduced the GvHD-related mortality of the murine recipients and the other one did not, although both lines can significantly suppress the allogeneic proliferation of T-cells in vitro. It indicates that each MSC line possesses different immune response in vivo. Using this mouse model, we investigated whether hcMSC can reduce the GvHD mortality. Surprisingly, xenogeneic hcMSC could prolong the survival of murine recipients and hcMSC also significantly inhibited the murine T-cell proliferation in vitro. Based on these results, we successfully established a MHC-unmatched B6 -> BALB/c GvHD model which might be useful for the evaluating human MSC's efficacy before the clinical trial.

P6.13.13
HLA-G: a possible biomarker for Graft versus Host Disease

U. Kanga[1], *M. Mourya*[1], *T. Seth*[2], *P. Sood*[2], *S. K. Gupta*[2], *L. Kumar*[3], *A. Sharma*[3], *M. Mahapatra*[2], *P. Mishra*[2], *N. K. Mehra*[1];
[1]*Dept of Transplant Immunology and Immunogenetics, All India Institute Of Medical Sciences, New Delhi, India,* [2]*Dept of Hematology, All India Institute Of Medical Sciences, New Delhi, India,* [3]*Dept of Medical Oncology, All India Institute Of Medical Sciences, New Delhi, India.*

Introduction: Graft versus host disease (GvHD) is the most common cause of morbidity and mortality after Hematopoietic Stem Cell Transplantation (HSCT) and identifying biomarkers for prediction of GvHD is important. HLA-G, an immunosuppressive molecule has been identified as a key mediator of tolerance, however its impact on stem cell transplantation outcome is under investigation. The exon-8, 14bp insertion/deletion in 3' UTR influences the HLA-G surface expression and soluble levels (sHLA-G). Objective: To understand the clinical relevance of HLA-G in HSCT, the present study was performed on recipients who underwent HSCT at our centre. Methodology: We evaluated the 14bp polymorphism (by PCR-SSP) and serum sHLA-G levels (by ELISA) in 120 healthy controls and 28 recipients at pre and post transplant stage (day 15, 30, 90 and at time of GVHD). Results: Seven (25%) recipients manifested GvHD. The +14bp allele was observed more frequently in recipients than controls. The sHLA-G levels correlated with 14bp polymorphism. Amongst controls, the subgroup with +/+14bp genotype had higher sHLA-G level in comparison to groups with -/- or -/+14bp genotype. Majority of the recipients carrying high secretary +/+14bp genotype (85%), did not develop GvHD. sHLA-G levels decreased in patients at the time of GVHD as compared with their pre-transplant levels. It is likely that higher sHLA-G levels may have influenced the alloreactivity and inhibited manifestation of GvHD. Conclusion: Our preliminary findings indicate that HLA-G might have influenced the occurrence of GvHD and evaluating larger cohort may confirm the role of HLA-G as a predictor of transplant outcome.

P6.13.14
Expression profile of candidate immune response genes in patients after haematopoietic stem cell transplantation

P. Klevcova[1], *F. Mrazek*[1], *R. Fillerova*[1], *Z. Navratilova*[1], *A. Vitek*[2], *M. Doubek*[3], *M. Petrek*[1];
[1]*Faculty of Medicine and Dentistry, Olomouc, Czech Republic,* [2]*Institute of Hematology and Blood Transfusion, Prague, Czech Republic,* [3]*University Hospital, Brno, Czech Republic.*

Graft-versus-host disease (GVHD) is a severe complication of allogeneic haematopoietic stem cell transplantation (aHSCT). The main effector cells of GVHD are donor T-lymphocytes that are addressed to the target tissues.
The aim of this study was therefore to determine the expression profile of genes for activating markers that characterise Th1 and Th2 type of immune response (TBX21 and GATA3, respectively), and surface lymphocyte integrins (ITGA4 and ITGB7) in patients after aHSCT.
The series of peripheral blood (PB) samples were collected from 16 aHSCT patients at 7 events (before conditioning, before aHSCT, 14, 21, 28, 100 and 180 days after aHSCT). Quantitative real time PCR was used to determine mRNA relative expression of candidate genes (TBX21, GATA3, ITGA4, ITGB7).
Conditioning regimen before aHSCT decreased the relative expression of ITGB7 and GATA3 (p =0.003; p=0.0001)). The number of TBX21 mRNA transcripts was up-regulated by conditioning (p=0.015) and decreased after transplantation (p=0.035). The mRNA expression of ITGB7 and GATA3 restored to the state before chemotherapy in samples 100 and 180 days after transplantation. By contrast, TBX21 expression was increased in late samples (100 days, p=0.005; 180 days, p=0.022). The expression of ITGA4 was not significantly affected after aHSCT within the study period.
In conclusion, our data indicate that the expression of Th1 marker (TBX21) in PB increases after conditioning and in later period after aHSCT. On the other hand, Th2 marker (GATA3) and integrin ITGB7 were strongly downregulated by conditioning regimen. Grant support: IGA MZCR NT12454, IGA UP 2013_009 and CZ.1.05/2.1.00/01.0030.

P6.13.15
KIR-ligand mismatch on allograft outcome

B. Manzanares, *R. González, C. Martín, M. Frías, C. Martínez, L. Castro, R. Rojas, P. Gómez, J. Peña;*
Hospital Reina Sofía, Córdoba, Spain.

Introduction: It has studied the possible effect of graft-versus-leukemia mediated by donor killer cell immunoglobulin-like receptor (KIR)-ligand HLA incompatibility between groups C1 and C2.
Patients: We included 31 patients that underwent an allogeneic UCBT: Group A: receptor is homozygous C2 and donor is C1/C2 or C2/C2, Group B: patients without anti-leukemic effect because they are C1/C2 or C1/C1 or C2/C2 with donor also C1/C1 or C2/C2, respectively and Group C: patients C1/C1 or C2/C2 whose donor lacked C2 or C1 respectively.
Results**:** With a median follow-up post-UCBT of 53 months, KIR ligand incompatible patients in the GVH direction (A) showed a lower actuarial probability of relapse at 5 years (33.3±17%vs68.5±18.1%vs61.1 ±28.4% p=.11). Thus, the GS is better in A than B and C (57.1±18.7%vs13.6 ±11.7%vs24.3±18.7%;p=.31). In A complete donor chimerism was reached in 85.7% of patients, with a median time of 37 days to achieve it, in 54.5% of B in a median time of 45 days and in 53.8% of C in a median time of 55 days. The median time to myeloid engrafment was 18 days for A, 24 days for B and 18 days for C (p=.42). Transplant related mortality at day 100 and at 1 year were 12.9% and 32% respectively for entire group, being 0% and 42,9% for A, 9.1% and 36.4% for B and 23.1% and 23.1% for C.
Conclusions: KIR/ligand incompatibility based on HLA C1/2 missmatch in the GVH direction is associated with a trend to lower probablility of leukemia relapse

P6.13.16
Non-myeloablative bone marrow transplantation for mdx mice muscular dystrophy therapy

V. M. Mikhailov[1], *A. V. Sokolova*[1], *E. V. Kaminskaya*[1], *V. V. Kravtsova*[2], *I. I. Krivoi*[2];
[1]*Instutute of Cytology RAS, St.Petersburg, Russian Federation,* [2]*SPb State University, St.Petersburg, Russian Federation.*

The replacement of the mutant stem cells for wild type stem cells is seen as radical approach to the treatment of monogenic diseases. Bone marrow (BM) transplantation is used to treat monogenic diseases such as β-thalassemia. We present the results of treatment of muscular dystrophy of mdx mice, the counterpart of human Duchenne muscular dystrophy, by C57BL/6 mice BM transplantation. Reason of mdx mice muscular dystrophy is absence of dystrophin synthesis by mutant muscle fibers (MF). Like another authors we did not observed a growth of dystrophin synthesis after 5 - 11 Gy irradiation of mdx mice and subsequent isogenic BM transplantation of C57BL/6 mice. The nuclear of transplanted BM stem cells was shown to occupy sacroplasma of mdx mice MF without following dystrophin gene expression. To overcome the silence of wild dystrophin gene we used X-ray irradiation of mdx mice in dose 3 Gy with next step of wild type C57BL/6 BM transplantation. Non-myeloablative bone marrow stem cells transplantation induced gradual rise of dystrophin positive striated MC fibers of diaphragm from 4.1 % at 2 months after irradiation and BM transplantation up to 27.7±6.7 % at 6th months after BM transplantation. There are also increase of striated MF without central nuclei up to 22 %. Accumulation of dystrophin positive MF are accompanied by reparation of structure of nerve-muscle junctions (NMJs) and of NMJs electrical resting membrane potential. Practically we cured mdx mice of muscular dystrophy because 20-30% of dystrophin positive MF is enough to cure Duchenne disease.

P6.13.17
Comparison of immunosuppressive effect on lymphocytes of bone marrow, umbilical cord blood and placenta mesenchymal stromal cells

M. Castro-Manrreza, A. Monroy, E. Flores-Figueroa, H. Mayani, ***J. Montesinos****;*
Oncology Hospital, IMSS, D. F., Mexico.

Bone marrow mesenchymal stromal cells (BM-MSCs) display immunoregulatory properties and have been used to treat steroid-refractory acute graft-versus-host disease (GVHD) in hematopoietic stem cell transplant patients. In this study, we have obtained MSCs from umbilical cord blood (UCB-MSCs), placenta (PL-MSCs) and BM and compared their immunosuppressive effect on activated CD3+ T-cells. We co-cultured activated CD3+ T-cells (by using CD3 and CD28 antibodies) and MSCs from the three sources, in absence and presence of cell-cell contact. Stimulated CD3+ T-cells cultured alone served as positive control. T cell proliferation (bromodeoxyuridine uptake of CD4+ populations) and CTLA-4 expression was evaluated by flow cytometry analysis on day 4 of culture. MSCs from all three sources significantly diminished the proliferation of CD4 lymphocytes only in cell-cell contact condition, however such effect was increased in presence of BM- and UCB-derived MSCs than in PL-MSCs. Furthermore, we observed an increase in CTLA-4 expression on CD4+ T-cells only in cell-cell contact co-cultures with BM- and UCB-derived MSCs. Our results indicate a higher capacity to decrease T cell proliferation by MSCs from BM and UCB compared with PL, indeed such capacity was similar in the formers two cells. Moreover, increase in CTLA-4 expression on T cells, could be involved in the mechanism through which BM- and UCB-derived MSCs decrease T cell proliferation. In conclusion, UCB-MSCs may prove useful in the development of cellular therapy protocols related with immunosuppression activity.

P6.13.18
In vitro **effect of rhG-CSF on cytokine production of cultured mononuclear cells**

M. A. Dueñas-Sanchez de Tagle[1], O. Rodríguez-Cortés[1], L. Montiel-Cervantes[1,2], J. Oliva-Ramírez[1], J. Vela-Ojeda[1,2], ***M. C. Moreno-Lafont****[1];*
[1]Escuela Nacional de Ciencias Biologicas-IPN, Mexico DF, Mexico, [2]CMN La Raza-IMSS, Mexico DF, Mexico.

Granulocyte colony stimulating factor (G-CSF) is used therapeutically for the treatment of neutropenia and mobilization of hematopoietic stem cells. It has been reported that G-CSF also has effect on other cell types such as monocytes and lymphocytes. *Ex vivo* studies have shown that recombinant human G-CSF (rhG-CSF) induces changes in the immune response in healthy donors, modifying T lymphocyte function and modulating cytokine production, thereby changing the balance between Th1 and Th2 responses. Here we report an *in vitro* model that allowed us to study the effect of rhG-CSF on cultured peripheral blood mononuclear cells (PBMN) from healthy donors. To establish optimal time and concentration of rhG-CSF required to induce changes on cytokine production, a five-days kinetic experiment was set up. Our results showed that cultures incubated for six hours with PMA/ionomycin plus 200 ng/mL rhG-CSF produced similar amounts of IFN and TNF by T lymphocytes and PBMN cells, respectively. Results from our *in vitro* model resemble those obtained from *ex vivo* studies, analyzing the effect of rhG-CSF on healthy donors PBMN. This *in vitro* model which allows basic studies will help us to better understand the potential use of rhGCSF as a therapeutic agent for autoimmune diseases.

P6.13.19
Mobilization effect on CD8+ T cells and their contribution in controlling the development of GVHD

A. Gutiérrez-Hoya[1], R. López-Santiago[1], J. Vela-Ojeda[1,2], O. Rodríguez-Cortés[1], L. Montiel-Cervantes[1,2], ***M. C. Moreno-Lafont****[1];*
[1]Escuela Nacional de Ciencias Biologicas-IPN, Mexico DF, Mexico, [2]CMN La Raza-IMSS, Mexico DF, Mexico.

Allogeneic hematopoietic stem cell transplantation is a therapy that can restore bone marrow function. The success of this procedure depends greatly on having an adequate number of stem cells (SC). To mobilize SC from bone marrow to peripheral blood the donor is subjected to a treatment with granulocyte colony stimulating factor (G-CSF). SC are collected by and subsequently infuse into the patient. Some of the drawbacks of this therapy include the graft versus host disease (GVHD), relapses, and infections caused by opportunistic microorganisms. The mobilization process promotes preferentially a Th2 phenotype. The aim of this study was to search for the effect of G-CSF on CD73 and CD39 expression and cytokine production by CD8+ T cells, and their correlation with the clinical course of the patients. Thirteen patients and their SC donors were studied. Seven healthy individuals were included as controls. The G-CSF induced the expression of regulatory molecules and cytokines such as CD73, CD39, IL-10 and TGF-β, by CD4+ and CD8+T cells. It was shown that CD8+ cells are stable, 80% expressed the anti-apoptotic protein BCL-2 and up to 5% expressed active proapoptotic protein caspase 3. Moreover, the low production of regulatory cytokines in response to polyclonal stimulus correlated with the development of GVHD. We conclude that the G-CSF promotes a low percentage of CD8+T cells with regulatory phenotype, which could contribute to the control of GVHD, whereas the lack of response of CD4+ and CD8+T cells to polyclonal activators is of poor prognosis.

Medizinische Klinik, Klinikum Rechts der Isar, Technical University, Munich, Germany, [4]Institut für Klinische Chemie und Pathobiochemie, Klinikum Rechts der Isar, Technical University, Munich, Germany, [5]Department of Dermatology, University Hospital, Zürich, Germany.

The success of allogeneic hematopoietic cell transplantation is limited by acute graft-versus-host disease (GvHD), a severe complication accompanied by high mortality rates. Yet, the molecular mechanisms initiating this disease remain poorly defined. Here, we show that after conditioning therapy (irradiation), intestinal commensal bacteria and the damage-associated-molecular pattern uric acid contribute to Nlrp3-inflammasome-mediated IL-1β production, while gastro-intestinal decontamination and uric acid depletion led to reduced GvHD severity. Early blockade of IL-1β or genetic deficiency of the IL-1 receptor in dendritic cells and T cells improved survival. The Nlrp3-inflammasome components Nlrp3 and Asc, which are required for pro-IL-1β cleavage, were critical for the full picture of GvHD. In transplanted mice, IL-1β originated from multiple intestinal cell compartments and exerted its effects on dendritic cells and T cells, the latter being preferentially skewed towards Th17. Compatible with these data from the mouse model, increased levels of active caspase-1 and IL-1β were found in circulating leukocytes and intestinal GvHD-lesions of patients. Thus, the identification of a crucial role for the Nlrp3-inflammasome sheds new light on the pathogenesis of GvHD and opens a new mechanism-based avenue for the targeted-therapy of this severe complication

Interleukin 7 (IL-7) signals via the IL-7 receptor (IL-7R) and drives homeostatic T-cell proliferation in patients after allogeneic hematopoietic stem cell transplantation (aHSCT); the role of IL-7R/IL-7 axis in driving graft-versus-host disease (GVHD) is debated. We performed a prospective study in adults (n=33) and children (n=29) undergoing aHSCT, by measuring plasma IL-7 and soluble CD127 (sIL-7R) concentrations in five time points between 1 and 12 months after aHSCT. In all patients sIL-7R, but not IL-7 was increased with time after HSCT. In adults, plasma IL-7 levels were elevated at 6 months ($p<0.05$) if donor age was <30 years. Low sIL-7R was associated with any grade of acute graft-versus-host disease (GVHD) at 2 and 6 months ($p=0.02$) and with CMV infection at 2 months after aHSCT ($p<0.05$). Patients with cytomegalovirus (CMV) reactivation had increased IL-7 values at 2 and 3 months ($p=0.02$) after HSCT. In multivariate analysis, high sIL-7R levels were associated with acute GVHD (relative hazard (RH): 0.70, $p>0.01$) and sibling donor (RH: 2.23, $p=0.004$). Recipients of sibling grafts showed high levels of IL-7 (RH: 1.38, $p<0.05$) and bone marrow recipients had low IL-7 levels (RH: 0.73, $p=0.04$). Measurement of the sIL-7R/IL-7 axis will help in guided immune monitoring after HSCT and guided interference with sIL-7R may be explored in GVHD management.

P6.13.22
Accelerated B cell recovery characterizes haploidentical T-repleted bone marrow transplantation

A. Roberto[1], *L. Castagna*[1], *S. Gandolfi*[1], *P. Tentorio*[1], *M. Roederer*[2], *D. Mavilio*[1,3], *E. Lugli*[1];
[1]*Humanitas Clinical and Research Institute, Rozzano (MI), Italy,* [2]*Vaccine Research Center, NIAID, NIH, Bethesda, MD, United States,* [3]*Department of Medical Biotechnologies and Translational Medicine (BioMeTra), University of Milan, Milan, Italy.*

T-repleted, haploidentical bone marrow transplantation (BMT) with post-transplant cyclophosphamide expands the pool of potential bone marrow donors for the treatment of certain haematological diseases. As revealed by multiple clinical trials, the incidence of bacterial and fungal infections is significantly lower compared to other haploidentical strategies. In search for a cellular immune mechanism responsible for this effect, we analysed B cell recovery and B cell subsets by polychromatic flow cytometry in 10 patients treated with the mentioned protocol and followed the patients for 1 year post BMT. Here we show that B cell counts normalize faster compared to classical haploidentical protocols, i.e. within 8-10 weeks after transplant. In the first three months the B cell ontogeny is recapitulated. CD10+ CD38 bright transitional B cells are first observed: within this subset, CD21 low precede CD21 high transitional B cells. CD10- CD38 dim/- mature, naïve B cells subsequently occur and comprise the vast majority of B cells. Conversely, IgG+ memory cells are undetectable during the first 2 months post BMT, develop only 1 month later and remain at low frequency over the following months. Our results suggest that the fast B cell reconstitution process observed in these patients is associated with a decreased susceptibility against infections in T-repleted, haploidentical bone marrow transplantation compared to other clinical protocols. Further analyses are required to investigate whether fully competent B cell memory is recovered in this particular BMT setting.

P6.13.23
Cell Subset Chimerism after HSCT - Clinical case

K. Gendzekhadze, ***D. Senitzer****;*
City of Hope, Duarte, CA, United States.

Allogeneic Hematopoietic Stem cell transplant (HSCT) is potential curative option for recurrent lymphomas. Early prediction of relapse, graft rejection or graft versus host (GvHD) can change patient management. Routine chimerism tests include quantification of polymorphic Indels as a group of informative markers by qPCR method. Cells from blood or marrow are frequently used for chimerism testing, however, lineage-specific populations increase sensitivity and diagnostic accuracy.
Here we describe a clinical case of 24 years -old female with Hodgkin Lymphoma. Samples were collected during 193 days after double cord HSCT. Patient's Hodgkin-Reed-Sternberg (HRS) cells were positive for CD3 and CD15, but negative for CD20. Chimerism was analyzed in Peripheral blood, and in enriched CD3, CD14, CD15, CD19 cell populations. On day 15 post HSCT, we could detect both cords, one of them less than 1% which later disappears. Even though % DNA from other cord2 reached 42% on day 42, only 9% was detected on day 193 (PB results). Similar trend was observed for CD14 and CD15, suggesting no engraftment contrary of CD3 and CD19 cells. Cord 2 CD3 cells were 11% on day 15, which on subsequent days (15-193) was 86-95%. Cord2 CD19 cells were 95% on the 2 time points measured (Day 93, 193). The highest cord 2 % DNA was observed on day 42 analyzing each subset: 42%PB, 96%CD3, 29%CD14, 25%CD15.
The final diagnosis was non-engraftment, However, CD3, and CD19 from Cord 2 have been stimulated. This scenario is suggestive of GVHD and/or GVL reactivity

P6.13.24
Chimerism patterns of long-term stable mixed chimeras post-HSCT in patients with non-malignant diseases

A. Stikvoort[1], *J. Gertow*[1], *M. Sundin*[2], *M. Remberger*[1], *J. Mattsson*[2], *M. Uhlin*[1];
[1]*Karolinska Institutet, Stockholm, Sweden,* [2]*Karolinska University Hospital, Stockholm, Sweden.*

Introduction: Long-term stable mixed chimerism (MC) is a rare phenomenon after hematopoietic stem cell transplantation (HSCT) characterized by 5-95% residual recipient hematopoietic cells. The mechanisms directing hematopoietic recovery to MC in some patients and to full donor chimerism (DC) in others are poorly understood. In this study we compared DC patients with long-lasting stable MC patients for a median of 9.5 years (range 5 - 16.5) post-HSCT in patients with non-malignant diseases.
Methods: Chimerism analysis was performed for all patients at regular intervals post-HSCT on peripheral blood samples. The cell lineages analysed were T-lymphocytes (CD3), B-lymphocytes (CD19) and myeloid cells (CD33).
Results: Several factors significantly associated with the likelihood of stable MC development were identified by univariate analysis, e.g. younger donor age, sibling donor and conditioning regimen. Despite a limited patient cohort, our multivariate analysis could confirm that a sibling donor was associated with stable MC development. Furthermore, development of acute-graft-vs.-host disease (aGvHD) and blood stream infection (BSI) was significantly more prevalent in the DC patient group. Additionally, significant fluctuations in the recipient:donor chimerism ratio decreased over time after HSCT in MC patients.
Discussion: Sibling donor cells are a closer HLA and minor histocompatibility antigen match than unrelated donor cells and will thus be less prone to induce immune-mediated killing of recipient cells. Additionally, milder conditioning regimens may also stimulate MC development. Furthermore, MC was not linked to a worse prognosis, as both aGvHD and BSI development were more prevalent in the DC group.

P6.13.25
Changes in the TCR repertoire in type 1 diabetes patients after autologous hematopoietic stem cell transplantation

J. Teixeira Cottas de Azevedo[1], *G. Lelis Vilela de Oliveira*[1], *N. Moreira Santos*[2], *G. Trentin Scortegana*[1], *L. Guilherme*[2], *D. Tadeu Covas*[1], *J. Voltarelli*[1], *K. Ribeiro Malmegrim*[1];
[1]*Universidade de São Paulo, Ribeirão Preto, Brazil,* [2]*Universidade de São Paulo, São Paulo, Brazil.*

Introduction and objective: Type I diabetes mellitus (T1D) is a autoimmune disease resulting from the immune-mediated destruction of β-cells. High dose immunosuppression followed by autologous hematopoietic stem cell transplantation (HDI/AHSCT) has emerged in last years as a therapeutic alternative for recent-diagnosed T1D patients. To address the immune mechanisms by which HDI/AHSCT induces remission in T1D patients, we evaluated the reconstitution of T cell repertoire diversity by the TCRBV CDR3 Spectratyping method in T1D patients treated with HDI/AHSCT. Methods: Peripheral blood mononuclear cells from healthy controls (N=5) and T1D patients (N=16) at pre-transplantation and at various time points after transplantation were isolated by Ficoll-Hypaque. Total RNA was isolated and used to analyze the T cell receptor Vβ repertoire by the TCRBV CDR3 Spectratyping method. Results: The overexpression of 4 Vβ families (Vβ 5, 6, 13, 22) was observed in T1D patients before AHSCT. However, in some cases, these overexpressed families were found in high frequency after transplantation. There were changes in the composition of the T cell repertoire after transplantation, evidenced by qualitative and quantitative alterations in the CDR3 peaks and in the frequency of the 24 Vβ families analyzed. Furthermore, it was identified four patterns of repertoire reconstitution after transplantation and the pattern that consisted of reconstitution of diversity from a normal diverse repertoire was the most dominant in the T1D patients analyzed. Conclusions: Our results suggest that the HDI/AHSCT induced changes in the composition of the TCR repertoire that might explain the induction of insulin-independency in the T1D patients.

P6.13.26
Analysis of the circulating Th1/Th17 lymphocyte repertoire after hematopoietic stem cell transplant may reveal opportunistic fungal infections rather than GvHD reaction

C. Vitale[1], *E. Montaldo*[1], *G. Morreale*[2], *P. Ambrosini*[1], *L. Moretta*[2], *M. Mingari*[1,3];
[1]*DIMES-Università di Genova, Genova, Italy,* [2]*Istituto Giannina Gaslini, Genova, Italy,* [3]*AOUSM/IST Genova, Genova, Italy.*

Human Th17 lymphocytes have been suggested to play a role in the pathogenesis of Graft versus Host Disease (GvHD). However, their actual involvement has not been clarified so far. We analysed the T cell recovery in the peripheral blood of 30 paediatric patients at different time intervals after allogeneic hematopoietic stem cell transplantation (HSCT).
We investigated the Th1 (CD4+CD161-CXCR3+CCR6-), Th1/Th17 (CD4+CD161+CXCR3+CCR6+) and Th17 (CD4+CD161+CXCR3-CCR6+) cell subsets repertoire in relation with the GVHD onset, the occurrence of opportunistic infections and/or viral reactivation. In the first 90 days after HSCT, we found no significant difference between patients developing or not acute GVHD. On the other hand, patients affected by chronic GVHD display a sharp reduction of circulating CD4+ lymphocytes. In addition, they were significantly enriched in CD4+CD161+. Analysis of cytokine production revealed that chronic GVHD patients display an increased production of IFN-gamma and IL-17. In patients with acute GVHD, increases of IFN-gamma and IL-17 production were statistically significant, however, no correlation could be found between surface phenotype and cytokine production. On the other hand, in four patients a clear correlation could be observed between the onset of Candida infection and increases of circulating IL-17-producing Th17 cells. Th17 increases were transient and paralleled the course of infection.
Our data suggest that chronic GvHD might involve Th1/Th17 cells. More importantly, they show that monitoring Th17 cell populations may provide an useful information on the onset and the severity of opportunistic fungal infections.

P6.13.27
Nonmitogenic form of acidic fibroblast growth factor protects against graft-versus-host disease without accelerating leukemia

Y. Wang[1,2], *H. Wang*[3,2], *Y. Yang*[3,2], *X. Li*[1];
[1]*Key Laboratory of Biotechnology Pharmaceutical Engineering of Zhejiang Province, School of Pharmaceutical Science, Wenzhou Medical College, Wenzhou, China,* [2]*Transplantation Biology Research Center, Massachusetts General Hospital, Harvard Medical School, Boston, MA, United States,* [3]*Columbia Center for Translational Immunology, Columbia University College of Physicians and Surgeons, New York, NY, United States.*

Acid fibroblast growth factor (aFGF) has been shown to prevent epithelial damage under various conditions, suggesting its potential to inhibit graft-versus-host disease (GVHD). However, because aFGF receptors are expressed on tumor cells, it may possibly offset the graft-vs.-tumor (GVT) effects of allogeneic bone marrow transplantation (allo-BMT). Here, we addressed these questions in a B6-B6D2F1 allo-BMT model. Although aFGF administration attenuated GVHD in non-leukemic recipients, aFGF treatment markedly accelerated death in mice that received recipient-type tumor (P815) cells along with allo-BMT. Similar protection against GVHD was also achieved by administration of a non-mitogenic form of aFGF (naFGF). Importantly, GVT effects were fully preserved in naFGF-treated recipients. Furthermore, aFGF, but not naFGF, significantly enhanced P815 cell proliferation in vitro. Our data indicate that the tumor-promoting, but not GVHD-protecting, effect of aFGF largely depends on its mitogenic activity, and suggest that naFGF may provide a safer approach to inhibiting GVHD in patients with malignancies.

P6.13.28
Post-Transplant Lymphocyte Reconstitution and Viral Reactivation in Paediatric Patients with Leukaemia

F. Yeap, *S. Bansal, M. Villegas, P. Tan;*
National University Hospital, Singapore, Singapore.

Method: We retrospectively reviewed kinetics of lymphocyte reconstitution and viral reactivation in 48 patients with acute leukaemia after Bone Marrow Transplant (BMT) from 2005 through 2012. Lymphocyte subsets were evaluated at 30, 100, 200, 365 days after BMT and correlated with viral reactivation.
Results: Median age at BMT was 11.0 (range, 1.2 to 20.7) years for indications of acute lymphoblastic leukaemia (ALL) (n=23) and non-ALL (n=25). Pre-BMT cytomegalovirus (CMV) serostatus was donor-patient positive in 35% and donor negative-patient positive in 23%. Majority (71%) of patients received unrelated donor transplants. Stem cell sources were from bone marrow (BM, n=24), peripheral blood (PB, n=11) and cord blood (CB, n=13). HLA was 8/8 allele matched in 48% and > 2 mismatches in 19%. Acute graft versus host disease requiring treatment occurred in 58%. At 100 days post-BMT, 13% of CB transplant patients achieved CD4>200 vs. 28% of BM and 45% of PB patients (p=0.27). CD8 reconstitution was of similar trend. At 1 year post-BMT, 95% achieved CD4>200. Viral reactivation occurred in 48%. Viral associated mortality was 4% and occurred in CB patients within 200 days after BMT; with 1 death each from adenovirus and CMV.
Conclusion: In our cohort, viral reactivation correlated with recipient CMV seropositivity (p=0.02) and delayed CD4 reconstitution while outcome was influenced by the source of stem cells reflecting the interplay of donor-derived immune reconstitution and post-BMT immunosuppression.

P6.13.29
Human T cell progenitors generated in vitro from stem cells facilitate thymus engraftment

J. Zuniga-Pflucker;
University of Toronto, Toronto, ON, Canada.

The thymus provides the necessary environmental cues for the differentiation and generation of T-cells. The thymus is continuously colonized by a rare subset of bone-marrow derived progenitors, which

in humans are characterized as CD34+CD45RA+CD7+ cells. Further characterization and directed expansion of this important progenitor subset would represent an important step in developing T-cell and thymus regenerative approaches. Here we show the induced generation of human progenitor T-cells (pro-T) with a thymus-colonizing phenotype from umbilical cord-blood CD34+CD38-/lo hematopoietic stem cells (HSCs) cocultured on OP9-DL1 stromal cells. To determine whether pro-T cells generated in vitro from human HSCs possess an intrinsic ability to home, engraft and reconstitute a thymus in vivo, sorted CD34+ CD7++ pro-T cells were injected into immunodeficient mouse strains, which can support human multilineage differentiation from CD34+ HSCs. Our results show high levels of human chimerism in the thymus of immunodeficient mice. Furthermore, our findings showed that T-lineage progenitors generated in vitro from HSCs exhibit key properties of being able to home to, settle, and effectively reconstitute the thymus of immunodeficient mice. Additionally, in vitro-generated pro-T cells, when transferred together with purified HSCs, were able to dramatically enhance the thymus reconstituting ability of HSC-derived progenitors in vivo. Taken together, the generation of humanized mice reconstituted with in vitro derived progenitor T-subsets offers a new means of therapeutic evaluation and the potential to rapidly restore the T-cell compartment for the treatment of immunodeficiencies.

Hsp70 inhibits the direct allorecognition, downregulating MHC class II through IL-10 driven MARCH-I expression via TLR2-ERK-STAT3 pathway

***T. J. Borges**, F. D. Machado, R. L. Lopes, N. G. Pinho, R. F. Zanin, A. D. Souza, C. Bonorino;*
PUCRS, Porto Alegre, Brazil.

The Hsp70 has a protective and anti-inflammatory role in several animal models of inflammation. We have previously demonstrated that incubation of skin allografts with Hsp70 can delay acute rejection and improve graft survival in mice. However, the pathways involved in this phenomenon have yet to be elucidated. We performed a skin allograft model which allografts from B6 mice were immersed in a solution containing OVA or Hsp70, and then grafted on BALB/c mice. Treatment with Hsp70 led to decreased expression of MHC II in donor DC that migrated to the host DLN. This MHC II downregulation was mainly on donor CD103+ DCs subset. Also, a diminished T CD4+ and CD8+ proliferation in host DLN was observed. Next, we determined that Hsp70 can induce both IL-10 mRNA and protein expression on mature DCs. IL-10 production and MHC II downregulation were dependent on TLR2-ERK-STAT3. We verified that donor expression of TLR2 and IL-10 were required for inhibition of acute rejection induced by Hsp70. Next, we elucidated which mechanism triggered by IL-10 was leading DCs to MHC II downregulation. We observed that Hsp70-treated DCs had a increase in MARCH-I mRNA expression related with untreated DCs. Hsp70-driven MARCH-I expression was dependent on TLR2-ERK-STAT3 pathway. Finally, IL-10 KO DCs treated with Hsp70 had no MARCH-I expression and no MHC II downregulation compared with WT DCs. Altogether, our results indicated that Hsp70 induces IL-10 in DCs via TLR2-ERK-STAT3 pathway. This IL-10 production leads to MARCH-I expression and MHC II downregulation, inhibiting allograft rejection.
Support: FAPERGS 11/0903-1.

P6.14.02
Glucosamine modulates T helper cells differentiation via the blockade of N-linked glycosylation pathway

***M. Chien**[1], S. Huang[2], H. Sytwu[3];*
[1]Graduate Institute of Life Sciences, National Defense Medical Center, Taipei, Taiwan, [2]Department of General Surgery, Tri-Service General Hospital, Taipei, Taiwan., Taipei, Taiwan, [3]Department and Graduate Institute of Microbiology and Immunology, Taipei, Taiwan.

Glucosamine is an amino sugar that has been widely used as supplement for patients with osteoarthritis. Previous studies have demonstrated that it can attenuate acute experimental autoimmune encephalomyelitis by inducing the secretion of Th2 cytokines and improve atopic dermatitis-like skin lesions by inhibition of Th2 development.
To evaluate the effect of glucosamine on effector T helper cell differentiation, we sorted and cultured naïve CD4 T cell from NOD mice on different T helper cell culture condition for 3 days with glucosamine (5mM) treatment. Glucosamine strikingly impeded the Th1, Th2 and iTreg cell differentiation but promoted Th17 cells differentiation. Furthermore, we found that glucosamine slightly attenuated STAT3, 4, and 6 phosphorylation, but significantly inhibited STAT5 phosphorylation during different T helper cell differentiation. We also found that the surface expression of IL-2 receptor subunit α (CD25) on T helper cells was significantly inhibited, but IL-2Rβ and γc were minimally affected by glucosamine treatment. However, we found that glucosamine blocks the N-linked glycosylation of CD25 without affecting CD25 gene expression. Therefore, our data suggested that N-linked glycosylation is required for CD25 surface expression to regulate IL-2 signaling pathways to modulate T cell differentiation. Interestingly, we found that 2DG and 2FDG (glycolytic pathway inhibitors) have similar effect to modulate T helper cell differentiation through blockade of N-linked glycosylation of CD25. Our data suggested that glucosamine might modulate T helper cell differentiation via blockade of the N-glycosylation throguh limiting IL-2 signaling.

P6.14.03
Dextromethorphan modulates the immune function of dendritic cells

***C. Chu**[1], D. Chen[2], P. Song[3], C. Lin[3];*
[1]Graduate Institute of Immunology, National Taiwan University, Taipei, Taiwan, [2]Taichung Veterans General Hospital, Taichung, Taiwan, [3]Institute of Biomedical Science, National Chung-Hsing University, Taichung, Taiwan.

Dendritic cells (DCs) are the most potent antigen-presenting cells (APCs) with a unique capacity to prime naïve T cells and connect innate to adaptive immunity. Accordingly, DCs are considered as a major target in the development of immunomodulators. Detromethorpahn (DXM), a clinical medicine for cough-suppression with a high safety profile, has been reported to possess anti-inflammation and immunomodulatory activities. In this study, we examined the effect of DXM on the immune function of DCs. In a non-cytotoxic condition, DXM significantly reduced the maturation of mouse bone marrow derived DCs (BMDCs) after LPS stimulation. DXM also impaired the amounts of reactive oxygen species (ROS), pro-inflammatory cytokines, and chemokines produced by LPS-stimulated BMDCs. Furthermore, the treatment of DXM decreased the T cell activation induced by LPS-stimulated BMDCs, as determined by the reduction of proliferation and IFN-γ secretion in mixed lymphocyte reaction. In the molecular approach, blockage of LPS-induced MAPK activation, IκB degradation and the translocation of NF-κB could be involved in the suppressive effect of DXM on BMDCs activation. In addition to mouse DCs, we also confirmed the suppressive activity of DXM on the activation of human monocytes-derived dendritic cells (MoDCs). In conclusion, we have identified the immunomodulatory role of DXM in attenuating the function of DCs, which suggests that DXM may have potential in the treatment of DC-related autoimmune and chronic inflammatory diseases.

P6.14.04

Inhibition of human allogeneic skin graft inflammation by ex vivo expanded human Treg in a humanized PBMC-SCID/Skin allograft model

*V. L. de Oliveira[1], M. Peppelman[1,2], E. Fasse[1], P. C. M. M. van der Kerkhof[2], P. van Erp[2], I. Joosten[1], **H. Koenen**[1];*
[1]Radboud University Nijmegen Medical Centre, Department of Laboratory Medicine, Laboratory of Medical Immunology, Nijmegen, Netherlands, [2]Radboud University Nijmegen Medical Centre, Department of Dermatology, Nijmegen, Netherlands.

Treg cell-therapy is of interest for therapeutic intervention in transplant rejection and autoimmunity. Although clinical Treg-therapy trials have started, the *in vivo* behavior of ex-vivo expanded human Treg is unclear. Therefore, we investigated the effect of ex-vivo expanded CD4+CD25+CD127low human Treg-cells on the inflammatory response of human skin allograft in a humanized-SCID mouse model. First, we demonstrated that ex-vivo expanded human Treg-cells maintained suppressive capacity *in vitro*. Next, these expanded Treg were studied *in vivo* in our humanized mouse model, in brief human skin-grafts were transplanted on immunodeficient SCID/beige mice, after healing mice were infused (i.p.) with allogeneic hu-PBMC with/without Treg-cells. After 3-weeks inflamed skin-grafts, spleen and peripheral blood were harvested and analyzed by histology and/or flowcytometry. Analysis of inflamed human skin-grafts revealed that Treg infusion restored the inflammation related aberrant K10/K16 epidermal marker expression and influx of hu-CD8 T-cells. The Infusion of Treg also affected the systemic response, they inhibited human CD4+ and CD8+ T cell activation and proliferation as indicated by reduced Ki67. We showed that under the conditions tested, ex-vivo expanded Treg-cells reduce but do not fully prevent hu-PBMC induced skin inflammation *in vivo*. The observed reduction of skin transplant inflammation by human Treg encourages the use of Treg-therapy in transplantation.

P6.14.05

An increase in B cell and cytotoxic NK cell proportions in peripheral blood of Natalizumab-treated patients with relapsing-remitting multiple sclerosis

***M. Edström**[1], J. Mellergård[1], M. C. Jenmalm[1], C. Dahle[1,2], M. Vrethem[1,3], J. Ernerudh[1,2];*
[1]Clinical and Experimental Medicine, Linköping, Sweden, [2]Clinical Immunology and Transfusion Medicine, Linköping, Sweden, [3]Neurology and Clinical Neurophysiology, Linköping, Sweden.

Background Multiple sclerosis is an autoimmune disease affecting the CNS, traditionally treated with immunomodulatory drugs, and the monoclonal anti-VLA-4 antibody natalizumab is the most effective drug currently in use. By VLA-4 binding, natalizumab supposedly prevents passage of lymphocytes across the blood-brain barrier
Materials and methods A panel of markers for blood lymphocyte populations was assessed by flow cytometry in 40 patients with relapsing MS before and after one-year natalizumab treatment. In addition, whole blood cultures were set up, and the CD4+ and CD8+ T-cell response to antigens and mitogens was assessed. For comparison of T-cell responsiveness, 20 healthy controls were included.
Results Absolute numbers of all investigated major populations of lymphocytes increased after treatment, most markedly for NK-cells ($p<0.001$) and B-cells ($p<0.001$). The fraction of both memory (CD27+, $p<0.0005$) and presumed regulatory B cells (CD25+, $p<0.005$) increased, as did CD3-CD56dim cytotoxic NK-cells ($p<0.005$), whereas CD3-CD56bright regulatory NK-cells decreased ($p<0.005$). The fraction of OX40L+ T-cells decreased ($p<0.005$). Responsiveness to recall antigens and mitogens was restored for both CD4+ (influenza $p<0.005$; PPD $p<0.005$) and CD8+ T-cells (PPD $p<0.01$; PWM $p<0.005$; CMV $p<0.01$).
Conclusions Our data confirm that natalizumab treatment has a pronounced effect on the peripheral blood lymphocyte composition. The expected main mode of action, reduction of lymphocyte extravasation, is likely not only to involve CNS trafficking, given the profound increase in lymphocyte numbers in blood and given the general expression of VLA-4/VCAM-1/MadCAM adhesion molecules. The intricate changes in proportions of subpopulations suggest that cell-signaling effects through VLA-4 may be operative.

P6.14.06

Refractory amyopathic dermatomyositis (CAMD) with interstitial lung disease (ILD) successfully treated with Rituximab

***M. Gazzola**, V. Ferri, C. Gurrieri, S. Di Maggio, C. Agostini, R. Marcolongo;*
Azienza Ospedaliera di Padova Dipartimento di Medicina - Immunologia Clinica, Padova, Italy.

Background: CADM is a unique subset of dermatomyositis (DM) with typical skin manifestations of DM but no evidence of myositis.
Herein, we describe a case of CAMD with interstitial lung involvement successfully treated with Rituximab.
Medical History and Presentation: A Caucasian, 60 y-old woman, was diagnosed with CAMD because of arthralgia, fever, heliotrope rash, Gottron's papules in the absence of muscular symptoms. Blood tests showed normal value of CPK, myoglobin and aldolase; hyperferritinemia, ANA and anti-SSA positivity; anti-Jo1 were negative. There was no evidence of malignancy at PET-CT and MRI-scans.
During steroid and cyclosporine association therapy patient developed dyspnea on moderate efforts. Chest HRCT documented diffuse sub-pleural interstitiopathy. Patient was then treated with pulses cyclophosphamide (500 mg/m^2 weeks, 4 administrations) without clinical improvement. Considering the risk of fatal ILD progression, we administered anti-CD20 monoclonal antibody Rituximab (375 mg/m^2, weekly, 6 courses) with gradually resolution of respiratory and systemic symptoms and disappearance of skin lesions. After 30 days, we started maintenance therapy with Rituximab (375 mg/m^2 monthly) and azathioprine; prednisone was successfully tapered. Patient condition is currently good and there are no signs of CADM and ILD recurrence.
Conclusion CADM is a rare condition at risk for progressive fatal ILD, often resistant to conventional immunosuppressant therapy. Some reports described the efficacy of B-cell depleting treatment in refractory cases of DM, overlap myositis and ILD associated with immune disorders. Rituximab could be a well-tolerated and safe option for induction and maintenance therapy in resistant cases of CADM with or without ILD.

P6.14.07

mTOR inhibitors therapy after liver transplantation allows a sustained increase in regulatory T cells while preserving their suppressive capacity

***K. Ghazal**[1], F. Stenard[1,2], L. Aoudjehane[3], G. Bisch[3], Y. Calmus[1,2], F. Conti[1,2];*
[1]UPMC Université Paris 6, Inserm, UMR_S938, Centre de Recherche Saint Antoine, Paris, France, [2]Centre de Transplantation Hépatique, Pôle Digestif, APHP, Hôpital Saint Antoine, Paris, France, [3]Human HepCell, Paris, France.

The mammalian targets of rapamycin (mTOR) inhibitors (sirolimus [SRL] and everolimus [EVR]) are used in liver transplantation for their immunosuppressive activity. Evidence indicates that CD4+CD25+CD127-FoxP3+ regulatory T cells (Tregs) have a crucial role in immune tolerance. Furthermore, mTOR inhibitors have been demonstrated to preserve Tregs and in contrast to Tacrolimus (Tac).
The aim of this study was to evaluate Tregs number and function, in liver transplanted recipients before and after conversion from Tac to mTOR inhibitors.
Twelve patients with stable graft function where converted from Tac to SRL (n=5) or EVR (n=7). We prospectively analysed, at day 0, 30 and 90 after conversion, using flow cytometry, Treg population (CD4+CD25+FoxP3+CD127-) on blood cells and then performed a functional assay to test Treg ability to suppress CD4+ Tcell activity.
mTOR inhibitors were well tolerated, no acute rejection was observed. All patients displayed sustained rise in Treg levels after the introduction of mTOR inhibitors, in the two groups, SRL or EVE (mean peak Treg level at 3 months: 6,18±1.17% of CD4 T cells, vs a mean baseline level of 3.49±1,06%, p=0.0004; mean fold increase=2,01±0.63); for SRL group: mean peak Treg level: 6.01±0.92 vs 3.79±0.94, p=0.019, and in the EVE group: 6.23±1,31 vs 3.24±1,106, P=0.0053. Moreover, Tregs preserved their functional ability to suppress activated CD4+ T cells.
Our results suggest that mTOR inhibitors introduction after liver transplantation induced sustain and significant increase in Tregs, and

the suppressive capability of these cells was maintained. We thus confirmed their potential role in graft tolerance.

P6.14.08
Cyclophosphane effect on peripheral blood leukocytes and organs of immune system in experimental animals

*O. V. Lebedinskaya, E. A. Lebedinskaya, **A. P. Godovalov**, D. V. Suvorov, A. N. Razdobreeva, A. V. Khorinko;*
Acad. E.A. Wagner Perm State Medical Academy, Perm, Russian Federation.

The aim of investigation was the analysis of cyclophosphane (CP) effect on the immune system organs, on peripheral blood leukocytes in experimental animals.
The study was conducted in 20 male rats (284±20 g). CP was administered intraperitoneally at a concentration of 100 mg/kg of body weight, 4 fold with 24h-interval. Blood samples were taken from the tail vein to determine the total leukocyte count and leukocyte formula. Pathomorphological changes in bone marrow, thymus, spleen and lymph nodes were analyzed through 48 h after final CP injection.
It was shown that leukocyte number reduced by 50% on the 2nd day after the first CP injection, and by 99% - in subsequent two days. After the final CP injection the recovery of initial leukocyte number was not detected. Following the first CP introduction there was noted statistically significant increase in segmented neutrophils that were sharply declined after the 2nd cytostatic injection and were not further recovered. The amount of monocytes and lymphocytes was lowered 24 h after the first injection of cyclophosphane and subsequently continued to reduce. The alteration in the functional activity was determined in phagocytic cells. The statistically significant reduction in thymus, spleen and lymph node weight, was detected, as well as degenerative changes therein and decrease nucleated cells in bone marrow.
Thus as a result of investigation the development of induced immunosuppression was revealed that involved the lowering in blood leukocyte count, alteration of their composition and functional activity, progression of degenerative changes in the organs of immune system.

P6.14.09
Influence of immunosuppressive drugs on regulatory T cells

***A. C. Gronert Alvarez**, P. Fytili, V. Schlaphoff, M. P. Manns, M. Cornberg, H. Wedemeyer;*
Hannover Medical School, Hannover, Germany.

Background and aims: Regulatory T-cells (Tregs) can promote tolerogenic immune responses after liver transplantation. But liver transplant recipients also receive a variety of immunosuppressive drugs to avoid rejection. The aim of this study was to assess the effect of immunosuppressive drugs on the Treg population.
Methods: Peripheral blood mononuclear cells from healthy donors were incubated with immunosuppressive drugs (Cyclosporin A (CsA), Tacrolimus, MMF, Everolimus, Prednisolon) in different concentrations over various time points. Phenotyping of these cells was performed using flow cytometric analysis. Cytokines in cell culture supernatant were analysed using Cytometric Bead Array (CBA). Suppression assays after incubation of Tregs with CsA were performed.
Results: FoxP3 and CTLA-4 expression on Tregs decreased after 48 hours of incubation with CsA in a dose dependent manner, but not with any other drug. TGFb expression showed no change. Incubation with Tacrolimus, another Calcineurin inhibitor, did not lead to any distinct phenotypic change. Pre-incubation of Tregs with CsA did not inhibit the suppressive function of Tregs but improved it. Additionally, production of MIP1a and MIP1b was reduced.
Conclusions: Cyclosporin A, but none of the other immunosuppressive drugs, induced consistent phenotypical alteration of Tregs by decreasing FoxP3 and CTLA-4, but enhanced Treg suppressive function. Our results suggest that CsA could improve Tregs inhibitory function being additionally beneficial in avoiding graft rejection.

P6.14.10
Oral tolerance improves transgene persistence in gene therapy setting

***R. Hardet**[1], B. Chevalier[1], L. Drouot[1], L. Jean[1], D. Pannetier[2], A. Salvetti[2], O. Boyer[1], S. Adriouch[1];*
[1]Inserm U905, Rouen, France, [2]Inserm U758, Lyon, France.

Gene therapy represents a promising strategy to treat monogenic diseases by providing a functional copy of an otherwise defective gene. This can be efficiently achieved in vivo using viral vectors such as recombinant Adeno-associated Viruses (rAAV). It is however well documented that immune responses can lead to destruction of transduced cells thereby limiting long-term transgene expression. Immunosuppressive treatments may be used to improve therapeutic efficacy but they are unspecific and may cause side effects. Here, we evaluated a strategy to inhibit antigen-specific immune activation using a protocol of oral tolerization.
We showed that intramuscular injection of rAAV2/1-Ova leads, as expected, to robust immune responses. Indeed, 14 days after Ova-transgene transfer we detected conspicuous anti Ova IgG humoral response and about 15% CD8+ T cell direct against the OVA-derived immunodominant peptide. Kinetic studies showed undetectable levels of Ova in serum after day 14 and absence of corresponding mRNAs in muscle at day 80. In striking contrast, Oral tolerization for 7 consecutive days completely abolished specific cellular and humoral immune responses and allowed long-term persistence and expression of Ova-transgene. This further correlates with the inability of lymphocytes from tolerized animals to reject Ova-bearing tumors. Mechanistically, tolerance was not exclusively mediated by Tregs as their depletion prior to rAAV2/1-Ova injection did not restore immune responses. Importantly, induction of tolerance by antigen feeding was efficient only in naïve but not in primed mice suggesting that this protocol may be suited to improve tolerance in gene therapy settings but not in autoimmune diseases.

P6.14.11
Targeting PKC in human T cell using sotrastaurin (AEB071) stabilizes regulatory T cells and prevents IL-17 production

***X. He**[1], H. Koenen[1], R. L. Smeets[2], R. Keijsers[3], E. van Rijssen[1], P. C. van de Kerkhof[3], A. M. Boots[4], I. Joosten[1];*
[1]Laboratory of Medical Immunology, Dept. of Laboratory Medicine, Radboud Univercity Medical Centre Nijmegen, Nijmegen, Netherlands, [2]Laboratory of Clinical Chemistry, Dept. of Laboratory Medicine, Radboud Univercity Medical Centre Nijmegen, Nijmegen, Netherlands, [3]Department of Dermatology, Radboud Univercity Medical Centre Nijmegen, Nijmegen, Netherlands, [4]Department of Rheumatology and Clinical Immunology, University Medical Centre Groningen, University of Groningen, Groningen, Netherlands.

Regulatory T-cells (Treg) are crucial for immune homeostasis and prevention of immune pathology. Yet, Treg may lose Foxp3 expression and start secreting IL-17, dependent on environmental cues. Our previous data revealed that Treg from severe psoriasis patients are particularly prone to such conversion. Thus, the question of how to maintain Treg stability in the context of inflammation awaits immediate resolution. Recently, the pan-PKC inhibitor Sotrastaurin was successfully used in clinical trials of psoriasis. Here, we show that Sotrastaurin inhibited effector T cell responses, whereas the regulatory response was enhanced. Sotrastaurin prevented TCR/CD28-induced conventional T cell (Tconv) activation characterized by pro-inflammatory cytokine production and expression of activation markers. In contrast, Sotrastaurin preserved a stable Treg phenotype as evidenced by maintenance of suppressive capacity, high Foxp3/CD25 expression, and lack of IL-17A and IFNγ production, even when stimulated with the Th17-enhancing cytokine IL-1β. Moreover, ex vivo incubation of CD4+ T cells from psoriasis patients with Sotrastaurin enhanced Foxp3 expression and prevented IL-17A and IFNγ production. In psoriatic Treg, Foxp3 expression was maintained even when stimulated with IL-1β. Thus, pharmacological inhibition of PKC may serve as a powerful tool to concurrently inhibit effector T cells and to facilitate Treg.

P6.14.12
Searching for an adenosinergic loop in immune privileged human corneal tissues

A. L. Horenstein[1,2], *F. Sizzano*[3], *F. G. Besso*[3], *G. Zaccarello*[1,2], *G. Chiorino*[4], *F. Malavasi*[1,2];
[1]*Lab of Immunogenetics, Department of Medical Sciences, University of Torino, Torino, Italy,* [2]*Research Center on Experimental Medicine (CeRMS), Torino, Italy,* [3]*Transplant Immunology Service, Città della Salute e della Scienza Hospital, Torino, Italy,* [4]*Cancer Genomics Lab, Fondo Edo Tempia, Biella, Italy.*

Corneal cells are epithelial stem-derived cells with immunoregulatory features. The aim of the present study was to demonstrate that corneal cells are endowed with the ability to produce an immunosuppressive soluble factor that modulate a number of physiological processes (e.g., signal transduction, immunological response, proliferation, wound healing, among the others).
The results obtained indicate that cells isolated from the human limbus, a compartment characterized as a niche for a corneal SC population, coexpress surface CD38 (NADase), CD39 (diphosphohydrolase, NTPDase), CD203a (pyrophosphatase, PC-1) and CD73 (5'-nucleotidase). These molecules are functionally connected and metabolize ATP and NAD^+ for the generation of the nucleoside adenosine (ADO), a powerful pleiotropic molecule involved in the modulation of immunity and inflammation. The ectoenzymes shaping the pathway have been analyzed by cell cytometry, and the signals implemented were confirmed by molecular cell profiling. The enzymatic activities were essayed by *ad hoc* constructed HPLC assays.
The results indicate that corneal limbal cells express CD38, CD39 and CD203a and metabolize extracellular adenine nucleotides, originating AMP. In sequence, this is converted to ADO by CD73, present in the corneal crypts.
These results demonstrate that a so far unreported ectoenzymatic signaling pathway(s) constitute an adenosinergic axis, which exerts key roles in corneal physiology.

Immunomodulatory properties of new conjugates muramyldipeptides derivatives with adenosine

M. Samsel[1], ***D. Iwaszkiewicz-Grzes***[1], *K. Dzierzbicka*[1], *P. Trzonkowski*[2];
[1]*Gdansk University of Technology, Gdansk, Poland,* [2]*Medical University of Gdansk, Gdansk, Poland.*

Muramyl dipeptide (MurNAc-L-Ala-D-isoGln; MDP) is the minimal biological structure of bacterial peptidoglycan with adjuvant activity[1]. MDP acts through intracellular NOD2 receptor expressed in immune cells [2]. Modifications of MDP structure gave derivatives with immunomodulative, antiviral or antitumor activity [3]. Interestingly, analogues were D-alanine was replaced with L-amino acid exerted immunosuppressive action. Adenosine is a purine nucleoside, an important homeostatic modulator in all cells. It acts through the four types of adenosine receptors: A1, A2A, A2B and A3, belonging to the G-protein-coupled receptor family. A2A receptors are expressed ubiquitously in the body, but they can be found mainly in the immune system [4].
We synthesized a series of muramyl dipeptide and nor-muramyl dipeptide derivatives conjugated with adenosine. MDP were modified in a peptide part, where L-Ala was replaced with D-amino acid (D-Ala, D-Ser, D-Val, D-Pro). Conjugates were evaluated as inhibitors of a leukemia cell line Jurkat and human peripheral blood mononuclear cells from healthy donors.

New potent IMPDH inhibitors

D. Iwaszkiewicz-Grzes[1], *G. Cholewinski*[1], *K. Dzierzbicka*[1], *P. Trzonkowski*[2];
[1]*Gdansk University of Technology, Gdansk, Poland,* [2]*Medical University of Gdansk, Gdansk, Poland.*

Organ transplantation is a well-established method for the therapy of end-stage organ failure, increasing life expectancy and improving quality of life. The long-term outcome of these patients is now challenged by life-threatening complications such as cardiovascular disease, infections and post-transplant malignancies [1]. In modern transplantology inosine-5'-monophosphate dehydrogenase (IMPDH) is a major therapeutic target.
Mycophenolic acid (MPA), an inhibitor of IMPDH, reduces the availability of guanine nucleotides, especially GTP. The morpholinoethyl ester of MPA, mycophenolate mofetil (MMF), has potent immunosuppressive properties and is used worldwide in transplantation medicine to prevent organ rejection [2].
Although nomerous compounds were received and examinated as potentantial immunosuppressants, the risk of graft rejection has been not eliminated so far.
We continue our project concerning amino acid derivatives of mycophenolic acid. First, mycophenolic acid was coupled with amino acid esters via amide bond formation. At this stage we compared antiproliferation activity of compounds bearing methyl ester group with bulky benzyl esters. Secondly, we investigated influence of the additional polar group in amino acid moiety on cytotoxic activity of target compounds. Thus, mycophenolic acid was coupled with threonine, arginine methyl esters followed by hydrolysis to products having free carboxylic group. Their biological activity was evaluated against lymphoid cell line Jurkat and activated peripheral blood mononuclear cells (PBMC) as in vitro model of immunosuppression. The obtained results will be presented.

The response to anti-TNF ab therapy is variable in patients with psoriasis

K. Komura;
Dermatology, Municipal Tsuruga Hospital, Tsuruga, Japan.

Psoriasis is a proliferative epidermal disorder with immunological background. While some monoclonal antibody therapies against immune mediators are available for the patients, efficacy of the therapy is highly variable. We describe the diversity of anti-TNF ab effects against the psoriasis. Seven psoriasis patients were treated by anti-TNF ab. The therapy was effective for 5 patients, while it was not effective for 1 patient. One patient developed pneumocystis carinii pneumonia after the therapy. The TNF resistant was successfully treated by IL23 blocker. There was no sign or specific clinical findings in this patient when compared to other patients who were improved by TNF therapy. Although it was unclear in this study, the identification of genetic and/or disease variants has the potential to improve the selection of the drug. A suitable approach in implementing such a strategy could potentially reduce medical costs and improve success of drug therapy. Since ~20% of patients do not respond to TNF therapy, we would focus on these patients and TNF related molecules. Further, the evaluation will include experimental/preclinical studies, using patient own skin/immune cells and candidate drugs. Thus, personalized medicine will mandate special physicians capable of understanding molecular medicine in addition to genetics and biomarkers for diagnosis, evaluation of the effect of drugs, and overall prognosis.

P6.14.16
Interleukin-35 mediated supression on neutrophilic airway inflammation with the IL-17/IFN-γ dominant phenotype

*C. Huang, E. X. Loo, G. Soh, L. Chua, H. Wen, K. Chua, **I. Kuo**; National University of Singapore, Singapore, Singapore.*

Interleukin (IL)-35 is a heterodimeric cytokine that is composed of Epstein-Barr virus-induced gene (EBI) 3 and IL-12p35 subunit. IL-35 is a member of the IL-12 family cytokines and has been found to have potent
immuno-supressive activities. In this study, we delivered a major dust mite allergen, Blo t 5, intranasally into Blo t 5-specific T cell receptor transgenic mice and found an neutrophil and lymphocyte dominant airway inflammation phenotype with upregulated IL-17 and IFN-γ. By pulmonary delivery of a construct expressing fusion EBI3 and IL12p35 subunit, we examined the effectiveness of pVAX1-IL-35 on the modulation of the neutrophilic and IL-17/IFN-γ dominant airway inflammation in the experimental model. Intra-tracheal administration of pVAX1-IL-35 was found to effectively reduce the infiltration of neutrophils, lymphocytes and total cell numbers in bronchoalveolar lavage fluid after intranasal Blo t 5 instillation. In addition, pro-inflammatory cytokines and chemotactic chemokines such as IL-17, IFN-γ, IL-1α, IL-6, LIF, MIP-1α/CCL3, MIP-1β/CCL4, RANTES/CCL5, KC/CXCL1, MIG/CXCL9 and IP-10/CXCL10 were significantly attenuated in bronchoalveolar lavage fluid from mice in the experimental pVAX1-IL-35 group as compared to that from the control pVAX1 group. These data suggested that IL-35 could be a promising therapeutic target in controling neutrophilic and IL-17/IFN-γ dominant airway inflammation.

P6.14.17
Immunohistochemical characterization of leukocyte infiltrates in minimally invasive gastric cancer

*I. N. Kabanovskaya, **O. V. Lebedinskaya**, A. E. Vydrina, V. V. Mochalnikova;*
Acad. E.A. Wagner Perm State Medical Academy, Perm, Russian Federation.

The aim of investigation was to study the immunohistochemical characteristics of leukocyte infiltrates of gastric mucosa in minimally invasive cancers.
To visualize and make photography of micropreparations of gastric biopsies from 14 patients with adenocarcinoma and mucinous carcinoma the Scope Photo program was used. The analysis of images was realized via ImageJ program. To reveal T-lymphocyte (CD3, CD8) and B-lymphocyte (CD20) marker expression the avidin-biotin method was applied (Novocastra, Switzerland) according to C.R. Taylor, R. Cote. [1994] and L.A. Sternberger [1979] procedures. Calculation of positively- and negatively-stained cells was made in square closed test-system. Statistical data processing was implemented with Biostat 5 program.
During the study of cell composition in leukocyte infiltrates of gastric mucosa affected with tumor process while using the hematoxylin- and eosin-stained preparations it was revealed that lymphocytes, plasmocytes and macrophages prevailed therein. The density of CD3-positive cells was nearly similar in focal and diffuse leukocyte accumulations (44,9 and 45,4%, respectively). Meanwhile, among T-lymphocytes the number of $CD8^+$ cells significantly differed between 1-type and 2-type infiltrates (38,1 and 50%, respectively). In contrast, B-lymphocyte ($CD20^+$) concentration was significantly higher in focal infiltrates as compared with diffuse ones (80,9 and 69,6%, respectively).
Thus, results obtained demonstrate significant differences in T- and B- lymphocyte subset distribution within the focal and diffuse leukocyte infiltrates of gastric mucosa in minimally invasive cancers. These data could be valuable under the development of immunocorrection methods for malignancy biotherapies.
This work was supported by RFBR grant №11-04-96037r_ural_a and administrative body of Perm Region.

P6.14.18
Influence of Stimforte on the immunologic characteristics of mice against induced immunosuppression

*E. A. Lebedinskaya[1], E. V. Fadeeva[1], **O. V. Lebedinskaya**[1], N. K. Akhmatova[2], D. G. Maldov[2], M. V. Kiselevsky[2];*
[1]Acad. E.A. Wagner Perm State Medical Academy, Perm, Russian Federation, [2]N.N. Blokhin Russian Cancer Research Center RAMS, Moscow, Russian Federation.

The aim of study was the analysis of Stimforte effect on immunological parameters in mice against induced immunosuppression. Investigation was carried out with 80 BALB/c mice there were injected either with cyclophosphane (CP) and Stimforte in different combinations or with physiological solution (control group). The immunophenotype of mononuclear leukocytes (ML) isolated from animal spleen and killer activity against YAK-1 tumor line were defined. Morphological investigations of Romanosvky-Giemsa-stained smears were administrated. CP administered (100 mg/kg) within 3 days evoked immunosuppression that was manifested in nearly 7-fold lowering of ML number in mice spleen as compared with control group. ML population in CP-received animal group was represented by mature lymphocytes, whereas control group demonstrated considerable amount of young lymphoid cells in spleen. Animals against CP introduction exhibited significant decrease in natural killer (NK) and pronounced reduction in their NK-activity. Stimforte injection against CP-induced immunosuppression increased more than by 2-fold the ML content in mice spleen, when immature forms such as pro-lymphocytes were detected. In addition, Stimforte favored the normalization of NK content in spleen ML and their NK activity increment nearly to the initial values. Peripheral blood of animals under study also demonstrated the increase in granulocyte number. Thus, CP resulted in marked immunosuppression manifesting in lowering in total lymphocyte amount in mice peripheral blood and spleen, as well as declining in NK content in lymphocyte population as compared with intact animals. Stimforte administration against cytostatic-induced immunosuppression resulted in significant increase in lymphocyte number and normalization of their immunophenotype and function characteristics.

P6.14.19
Triptolide ameliorates autoimmune diabetes and prolongs islet graft survival in nonobese diabetic mice

*S. Huang[1], **G. Lin**[2], C. Chu[1], J. Yu[1], T. Chen[1], Y. Chen[3], M. Chien[4], C. Chu[5], H. Sytwu[6];*
[1]Department of General Surgery, Tri-Service General Hospital, Taipei, Taiwan, [2]Department of Biology and Anatomy, National Defense Medical Center, Taipei, Taiwan, [3]Department of Oral and Maxillofacial Surgery, Tri-Service General Hospital, Taipei, Taiwan, [4]Graduate Institute of Life Sciences, National Defense Medical Center, Taipei, Taiwan, [5]Department of Anesthesiology, Chi Mei Medical Center, Tainan, Taiwan, [6]Department of Microbiology and Immunology, National Defense Medical Center, Taipei, Taiwan.

Triptolide (TPL) possesses profound immunosuppressive effects and has potential in allograft transplantation. We investigated whether TPL treatment prevents autoimmune diabetes in nonobese diabetic (NOD) mice and prolongs the survival of islet grafts against autoimmune attack or allograft rejection. In this study, diabetic incidence was monitored in TPL-treated NOD mice. NOD or BALB/c islets were transplanted into diabetic recipients treated with TPL. Different T cell subsets in grafts or spleen were analyzed. The proliferation, apoptosis, cytokines and activities of AKT, NFκB, caspases 3, 8 and 9 of T cells were determined. Our results revealed that diabetic incidence was reduced and inflammatory cytokines were decreased in islets and spleen under TPL treatment. T cell proliferation was reduced and the survival of syngeneic or allogeneic grafts was significantly increased in TPL-treated mice. The populations of CD4, CD8, CD4CD69, CD8DC69 and IFN-γ-producing T cells in islet grafts and spleen were reduced. TPL treatment increased the apoptosis of T cells in the spleen of recipients. Levels of p-AKT and p-IκB in splenocytes were reduced and caspase-3, -8 and -9 were increased in TPL-treated mice. In conclusion, TPL treatment not only reduced the diabetic incidence in NOD mice but also prolonged the survival of syngeneic or allogeneic grafts.

P6.14.20

Highly suppressive and non-toxic Trichosanthin-derived peptide induces skin transplantation tolerance via expanding $CD4^+CD25^+Foxp3^+$ Tregs

L. M. Lu[1,2], *Q. Li*[1], *L. Zhou*[1], *K. Y. Chou*[1];
[1]*Shanghai Jiaotong University School of Medicine, Shanghai, China,* [2]*Shanghai Institute of Immunology, Shanghai, China.*

Trichosanthin (Tk), a component isolated from a Chinese medicinal herb *Trichosanthes kirilowii,* is active in abortifacient, anti-tumor, anti-HIV, as well as functions as an immune down-regulator. To separate its toxic property, a Tk-derived peptide Tk-PQ, containing forty C-terminal amino acids, was synthesized. We found that 10~50 μg/ml of Tk-PQ inhibited cell proliferation in a dose-dependent way without cytotoxicity as compared with native Tk. In the Tk-PQ-treated allogeneic mixed lymphocyte reaction, there were an increased production of IL-10/TGF-β and a decreased secretion of IFN-γ/IL-17A. Moreover, Tk-PQ promoted the activation of $CD4^+CD25^+Foxp3^+$ Treg subset and remarkably increased the expression of interferon-regulatory factor 4 (IRF4). Pearson correlation analysis shows a significant positive correlation of IRF4 and Foxp3 expression (r=0.99; p=0.0003, n=5). Using murine full-thickness trunk skin allo-grafting model, we were able to show that Tk-PQ remarkably increased the survival of the allografts in the recipients from 9.0±1.1 days (control) to 22.2±2.8 days. Histological analysis of the allografts on day 9 post transplantation showed that the Tk-PQ treatment reduced the infiltration of mononuclear cells. The in vivo ratio of $CD4^+CD25^+Foxp3^+$ Tregs was expanded in both spleen and peripheral blood of the recipients. Intracellular staining indicated that the percentages of IL-10^+ cells were also increased in splenocytes and the $CD4^+CD25^+Foxp3^+$ Treg population, while the IFN-γ^+ cell percentages were decreased. Furthermore, Tk-PQ inhibited the phosphorylation of IκBα and the nuclear translocation of NF-κB. These results indicate that Tk-PQ may have potential therapeutic values for the delay of graft rejection and the treatment of other inflammatory diseases.

P6.14.21

Effects of cyclosporine A and rapamycin on the ability of dendritic cells to activate T cells

M. Machcińska[1], *K. Bocian*[1], *G. Korczak-Kowalska*[1,2];
[1]*Department of Immunology, Faculty of Biology, University of Warsaw, Warsaw, Poland,* [2]*Transplantation Institute, Medical University of Warsaw, Warsaw, Poland.*

Introduction: The most important antigen-presenting cells are dendritic cells (DCs), which present antigen to T cells. The state of maturation of DCs is crucial for induction of a T-cell lymphocyte response. It was noted that immature DCs play an important role in peripheral tolerance, whereas mature DCs induce immune response.
We have studied the effect of immunosuppressive agents: rapamycin and cyclosporine A on dendritic cells cytokine production and the ability to induce the proliferative T cells activity.
Methods: Human peripheral blood monocytes were induced by using cytokines: IL-4 and GM-CSF, in the direction of DCs in the presence of rapamycin (Rapa-DCs) and cyclosporine A (CsA-DCs) or without drugs. Then these immature DCs were stimulated with LPS to create mature DCs. The supernatants have been collected and measurements of DC pro-inflammatory cytokine (IL-6, IL-12) levels were performed by ELISA. Mature DCs were then incubated with T cells in mixed leukocyte reaction and the proliferative T cells activity was determined by measuring the fluorescence intensity of CFSE dye using flow cytometry.
Results: We have noted that the percentage of proliferating T cells do not change significantly after incubation with Rapa-DCs and CsA-DCs. We have also observed a diminished production of IL-6 by immature DCs and LPS-activated DCs, when these cells were differentiated in the presence of immunosuppressive agents. Production of IL-12 was notably undetectable in all culture conditions.
Conclusions: We have shown that the immunosuppressive agents: rapamycin and cyclosporine A do not change the ability of dendritic cells to activate T cells.

P6.14.22

Mir-142-3p target sequences reduce transgene directed immunogenicity following intramuscular AAV vector-mediated gene delivery

A. Majowicz[1,2], *P. Maczuga*[1,2], *K. L. Kwikkers*[1], *S. van der Marel*[1,2], *R. van Logtenstein*[1], *H. Petry*[1], *S. van Deventer*[1,2], *P. Konstantinova*[1], *V. Ferreira*[1];
[1]*uniQure B.V., Amsterdam, Netherlands,* [2]*Department of Gastroenterology & Hepatology, Leiden University Medical Center, Leiden, Netherlands.*

Appearance of immune responses against the transgene product after adeno-associated virus (AAV) vector-based gene therapy is one of the concerns that limit efficacy of the treatment. Use of microRNAs (miRNAs) that are specifically expressed in antigen-presenting cells (APCs) is a promising approach to avoid those immune responses. Cellular mir-142-3p, which is APC-specific, is able to repress translation of its target cellular transcripts by binding to a specific target sequences.
We explored the potential of mir-142-3p specific target sequences to reduce or abolish immune responses directed against ovalbumin (OVA), a highly immunogenic protein, expressed as transgene and delivered by AAV vector administered intramuscularly.
The occurrence of humoral and cellular immune responses against OVA transgene following intramuscular delivery by AAV have been previously described and resulted in loss of OVA protein expression. In our study we demonstrate that OVA protein expression was maintained when mir-142-3pT sequences were incorporated in the expression cassette. The sustained expression of OVA protein over time correlated with a reduced increase in anti-OVA antibody level. Furthermore, no cellular infiltrates were observed in the muscle tissue when AAV1 vectors containing 4 or 8 repeats of mir-142-3p target sequences after OVA sequence were used.
Our data provides the evidence that humoral and cellular immune responses against OVA protein after intramuscular delivery can be efficiently reduced by use of mir-142-3p target sequences. Overall, this study identifies a promising approach for gene therapy applications as it could be applied as a “safety lock” for any intramuscular AAV vector based therapeutic gene delivery.

P6.14.23

Induction of antigen-specific regulatory T cells as a therapy for autoimmune diseases

A. M. Malara*, C. Finlay, A. M. Stefanska, K. H. G. Mills;*
Trinity College Dublin, Dublin, Ireland.

Regulatory T (Treg) cells play a fundamental role in maintaining peripheral tolerance to self-antigens. Defect in Treg cells can result in uncontrolled effector T cell responses to autoantigens and development of autoimmune disorders. Conversely, approaches that enhance the generation of autoantigen-specific Treg cells have potential to prevent or treat of autoimmune disease. The induction of Treg cells is enhanced by anti-inflammatory cytokines, with IL-10 and IL-27 promoting the generation of IL-10 secreting Tr1-type Treg cells and TGF-β with retinoic acid inducing peripheral conversion of naïve T cells into conventional $CD4^+CD25^+Foxp3^+$ Tregs. Finally, certain immunomodulatory molecules form bacteria or helminths can activate dendritic cells (DCs) to promote induction of Treg cells *in vivo.* The aim of this study was to examine the capacity of IL-10, TGF-β or IL-27 or pathogen-derived molecules that induce IL-10 and TGF-β and suppress IL-12 from DCs to act as adjuvants to promote the induction of Treg cells against self-antigen and thereby prevent or reduce the clinical course of an autoimmune disease in a mouse model. The results to date have shown that TGF-β enhanced survival of $CD4^+$ T cells and upregulated expression of Foxp3, which was enhanced by IL-10 and IL-27. *In vivo* studies demonstrated that a low molecular weight fraction from the helminth, *Fasciola hepatica*, enhanced the frequency of $Foxp3^+$ Treg cells, whereas supernatant from homogenate of liver fluke enhanced IL-10-secreting T cells. These helminth-derived fractions are currently being tested as adjuvants to induce Treg cells against autoantigen, MOG, and to prevent experimental autoimmune encephalomyelitis.

P6.14.24
PD-1 dependent exhaustion of autoaggressive effector T cells following tolerogenic peptide administration

***R. C. McPherson**, J. E. Konkel, M. D. Leech, A. J. Drake, S. M. Anderton;*
University of Edinburgh, Edinburgh, United Kingdom.

The clinical requirement for antigen-based therapy is to target and switch-off the activated antigen-experienced T cells involved in ongoing disease pathogenesis. Various experimental models of both autoimmune and allergic disease have demonstrated that prophylactic administration of soluble auto-antigenic peptides can be effective at inducing tolerance in naïve antigen-reactive T cells and protecting from subsequent disease induction. However, antigen-experienced T cells possess distinct activation requirements to those of naïve T cells and there exists the potential for soluble peptide administration to enhance activation of effector T cells and exacerbate ongoing disease. Using traceable TCR transgenic T cells in a model of experimental autoimmune encephalomyelitis (EAE) we demonstrate that tolerogenic peptide administration can result in a substantial expansion of antigen-experienced effector T cells (Teff). Despite the considerable increase in the number of antigen-reactive Teff cells, these cells were no longer pathogenic and were unable to drive CNS autoimmune disease. Phenotypic analysis of the Teff cells following infusion of soluble peptide revealed a lack of IL-2 and effector cytokine production and high level expression of the co-inhibitory molecule PD-1. PD-1 expression was maintained for at least 16 days following peptide treatment and was required for the induction of tolerance in Teff cells, as PD-1 deficient T cells retained the ability to induce EAE following peptide treatment. Furthermore, epigenetic modifications were detected within the PD-1 promoter of Teff cells post-peptide administration, which may provide a potential mechanism for the long-term expression of this co-inhibitory molecule and the enduring tolerant phenotype observed in these cells.

P6.14.25
Role of calcineurin/NFAT signalling in myeloid cell haematopoiesis and function

***A. Mertes**[1,2], J. Fric[1], C. X. F. Lim[1], H. Tay[1], T. Zelante[1], J. Chen[1], P. Ricciardi-Castagnoli[1];*
*[1]Singapore Immunology Network (SIgN), Agency for Science, Technology and Research (A*STAR), Singapore, Singapore,*
[2]Nanyang Technological University, Singapore, Singapore.

Myeloid cell homeostasis, a complex process regulated by multiple factors, plays a major role in innate immune responses as these cells present the first line of defense by recognition and elimination of pathogens. We have recently reported a novel role for calcineurin/NFAT signalling as a negative regulator of myeloid haematopoiesis. Here we uncover the underlying mechanisms by which calcineurin/NFAT signalling regulates innate immune responses and the steady state renewal of myeloid cells and their progenitors. Our data provides evidence that specific inhibition of NFAT signalling during differentiation of bone marrow progenitors in vivo results in preferential expansion of myeloid cells as well as increased proliferation of granulocyte-macrophage precursors. This phenomenon can be explained through the interaction of NFAT with cell cycle-regulating genes as shown by global gene expression analysis of c-kit-enriched progenitors impaired in NFAT signaling by treatment with cyclosporine A or tacrolimus. Analysis of FACS-sorted individual progenitor subsets impaired in calcineurin/NFAT signaling confirmed changes in the expression of cell cycle-regulating genes. To address the role of NFAT signalling in vivo, different mouse models are used to study the frequency, differentiation and proliferation of myeloid progenitors during steady state and inflammatory conditions under treatment inhibiting calcineurin/NFAT signalling. Conditional deletion of calcineurin in mouse haematopoietic cells reveals which progenitor subsets are involved in the enhancement of myeloid development after calcineurin/NFAT inhibition. Our findings may have important clinical applications since immunosuppressive drugs that target the calcineurin/NFAT pathway (e.g. cyclosporine A) to inhibit T cell functions may also impact myeloid cell homeostasis.

P6.14.26
CD6-targeted therapy validation with Itolizumab in autoimmune diseases

***E. Montero**[1], R. Melarkode[2], P. Nair[2], P. Hernandez[1], C. G. Prasanna[2], C. Rodriguez[1], A. Bhatnagar[2], A. Castillo[1], I. Cuenca[1], J. Iyer[2];*
[1]Center of Molecular Immunology, Havana, Cuba, [2]Biocon, Bangalore, India.

CD6 is a membrane glycoprotein implicated in lymphocyte activation and trafficking, through its membrane-proximal domain (Scavenger Receptor Cysteine-Rich, SRCR3) interaction with ALCAM (Activated Leukocyte Cell Adhesion Molecule, CD166). We found that CD6 synergizes lymphocyte costimulation in vitro, enhancing the intrinsic activity of the CD3 activation pathway and boosting the IL-2 sensitivity of recent activated cells, skewing the response to a pro-inflammatory commitment. Unexpectedly, generated CD6 membrane-distal domain 1 (SRCR1) specific monoclonal antibody (mAb) modulated in vitro CD6-ALCAM induced lymphocyte effector differentiation, without blocking their binding and, in vivo disease control without peripheral lymphocyte depletion in autoimmunity models. Itolizumab is an anti-human CD6 SRCR1 specific non-agonistic humanized IgG1 mAb. It recognizes with an intermediate affinity constant, a conserved conformational epitope independent of N-glycosylation. Itolizumab inhibits CD6-ALCAM mediated co-stimulation, reducing lymphocyte proliferation, pro-inflammatory cytokines production i.e.: IL-17A, IFNγ, IL-6, TNFα; intracellular activation pathways i.e.: AKT, MAPK, STAT3 and cell adhesion associated molecules. Dose-finding, single-blind, randomized studies were performed in active moderate-to-severe Psoriasis and active Rheumatoid Arthritis patients, administering Itolizumab as monotherapy, or in combination with Methotrexate in the latter. Itolizumab is poorly immunogenic and well-tolerated; mild adverse events were observed mainly associated to the first infusion, reducing afterwards. Itolizumab promotes a significant clinical response persisting after the last administration, without rebound effect or immunosuppression. These results have been validated in a randomized, double-blind, placebo-controlled, pivotal phase III clinical trial in Psoriasis. Current preclinical and clinical findings in more than 400 patients support CD6 as a novel therapeutic target for autoimmune immunopathology modulation.

P6.14.27
Erythrina abyssinica reduces astrocytosis in T.brucei chronic mouse model

***J. Nasimolo**[1], S. G. Kiama[1], J. Kagira[2], A. Makanya[1], P. K. Gathumbi[1];*
[1]University of Nairobi, Nairobi, Kenya, [2]Jomo Kenyatta University of Agriculture and Technology, Nairobi, Kenya.

Human African trypanosomiasis is prevalent in Sub-sahara African countries that lie between 14° North and 29° south of the equator.Trypanosoma brucei gambesience occurs in West and Central Africa while Trypanosoma brucei rhodesience occurs in East and Southern Africa. In this region, close to 60 million people are at risk of infection. The neurological stage of the disease is characterized by neuroinflammation and 10% of patients treated with the recommended drug develop PTRE (Post treatment reactive encephalopathy) which is fatal. Our study aimed at screening medicinal plants used by local communities for potential activity in reducing these side effects. Erythrina abbysinica was selected based on its wide use by different communities in Kenya and other parts of Africa. We used histology, GFAP immunohistochemistry and electron microscopy (TEM and SEM) to study the pathogenesis and grading neuroinflammation.We also used SDS-PAGE electrophoresis to compare the protein profiles of the different test groups. Data was analyzed by one way ANOVA to compare difference between treatment groups. Results indicated water extract ameliorates neuroinflammation and conserves some high molecular weight proteins. AKNOWLEDGEMENT This work was supported by a fellowship grant from Carnegie Newyork through RISE-AFNNET.

P6.14.28

Intravenous immunoglobulins in the treatment of toxic epidermal necrolysis due to omeprazole in a patient with systemic lupus erythematosus

M. Nikolic[1]*, M. Gajic-Veljic*[1]*, B. Bonaci-Nikolic*[2]*;*
[1]*University of Belgrade, Faculty of Medicine, Department of Dermatology, Belgrade, Serbia,* [2]*University of Belgrade, Faculty of Medicine, Department of Allergy and Clinical Immunology, Belgrade, Serbia.*

Toxic epidermal necrolysis (TEN) may supervene during systemic lupus erythematosus (SLE). Omeprazole has been reported as a drug inducing TEN.
We present a 19-year-old girl with a history of discoid lupus erythematosus since the age of 12. She was treated with antimalarials and topical corticosteroids. She was in remission up to March 2012, when she developed fever, arthralgia and myalgia. On the basis of 6 ACR criteria (malar rash, photosensitivity, polyserositis, leucopenia, ANA, anti-dsDNA) the diagnosis of SLE was established. Two weeks after the commencement of systemic prednisone and omeprazole, numerous erythematous target lesions rapidly appeared on the face, trunk and extremities. Two days later, extensive erythema, widespread bullae and erosions of the lips, face, neck, trunk, oral and conjunctival mucosa developed, with positive Nikolsky sign, accompanied by high fever and malaise.
Except high ESR, routine laboratory analyses and renal function tests were normal. Cardiac echography showed pericardial effusion. Skin histology showed basal and suprabasal epidermal cell necrosis with dermo-epidermal separation. DIF test was negative. The diagnosis of TEN was made. SCORTEN was 2.
The patient received IVIg 2 g/kg, divided in two days. One week after starting the IVIg, erosions completely epithelized. The prednisone dose was gradually tapered and azathioprine was added.
According to our patient's history and the course of the disease, omeprazole was the most probable cause of TEN. IVIg was very efficacious in our patient.

P6.14.29

Salivary evaluation of pediatric patients with cancer, before and after antineoplastic treatment

R. N. M. Guerra, ***J. J. Oliveira Jr****, J. E. Mouchrek Filho, S. A. Liberio, D. B. Schmidt, C. X. L. Brito, C. Mendonca, F. R. F. Nascimento, A. L. A. Pereira;*
Universidade Federal do Maranhão, São Luís, Brazil.

This study evaluated the salivary biochemical and immunological status of children with cancer undergoing to antineoplastic treatment in an attempt to identify alternatives for a less invasive and less painful monitoring of these patients. Materials and methods: Unstimulated whole saliva samples were obtained from 115 children without cancer (control) and 32 children with cancer (CA). Children with cancer were also evaluated after antineoplastic treatment (CAT, n = 17). The salivary concentrations of glucose, triglycerides, total cholesterol, alkaline phosphatase, gamma-glutamyltransferase (GGT), urea, insulin, thyroid-stimulating hormone (TSH), triiodothyronine (T3), levothyroxine (T4), and immunoglobulin A (IgA) were determined. Results: Acute lymphocytic leukemia, acute myeloid leukemia, and Hodgkin's lymphoma were the most frequent cancers, although cases of non-Hodgkin's lymphoma, medulloblastoma, ependymoma, osteosarcoma, nephroblastoma, Ewing's sarcoma, and endodermal sinus tumor were also observed. The salivary concentration of cholesterol, triglycerides, or GGT did not differ between groups. Instead, the concentrations of alkaline phosphatase and T4 were higher in patients with cancer, irrespective of treatment. TSH levels were higher in the CA group and urea concentration was lower in the CAT group. T3 was undetectable in all groups. Antineoplastic treatment increased the glucose level and decreased the insulin concentration. Salivary concentration of total IgA was lower in children with cancer, irrespective of treatment. Conclusions: Cancer and antineoplastic treatment affected biochemical and immunological parameters in the saliva of children, shedding new light on the potential usefulness of saliva for monitoring children with cancer, especially to patients undergoing immunosuppressive therapy.

P6.14.30

IVIg suppresses allogeneic mixed lymphocyte reactions by induction of anti-inflammatory monocytes ($CD14^{LOW}$, $HLA\text{-}DR^{HIGH}$) with $CD80^{LOW}$ and $PDL1^{HIGH}$ expression

L. Padet[1,2]*, R. Bazin*[1,2]*;*
[1]*Héma-Québec, Québec, QC, Canada,* [2]*Department of Biochemistry, Microbiology and Bioinformatics, Laval University, Québec, QC, Canada.*

Intravenous immunoglobulin (IVIg) is a therapeutic preparation of human IgG isolated from thousands of plasma donations and has been proposed as a therapy to improve the rate of graft survival in patients with a high risk for antibody-mediated-rejection. Blocking of anti-HLA antibodies by anti-idiotypic IgG present in IVIg was proposed to explain the rapid anti-inflammatory effect of IVIg. However, peripheral tolerance beyond the half- life of IVIg was observed in IVIg-treated patients, suggesting that IVIg modulates the functions of immune cells. In the present study we showed, using the allogeneic mixed lymphocyte reaction (MLR) as an in vitro model of allograft rejection and GvHD, that IVIg strongly inhibits IL-2 secretion (T cell activation) and modulates the level of other pro- and anti-inflammatory cytokines secretion (IL-6, INF-γ, TNF-α, IL-1RA). To determine the mechanisms underlying the inhibition of T cell activation in MLR, we studied the effect of IVIg on the phenotype of the cells involved in MLR (mainly T cells and monocytes). Our results revealed that MLR inhibition by IVIg correlates with the induction of anti-inflammatory monocytes ($CD14^{LOW}$, $HLA\text{-}DR^{HIGH}$) with a low CD80 and high PDL1 expression. To evaluate the importance of PDL1 on the MLR inhibition, anti-PDL1 was added during the MLR. Blocking of PDL1 restored the MLR, as evaluated by IL-2 secretion by activated T cells. We thus propose that PDL1 plays a central role in the inhibition of MLR. Our results help to better understand how IVIg induces long-term peripheral tolerance and improves graft survival in transplanted patients.

A comprehensive and quantitative analysis of the specificities in rabbit antithymocyte globulin preparations

I. Popow[1]*, J. Leitner*[1]*, K. Grabmeier-Pfistershammer*[2]*, O. Majdic*[1]*, G. J. Zlabinger*[1]*, M. Kundi*[3]*, P. Steinberger*[1]*;*
[1]*Institute of Immunology, Medical University of Vienna, Vienna, Austria,* [2]*Department of Dermatology, Medical University of Vienna, Vienna, Austria,* [3]*Institute of Enviromental Health, Medical University of Vienna, Vienna, Austria.*

Antithymocyte globulins (ATGs) are the polyclonal IgG fraction of sera from rabbits that are immunized with human thymocytes or Jurkat cells. Their polyclonal composition is reflected by various immunomodulatory activities and therefore ATGs are used as strong immunosuppressants for the treatment of graft rejection, graft versus host disease and aplastic anaemia. In order to better control the outcome but also the side effects of an ATG treatment, it is important to determine the qualitative and quantitative aspects of antibody specificities in ATGs. Therefore, we developed a method based on retroviral expression cloning for the identification of novel ATG specificities directed to antigens on human leukocytes. Furthermore, we established methodologies that allow for the quantification of ATG antibodies to a given antigen. The functional consequences of the ATG antigen binding interaction on pBMCs in vitro, were investigated. In this study, ATG antigens directed to human leukocytes that have not been described in the literature could be identified. A profile of about 90% of the major antibody specificities directed to leukocyte antigens of ATG-Fresenius and Thymoglobulin was calculated. In addition, the role of specific ATG antibody binding to target antigens involved in T cell activation was analysed.This study gives for the first time comprehensive and quantitative information on the composition of both rabbit ATG preparations that are in clinical use. Furthermore, the data contribute to a more complete understanding of the immunosuppressive and immunomodulatory effects exerted by ATGs and can be used for the establishment of a more patient orientated regimen.

P6.14.32
CD38 and PC-1 pathway leading to the production of adenosine: a rescue pathway for the immune system at the maternal-fetal interface

V. Quarona[1], *M. Cecati*[2], *M. Emanuelli*[2], *S. R. Giannubilio*[2], *F. Malavasi*[1], *A. L. Tranquilli*[2], *F. Saccucci*[2];
[1]*Laboratory of Immunogenetics, Department of Medical Sciences, Univerity of Torino Medical School, Torino, Italy,* [2]*Department of Clinical Sciences, Università Politecnica delle Marche, Ancona, Italy.*

Pregnancy is considered to be an in vivo transplant and the interactions taking place at the maternal-fetal interface have been the focus of several studies in recent years. Maternal and fetal immune defenses establish a condition of reciprocal tolerance which lasts throughout the pregnancy.
Beside dominant immunogenetic components, the ectoenzyme network contributes with a chain of surface molecules mainly operating in closed environments. The products of the reactions provide inhibitory or activating signals. Adenosine (ADO), a purine nucleoside that plays multiple roles in almost all tissues and organs, is one of the soluble products of the ectoenzyme network with immune suppressory potential.
The working hypothesis of this work, i.e., that the adenosine generating network contributes to immune tolerance in pregnancy, has been studied in women with recurrent pregnancy loss (RPLs), which remain unexplained in over 50% of cases. We analyzed the expression of CD39 (ectonucleoside triphosphate diphosphohydrolase-1) and CD73 (ecto-5'-nucleotidase), the main pathway for adenosine generation. The study included the evaluation of the expression of TNF-α (a pro-inflammatory cytokine) and of an alternative pathway of adenosine generation run by CD38 (ADP-ribosyl cyclase/cyclic ADP-ribose hydrolase) and PC-1/ENPP1 (ectonucleotide pyrophosphatase/phosphodiesterase 1).
Comparison of the gene expression patterns between RPL and control group suggested that the ectoenzyme network may provide an important contribution to the generation of local tolerance and may significantly influence the clinical outcome in RPL.
These findings may directly prove useful in the design of protective therapies for women at risk for RPL.

P6.14.33
Regulatory T cell epitopes in IgG (Tregitopes) suppress immune responses without skewing toward TH2

Y. Su[1], *L. P. Cousens*[2], *A. S. De Groot*[2], ***D. W. Scott***[1];
[1]*Uniformed Services University of the Health Sciences, Bethesda, MD, United States,* [2]*EpiVax, Inc., Providence, RI, United States.*

Immunoglobulins (IgG) have been shown to be excellent tolerogenic carriers, although the basis for this tolerogenicity is not clear. Five years ago, De Groot and colleagues reported that IgG contains epitopes, termed Tregitopes, that stimulate T regulatory cell expansion and suppress T cell responses in vitro and in vivo. In this study, we asked whether these Tregitopes triggered detectable T cell responses or skewed immune responses per se even when delivered in complete or incomplete Freund's adjuvant. While administration of Tregitopes in IFA led to an increase in CD25+ FoxP3+ cells, there was no proliferation and minimal cytokine production detected in response to those peptides, and no increase in transcription factors typifying a TH2 response. Based on our results, we suggest that Tregitopes can be used to expand Tregs and that these epitopes may represent a new paradigm for treatment of undesirable immune responses in autoimmunity and adverse drug reactions. P6.14.34
An immunotherapy study to compare immunomodulatory properties of Mesenchymal Cells derived from bone marrow and adipose tissues for application in non-human primate kidney transplantation

F. Sotoodehnejadnematalahi*, N. Aghdami, H. Baharvand; Royan, Tehran, Iran.*

Multipotent non-hematopoietic progenitor mesenchymal stem cells are originally isolated from bone marrow (BM) as well as adipose tissues and they are capable of differentiating into various mesodermal lineages. Several studies have reported low immunogenicity for MSCs as they appear to have great potential to be used as modulators of immune responses in a variety of diseases related to alloreactive immunity in addition to organ transplantation. In vitro studies have shown immunosuppressive effect of MSCs on T cells, B cells and natural killer cells as well as in vivo prolong skin graft survival. Studies have proposed human adipose tissues (hAD) as an unlimited source of MSCs which showed to have very similar immunological properties to MSCs derived from hBM. As MSCs isolation from BM is an aggressive method, therefore in this project we aim to isolate MSCs from adipose tissues and then study in vivo immunomodulatory effect of hAD-MSCs on immune responses in kidney xenografts. In addition, we aim to compare the immune regulation of hAD-MSCs in kidney transplantation in nonhuman primates with hBM-MSCs and identify any possible immunomodulatory differences between hAD-MSCs and hBM-MSCs. The understanding of immune modulation consequences by hMSCs is required for their use as derivatives of adipose tissues which provide cells for immunotherapy in clinical applications.

Oral Tolerance through Treg cells promotes reduction of inflammatory lesions in mice infected with *Leishmania amazonensis*

D. A. G. Tavares[1], *A. M. L. Xavier*[2], *J. O. Santos*[1], *M. Bellio*[3], *A. C. da Silva*[1], *A. F. B. Andrade*[1];
[1]*Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil,* [2]*Universidade Federal Fluminense, Niteroi, Brazil,* [3]*Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil.*

The Oral Tolerance is a physiological mechanism of systemic hyporeactivity to an immunogen previously ingested and bystander suppression is a inhibited response to a second immunogen when it is presented along with the immunogen for which oral tolerance was established. Previous studies with mouse strains, extreme phenotypes to susceptibility (TS strain) and resistance (TR strain) to Oral Tolerance, showed that when infected with *Leishmania amazonensis*, TR strain develops an exacerbate lesion while a regulatory activity of the TS strain depresses the inflammation and avoid acute lethal response. The bystander suppression reduced the inflammatory lesion in TR strain, similarly to the swelling of infected TS strain. Mice previously tolerized and immunized showed an increase of CD4+ CD25+ FoxP3+ cells, increase of IL-10 and decrease of IFN-g in draining lymph nodes of the bystander site when compared with naïve or immunized mice. The transfer of regulatory T cells (CD4+ CD25+), from tolerized to infected mice, resulted in reduction of inflammatory lesion. These results suggest the involvement of Treg cells in the bystander suppression mechanism and demonstrate their importance in the reduction of inflammatory lesions in animals infected with *Leishmania amazonensis.*

P6.14.36
Immunosuppressive circular plant peptides

K. Thell[1], *R. Hellinger*[1], *E. Sahin*[1], *C. Gründemann*[2], *G. Schabbauer*[1], *C. Gruber*[1];
[1]*Center for Physiology and Pharmacology, Medical University of Vienna, Vienna, Austria,* [2]*Center for Complementary Medicine, University Medical Center Freiburg, Freiburg, Germany.*

Background: The immune system is constantly detecting and removing endogenous and exogenous threats, but sparing the organism`s own cells and tissues. In case of a dysregulated immune system, like in autoimmunity, this homeostasis is destroyed. Cyclosporine A, a naturally-occurring circular depsipeptide, is routinely used in clinics as immunosuppressant, but provokes many and often severe side-effects. Recently we identified circular peptides from plants, which exhibit promising anti-proliferative effects towards T-cells. These so-called cyclotides are composed of about 30 amino acids with a head-to-tail cyclized backbone. Their six conserved cysteines that are arranged in a typical cyclic cystine-knot motif, confers them with resistance to enzymatic, chemical or thermal degradation, making them attractive pharmaceutical tools.
Aim: The aim of this study is to investigate the immunosuppressive properties and mechanism of native and synthetic cyclotides in vitro and in vivo, and compare their mode-of-action to other immunosuppressive drugs such as cyclosporine A.
Methods & Results: We were able to demonstrate their anti-proliferative characteristics towards human activated primary lymphocytes in vitro. This significant inhibitory effect was dose-dependent and no cytotoxicity was observed in the active concentration range. Furthermore an experimental autoimmune encephalomyelitis mouse model was used to test the therapeutic impact on lymphocyte proliferation in vivo. We could show significantly delayed and minor symptoms of disease in mice treated with cyclotides. Moreover the anti-proliferative effects could be confirmed in isolated restimulated mouse splenocytes in vitro.
Conclusion: Cyclotides have great potential as peptide-based drugs and display promising immunosuppressive properties towards lymphocytes in vitro and in vivo.

P6.14.38
Apolipoprotein E attenuates acute rejection of experimental renal allografts

A. Zakrzewicz[1], *S. Atanasova*[1], *D. Zakrzewicz*[2], *G. Fuchs-Moll*[1], *S. Wilker*[1], *K. Petri*[1], *W. Padberg*[1], *V. Grau*[1];
[1]*Laboratory of Experimental Surgery, Department of General and Thoracic Surgery, Justus -Liebig-University, Giessen, Germany,* [2]*Department of Biochemistry, Justus -Liebig-University, Giessen, Germany.*

Apolipoprotein E (ApoE) is a multifunctional protein, originally described in the context of lipoprotein metabolism and cardiovascular disease. More recently, anti-inflammatory functions of ApoE have been documented. In this study, we test the hypothesis that ApoE attenuates acute renal allograft rejection.
The Brown Norway to Lewis rat strain combinations was used to investigate fatal acute rejection. In addition, Fischer 344 kidneys were transplanted to Lewis rats to study reversible acute rejection. Isograft recipients and untreated Lewis rats were used as controls. ApoE mRNA expression was quantified in intravascular leukocytes accumulating in the blood vessels of renal grafts and in graft tissue. ApoE protein levels were assessed in blood plasma. To test the protective potential of ApoE, recipients of Brown Norway kidneys were treated with ApoE-mimetic peptide. The number of different graft infiltrating leukocytes was evaluated by immunohistochemistry.
Intravascular graft leukocytes and renal tissue obtained from animals undergoing reversible acute rejection expressed increased levels of ApoE mRNA, whereas during fatal rejection, ApoE expression remained unchanged. On the protein level, no changes in ApoE were seen in plasma. However, the local leukocytic ApoE expression could result in increased ApoE concentrations inside graft blood vessels. Treatment of allograft recipients with peptide reversed fatal rejection and significantly improved animal survival. Immunohistochemical analysis revealed reduced number of infiltrating T cells. Furthermore, reduced mRNA expression of granzyme B could be detected.
ApoE plays a protective role in acute organ rejection. This effect is probably mediated by a reduced influx of cytotoxic T cells.

P6.14.39
Production of mmLFA3-Ig with immunosuppressive activity by recombinant expression in Pichia pastoris

J. Zhu[1], *S. Zhu*[2], *H. Yang*[1], *J. Cheng*[1], *X. Lu*[1,2], *L. Wan*[1,2];
[1]*Key Lab of Transplant Engineering and Immunology, Ministry of Health,West China Hospital, Sichuan University, Chengdu, China,* [2]*Regenerative Medicine Research Center, West China Hospital, Sichuan University, Chengdu, China.*

Engagement of lymphocyte function antigen 3 (LFA3) and CD2 can increase the activation of T cells. Blockade of LFA3-CD2 pathway efficiently down-regulated the abnormal immune activation, thus resulting in the development of human LFA3-Ig (hLFA3-Ig) as a treatment for psoriasis. Nevertheless, it is far from to unravel the role of LFA3-CD2 in regulation of immune system. Rhesus monkey macaca mulatta has been widely used as animal models for human immune disorders. Due to specificity of the immune system, *M. mulatta* LFA3-Ig (mmLFA3-Ig) might be required for pathogenesis of immune disorders in rhesus monkey models. The gene encoding mmLFA3 were amplified from peripheral blood mononuclear cells (PBMCs) by RT-PCR. Amino acid sequence analysis demonstrated that the identity between the predicted extracellular domain (ECD) of mmLFA3 and that of hLFA3 is about 86%. To prepare mmLFA3-Ig, the ECD of mmLFA3 was fused to the N-terminus of human IgG1 Fc fragment. The gene encoding mmLFA3 ECD was firstly optimized according to the codon bias of *P. pastoris*. MmLFA3-Ig produced by *P. pastoris* specifically bound CD2-positive cells. Positive staining was detected by flow cytometer in approximately 90% CD2-positive Jurkat cells, compared to that in 5% CD2-negative Raji cells. Moreover, mmLFA3-Ig showed dose-dependent suppression on monkey and human lymphocyte proliferation in both Con A- and allogenic antigen-stimulated systems. Interestingly, mmLFA3-Ig showed stronger immunosuppression on monkey lymphocyte proliferation than that of human. These results suggest that mmLFA3-Ig produced by *P. pastoris* might be a used for pathogenesis of immune disorder in rhesus monkey model.

P6.15.01
Production of TNF-α-specific monovalent and bivalent variable domain of llama heavy-chain antibody fragment in transgenic rice

M. Abe[1,2], *Y. Yuki*[2], *M. Mejima*[2], *S. Kurokawa*[2], *E. Park*[2], *J. Scheller*[3], *U. Nakanishi*[1,2], *H. Kiyono*[2];
[1]*MG Pharma Inc., Osaka, Japan,* [2]*The Institute of Medical Science, The University of Tokyo, Tokyo, Japan,* [3]*Institute for Biochemistry and Molecular biology II, Heinrich-Heine University, Düsseldorf, Germany.*

Tumor necrosis factor-α (TNF-α) plays a pivotal role in chronic inflammation such as Rheumatoid Arthritis and Crohn's disease. Although anti-TNF-α antibody therapy is now commonly used for the treatment of patients suffering from those inflammatory diseases, the cost of treatment remains to be a major concern. We have developed a novel system for the production of a single variable domain of llama heavy-chain antibody fragment (VHH) specific for mouse TNF-α in rice seeds (MucoRice-TNF-VHH). MucoRice-TNF-VHH was produced at high levels in rice seeds using our most recent transgene (Tg)-overexpression system with RNAi technology to suppress the production of major rice endogenous storage proteins but enhances the Tg- derived protein expression. Two molecular forms of TNF-α specifc monovalent (mVHH) and bivalent (bVHH) were expressed in the rice seed of MucoRice. Production levels of mVHH and bVHH were shown to reach an average of 0.82% and 0.47% of rice seed weight, respectively. Further, approximately 85% of mVHH and bVHH were released easily when the powder form of MucoRice-TNF-VHH was mixed with PBS (rice-water). To examine inhibitory activity of MucoRice-TNF-VHH in the rice-water, we used in vitro TNF-α cytotoxicity assay using WEHI164 cells. Although the both forms of MucoRice-TNF-VHH showed the neutralizing activity, bVHH was 50 times higher than that of mVHH. These results show that the rice-expression system (MucoRice) is useful for the production of neutralizing VHH specific for TNF-α. In our ongoing study, we are currently investigating whether purified MucoRice-TNF-VHH can suppress the progression of mouse collagen-induced arthritis or not.

P6.15.02
Involvement of histamine H2-receptors in gastric tissue inflammation and oxidative stress induced after scorpion envenomation

S. Adi-Bessalem[1,2], *A. Lamraoui*[1], *F. Laraba-Djebari*[1,2];
[1]*USTHB, Faculty of Biological Sciences, Laboratory Cellular and Molecular Biology, Department Cellular and Molecular Biology, Algiers, Algeria,* [2]*Laboratory of Research and Development on Venom, Pasteur Institute of Algeria, Algiers, Algeria.*

The activation and release of pro-inflammatory mediators such as cytokines and vasoactive substances (Histamine, eicosanoids···) may play an important role in the pathophysiology of scorpion envenomation. The mechanism of gastric inflammation induced by scorpion venom has not yet been elucidated and was little investigated.
The aim of this study is to investigate the potential role of histamine H2-receptors in gastric tissue inflammation and oxidative stress following experimental scorpion envenomation by *Androctonus australis hector* (Aah) venom. Gastric inflammation was assessed by evaluating the index of increased vascular permeability, by histological analysis and by measuring the myeloperoxydase (MPO) and eosinophil peroxydase (EPO) activities in the gastric tissue. Lipid peroxidation expressed as malondialdehyde (MDA) level, glutathione (GSH) and catalase (CAT) activities were measured to assess the oxidative stress.
Envenomed mice displayed an installation of an inflammatory response marked by neutrophil and eosinophil infiltration. This infiltration was preceded by the increase in the vascular permeability. Severe imbalanced redox status with decreased catalase and GSH activities, but increased MDA level was observed. Pre-treatment of animals with the ranitidine or cimetidine (H2-receptor antagonists), two hours before venom injection, significantly inhibited vascular permeability, edema formation and tissue recruitment of inflammatory cells. Lipid peroxidation products were found to be significantly reduced, but catalase or GSH activities were partially restored.
These results suggest that the histamine by acting with the H2 receptors is involved in the triggering of the inflammatory response and also in the alteration of the oxidant/antioxidant balance in the gastric tissue caused by the *Aah* venom.

P6.15.03
Novel anti-inflammatory strategies through protein engineering of Evasins

P. Bonvin[1,2], *M. Déruaz*[3], *I. Severin*[3], *C. Power*[3], *A. Proudfoot*[1];
[1]*NovImmune, Plan-Les-Ouates, Switzerland,* [2]*University of Geneva, Geneva, Switzerland,* [3]*Merck Serono, Geneva, Switzerland.*

We have identified 3 chemokine binding proteins (ChBP) from a tick salivary gland library which were named Evasin-1, -3 and -4. Evasin-1 and -4 bind CC-chemokines, the first being highly selective whilst the second has a broad pattern of selectivity. Evasin-3 binds the neutrophil chemoattractant ELR CXC-chemokines. In order to create therapeutic modalities for the treatment of chronic inflammatory diseases, the Evasins have been fused to Fc to produce molecules with a long half-life. The fusions have been made both at the N- and the C-terminus of the Evasins. Both Evasin-3 fusions showed similar activity whereas Fc-Evasin-4 was superior to Evasin-4-Fc. We then took advantage of this property to create a bi-specific molecule by fusion of Evasin-4 to Enbrel®, a commercialized anti-TNF in order to inhibit simultaneously cytokine and chemokine pathways. As both Evasin-4 and Enbrel® have been shown to be effective in murine models but still also allow space for improved efficacy, this combination will provide an answer to the potential synergistic effect of the two strategies. We have characterized both their binding properties and their neutralizing activities in vitro. The strategy to test the efficacy of these Evasin/Fc fusions in vivo will be discussed.

P6.15.04
Eugenol bronchodilator potential on il-13-induced hyper-reactivity of murine tracheal smooth muscle

K. Campos, *T. Teixeira, A. Cerqueira-Lima, L. Pontes de Carvalho, N. Alcantara Neves, D. Silva, C. Figueiredo;*
Ufba, Salvador, Brazil.

Introduction:Muscle cells are potentially linked with many features of asthma, including the production of cytokines and inflammatory mediators involved in tissue remodeling. Interleukin-13 has been implicated as a key cytokine in the pathogenesis of allergy and asthma. Eugenol (Eug), an aromatic product, exhibit anti-inflammatory properties and a possible relaxing effect on smooth muscle, so we examined in vitro the bronchodilator potential of this compound in hyper- reactive murine tracheal smooth muscle induced by IL-13. Methods: Animals were euthanized, trachea was rapidly removed and tracheal segments were placed individually in each well of a 48-well plate and incubated at 37°C in the presence or absence of IL-13 at 10ng/mL in supplemented DMEM for 24h. Trachea smooth muscle reactivity was assessed at organ baths containing Krebs-bicarbonate at 37°C and aerated with a carbogenic mixture.Results: We demonstrated the increased contractility in response to CCh in airway smooth muscle induced by IL-13.Our study showed that the effects of IL-13 on contractility were principally to increase Emax, and no significant changes in EC50 were observed, indicating that IL-13 seemed to increase smooth-muscle contractility rather than induce increased sensitivity to contractile agents (CCh), thus demonstrating hyper-reactivity. The effect of eugenol was not altered in hyper-reactive smooth muscle (sensitized with IL-13) when compared to its effect on normal smooth muscle, showing that the bronchodilatory potential of eugenol is not selective for hyperactivity induced by IL-13 pathway. More studies are needed to verify if eugenol may have a selective effect on other mechanisms involved in the hyper-reactivity.

P6.15.05
***In vitro* treatment with ganciclovir restores the functionality of exhausted T cells from cancer patients**

C. Chang[1], *C. Wu*[2,3], *I. Chen*[4], *K. Hsu*[1], *H. Ho*[2,5], *I. Chuang*[1], *Y. Lu*[3,6];
[1]*Department of Medical Research, Mackay Memorial Hospital, New Taipei, Taiwan,* [2]*Mackay Medicine, Nursing and Management College, Taipei, Taiwan,* [3]*Chest Division, Medical Department, Mackay Memorial Hospital, Taipei, Taiwan,* [4]*Cancer Center, Kaohsiung Medical University Hospital, Kaohsiung, Taiwan,* [5]*Department of Laboratory Medicine, Mackay Memorial Hospital, Taipei, Taiwan,* [6]*Medical Department, Mackay Medical College, New Taipei, Taiwan.*

Human cytomegalovirus (CMV) is a lifelong and often asymptomatic infection, with the virus maintained in latently infected myeloid cells. Patients with cancer on immunosuppressive therapy are at high risk for reactivation of latent CMV, which may further contribute to a poor anti-tumor immune response. Pre-emptive anti-CMV medication may, therefore, serve as an adjunct therapy, preventing deterioration of the patient's immunity during treatment for cancer.
We evaluated ganciclovir treatment's *in vitro* effects on CMV-associated T cell exhaustion and the anti-tumor capacity of cells from cancer patients. Following ganciclovir treatment, there was a redistribution of T cell subpopulations which was clearly distinct from the baseline pattern of T cell exhaustion. Treatment resulted in increases in early differentiated populations, including naïve, IL-7Rα$^+$, and CD28$^+$CD8$^+$ T cells, and a decrease in the proportion of effector memory T cells in cancer patients. Ganciclovir treatment significantly improved tumor killing capacity, with a concomitant downregulation of T cell exhaustion marker PD-1. These findings demonstrate that ganciclovir treatment *in vitro* affects immune function by partially reconstituting T cell subsets and restoring the T cell anti-tumor response.

P6.15.06
Direct and natural killer cell-mediated antitumor effects of CB1 receptor antagonist rimonabant in human glioblastoma

E. Ciaglia[1], *S. Pisanti*[1], *P. Picardi*[1], *C. Laezza*[2], *G. Torelli*[3], *P. Gazzerro*[1], *M. Bifulco*[1];
[1]*University of Salerno, Fisciano, Italy,* [2]*Institute of Endocrinology and Experimental Oncology, IEOS CNR, Naples, Italy,* [3]*" G. Rummo" Medical Hospital, Dept of Neurosurgery, Benevento, Italy.*

The failure of conventional cancer therapy renders glioblastoma (GBM) an attractive target for novel combined chemo-immunotherapeutic strategies. In the last years the pharmacological tuning of (endo)cannabinoid system has constituted a promising tool for the management of GBM patients. In this study we investigated the therapeutic exploitation of CB1 inactivation with regard to direct and NK cell-mediated effects against GBM.
We show for the first time that Rimonabant treatment inhibited growth and viability of a panel of human glioma cell lines in both monolayer culture and 3D Minitumour spheroid models by decreasing the expression levels of Bcl-2, Bcl-XL and Survivin anti-apoptotic factors and concomitantly by inducing tumor necrosis factor (TNF)-related apoptosis-inducing ligand death receptor 4 (DR4) and DR5.
Interestingly Rimonabant lead also to functional expression of MHC class I-related chain A and B (MICA/B) on surface of malignant p53mut U251MG and T98G glioma cell lines but not on normal human astrocyte (NHA). This make GBM cells potent targets for natural killer (NK) cell mediated recognition through a NKG2D restricted mechanism, thus stimulating cytotoxicity and IFN-Ɣ production of cocultured NK cells. This last effect relies on the inhibition of STAT3 signaling, whose constitutive activity has been previously seen to promote escape to NKG2D-mediated immune-surveillance.
Our study suggests that, in addition to the direct cytotoxic effect, Rimonabant also can make GBM immunovisible priming it for NK cell antitumor reactivity. Taking into account that the brain tumor microenvironment is more commonly associated to CD56-positive NK cells, GBM patients may benefit from Rimonabant treatment.

P6.15.07
Towards predictive pharmacogenetic profiling for azathioprine treatment: characterization of SNPs in TPMT and XDH genes

L. Colleoni, *D. Kapetis, S. Franzi, L. Maggi, G. Camera, E. Canioni, F. Baggi, C. Antozzi, R. Mantegazza, P. Bernasconi;
Neurological Institute Foundation "Carlo Besta", Milan, Italy.*

Azathioprine (AZA) is an immunosuppressant drug used for myasthenia gravis (MG) treatment. Intolerance or not responsiveness is a limiting problem for drug treatment in the 30% of the patients. Aim of this study is to determine genotype-phenotype association that can be applied as predictive biomarker for AZA treatment of MG. We analyzed thiopurine S-methyltransferase (TPMT) and xanthine dehydrogenase (XDH) single nucleotide polymorphisms (SNPs) in 124 Italian MG patients in the context of their response to AZA. Haplotype analysis and linkage disequilibrium (LD) of TPMT SNPs detected a new haplotype associated with intolerance to AZA (Psim=0.0026): TPMT*3E, including the intronic T140+114A SNP and the previously reported TPMT*3A allele . TPMT*3E was detected in five of the 23 AZA-intolerant patients and was not observed in unresponsive or responsive patients. Therefore this haplotype should be taken into account when considering AZA treatment. LD analysis of XDH detected different haplotype blocks, one of those was significantly associated with intolerance (Psim = 0.037). Composed by three SNPs located in the 3' untranslated region, it is not clear how this haplotype induces intolerance to AZA. One possibility is that SNPs alter the target sites for microRNAs, thus influencing the expression of the protein XDH.
In this work, we identified new haplotypes that should be taken into consideration in pharmacogenetic profiling for AZA.Work supported by 7th Framework Programme of the European Union FIGHT-MG (Grant no. 242210).

P6.15.08
Molecular characterization and valorization of cuban natural products, in particular Vimang® and its naturally Glucosylxanthone Mangiferin, for therapeutic applications against cancer and Inflammation

R. Delgado[1], *D. García-Rivera*[2], *I. Hernandez*[3], *I. Rodeiro-Guerra*[3], *N. Bougarne N*[4], *G. Haegeman*[4], *W. Vanden Berghe*[5];
[1]*Drug Research and Development Center, Havana, Cuba,* [2]*Center of Biomolecular Chemistry, Havana, Cuba,* [3]*Center of Marine Bioproducts, Havana, Cuba,* [4]*Laboratory of Eukaryotic Gene Expression and Signal Transduction (LEGEST), Department of Physiology, Ghent University, Gent, Belgium,* [5]*5. Laboratory of Protein Science, Proteomics and Epigenetic Signaling (PPES), Department of Biomedical Sciences, University Antwerp, Antwerp, Belgium.*

Vimang is a standardized extract derived from Mango bark (Mangifera Indica L.), commonly used as anti-inflammatory phytomedicine, which has recently been used to complement cancer therapies in cancer patients. We have further investigated potential anti-tumour effects of glucosylxanthone mangiferin and indanone gallic acid, which are both present in Vimang extract. We observed significant anti-tumour effects of both Vimang constituents in the highly aggressive and metastatic breast cancer cell type MDA-MB231. At the molecular level, mangiferin and gallic acid both inhibit classical NFκB activation by IKKα/β kinases, which results in impaired IκB degradation, NFκB translocation and NFκB/DNA binding. In contrast to the xanthone mangiferin, gallic acid further inhibits additional NFκB pathways involved in cancer cell survival and therapy resistance, such as MEK1, JNK1/2, MSK1, and p90RSK. This result in combinatorial inhibition of NFκB activity by gallic acid, which results in potent inhibition of NFκB target genes involved in inflammation, metastasis, anti-apoptosis and angiogenesis, such as IL-6, IL-8, COX2, CXCR4, XIAP, bcl2, VEGF. The cumulative NFκB inhibition by gallic acid, but not mangiferin, is also reflected at the level of cell survival, which reveals significant tumour cytotoxic effects in MDA-MB231 cells. Altogether, we identify gallic acid, besides mangiferin, as an essential anti-cancer component in Vimang extract, which demonstrates multifocal inhibition of NFκB activity in the cancer-inflammation network.

P6.15.09
Study of the immunomodulatory role of heteroglucan on a 3D tumor spheroid and macrophage co-culture milieu

K. S. P. Devi, *T. K. Maiti;
Indian Institute of Technology, Kharagpur, Kharagpur, India.*

Over the past several years, glucans have garnered much attention due to their immunomodulatory properties. Till date most studies of glucans has been done in vivo or in two dimensional cultures. A 3D platform may thus serve as a tool to optimize drug effects in tissue environment as well as reduce animal testing and economical wastage. The present study was focussed on establishing a three dimensional tumor spheroid model and its co-culture with glucan (isolated from Pleurotus ostreatus mycelia) stimulated macrophages to mimic the complexity retained in tumor tissues and the immunological phenomena of stimulated phagocytes. Spheroids of HT-29 were incubated with glucan activated human THP-1 macrophages at an effector:target cell ratio of 1:1 and the invasive property of the phagocytes were examined. Interestingly, about 46% increase in the migration and penetration of activated macrophages to the tumor spheroids was observed by confocal microscopy using a two dye staining method. Concomitantly, immunohistological studies further corroborated these facts whereby activated macrophages were found to deeply penetrate the spheroidal layer. Tumor cell death was also found to be increased in the peripheral zones of spheroids incubated with glucan treated macrophages. The degree of distortion of the spheroidal morphology attained higher growth with an increase in the co-culture incubation period. Untreated macrophages apparently exhibited lower invasiveness, death and distortion of the tumor spheroids. Spatiotemporal and micro environmental influences in the behaviour of cells monitored in such 3D system are therefore prospects to be accounted for deeper understanding of the complex immune network.

P6.15.10
Specific targeting of extracellular Cyclophilins for treatment of inflammatory diseases

K. M. Dinkel[1], *M. Baumann*[1], *B. Klebl*[1], *M. Malesevic*[2], *P. Nussbaumer*[1], *G. Rühter*[1], *G. Fischer*[2];
[1]*LDC GmbH, Dortmund, Germany,* [2]*Max Planck Research Unit for Enzymology of Protein Folding (MPF), Halle, Germany.*

Cyclophilin A (CypA) is a ubiquitously distributed peptidyl prolyl cis/trans isomerase (PPIase) which is secreted under inflammatory conditions. Extracellular CypA has been reported to display chemotactic activity and may thus contribute to inflammation-mediated diseases. The objective of this study was to determine the impact of blocking the PPIase activity of cyclophilins using cell-impermeable derivatives of cyclosporin A (CsA) to specifically target the extracellular pool of cyclophilins (eCyp).
We have developed novel selective inhibitors of eCyp PPIases LDC043199 (MM-284) and LDC045325 which display significantly less calcineurin inhibiton and cytotoxicity compared to the parent CsA. No liabilities were detected by early ADME and PK analysis thus qualifying these compounds as lead structures suitable for pharmaceutical drug development. These compounds lack the significant immunosuppressive activity of CsA as demonstrated in primary human T cell proliferation and in vivo mouse T cell proliferation analysis.
We show excellent efficacy of the i.p. administered compounds in an antigen specific (Keyhole limpet hemocyanin) delayed type hypersensitivity ear swelling mouse model as well as significant efficacy in a therapeutically relevant mouse asthma model. Furthermore the compounds displayed complete inhibition of CypA-induced chemotaxis by primary human dendritic cells and neutrophils.
We have developed high quality leads in the field of selective inhibitors of extracellular cyclophilins. Our findings validate the concept that cell-impermeable derivatives of CsA provide strong anti-inflammatory activity without dose-limiting immunosuppressive toxicity as observed with CsA. Specifically blocking the activity of extracellular cyclophilins may provide a novel approach towards a safer and more effective treatment of inflammatory diseases.

P6.15.11
Selective targeting of the immunoproteasome for treatment of autoimmune diseases

K. M. Dinkel[1], *A. Unger*[1], *C. Degenhardt*[1], *B. Klebl*[1], *P. Nussbaumer*[1], *U. Koch*[1], *G. Zischinsky*[1], *R. Huber*[2];
[1]*LDC GmbH, Dortmund, Germany,* [2]*Max-Planck-Institute for Biochemistry, Martinsried, Germany.*

The proteasome is a multicatalytic enzyme complex playing a key role in antigen presentation, cellular protein homeostasis and signal transduction. Two major forms of the proteasome have been described based on different incorporated beta-subunits: while the constitutive proteasome (CPS) is ubiquitously expressed, the immunoproteasome (IPS) is predominantly expressed in hematopoetic cells and is inducible under inflammatory conditions.
We have developed novel selective, non-covalent inhibitors of the IPS specific subunit beta5i (LMP7). LDC compounds were profiled in enzymatic and cell based assays in comparison to the CPS inhibitor Bortezomib and the covalent IPS inhibitor PR-957. LDC compounds are highly potent (nM range) and selective (>1000x over CPS) IPS inhibitors showing a pronounced species specificity (hu>rat>ms). We also found that PR-957 due to its irreversible, covalent binding to the target is not truly selective for the IPS over time. After several hours of incubation PR-957 also inhibited the CPS activity while the non-covalent LDC compounds did not lose the IPS selectivity over time. In line with these findings LDC compounds were significantly less neurotoxic compared to Bortezomib and PR-957 using a SY5Y neuroblastoma cell viability assay. Preliminary data indicate that LDC compounds are effective inhibitors of (auto)antibody secretion.
We have developed high quality leads in the field of truly selective and non-covalent immunoproteaseome inhibitors. Considering the reported toxicities for covalent CPS inhibitors such as Bortezomib, an IPS selective inhibitor may represent a safer therapeutic alternative in the treatment of autoantibody mediated autoimmune diseases such as SLE or Myasthenia gravis.

P6.15.12
Role of protein phosphatases in the functional desensitization of β-adrencoceptor-mediated responses in human lung mast cells

N. Eskandari[1], *R. Bastan*[2];
[1]*Isfahan University, Isfahan, Iran,* [2]*Abadan University of Medical Sciences., Abadan, Iran.*

Adrenoceptor agonists are potent bronchodilators, which have also been shown to inhibit the release of histamine and eicosanoids from dispersed human mast cells. Long-term exposure of mast cellto β-agonists attenuates the subsequent ability of β-agonists to inhibit histamine release. Since phosphorylations of the β_2-adrenoceptors are probably important in inducing desensitization. In the present study the effects of fostriecin, a selective inhibitor of pp2a, and okadaic acid, an inhibitor of pp2a and pp1, on the functional desensitization of β-adrenoceptor-mediated responses in mast cells were investigated.
To evaluate the effects of the pp2a inhibitor fostriecin on the isoprenaline inhibition, cells were incubated for 2 or 4 h or 24 h with fostriecin before incubation with isoprenaline and then challenged with anti-IgE. Treatments with fostriecin had no significant ($p > 0.05$) effect on either the efficacy or the potency of isoprenaline on mast cell which were treated with either buffer or fostriecin and with or without isoprenaline for 24 h. Isoprenaline pre-treatment reduced the maximal response to isoprenaline by about 50% and fostriecin had little effect on the extent of functional desensitization. In addition the effects of okadaic acid on the functional desensitization induced by prolonged exposure to isoprenaline were investigated. Although, long-term treatment with okadaic acid had no effect on the ability of isoprenaline to inhibit histamine release, okadaic acid significantly ($p < 0.05$) enhanced the extent of isoprenaline-induced desensitization.
These data suggest that pp2a has an important role in regulating mast cell β_2-adrenoceptors.

P6.15.13
ImmuDrug platform: high throughput screening for novel immunomodulators

S. Frischbutter, *S. Schuengel, A. Hamann;*
German Rheumatism Research Center, Berlin, Germany.

Immune diseases like rheumatism, diabetes type I, multiple sclerosis, and other autoimmune diseases and allergies are commonly treated by unspecific pharmacologic immunosuppression. However, the treatment effect is only transient and side effects like risk of infections are inherent. Therefore, we want to target endogenous mechanisms of self-regulation in the immune system such as regulatory cells or suppressive cytokines. To discover new drug candidates that address these mechanisms, we have developed a micro cell culture system that allows the simulation of inflammatory conditions in the presence of either synthetic or natural compounds. Using high throughput multichannel flow cytometry, we are able to analyze thousands of substances per week by monitoring changes in reporter protein (GFP) and/or surface molecule expression, viability, and cell number. Here we show results of a screening for regulatory T cell (Treg) inducing compounds using cells from Foxp3-GFP reporter mice. A library of 35.000 compounds provided by the Leibniz-Institut für Molekulare Pharmakologie (FMP) Berlin was screened and a number of promising hits were obtained which are currently validated. The versatile assay setup can easily be adapted to different functional assays and will not only help to discover new candidates for future treatment of immune-mediated diseases but will also enable insights into molecular mechanisms of immunoregulation.

B7H triggering inhibits the migration of tumor cell lines

*C. L. Gigliotti[1], C. Dianzani[2], S. Occhipinti[3], M. Giovarelli[3], L. Conti[3], E. Boggio[1], **E. Tóth**[1], G. Baldanzi[4], A. Chiocchetti[1], U. Dianzani[1];*
[1]IRCAD and Department of Health Sciences, University of Eastern Piedmont A.Avogadro, Novara, Italy, [2]Department of Drug Science and Technology, University of Turin, Torino, Italy, [3]Department of Molecular Biotechnology and Health Sciences, University of Turin, Torino, Italy, [4]4Department of Translational Medicine, "A. Avogadro" University of Eastern Piedmont, Novara, Italy.

Vascular endothelial cells (EC) and several cancer cells express B7h, which is the ligand of the ICOS T cell costimulatory molecule. We have previously shown that B7h triggering by a soluble form of ICOS (ICOS-Fc) inhibits the adhesion of polymorphonuclear and tumour cell lines to human umbilical vein EC (HUVEC), and we have suggested that it may act as an anti-inflammatory and antitumour agent. Since cancer cell migration and angiogenesis are crucial for metastasis dissemination, the aim of this work was to evaluate the effect of ICOS-Fc on migration of cancer and EC. ICOS-Fc specifically inhibited the migration of HUVEC, human dermal lymphatic EC, and the HT29, HCT116, PC-3, HepG2, JR8, and M14 tumour cell lines, expressing high levels of B7h, whereas it was ineffective with the RPMI7932, PCF-2, and LM cell lines, expressing low levels of B7h. Furthermore, ICOS-Fc down-modulated hepatocyte growth factor (HGF)-induced epithelial to mesenchymal transition in HepG2 cells. Moreover, ICOS-Fc down-modulated the phosphorylation of FAK and the expression of β-Pix in both HUVEC and tumour cell lines. Finally, treatment with ICOS-Fc inhibited the development of lung metastases in NOD-SCID-IL2Rγnull mice injected with the CF-PAC1 luc tumour cell line in the tail vein. In conclusion, the B7h:ICOS interaction may modulate the spread of cancer metastases, which introduces a novel view on the use of ICOS-Fc as an immunomodulatory drug.

P6.15.15
Effect of beta-adrenoceptor agonist and antagonist on immune response under thyrotoxicosis

***A. P. Godovalov**[1], J. I. Shilov[1,2];*
[1]Acad. E.A. Wagner Perm State Medical Academy, Perm, Russian Federation, [2]Institute of Ecology and Genetics of Microorganisms of UB RASciences, Perm, Russian Federation.

It is known that thyroid hormones may increase the expression of beta-adrenoceptors and/or transduction of intracellular signals in target cells. The aim of this study was to investigate the influence of agonist and antagonist of beta-adrenoceptors on immune response under experimental thyrotoxicosis. Rats were injected L-thyroxine (T4) subcutaneously during 14 days in a daily doses of 0.04 or 4 mg/kg of body weight (b. wt.) for modeling mild or severe forms of thyrotoxicosis respectively. It was established that mortality of rats directly depends on the dose of T4. The increase in number of antibody-forming cells (AFC) and the activation of the delayed type hypersensitivity (DTH) response were revealed under mild form of thyrotoxicosis. The level of AFC and DTH response was decreased under severe form of thyrotoxicosis. The stimulation of AFC response under mild form of thyrotoxicosis was canceled in rats which received the agonist of beta-adrenoceptors (hexoprenaline sulfate i.p. in a daily dose of 0,001 mg/kg b. wt. during 14 days). Hexoprenaline sulfate led to decrease in DTH response level under both forms of thyrotoxicosis. The antagonist of beta-adrenoceptors (sotalol hydrochloride i.p. in a daily dose of 10 mg/kg b. wt. during 14 days) inhibited immunosuppression in severe thyrotoxicosis and increased immunostimulation under mild form of thyrotoxicosis. This study was supported by the programs of the Presidium of the Russian Academy of Sciences "Molecular and Cell Biology" and "Fundamental Science for Medicine".

P6.15.16
Effect of hexoprenaline sulphate on the immunoglobulin production in the presence of thyroxine and hydrocortisone in vitro

*D. J. Shilov[1], **A. P. Godovalov**[1], J. I. Shilov[1,2];*
[1]Acad. E.A. Wagner Perm State Medical Academy, Perm, Russian Federation, [2]Institute of Ecology and Genetics of Microorganisms of UB RASciences, Perm, Russian Federation.

Adrenergic compounds, thyroid hormones and glucocorticoids play an important role in the neuroendocrine regulation of the immune system in health and disease. It is known that administration of thyroid hormones and glucocorticoids lead to the increase in expression of beta-adrenoceptors and/or intracellular signal transduction in target cells of various organs. Functional implications of such interaction at the level of the immune system are not fully understood yet. The aim of this work was to investigate the effect of beta-adrenoceptor agonist hexoprenaline sulphate on the production of immunoglobulins in the presence of thyroxine and hydrocortisone in vitro in cultures of human mononuclear cells of practically healthy volunteers. It was established that addition of thyroxine (10^{-8} M) in cultures with pokeweed mitogen (PWM) led to increase in the IgG production. Hexoprenaline sulfate (10^{-6} M) abolishes this effect in cultures with thyroxine, but has no effect on the IgG production in cultures without thyroxine. Hydrocortisone (10^{-6} M) has no influence on production of IgG alone and along with hexoprenaline sulfate (10^{-6} M). All compounds have no effect on production of IgM. This study was supported by the programs of the Presidium of the Russian Academy of Sciences "Molecular and Cell Biology" and "Fundamental Science for Medicine".

P6.15.17
Study of adverse events reported to the center of health surveillance related to the use of intravenous immunoglobulin (IVIG)

***I. C. Gubert**[1], V. C. Zanetti[2], M. M. A. Santos[2];*
[1]Universidade Federal do Parana, Curitiba, Brazil, [2]Secretaria de Estado da Saude, Curitiba, Brazil.

Antibody replacement therapy was first introduced for clinical use in the 1950s, mainly for the treatment of primary immunodeficiency conditions, usually used subcutaneously or intramuscularly, either as an adjunctive or first line therapy. Due to the recognition of its modulator effects, subsequently suitable preparations for intravenous use have been developed. Intravenous immunoglobulin has been, since then, increasingly used in many inflammatory and autoimmune conditions, although only a few have received approval by FDA and EMEA and unlabeled use is now common. Clinical preparations consist of IgG antibodies and all four subclasses, obtained from a pool of thousands of healthy donors, comprising the entire repertoire of antigen binding sites expectedly found in normal human serum. Intravenous immunoglobulin mechanisms of action are complex and include anti-infective, immunoregulatory, and anti-inflammatory properties. However, adverse events due to the use of this immunobiological have been reported. It was the purpose of this study to identify the adverse events most commonly reported to the center of health surveillance related to the use of intravenous immunoglobulin. Notification forms, spreadsheets and database files have been analyzed and data were organized and systematized in order to provide easy access to the information for health professionals and surveillance center. Hypersensitivity reactions, thrombotic events, acute renal failure, aseptic meningitis syndrome, chills, fever during infusion, artralgia, mialgia, abdominal pain and headache are some of the adverse events commonly reported. High cost, supplies demand and safety of the product are some of the concerns related to the use of intravenous immunoglobulin.

P6.15.18
Inflammatory pathogenesis induced by scorpion venom: In vitro and in vivo analysis of immune cells activation

D. Hammoudi-Triki[1,2], *D. Khemili*[1], *K. Zerrouti*[1], *L. Bechohra*[1], *F. Laraba-Djebari*[1,2];
[1]*University of Sciences and Technology Houari Boumédiène, Algiers, Algeria,* [2]*Institute Pasteur of Algeria, Algiers, Algeria.*

Scorpion venom is a complex biological mixture of many substances such as toxins, enzymes with a wide spectrum of biological activities. Many effects are induced by this venom, such as inflammation tissue damage and cardiorespiratory distress. This study aimed to evaluate the inflammatory activity promoted by Androctonus australis hector (Aah) venom. The cytotoxic effects were evaluated by several cell viability assays (MTT, Neutral Red and LDH activities). The results obtained showed that Aah venom induced an activation of neutrophils and monocytes revealed by an increased ability of these cells to increase myeloperoxidase into the extracellular medium, lipid peroxidation as measured by thiobarbituric acid-reactive species level. It was also observed that venom induced higher IFNγ, IL-6 and IL-10 production. Nitric oxide and H2O2 were significantly produced, which showed a higher rate of cell death induction when compared with control. Results obtained also showed that venom induced same response in vitro through cell injury, cytokines and H202 productions. The release of LDH in the supernatants of spleen cultures and fragmentation of cellular DNA are the consequence of an oxidative stress responsible for the alterations of the cell membranes and probably to the inhibition of the activity of some enzymatic proteins.

P6.15.19
The immuno-modulatory effects of heparin and LMW-heparin in mite-allergic mice model

J. Huang*, L. Fu;*
Taichung Veterans General Hospital, Taichung, Taiwan.

Background: Previous studies have shown (1)the airway anti-inflammatory and anti-allergic activity of heparin (2) the anti-inflammatory potency of heparins are molecular-weight-dependent.We investigate the immuno-modulation effects in mite-induced allergic animal model treated with inhaled heparin and compared the effects of inhaled LMW-heparin.
Method: BALB/c mice were divided into five groups: 1. Control, 2. Mite intratracheal (mIT), 3. Inhaled heparin(hIN), 4. Inhaled LMW-heparin(lmwhIN), 5. Inhaled half dosage of heparin and LMW-heparin. Group 2,3,4,5 were sensitized twice with Der p allergen subcutaneously on day 1 and 8. Der p allergen was administered intratracheally on day 15. Groups 3, 4, and 5 were treated with heparins for 22 days. Splenocytes alone or co-cultured with dendritic cell, stimulated with Der p 16mg/ml were cultured for 72 hours after mice scarification on day 23. Supernatants of splenocyte were collected to analyze the effect of INF-γ, Interleukin (IL)-10, IL-13. Serum was also collected for IgE level on day 23.
Results: Both hIN and lmwhIN groups had lower serum IgE level than mIT group (both p<0.0001. The p values of inhaled hIN and lmwhIN groups compared with mIT group in splenocyte supernant are shown as following: IFN-γ(p=0.002,0.007 respectively), IL-17(both p<0.001), IL-13(p=0.0002, 0.01 respectively). hIN group had lower IL-10 level than mIT group(p=0.03). Supernatant from co-cultured dendriticyte+splenocyte+ Der P 16mg/ml showed decrease in IL-17A/F in lmwhIN group than mIT group(p=0.017).
Conclusions: Intranasal administration of heparin and low molecular weight heparin can also decrease serum IgE level. From cultured splenocyte, IL-17A/F decreased serections; which implied systemic immuno-modulation effects on Th deviation.

P6.15.20
Cimetidine enhances delayed-type hypersensitivity responses and serum interleukin (IL)-2, IL-10, IL-12, and IL-17 levels after thermal trauma in an animal model

A. Jafarzadeh[1], *M. Nemati*[2], *M. T. Rezayati*[1], *M. Ebrahimi*[3], *Z. M. Hassan*[4];
[1]*Rafsanjan University of Medical Sciences, Rafsanjan, Iran,* [2]*Kerman University of Medical Sciences, Kerman, Iran,* [3]*Shiraz University of Medical Sciences, Shiraz, Iran,* [4]*Tarbiat Modarres University, Tehran, Iran.*

The immunosuppression that occurs after burn injury causes an increase in susceptibility to infection. The aim was to investigate time-related alterations in various cytokines following thermal injury and to modulate cytokines by using cimetidine. Male Balb/c mice anesthetized and given a 10% total body surface area full-thickness burn. Time-dependent changes in delayed type hypersensitivity (DTH) and serum levels of the cytokines IL-2, IL-10, IL-12, IL-17 and TGF-[[Unsupported Character - Symbol Font β]] were then assessed at various post-burn day (PBD) timepoints. Effects of 10 mg cimetidine/kg on DTH responses and cytokine levels were evaluated up to PBD 14. In comparison to healthy non-burned control mice, levels of IL-2 and IL-17 significantly decreased at PBD 3, 5, 10, and 14, those of IL-10 at PBD 1, 3, 5, and 10, and those of IL-12 at PBD 1, 3, 5, 10, and 14. Administration of cimetidine significantly augmented the levels of IL-2 (at PBD 3, 5, and 10), IL-10 (at PBD 1 and 5), IL-12 (at PBD 3, 5, 10, and 14), and IL-17 (at PBD 3 and 14) as compared to those in burned counterparts who did not receive drug. Cimetidine also significantly augmented DTH responses at PBD 5, 10, and 14 as compared to responses in non-drug-treated burned hosts. These results showed significant time-dependent changes in serum cytokines levels after burn injury and that cimetidine was able to significantly augment IL-2, IL-10, IL-12 and IL-17 levels as well as DTH response that are normally suppressed following thermal trauma.

P6.15.21
A single dose of rituximab does not deplete B cells in secondary lymphoid organs, but alters phenotype and function

E. Kamburova[1], *H. J. Koenen*[1], *K. Borgman*[1], *I. ten Berge*[2], ***I. Joosten***[1], *L. Hilbrands*[1];
[1]*Radboud University Medical Centre, Nijmegen, Netherlands,* [2]*Academic Medical Centre, Amsterdam, Netherlands.*

A single dose of the anti-CD20 monoclonal antibody rituximab induces a nearly complete B-cell depletion in peripheral blood, but not in secondary lymphoid organs. Modulation of this remaining B-cell population due to rituximab treatment may contribute to the therapeutic effects of rituximab. To assess the *in vivo* effects of rituximab we used lymph nodes collected during renal transplant surgery in patients who had received rituximab four weeks earlier in preparation for an ABO-incompatible transplantation. Rituximab treatment resulted in a lower percentage of naïve (IgD^+CD27^-) and a higher percentage of switched memory (IgD^-CD27^+) B cells. Remarkably, transitional ($CD24^{++}CD38^{++}$) B cells were virtually lacking in the lymph nodes of rituximab-treated patients. Moreover, lymph node-derived B cells from rituximab-treated patients produced different amounts of various Ig-subclasses after anti-CD40/IL-21 stimulation *ex vivo*. Finally, after stimulation of allogeneic T cells with lymph node-derived B cells from rituximab-treated patients, the proliferated T cells showed a decreased production of IL-17. In conclusion, after treatment with rituximab there remains a B-cell population with different functional capacities. Consequently, the effect of rituximab on the immune response will not only be determined by the extent of B-cell depletion, but also by the functional properties of the remaining B cells.

P6.15.22
Morin attenuates airway hyperresponsiveness of allergic asthma via down regulation of immune-inflammatory biomarkers

***A. D. Kandhare**, P. Ghosh, S. L. Bodhankar;*
Department of Pharmacology, Poona College of Pharmacy, Bharati Vidyapeeth Deemed University, Erandwa, Pune, India.

Introduction: Asthma is immune-inflammatory airway disorder characterized by airway obstruction and hyperresponsiveness. Morin [2-(2,4-dihydroxyphenyl)-3,5,7-trihydroxy-4H-1-benzopyran-4-one] is a flavonoid reported to have inhibition of IgE-mediated allergic response in mast cells.
Aim: Aim of present investigation was to evaluate antiasthmatic activity of morin against ovalbumin (OVA)-induced airway hyperresponsiveness (AHR) in rats.
Materials and methods: AHR was induced in the male Sprague Dawley rats by intraperitoneal injection of OVA. Rats were treated with morin (10, 30 and 100 mg/kg, p.o.) for 28 days followed by OVA-aerosol intranasal challenge. Lung function test was performed. Biochemical and molecular parameters were assessed in blood, bronchoalveolar lavage fluid (BALF) and lung tissue.
Results: Total cell counts, eosinophil counts in BALF and blood increased significantly ($P < 0.001$) in AHR control rats whereas treatment with morin (30 and 100 mg/kg, p.o.) significantly reduced cell counts ($P < 0.001$). Significant decrease ($P < 0.001$) in spirometry flow and peak inspiratory flow whereas peak expiratory flow and force expired volume was significantly increased ($P < 0.001$) in morin treated rats. Increased levels of nitric oxide, malondialdehyde, IgE and histamine were significantly ($P < 0.001$) inhibited by morin. RT-PCR analysis of lung revealed that morin (30 and 100 mg/kg, p.o.) significantly ($P < 0.001$) suppressed mRNA expression of TNF-α, interleukin (IL)-1β, IL-4, IL-6, COX-2 and leukotriene B4 (LTB-4) in a dose-dependent manner.
Conclusion: It is concluded that morin has anti-asthmatic effects mediated by reduction of oxidative stress and airway inflammation via down regulation of IgE, COX-2, IL-4, IL-6 and LTB-4 expression.

P6.15.23
Effect of (E)-2-(3,4-dimethoxyphenyl)-4-oxo -4H-chromen-7-yl-3-(3,4-dimethoxyphenyl) acrylate on the development of atopic dermatitis-like lesions

***I. Kim**[1], J. Lee[2];*
[1]Eulji University, Daejeon, Republic of Korea, [2]Wonkwang Health Science University, Iksan, Republic of Korea.

In this study, we synthesized a novel chemical, (E)-2-(3,4-dimethoxyphenyl)-4-oxo-4H-chromen-7-yl-3-(3,4-dimethoxyphenyl) acrylate (CSH) and investigated the effect of CSH on atopic dermatitis (AD) by evaluating the anti-inflammatory effect of CSH on immune cells *in vitro* and on atopic dermatitis-like lesions *in vivo*. Human monocytic THP-1 cells and human eosinophilic EoL-1 cells were treated with house dust mite extract in the absence and presence of CSH. Nc/Nga mice were sensitized to 2,4-dinitrochlorobenzne (DNCB) for 5 weeks and then orally and dorsally administered with CSH or dexamethasone for 3 weeks. CSH inhibited the secretion of monocyte chemotactic protein-1 (MCP-1), interleukin (IL)-6 and IL-8 due to house dust mite extract in THP-1 cells. CSH also suppressed the secretion of MCP-1 and IL-8 in EoL-1 cells. *In vivo*, the skin severity score decreased after CSH treatment as compared to the control group. CSH suppressed the inflammatory cell infiltration into the dermis and thickened the epidermis. CSH reduced serum IgE level as compared to the control group. The levels of IL-4, IL-5, IL-13 and eotaxin in mouse splenocytes increased after treatment with concanavalin A and the increase of the cytokines was decreased by pre-treatment with CSH. The inhibitory effects of CSH on atopic lesions of DNCB-treated Nc/Nga mice were similar to those of dexamethasone, despite differing degrees depending on results evaluated in this study. These results may contribute to the development of a therapeutic drug for the treatment of AD.

P6.15.24
Immunostimulatory activity of low-molecular weight components of lysates of probiotic bacteria

***E. Kmonickova**[1], P. Kostecka[2], A. Dusilova[2], M. Kverka[3], Z. Zidek[1];*
[1]Inst. Experimental Medicine, Acad. Sci., Prague, Czech Republic, [2]Inst. Experimental Medicine, Acad. Sci., 1st Fac. Medicine, Charles Univ., Prague, Czech Republic, [3]Inst. Microbiology, Acad. Sci., Prague, Czech Republic.

The ability of probiotic bacteria to modulate the innate and acquired immune responses is presumed to be due to complex molecules of their outer membrane. The major representatives of immunobiologically active polymeric components are lipoteichoic acid (LTA) of Gram+ bacteria, lipopolysaccharide (LPS) of G- bacteria, and peptidoglycan (PGN) occurring mainly in G+ species. We investigated possible immunostimulatory functions of other chemical, notably the low-molecular weight (LMW) entities prepared from lysates of probiotic bacteria *Lactobacillus casei* DN-114001 and *Escherichia. coli* strain Nissle 1917. The lysates were prepared by passing bacteria through a French press (1500 psi) followed by lyophilisation. The LMW fractions were obtained by microfiltration of lysates using the 3-, 10-, 30-, 50-, and 100-kDa cutoff centrifugal devices (Amicon®, Millipore). Nitrite and cytokines levels in supernatants of rat peritoneal cells were determined at the 24-h interval of culture, using Griess reagent and ELISA, respectively. All live and dead bacteria, LPS, LTA, and PGN as well as crude lysates activated the cytokine secretion and nitric oxide (NO) production. The effects of LPS, LTA and PGN were completely abolished by the 100-kDa cutoff microfiltration. On the other hand, the high stimulatory activity was retained after the reduction of chemical constituent diversity of crude lysates to LMW fractions. Those containing molecules up to 3 kDa exhibited approximately 80% of the stimulatory potential of the fraction containing molecules up to the 100 kDa.*The research was supported by grant CZ:GA ČR:303/12/0535 from the Grant Agency of the Czech Republic.*

P6.15.25
The efficient use of the anti-inflammatory cyclic peptide T*np* in the treatment of experimental autoimmune encephalomyelitis

***E. N. Komegae**[1,2], M. Lopes-Ferreira[1], C. Lima[1];*
[1]Immunoregulation Unit, Special Laboratory of Applied Toxinology (CEPID/FAPESP) - Butantan Institute, Sao Paulo, Brazil,
[2]Department of Immunology ICB - USP, Sao Paulo, Brazil.

The currently available therapies for the treatment of multiple sclerosis (MS) have a modest effect in reducing relapses and remission. *Tnp* is a described anti-inflammatory cyclic peptide identified in the venom of *Thalassophryne nattereri* Brazilian fish. Here we examine the ability of T*np* to ameliorate the experimental autoimmune encephalomyelitis (EAE) in mice, a representative model of MS. In female C57BL/6 mouse model of EAE induced by sensitization to myelin oligodendrocyte glycoprotein$_{35-55}$ peptide, we found that prophylactic (0-9 days), therapeutic (10-19 days) or continuous (0-19 days) s.c. injections of *Tnp* (3 mg/kg/day) significantly reduced the clinical severity of EAE. The analyses by histology, zymography and flow cytometry allowed us to observe that modulation of EAE by T*np* was related with: 1) suppression of the activation state of conventional dendritic cells (DC) and the emergence of plasmacytoid DC during the induction phase of EAE, 2) blocking the traffic and leukocyte infiltration in the central nervous system (CNS) by suppression of metalloproteinases (MMP-9) activity and synthesis, 3) blocking of the reactivation and retention of Th1 and Th17 pathogenic clones in the CNS, 4) prevention the growth of microglia cells and the infiltrate of macrophages in the CNS, 5) increasing of regulatory cells (pDC, T and B cells) in the secondary lymphoid organs and in the CNS. These results shed light on the role of *Tnp* a small molecule in the regulation of inflammation and provides a new therapeutic opportunity for the treatment of MS. Support by: Fapesp and CNPq.

GKS284 ameliorates inclusion formation in a primary neuronal model of SBMA

***E. Larsen**;*
CHC, Chadds Ford, PA, United States.

Spinal and bulbar muscular atrophy (SBMA) is a polygutamine repeat disorder that results in gradual degeneration of the lower motor neurons of the anterior horn of the spinal cord and bulbar muscle of the jaw. Histologically, the disease is characterized by the formation of neuronal nuclear inclusions (NII) of mutant androgen receptor (AR) protein. Androgen ablation has been shown to halt or even reverse symptoms in transgenic mouse models of disease. Thus, selective androgen receptor modulators (SARMs) may provide an effective strategy for treatment of SBMA. PC-12 cells containing a mutant, expanded androgen receptor were treated with variety of SARMs.

P6.15.27
Cyclophosphane-induced in vitro phagocyte activity of peripheral blood leukocytes from healthy donors

*E. A. Lebedinskaya, **O. V. Lebedinskaya**, A. P. Godovalov, Y. N. Troynich, A. E. Malykina;*
Acad. E.A. Wagner Perm State Medical Academy, Perm, Russian Federation.

The aim of research was to study the effect of cyclophosphane (CP) on phagocyte activity of blood cells from healthy donors. Investigations were carried out with peripheral blood samples of 14 healthy donors. Blood samples were incubated for 1 h with CP (100; 10; 1; 0,10 and 0,01 µg/ml), then with formalinized sheep erythrocytes in 20 or 60 min at 37°C. All phagocyte parametres of neutrophils and monocytes were counted.
Low CP concentrations are found to increment the relative amount of phagocytizing neutrophils as compared with the control and data obtained at high doses. At CP concentrations of 100 µg/ml the amount of phagocytizing neutrophils comprised 40,00±3,69%, while at CP concentration of 0,01 µg/ml it was 59,88±3,72% (p<0,05). Introduction of 0,01 µg/ml CP also provoked the elevation of the phagocytizing monocyte number. CP applied in high doses resulted in lowering of phagocyte number as compared with the control. The absolute number of non-phagocytizing neutrophils under CP concentration of 100 µg/ml was statistically greater than under the dose of 0,01 µg/ml. Absolute amount of phagocytizing monocytes under the CP concentration of 100 and 10 µg/ml was statistically less than in control samples. While assessing the uptaking ability of phagocytes it was found that index of phagocytosis completeness was less than 1 with all of CP doses analyzed.
Thus, cytostatic cyclophosphane modulates the leukocyte phagocyte activity. High CP doses reduce all known parameters of monocytes and neutrophils.
This work was supported by RFBR grant №11-04-96037r_ural_a and administrative body of Perm Region.

Phycocyanobilin positively modulates inflammatory genes in acute cerebral hypoperfusion in rats

*J. Marín-Prida[1], N. Pavón-Fuentes[2], A. Llópiz-Arzuaga[3], J. R. Fernández-Massó[3], A. Cruz-Ramírez[3], N. Polentarutti[4], F. Riva[5], E. Pentón-Arias[3], A. Mantovani[4], **G. Pentón-Rol**[3];*
[1]Center for Research and Biological Evaluations (CEIEB), Institute of Pharmacy and Food (IFAL), University of Havana (UH), Havana, Cuba, [2]International Center for Neurological Restoration, Havana, Cuba, [3]Center for Genetic Engineering and Biotechnology, Havana, Cuba, [4]Istituto Clinico Humanitas, Rozzano, Italy, [5]Department of Veterinary Science and Public Health, University of Milano, Milano, Italy.

Stroke causes high mortality rates and serious disability worldwide. Ischemic penumbra rescue is the main objective of acute interventions, such as thrombolysis and neuroprotection, but they show low translational success. Increasing evidence demonstrates that inflammatory response is involved in the stroke cascade. Here we evaluated the effects of Phycocyanobilin (PCB), the C-Phycocyanin linked tetrapyrrole, on gene expression in the anterior cortex of hypoperfused brains of rats. The acute drop of cerebral blood flow in this model is comparable to ischemic penumbra, thus offering a reliable tool for studying molecular mechanisms. After the permanent bilateral common carotid arteries occlusion, the animals were treated therapeutically with saline or PCB. Samples were taken 24h after the surgery. Global gene expression was analyzed with GeneChip Rat Gene ST 1.1 from Affymetrix, and the expression of particular genes was assessed by the Fast SYBR Green RT-PCR Master Mix method. The PCB treatment significantly modulated 190 genes (93 up- and 97 down-regulated) associated to several immunological processes in both the regulatory and effector subsets. Furthermore, PCB was able to positively modulate 13 genes mostly related to a detrimental pro-inflammatory environment. Our results support the view of major inflammatory mediators in acute cerebral hypoperfusion, effectively counteracted by PCB. These results may justify the application of PCB as a new acute disease modifying drug against ischemic stroke.

P6.15.29
Nitro-oleic acid regulates the classical and alternative activation of macrophages

***H. Martiskova**[1], G. Ambrozova[1], L. Kubala[1], T. K. Rudolph[2], A. Klinke[2], T. Ravekes[2], L. Bino[1], J. Navratilova[1], H. Kolarova[1], S. Gajdova[1], M. Pekarova[1];*
[1]Institute of Biophysics, AS CR, v.v.i., Brno, Czech Republic, [2]Department of Experimental Cardiology, Cologne, Germany.

Nitrated fatty acids (NO2-FAs) are endogenously generated as an adaptive response of organism to oxidative conditions. NO2-FAs were shown to exert significant anti-inflammatory signaling action in immune and vascular cell models; nevertheless, detailed mechanisms of their action in regulation of innate immune responses are not completely understood. Therefore, we investigated the role of nitro-oleic acid (OANO2) in classically and alternatively activated macrophages.
In this study we used the concentration range of 0-2000 nM of OANO2. RAW 264.7 and bone marrow-derived macrophages were treated with OANO2 in the presence of lipopolysaccharide (LPS) and interleukin-4 (IL-4) for different time periods. The following analyses (cytokine array, ELISA, luminol-enhanced chemiluminescence, Griess reaction, Western blot, PCR) were focused on the basic physiological responses of macrophages.
Our results showed that OANO2 significantly regulated the activation of macrophages in a dose-dependent manner. More importantly, changes in the production of pro-and anti-inflammatory mediators were associated with reduced activation of c-Jun N-terminal kinase and expression of nuklear factor-kB and CD36, as well as with increased activation of signal transducer and activator of transcription 6.
In conclusion, NO2-FAs are able to serve as a protective compounds that can effectively down regulate the activation of macrophages. Our results have significant implications since the identification of key regulators of immune functions and information about the mode of their action may provide very important data for future clinical investigations.
This work was supported by the Academy of Sciences of the Czech Republic (M200041208, AV0Z50040702).

A non toxic concentration of ethyl acetate extract of Cordia verbenacea D.C. reduces the expression of proinflammatory cytokine IFN-γ in human peripheral blood lymphocytes

*M. G. Santos, J. A. T. Santos, B. A. A. Freitas, V. G. Almeida, C. F. F. Grael, **G. E. A. B. Melo**;*
Federal University of Jequitinhonha and Mucuri Valleys, Diamantina, Brazil.

Cordia verbenacea is a native Brazilian plant popularly used as anti-inflammatory. Although this activity has been demonstrated previously, the molecular mechanisms are not yet fully understood. Likewise, few studies have reported the cytotoxic potential of this

plant. Thus, the aim of this study was to evaluate the toxicity of the ethyl acetate extract of C. verbenacea (EACV) on human erithrocytes and peripheral blood mononuclear cells (PBMC) as initial phase of the study about the probable anti-inflammatory activities of the plant. Cell viability and hemolytic activity were evaluated by trypan blue exclusion test. Furthermore, we performed an evaluation of immunomodulatory potential of EACV on proinflammatory cytokines expression. For this propose PBMC cultures stimulated with PMA in the absence or presence of a non-toxic concentration of the EACV was used to evaluate the intracytoplasmatic cytokine profile, using flow cytometry. According to the results, the EACV showed no hemolytic activity, neither cytotoxicity action on PBMC at the concentrations equal to or lower than 50µg/mL, when compared to control cell cultures. Moreover, the extract at 50µg/ml, added together PMA, reduced the percentage lymphocytes-IFN-γ + compared to cell cultures stimulated with PMA alone. These data presented here suggest that the anti-inflammatory effect observed in the folk use of the plant Cordia verbenacea can be partly explained by its inhibitor effect on type 1 cytokine expression.

P6.15.31
Pseudobrickellia brasiliensis (Spreng) R. M. King & H. Rob. (Asteraceae) aqueous extract decreases IFN-gamma and TNF-alpha expression on human peripheral blood mononuclear cells, in vitro

*V. G. Almeida, J. A. T. Santos, B. A. Avelar, M. G. Santos, H. Lopes, M. L. L. Amorim, C. F. F. Grael, E. R. Vieira, **G. E. A. B. Melo**;*
Federal University of Jequitinhonha and Mucuri Valleys, Diamantina, Brazil.

Pseudobrickellia brasiliensis (Asteraceae), known as “Arnica-do-Campo”, is a native plant from Brazilian flora and its alcoholic preparation has been used as anti-inflammatory in folk medicine. However, the biological mechanisms involved in this biological activity are not well elucidated. In our study we aimed verify the anti-inflammatory potential of P. brasiliensis aqueous extract (AQU) by performing an anti- and pro- inflammatory cytokine expression analysis on human peripheral blood leucocyte surface. The cytotoxicity promoted by the AQU, in vitro, was evaluated using trypan blue assay. For cytokine analysis, humans-PBMC were incubated in medium containing PMA plus Ionomycin as inespecific stimulating agents, in the absence or presence of AQU at the concentrations 25, 50 or 100 µg/ml. According our results, AQU showed no toxic effects on human PBMC and AQU at 100 µg/ml promoted a significant reduction in IFN-γ and TNF-α expression in response to PMA stimulation. These findings suggest that P.brasiliensis anti-inflammatory effect can be, at least in part, due PBMC pro-inflammatory cytokines inhibition.

Silymarin Normalizes Immune Dysfunction in Beta-Thalassemia Major Patients

H. R. Mirzaei[1]*, H. Mirzaei*[2]*, B. Bagherpour*[3]*, M. Eghbali*[3]*, J. Jalili*[1]*, N. Bagherpour*[4]*;*
[1]*Tehran University of Medical Sciences, Tehran, Iran,* [2]*Mashhad University of Medical Sciences, Mashhad, Iran,* [3]*Isfahan University of Medical Sciences, Isfahan, Iran,* [4]*Science & Research Branch, Islamic Azad University, Tehran, Iran.*

Iron overload conditions in beta-thalassemia major is the principal cause of oxidative stress and cell-mediated immune deficiencies. Despite indicative signs of severe oxidative deficiencies associated with beta-thalassemia major, little is known about intracellular redox status of immune cells. Once glutathione is a primary intracellular antioxidant and plays a fundamental role in the many T cell functions, present study was aimed to investigate intracellular glutathione (GSH) levels as well as proliferation of PHA-activated peripheral blood mononuclear cells (PBMC) in 28 beta-thalassemia major patients and 28 healthy age-matched individuals. In respect to potential benefits of flavonoids in the oxidative stress therapy, the effects of silymarin on the GSH levels and proliferation of PBMC from normal and thalassemia individuals were further examined. Quantitative determination of intracellular GSH and proliferative response of PBMC to PHA were performed before and after 72 h incubation of PBMC with various concentrations of silymarin (0, 5, 10, or 20 mug/ml). Our results revealed a significant reduction of GSH and proliferation in beta-thalassemia major cells; though treatment with silymarin led to restoration of both GSH levels and PBMC proliferation in thalassemia patients. Considerably low levels of GSH and depressed proliferative response of PBMC in beta-thalassemia major may be responsible for the cell mediated immune abnormalities in iron overload conditions. Moreover, the GSH restoration and improvement of PBMC growth by silymarin is a possible explanation for its reported antioxidant and immunostimulatory activities. These data suggest the benefit of using flavonoids to improve immune dysfunction in beta-thalassemia major.

Establishment of Experimental Autoimmune Encephalomyelitis in Cynomolgus Monkeys, A Model for Multiple Sclerosis

J. NI*, J. Liu, G. Cui, S. Wang, J. Deng, L. Le, K. Zhang;*
Prisys Biotechnologies Co., Ltd, Shanghai, China.

The current high failure rates of clinical trials for multiple sclerosis (MS) therapeutics impede the correct translation of the new treatments from concept to the patients. One of the major drawbacks leading to the failure is the use of rodent models in the preclinical studies. To improve this, we established the EAE model in non-human primate (NHP) that provide the much closer–to-human immune system for modeling MS. Three different antigens: brain white matter, spinal cord and MOG peptides, were tested for induction of EAE in Cynomolgus monkeys by two injections of antigen-adjuvant followed by daily monitoring of the disease progression. Two weeks after the immunization, monkeys started to show the typical disease related neurological symptoms, such as anorexia, weight loss, ataxia, neck spasticity, and blindness. MRI examinations discovered the multiple hyper-intense areas in the brain of the EAE monkeys at disease active stages, similar to those found in MS patients. The findings of gross autopsy indicated multiple hemorrhagic lesions in the white matter of the affected monkey brains. Both disease incidence and severity of the EAE were antigen-dose dependent. Interestingly, the disease progression induced by brain white matter and spinal cord presented mixed types of the EAE episodes, while only the typical relapsing-remitting disease, representing the major type of MS in patients, was induced by MOG peptide.
Our results demonstrated the successful establishment of the EAE models and, for the first time, evidenced the relapse-remitting EAE induced by MOG peptide in Cynomolgus monkeys.

P6.15.34
Novel S1P1 receptor agonist, CP9531, has desirable characteristics as a next generation agonist

T. Ninomiya*, S. Yoshida, S. Sugimoto, Y. Yagi, K. Kato, C. Yoshida, K. Suzuki, T. Kikkoji;*
Meiji Seika Pharma Co.,Ltd. Pharmaceutical Research Center, Yokohama, Japan.

Fingolimod, a non-selective S1P1 receptor agonist, has been already launched for relapsing-remitting multiple sclerosis, and other agonists are under development for autoimmune diseases. These S1P1 agonists, however, provoke AV blocks and heart rate reductions. GIRK channel activation of cardiomyocytes is considered to be crucial, and it is activated by Gi and inhibited by Gq. We therefore tried to create a compound with fast receptor uptake and high selectivity to Gq as a next-generation S1P1 agonist.
Novel S1P1 agonist, CP9531 showed an ability to internalize 50% of the receptors by 30 minute-treatment at 10 nM. In addition, "EC_{50} of Ca influx" / "EC_{50} of GTP binding" ratio of CP9531 was approximately 2, which is 5-50 times lower than other S1P1 agonists.
Male SD rats were orally administered with CP9531 and the number of blood lymphocytes was counted at 6 and 24 hours after administration. ED_{50} was 0.17 mg/kg at 6 h and 0.65 mg/kg at 24 h. Similar PKPD profile was also confirmed in cynomolgus monkeys.

The preventive and curative effect of CP9531 in a mouse EAE model showed remarkable improvement in the EAE score in either conditions at 1 mg/kg p.o., q.d. The cardio toxicity of fingolimod phosphate in anesthetized rats was observed at 0.01 mg/kg, but not at 0.1 mg/kg of CP9531.
These results suggest that novel S1P1 selective agonist CP9531 with potent receptor uptake activity and Gq biased-activity has high efficacy and safety. We believe CP9531 has desirable characteristics for the next generation of S1P1 agonists.

P6.15.35
Evaluation of toxicity of the dichloromethane and ethyl acetate extracts from Ageratum fastigiatum in human peripheral blood mononuclear cells

M. H. F. Ottoni*, V. G. Almeida, B. A. Avelar-Freitas, M. G. Santos, C. F. F. Grael, L. E. Gregório, G. E. A. Brito-Melo;*
Federal University of the Jequitinhonha and Mucuri Valleys, Diamantina, Brazil.

Ageratum fastigiatum is a common Brazilian medicinal plant used by folk medicine as topical anti-inflammatory agent. However, little is known about its anti-inflammatory mechanisms, as well as its cytotoxicity. Thus, before assessing the possible actions of the plant on the immune system, we investigated the toxicity of the dichloromethane and ethyl acetate extracts of A. fastigiatum on human PBMC, using the 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay. PBMCs obtained from five healthy volunteers were cultured with supplemented RPMI in the presence or absence of dichloromethane (DCM) and ethyl acetate (EA) extracts of the plant at different concentrations. Cells treated with DMSO or cadmium chloride (CdCl2) were used as solvent control and cytotoxicity positive control, respectively. EA extract from A. fastigiatum did not reduce cell viability at the tested concentrations, when compared to DMSO (EA at 0.8 µg/ml: 89.32 ± 11.49%; EA at 1,5µg/ml: 91.73 ± 9.062%; EA at 3µg/ml: 88.93 ± 7.316%, DMSO: 86.52 ± 5.693%). Conversely, the DCM extract decreased cells viability at the tested concentrations compared to DMSO (DCM at 20µg/ml: 52.12 ± 10.29%; DCM at 60µg/ml: 49.62 ± 5.502%; DCM at 125µg/ml: 52.55 ± 3.158%). These results indicate that ethyl acetate extract from A. fastigiatum, but not the dichloromethane extract can be used in PBMC cultures, at the tested concentrations, for further in vitro analysis.

P6.15.36
Effects of venoms from five Brazilian snake species on the viability of human peripheral blood mononuclear cells

J. Ruiz[1], F. O. F. Castro[1], L. DOBRACHINSKI[1], M. Maineri[1], A. S. Stival[1], S. G. Fonseca[2], ***I. A. H. Pfrimer****[1];*
[1]Pontifícia Universidade Catolica, Goiania, Brazil, [2]Tropical Pathology and Public Health - Federal University of Goias, Goiania, Brazil.

Snake venoms are complex mixtures of proteins, peptides, amino acids, nucleotides, lipids, carbohydrates, enzymes showing a broad range of biological activities. Venom derived components have been used as a pharmacological drugs in humans. The present work aimed to assess the cytotoxic effects of crude venom from 5 different species of snakes from Central region of Brazil on human peripheral blood mononuclear cells (PBMC) in order to further investigate the biological effects of them. $2x10^5$ cells/well from 12 healthy donors were stimulated with phytohemagglutinin PHA and IL-2 in presence of different concentrations of venoms (50, 5, 0.5, 0.05, 0.005 and 0.0005 µg/mL) from the following Brazilian snake species : *Bothrops pauloensis, Bothrops moojeni, Bothrops jararacussu, Caudisona durissa collilineata, Caudisona durissa terrificus. C*ytotoxic activity, DNA fragmentation were analyzed after 24, 48 and 72 hours of culture. Cell counts were done using hemocitometer chamber and trypan blue, and DNA fragmentation by gel analysis. Our results show that the absence of cytotoxic effects of all 5 venoms at concentrations of 0.05 ug/mL and 0.005 and 0.0005 ug/ml. However at concentration of 5ug/ml and 0.5 ug/ml the venoms killed the cells and a DNA fragmentation were also observed. Cytokine production and the expression of innate and adaptive receptors induced by those venoms on PBMC are under investigation. Our results suggest that at high concentration levels those venoms may induce apoptosis and open the possibility to further investigate the microbicidal, stimulatory and inhibitory effect of those snake venoms. P6.15.37
Activation of telomerase by novel compounds in human lymphocytes

E. Priel*, L. Ben-Yakov, A. Gazit, S. Slavin;*
Ben-Gurion University, Beer-Sheva, Israel.

Recent studies demonstrate the importance of telomere length and telomerase activation on the viability and functionality of the immune system cells. Telomerase is a ribonucleoprotein that catalyzes the addition of telomeric repeats to the telomeres ends thus enables cell proliferation and controls cell lifespan. The ability of telomerase activation in lymphocytes, as a response to antigen, is decreased with age. Therefore, telomerase activation in human lymphocytes may improve their functionality. We have synthesized novel compounds (AGS) that activate telomerase expression and activity in vitro and in vivo. Here we investigated the effect of treatment of human lymphocytes with AGS in the presence and absence of mitogen on the expression and activity of telomerase. We found that naïve lymphocytes have a detectable level of telomerase protein and activity, both in the cytoplasm and in the nucleus. AGS compounds (25nM-250nM) increased telomerase expression and activity in normal human lymphocytes after treatment of 3h-15, while a significant increase of telomerase in concanavalin A (ConA) treated lymphocytes was detected 60 hrs. after treatment. However, AGS compounds did not increase the level of telomerase beyond that observed with ConA alone and did not cause cell proliferation. Increasing telomerase by AGS in oxidative stressed lymphocytes enhanced their survival up to 80%. These results suggest that pharmaceutical activation of telomerase in lymphocytes may improve their survival under stress conditions and may serve as possible therapeutic strategies in age related diseases.

P6.15.38
HLA-B allele frequencies in the Thai population

A. Puangpetch*, C. Sukasem, S. Santon, M. Chamnanphol, T. Jantararoungtong, N. Koomdee, S. Promas;*
Laboratory for Pharmacogenomics and Personalized Medicine, Department of Pathology Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok, Thailand, Bangkok, Thailand.

There are 3 classes of *HLA* molecules; *HLA* class I, II and III, different classes each of which has different functions. The most important class for predicting drug allergies is *HLA-B* which belongs to *HLA* class I. Variations in *HLA-B* genes account for drug-response differences among individuals. *HLA-B**1502 has been reported to be associated with Stevens - Johnson syndrome (SJS) and toxic epidermal necrolysis (TEN) (SJS/TEN) in patients who received Carbamazepine, Allopurinol, Phenytoin, Amoxicilin and Co-trimoxazole etc. We determined *HLA-B* allele frequencies in Thai population which is useful for estimating the incidence of drug hypersensitivity. Blood samples from seven hundred and thirty nine Thai individuals were collected and DNA was extracted. The *HLA-B* genotyping was performed using bead array technique and we found that the allele frequencies in *HLA-B**4601, *HLA-B**4001, *HLA-B**5801 and *HLA-B**1502 are 12.72%, 8.32%, 8.32%, and 7.51% respectively. The *HLA-B**4601 did not classify as a marker for any drug hypersensitivity. *HLA-B**4001 was associated with Stavudine hypersensitivity, the drug in Acquired Immune Deficiency Syndrome (AIDs) treatment whereas *HLA-B**5801 was associated with Allopurinol hypersensitivity, a rheumatoid arthritis treatment. Moreover, *HLA-B**1502 was associated with response to Carbamazepine hypersensitivity, an anti-epileptic drug. However, the tendencies for drug hypersensitivity besides the HLA-B genotype depend on the drug exposure and pharmacodynamics interaction.

P6.15.39
Cationic liposomes bearing IL -2 induce cytotoxic lymphocytes

***R. Rangel-Corona**, K. Ortiz-Medrano, B. Weiss-Steider;*
UNAM, México, Mexico.

We have recently described a cationic liposome that contains spermidine in its lipidic bilayer, and which is able to bind IL-2 (CL-IL-2) in such a way that this cytokine is expressed on its external surface. We also demonstrated that this liposome binds to INBL, a cervical cancer cell line that expresses IL-2 receptors, thus making the cells themselves IL-2 presenters. In this work, we demonstrated that when the lymphocytes are stimulated with of CL-IL-2, the leukocytes proliferate and become cytotoxic. Almost 50% of the cells were CD4 /CD45 RO, and the maining 50% were CD8/CD45 RO thus hinting that lymphocytes are responsible for the tumor burden reduction. The presence of a large number of lymphocytes and the fact that many had a CD8+ phenotype suggests that these lymphocytes were the cytotoxic cells are responsible for the previously observed antitumor effect. The possible formation of a bridge between the IL-2R receptors on both, the lymphocytes and the INBL cells, by the IL-2 bearing liposomes, and its possible effect on the activation of antitumor cytotoxic lymphocytes is discussed.

P6.15.40
Activity of beta-adrenergic receptors in vascular lesions associated with proteins inflammatory in the periodontal disease

***W. F. Rodrigues**[1], C. B. Miguel[1], J. E. Lazo-Chica[1], J. T. C. Napimoga[2], C. J. F. Oliveira[1], M. H. Napimoga[3];*
[1]Federal University of Triângulo Mineiro, Uberaba, Brazil, [2]Faculty of Dentistry at Piracicaba-UNICAMP, Piracicaba, Brazil, [3]São Leopoldo Mandic Institute and Research Center, Campinas, Brazil.

Introduction:Nervous system may play an important role in regulating inflammatory mediators by adrenoceptors.**Objectives:W**e evaluated the proteins related to vascular damage after the action of β antagonist in an experimental model for Periodontal Disease(PD).**Methodology:**The groups:1) animals that received vehicle without ligature (SPD), 2) with ligature that received vehicle (PD),3) with ligature receiving 0.1 mg of propranolol (P),4) animals with ligature treated with 5mg of P and 6)animals with ligature that received 20mg of P. Thirty days after induction of PD, it was collected the whole blood for a hemogram analysis and serum for measurement of TNF-α and IL-6 and C-reactive protein (CRP).Blood counts were obtained using an automated method.Cytokines were quantified by ELISA and CRP by turbidimetry.The mandibles were evaluation the bone resorption. **Results:**We found changes in the systemic levels of TNF-α and IL-6 when compared the groups SPD and PD as well as in the P-treated animals CRP was bigger in the PD group (67.3%-PD=0.875±0.46) in comparison to SPD(0.52±0.37) Both treated groups 0.1(0.75±0.25) and 5 mg/kg(0.45±0,24) had decreased the CRP in comparison to the group PD, in contrast with the treated group, the group with 20mg/kg increased by 96.15%(1.02±0.63) the amount of CRP related to the group SPD an increase of 16.57% compared to PD-group.Regarding the systematic evaluation of hemogram there was no change.The resorption was confirmed by histological evaluation, in which the group treated with 0.1and 5mg/kg inhibit the bone resorption.**Conclusion:**The data indicate an indirect contribution of the beta-adrenergic blockade in development of vascular changes. **Financial Support:**FAPEMIG 097/09

P6.15.41
A new immunomodulatory therapy to treat pathologies related to a defective cell-mediated immunoresponse

***G. Rossi**, S. Scarpona;*
School of Veterinary Medical Sciences, University of Camerino, Matelica (MC), Italy.

A new immunomodulatory therapy based on association of intradermal administration and anti-COX2 drug has been used to treat pathologies related to a defective cell-mediated immune response in animals, which represent a good model for similar disease in humans. In particular, we treated canine Leishmaniasis (CL), feline inflammatory induced sarcomas (FIIS), a bird model of Guillame Barrè syndrome (Proventricular dilatation Disease or PDD), and a chronic-granulomatous progressive and lethal pathology of the cat, known as Feline Infectious Peritonitis (FIP). We investigate the changes of lymphocyte subsets, immunological indexes, in vitro macrophage function, IgG1/IgG2 ratio with determination of levels in Th1/Th2 response induction, and clinical data. The study involved 30 dogs with CL, 12 cats with FIIS, 25 parrots with PDD, and 10 cats with FIP. Compared to the control groups, only the patients treated with the immunomodulatory protocol showed an enhancement of cell-mediated immune response, which resulted in remission of symptoms in CL (89%, included PCR negativization), PDD (93%), FIP (52%), and absence of tumor recurrence in FIIS (78%). Usually, in the last three diseases listed above the conventional therapy has always bad prognosis. Combined immunomodulatory therapy appears to yield improved survival for patients with different pathological conditions in which the cell-mediated immune response is altered or depressed; these findings should be verified in larger clinical trials.

P6.15.42
Ageratum fastigiatum essencial oil compounds decrease the expression of proinflammatory cytokine TNF-alpha in peripheral blood leukocytes stimulated with Phorbol Myristate Acetate (PMA) in vitro

*B. A. A. Freitas, **J. A. T. Santos**, V. G. Almeida, M. G. Santos, C. F. F. Grael, L. E. Gregório, E. R. Vieira, G. E. A. B. Melo;*
Federal University of Jequitinhonha and Mucuri Valleys, Diamantina, Brazil.

Ageratum fastigiatum (Gardner) R. M. King & H. Rob, a plant also known as "matapasto", belongs to Asteraceae family utilized by folk medicine as a plant with anti-inflammatory and analgesic proprieties. However, little is known about its potential to alter parameters of the inflammatory response. The aim of this study was to charachterize the main chemical compounds present in Ageratum fastigiatum essencial oil (AFOE) and to evaluate the intracelluar TNF-alpha, IFN-gamma and IL-10 profile on human peripheral blood lymphocytes stimulated in vitro with PMA (phorbol myristate acetate) in the presence or absense of AFOE. Addicionally, the nontoxic concentrations of EOAF on PBMC was evaluated by trypan blue exclusion test. The CG/MS analysis revealed the main compound observed in EOAF was α-pinene (7.51%), limonene (5.9%), trans-caryophylleno (2.04%) and α-Humoleno (3.52). According to our results, EOAF at 5x10-3 and 1x10-2µL/mL did not alter the viability of leukocytes when compared to the control group and both concentrations reduced the percentage of lymphocytes-TNF-α+. No changes were observed in percentage of cells stained for the IFN-gamma and IL-10 cytokines. Our results suggest that part of anti-inflammatory activity attributed to Ageratum fastigiatum can be, at least in part, due the action of its constituents in reducing the pro-inflammatory cytokine TNF-α.

Biochemical and cellular correlates of embelin against bacterial endotoxin induced airway inflammation

***M. Saraf**, R. Shirole, L. Badgujar, A. Kshatriya;*
Bombay College of Pharmacy, Mumbai, India.

To investigate mechanism of anti-inflammatory activity of embelin against bacterial endotoxin induced acute lung inflammation.
Embelin was isolated from dried seeds of *Embelia ribes.* Female Sprague Dawley rats (180-230g) were divided in six groups. Saline (5ml/kg/day,*p.o.*) Embeline (5,10&20mg/kg/day,*p.o.*), Roflumilast (1mg/kg/day,*p.o.*) were administered for four days. Animals were anesthetised with ketamine-xylazine (80:20 mg/kg,*i.p.*) and administered with sterile solution of LPS (Lipopolysaccharide) intratracheally. After four hours bronchoalveolar lavage was done with icecold phosphate buffer. Bronchoalveolar lavage fluid (BALF) and lung samples were investigated for total cell count, differential cell count and myeloperoxidase, nitrate/nitrite, total Protein, albumin, histopathology respectively.

Data was analysed by GraphPad Prism 5.01 and results were expressed as means ± SEM. P value of <0.05 was considered to be significant.
Saline treated animals showed significant increase in total and differential cell count (p<0.05). Embelin (5,10&20mg/kg) & Roflumilast (1mg/kg) treated animals showed significant decrease in total and differential cell count compared to saline treated animals (p<0.05).
Saline treated animals showed significant increase in myeloperoxidase, nitrosative stress, albumin and total protein in lung samples but embelin (5, 10 & 20mg/kg) and roflumilast (1mg/kg) showed reduction compared to saline treated animals (p<0.05). Mild diffused lesions involving focal interalveolar septal, intraluminal infiltration of neutrophils were observed in embelin (5&10 mg/kg) pretreated while no abnormality was detected in embelin (20 mg/kg) rofelumilast (1mg/kg) pretreated rats.
Embelin showed anti inflammatory and protective effect against LPS induced airway inflammation by reducing nitrosative stress and inhibiting mononucleated cellular infiltration. Further studies on molecular level are in progress.

Immunotropic drugs for local use in stomatology

N. G. Sarkisian[1], *G. I. Ron*[1], *I. N. Shtan'ko*[2], *T. G. Khonina*[2], *I. A. Tuzankina*[3], *A. S. Simbirtsev*[4];
[1]*Ural State Medical Academy, Ekaterinburg, Russian Federation,* [2]*I. Ya. Postovsky Institute of Organic Synthesis of Ural Branch of the Russian Academy of Sciences, Ekaterinburg, Russian Federation,* [3]*Institute of Immunology and Physiology of Ural Branch of the Russian Academy of Sciences, Ekaterinburg, Russian Federation,* [4]*Institute of Ultra Pure Biopreparations, St. Petersburg, Russian Federation.*

The problem of the treatment of inflammatory periodontal and oral mucosa diseases is one of the important problems in stomatology. A complex therapy using medicines of topical application plays crucial role in the treatment of these diseases. Taking into account that the forming and development of the most of the known pathological processes are determined by the nature of immunopathogenetic changes, development of a new immunotropic drugs for local application is especially relevant.
The number of new pharmaceutical compositions for local treatment of inflammatory oral cavity diseases using immunotropic substances of cytokine agents, phthalhydrazide and piperazine derivatives and zinc-containing components were suggested [1]. Silicon-and silicontitanium-containing glycerohydrogels were proposed as an ointment bases. These hydrogels shown a strong regenerating activity due to the presence of silicon in biologically active form, as well as antioxidant and cytoprotective action in the case of titanium in a biologically active form. In addition, these bases have a high transcutaneous activity, which allows to reduce the concentration of immunotropic substances and leads to a deeper penetration into the affected tissue.
High pharmacological activity (anti-inflammatory, healing and regenerating) and safety of developed medicines were shown in experiments with laboratory animals. The acute local inflammation of the mucous membrane of the lower lip (thermal burns) and mechanical injury of gingival of rats of the Wistar population were used as models.
The work was supported by the Presidium of the Russian Academy of Sciences - programs №№ 12-М-34-2071 and 12-П-3-1030.

T-cell Electrophysiology Dynamics

C. D. Schmeitz[1], *M. E. Meyer-Hermann*[1,2];
[1]*Helmholtz Centre for Infection Research, Braunschweig, Germany,* [2]*Bio Center for Life Sciences, Technische Universität Braunschweig, Braunschweig, Germany.*

The presence of T-lymphocytes, in particular T-helper-cells, is in the context of great importance, but in some medical issues their immunological implication must be repressed. For example, the appearance of graft rejection is a major problem in transplantation medicine. In order to suppress the causative immunological reaction, the pharmaceuticals cyclosporin A (CsA) and tacrolimus (FK506) are in use as standard drugs. Both immunomodulators affect electrophysiological processes by blocking the relevant signaling cascade in activated T-cells and in this way also modulating the calcium influx passing through the calcium-release activated channel (CRAC) in the plasma membrane of T-lymphocytes.
With regard to the significance of electrophysiology in coherence with immunological interactions and pharmacological issues, a mathematical modeling approach is demanded in order to quantitatively understand the associated ion dynamics in T-lymphocytes, embedded in a systems immunological context. Building on the results from electrophysiological measurements, the in silico T-cell model includes single transmembrane protein characteristics in order to derive ion dynamics patterns on the whole cell level with a particular focus on calcium. Beside of the most central CRAC, ionic pumps and channels for calcium, sodium and potassium, as well as the endoplasmatic reticulum acting as a calcium store are represented in the model.
Starting with simulations of a naive T-cell, the model will then be used to analyse the electrophysiological changes following T-cell activation. Further, the modeling approach will finally provide a starting point for in silico studies relating to the therapeutic immune modulation of ion-conducting proteins in T-lymphocytes.

Background: In recent years, several studies have been focused on the effects of Curcumin, the principal active component of turmeric, on neurodegenerative diseases. Astrocytes contribute to the pathogenesis of Multiple Sclerosis. Therefore, we investigated the influence of Curcumin on LPS-induced astrocytes cell line (U-373 MG) compared with HEK293 cell line as a control.
Methods: After selecting the optimal concentration of Curcumin by MTT assay, cells were treated with purified Curcumin. Then, the activity of MMP-9, involved in the destruction of the Brain Blood Barrier, was measured by gelatin zymography. The expression of different genes including CTLA-4, neurotrophin 3, CCL-2 and insulin-like growth factor 1 were evaluated by Real-Time PCR. At the end, five pro and anti-inflammatory cytokines were assessed with quantitative ELISA.
Results and Conclusion: Curcumin demonstrates anti-inflammatory effects in activated astrocytes.

Daphanetin prevents acute inflammatory lung injury in mice via a TNFAIP3-dependent mechanism

L. Shi[1], *W. Yu*[2], *Y. Kang*[1], *D. Wang*[3], *D. Chen*[1];
[1]*Hangzhou Normal University, Hangzhou, China,* [2]*Zhejiang Chinese Medical University, Hangzhou, China,* [3]*Zhejiang Sci-Tech University, Hangzhou, China.*

Daphnetin, a Chinese herb-derived compound, has been used to treat chronic inflammatory and autoimmune diseases, but its mechanism is not well understood. We here showed that Daphnetin significantly reduced lipopolysaccharide (LPS)-induced production of TNF-α, IL-1β and IL-6 in both RAW264.7 cells and mouse primary peritoneal macrophages, and inhibited LPS-induced activation of p38 and ERK MAPKs. Moreover, Daphnetin exhibited to retard the LPS-induced activation of IκB kinase, IκBα degradation, p65 nuclear translocation and phosphorylation, as well as NF-κB-driven promoter activity. Further study indicated that TNFAIP3 (also A20) was remarkably induced by Daphnetin in macrophages, which appeared

to be largely responsible for the down-regulation of NF-κB-dependent inflammatory gene expression. Accordingly, intratracheal administering Daphentin significantly protected mice from LPS-induced acute lung injury and inflammation, in parallel with the up-regulation of TNFAIP3 levels in lung tissues. Our results indicate that Daphnetin exerts anti-inflammatory effects, at least partially through TNFAIP3-regulated NF-κB-dependent inflammatory signaling in vivo as well as in vitro.

P6.15.48

Proteasome inhibition by bortezomib increases IL-8 expression in ovarian cancer cells by IKK and EGR-1 dependent mechanism

*B. Singha, S. Manna, T. Chang, S. Sanacora, A. Vancura, **I. Vancurova**;*
St. John's University, Queens, NY, United States.

Interleukin-8 (IL-8) has a crucial role in ovarian cancer progression through its induction of tumor cell survival, proliferation, angiogenesis, and metastasis. IL-8 expression and serum levels are increased in patients with ovarian cancer, and correlate with poor prognosis. Bortezomib (BZ) is the first clinically approved proteasome inhibitor that has shown a remarkable activity in patients with multiple myeloma and other hematological malignancies. One of the main mechanisms of BZ function is the suppressed proteasomal degradation of IκBα, resulting in the inhibition of NFκB activity and expression of NFκB-dependent anti-apoptotic genes. Bortezomib has so far failed to exhibit a significant clinical activity in ovarian cancer patients. However, the mechanisms underlying ovarian cancer resistance to BZ are largely unknown. In this study, we investigated how BZ regulates transcription of IL-8 in ovarian cancer OVCAR-3 cells. Our data demonstrate that BZ markedly increases IL-8 expression, while expression of other NFκB -regulated genes is unchanged or suppressed. The mechanism consists of an increased recruitment of S536-p65 NFκB, IκB kinase (IKK) and the transcription factor EGR-1 to the endogenous IL-8 promoter. In addition, IKK inhibition and EGR-1 suppression significantly inhibit the BZ-increased IL-8 expression in OVCAR-3 cells. Together, our data indicate that combining proteasome inhibition with anti-inflammatory drugs targeting IKK could provide a new effective strategy for IL-8 suppression in ovarian cancer and other tumors characterized by excessive IL-8 expression.

Safety, tolerability and pharmacokinetics (PK) of human immune globulin subcutaneous (IGSC), 20%: interim analysis of a phase 2/3 study in patients with primary immunodeficiencies (PI)

*G. Kriván[1], M. Borte[2], L. Maródi[3], T. Harrer[4], R. Ganschow[5], W. Engl[6], H. Leibl[6], B. McCoy[6], **L. Yel**[7];*
[1]Szent László Hospital, Budapest, Hungary, [2]ImmunoDeficiencyCenter Leipzig (IDCL) at Klinikum St. Georg gGmbH, Leipzig, Germany, [3]Medical and Health Science Center, University of Debrecen (LM), Debrecen, Hungary, [4]Dept. of Internal Medicine 3, University Hospital Erlangen, Erlangen, Germany, [5]Medical Center Hamburg-Eppendorf, Hamburg, Germany, [6]Baxter BioScience, Vienna, Austria, [7]Baxter BioScience, Westlake Village, CA, United States.

Background: IGSC 20% is a new, ready-for-use, liquid preparation of highly purified human IG for SC administration. We report interim analyses from data cutoffs in June 2012 (safety/tolerability) and September 2012 (PK) of IGSC 20% in patients with PI in Europe.
Methods: This is a phase 2/3 open-label study in patients with PI aged ≥2 years. Epoch 1: IGSC 16% or intravenous IG (IGIV) 10% administered at pre-study doses for 3 months. Epoch 2: IGSC 20% administered once-weekly for 12 months at Epoch 1 doses. IgG trough levels are maintained >5 g/L. The primary endpoint is the rate of acute serious bacterial infections (SBIs). PK was evaluated in patients treated with IGIV in Epoch 1.
Results: At this time, 31 of 43 patients who started the study are in Epoch 2. Interim analysis (n=30) showed no acute SBI episodes or severe infections with IGSC 20%. Overall infection rates/patient-year: 4.6 (IGSC 20%), 8.1 (IGSC 16%) and 7.3 (IGIV). There were no serious adverse events (AEs) considered related to any treatment. All local adverse drug reactions were mild in severity; no severe drug-related systemic AEs were reported with IGSC 20%. Of 385 IGSC 20% infusions, 99.7% required no administration changes. $AUC_{IGSC20\%}/AUC_{IGIV}$ (n=9) was PK-equivalent at 83.9%. Median trough IgG levels (n=13): 8.5 g/L (IGSC 20%) and 7.5 g/L (IGIV).
Conclusion: To date, IGSC 20% has provided a well-tolerated, self-administered therapy, with no dose adjustments needed from pre-study IGIV dose. This study is ongoing to confirm IGSC 20% efficacy/safety/PK over 12 months.

P6.15.50

Tolerability, efficacy and pharmacokinetics (PK) of facilitated-subcutaneous infusion of human immunoglobulin G, 10% (IGSC) and recombinant human Hyaluronidase (rHuPH20) [IGHy] in adult patients with primary immunodeficiency (PI): results from a Phase 3 study

*M. Stein[1], R. L. Wasserman[2], I. Melamed[3], A. Rubinstein[4], J. Puck[5], S. Gupta[6], W. Engl[7], H. Leibl[7], **L. Yel**[8], R. Schiff[8];*

Background: IGHy, compared with IGSC alone, has reduced the need for multiple infusion sites and weekly IGSC dosing, and has permitted infusion rates and dosing intervals equivalent to intravenous administration (IGIV). We report a data subset, for patients aged≥18 years at study entry, from the final tolerability/efficacy/PK data of a pivotal phase 3 trial of IGHy in pediatric and adult patients with PI.
Methods: Patients were treated with IGIV for 3 months at prestudy doses and frequency. Subsequently, IgG, 10% was administered SC, at a dose that was 108% of the weekly equivalent of the IV dose, preceded by rHuPH20 infused through the same SC needle at a dose of 75U/g IgG. Patients received IGHy for 12 months.
Results: Fifty-nine patients received 985 IGHy infusions, 98% of which were completed without a change in rate due to adverse drug reactions (ADRs). Median infusion sites/month was 1.13. There were no serious ADRs. Local ADR rate was 0.286/infusion. Temporally associated systemic AE rate was 0.20/infusion for IGHy vs. 0.33/infusion for IGIV. The annual rates were 0.00 for acute serious bacterial infections and 3.20 for all infections. AUC_{IGHy}/AUC_{IGIV} was pharmacokinetically-equivalent at 91.8% (90% CI: 89.9-93.7%).
Conclusion: In patients with PI aged≥18 years, IGHy was effective and well tolerated at infusion rates comparable to prestudy IGIV administration. The majority of patients were treated every 3-4 weeks in 1 site without a rate change due to ADRs. Bioavailability (per AUC) was similar to IGIV, and significantly better compared with IGSC without rHuPH20.

Aim of the study: the aim of this study was to investigate in vitro cytotoxic activity of four methanolic crude of four Persian plant extract against panel cell lines. **Material and Methods:** Methanolic extracts were tested for their possible antitumor activity and cytotoxicity using the 3-(4,5-dimetylthiazol-2-yl)-2,5- diphenyltetrazolium bromide (MTT) assay on six cancer cell line; non-Hodgkin's B-cell lymphoma (Raji), human leukemic monocyte lymphoma (U937), Human acute myelocytic leukemia (KG-1A) cell lines, Human breast carcinoma cell line (MCF-7 cells), human prostate cancer cell line (PC3) and mouse fibrosarcoma cell line (WEHI-164) and one normal cell line; Human

umbilical vein endothelial cells (HUVEC). **Results:** All species showed dose dependent inhibition of cell proliferation. IC50 values ranging from 25.66±1.2 to 205.11±1.3 µg/ml. The highest cytotoxity activity *Chelidonium majus L> Ferulago Angulata DC> Echinophora platyloba DC> Salvia officinalis L*, respectively. **Conclusion:** all extracts demonstrate promising cytotoxity activity as a natural resource for future bio-guided fractionation and isolation of potential antitumor agents.

Cancer is a disease that is characterized by too little apoptosis. Understanding apoptosis regulation is a main concern in the development of chemotherapeutic anticancer drugs on malignant cells. *Echinophora platyloba DC* plant is one of the indigenous medicinal plants in Iran. The objective of this study was to examine the in vitro cytotoxic activity and the mechanism of cell death of crude methanolic extracts of *E. platyloba*, on WEHI-164 cell line. Cytotoxicity and viability of methanolic extract was assessed by 3- (4, 5-dimethylthiazol-2-yl) - 2, 5-diphenyltetrazolium bromide (MTT) and dye exclusion assay. Cell death detection was employed to quantify the nucleosome production during apoptosis. The cell death was confirmed as apoptosis using terminal deoxynucleotidyl transferase-(TdT) mediated dUTP nick end labeling (TUNEL) assay and DNA fragmentation (Gel Electrophoresis). Semi-quantative RT PCR was used to evaluate the mRNA expression levels of c-myc, Bcl2, and caspase 3 in WEHI-164 cells. Our results demonstrated that the extract decreased cell viability, suppressed cell proliferation, and induced cell death in a time- and dose dependent manner in WEHI-164 cells when compared with a chemotherapeutic anticancer drug, Toxol. Observation proved that apoptosis was the major mechanism of cell death. WEHI-164 cell death elicited by the extract was found to be apoptotic in nature based a clear indication of DNA fragmentation and TUNEL assay, which are a hallmark of apoptosis. Furthermore, RT-PCR analysis showed that the extract induced apoptosis in WEHI-164 cells by activating Caspase-3 and down-regulating Bcl-2.

Ferulago Angulata (FA), also known as Chovir, is an indigenous plant, which has been used in Persian medicinal herb therapy. Although recent studies have demonstrated its anti-tumor activities on cancer cells in vitro, the exact mechanism is not completely explained. Furthermore, the objective of this study was to examine the in vitro cytotoxic activities of methanolic extract prepared from Ferulago Angulata (FA) on prostate cancer (PC3), fibrosarcoma (WEHI-164), B-cell lymphoma (Raji), human leukemic monocyte lymphoma (U937), Human acute myelocytic leukemia (KG-1A) and Human Umbilical Vein Endothelial (HUVEC) cell lines using a Micro-culture tetrazolium test (MTT) cytotoxicity assay, and to test whether the mechanism involves induction of apoptosis. Cell death ELISA was applied to quantify the nucleosome production subsequent nuclear DNA fragmentation during apoptosis. Results have shown that methanolic extract at 50 to 800 µg/ml dose-dependently suppress the proliferation of WEHI-164, PC3, Raji, U937 and KG-1A cells by more than 80% ($p < 0.01$), with ascending order of IC50 values in 24h : WEHI-164 > PC3 > KG-1A > U937 > Raji. The extract did not exert any significant cytotoxic effect on normal cell line HUVEC (IC50 > 800 µg/ml). Nucleosome productions in WEHI-164, PC3, Raji, U937 and KG-1A cells were significantly increased by 8-fold respectively upon the treatment of FA extract, while no significant nucleosome production was detected in extract-treated HUVEC cells. The FA extract was found to selectively and dose-dependently inhibit the proliferation of lymphoma and leukemic cells possibly via an apoptosis-dependent pathway.

Immunosuppressive and anti-inflammatory properties of pyrimidine derivatives

Z. Zidek[1]*, E. Kmonickova*[1]*, Z. Janeba*[2]*, V. Kolman*[2]*, P. Jansa*[2]*;*
[1]*Inst. Experimental Medicine, Acad. Sci., Prague, Czech Republic,* [2]*Inst. Organic Chemistry and Biochemistry, Acad. Sci., Prague, Czech Republic.*

We synthesized novel C5-substituted pyrimidine analogues belonging to the groups of 2-amino-4,6-dihydroxypyrimidines (I), 2-amino-4,6-dichloropyrimidines (II), 4,6-dichloro-2-[(*N*,*N*-dimethylamino)methyleneamino]pyrimidines (III), and 4,6-dichloro-2-formamidopyrimidines (IV). The C5 substituents were represented by hydrogen (1), isopropyl (2), allyl (3), butyl (4), *sec*-butyl (5), and benzyl (6). The immunobiological properties of compounds were screened under the *in vitro* conditions using mouse and rat peritoneal macrophages ($2x10^6$/ml; 24-h culture in RPMI-1640 medium; the concentration of compounds being 50 µM). The effects were found to be closely dependent on the structure of analogues. Compounds from the groups III and IV proved to interfere with the immune (LPS)-activated production of nitric oxide (NO) and prostaglandin E_2 (PGE_2) that were determined by Griess reagent and ELISA, respectively. Both NO and PGE_2 were inhibited by about 90%. Many derivatives significantly reduced secretion of proinflammatory cytokines IL-1β, IL-6 and TNF-α. The compounds had no effect on the viability of cells. No substantial biological significance of the C5 substituents was observed. The compounds from the group II were less effective,

reducing the production of NO by approximately 50%, and only some of them (II4, II5, II6) significantly reduced the PGE_2 production. The group I compounds were virtually biologically inactive. Compounds from the groups II and IV proved to possess anti-inflammatory activity under conditions *in vivo*. They were effective in alleviation of carrageenan-induced acute paw oedema and in substantial reduction of severity of adjuvant-induced arthritis in rats. *The research was supported by grant CZ:GA ČR:303/12/0172 from the Grant Agency of the Czech Republic.*

Slceroderma: from clinical classification to autoantibodies profile

R. M. A. Montanelli*;*
Humanitas Clinical and Research Center, Via Manzoni, 56 20089 Rozzano (MI)-Italy., Rozzano, Italy.

Background: Scleroderma (SSc) is an autoimmune condition strongly associated with the presence of antinuclear antibodies (ANA) with more than 90% of patients showing seropositivity.
Aim: We had investigated the relationship between SSc-specific autoantibodies (Aab) and clinical phenotype in monocenter patients with SSc.
Method: 97 sera of consecutive patients with diagnosis of SSc were analyzed for anticentromere (ACA), anti-Scl70, anti-RNA polymerase III, anti-U1RNP, anti-Th/To, anti-Pm/Scl, anti-Ku and anti-fibrillarin Aab using the Euroline immunoblot assay.
Results: In sera from 97 patients with scleroderma, ACA was present in 37 (38.1%), Scl70 in 22
(22.6%), RNA Pol III in 4 (4.2%), U1RNP in 20 (20.6%), Th/To in 4 (4.14%), Pm/Scl in 5 (5.3%) Ku in 3 (3.1%) anti-fibrillarin antibodies in 2 patients (2.06%).
Limited SSc (=46) were associated with ACA (n=34,74%, P < 0.001) and Th/To (=3, 6.6%)
antibodies. Diffuse SSc (=28) were associated with Scl70 (=18, 64.2%, P = 0.002) and RNA polymerase III (=4, 14.2%). Overlap syndrome (=23) were associated with U1RNP antibodies (=18, 78.2 %,P<0.001) . Significant associations between Scl70 and interstitial lung disease (9/23, 39.1%,), RNA Pol III and renal crisis (4/4 100%,), U1RNP and pulmonary hypertension (10/20, 50%) were seen. SSc patients that were anti-fibrillarin positive had severe lower gastrointestinal involvement.
Conclusions: SSc-specific ANA are associated with both clinical, organ complications and survival. Autoantibody status could confer relative protection from specific organ disease or an overall good prognosis. Clinical features in SSc are remarkably heterogeneous but grouping patients based on autoantibody profiles can be a useful approach for clinicians.

P6.16.02
Biomarkers associated with treatment failure in Kawasaki disease

J. Abe*, S. Fukuda, H. Masuda, N. Sakamoto, S. Oana, H. Kato;*
National Center for Child Health and Development, Tokyo, Japan.

[Background and Purpose] Non-response to intravenous immunoglobulin (IVIG) is a risk factor for developing coronary artery lesions (CAL) in children with Kawasaki Disease (KD). Our DNA microarray analysis on whole blood leukocytes demonstrated that IVIG influenced the gene expressions in a broad functional range favoring down-regulation. Among them, Polycythemia Rubra Vera-1 (PRV-1), a differentiating granulocyte-specific gene, was most abundantly expressed in non-responsive KD patients than in responsive patients and febrile controls. Thus we measured the protein levels of PRV-1 as well as other inflammatory cytokines in KD patients to identify biomarkers associated with IVIG non-response and CAL development.
[Methods] Plasma levels of G-CSF, IL-6, IL-8, IL-10, IL12p40, IL-17, TNF-α, IFN-γ, MCP-1, VEGF, sIL-2R, sTNFR1, sTNFR2 and protein contents of PRV-1 and intracellular phosphorylated-STAT3 were measured before and after IVIG treatment using multiple beads assay and flow cytometry, respectively.
[Results] Among 100 eligible patients, G-CSF, IL-6, sTNFR1, sTNFR2 and PRV-1 expression were significantly elevated in non-responders ($p<0.01$) and in patients who developed CAL ($p<0.01$). Logistic regression analysis showed a combination of sTNFR1 and PRV-1 to be associated with both IVIG non-response and CAL development. Using these two parameters, IVIG non-response can be predicted with 81.3% sensitivity and 78.3% specificity; CAL development with 85.7% sensitivity and 74.4% specificity.
[Conclusion] These results provide evidences for dysregulated immunological pathways in KD patients. Especially, our study suggests that sTNFR1 and PRV-1 are useful biomarkers to predict IVIG non-response and CAL development.

P6.16.03
Is Basophil Activation Test as a Safe Diagnostic Tool for Immediate Drug Hypersensitivity to Proton-Pump Inhibitors?

N. Akdeniz*[1], L. Pur Ozyigit[1], B. Ertek[2], B. Aydin[1], D. Unal[2], M. Demirturk[2], A. Gelincik[2], S. Buyukozturk[2], B. Colakoglu[2], G. Deniz[1];*
[1]Istanbul University, Institute of Experimental Medicine, ISTANBUL, Turkey, [2]Istanbul Faculty of Medicine, Division of Allergy, Department of Internal Medicine, Istanbul University, ISTANBUL, Turkey.

Declared immediate hypersensitivity (HS) reaction to widely used proton pump inhibitors (PPIs) are rare but can be life-threatening. For the diagnosis, skin tests have limited sensitivity and the oral provocation test (OPT) is not devoid of risks.
This study assessed the reliability of an *in vitro* test, flow cytometry-assisted basophil activation test (BAT) as a safe diagnostic method for PPIs-induced HS.
The BATs were performed in 7 patients with immediate PPI HS reactions and in 6 specimens from healthy volunteers tolerating these drugs. Heparinized whole blood samples from all subjects were stimulated with diluted various PPI solutions and allergen derivatives. The basophils of samples were labeled with PE conjugated anti-CD203c. The basophils were detected by FACSCalibur. Results of the test are considered positive when the difference within activated basophils of the patient and negative control is greater than or equal to 15%.
Patients with HS to PPIs were predominantly presented with an urticaria or angioedema (%70), the indicated allergy was with lansoprozole for six cases, with esomeprazole with one case. The test remained negative for all the controls tolerating PPIs, but positivities for the culprit PPI (lansoprazole: 33%) were present for allergic patients. BAT results were compared with patients' histories and skin tests.
BAT is a rapid, safe and useful additional method for diagnosis of hypersensitivity reactions and this study is the first, to our knowledge, reporting its use in PPI hypersensitivity.

P6.16.04
HLA-G 14-bp Deletion/Insertion, 3003C/T, 3010C/G and 3027A/C polymorphisms in HTLV-1 infection

D. C. C. Alves*[1], M. Rocha-Júnior[2], R. Haddad[3], W. Virginia[4], O. Takayanagui[1], D. Covas[5], S. Kashima[6], E. A. Donadi[1];*
[1]Faculdade de Medicina de Ribeirão Preto - USP, Ribeirão Preto, Brazil, [2]Fundação Hemocentro de Ribeirão Preto and Faculdade de Ciências Farmacêuticas de Ribeirão Preto - USP, Ribeirão Preto, Brazil, [3]Universidade de Brasília, Faculdade de Ceilândia – UNB/FCE, Ribeirão Preto, Brazil, [4]Fundação Hemocentro de Ribeirão Preto – USP, Ribeirão Preto, Brazil, [5]Fundação Hemocentro de Ribeirão Preto and Faculdade de Medicina de Ribeirão Preto - USP, Ribeirão Preto, Brazil, [6]Fundação Hemocentro de Ribeirão Preto and Faculdade de Ciências Farmacêuticas de Ribeirão Preto – USP, Ribeirão Preto, Brazil.

The most of HTLV-1 infected patients remain asymptomatic (HAC) throughout life, and the risk factors associated with the development of related diseases, such as HAM/TSP and ATL, are not fully understood. The human leukocyte antigen-G molecule (HLA-G), is expressed in several pathological conditions, and is related to

immunosuppressive effects that allow the virus-infected cells to escape the antiviral defence of the host. In this work, we evaluated the correlation between HLA-G polymorphisms in symptomatic and asymptomatic HTLV-1 infected patients. Four polymorphisms of the exon 8 of the HLA-G gene were analysed by gene sequencing in 46 HAC and 42 HAM HTLV-1 infected patients and 155 healthy control patients. HTLV-1 infected patients group showed higher frequency of the 14-bp D/I genotype, responsible for increased transcription of the HLA-G, than healthy control group (p=0,0642). HAC and HTLV-1 infected patients groups, compared to healthy control group, showed increased frequency of the 3003TT genotype, responsible for increased transcription of the HLA-G, (p=0,0146 and p=0,0058 respectively) and decreased frequency of the 3003CT genotype (p=0,0142 and p=0,0037 respectively). Still, HAC and HTLV-1 infected patients groups showed increased frequency of the 3003T allele and decreased frequency of the 3003C allele compared to healthy control group (p=0,0147 and p=0,0042 respectively). We found no relation among the groups in studies to 3010C/G and 3027A/C polymorphisms. In conclusion, the 14-bp D/I and 3003TT genotypes were associated with risk factor against HTLV-1 infection and 3003CT genotype was associated with protection factor against HTLV-1 infection.

P6.16.05
Different *In vitro* profiles of biologicals in human PBMC lymphocytes activation assay

***F. Andreetta**, E. Vicentini, F. Zanderigo, E. Zambello, J. Chappell;*
Aptuit Verona, Verona, Italy.

The development of biopharmaceuticals which includes recombinant proteins and monoclonal antibodies, has been on the increase due to the commercial success of many biological products. Regulatory agencies have become interested in potential invitro assays using human cells that may predict immunotoxic and immunostimulatory events in humans especially after the Tegenero incident in London. Aim of this work was to develop *in vitro* assays to characterize and potentially predict the activation of human PBMC lymphocytes induced by different biological compounds. Human PBMC were isolated from different donors and culture in the presence of different biologicals. At different time points, cytokines release involved in the innate and adaptive immunity were measured in medium by quantitative immunoassay and in parallel, the expression of lymphocytes activation markers, CD69, CD25, HLA-DR were also assessed by flow cytometry. Biologicals showed a concentration-dependent release of cytokines in medium with a different profile of response in term of type of cytokine released and the concentration in the medium compared to vehicle treated cells. Some biologicals showed also an activation of lymphocytes activation markers with an effect that was dependent to the time of incubation. In conclusions, different kind of biologicals were tested to human PBMC lymphocytes activation assay. Biologicals showed to induce a release of cytokines and/or an increase of lymphocytes activation markers expression with a profile that reflect their biological interaction with innate or adaptive immunity. This *in vitro* assay was then suitable to predict a possible immunostimulatory effect of biological compounds in human lymphocytes.

P6.16.06
Standardization of ELISPOT counts for accurate assessment of human T cell responses performed by 10 different laboratories

***T. Ansari**, A. Y. Karulin, P. V. Lehmann, S. Sundararaman;*
Cellular Technology Limited, Shaker Heights, OH, United States.

Introduction: There are a defined number of T cells specific for any given antigen within a PBMC pool. However, an accurate and reproducible method to measure this response, between different laboratories has been controversial. In ELISPOT assays, antigen-induced spots show a broad spectrum of sizes and densities over variable background. Therefore, even for experienced investigators using ELISPOT analysis software, it is difficult to judge the minimal spot size/density to be counted, and the gates for upper threshold to distinguish single cell-derived spots vs. clusters.
Methods: We studied PBMC plated in serial dilutions, with 24 replicates per dilution, to establish the distributional properties of IFN-γ ELISPOTS elicited by antigens with defined HLA-Class I or Class II restriction. We also sent ELISPOT plates, and image files of such, to 10 different laboratories for independent counting. The plates were machine counted by each laboratory relying on the subjective counting parameters assessment by different investigators, and by the statistics-based auto-gating method in conjunction with auto-threshold algorithm.
Results: Both these CD8- or CD4 cell-derived spots were found to closely follow log-normal distribution. These log-normal distributional properties of ELISPOTs permit to set the lower and upper gates for counting by means of statistics, automatically, with a 95% confidence interval.
Conclusions: While counts based on judgment call of the investigator showed considerable variability, the counts obtained in the laboratories by the statistic gating method were comparable to each other and thus establishes the prospect of harmonizing ELISPOT counting.

P6.16.07
A novel mechanism for recognition of a small molecule carbohydarte immunotherapeutic by human myeloid cells: Potential for modulation of efficacy in the clinic

***M. A. Antonysamy**, M. I. Nelson, R. Walsh, N. R. Ottoson, B. Rathmann, W. Grossman;*
Biothera, Eagan, MN, United States.

Imprime PGG® (Imprime), is a soluble β-1,3/1,6 immunomodulatory glucan, being developed in combination with monoclonal antibody therapy for multiple oncologic indications. To date, limited studies exist on the recognition and immunomodulatory activities of soluble glucans on the human immune system. Although yeast β-glucans have been shown to be capable of binding human cells through leukocyte complement receptor 3 (CR3, Mac-1, αM β2 integrin), the key components for this event were not elucidated. Here, we demonstrate that Imprime, a soluble carbohydrate pathogen associated molecular pattern (PAMP), is recognized by only certain human cells expressing CR3 (i.e., bind to CR3-expressing myeloid and T cells, but not to CR3 expressing NK cells) and requires opsonization by complement components such as iC3b. Inactivation of serum complement components resulted in loss of binding and function. Surprisingly, not all healthy donor myeloid cells were capable of binding Imprime despite the presence of complement components. Looking into potential reasons for differential binding led to a strong correlation between being a high-Imprime binder and having a high-natural receptor anti-β glucan titer. Both, in vitro and in vivo feasibility studies in human demonstrate the potential for converting a low-Imprime binder to a high-binder with anti-β glucan antibodies. Given the preclinical requirement for Imprime binding to myeloid cells for antitumor effects, we propose that assessing Imprime binding to blood immune cells could be a predictive biomarker, and enriching for high-binder patients or converting low-binders to high-binders by treating with high-titer plasma or IVIG, would enhance therapeutic efficacy.

P6.16.08
Surface Plasmon Resonance Imagery-based strategy to study hnRNPA2/B1 peptides as specific biomarkers in systemic lupus erythematosus, rheumatoid arthritis and autoimmune hepatitis

*E. Beleoken[1,2], H. Leh[3,4], **E. De Martin**[1,2], C. Johanet[1,5,6], D. Samuel[7,1,2], J. Duclos-Vallée[1,2,7], M. Buckle[4,3], E. Ballot[5,1,2];*
[1]INSERM, Unité 785, Villejuif, France, [2]Univ Paris-Sud, Unité Mixte de Recherche en Santé 785, Villejuif, France, [3]Institut d'Alembert, Laboratoire de Biologie et Pharmacologie appliquées (LBPA), Cachan, France, [4]CNRS - ENS Cachan, UMR 8113 Laboratoire de biologie et pharmacologie appliquée, Cachan, France, [5]AP-HP, Hôpital Saint Antoine, Immunologie et Hématologie Biologiques, Paris, France, [6]Université Pierre et Marie Curie, UFR 967 Faculté de Médecine, Paris, France, [7]AP-HP, Hôpital Paul Brousse, Centre Hépato-Biliaire, Villejuif, France.

Heterogeneous nuclear ribonucleoprotein (hnRNP) A2/B1 is one of antinuclear autoantibodies targets in systemic lupus erythematosus (SLE), rheumatoid arthritis (RA), and autoimmune hepatitis (AIH).

Aim. To monitor molecular interactions between peptides spanning the entire sequence of hnRNP and sera from patients and healthy controls.
Methods. Sera from 8 patients from each pathology and controls were passed across a Surface Plasmon Resonance Imagery (SPRi) surface containing 39 overlapping peptides of 17 mers covering the human hnRNP B1. Interactions involving the immobilised peptides were followed in real time and the dissociation rate constant koff for each interaction were calculated.
Results. Several significant interactions were observed: i) high stability (lower koff values) between P55-70 and the AIH sera compared to controls (p= 0.003); ii) less stability (higher koff values) between P118-133 and P262-277 and SLE sera, P145-160 and RA sera compared to controls (p=0.006, p=0.002, p=0.007). The binding curves and koff values observed after the formation of complexes with anti-IgM and anti-IgG antibodies and after nuclease treatment of the serum indicate that i) IgM isotypes are prevalent and ii) nucleic acids participate in the interaction between anti-hnRNAP B1 and P55-70 and also between controls and the peptides studied.
Conclusions. These results indicate that P55-70 of hnRNP B1 is a potential biomarker for AIH in immunological tests and suggest the role of circulating nucleic acids, (eg miRNA), present or absent according to the autoimmune disorders and involved in antigen-antibody stability.

P6.16.09
A novel cell-based assay for measuring neutralizing autoantibodies against type I interferons in patients with autoimmune polyendocrine syndrome type 1

***L. Breivik**, E. Bratland, A. Hellesen, B. Oftedal, A. S. Bøe Wolff, E. S. Husebye;*
University of Bergen, Bergen, Norway.

Autoimmune polyendocrine syndrome type 1 (APS-1), also known as autoimmune-polyendocrinopathy-candidiasis-ectodermal dystrophy (APECED) is a unique monogenic disorder caused by loss-of-function mutations in the autoimmune regulator (AIRE) gene. The loss of a functional AIRE protein presumably causes defects in central thymic tolerance and the escape of pathogenic autoreactive T cells into peripheral tissues. The most prevalent clinical manifestations are chronic mucocutaneous candidiasis, hypoparathyroidism and primary adrenocortical failure although a wide range of other autoimmune manifestations may occur. An important characteristic feature of APS-1 is the presence of neutralizing serum autoantibodies against type I interferons (subtypes -α and -ω) at frequencies approaching 100 %. These autoantibodies may therefore serve as an important diagnostic tool, complementing genetic mutation analysis of AIRE when APS-1 is suspected. Several techniques for measuring these antibodies are currently available, including fluid-phase binding assays using recombinant antigens labeled with radioactivity or luciferase, and assays measuring the actual interferon-neutralizing capabilities of the antibodies such as the antiviral interferon neutralizing assay (AVINA). We report here on a novel cell-based assay using a commercially available reporter cell-line that provides a simple, rapid and reliable way of assaying autoantibodies against type I interferons.

P6.16.10
Increased circulating levels of leukocytes, lymphocytes and atypical lymphocytes in patients with dengue hemorrhagic fever

*A. I. V. Fernandes[1], F. J. Rolim[1], L. H. Simões[1], **L. R. Castellano**[2];*
[1]Division of Infectious Diseases, Hospital Universitário Lauro Wanderley, Universidade Federal da Paraíba, João Pessoa Paraíba, Brazil, [2]Escola Técnica de Saúde da UFPB, João Pessoa Paraíba, Brazil.

Dengue hemorrhagic fever (DHF) is a severe clinical manifestation of dengue virus infection in tropical areas worldwide. Diverse hematological parameters have an important diagnostic value in case definition. Here we evaluated the potential usefulness of leukocytes (Lk), lymphocytes (Ly) and atypical lymphocytes (aLy) counting in dengue classification and prognosis. Patients (n=554) attending Dengue Medical Service of the UFPB University Hospital between 2009-2011 were prospectively enrolled. They were grouped as Dengue Fever (DF, n=) or DHF (n=) according to WHO1997 classification. Blood samples were collected on days 5, 7 and 10 after start of disease symptoms and proceeded to cell counting. At d5 and 7, patients with DHF I&II presented higher numbers of Lk, Ly and aLy than DF patients. At d10, DHF I&II still showed higher numbers of Lk and Ly but not aLy than DF. Patients with DHF III presented higher levels of aLy at d5 and Lk at d7 than DF patients. No differences were observed between DHF I&II and DHF III patients. Moreover, DF patients showed lower numbers of Ly and aLy at d5 compared to d7 and d10, while DHF patients presented lowest levels of Ly at d5 but the highest levels of aLy at d7. Although significant differences on cell numbers could be observed between DF and DHF during follow-up, this experimental determination seemed not to be useful in dengue prognosis as determined by ROC curves. The differential cell counting observed between DF and DHF patients suggests their important role in disease progression.

P6.16.11
Cancer Testis Antigens Expression: Sex and Multiple Myeloma

***M. Chiriva-Internati**[1], L. Mirandola[1], Y. Yu[1], M. Jenkins[2], J. A. Figueroa[1], E. Cobos[1];*
[1]Texas Tech University Health Sciences Center, Lubbock, TX, United States, [2]Texas Tech University Health Sciences Center and The Laura W. Bush Institute for Women's Health, Lubbock, TX, United States.

Background: Multiple myeloma (MM) is a cancer of plasma cells wherein aberrant cells accumulate in the bone marrow leading to bone damage and interference with normal blood cell production. Although MM remains incurable, it is treatable, and early detection is the key to avoiding permanent damage. Cancer Testis Antigens (CTAs) are a class of proteins that are expressed in gametogenic tissue but generally not in the somatic tissue of healthy adults. However, a number of cancer types have been shown to produce these proteins and their expression has been correlated with malignancy. Ropporin is a specific CTA shown to be associated with MM, and this protein represents a potential target for MM diagnosis as well as immunotherapy.
Objectives: Here we examine the impact of gender on the expression of the CTA, Ropporin, in MM patients.
Methods: The expression of the CTA, Ropporin, in MM patients was analyzed using PCR, ELISA, and immunohistochemistry.
Results: In a cohort of 34 MM patients (23 male and 11 female, 44% were positive for ropporin. Of the ropporin-positive group, 65% were female while 28% were male. In addition, 90% of the female ropporin-positive group were deceased.
Conclusion: Our results provide for the first time indications that sex can shift the expression of CTA and possibly the prognosis for female MM patients. Further studies in a large cohort of patients are warranted to validate the correlation of CTA/ropporin in MM patients and sex.

P6.16.12
Cancer treatment and diagnosis using cancer testis antigens for multiple myeloma

***M. Chiriva-Internati**, L. Mirandola, Y. Yu, F. Hardwicke, N. D'Cunha, L. Tijani, D. D. Nguyen, J. A. Figueroa, E. Cobos;*
Texas Tech University Health Sciences Center, Lubbock, TX, United States.

Despite recent improvements in standard pharmacological treatments of multiple myeloma (MM), immunotherapy may prove to be more effective due to its higher specificity and lower toxicity. Cancer testis antigens (CTAs) are a family of proteins with testis-restricted expression that are not present, or barely present, in other tissues, but are associated with many tumors. Here we characterized the expression of two novel MM CTA, Ropporin and AKAP4, in tumor plasma cells from patients and cell lines. We showed that Ropporin and AKAP4 are strongly immunogenic and are therefore potential targets for effective MM vaccines. Additionally, because of their preferential expression in tumor cells, Ropporin and AKAP4 are outstanding biomarkers for tumor detection and monitoring in vivo. Recently, a modified NOD strain, carrying disrupted Rag1 and the

IL2-R γ chain genes (NOD-Rag1null/IL2rgnull, NRG), has been reported to tolerate higher levels of radiation compared with NOD/SCID strain and to allow for efficient engraftment of human tumors and HSC. The development of successful animal models for MM also relies on the choice of the biomarkers used to track the disease course and to identify tumor cells. Here we used the NRG strain to establish an innovative model of MM, allowing for the growth and the spread of MM cell lines and primary patients' cells, which can be monitored by using AKAP4 as a tumor biomarker.

P6.16.13
The cancer/testis antigens, SP17, AKAP4, and PTTG1 are expressed in non-small cell lung cancer: new biomarkers and vaccine targets

***M. Chiriva-Internati**, L. Mirandola, Y. Yu, C. Jumper, R. Alalawi, J. A. Figueroa, E. Cobos;*
Texas Tech University Health Sciences Center, Lubbock, TX, United States.

Cancer testis antigens (CTA) are a class of tumor associated antigens, showing a restricted expression in cancer, strong immunogenicity, and weak expression in normal tissues. SP17/AKAP4/PTTG1 have been previously investigated, showing promising results as a target antigens (Chiriva-Internati et al, 2001; 2003; 2008; 2010; 2011). Our aim was to investigate the expression of Sp17/AKAP4/PTTG1 in lung cancer patients. We analyzed two lung cancer cell lines, one normal bronchus cell line, a panel of normal tissues and patient's cells by RT-PCR, flow-cytometry, immunocytochemistry (ICC), and immunofluorescence (IF). CTA immunogenicity was investigated by measuring circulating specific antibodies in the sera of lung cancer patients ELISA analyses show the presence of circulating CTA-specific antibodies in the sera of lung cancer patients, indicating the immunogenicity of SP17, AKAP-4 and PTTG1. We showed that CTA, SP17, AKAP-4 and PTTG1 can be detected in both sera and tissue of patients with NSCLC. Furthermore, CTA can elicit an immunogenic response in patients affected with this disease.

P6.16.14
Proteomic analysis of aqueous humor from uveitis patients

***P. Choopong**, N. Tesavibul, V. Thongboonkerd;*
Siriraj Hospital, Mahidol University, Bangkok, Thailand.

Introduction: Uveitis is an ocular inflammatory condition that is one of the leading causes of irreversible blindness worldwide. However, the study in immunopathogenesis is limited and how overt inflammation arises in this immune privilege site is not clearly understood. The proteomic study could lead to a global understanding of proteins involved in the pathogenesis of the disease. We hereby performed proteomic analysis of aqueous humor to detect proteins involved in uveitis.
Method: Proteome of aqueous humor from 15 uveitis patients were analyzed in comparison to those from 30 non-inflammatory cataract patient controls. Proteins from 2 groups of samples were resolved by two-dimensional gel electrophoresis and the results were compared. The protein spots found in uveitis but not control samples were then further analyzed by tandem mass spectrometry and matched with NCBI database for protein identification.
Results: Five different protein spots were found only in uveitis samples but not in controls. Further analysis by tandem mass spectrometry identified two proteins including uromodulin and plasma serine protease inhibitor.
Conclusion and Perspective: Uromodulin and plasma serine protease inhibitor were identified as proteins found in uveitis but not in controls suggesting their potential roles in the pathogenesis of uveitis. Further functional studies are needed to delineate their roles in this disease.

P6.16.15
Intracellular modulation, extracellular disposal and serum circulating increase of miR-150 upon lymphocyte activation

***P. de Candia**[1], A. Torri[1], T. Gorletta[1], E. Bulgheroni[1], M. Fedeli[2], L. Romanò[3], S. Esposito[4], G. Casorati[2], M. Pagani[1], S. Abrignani[1];*
[1]INGM, Milan, Italy, [2]Experimental immunology Unit; Division of Immunology; Transplantation and Infectious Diseases; San Raffaele Scientific Institute, Milan, Italy, [3]Department of Biomedical Sciences for Health, University of Milan, Milan, Italy, [4]Department of Pathophysiology and Transplantation, University of Milan, Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Milan, Italy.

Activated lymphocytes release a large amount of nano-sized vesicles (or exosomes), containing microRNA (miRNA) that may be monitored non-invasively in the bloodstream. We have evaluated whether lymphocyte activation in vitro results in selective extracellular release of miRNAs, and consequently whether elicitation of immune responses by vaccination in vivo is followed by changes in the serum levels of lymphocyte-specific miRNAs. We have found that, upon activation in vitro of both human and mouse lymphocytes, miR-150, a key regulator of lymphocyte differentiation and functions, gets dramatically down-modulated at the intracellular level and in parallel accumulates in extracellular vesicles. Upon activation of immune responses in vivo, in both adults and infants vaccinated with an adjuvanted flu vaccine and in mice immunized with adjuvanted ovalbumin, miR-150 serum levels increased significantly. Notably, this increase was enriched in purified circulating nano-sized vesicles, while was not recordable in purified larger vesicles, suggesting an exosome specific phenomenon. The increase in the serum level of miR-150 post-immunization correlated with elevation of antibody titers, and immunizations of immunodeficient mice resulted in little or no elevation of circulating miR-150, demonstrating that increase in the serum level of miR-150 depends on the elicitation of immune responses. We thus provide proof of concept that serum-miRNAs can be searched as non-invasive biomarkers of adaptive immune responses. Finally, the fact that activated lymphocytes reduce the intracellular levels of miR-150 while releasing it in the external milieu suggests that extracellular disposal of selected miRNAs can be an additional way to regulate gene expression during lymphocyte differentiation.

P6.16.16
Identification of biomarkers associated with treatment for latent tuberculosis by microarray

***E. de Oyarzabal**[1], T. Herrera[1], L. Orozco[2], C. Rangel-Escareño[2], L. Ferreyra-Reyes[3], P. Cruz-Hebert[3], L. Garcia-Garcia[3], R. J. Wilkinson[4], E. Sada[1], M. Torres[1];*
[1]Instituto Nacional de Enfermedades Respiratorias Ismael Cosio Villegas, Mexico, Mexico, [2]Instituto Nacional de Medicina Genomica, Mexico, Mexico, [3]Instituto Nacional de Salud Publica, Cuernavaca, Mexico, [4]Imperial College, London, United Kingdom.

Latent tuberculosis (LTB) is characterized by a positive tuberculin skin test (TST) or IFN-γ release assay (IGRA). The risk for TB reactivation is estimated as 10% for lifetime, but the risk is greater in immunocompromised persons. Treatment with isoniazid (INH) is recognized as the standard therapeutic agent in LTB infection. However, the effect of treatment on immune response genes potentially involved in reactivation or protection is not known. With the aim of assessing biomarkers associated with treatment of LTB, we investigated 27 TST positive individuals with documented contact with TB cases who received INH treatment using microarrays. Genome-wide transcriptional profiles were generated from whole-blood RNA obtained before, 1 month and after INH treatment. A distinct 202-transcript signature was defined in individuals with INH treatment using a combination of expression-level and statistical filters and hierarchical clustering. Normalizing across arrays, from 202-transcript signature, 124 genes were downregulated while 78 upregulated as compared to baseline (14.3% (at 1 month post-treatment); 30.19% (at 6 months post-treatment); 55.5% throughout treatment, fold change ≥1.2, p value 0.01. Our study provides a broad range of transcriptional biomarkers with potential as treatment prognostic tools. The biomarkers candidates include: CCR8, CXCR5, CXCL-10, IFNα, IFN-γ, IL-6, IL-13, IL-17C and IL-23R. Biomarkers candidates were validated by qRT-PCR. INH modifies the LTB

signature, it potentially indicating a reduction in risk of active disease. These data improve our understanding of LTB-immune host genes interactions and may offer future leads for biomarkers of treatment efficacy.

P6.16.17
Novel monoclonal antibodies against human Carbonic Anhydrase XII, a potential biomarker of tumor cells

D. Dekaminaviciute[1], *R. Lasickiene*[1], *M. Zilnyte*[1], *V. Jogaite*[1], *V. Michailoviene*[1], *S. Parkkila*[2], *D. Matulis*[1], *A. Zvirbliene*[1];
[1]*Institute of Biotechnology, Vilnius University, Vilnius, Lithuania,* [2]*Institute of Biomedical Technology, University of Tampere, Tampere, Finland.*

Carbonic anhydrases (CAs, EC 4.2.1.1) are zinc enzymes that catalyse the reversible hydration of carbon dioxide to bicarbonate. CAs have important physiological and pathological functions in human organism. CA IX is well-recognized tumor marker. Recently, the association of CA XII with human cancers has been demonstrated. The CA XII is a transmembrane protein with an extracellular catalytic domain. It is involved in tumor progression by acidification of the extracellular milieu and regulation of intracellular pH. Recent studies indicate that CA XII is aberrantly overexpressed in breast, cervix, brain cancers, renal carcinomas. Therefore, CA XII might be considered as a useful biomarker of tumor cells and a promising target for specific therapies. The aim of the current study was to develop new monoclonal antibodies (MAbs) against human recombinant CA XII and evaluate their diagnostic potential.
Seven stable hybridoma cell lines producing IgG antibodies against human CA XII were generated. The MAbs were highly specific to CA XII and did not cross-react with other human recombinant CAs. In order to demonstrate the diagnostic value of the MAbs, they were employed for the IHC staining of CA XII in human tumor tissue specimens. The MAbs demonstrated a strong and specific reaction with colon and renal carcinoma specimens and did not show any unspecific background staining of the respective normal tissues. Flow cytometry analysis revealed a specific immunostaining of CA XII in human tumor cell lines.
The newly developed MAbs represent a promising diagnostic tool for the immunodetection of CA XII-expressing tumor cells.

P6.16.18
Tertiary lymphoid structures have features of an ongoing humoral immunity with a benefit for lung cancer patients

M. Dieu-Nosjean[1,2,3], *F. Tamzalit*[1,2,3], *C. Germain*[1,2,3], *A. Lepelley*[1,2,3], *R. Remark*[1,2,3], *A. Lupo*[1,3,4], *D. Damotte*[1,3,4], *P. Validire*[1,5], *W. Fridman*[1,3,6], *C. Sautès-Fridman*[1,3,2];
[1]*UMRS872 INSERM, Cordeliers Research Center, Paris, France,* [2]*Université Pierre et Marie Curie, Paris, France,* [3]*Université Paris Descartes, Paris, France,* [4]*Department of Pathology, Hotel Dieu Hospital, AP-HP, Paris, France,* [5]*Department of Pathology, Institut Mutualiste Montsouris, Paris, France,* [6]*Department of Immunology, European Georges Pompidou Hospital, AP-HP, Paris, France.*

It is now well established that immune responses can take place at distance of secondary lymphoid organs, in tertiary lymphoid structures (TLS). We have previously shown that such structures can develop in human lung cancer (LC), and may represent an activation site for tumor-specific T cells. The aim of this study was to determine whether a protective humoral immunity can take place within TLS.
We showed that B-cell follicles of TLS present the same cellular composition and organization as in lymph nodes, with all B-cell differentiation stages. The somatic mutation and isotype switching machineries were activated in these B-cell follicles. Intra-tumoral PNAd+ high endothelial venules were exclusively associated with TLS. The PNAd+ ligand, CD62L, was selectively detected on TLS B cells except by germinal center B-cells, as reported for lymph nodes. CXCR5 expression decreased on fully differentiated B cells, a known key regulatory process that allows effector cells to leave CXCL13+ germinal centres. In a retrospective study, the density of TLS B cells was associated with a favorable clinical outcome in patients with early-stage LC. More interestingly, combination of both markers of APC (mature dendritic and B cells of TLS), indicated that they are strongly correlated with long-term survival for patients with early-stage LC and patients with advanced-stage of LC treated by neo-adjuvant-chemotherapy.
Altogether, TLS may represent an active site for the initiation of a protective humoral immunity. Preliminary data on the specificity of antibodies secreted locally by intra-tumoral B cells will be discussed in the physiopathology of human LC.

Assessment the immune responses in the microenvironment of breast cancer tissues

R. Eftekhari[1], *H. Shirzad*[2], *R. Esmaeili*[3], *K. Majidzadeh*[3], *J. Hadjati*[1];
[1]*Department of immunology, school of medicine ,Tehran university of medical sciences, Tehran, Iran,* [2]*Shahrekord university of medical sciences, Shahrekord, Iran,* [3]*Iranian Center for Breast Cancer (ICBC); Academic Center for Education, Culture and Research (ACECR), Tehran, Iran.*

Introduction: Breast cancer is the most prevalent cancer among women. Several therapeutic approaches such as immunotherapy have been suggested for cancer therapy. However, immunotherapy approach is not very effective in activating immune responses against tumor antigens. It is believed that clarifying the tumor microenvironment and illustrating the type of infiltrated cells could be helpful for increasing the effectiveness of cancer immunotherapy. Therefore, this study was done to illustrate the tumor microenvironment in human breast cancer tissues.
Methods and Materials: Fifty five human breast cancer tissues from 4 stages and 11 normal tissues were collected. Subsequently, mRNA was extracted from the tissues and cDNA was synthesized. Then, the mRNA expression of 9 genes related to T helper 1(T-bet), T helper 2(GATA3), T helper17(RORC) and T regulatory(FOXP3) cells and also some inhibitory mediators of immune system (IDO,VEGF,IL-10,FASL,TGF-betta) were determined by Real time PCR method. In this study betta-actin was measured as housekeeping gene. Results: The results showed that the expression of genes related to Th1 and Th17 decreased significantly along with tumor progression. In contrast, the genes expression assessment of Treg, Th2 and also inhibitory mediators showed that the expression of these genes significantly increased in advanced stages. Conclusion: Based on the achieved results, we conclude that considerable changes in tumor microenvironment were seen during tumor progression. These changes can be used to improve the efficacy of therapeutic methods and to introduce novel biomarkers.

IgE-mediated allergies affect more than 25% of the world's population. Diagnostic tests based on natural allergen extracts are composed of relativelyill-defined mixtures of non-allergenic materials, major allergens, and cross reactive allergens, with the result that it is difficult and often impossible to precisely identify the disease-eliciting allergen, particularly in patients sensitized to more than one allergen source like milk protein. The term component-resolved diagnosis has been coined to designate diagnostic tests based on pure allergen molecules which are either produced by recombinant expression of allergen-encoding cDNAs or by purification from natural allergen sources. Materials & Methods: 64 milk allergic young infants were 7,7 ± 8,2 month old. Specific IgE toward purified milk allergens was explored with Fluorescent immune-enzymatic test (F-ELISA) and by component resolved diagnostics using milk allergen microarray: pure natural and recombinant allergen molecules have been used for this purpose. Diagnostic was approved clinically by oral challenge and with a convincing history of reactions on exposure. Positif specific IgE cutoff value measured by F-ELISA was 0,35 kUA/L.

The results obtained after IgE exploration shown that most allergic patients were ploysensitized to more than one milk allergens. Bovine milk allergen microarray demonstrates that lactoferrin present in milk in very low quantity could be a strong allergen. Thus, microarray test allow us to assess the IgE binding ability of IgE to milk allergen using reduced amount of clinical material. Component resolved diagnostics tests could be efficient and reliable test to manage, and helping in vitro diagnosis of milk protein and other food allergies .

P6.16.21
Timing of blood sampling for CD4 T-cell count influences HAART decisions

Y. B. Feyissa[1,2];
[1]*Armauer Hansen Research Institute, Addis Ababa, Ethiopia,* [2]*karolinska institute, Stockholm, Sweden.*

BACKGROUND: Variability in CD4 T-cell counts has been described for both healthy and HIV-infected persons. It may influence decisions with respect to initiation and monitoring of antiretroviral treatment.
OBJECTIVE: to measure the effect of timing of blood sampling for blood cell count measurement. METHOD: The study population consisted of 71 Ethiopian patients in an observational cohort, either being monitored prior to HAART (n = 40) or receiving HAART (n = 31) at an ART Clinic in Addis Ababa.
RESULT: The median CD4 count demonstrated significantly increasing trends from the morning (8 am) to the afternoon (4 pm), both for patients on HAART (increase of 137 CD4 cell/microl; p = 0.003) and for patients initiating HAART (increase of 56 CD4 cells/microl; p = 0.038). This trend was also observed for CD8+ and CD3+ T-lymphocytes, (initiating HAART p = 0.002 and p = 0.001; patients on HAART p = 0.015 and p = 0.004, respectively).
CONCLUSION: The implications of these findings are for the decision to start HAART or the decision to start prevention of opportunistic infections in Ethiopian patients on HAART.

P6.16.22
***ACTC1, CCR5, TNF/LTA, CCL2, IL12B, IL10, MAL/TIRAP* genes are associated to the development of Chronic Chagas disease cardiomyopathy**

A. F. Frade-Barros[1], *P. C. Teixeira*[1], *M. Baron*[1], *B. Ianni*[1], *A. C. Pereira*[1], *C. W. Pissetti*[2], *V. Rodrigues*[3], *J. Kalil*[1], *C. Chevillard*[4], *E. Cunha-Neto*[1];
[1]*Incor-FMUSP, Sao Paulo, Brazil,* [2]*Faculdade de Medicina do Triangulo Mineiro, Uberaba, Brazil,* [3]*Universidade Federal do Triangulo Mineiro, Uberaba, Brazil,* [4]*2INSERM, U906, Faculté de Médecine, Marseille, Brazil.*

Chagas disease, due to *Trypanosoma cruzi*, occurs mainly in the Americas. An estimated 300,000 new cases and 50,000 fatalities occur per year. Chronic Chagas cardiomyopathy(CCC) is an inflammatory cardiomyopathy that affects approximately 30% of infected individuals. Approximately 1/3 of patients developing CCC present a dilated cardiomyopathy, with short survival. Familial aggregation of CCC suggests that might be a genetic component to disease susceptibility.
We conduct a genetic study on a large Brazilian population.This study enrolled 315 CCC cases and 118 asymptomatic (controls) subjects. Significant associations were detected: *CCR5*(rs3176763:p=0.006 OR=1.79; rs11575815:p=0.030 OR=1.41), *TNF/LTA* (rs2844484:p=0.007OR=1.51; rs909253:p=0.035; OR=1.50), *CCL2* (rs909253:p=0.037 OR=1.56; rs2530797: p=0.028 OR=1.28), *IL12B* (rs1003199:p=0.008 OR=1.49; rs919766: p=0.007 OR=1.45), *IL10* (rs3024496: p=0.020 OR=1.47), *MAL/TIRAP* (rs8177376:p=0.004 OR=1.42). These associations are consistent with the fact patients who develop CCC display an exacerbated Th1 response and a reduced numbers of IL-10-producing and CD4+CD25+FOXP3$^+$ regulatory T cells.
Cardiac muscle alpha Actin 1 is a protein encoded by the *ACTC1* gene in humans. Proteomic analysis (by 2-D DIGE) on heart biopsies from cases and controls has shown ACTC1 proteins are underrepresented into patient heart biopsies compared to control heart biopsies (confirmed by westernblot).Significant associations were detected with 1 polymorphism located into the promoter (rs640249: p=0.006 OR=1.59). Based on linkage disequilibrium map, a promoter haplotype of susceptibility was identified (rs640249-rs641563). Functional studies done in human cardiomyocytes and an imputation analysis are ongoing to identify functional variants. We hypothesize that *ACTC1* mutations could affect sarcomere contraction and force transmission from the sarcomere to the syncytium leading to cardiomyopathy.

P6.16.23
Serological proteome analysis (SERPA) as a tool for the identification of tumor antigens capable of eliciting immune responses in chronic lymphocytic leukemia (CLL)

V. Griggio[1,2], *G. Mandili*[2], *C. Vitale*[1,2], *M. Capello*[2], *F. Novelli*[2], *M. Boccadoro*[1], *M. Massaia*[1,2], *M. Coscia*[1,2];
[1]*Dipartimento di Biotecnologie Molecolari e Scienze per la Salute, Sezione di Ematologia, Torino, Italy,* [2]*Centro di Ricerca in Medicina Sperimentale (Cerms), A.O. Città della Scienza e della Salute, Torino, Italy.*

In this study, serological proteome analysis (SERPA) was applied for the first time to identify tumor-associated antigens (Ag) capable of eliciting humoral immune responses in 35 untreated patients (pts) with chronic lymphocytic leukemia (CLL).
Proteins from CLL cells were separated to obtain proteomic maps which were blotted with autologous sera to reveal antibody (Ab)-based reactivity. To verify the CLL-specificity of recognition, 7 pts maps were also probed with sera of 7 healthy donors (HD). Ag spots were identified by Mass Spectrometry (MS). Effector responses were evaluated by IFNγ-ELISPOT upon stimulation of T cells from 6 pts and 4 HD with autologous ENOA-pulsed and control dendritic cells (DC).
Twenty-nine out of 35 CLL sera were immunoreactive and produced 145 Ag spots. By contrast, HD sera were significantly less reactive with 3 spots (p=.007). MS identified 50 different proteins recurrently recognized by autoAb. Sera from 54% of pts exhibited reactivity toward α-Enolase (ENOA). Whereas none of the HD sera was ENOA-reactive. ENOA-pulsed DC stimulated autologous T cells to secrete IFNγ in 4 out of 6 pts. This response was ENOA-specific because it was not induced by unpulsed DC and CLL-specific because IFNγ release was not induced in controls. ENOA Ab-reactivity correlates with parameters of progressive disease, higher lymphocytosis and lower platelet counts.
In conclusion ENOA is a shared Ag eliciting humoral and cellular immune responses in most CLL pts. Our results suggest that the immunoreactivity against self-Ag detected in pts with progressive disease may be the expression of a dysfunctional immune system.

P6.16.24
Impact of excipients and pH on the *in vitro* hemolysis by IgG solutions

A. Heger[1], *A. Zöchling*[1], *G. Kohla*[2], *T. Svae*[3], *J. Römisch*[1];
[1]*Octapharma PPGmbH, Vienna, Austria,* [2]*Octapharma Molecular Biochemistry, Berlin, Germany,* [3]*Octapharma AG, Lachen, Switzerland.*

Background & Objectives: In the recent years, an increased number of severe hemolytic reactions associated with the use of intravenous administered IgG solutions (IVIG) have been reported. The aim of this study was to develop an *in vitro* assay to investigate in particular the impact of excipients and the pH value on the IVIG-induced hemolysis. In addition, commercially available IVIG products were compared in this assay.
Methods: The following excipients were used: glycine and L-proline (amino acids), maltose (sugar/disaccharide) and D-sorbitol (sugar alcohol). The excipients were added to the 10% IgG solution at a final concentration of 230-290 mmol/l. In addition, eight commercially available IVIG products were tested. *In vitro* hemolysis was performed using red blood cells (RBCs) prepared from blood samples of healthy donors of different blood groups, including blood group O, Rh- donors.
Results: For all excipients tested, a significant impact of the pH value on the hemolysis was observed. Four of the IVIG products showed significant lysis of RBCs of all blood groups. IgG solutions with

maltose showed lower hemolysis than IgG solutions containing amino acids.
Conclusions: IVIG products vary in pH and concentration of different excipients used in the final formulation. Our studies showed that the kind of excipients and pH have a significant impact on RBC lysis *in vitro*, independent from (or in addition to) hemolysis caused by high haemagglutinin titers. An impact on the *in vivo* hemolysis induced by the IVIG profile cannot be excluded.

P6.16.25
Exhausted CD8 T cells in peripheral blood of breast cancer patients

J. Hernandez-Ruiz[1], *C. Lara-Gutierrez*[2], *H. Miranda-Hernandez*[2], *E. Gutierrez-Reyes*[1];
[1]*HIPAM. Experimental Medicine. UNAM. Hospital General de Mexico Dr. Eduardo Liceaga, Mexico, Mexico,* [2]*Oncology Department, Hospital General de Mexico Dr. Eduardo Liceaga, Mexico, Mexico.*

Breast cancer (BC) is the most common malignant neoplasm worldwide in women. CD8 T cells have particular importance in mediating elimination of malignant cells, but can become functionally inept. These exhausted CD8 T cells has been identified in several neoplasm but its presence in BC has been only identified in the tumor. Has not been studied whether these cells are increased in peripheral blood respect to healthy women.
Aim: Evaluate and compare the exhausted CD8 T cells in peripheral blood of BC patients and healthy women.
Methods: 48 women were included, 32 BC, 9 benign tumor and 8 healthy. After informed consent, 15 ml of peripheral blood and guided biopsy was obtained. Patients were classified in clinic stage (CS) I, II, III and IV according to clinical criteria and estrogen receptor in biopsy. Mononuclear cells were stained with MoAb against CD3, CD8, CD45RA, PD1 and TIM3. 50,000 cells were analyzed by flow cytometry. Mann-Whitney U and Spearman were used.
Results: Patients were classified in CS-I (n=6), II (n=9), III (n=10) and IV (n=7). Significant differences were found in CD3+CD8+CD45RA-PD1+ percentage between CS-I and healthy women (8.51%±1.37 vs 5.28%±1.84; p=0.035) and CS-I and III (8.51%±1.37 vs 5.87%±1.55; p=0.042). Spearman analysis revealed correlation between CD3+CD8+CD45RA-PD1+ cells and estrogen receptors (Rho=0.411, p=0.024).
Conclusions: Subpopulation CD3+CD8+CD45RA-PD1+ cells are increased in CS-I patients and have positive correlation with expression level of estrogen receptor in biopsy. This subpopulation could be used as a non-invasive tool to predict the tumor aggressiveness in breast cancer. Supported by CONACyT134341

P6.16.26
The impact of polymorphisms in the host immune response genes on the severity of chronic hepatitis C

X. S. Hoang[1,2], *M. Thelu*[1,2], *E. J. Marche*[1,2], *N. Sturm*[1,3], *V. Leroy*[1,2,4], *J. P. Zarski*[1,2,4], *P. Marche*[1,2];
[1]*Institute of Albert Bonniot, Joseph Fourier University, Grenoble, France,* [2]*INSERM-U823, Grenoble, France,* [3]*Department of pathology, Center of Hospital University of Grenoble, Grenoble, France,* [4]*Department of Gastroenterology and Hepatology, Center of Hospital University of Grenoble, Grenoble, France.*

Introduction: Polymorphisms in the host immune response genes have been shown to be associated with HCV infection outcome and treatment response. Recently, genetic variations near the IL28B gene have been identified to be associated with spontaneous and treatment-induced clearance of HCV. Therefore, in this study, we investigate the impact of polymorphisms in IL28B, IFN γ and IL10 gene with the severity of chronic hepatitis C.
Materials and methods: 54 patients were included and divided into two subgroups according to the presence or absence of hepatocellular carcinoma. For the IL28B polymorphism, we employed an *in-house* PCR-RFLP method. For the IFN γ and IL10 polymorphisms, we used method published by Dolores L.M. et al. Statistical analysis was done with SPSS 13.0 and $p < 0.05$ is significant.
Results and discussion: Distribution of IL28B, IFN γ and IL10 genotype frequency: There was a significant difference between two groups about CT, AG and TT genotype frequency of IL28B, IL10 and IFN γ gene (65.38%; 75% and 35.71% versus 28.57%; 30.76% and 3.84%) respectively, ($p < 0.05$). Using logistic regression analysis indicated that the severity of liver disease was higher in patients bearing TT genotype of both IL28B and IFN γ ($p < 0.05$). There was no significant correlation observed among IL10 genotypes ($p > 0.05$).
In conclusion, the study indicated that polymorphisms in IL28B and IFN γ gene strongly correlate with the severity of liver disease and this will be able to reach closer step to personalized medicine for treatment of hepatitis C.

P6.16.27
Peptide Microarrays with Near Zero background enable high quality and massive data production from seroscreening of autoimmune diseases

M. Huang, *Y. Lu, C. Liu, Z. Li, X. Liu, H. Ma;*
Suzhou Institute of Nano-Tech and Nano-Bionics, Chinese Academy of Sciences, Suzhou, China.

For the ability of simultaneous analysis of thousands of substances, protein/peptide microarray technology has emerged as an important tool in many fields including disease diagnosis,protemics, and drug discovery. But the high background intensity due to nonspecific protein adsorption has made the data extraction and analysis of protein/peptide microarray more complicated, and then hindered application of the technology in high throughput screening. Here we show the peptide microarray based on iPDMS, an advanced biomaterial which has the intrinsic nonfouling property, can maintain near zero background, which enable high quality and massive data production from seroscreening.
In our previous study, we found the substrate iPDMS showed excellent nonfouling property in sandwich ELISA for tumor marker detection. Here in the seroscreening by peptide microarray based on iPDMS, a maximal [IgG] of 0.5 mg mL-1 was determined to achieve near zero background without any blocking procedure. Since typical [IgG] in human serum is 10-14 mg mL-1, a minimal of 20 fold serum dilution is required. With this near zero background performance, peptide microarray has been successfully applied in epitope identification of autoimmune diseases, such as type 1 diabetes mellitus, systemic lupus erythematosus, and autoimmune thyroid disease. And we believe that peptide microarray based on iPDMS has enormous potentiality in epitope identification and clinical diagnosis of autoimmune diseases.

P6.16.28
Chronic myeloid leukemia patients in prolonged remission after interferon monotherapy have constantly active NK-cells

M. M. Ilander[1], *A. Kreutzman*[1], *P. Rohon*[2], *T. Melo*[3], *E. Faber*[2], *K. Porkka*[1], *J. Vakkila*[1], *S. Mustjoki*[1];
[1]*Hematology Research Unit Helsinki, Department of Medicine, University of Helsinki and Helsinki University Central Hospital, Helsinki, Finland,* [2]*Department of Hemato-oncology, University Hospital Olomouc, Olomouc, Czech Republic,* [3]*Hospital de S. Joao, Porto, Portugal.*

Chronic myeloid leukemia (CML) is caused by a BCR-ABL oncokinase. Without any treatment, the disease transforms to fatal acute leukemia in a few years. Before tyrosine kinase inhibitors, CML patients were treated with IFN-α, and a small proportion of patients responded well. Interestingly, about half of the responding patients were able to discontinue the treatment without disease relapse and be cured.
In this study, we aimed to analyze the function of immune cells in well-responded IFN-α treated CML patients in order to understand the putative anti-leukemic effects (IFN-ON (n=5), patients still using IFN-α; IFN-OFF (n=8), patients were off from any treatment and in remission).
Compared to healthy controls, IFN-patients seemed to have a higher amount of NK-cells (median 19.6% vs. 13.2%, p=0.11), and especially in IFN-OFF group the proportion of NK-cells was increased (23.5%, p=0.0031). The phenotype of NK-cells was

CD56DIMCD57+CD62Lneg in IFN-OFF group, whereas IFN-ON patients had more immature CD56DIMCD57-CD62L- NK-cells.
Interestingly, in IFN-α treated patients the baseline degranulation of NK-cells was higher than in healthy volunteers, but due to small number of patients, the difference was not statistically significant (p=0.13). However, especially IFN-ON patients seem to have active, degranulating NK-cells (19.4% vs. 2.8% in healthy, p=0.05). When stimulated with K562 cells, the in vitro cytotoxicity of NK-cells was poor which is in line with the excessive in vivo baseline activation. No differences were observed in the cytokine secretion. To conclude, IFN-α treated patients in remission have increased number of functionally active NK-cells, which may contribute to good response.

P6.16.29
Neutrophil gelatinase-associated lipocalin in chronic heart failure

***N. Isiksacan**, M. Koser, M. Erturk, I. Akturk, S. Yazan, M. Yildirim, V. Ornek Diker, I. Bakir;*
Istanbul Mehmet Akif Ersoy Cardiovascular Traning & Research Hospital, Istanbul, Turkey.

Introduction: Chronic heart failure (CHF) is a progressive and complicated clinical syndrome, it is mostly accompanied by chronic renal disease. Glomerular filtration rate (GFR) is decreased in 30 to 50 % of patients with CHF. NGAL, neutrophil gelatinase-associated lipocalin, which is expressed mainly from neutrophils as a response to bacterial infections in innate immunity, is a new marker for renal function. The aim of this study is to evaluate the renal functions of the patients with CHF and determining the clinic importance of NGAL parameter as a biomarker in CHF.
Material and Method: Hundred patients (mean age: 67 ± 12 years) from cardiology outpatient clinic diagnosed as CHF enrolled to this study. Creatinine, CRP, BUN and NGAL levels were measured from venous blood samples in 2 hours after collection. According to CRP results, a possible bacterial infection is excluded. All the cases received written inform on the study including Ethics Committee Approval before the study was initiated. Spearman Correlation Analysis is performed.
Results: Patients with high CRP levels were excluded and NGAL levels did not correlate with normal CRP results(r=0.093, p=0.364). A weak correlation but a statistically significance was observed between NGAL and BUN levels (r=0.293, p=0.03). Also a correlation and a highly statistically significance was found between NGAL and creatinine (r=0.520, p<0.001).
Conclusion: In this study NGAL performance was found significantly better than BUN. A good correlation between NGAL and creatinine indicates that NGAL may be a candidate biomarker for renal functions in patients with CHF.

P6.16.30
Post-traumatic Immunosuppression and its Reversal

***N. Islam**[1,2], M. Whitehouse[3], S. Mehandale[3], M. Hall[2], A. Blom[3], G. Bannister[3], J. Hinde[4], R. Ceredig[1], B. Bradley[1,2,3];*
[1]Immunology & Transplant Biology Group, Regenerative Medicine Institute, School of Medicine, National University of Ireland Galway, Galway, Ireland, [2]Shannon Applied Biotechnology Centre, Institute of Technology Tralee, Tralee, Co.Kerry, Ireland, [3]Orthopaedic Research Unit, Avon Orthopaedic Centre, Southmead Hospital, University of Bristol, Bristol, United Kingdom, [4]Department of Statistics, School of Mathematics, Statistics and Applied Mathematics, National University of Ireland Galway, Galway, Ireland.

Major trauma suppresses immune defences, and increases vulnerability to nosocomial infections by unknown mechanisms. Post-traumatic immunosuppression (PTI) is further compounded by haemorrhage, surgery, blood transfusions, sepsis and age1. Sterile surgical trauma offered an opportunity to investigate mechanisms underlying PTI. Furthermore, we observed that autologous blood salvaged from the wound site (ASB) and re-infused post-operatively reversed PTI, suggesting novel therapeutic avenues.
Two cohorts of knee arthroplasty patients were recruited; one (n=18) received no ASB whereas another (n=25) received unwashed ASB collected from the wound site within six hours after surgery. Venous bloods were taken pre-operatively and within 3-7 days post-operatively. ASB was sampled at one and six hours after surgery. Fold-changes in cytokine, chemokine and DAMP levels were analysed.
PTI was evidenced in the non-ASB cohort by suppressed pro-inflammatory (IL-1β/2/17A, IFN-γ, TNF-α) and elevated anti-inflammatory (IL-5) cytokine levels. However, PTI was reversed in the ASB cohort as evidenced by increased pro-inflammatory (IL-1β/2/17A, IFN-γ, TNF-α) and decreased anti-inflammatory (IL-4/5/9/10/13) cytokines. This phenomenon was attributed to ingredients in wound blood plasma that included DAMPS (HMGB-1, HSP-27/60/70, S-100A8/A9, α-Defensin, Annexin-A2), chemokines (IL-8, MCP-1, MIP-1α), and pro-inflammatory cytokines (IL-1β/2/6/12p70/17A, IFN-γ, TNF-α).
Thus pro-inflammatory cascades triggered within traumatised tissue involved release of DAMPs which activated inflammasomes (e.g. NALP3) and triggered cytokine and chemokine synthesis. A simultaneous anti-inflammatory process evident systemically accounted for PTI. The fact that PTI was reversed by re-infusion of ASB led us to speculate that ingredients within 'wound-cocktails' may have future application in prophylaxis against infection after major trauma.

Monocyte surface antigen expression in severe sepsis

***J. Jamsa**[1], V. Huotari[2], E. Savolainen[2], H. Syrjala[3], T. Ala-Kokko[1];*
[1]Department of Anaesthesiology, Division of Intensive Care Medicine, Oulu University Hospital, University of Oulu, Oulu, Finland, [2]Department of Clinical Chemistry, Oulu University Hospital, University of Oulu, Oulu, Finland, [3]Department of Infection Control, Oulu University Hospital, University of Oulu, Oulu, Finland.

Background:
Leukocyte immunophenotyping could improve sepsis diagnostics. Our hypothesis was that monocyte CD14, CD40, CD80 and HLA-DR antigen expressions differ between severe sepsis, non-inflammatory ICU patients and non-septic inflammation (off-pump coronary artery bypass; OPCAB).
Materials and Methods:
Monocyte CD14, CD40, CD80 and HLA-DR expressions were analyzed from 27 patients with severe sepsis, from 7 OPCAB patients and from 8 ICU patients who did not fulfill any SIRS criteria. Blood samples were collected within 48 hours from the beginning of severe sepsis or in non-SIRS patients from ICU admission and on two consecutive days (D0, D1, D2). From OPCAB patients, the first samples were taken on the day of surgery before the skin incision and on two consecutive days (D0, D1, D2). In addition 10 healthy individuals served as controls. Samples were collected, processed and analyzed by using flow cytometry as previously described [1].
Results:
The peak expression of monocyte CD40 was highest in severe sepsis patients compared to the other groups (p<0.05). In severe sepsis, CD40 expression decreased over time (p<0.05). In OPCAB group, CD40 expression slightly increased after surgery (p<0.05).
Conclusions:
Based on this study, monocyte CD40 could be helpful in distinguishing severe sepsis from non-septic inflammation and healthy controls.

Change in immune cells population following exposure to the venom from *Hemiscorpius lepturus* scorpion venom

***A. Khodadadi**[1,2], M. Pipelzadeh[1], Y. Heike[3], M. Assarehzadegan[1], B. Vazirianzadeh[1];*
[1]Ahvaz Jundishapur University of Medical Sciences,, Ahvaz, Iran, [2]cancer research center of Ahvaz Jundishapur University of Medical Sciences,, Ahvaz, Iran, [3]National Cancer Hospital, Tokyo, Japan.

Introduction: A previous study on the serum of human showed a marked increase in TNFα level in patients envenomed by *H lepturus*

scorpion. The aim of the present *in vitro* study was to assess the changes in change immune cells counts.
Method: Peripheral blood mononuclear cells (PBMC) and heparinized blood samples were exposed to 1 µg/ml of *H. lepturus* venom for 24 hr. Control samples of both preparations were treated similarly in the absence of the venom. Based on specific surface markers, identification and quantization of TC, NK, Th, activated and regulatory T cells and GITR cells was carried by flow cytometry method (BD, USA). The collected data were analyzed by WINMDI software.
Results: Following exposure to *H lepturus* venom the cytometric results for PBMC showed the following changes: a reduction of CD4/CD8 ratio (from 3.14 to 2.08), reduction in CTL cells (from 1.46 % to 089 %); regulatory cells were also reduced from 1.06 % to 0.89%. While a significant increase in Th-activated cells (from 0.21 to 0.65 %) and GITR cells (from 1.94% to 3.03%). No significant changes were observed for NK and B cells. Similar pattern of changes were observed with whole blood.
Conclusion: Besides its cytotoxic properties; the venom from this scorpion has direct immune suppressive and possible indirect immune stimulating actions which may be utilized in development of novel agents for treatment of illnesses that require immune boosting or suppressing interventions

P6.16.33
Clinical utility of interferon-γ releases assay (IGRAs) in new and retreated cases of Pott's disease at a tertiary care hospital

M. Kumar[1]*, R. Kumar*[2]*, A. K. Srivastava*[2]*, V. L. Nag*[2]*, N. Krishnani*[2]*, A. K. Maurya*[2]*, T. N. Dhole*[2]*, S. G. Babu*[1]*;*
[1]Babasaheb Bhimrao Ambedkar University, Lucknow, India, [2]Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India.

Objective:Interferon-γ release assay (IGRAs) promised a sensitive and specific diagnosis of latent and active infection of *Mycobacterium tuberculosis(M.tb)*. Therefore, the intent of this study was to appraise the clinical usefulness of Quantiferon-Gold in Tube (QFT-GIT) for diagnosis of *M.tb* infection of Pott's disease.
Method: We prospectively observed 55 clinical-radiological suspected cases of Pott's disease. They were undergone to the detection of tubercular infection and Acid fast bacilli, on QFT-GIT followed by microscopy, culture and histopathological methods. The significance was observed between new and retreated cases. The sensitivity and specificity of QFT-GIT was calculated against the combined results of all performed tests were carried out.
Results:Patients were classified into 2 groups. Group A: 24 (43.6%) were new cases and Group B: 31 (56.4%) were retreated cases. The diagnostic efficiency among group A and B were; 21(87.5%) and 19(61.3%) on QFT-GIT, 10(42%) and 10(32.2%) on microscopy, 14(58.3%) and 13(54%) on culture, 21(87.5%) and 18(58%) on histopathology were analyzed. The significant differences (pvalue <0.05) among group A and B were found by QFT-G IT and histopathology results. Moreover, we found 45 cases as a definite TB and 10 cases were negative by performed tests; on microscopy, culture and histopathology observations. Thus, the overall sensitivity was 84% and 80% specificity calculated for QFT-GIT respectively.
Conclusion:QFT-GIT revealed higher sensitivity in new cases with significant differences of retreated cases. Despite, QFT-GIT showed notable sensitivity and specificity against combined results of laboratory proven methods. Hence, we can use in routine clinical diagnosis of Pott's disease.

P6.16.34
Collagen Triple Helix Repeat Containing 1 (CTHRC1) Acts via ERK-Dependent Induction of MMP9 to Promote Invasion of Colorectal Cancer Cells

J. Kim[1]*, Y. Choe*[2]*, B. Kim*[2]*, K. Kim*[3]*, J. Kim*[2]*, S. Lee*[2]*,* ***H. Lee***[2]*;*
[1]Department of laboratory medicine, DanKook University, Chunan, Republic of Korea, [2]Korea Research Institute of Bioscience and Biotechnology, Daejeon, Republic of Korea, [3]Gyeongsang National University, Jinju, Republic of Korea.

Collagen triple helix repeat-containing 1 (CTHRC1) is known to be aberrantly upregulated in most human solid tumors, although the functional roles of CTHRC1 in colorectal cancer remain unclear. In this study, we investigated the occurrence of CTHRC1 upregulation and its role *in vivo* and *in vitro*. The expression profile and clinical importance of CTHRC1 were examined by reverse transcription-polymerase chain reaction and immunohistochemical analyses in normal and tumor patient samples. CTHRC1 was not detectable in normal tissues, but was highly expressed in tumor specimens. CTHRC1 upregulation was significantly associated with demethylation of the *CTHRC1* promoter in colon cancer cell lines and tumor tissues. Clinicopathologic analyses showed that nodal status and expression of CTHRC1 (95% CI 0.999-3.984, p=0.05) were significant prognostic factors for disease-free survival. Promoter CpG methylation and hypermethylation status were measured by bisulfite sequencing and pyrosequencing analysis. Furthermore, we showed that overexpression of CTHRC1 in the SW480 and HT-29 cell lines increased invasiveness, an effect mediated by extracellular signal-regulated kinase (ERK)-dependent upregulation of matrix metalloproteinase 9 (MMP9). Consistent with this, we found that knockdown of CTHRC1 attenuated ERK activation and cancer cell invasivity. These results demonstrate that CTHRC1 expression is elevated in human colon cancer cell lines and clinical specimens, and promotes cancer cell invasivity through ERK-dependent induction of MMP9 expression. Our results further suggest that high levels of CTHRC1 expression are associated with poor clinical outcomes.

P6.16.35
High expression of prolactin receptor is associated with cell survival of cervical cancer cells

E. I. López-Pulido[1]*, R. Ascencio-Cedillo*[1]*, J. F. Muñoz-Valle*[1]*, S. Del Toro-Arreola*[1]*, C. Estrada-Chávez*[2]*, A. L. Pereira-Suárez*[1]*;*
[1]Universidad de Guadalajara, Guadalajara, Mexico, [2]Centro de Investigación y Asistencia en Tecnología y Diseño del Estado de Jalisco, Guadalajara, Mexico.

Prolactin (PRL) regulates many physiological functions such as proliferation, differentiation, cell survival and act as an immunomodulatory. Altered expression of PRL and its receptor (PRLR) has been implicated in carcinogenesis as breast, prostate, laryngeal and colorectal. There are few studies focused in the analysis of the PRL/PRLR in cervical cancer, where the variation of the hormonal status influences in its development. The objective of this work was evaluating the expression of PRL/PRLR and cell survival effect in cervical cancer, as well as to analyze cellular signaling pathways involved. PRL/PRLR expression were evaluated by Western blot, immunofluorecence and Real time PCR in biopsies, cell lines (HeLa, SiHa, and C-33A) derivate of cervical cancer and immortalized human keratinocytes (HaCaT). Proliferation and apoptosis were measured by MTT and TUNEL assays, respectively. The activation of STAT3, Akt and ERK were evaluated by western blot. High PRLR expression was observed in cervical cancer in compare with premalignant lesions and non-tumorigenic keratinocytes. These cells also express variants of PRL of 60-80kDa. Treatment with PRL not induces significant proliferation, but reduce the apoptosis in all cervical cancer cell lines. PRL stimulated phosphorylation of STAT3 in HeLa and C-33A, also increase the phosphorylation of ERK in SiHa. In conclusion, the PRLR over-expressed may acts as important survival factor through the inhibition of apoptosis by signaling pathway STAT3 or ERK in the cervical cancer. PRL autocrine non-induce proliferation or apoptosis in cervical cancer cells maybe exerts a function on immune cells of tumor microenvironment.

P6.16.36
A standardized long-term culture assay to measure antigen-specific memory T cells

F. Lori[1]*, G. Cugia*[1]*, C. Pisano*[1]*, D. De Forni*[1]*, T. Bitai*[2]*, S. A. Calarota*[3]*, J. Lisziewicz*[2]*;*
[1]ViroStatics srl, Alghero, SS, Italy, [2]Genetic Immunity kft, Budapest, Hungary, [3]IRCCS Policlinico San Matteo, Pavia, Italy.

Background: Control of viral infections correlates with the availability of memory T cells with high proliferative capacity and not of activated effector T cells. However, while effector T cells are reliably measurable, measuring memory T cells requires long-term culture

assays that are difficult to standardize. We addressed the unmet need to design a long-term assay that is precise, repeatable and reproducible.
Methods: We quantified antigen-specific T cell precursors with high proliferative capacity (PHPC) using a peptide-based long-term cultured IFN-gamma ELISPOT assay (PHPC assay), shown to identify expandable memory T cells correlating with control of HIV-1 (Calarota S, J Immunol 2008). PBMC from several untreated HIV-1-infected individuals were evaluated in response to HIV-1 Gag p17, p24, and p15 peptide pools. Inter-operator and inter-day variability were assessed with the Intraclass Correlation Coefficient (ICC) with 95% Confidence Interval, intra-sample variability was assessed with the Coefficient of Variation (CV).
Results: Intra-sample repeatability range drastically improved from 5-36%, 8-26% and 50-104% to 0-12%, 8-26% and 1-25% for p17, p24 and p15 CV, respectively. Inter-operator reproducibility also improved from 0.86, 0.68 and 0.42 to 0.94, 0.94 and 0.70 for p17, p24 and p15 ICC, respectively. Inter-day precision remained good with ICC from 0.78, 0.96 and 0.54 to 0.71, 0.92 and 0.63 for p17, p24 and p15, respectively.
Conclusions: We succeeded to make the PHPC test precise, repeatable and reproducible. A standardized test to measure antigen-specific memory T cells will be invaluable to predict and monitor the success of vaccination and immunotherapies.

P6.16.37
Development of the MeDALL allergy-chip, an allergen micro-array comprising 176 components for sensitive detection of allergen-specific antibodies

C. Lupinek[1], *E. Wollmann*[1], *J. Bousquet*[2], *J. M. Anto*[3], *C. Harwanegg*[4], *R. Valenta*[1];
[1]*Dept. of Pathophysiology and Allergy Research, Division of Immunopathology, Medical University of Vienna, Vienna, Austria,* [2]*University Hospital of Montpellier, Hopital Arnaud de Villeneuve, Montpellier, France,* [3]*Centre for Research in Environmental Epidemiology (CREAL), Barcelona, Spain,* [4]*Phadia Multiplexing, Thermo Fisher Scientific, Vienna, Austria.*

In the EU-funded project “MeDALL”, 14 birth cohorts from different European countries provide several thousand serum samples for measurement of different biological parameters to unravel factors and the time course of the development of IgE-reactivities in childhood. The measurement of allergen-specific IgE in these samples using a highly sensitive technology that consumes only 35µl serum will allow to determine the period of allergic sensitization with accuracy.
The MeDALL allergy-chip, a customized version of the ISAC allergen micro-array (Phadia Multiplexing, Vienna, Austria), was developed comprising 176 allergen molecules. Modifications of the protocol and of reagents for antibody detection further increased sensitivity and reduced background of the test. Sensitivity and variation for IgE- and IgG-detection were determined using dilution-series of monoclonal IgE- and IgG_1-antibodies binding to Bet v 1 or Phl p 2, respectively, in direct comparison to ImmunoCAP (for IgE-measurement). To study competition on the chip between antibodies of different isotypes that combine with the same epitope, Bet v 1-specific monoclonal IgE was mixed with a monoclonal IgG-antibody that binds exactly the same epitope, and IgE-levels were measured by micro-array and ImmunoCAP.
The MeDALL allergy-chip is a highly sensitive tool for the reliable measurement of even very low concentrations of allergen-specific IgE and IgG and covers almost all clinically relevant allergen-components. In contrast to ImmunoCAP, it detects competition between IgE and blocking antibodies and is therefore closer to *in vivo* conditions. The MeDALL allergy-chip therefore is a suitable research- and diagnostic tool for the early detection of IgE-reactivities in children.

Association between reduction of plasma adiponectin levels and risk of bacterial infection after gastric cancer surgery

K. Maeda[1,2], *H. Yamamoto*[3], *Y. Uji*[3], *H. Tsuchihashi*[3], *T. Shimizu*[3], *Y. Endo*[3], *A. Kadota*[4], *K. Miura*[4], *T. Ito*[1], *T. Tani*[4];
[1]*Department of Complementary & Alternative Medicine, Osaka University Graduate School of Medicine, Suita, Osaka, Japan,* [2]*Department of Metabolic Medicine, Osaka University Hospital, Suita, Osaka, Japan,* [3]*Department of Surgery, Shiga University of Medical Science, Shiga, Japan,* [4]*Department of Health Science, Shiga University of Medical Science, Shiga, Japan.*

Background Infections are important causes of postoperative morbidity after gastric surgery; currently, no factors have been identified that can predict postoperative infection. Adiponectin (ADN) mediates energy metabolism and functions as an immunomodulator. Perioperative ADN levels and perioperative immune functioning could be mutually related. Here we evaluated a potential biological marker to reliably predict the incidence of postoperative infections to prevent such comorbidities.
Methods We analyzed 150 consecutive patients who underwent elective gastric cancer surgery. The patient characteristics and surgery-related factors between two groups (with and without infection) were compared by the paired *t*-test and χ^2 test, including preoperative ADN levels, postoperative day 1ADN levels, and ADN ratio (postoperative AND /preoperative ADN) as baseline factors. Logistic regression analysis was performed to access the independent association between ADN ratio and postoperative infection. Finally, ROCs were constructed to examine its clinical utility.
Results Sixty patients (40%) experienced postoperative infections. The baseline values of age, physical status, operating time, blood loss, surgical procedure, CRP, preoperative ADN, and ADN ratio were significantly different between groups. Logistic regression analysis indicated that T2DM and ADN ratio were significantly independent variables ($p < 0.05$, $p < 0.01$, respectively). ROC analysis revealed that the useful cutoff values (sensitivity/specificity) for preoperative ADN levels, ADN ratio, blood loss, operating time, and CRP levels were 8.81(0.567/0.568), 0.76 (0.767/0.761), 405 g (0.717/0.693), 342 min (0.617/0.614), and 8.94 mg/dl (0.583/0.591), respectively.
Conclusion T2DM and ADN ratio were independent predictors of postoperative infection and ADN ratio was the most useful predictor for postoperative infection.

Mitral valve proteomic analysis: novel insights into rheumatic heart disease mechanisms

C. O. Martins[1,2], *K. S. Santos*[1,2], *F. M. Ferreira*[1,2], *E. Cunha-Neto*[1,2], *J. Kalil*[1,2], *L. Guilherme*[1,2];
[1]*InCor/HC-FMUSP, São Paulo, Brazil,* [2]*Immunology Investigation Institute, National Institute for Science and Technology, University of São Paulo, São Paulo, Brazil.*

Introduction: Rheumatic heart disease (RHD) is a life-threatening complication of untreated *Streptococcus pyogenes* infection in susceptible children, leading to severe heart valve damage. Cross-reactivity, T-cell mimicry and epitope spreading are the main mechanisms connecting valve lesions and the infection. The valve proteins which are target of autoimmune reactions are poorly known.
Objectives: To identify protein expression alterations between normal and RHD valve-tissue by a proteomic approach, and to suggest mechanistic involvement in the disease.
Materials and Methods: Mitral valve fragments of RHD patients with regurgitation (n=8) or stenosis (n=6) were compared to control ones (n=7). Protein separation and differential expression analysis was performed by two-dimensional differential gel electrophoresis (2D-DIGE). The differentially expressed spots were identified by mass spectrometry (LC-ESI-MS/MS). Quantification and *in situ* analyses were performed by western blotting and immunoperoxidase staining, respectively. We also performed confocal microscopy for co-locatization studies. Computational metabolic studies were carried out with the Ingenuity Pathway Analysis (IPA) software.
Results: We found 19 differentially expressed proteins out of 451 identified spots. Vimentin, collagen-VI, lumican and vitronectin presented important expression alterations. Collagen-VI and lumican had an increased co-localization pattern in RHD valves.

Computational pathway analysis suggested an involvement of humoral response, antigen presentation and inflammation with the progression of end-stage valve lesions.
Conclusions: Our results demonstrated a differential pattern of valve proteins in RHD, and a network of interactions which are likely attributed to the etiology of the disease.

P6.16.40
Transient alteration in cytokine patterns following influenza vaccination detected by Ki-67 expression and automated multiparameter analysis of flow cytometry

***T. R. Mosmann**, D. Roumanes, I. Naim, A. Rosenberg, J. Weaver, Y. Qi, A. M. Livingstone, G. Sharma;*
University of Rochester, Rochester, NY, United States.

We previously showed that seasonal Trivalent Inactivated Influenza Vaccine (TIV) induces a strong, transient CD4 T cell response in healthy adults, measured at days 4-6 after vaccination as influenza-specific CD4 T cells expressing Ki-67. As elderly subjects have blunted immune responses to some vaccinations, we tested whether elderly subjects also induced the transient Ki-67+ population in response to inactivated influenza vaccine. Blood samples were taken before and after vaccination, and analyzed by intracellular cytokine staining and immunophenotyping by flow cytometry. Datasets were analyzed with SWIFT, our new, high resolution flow cytometry algorithm, that uses model-based clustering to objectively detect very small altered populations in large, high-dimensional datafiles. Assigning samples to cluster templates allows rigorous comparison between samples. A strong Ki-67+ influenza-specific CD4 T cell response was detected in subjects of all ages. Using a training/test set strategy, we identified multiple cell populations that were significantly altered in elderly subjects, as evaluated by each of four phenotyping panels. The high resolution provided by SWIFT, operating simultaneously in all dimensions, allowed the identification and quantification of large numbers of clusters, thus facilitating the agnostic discovery of clusters that were consistently altered in elderly subjects. Thus elderly subjects respond to influenza vaccination by transient up-regulation of Ki-67+ CD4 T cells, but have multiple immune cell alterations revealed by automated multiparameter analysis of flow cytometry data.

P6.16.41
Recurrent ulcerative stomatitis and its correlation with psychological factors

***M. Naghavi - Behzad**[1], A. Naghavi-Behzad[1], M. Ghojazadeh[2], R. Piri[1], F. Pournaghi Azar[2];*
[1]Students' Research Committee, Tabriz University of Medical Sciences, Tabriz, Iran, [2]Tabriz University of Medical Sciences, Tabriz, Iran.

Introduction: recurrent ulcerative stomatitis is one of the most common and painful diseases of mouth epithelium. Effect of depression and anxiety as psychological factors on pathology of this disease is controversial
Methods: In a correlative study at faculty of dentistry of Tabriz University of Medical Sciences in 2011, 75 patients were divided into 3 groups: patients with recurrent ulcerative stomatitis, positive control group (patients with painful mouth syndrome, unusual facial pain and pain due to facial muscles dysfunction) and negative control group (healthy people). These groups were investigated with Spielberger anxiety test and beck depression test.
Results: patients in recurrent ulcerative stomatitis and positive control groups had higher levels of anxiety and depression in comparison to negative control group. Although difference in anxiety level of patients with recurrent ulcerative stomatitis and positive control group was not statistically significant, but difference in depression level between these two groups was statistically significant.
Conclusion: According to these findings, depression and anxiety have a significant effect on pathology of recurrent ulcerative stomatitis and they act as important initiation factors for recurrent ulcerative stomatitis.

Naturally occurring sepsis in the dog induces changes in transcript levels of genes associated with human apoptosis, autophagy and necrosis

***S. K. Nordone**, M. D'Annabale, D. Tyson, E. Lennon, K. Clark, H. Marr, J. Yoder, A. Birkenheuer;*
North Carolina State University College of Veterinary Medicine, Raleigh, NC, United States.

A recent retrospective analysis found transcriptomic responses in murine models of disease are not representative of human inflammation gene profiles. These data support the growing recognition that induced animal models of disease result in an oversimplification of disease pathogenesis and thus provide limited utility in therapeutic evaluation. We hypothesize the dog may be an alternative model for inflammation, particularly for sepsis, because of similarities in disease phenotype and the fact that canine veterinary patients are treated in a manner analogous to humans. To determine if naturally occurring sepsis is similar across species at the molecular level, we compared inflammation and apoptosis gene profiles in dogs with sepsis and systemic inflammatory response syndrome to that of healthy dogs, using canine orthopedic patients as a model for sterile inflammation. We found that gene expression in septic dogs was significantly enhanced for those genes defining apoptosis, autophagy and necrosis, with significant repression of genes responsible for cell survival. Transcriptomic responses across all disease categories were generally pro-apoptotic. Sterile inflammation was differentiated from sepsis and SIRS by enhanced expression of genes associated with cellular proliferation and repression of genes associated with autophagy. These data strongly suggest that naturally occurring disease in the dog is analogous to human sepsis at the molecular level and is therefore an important resource in therapeutic discovery.

P6.16.43
Serum hepcidin levels in patients with Brucellosis

*E. Yılmaz[1], A. Oğuz Ayarcı[1], D. Sığırlı[2], M. Öner Torlar[1], F. Budak[3], G. Göral[4], **H. B. Oral**[3];*
[1]Uludag University Faculty of Medicine, Department of Infectious Diseases and Clinical Microbiology, Bursa, Turkey, [2]Uludag University Faculty of Medicine, Department of Biostatistics, Bursa, Turkey, [3]Uludag University Faculty of Medicine, Department of Immunology, Bursa, Turkey, [4]Uludag University Faculty of Medicine, Department of Medical Microbiology, Bursa, Turkey.

Both $CD4^+$and $CD8^+$ T lymphocytes play crucial roles in immunity to *Brucella*, in part because they secrete interferon (IFN)-γ and activate the bactericidal functions in macrophages. Hepcidin is an antimicrobial and iron regulatory peptide produced by the liver in response to inflammation and elevated systemic iron. Recent studies suggest that circulating monocytes and resident liver macrophages - Küpffer cells - may influence both basal and inflammatory expression of hepcidin, and cross-talk between macrophages and hepatocytes and that during inflammation these two cell types act in concert to regulate hepcidin production. Here, we aimed to investigate the association of hepcidin levels with Brucellosis. Serum hepcidin levels in 49 Brucellosis patients were compared with 52 healthy control subjects. Serum hepcidin levels were significantly higher in Brucellosis patients compared those of with healthy controls ($p < 0.001$). There was no statistically significant difference in serum levels of levels among acute, subacute and chronic cases with Brucellosis. However, hepcidin levels seem to be higher in chronic cases in comparison to acute and subacute cases. According to our first results, it may be suggested that the levels of Hepcidin may be a diagnostic marker for Brucellosis, but future studies are needed to evaluate whether hepcidin levels may be used for discriminating three different forms of Brucellosis (acute, subacute, chronic).

P6.16.44
A unique endotoxin tolerance profile strongly predominates during clinical sepsis

O. M. Pena[1], *D. G. Hancock*[2], *J. Xia*[1], *C. D. Fjell*[3], *R. E. W. Hancock*[1];
[1]*The Centre for Microbial Diseases and Immunity Research , University of British Columbia, Vancouver, BC, Canada,* [2]*Centenary Institute of Cancer Medicine and Cell Biology, Camperdown, Australia,* [3]*James Hogg Research Centre-St Paul's Hospital, University of British Columbia, Vancouver, BC, Canada.*

Bacterial products like lipopolysaccharide (LPS), can be potent inducers of inflammation, promoting a systemic production of pro-inflammatory mediators and recruiting/activating immune cells to eliminate the pathogen. However an excessive inflammatory reaction may lead to septic shock, characterized by organ failure and eventually death. In contrast, LPS can also generate an interesting effect known as endotoxin tolerance or cell reprogramming, defined as the reduced capacity of the immune cell to respond to LPS or other bacterial products following a first exposure to this stimulus. A septic patient is normally characterized by undergoing an excessive inflammatory response. To confirm this, we did an extensive bioinformatic meta-analysis using our previously published data characterizing unique LPS and endotoxin tolerance gene signatures in human blood mononuclear cells. We compared these signatures with transcriptional changes observed in human sepsis cohorts performed in our lab and the literature. We also analyzed signaling pathways and cytokine expression. Very interestingly, we found that septic patients strongly present an immunological profile associated with an endotoxin tolerance gene signature, rather than a dominant pro-inflammatory response as believed. In conclusion, these findings challenges the dogma that sepsis is a hyper-inflammatory (cytokine storm) disease, suggesting instead that endotoxin tolerance (an immuno-suppressive state) might occur much earlier in sepsis than previously suspected. This unique endotoxin tolerance gene signature can be used as possible biomarkers, helping us to characterize the critical immunological status of the septic patient, enabling appropriate immunological and supportive therapies that could improve the survival rate during this deadly syndrome.

P6.16.45
Changes in IgA and IgM in saliva and serum of newborns during the first 30 days of life

S. Pineda-Martínez[1], *J. Hernández-Islas*[2], *B. Tecuatl-Herrada*[3], *D. Correa*[2];
[1]*Programa Posg en C. Odontológicas, UNAM- INPed, SSA, Mexico City, Mexico,* [2]*INPed, SSA, Mexico City, Mexico,* [3]*Programa Posg en C. Médicas, UNAM- INPed, SSA, Mexico City, Mexico.*

IgM and IgA may be used as serum biomarkers of some congenital disorders in newborns because they do not cross the placenta. Saliva may be a good sample for diagnosis, because it is not invasive. Altered IgM and IgA -total or specific- levels have been demonstrated in saliva as biomarkers of some disease conditions in adults, but not in newborns. Changes in basal IgA and IgM levels in saliva and serum of newborns from birth to 30 days of age are unknown, as well as whether there is correlation between these samples. The concentration of IgA and IgM was determined in paired serum and saliva samples from 15 female and 16 male newborns by ELISA. All samples were taken not before three hours of lactation. IgA serum levels clearly increased with age, while in saliva two groups were identified, one characterized by increasing levels along age, and the other without change. This could be due to differences in genetic factors, exposure to microbes or feeding habits. Increase of seric IgM along age was more erratic. This Ig was absent in saliva except for two cases, who were positive at low levels. Two cases with abnormally high IgA concentration in serum, i.e. above 130µg/mL, were identified and four presented abnormally high levels of IgM (>870 µg/mL). One case with congenital toxoplasmosis presented both IgM and IgA in serum and saliva. The results suggest that one or both immunoglobulins may be useful biomarkers in saliva of newborns.

P6.16.46
Lipid profile analysis in spinal trauma patients shows severe distortion of AA/DHA after injury

D. Radzioch[1,2], *J. B. De Sanctis*[3], *G. Wojewodka*[1,2], *M. Radhakrishna*[1,4], *I. Makriyianni*[1,2], *S. Parent*[5,6], *J. Ouellet*[1,4], *S. David*[1,2];
[1]*McGill University, Montreal, QC, Canada,* [2]*Montreal General Hospital Research Institute, Montreal, QC, Canada,* [3]*Central University of Venezuela, Caracas, Venezuela,* [4]*Montreal General Hospital, Montreal, QC, Canada,* [5]*University of Montreal, Montreal, QC, Canada,* [6]*Montreal Sacre-Coeur Hospital, Montreal, QC, Canada.*

Studies have shown fatty acid abnormalities in various neurological disorders with increased arachidonic acid (AA), an omega-6 pro-inflammatory fatty acid, and decreased levels of docosahexaenoic acid (DHA), an omega-3 fatty acid which reduces inflammation. Using a mouse model of spinal contusion injury, we previously showed rapid increases in AA/DHA ratio after spinal injuries. We found that treatment with the drug fenretinide corrected the fatty acid defects and improved recovery in mice. In this study, we hypothesized that AA and DHA may also be impaired in patients following traumas to the spine.
Here we report preliminary results from our study including 23 spinal contusion injury patients, 11 spinal fracture patients. Plasma samples were taken at various times post injury: 1, 2, 3, 8-16, 25-49 days and 1-2 years. We assessed the levels of AA, DHA and malondialdehyde (MDA), a marker of lipid peroxidation.
The greatest changes in fatty acids occurred immediately after spinal trauma with increased AA and decreased DHA in both types of injuries. Thus the AA/DHA ratio was distorted towards a more pro-inflammatory status. Additionally, MDA increased after spinal injury which indicated a higher levels of peroxidation. At later time points, the fatty acid levels returned to normal and peroxidation decreased as well.
Our results provided confirmation for our hypothesis that AA/DHA ratio is distorted immediately after spinal injuries and may be a factor in causing further neuronal damage. Our data suggest that immediate application of fenretinide after a spinal injury might decrease secondary damage and improve neurological outcomes.

P6.16.47
Kinetics of inflammatory markers following traumatic injuries to the spinal cord

D. Radzioch[1,2], *G. Wojewodka*[1,2], *S. David*[1,2], *I. Makriyianni*[1,2], *M. Radhakrishna*[1,3], *S. Parent*[4,5], *J. Ouellet*[1];
[1]*McGill University, Montreal, QC, Canada,* [2]*Montreal General Hospital Research Institute, Montreal, QC, Canada,* [3]*Montreal General Hospital, Montreal, QC, Canada,* [4]*University of Montreal, Montreal, QC, Canada,* [5]*Montreal Sacre-Coeur Hospital, Montreal, QC, Canada.*

Inflammation following traumatic spinal cord injuries precedes the wound healing process, however, excessive inflammation may lead to irreversible neuronal damage. In this study we assessed whether there are differences in elevation of inflammatory markers in patients with spinal cord injuries (SCI) as compared to those with spinal fractures (SF) without CNS damage.
Patients with SCI and SF were recruited to the study. Blood samples were collected at 1, 2, 3, 8-16, 25-49 days and 1-2 years post injury. We analyzed inflammatory markers in blood plasma (IL-1β, IL-6, IL-7, IL-8, IL-10, IL-12p70, IL-13, IL-17A, IFNα2, IFNγ, and TNFα) and assessed the differences in their levels between patients with SCI and SF injuries. Here we report preliminary data on 7 SCI and 10 SF patients.
IL-6 levels were higher in SCI than SF patients from days 1 to 3, whereas at 8-16 days post injury, IL-6 became significantly lower in SCI patients than SF ($p = 0.0428$). At day 2, IL-10 levels were significantly higher in SCI patients compared to SF ($p = 0.0341$). IFNγ levels were higher in SCI and SF patients at day 3 ($p = 0.0216$). At 8-16 days post injury , IL-17A and IL-8 were higher in SCI than SF patients ($p = 0.0079$ and $p = 0.0033$, respectively).
SCI patients had significantly higher levels of inflammatory markers than SF patients from the first day of injury suggesting that SCI patients may benefit from therapies reducing systemic inflammation immediately following SCI injury.

P6.16.48
Circulating IL-12 and response to therapy in HCV-infected patients: Potential biomarker for a non-favorable outcome?

*F. A. Pereira[1], L. A. O. Pereira[1], T. M. A. Carmo[1], R. Paraná[2], A. T. Carvalho[3], O. A. Martins-Filho[3], J. Hagan[1], E. A. G. Reis[1], **M. G. Reis**[1];*
[1]Research Center Gonçalo Moniz, Salvador/Ba- Brazil, Brazil, [2]University Federal of Bahia, Salvador/Ba- Brazil, Brazil, [3]Research Center René Rachou, Belo Horizonte, Brazil.

Objective: Cytokines play an important role in the regulation of immune responses. In hepatitis C virus infection, the production of abnormal cytokine levels appears to contribute in the progression of the disease, viral persistence, and affects response to therapy. The aim of this study was to explore a possible association between the pattern of serum cytokines with response to therapy in HCV-infected patients.
Methods: The cohort was composed of eighty-three SVR (sustained virological responders) and seventy-seven NR (non-responders). All patients were administered complete pegylated interferon-α and ribavirin combination therapy followed for twenty-four weeks after the cessation of treatment and divided into different groups according to outcomes of treatment based on HCV-RNA tests. Cytokine-bead-array (CBA) was performed by flow cytometry analysis to determine the pro- and anti-inflammatory cytokines plasma levels (IL-1β , IL-2, IL-4, IL-5, IL-6, IL-8, IL-10, IL-12, IFN-γ and TNF-α).
Results: Increased plasma levels of IL-12 was observed in the group of NR when compared to SVR patients (p<0.0001). Interestingly, IL-12 plasma levels were increased in NR patients when compared to SVR patients independently of viral genotype 1 (p=0,0016) and 2-3 (p=0.0073). In addition, when NR and SVR patients were stratified by progression of liver fibrosis according to METAVIR score, no statistically significant differences were observed in IL-12 plasma levels. None of the remaining cytokines plasma levels were associated with response to HCV-therapy.
Conclusion: These results suggested that IL-12 levels may be used as a predictive biomarker of therapy response in chronic HCV-infected patients.

P6.16.49
Association of IL28B (rs12979860) and IL-12B (rs3212227) polymorphisms with response to HCV-therapy in patients with a mixed genetic background

*F. A. Pereira[1], L. A. O. Silva[1], T. M. A. Carmo[1], J. Hagan[1], R. Paraná[2], **M. G. Reis**[1];*
[1]Research Center Gonçalo Moniz, Salvador/Ba- Brazil, Brazil, [2]University Federal of Bahia, Salvador/Ba- Brazil, Brazil.

Objective: Hepatitis C virus is a major cause of chronic liver disease. Although the standard therapy, Peg-interferon-α and ribavirin, it is well known that many patients will not be cured. In addition, genetic variations among ethnic groups have an important role in determining response.
Methods: Our aim was to study association between genetic polymorphisms (IL-1 rs16944, IL-2 rs2069762, IL-4 rs2243250, IL-5 rs2069812 , IL-6 rs1800795, IL-8 rs4073, IL-10 rs1800871; rs1800872; rs1800896, IL-12B rs3212227, IL22RA2 rs2064501, IL22RA2 rs6570136, IL-28B rs12979860, CTGF rs3037970, CTGF rs6918698, CTGF rs9402373, IFN rs2430561, TNF rs1800629, MMP-1 rs17886084, MMP-9 rs17576, TIMP-2 rs9900972) and antiviral therapy efficiency for HCV-infected patients among a Brazilian cohort. All patients, 92 sustained virological responders and 83 non-responders, were administered Peg-Interferon-α and ribavirin, followed for 24 weeks after the cessation of treatment, and divided according to outcomes. Polymorphisms were genotyped using primers and probes designed for a Taqman Allelic Discrimination Assay.
Results: According to univariate analysis, TT IL-4 rs2243250 (p=0,037;OR=0.325;95%CI=0.119-0.886), CC IL-10 rs1800871 and CC IL-10 rs1800872 (p=0,047;OR=2.062;95%CI=1.052-4.045), AA IL-12B rs3212227 (p=0.013;OR=0.446;95%CI=0.232-0.857), and CC IL-28B rs12979860 (p=1,21x10-5;OR=4.153;95%CI=1.853-9.308) polymorphisms were significantly associated with response to therapy. By multivariate model, AA IL-12B rs3212227 (p=0.00178;OR=0.353;95%CI=0.167-0.744), CC IL-28B rs12979860 (p=0.0009;OR=3.765;95%CI=1.567-9.044) polymorphisms were independent predictors for NR and SVR, respectively.
Conclusion: These findings suggest that IL-28B in combination with IL-12B polymorphism could be used as biomarkers to predict the efficacy of anti-viral HCV therapy.

P6.16.50
HLA-G expression is an independent predictor for survival in high grade ovarian carcinomas

***M. J. Rutten**[1], D. Meijer[1], M. R. Buist[1], M. J. Van de Vijver[2], G. G. Kenter[1], E. S. Jordanova[3];*
[1]AMC, Center Gynaecologic Oncology Amsterdam, Amsterdam, Netherlands, [2]Department of Pathology, Academic Medical Centre, Amsterdam, Netherlands, [3]VUMC, Center Gynaecologic Oncology Amsterdam, Amsterdam, Netherlands.

Background: Expression of classical and non-classical HLA is respectively associated with favourable and unfavourable survival in cancers. However, controversy exists concerning non-classical HLA-G expression and prognosis. The aim of this study was to evaluate the prognostic value of classical and non-classical HLA expression levels in high grade epithelial ovarian cancer.
Methods: Tissue microarrays of formalin fixed paraffin embedded tumour tissue of 167 primary high grade epithelial ovarian cancer patients were constructed. These were immunohistochemically stained for classical and non-classical HLA. Expression was compared with clinicopathological factors and progression free and overall survival using chi-square and log rank test with additional Kaplan-Meier curves. For multivariate analysis Cox Proportional Hazard regression model was used.
Results: Patient with high grade epithelial tumours expressing HLA-G had a better survival (p= 0.014). Median disease specific survival was 26 months shorter for cases without expression of HLA-G. Furthermore, HLA-G expression was associated with longer progression free survival (p=0.036) and chemosensitivity (p=0.016). Also, in multivariate analyses HLA-G expression was found to be an independent predictor for better survival (p=0.011) and for optimal surgery result (p=0.010). Expression or loss of expression of HLA-A, -B, -C and -E was not associated with survival or clinicopathological factors.
Conclusion: Expression of HLA-G is an independent prognostic factor for improved survival in high grade epithelial ovarian cancer. The survival advantage is related to better chemosensitivity and surgery results, suggesting a new role for HLA-G as a prognostic indicator in high grade epithelial ovarian cancer.

P6.16.51
Phenotypic signature of B cell subsets as a tool for the investigation of immunogenicity

***W. J. Sanderson**[1], E. C. Jury[1], J. Manson[2], C. Mauri[1];*
[1]University College London, London, United Kingdom, [2]University College London Hospital, London, United Kingdom.

It has recently become clear that different B cell subsets contribute to both the pathogenesis of immune disorders, as well as the maintenance of tolerance, and are therefore implicated in the development of autoimmunity. Patients with rheumatoid arthritis (RA) and systemic lupus erythematosus are characterised by an increase in pathogenic B cells (e.g. memory), and a decrease or functional impairment of regulatory B cells (Bregs), which promote tolerance via the production of interleukin-10. In humans, we and others have shown that B cells with suppressive capacity are enriched in the $CD19^{+}CD24^{hi}CD38^{hi}$ compartment. These cells can interrupt T cell-B cell positive feedback, suppress effector T cell proliferation, and induce regulatory T cell differentiation. Yet conclusive markers for the identification of a pure Breg population, distinct from those with pathogenic capacity, have not been found. Here we describe a new immunophenotyping platform, with which we can screen the expression of 242 cell-surface markers in parallel by flow cytometry. This has enabled us to generate a surface marker “signature” for different B cell subsets, and provided us with a phenotypic counterpart to gene array data. A major goal in the development of biopharmaceutical drugs is to predict which patients are likely to

respond with anti-drug antibodies (ADAs) - one of the principal drawbacks of biological therapies. We will implement our method to compare B cell subset signatures in a longitudinal cohort of RA patients treated with anti-TNFa in order to identify predictive markers for those patients who will become ADA positive.

P6.16.52
Role of the immunity in the aggressive forms of breast cancer seen in Western Kenya

R. T. Sawe;
MOI, Eldoret, Kenya.

Breast cancer in African women has a poor prognosis and a high rate of recurrence. There is an urgent need to define the role of the host immune response to tumor in the seemingly aggressive forms of breast cancer in African women. Studies have indicated that the immune system has anti-tumor function and can also facilitate tumor escape and progression. Tumor infiltrated with cells such as CD4, CD8 and macrophages have shown both positive and negative association with tumor relapse and metastasis. Tumor associated M1 and M2 subtypes have a role in suppressing the tumor and enhancing tumor growth respectively. Little has been done on the prognostic value of the immune system in breast cancer. Identifying the role played by the host response to tumor in aggressive breast cancer forms could give an insight in the tumor biology of the unique forms of tumors seen in African women. This study will determine the significance of inter-relationship between tumors and host immune response in the aggressive forms of breast cancer seen in Kenyan young women.

Gastrointestinal autoimmunity to tryptophan hydroxylase in Autoimmune Polyendocrine Syndrome type 1 (APS-1)

R. Scarpa[1], *R. Alaggio*[2], *L. Norberto*[3], *B. Smith*[4], *M. Plebani*[5], *F. De Luca*[6], *M. Salerno*[7], *L. Ghizzoni*[8], *C. Betterle*[9];
[1]*Allergy and Clinical Immunology, Department of Medicine, University of Padova, Padova, Italy,* [2]*Department of Pathology, University of Padova, Padova, Italy,* [3]*Department of Surgical and Gastroenterological Sciences, University of Padova, Padova, Italy,* [4]*FIRS Laboratories, Cardiff (UK), Cardiff, United Kingdom,* [5]*Department of Laboratory Medicine, University of Padova, Padova, Italy,* [6]*Department of Pediatrics, University of Messina, Messina, Italy,* [7]*Department of Pediatrics, University Federico II of Naples, Napoli, Italy,* [8]*Division of Endocrinology, University of Turin, Torino, Italy,* [9]*Department of Medicine, University of Padova, Padova, Italy.*

Background: Autoantibodies to tryptophan hydroxylase (TPHAbs) directed against serotonin-producing enterochromaffin cells (EC) have been reported in APS-1 patients with gastrointestinal dysfunction (GID). Serotonin plays a critical role in enteric function and its serum levels reflect serotonin release from the gastrointestinal tract.
Hypothesis: TPHAbs could mark a distinct autoimmune component of APS-1 characterized by an autoimmune attack toward EC, with subsequently GID.
Methods: TPHAbs were measured in 64 APS-1 patients. Gastric and duodenal biopsy was carried in 16 TPHAbs+ patients (8 with and 8 without GID) and in 2 TPHAbs- patients (without GID); in these patients serotonin serum levels were measured. Immunohistochemistry was performed using antibodies to serotonin, chromogranin-A, CD3, CD4, CD8, and CD20.
Results: 37 of 64 patients were TPHAbs+ (11/12 with GID and 26/52 without GID;P<0.001). Biopsies in 8 TPHAb+ patients with GID showed lymphocytic infiltration (with increased CD3+CD8+ intraepithelial lymphocytes) and absence of EC; mean serotonin serum levels were below the normal range in TPHAb+ patients with GID (P<0.01). In 8 TPHAb+ patients without GID biopsies showed different grades of inflammatory infiltration and reduced number of EC. Mean serotonin serum levels were near the lower limit of the normal range. In all TPHAbs+ patients, biopsies showed a reduced number of chromogranin-A positive cells consistent with enteroendocrine cells depletion. TPHAbs- patients without GID showed no histogical and biochemical abnormalities.
Conclusions: TPHAbs appear to be markers of a distinct autoimmune component of APS-1. Progressive involvement of the gastrointestinal EC leads to the transition from preclinical to clinical disease.

P6.16.54
Blood pulmonary tuberculosis biomarkers on diabetic individuals

C. J. Serrano, *R. A. González, L. Enciso, N. Macías, J. A. Enciso;*
Unidad de Investigación Médica Zacatecas, IMSS, Zacatecas, Mexico.

SETTING. Tuberculosis (TB) associated to chronic health conditions such as non-insulin-dependent diabetes mellitus (NIDDM) could represent nowadays a worldwide Public Health threat. The relative odds of developing tuberculosis in diabetic patients ranges from 3 to 8 compared with non-diabetic patients. No molecular diagnostic or prognostic test to distinguish latent (LTB) from active TB (ATB) exists, neither biomarkers to follow TB pharmacology interventions. Given exacerbated inflammation by TB leads to pulmonary damage; key molecules on the inflammation process could be useful as diagnosis biomarkers for TB states, even in individuals with NIDDM.
METHODS. Previous microarrays analysis at our laboratory identified a group of overexpressed genes on mice lungs infected with a Mycobacterium tuberculosis virulent strain that were not induced by a persistent strain that induces no inflammation. Based on the hypothesis that PBMCs from individuals with different TB infectious status could exhibit distinct transcription profiles, the present study evaluated the gene expression capability of 7 mice overexpressed genes on human whole blood, to discriminate subjects with pulmonary TB (PTB) (with or without NIDDM) from non infected or LTB subjects.
RESULTS. In the no NIDDM group, CXCR5 presented lower expression on PTB compared to LTB, while PSTP1 expression was higher. On the other hand, NIDDM-PTB individuals showed higher expression for GBP2, ARHGAP30, NCF1, and FPR2 compared to the LTB individuals, while CXCR5 expression was lower.
CONCLUSIONS. Gene expression profile of four overexpressed genes on TBA were found with potential utility to discriminate on NIDDM, LTB persons from those with activated pulmonary TB.

P6.16.55
Anti-carbamylated protein antibodies (Anti-CarP) precede the onset of Rheumatoid Arthritis

J. Shi[1], *L. A. van de Stadt*[2,3], *E. W. N. Levarht*[1], *T. W. J. Huizinga*[1], *D. Hamann*[4], *D. van Schaardenburg*[2,5], *R. E. M. Toes*[1], *L. A. Trouw*[1];
[1]*Leiden University Medical Center, Leiden, Netherlands,* [2]*Jan van Breemen Research Institute | Reade, Amsterdam, Netherlands,* [3]*Sanquin Research and Landsteiner Laboratory, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands,* [4]*Sanquin Blood Supply, Division Diagnostic Services, Amsterdam, Netherlands,* [5]*VU University Medical Center, Amsterdam, Netherlands.*

Objective
Anti-citrullinated protein antibodies (ACPA) and IgM-Rheumatoid Factor (IgM-RF) are auto-antibodies that can be detected many years before the clinical diagnosis of Rheumatoid Arthritis (RA). Since ACPA and IgM-RF are known as predictive and prognostic markers of RA, it is conceivable that these antibodies play a pathogenic role in RA. Recently we discovered anti-carbamylated protein (anti-CarP) antibodies as a prognostic marker in RA and are associated with a conversion to RA in patients suffering from arthralgia. In this study we analyzed whether anti-CarP antibodies can also be detected prior to the onset of the symptoms of RA and which auto-antibody appears first over time.
Methods
Sera of 79 RA patients prior to the onset of symptoms and 141 age and sex matched controls that were regular blood donors were tested for the presence of anti-carbamylated fetal calf serum (Ca-FCS) antibodies, anti-carbamylated fibrinogen (Ca-Fib) antibodies, anti-cyclic citrullinated peptide 2 (CCP2) antibodies and RF-IgM.
Results
Anti-CarP antibodies were present in 39% of the serum samples that were drawn just prior to the diagnosis of RA compared to 4% of the

matched control samples. Anti-CarP antibodies were present in both ACPA positive and ACPA negative patients.
Analysis of the longitudinal samples revealed that anti-CarP antibodies could be detected many years before the onset of symptoms (median 8 years). Both ACPA and anti-CarP antibodies appear (similarly) earlier in time as compared to IgM-RF.
Conclusions
Next to ACPA and IgM-RF also anti-CarP antibodies appear many years before the onset of clinical symptoms of RA.

P6.16.56
An innovative method to identify autoantigens expressed on the cell surface: SARF

*T. Shirai[1], **H. Fujii**[1], M. Ono[2], R. Watanabe[1], Y. Shirota[1], S. Saito[1], T. Ishii[1], H. Harigae[1];*
[1]Department of Hematology and Rheumatology, Tohoku University Graduate School of Medicine, Sendai, Japan, [2]Department of Histopathology, Tohoku University Graduate School of Medicine, Sendai, Japan.

Background: Although autoantibodies against integral membrane proteins are generally considered to be pathogenic, identification of such molecules was difficult by conventional methods, including proteomics. Anti-endothelial cell antibodies (AECAs) are important but unsolved autoantibodies that target cell-surface autoantigens and may play roles in vascular lesions in collagen diseases. To specifically identify cell-surface autoantigens, we constructed a Serological identification system for Autoantigens using a Retroviral vector and Flow cytometry (SARF).
Methods: A cDNA library of human umbilical vein endothelial cells (HUVEC) was retrovirally transfected into a rat myeloma cell line, from which AECA-binding clones were sorted by flow cytometry. Integrated cDNA of the cells was analyzed to identify autoantigens, and the functional significance of the autoantibodies was analyzed.
Results: Distinct AECA-positive clones were isolated using different serum IgG from patients with AECA-positive collagen diseases, including systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA). By DNA sequencing and microarray, we identified three cDNA inserted to each clone, which were fibronectin leucine-rich transmembrane protein 2 (FLRT2) and Pk (Gb3/CD77) from SLE, and intercellular adhesion molecule 1 (ICAM-1) from RA. HUVEC expressed these proteins and the prototype AECA IgGs bound specifically to these molecules-transfected cells. Anti-FLRT2 antibody induced complement-dependent cytotoxicity against FLRT2-expressing cells.
Conclusion: Using SARF, we successfully identified three membrane proteins as targets for AECAs. SARF is useful for specific identification of autoantigens expressed on the cell surface. By thorough identification of cell-surface autoantigens, it may be possible to achieve a comprehensive understanding and the development of more specific intervention strategies of autoantibody-mediated injury.

P6.16.57
Significant cancer-associated autoantibody signatures for early diagnosis and prognosis of gastric cancer

***K. Silina**[1], P. Zayakin[1], G. Ancans[2,3], Z. Kalnina[1], I. Meistere[1], A. Pismennaya[1], M. Leja[2,3], A. Line[1];*
[1]Latvian Biomedical Research and Study Centre, Riga, Latvia, [2]Riga Eastern Clinical University Hospital, Latvian Oncology Center, Riga, Latvia, [3]University of Latvia, Faculty of Medicine, Riga, Latvia.

Gastric cancer (GC) is one of the most common reasons of cancer-related deaths due to asymptomatic early stages and poor treatment efficiency for late stage patients. Cancer autoantibodies (AAb) are attractive biomarkers for early diagnosis as they are specific and stable in blood and form early in disease progression. However no AAb-based test has been developed so far as each individual tumour differs in its antigen repertoire and the frequency of AAbs against each individual antigen is too low.
We have identified >1000 B cell antigens and used them for generation of antigen microarrays. GC-associated antigens were identified by screening sera from 100 GC patients and 100 cancer-free controls (HD). 86 most reactive antigens were selected for production of a validation array screened with an independent set of sera from 235 GC, 154 peptic ulcer and gastritis patients and 213 HD. ROC curve analysis showed that 45 AAb signature could discriminate GC and HD in the validation set with a 90% specificity and 59% sensitivity (AUC 0.79, p=2e-31), thereto early GC was detected with the same precision as advanced GC. Also two sets of seven AAbs were determined as the most significant independent prognostic factors correlating to longer (>1 year) (HzR=0.21, p=0.048) or shorter (<1 year) (HzR=7.7, p=0.002) survival after surgery of late stage patients by the multivariate Cox regression analysis.
We show here that cancer AAbs can be used for early diagnosis and prognosis of GC, and further work is in progress to increase the sensitivity of the test.

P6.16.58
Rates of Persistent Positivity for Anti-Cardiolipin and Anti-Beta-2-Glycoprotein I Antibodies in Routine Clinical Practice

***M. R. Snyder**, M. W. Ettore;*
Mayo Clinic College of Medicine, Rochester, MN, United States.

Purpose: Assessment of anti-phospholipid antibodies is an established practice in the evaluation of patients with suspected anti-phospholipid syndrome (APS). Positivity of anti-cardiolipin (aCL) or anti-beta-2-glycoprotein I (aB2) antibodies (IgG or IgM) on 2 occasions separated by ≥12 weeks fulfills current laboratory classification criteria for APS. The purpose of this study was to assess the frequency of positive serial test results in routine clinical practice.
Methods: aCL and aB2 IgG and IgM antibody results were collected from samples submitted for routine testing between April 1, 2008 and April 30, 2010. Testing was performed by enzyme immunoassay (Phadia). Antibody titers ≥40U/mL were considered positive.
Results: A total of 6,064 patients were identified for whom repeat aCL and/or aB2 IgG and/or IgM testing was performed. Of the positive samples, 63 had repeat testing performed 2-6 weeks following the initial result, 71.4% of which remained positive. For samples in which repeat testing was performed 6-12 weeks (n=89) and ≥12 weeks (n=296), 74.2% and 76.4%, respectively, remained positive. When repeat testing was performed ≥12 weeks following the initial result, 76.4% of samples positive for aCL IgG (n=191) and 72.8% of samples positive for aCL IgM (n=114) remained positive. For aB2 IgG (n=17) and aB2 IgM (n=4), 63.2% and 75.0%, respectively, remained positive.
Conclusions: The frequency of positive aCL and aB2 follow up tests was consistent regardless of the time frame during which the testing was performed. Whether serial positive test results over any specific time period improves the diagnostic specificity for APS remains unclear.

P6.16.59
The effect of dipeptidyl peptidase-IV inhibitor sitagliptin on the immune functions in patients with type 2 diabetes

***L. Sromova**[1], P. Bušek[1], H. Mareckova[2], M. Andel[3], A. Sedo[1];*
[1]1st Faculty of Medicine, Charles University in Prague, Institute of Biochemistry and Exp. Oncology, Prague 2, Czech Republic, [2]1st Faculty of Medicine, Charles University in Prague, Institute of immunology and microbiology, Prague 2, Czech Republic, [3]2nd Dept. of Internal Medicine, 3rd Faculty of Medicine, Charles University Prague and Faculty Hospital Královské Vinohrady, Prague, Czech Republic.

Gliptins (e.g. sitagliptin, vildagliptin) are novel anti-diabetic drugs that improve insulin secretion by a GLP-1 mediated mechanism by inhibiting the protease dipeptidyl peptidase-IV (DPP-IV) with a consequent increase in the bioavailability of incretins. DPP-IV is a multifunctional membrane bound serine protease identical with the marker of activated lymphocytes CD26 and its soluble form is found in blood plasma. In addition to incretins, DPP-IV is responsible for the breakdown of several other biologically active peptides such as chemokines and neuropeptides. Given that DPP-IV has diverse effects on the modulation of cell growth and immune functions, its long-term inhibition could lead to unfavorable effects including immune dysregulation.

The aim of this study is to assess the possible differences in lymphocyte differentiation and cytokine production in patients with type 2 diabetes mellitus treated with sitagliptin in comparison to patients treated with other hypoglycemic medications (control group). Patients from both groups are examined before and 4 weeks after the enrolment in the study. The DPP-IV enzymatic activity of plasma, mononuclear cells and immunophenotyping of lymphocytes (Treg, NK, Th1, Th2 and Th17 cells) are performed in heparinized peripheral blood. Our preliminary data show that short term (4 week) sitagliptin treatment leads to changed proportion of lymphocyte populations in peripheral blood in patients with type 2 diabetes. A further follow-up examination is planned at 1 year. These data should improve our understanding of the possible immunological implications of the DPP-IV enzymatic activity inhibition.

Tonsils of patients with IgA nephropathy contain cells producing aberrantly glycosylated IgA1 and anti-glycan antibodies: implications for tonsillectomy

H. Suzuki[1], *Y. Suzuki*[1], *H. Yanagawa*[1], *Y. Makita*[1], *J. Novak*[2], *Y. Tomino*[1];
[1]*Juntendo University Faculty of Medicine, Tokyo, Japan,* [2]*University of Alabama at Birmingham, Birmingham, AL, United States.*

Background: IgA1 in circulating immune complexes and in the glomerular deposits of patients with IgA nephropathy (IgAN) is aberrantly glycosylated, galactose-deficient in *O*-glycans (Gd-IgA1) and is bound by antiglycan IgG/IgA1 autoantibodies. However, the origin of cells producing Gd-IgA1 and the autoantibodies is unknown. Upper-respiratory tract infections and/or tonsillitis are frequently associated with clinical presentation and exacerbation of IgAN, suggesting a link with the disease pathogenesis. Moreover, there is a need to assess the mechanisms and effectiveness of tonsillectomy combined with glucocorticoids on the progression of IgAN.
Methods: In this study, we studied 27 patients with IgAN who underwent tonsillectomy and glucocorticoid therapy (TSP). Tonsillar cells were immortalized with Epstein-Barr-virus and Gd-IgA1 and anti-glycan IgG secreted by these cells were measured. Urinary protein and hematuria, and serum levels of Gd-IgA1, anti-glycan IgG, and anti-glycan IgA were measured before and after the TSP therapy.
Results: Sixteen of twenty-seven patients showed less 0.3 g/gCr proteinuria and 5 red-blood cells/HPF after TSP (Remission group). A rate of decrease in serum levels of Gd-IgA1, anti-glycan IgG, and anti-glycan IgA were greater in the Remission group than in non-Remission group (P<0.01). Furthermore, tonsillar B cells from Remission group secreted greater amounts of Gd-IgA1 and anti-glycan IgG than those from non-Remission group (P<0.01 for both).
Conclusion: In summary, tonsillar immunoglobulin-producing cells from patients with IgAN secreted Gd-IgA1 and anti-glycan antibodies. Moreover, IgA1 and anti-glycan antibodies may be useful serum biomarkers to assess therapeutical responses in IgAN patients.

Distribution of prostate specific antigen (PSA) among senegalese men with immunoenzymatic sandwich method

M. D. Sylla Niang[1,2], *B. Mbengue*[1], *N. Dramé*[1], *M. Jalloh*[2], *I. Labou*[2], *L. Niang*[3,2], *G. Woto Gaye*[3], *T. N. Dièye*[1], *S. Guèye*[3,2], *A. Dièye*[1];
[1]*Faculté de Médecine, de Pharmacie et d'Odontologie. Service d'Immunologie. Université Cheikh Anta Diop de Dakar - SENEGAL, Dakar, Senegal,* [2]*Hôpital Général de Grand-Yoff, BP 3270, Dakar, Senegal,* [3]*Université Cheikh Anta Diop de Dakar - SENEGAL, Dakar, Senegal.*

Objective :To explore distribution of total prostate specific antigen (tPSA) values among senegalese men only aged 40 years and upper. Six hundred and eighteen sera were tested. Mean age was 58.67 years. An immunoenzymatic sandwich assay with final detection in fluorescence was used for tPSA measurements. The median tPSA level was 1.32 ng/ml. Approximately 82% presented normal values of tPSA (< 4 ng/ml) and high PSA was found in 18.4% of cases. In healthy subjects, according to the age categories, median tPSA level was respectively 0.92, 1, 1.3, 1.45, 1.45 and 3.61 ng/ml for age strata of 40-49, 50-59, 60-69, 70-79, 80-89, 90 years and above. Among patients suspected of prostate cancer (n = 114), median tPSA level was 8.98 ng/ml. Prostate cancer was confirmed by biopsy in 94 patients. Mean age of diagnosis of prostate cancer was 65.5 years and mean tPSA among the prostate cancer group was 125.7 ng/ml.

P6.16.62
A Peptide based approach for the serological diagnosis of Chikungunya fever

P. Verma, *D. N. Rao;*
AIIMS, Department of Biochemistry, New Delhi, India.

Chikungunya is a mosquito borne alpha virus, affected large population in Asia and Africa. In general, Chikungunya virus (CHIKV) and Dengue virus (DENV) share common clinicopathological symptoms. In most of the cases, diagnosis of CHIKV is symptomatic but RT-PCR, virus Isolation and immunological approaches are the existing methods of diagnosis of the disease. Some of these methods showed cross reactivity with other related alpha virus family. Confirmatory diagnosis of Chikungunya before treatment initiation is essential to avoid non target effect of drugs. Thus, there is an urgent need to develop diagnostic reagents to diagnose Chikungunya without cross reactivity with other related alpha viruses.
The present study highlights the peptide based detection of IgM antibodies specific for Chikungunya as an efficient and reliable approach for the diagnosis of the disease. To achieve the aim we have selected 7 peptides from E1, 17 peptides from E2 and 1 peptide from E3 by Bcelpred and DNAstar software and surface localization was done by PYMOL software. To evaluate the assay, peptide based ELISA for IgM detection in 83 CHIKV positive, 35 negative control and 33 DENV positive sera was done. Prism Ver: 5 software was used to analyze the data. Of 17 E2 peptides chosen, 10 showed significant seropositivity with all the positive sera similar to virus lysate/E2 protein. The sensitivity and specificity of these peptides were found between 95-97% and 100%, respectively. Importantly, none of the peptides showed serological cross-reactivity with Dengue sera.

P6.16.63
Kinetics of expression of CD62L and CXCR3 on CD8+ T cells during treatment of hepatocellular carcinoma with TACE

Y. Wang[1], *J. Zheng*[2], *B. Sun*[2], *D. Liu*[1], *L. Yan*[1];
[1]*Beijing Institute of hepatology, Beijing You An Hospital, Capital Medical University, Beijing, China,* [2]*Intervention therapy Center of Liver Diseases, Beijing You An Hospital, Capital Medical University, Beijing, China.*

Aim To investigate the effect of treatment with transcatheter arterial chemoembolization (TACE) on the expression of chemokine receptors (CR) on memory T cells in HCC patients. Methods Blood samples from hepatic artery and peripheral vein were collected from 100 patients with HCC before and 4w post treatment with TACE, respectively. PBMCs were isolated to examine the expression of CRs: CD62L and CXCR3 on CD8+T cells in HCC patients. Results Both frequency and quantitation of $CD62L^{low}$CXCR3+ proinflammatory effector T cells in HCC patients post treatment increased significantly than pretreatment with 61.92±8.69% vs 24.45±7.36%, P<0.05. and 18.98±2.33e7/L vs 6.10±1.21e7/L, P<0.001, respectively. No significant difference in their frequency between in artery and peripheral vein was displayed. Furthermore, activated CD69+T cells in HCC patients rose from 2.53±0.51% in artery and 2.38±0.49% in vein respectively to 3.80±0.62% and 4.48±0.75% post treatment, both P<0.05. Conclusion Treatment with TACE may lead to an increase of $CD62L^{low}$ CXCR3+ proinflammatory effector T cells in HCC patients.

P6.16.64
Cord blood graft composition and its impact on clinical outcome after allogeneic stem cell transplantation

***H. Wikell**, J. Gertow, M. Uhlin, J. Mattsson;*
Karolinska Institutet, Stockholm, Sweden.

Today allogeneic hematopoietic stem cell transplantation (ASCT) is used for treatment of hematological malignancies, immunodeficiencies and other non-malignant diseases such as genetic and metabolic disorders. Umbilical cord blood (UCB) is a suitable source of hematopoietic stem cells when no HLA-matched related or unrelated donor is found.
We analyzed material from 29 cord blood units used for allogeneic hematopoietic stem cell transplantation with multi-color flow cytometry. Phenotypical data were correlated with different clinical outcome parameters e.g. survival, graft versus host disease (GVHD), relapse, rejection, viral reactivation, bacteremia etc. The aim was to find cell surface markers that can be used as tools to predict clinical outcome post transplantation.
We found that above-median frequency of CD69+ T cells was associated to patient survival (p=0.025). Additionally, above-median levels of naïve CD8+ T cells (p=0.028) correlated with survival, and an association between patient survival and above-median levels of CD127+ cells B cells (p=0.013) in the graft was found. Moreover, there was a statistically significant correlation between higher levels of CD94+ total T cells (p=0.0031) as well as CD8+ T cells (p=0.0024) and HSV+VZV reactivation post transplantation. This correlation was also seen for the frequency of CD95+ total T cells (p=0.013), as well as CD4+ (p=0.0067) and CD8+ (p=0.033) T cell subsets. Finally, a higher frequency of naïve CD8+ T cells seemed to correlate with aGVHD (p=0.017).
This study highlights the importance of further characterization of cellular graft composition and its impact on clinical outcome after cord blood transplantation

P6.16.65
Characterising the effect of remote ischaemic preconditioning on the immune response in healthy volunteers

***J. M. Williams**[1], J. Pilcher[2,1], R. Beasley[2], A. C. La Flamme[1];*
[1]Victoria University of Wellington, Wellington, New Zealand, [2]Medical Research Institute of New Zealand, Wellington, New Zealand.

Remote ischaemic preconditioning (RIPC) describes the phenomenon where brief intermittent periods of limb ischaemia are used to protect the heart and other organs from subsequent prolonged ischaemic insults. The precise mechanism through which RIPC exerts its protective effect is unknown but appears to involve inflammatory pathways. This study aims to determine the effect of RIPC on the immune response in healthy human volunteers. Preliminary results indicate that RIPC does not alter the circulating levels of neutrophils or monocytes, but significantly reduces expression of the activation marker, CD11b, in these populations after *in vitro* stimulation with phorbol 12-myristate 13-acetate (PMA) and ionomycin. In addition, RIPC does not have a direct effect on the response to polyclonal stimuli, or recall T cell responses to the tetanus toxoid; however, PMA and ionomycin stimulated T cells show a greater level of activation and production of the inflammatory cytokine, interleukin 6, following RIPC. These early findings indicate that RIPC has subtle but direct effects on both the innate and acquired immune responses. In light of the challenges translating the success of RIPC from animal studies into human trials, the findings from this study may be useful to help define the clinical indication and limitations of RIPC.

Validation of in vitro human PBMC assay to determine Lymphocytes activation of new Biotherapeutics

***E. Zambello**, E. Vicentini, F. Andreetta, F. Zanderigo, J. Chappell;*
Aptuit Verona, Verona, Italy.

The development of biopharmaceuticals which includes recombinant proteins and monoclonal antibodies has been on the increase due to the commercial success of many biological products. Regulatory agencies have become interested in potential *in vitro* assays using human cells that may predict immunotoxic and immunstimulatory events in humans especially after the Tegenero incident in London. After the development of *in vitro* assay to characterize and potentially predict the activation of human PBMC lymphocytes induced by different biological compounds, this method were formally validated to the principals of Good Laboratory Practice and based on various white papers and regulatory guideline. Multiple cytokines involved in innate and adaptive immunity were analysed in medium by quantitative immunoassays and in parallel, the expression of lymphocytes activation markers, CD69, CD25, HLA-DR were also assessed by flow cytometry. For validation purposes, human PBMC were isolated from at least six different donors on multiple days and cultured in the presence of vehicle and positive controls. The positive control PHA was found to be the most appropriate control for both Flow Cytometry and Immunoassays and this compound was used to induce an inflammatory response. The aim of the formal validation was to assess reproducibility and robustness of the analytical method but also to assess the biological variability associated with Human PBMC collection from different subjects. Formal validation included evaluation of intra and inter-day precision, subject variability, dilution linearity, stability. All methods were proven to be reliable and to be fit for their intended purpose.

Malnutrition and thymic hypoplasia in the infancy

***E. Catellanos**;*
University Hospital "General Calixto García", La Habana, Cuba.

Background and objectives: The thymus is an organ primary linfoide; decisive for the thymopoiesis and development of system inmunitario in the early childood, the nutritional lacks, result in thymus structural and functional changes and in the appearing of infectious complications.
Methods: In this study longitudinal prospective were studied 125 patients undernourished in during 6 moths with thymic hypoplasia and recurrent sepsis among 1-7 years old. The patients stratified in working groups according to the measurement of thymic area for ultrasound themselves: Critical (less than 500mm^2), moderated (501-999 mm^2) and normal (100-1500 mm^2).We realized correlation test between groups.
Results: We found a positive correlation among the malnutrition and the thymic hypoplasia, being more significant in the critical respect to the ones that having the normal thymic area and had a positive correlation also among the malnutrition and the appearing sepsis complicated in the infants, with significant changes in the critical and moderated in relation to them with normal thymic area.
Conclusions: Our results show that the malnutrition result in altered thymic activity in early life, therefore, its monitoring in the infants is very important in the development and functioning of thymus, for the opportune intervention in the fight against the infectious illnesses.

P7.01.02
TIM-1 Protein Trafficking Toward Cell-Cell Contacts

***M. Echbarthi**;*
Centro Nacional De Biotecnología, Madrid, Spain.

The T-cell/Transmembrane, Immunoglobulin (Ig) and Mucin domain (TIM) proteins are involved in the regulation of immune responses by modulating effector T cell functions. The TIM gene family is located in a genomic locus linked to autoimmune disease and asthma both in mouse and humans, and they have been associated with immune-related diseases, cancer and viral infections. The TIM proteins are a family of cell surface phosphatidylserine (PtdSer) receptors that can mediate elimination of apoptotic cells. We determined that the Ig variable (IgV) domain of the TIM proteins binds to PtdSer through a conserved pocket termed Metal Ion-dependent Ligand Binding Site (MILIBS). TIM-1 has mostly an intracellular distribution and accumulates in cell-cell adhesive contacts. Currently, we are using

Confocal Microscopy, fluorescent protein and several cell lines to uncover TIM-1 intracellular trafficking and its accumulation at cell-cell junctions. We found that TIM-1 accumulates in endocytic vesicles rather than on the cell surface. This TIM-1 phenotype and its migration to cell-cell contacts is dependent of the integrity of the TIM-1 extracellular portion, including IgV-MILIBS and mucin domain. Currently, we are studying translocation of TIM-1 to the immunological synapse. The accumulation of TIM-1 on cell-cell contacts might trigger costimulatory signals leading to cell activation.

P7.01.03
Cell death detection using antibody-based microarrays and digital holography microscopy on lymphocytic cell lines

Z. El-Schich[1], *E. Nilsson*[1], *C. Wingren*[2], *A. G. Wingren*[1];
[1]*Malmö University, Malmö, Sweden,* [2]*Lund University, Lund, Sweden.*

We have combined antibody-based microarray technology with digital holographic microscopy enabling us to capture cells by binding of surface antigens to specific antibodies. We perform holographic measurements for analysis of cancer cell death in terms of loss in cell volume. Development for fast and accurate evaluation tools for cancer treatments will be of great value for clinicians in deciding the most appropriate treatment for patients. We have studied two different leukemia/lymphoma cell lines subjected to high concentrations of cell-death inducing etoposide. T-cell acute lymphoblastic leukemia (T-ALL) cells or diffuse large B cell lymphoma (DLBCL) U2932 cells adhered to antibody-based microarrays and subsequently the mean cell area, cell thickness and cell volume were measured using digital holography. Results showed that the cell number was stable over time. Changes in cell volume of treated cells could be analyzed in experiments performed for up to 980 minutes, whereas untreated cells showed no such decrease in volume. Results support the idea of using the combination of digital holography and antibody-based microarray technology as an evaluation tool for cancer therapies.

Imaging studies of immunological synapse formation and signaling events using the FlowSight and ImageStream imaging flow cytometers

S. L. Friend*, H. R. Pugsley, B. E. Hall, D. A. Basiji;*
Amnis - part of EMD Millipore, Seattle, WA, United States.

Interaction between antigen-specific T cells and antigen presenting cells (APC) cognate ligand involve reorganization of the cytoskeleton and recruitment of adhesive and signaling molecules to the site of intercellular contact. Sustained adhesion of T cells to APCs and formation of the immunological synapse (IS) after T cell receptor stimulation are required for the antigen-specific response. One way to measure IS is by fluorescently labeling the molecules being recruited to the synapse and imaging by fluorescence microscopy. However, these events are rare and therefore difficult to analyze objectively and statistically by traditional microscopy methods. To overcome these problems, we employed the Amnis imaging flow cytometers to objectively collect imagery of large numbers of cells. We report the percentage of T cells involved in an organized immunological synapse, the recruitment of adhesion molecule LFA-1 and signaling molecule Lck to the synaptic complex and translocation of NFkB from the cytoplasm to the nucleus in the T cell. In this study, T cell-APC conjugates are formed with Raji B cells loaded with Staphylococcal enterotoxin B and human T cells. Results from the FlowSight and the ImageStream imaging flow cytometers are compared. Using the FlowSight imaging flow cytometer we demonstrate image-based parameters used to assess the frequency of conjugates with an organized immunological synapse. Employing the ImageStream imaging flow cytometer we further evaluate the specific location of the adhesion and signaling molecules LFA-1 and Lck within the immunological synapse complex in T cells and measure the nuclear localization of NFkB in the T cell.

Monitoring immunological dynamic processes using large-area high-speed multicolor nonlinear optical microscopy

H. Li[1,2], *Q. Cui*[1,2], *Q. Luo*[1,2], ***L. Fu***[1,2];
[1]*Wuhan National Laboratory for Optoelectronics-Huazhong University of Science and Technology, Britton Chance Center for Biomedical Photonics, Wuhan, China,* [2]*Key Laboratory of Biomedical Photonics of Ministry of Education, Huazhong University of Science and Technology, Wuhan, China.*

Studies of immunological dynamic processes in native physiological environment, call for live imaging methods that have not only high spatial resolution but also the capability of large area, high-speed and multicolor imaging. High-resolution large-area imaging can avoid cell escaping out of the observation volume during long-term monitoring, and allows the visualization of cell-cell, and cell-molecule interactions within proper context of surrounding tissue environment; while, high-speed imaging is essential to provide an accurate readout of instantaneous velocities from multidimensional (x, y, z, time) information; moreover, multicolor imaging allows simultaneous observation of differently labeled cell types, molecules and surrounding environment like vessels, connective tissue, etc. We present a large-area high-speed, multicolor nonlinear optical imaging system that is designed specifically for live animal immunological imaging. The scanning platform of the system is based on the combination of a polygonal mirror and a galvanometer scanner. Thus, an imaging speed beyond 30 frames/s is acquired. In addition, a three-dimensional robotic stage is integrated into the system for sample and objective translation. As a result, large-area and depth-scanning imaging speed is 10 frames/s and 6 sections/s respectively. Furthermore, the realization of multicolor imaging is based on four detection channels covering most of the visual spectrum normally used for fluorescence imaging. This study has the potential to provide new insights into immune system and immune response based on the investigation of cell trafficking.

P7.01.06
Optimization of single- and double-staining indirect immunofluorescence for the detection of anti-pituitary (APA) and anti-GH-producing cells

F. Guaraldi*, S. Grottoli, L. Ghizzoni, F. Settanni, E. Ghigo, E. Arvat;*
University of Turin, Turin, Italy.

Anti-pituitary antibodies (APAs) have been reported in patients affected by autoimmune endocrine disorders, hypopituitarism and pituitary tumors since 1960s, using ELISA, radioligand assay, immunoblotting and indirect immunofluorescence (IIF). A few pituitary cytosolic proteins, factors and hormones, have been suggested as possible immune targets, being GH one of the most attractive especially in the field of pituitary tumors, although the specific autoantigens recognized by anti-pituitary antibodies and their clinical significance remains to be determined. IIF is considered the gold standard method in this field. Major limitations to the detection of APA using traditional methods on commercially available kit/home-made pituitary tissue's slides are the high tissue autofluorescence (due to specific and non-specific Ag-Ab bindings) and the absence of markers for cellular localization (nuclear vs cytoplasm) which highly impair diagnosis and are responsible for false (especially falsely positive) results. We describe the method we optimized for the detection of APA and anti-GH secreting cells using single and double staining IFI working on monkey pituitary tissue from a commercially available kit, and provide images demonstrating the improvements in terms of sensitivity and specificity, leading to an overall significant increase of the method's reliability and results' reproducibility.

P7.01.07
Development of a novel system to visualize basophil degranulation

***K. Horiguchi**, S. Yoshikawa, A. Saito, L. Li, T. Ohta, Y. Kawano, H. Karasuyama;*
The Department of Immune Regulation, Tokyo Medical and Dental University, Tokyo, Japan.

Basophils play pivotal roles in allergic reactions, and protective immunity against parasitic infections. They circulate in peripheral blood under steady-state conditions, and are recruited to and accumulated in affected tissues during allergic reactions and parasitic infections. In terms of their functions, it is important to know whether those basophils are indeed activated after infiltrating tissues. It is well known that antigen/IgE-induced cross-linking of the high-affinity IgE receptors on basophils triggers their degranulation and release of inflammatory mediators including lipid mediators and proteases. In this study, we sought to visualize basophil degranulation in order to detect basophil activation in affected tissues. We constructed a novel fluorescent protein-based indicator for monitoring basophil degranulation and introduced them into basophils. The fluorescence intensity in basophils was remarkably increased after antigen/IgE stimulation, whereas it was hardly detected before stimulation. Furthermore, the increase of fluorescence corresponded to the up-regulation of CD63, known as a degranulation marker. Thus, this system appears to be useful for the visualization of basophil degranulation. We are currently applying this technique to the *in vivo* imaging of basophil degranulation.

P7.01.08
Bull's-eyes immunological synapses(ISs),but not multifocal ISs is formed between dendritic cells and T cells

***W. Lin**[1], Z. Fan[2,3,4], X. Wei[2,3,4], Y. Chu[1];*
[1]Department of Immunology, Shanghai Medical College, Biotherapy Research Center of Fudan University, Shanghai, China, [2]Med-X Research Institute and School of Biomedical Engineering, Shanghai Jiao Tong University, Shanghai, China, [3]Department of Chemistry, Fudan University, Shanghai, China, [4]Institutes of Biomedical Sciences, Fudan University, Shanghai, China.

Immunological synapses (ISs) are multimolecular assembly place of receptors and adhesion molecules, formed at the T cell-antigen-presenting cell (APC) interface during antigen recognition.They play a central role in T cells activation. Usually, multifocal ISs are formed between dendritic cells (DCs) and naive CD4+T or CD8+T cells as well as activated CD4+T cells. On the contrary, classical bull's-eye ISs are formed between B cells, supported planar bilayers and naïve or activated T cells. In our experiments, we found interestingly that bull's-eye ISs, but not multifocal ISs are formed at the murine T cell-DCs interface induced by staphylococcal Enterotoxin B (SEB) stimulation. Similar to the bull's-eye ISs of T-B cells, bull's-eye ISs of T -DCs have mature classical shape and size, and lead to the long time stable contact between T cells and DCs. Compared with the multifocal synapse, bull's-eye ISs lead to different calcium flux in T cells. A dynamic imaging analysis revealed that the mature DCs form more bull's-eye ISs and long-lasting interactions conjugates with naive T cells than immature DCs. Further analysis of the molecular mechanism of bull's-eyes ISs, we found some costimulatory molecules, such as ICAM-1, acting as an important molecular associated with cell cytoskeletal, dynamically participate in formation of bull's-eye ISs. Our results provide an alternative synapse formation between DC-T cells, which will potentially explore the new signal pathway in T cells activation

P7.01.09
Dynamic intravital analysis of T cell activation in the tumor parenchyma and stroma

***F. Marangoni**[1,2], T. T. Murooka[1,2], E. Carrizosa[1,2], T. Manzo[3], E. Y. Kim[1,2], N. M. C. Elpek[1], T. R. Mempel[1,2];*
[1]Massachusetts General Hospital, Charlestown, MA, United States, [2]Harvard Medical School, Boston, MA, United States, [3]San Raffaele Scientific Institute, Milan, Italy.

Local activation of cancer-associated T cells crucially shapes the tumor immune response; nonetheless, the efficiency of T cell activation in distinct tumor areas in vivo, and following direct- versus cross-presentation, is unknown. We set up a platform allowing the dynamic visualization of the nuclear translocation of the NFAT-GFP reporter in T cells, a hallmark of activation. We recently reported that NFAT is characterized by long deactivation kinetics (~20min) in T cells in vivo, and that during sequential interactions of antigen-specific CD8+ T cytotoxic T cells (CTLs) with cancer cells in the tumor parenchyma, it allowed the integration of intermittent TCR triggering into a continuous transcriptional response.
To study CTL activation upon interaction with hematopoietic elements of the tumor stroma cross-presenting tumor associated antigens, we used mice bearing genetically labeled myeloid cells as recipients of hemagglutinin (HA)-expressing CT26 tumors and HA-specific NFAT-GFP expressing CTLs. Upon MP-IVM, we observed that the myeloid stroma is organized as a rim surrounding the cancer, which CTLs cross on their way to the tumor parenchyma. In this myeloid-rich area, T cells stopped and activated NFAT, with similar kinetics but lower frequency as compared to the tumor nest. Therefore, before tumor invasion, CTLs can get activated during productive interactions with HA-cross-presenting myeloid cells, which strategically surround the cancer parenchyma and likely constitute an important area of immune instruction. We are currently investigating the motility and activation of other lymphocyte types within the myeloid rim, and which other signaling pathways are triggered there.

P7.01.10
Quantitative analysis of single cell distribution inside entire lymph nodes using laser sheet microscopy

***A. J. Ozga**[1], J. Ripoll[1], M. Hons[1], J. Meyer[2], J. Swoger[3], J. Sharpe[3], J. V. Stein[1];*
[1]Theodor Kocher Institute, Bern, Switzerland, [2]Centre for Genomic Regulation, Barcelona, Spain, [3]Centre For Genomic Regulation, Barcelona, Spain.

Peripheral lymph nodes (PLNs) and other lymphoid organs perform central functions as a structural interface between the innate and adaptive immune systems. The precise three-dimensional (3D) localization of antigen (Ag)-presenting cells and rare specific lymphocytes (approx. 1-10 cells/PLN) is central for the modeling of relevant molecular and cellular interactions during adaptive immune responses. Thus far, the overall internal organization of lymphoid organ microenvironments and cellular interactions have been mainly determined by two-dimensional tissue sectioning, whereby 3D information is lost, while rare events are difficult to detect.
Laser sheet microscopy, such as selective plane illumination microscopy (SPIM), is a fluorescence imaging technique suited for optical sectioning of whole biological samples at single cell resolution, yet it has not been applied in immunological research thus far. Here, we have used a customized SPIM setup to visualize low numbers of adoptively transferred immune cells and their spatial relation to vascular network structures in entire murine PLNs. Our findings show that SPIM has the resolution to reliably and reproducibly identify fluorescently labeled single cells within an entire, fixed PLN. Anatomical landmarks such as high endothelial venules can be easily stained with the use of fluorescently coupled monoclonal antibodies. Visual information about 3D localization of the cells, such as the distance between cells and anatomical landmarks, can be quantified with appropriate software. In summary, SPIM, by enabling tracking of very small amount of cells, opens the door to a detailed "optical footprinting" of initial events of adaptive immune response with physiologically low Ag-specific cell numbers.

P7.01.11
Imaging T-cell signal transduction by integrative and correlative nanoscopy

***T. Rose**, A. Salles, B. Tamarit, P. Bochet, M. Cumont;*
Institut Pasteur, Paris, France.

Recent advances in microscopy overcome the optical diffraction limit. Super resolution (SR) optical microscopy or nanoscopy refers to stochastic and deterministic approaches of fluorescent object microimaging with resolution from 200 to 20nm. Stochastic techniques- photoactivated localization microscopy (PALM) or stochastic optical reconstruction microscopy (STORM)- allow to see single fluorescent molecules blinking randomly, leading to resolutions of 20-30 nm in heavily reconstructed images. Deterministic techniques group stimulated emission depletion (STED), ground state depletion (GSD), spatially structured illumination (SSIM) and conical diffraction (SRCD) microscopy; they allow to select few stable fluorescent probes with space resolution from 100 to 35nm by depleting the fluorescence of most others. Fast events can be imaged (sec/frame, msec/line, microsec/pixel) without much computation for the reconstruction of images and allow particle tracking (PT) or raster-image correlated spectroscopy (RICS). We assay molecule numbers, complex stochiometry and dissociation constant in living T-cells by fluorescence correlated spectroscopy (FCS) using labelled antibodies targeting proteins at the cell surface or reporter-fused proteins expressed by transfected T-cells.
We compare the performances and the specificities of these techniques to image cytokine-induced cytoskeleton dynamics and delineate molecular mechanism of signal transduction in fixed and living human primary T-cells. We explore their compatibility with TEM and FIB-SEM electronic microscopy techniques to correlate optical and electronic images in 2D and 3D-cell reconstructions and build up animated models to reconstruct and simulate the signalling machinery in the full T-cell view.

P7.01.12
Use of Nuclear Imaging in tracking of adoptive Treg therapy in transplantation: a pre-clinical model

***E. Sharif-Paghaleh**[1,2], J. Leech[1], R. Lechler[1], L. Smyth[1], G. Mullen[1,2], G. Lombardi[1];*
[1]MRC Centre for Transplantation, London, United Kingdom, [2]Imaging Sciences, King's College London, London, United Kingdom.

Regulatory T cells (Tregs) are key in controlling autoimmune diseases and limiting immune responses to foreign antigens. Tregs are being studied for adoptive transfer immunotherapy for various diseases such preventing transplant rejection. However, key questions such as where therapeutic Tregs go and how long they stay viable in patients remains unsolved. Here we are trying to answer these questions in a pre-clinical set up with the help of nuclear medicine imaging technology.
Imaging of the human sodium/iodide symporter (NIS) via Single Photon Emission Computed Tomography (SPECT) has been used to image various cell types in vivo. This study addresses whether SPECT/CT imaging can be used to visualise the migratory pattern of Tregs in vivo. Murine Tregs were transduced with a construct encoding for NIS.
NIS expressing Tregs were specifically radiolabelled in vitro with Technetium-99m pertechnetate (99mTcO4-) and exposure of these cells to radioactivity did not affect cell viability, phenotype or function. Moreover, we have demonstrated that this method of imaging can be utilised to image migration of Tregs with direct and indirect allo-specificity in a skin transplant model. Interestingly, Tregs that prolonged the transplant survival demonstrated a different pattern of migration compared to Tregs that were unable to prolong the transplant survival.
The data presented here suggests that SPECT/CT can be utilised in preclinical imaging studies of adoptively transferred Tregs without affecting Treg function and viability thereby allowing longitudinal studies within disease models. Moreover, this technology has also the potential to be applied to human Treg studies in future.

P7.01.13
Imaging innate immune response in non-human primates after DNA vaccination against HIV

***B. Todorova**[1,2], F. Martinon[1,2], L. Adam[1,2], R. Boisgard[3], T. Kortulewski[4], R. Le Grand[1,2], C. Chapon[1,2];*
[1]CEA, Division of Immuno-Virology, Institute of Emerging Diseases and Innovative Therapies (IMETI), DSV, Fontenay-aux-Roses, France, [2]Université Paris-Sud, UMR E1, Orsay, France, [3]CEA, Institute of biomedical imaging (I2BM), DSV/I2BM/SHFJ/INSERM U1023, Orsay, France, [4]CEA, Photonic microscopy platform, Institute of cellular and molecular radiation biology (IRCM), UMR217 CNRS/CEA, Fontenay-aux-Roses, France.

Innate immunity is widely considered to be critical in shaping the immune response and its manipulation may improve the design of vaccine strategies. We know that antigen presenting cells (APC) form the bridge between innate and adaptive immunity and they have important immunostimulatory and migratory activities. Thus, improving our understanding of APC behavior at the injection site during the first hours after vaccination is needed.
Here we used a model of DNA vaccination against HIV in non-human primates (NHP) to investigate the spatio-temporal dynamics of skin APC after vaccination with or without electroporation (EP) by *in vivo* fluorescence imaging. Using non-invasive *in vivo* fibered confocal microscopy, we demonstrated the epidermal APC mobilization at 48h after vaccination and their density reduction over time. Moreover, skin APCs were monitored continuously during 24h by confocal fast laser scanning microscopy on skin explants after DNA vaccination. We observed the epidermal APC departure and the analysis of cell velocity and displacement showed the higher activation state of skin APC after DNA vaccination with EP than without EP.
In vivo fluorescence imaging approaches allowed us to track skin APC on the vaccination site in their native environment in NHP. The knowledge about immune cell activation is essential for the optimization of DNA vaccines efficacy.

P7.01.14
Contrasting quiescent G0 phase with mitotic cell cycling in the mouse immune system

***M. Tomura**[1,2], A. S. Sawano[3], A. Hata[4], O. Kanagawa[5], A. Miyawaki[3];*
[1]Center for Innovation in Immunoregulative Technology and Therapeutics, Kyoto University Grad. Sch., Kyoto, Japan, [2]Autoimmune Reg., RCAI, RIKEN, Yokohama, Japan, [3]BSI, RIKEN, Wako, Japan, [4]Center for Innovation in Immunoregulative Technology and Therapeutics Kyoto University Grad. Sch. Med., Kyoto, Japan, [5]Autoimmune Reg., RCAI, RIKEN, Kyoto-city, Japan.

Most lymphocytes are assumed to withdraw from and reenter the cell cycle repeatedly throughout their lifetime. We studied dynamic transition between quiescence and proliferation of lymphocytes using double-Tg mice (#639/#474) generated by crossing FucciG1-#639 and FucciS/G2/M-#474 mice, which expressed mKO2-hCdt1(30/120) and mAG-hGem(1/110) in the hematopoietic cells, respectively. Most cells in LNs, spleen and PP exhibited strong mKO2 signal but no mAG signal and were Ki-67-, which should represent the mKO2++/mAG- G0 cells. After stimulation of mKO2++/mAG- T and B cell, as mKO2++/mAG- cells decreased, both mKO+/mAG+ and mKO-/mAG+ cells increased transiently. Then, mKO2+/mAG- and mKO2++/mAG- cells increased again, indicating that mKO2++/mAG- and mKO2+/mAG- cells correspond to populations of cells in G0 and G1, and mKO2-/mAG-, mKO2+/mAG-, mKO2+/mAG+ and mKO2-/mAG+ cells correspond to cells in the early G1, G1, G1/S, S/G2/M cells, respectively. By intravital microscopy, intact LNs were mostly filled with cells with bright red nuclei. However, a considerable number of migrating cells with green and red nuclei were observed in the draining LN after immunization.
Cells in BM and thymus showed substantital heterogeneity of Fucci-signals. In both differentiating T cells in thymus and B cells in BM, the most immature cells had much more mKO2-/mAG- and mKO2-/mAG+ cells, however as maturation, these cells decreased and intensity of mKO2 increased close to its mature cell level (mKO2++), indicating Fucci-Tg mice visualize cell-cycle progression during differentiation.
In conclusion, we propose that FucciG1-#639 and/or FucciS/G2/M-#474-Tg mice can provide reliable readouts of the cell-cycle regulation of lymphocytes, both in vitro and in vivo.

P7.01.15
High Concentration Of Serum Soluble Fas In Patients With Head And Neck Carcinoma: A Comparative Study Before And After Surgical Removal Of Tumor

H. R. Zare[1]*, M. Habibagahi*[1]*, F. Ghatei*[2]*;*
[1]Department of immunology Medical School, Shiraz University of Medical Sciences, Shiraz, Iran, [2]Medical School, Shiraz University of Medical Sciences, Shiraz, Iran.

Introduction and Aims: Alternative splicing of Fas transcript can produce a natural secreted isoform of this molecule. Some cancer cells also can make soluble Fas (sFas) which may have suppressive effects on anti-tumor response of the immune system. Elevated concentration of sFas has been detected in serum of patients with different malignancies. To correlate the sFas concentration in sera of head and neck cancer patients with disease indices.
Materials and Methods: Concentration of sFas in sera of patients with head and neck carcinoma, HNC (n=98) and healthy individuals (n=30) were measured by Sandwich ELISA (Bendermed Systems, Austria) and compared to values obtained 6 months after surgical removal of tumor (n=48). Data were correlated with different clinical findings of the patients.
Results: Serum sFas in sera of HNC patients were found to be significantly higher in patients with different tumor stages. Concentration of sFas was not correlated with age or tumor invasiveness however more sFas was found in sera of patients with higher grades of tumor. Surgical removal of tumor in patients resulted in substantial decrease in sFas concentration.
Conclusion: Initial raise in sFas concentration in sera of HNC patients and its consequent decrease could be regarded as a sign of suppressive mechanisms by tumors. Additional studies are needed to fully elucidate this mechanism however these finding may show the prospective use of such biomarkers of the immune system for prognosis of the disease and even immunotherapeutic applications.

P7.02.01
Emergence of tissue-level NF-kappaB dynamics during inflammation

C. R. Boddington*, J. Bagnall, L. Schmidt, D. G. Spiller, D. A. Jackson, M. R. H. White, P. Paszek;*
University of Manchester, Manchester, United Kingdom.

Tissue level dynamics is a function of complex and nonlinear interactions between individual cells that may exhibit emergent properties. During inflammation, these interactions arise via a set of a cellular and molecular cytokine networks including cells of the immune system and key transcription factors such as Nuclear Factor kappa B (NF-kappaB). Pro- (including Tumor Necrosis Factor alpha) and anti-inflammatory cytokines may propagate and resolve inflammatory signals, but many of these cues are inherently noisy and dynamic. Using live-cell imaging and mathematical modeling we previously showed that in response to cytokine stimulation the NF-kappaB system undergoes nuclear-to-cytoplasmic oscillations, which constitutes a key positive cytokine feedback regulation (Science, 324:242, 2009, PNAS 107:11644, 2010).
Here, using systems biology approaches we develop a new quantitative understanding of how tissue-level dynamical phenotype emerges from individual cells during inflammation. We investigate the role of positive cytokine feedback in the control of the NF-kappaB response in single cells as well as multi-scale tissue mathematical models. These models are informed with time-lapse confocal microscopy measurements using RAW264.7 macrophages and mice embryonic fibroblast co-cultures. We hypothesize, that only appropriate control of cellular coupling and molecular noise allows avoiding out-of-control tissue-level inflammatory responses, characteristic to many diseases of the immune system.

P7.02.02
Cytokines prophyle in Gaucher disease type I patients with bone metabolic changes.

A. M. Craciun[1]*, P. Grigorescu-Sido*[1]*, A. Zimmermann*[2]*;*
[1]University of Medicine and Pharmacy, Cluj-Napoca, Romania, [2]Johannes Gutenberg-Universität, Internal Medicine, Mainz, Germany.

Gaucher disease (GD) is caused by an inherited deficiency of glucocerebrosidase, a lysosomal enzyme responsible for the cleavage of glucosylceramide, a substrate accumulating mainly in macrophages. In addition to organomegaly and haematological abnormalities, type 1 (non-neuronopathic) disease is also characterised by insidiously progressive and often severe skeletal involvement. We hypothesized that cellular alteration in Gaucher disease produces a proinflammatory environement that might be connected to osteoclast activity.
Serum biochemical bone turnover markers and bone mineral density (BMD) were measured in 16 type 1 GD patients and in 50 age-matched controls in order to evaluate bone balance. Cytokines were determined in serum of same GD patients and controls.Our results indicate a marked decrease of bone markers in GD patients, compared to the unaffected controls. These low values were observed in all patients, irrespective of their age, indicating a failure of osteoblastic and osteoclastic function in GD. Additionally we found correlations between bone resorption markers and inflammatory citokines, especialy with IL-6, IL-1β, TNF_{α}. The findings suggest that cytokines play a role in osteoclast formation in Gaucher disease. In conclusion, our data suggests that along with concomitant glucosylceramide accumulation, generates a state of osteoclastogenesis mediated in part by pro-resorptive cytokines.

P7.02.03
Clostridium difficile infected human signaling pathways: An integrated model

R. K. De*, N. Tomar;*
Indian Statistical Institution, Kolkata, India.

A theoretical model can explore a system of host-pathogen interactions and thus clinical treatment can be optimized to lower the microbial toxin burden in the host. The present method generates data on reaction fluxes in an integrated pathway of the host-pathogen interactions at quasi steady state. The objective function for minimizing toxin expression, with respect to some parameters, viz., concentration of signaling molecules, was formulated and a set of constraints was incorporated. We integrated the toxin expression regulatory pathway in Clostridium difficile, and apoptosis and mitogen-activated protein kinase (MAPK) pathways in an infected host (Homo sapiens). We applied the proposed method in three following cases: 1) integrated toxin expression regulatory pathway of C. difficile and apoptosis pathway of H. sapiens; 2) integrated toxin expression regulatory pathway of C. difficile and MAPK pathway of H. sapiens; and 3) integrated toxin expression regulatory pathway of C. difficile, and apoptosis and MAPK signaling pathways of H. sapiens. On minimization of the toxin expression, we observed that the signal flow values for most of the survival genes were at the higher side, whereas it was the reverse for most of the proapoptotic genes. We also observed increased signal flow values of the molecules in the host ERK pathway as compared to that of the molecules present in the host c-JNK/p38 pathway. In light of these observations, we hypothesize that lower toxin level in a pathogen leads to higher chance of host survival. We validated the results extensively using existing experimental observations.

P7.02.04
Systems Biology Approaches for Predicting and Controlling the Reactivity of Tumor Infiltrating Lymphocytes

M. Hod-Marco[1]*, K. Oved*[1]*, M. Besser*[2]*, Y. Reiter*[1]*;*
[1]*Technion-Israel Institute of Technology, Haifa, Israel,* [2]*Ella Institute for Melanoma Research and Treatment, Sheba Medical Center., Tel-Hashomer, Israel.*

Tumor infiltrating lymphocytes (TIL) is a heterogeneous population with potential anti-tumor reactivity. TIL recognition and reactivity with autologous tumor is associated with increased secretion of IFN-γ. Despite the encouraging results obtained from the use of adoptive cell transfer, in stage IV metastatic melanoma patients, and despite extensive research efforts, little is known about the cellular interactions that determine TIL reactivity. In previous work, we demonstrated that by extensive phenotypic analysis of Selected-TILs combined with computational tools we generated a decision tree algorithm that accurately predicts the degree of TIL reactivity in terms of its subpopulation constituents. Our current studies are focused on understanding the molecular basis that enables the control and prediction of TILs. Analyzing pre-REP young-TILs, we found significant correlation between reactivity and non-reactivity, and subpopulation signatures. These signatures are distinctive. Importantly, we revealed that pre-REP Young and Selected TILs share similar signatures for reactivity vs. non-reactivity. Further analysis of Pre-REP vs. post-REP Young-TILs revealed the unexpected finding that they differ in the signatures for reactivity. Expansion of TILs induces alternations in subpopulation composition and thus, changes TIL reactivity and subpopulation signatures. We aim to determine the biological processes that govern TIL reactivity during the expansion and the relationships between the TIL subpopulations and functions using systems biology approaches. Our studies may shed light on the molecular mechanism that control TIL reactivity combined with controlling the long-term reactivity, and improve the clinical efficacy of TILs. It will also set the foundations to study other types of heterogeneous cell populations.

P7.02.05
Utilizing next-generation sequencing of the humoral repertoire for monoclonal antibody discovery

T. A. Khan*, A. Mirsky, S. T. Reddy;*
ETH Zurich, Basel, Switzerland.

Historically, monoclonal antibody (mAb) discovery has relied on high-throughput screening of hybridomas or recombinant surface display libraries. While these techniques have been incredibly successful they require extensive labor, resources, and time for discovery; furthermore, potentially valuable candidates may go undiscovered due to the constraints of the screening method chosen. Here, we present mAb discovery methods that rely on analysis of the in vivo humoral repertoire of antibodies in order to isolate clones of interest. These novel methods utilize next-generation DNA sequencing (NGS, Illumina miSeq system) and bioinformatic analysis of antibody variable region repertoires obtained from B cell populations of protein antigen immunized animals. Specific candidate antibody genes are identified based on bioinformatic and statistical analysis of repertoires, primarily by clonal frequencies and ranking. These antibodies are then recombinantly expressed for characterization by biochemical and biophysical binding assays (e.g., ELISA). While our methods bypass extensive screening steps, repertoire analysis by NGS can also be combined with surface display screening technologies to further optimize mAb discovery. Finally, by performing a deep analysis of the antibody repertoire following immunization, we are able to gain quantitative insight on the diversity of B cell responses.

P7.02.06
Therapeutic Potential of Inhibition of Complement Activity for Alleviating Degenerative Eye Diseases

K. Valter[1]*, D. Garnett*[1]*, J. Zhou*[2]*,* ***G. J. Kotwal***[3]*;*
[1]*ARC Centre of Excellence in Vision Science,, Canberra, Australia,* [2]*InflaMed Inc., Louisville, KY, United States,* [3]*University of Medicine and Health Sciences, Camps, Saint Kitts and Nevis.*

Vaccinia virus complement control protein (VCP) has structural similarity to complement control proteins (Kotwal and Moss Nature 335(6186):176-8,1988). VCP exerts control over the complement (C) system (Kotwal et al. Science 250(4982):827-30, 1990). During the past decades, VCP has been extensively used in preclinical inflammatory disease models to demonstrate that controlling C mediated inflammation has improved outcomes and potential for therapeutic treatment. Published reports suggest controlling inflammation using VCP has therapeutic potential in CNS diseases, eg. AD, as well as CVS diseases eg. atherosclerosis and autoimmune diseases, eg. rheumatoid arthritis. Age-related macular degeneration (AMD) is the leading cause of vision loss amongst the aging population in the western world. A defect in C regulation in the eye has been associated with AMD. Recently, the role of C regulation in degenerative diseases of the eye in 2 separate models was investigated. In one model, mice are anesthetized and their pupils dilated. Krypton red laser photocoagulation was used to generate multiple laser spots in each eye. VCP was injected in one eye and the other served as control. Choroidal neovascularization (CNV) was measured by analysis of confocal microscopy of the tissue and VCP was shown to be effective in preventing and/or treating CNV, a hallmark of wet AMD. In light-induced retinal degeneration in albino rats, a model for dry AMD, VCP showed protective potential as judged by the quality of cell layer integrity, the reduction of photoreceptor loss and by inhibiting C activity as measured by C3d deposition in the tissue.

P7.02.07
Hgshs

N. Patel*;*
University of Manchester, Manchester, United Kingdom.

Neurodegenerative diseases, such as Alzheimer's, are characterized by a progressive loss of neural function. With symptoms including dementia, movement difficulties and speech problems, these diseases are devastating and sometimes even fatal. Despite this, and the large economic burden that they represent, there is no known cure. Recently, however, research on neural progenitor cells (NPCs) has offered hope for treatment of these diseases.
NPCs are potent immunomodulatory agents, capable of promoting tissue repair in neurodegenerative disease. Conversely, microglia, the primary immune cells of the brain, are a major instigator of cell death in disease states. Interestingly, it has been shown that mesenchymal stem cells modulate the action of microglia, encouraging a therapeutic phenotype. Here, we investigate the interactions between NPCs and microglia, by observing the dynamics of a major neuroinflammatory mediator, the gene transcription factor Nuclear Factor kappaB (NF-κB).
NF-κB regulates the expression of a variety of vital inflammatory genes, in a cell-type and stimulus-specific manner. Its complex pattern of shuttling between the nucleus and cytoplasm determines gene expression profile and, therefore, contributes to cell fate during neuroinflammation.

P7.02.08
A new model for estimation of cell proliferation dynamics using Carboxyfluorescein succinimidyl ester (CFSE) data

C. Peligero[1]*, J. M. Argilaguet*[1]*, W. C. Thompson*[2]*, H. T. Banks*[2]*, A. Meyerhans*[1]*;*
[1]*Universitat Pompeu Fabra, Barcelona, Spain,* [2]*North Carolina State University, Raleigh, NC, United States.*

Lymphocyte proliferation, which follows antigenic stimulus resulting from an invading microorganism, is a hallmark of the adaptive

immune system. Studying the quantitative dynamics of lymphocyte proliferation is essential for a better understanding of immune responses. Since it was first described, serial dilution of the fluorescent dye carboxyfluorescein succinimidyl ester (CFSE) has become the almost universal method for the determination of cellular division histories. To obtain dynamic information from CFSE-labelled proliferating cell populations, the fluorescence intensity profiles need to be analysed. Individual peaks can be fit with predefined shapes, usually normal or log-normal distributions, so that cell numbers per generation can be estimated. Therefore, the ability to reliably estimate cell numbers per fluorescence peak depends on clear peak separations that is often not attained in experiments using blood-derived human lymphocytes.
Here, we have developed a mathematical model that predicts the population structure evolution of human CD4 and CD8 T cells from histograms of time-series measurements of CFSE-labelled, phytohaemagglutinin-stimulated peripheral blood mononuclear cells. It combines (i) the direct analysis of flow cytometry-derived CFSE histograms with (ii) a statistical evaluation of the variability in the histogram data and (iii) a cyton model-based description of cell fate decisions. This model enables to derive biologically meaningful proliferation parameters and to reconstruct the population generation structure for viable cells. As the model is not dependent on clear CFSE peak separations, it is potentially of broad utility for the detailed characterization of the immune cell dynamics from human PBMCs in studies of human infections or vaccinations.

P7.02.09
High-throughput antibody repertoire analysis in S. pneumoniae immunized mice

*U. Haessler[1], M. Tamborrini[2], S. Cook[1], G. Pluschke[3], **S. T. Reddy**[1]; [1]ETH Zurich, Basel, Switzerland, [2]Swiss Tropical and Public Health Institute, Basel, Switzerland, [3]Swiss Tropical and Publich Health Institute, Basel, Switzerland.*

Despite currently existing conjugate vaccines, Streptococcus pneumoniae remains a considerable threat for infants and immune-compromised individuals1. This is mainly due to the small coverage and the rapid evolution of bacterial serotypes, which evade current vaccines and antibiotic treatment. Here, we present a systems immunology approach to gain a quantitative molecular description of the humoral immune responses that develops against S. pneumonia.
We have previously shown that next-generation DNA sequencing and bioinformatics analysis of plasma cell antibody repertoires can be used to rapidly generate recombinant monoclonal antibodies against protein antigens2. Here, we apply a similar approach to gain a comprehensive picture of the antibody repertoires that develop in mice following exposure to the complex pathogen S. pneumoniae. Specifically, we isolate plasma cells from spleen and bone marrow, which is followed by RNA extraction and antibody variable region VL (light chain) and VH (heavy chain) library generation by PCR. Libraries are sequenced using the Illumina miSeq platform, which enables full-length reads of VL and VH regions. Bioinformatic analysis of variable regions will include ranking according to transcript frequencies, revealing which B cells have expanded the most after immunization. Next, we combine recombinant antibody expression with high-throughput screening to determine whether high-frequency antibodies are pathogen-specific.
In summary we are demonstrating a novel systems immunology approach to quantitatively profile humoral immune responses that develop following immunization with the complex pathogen S. pneumonia. This platform might develop into a valuable tool for rapid monoclonal antibody discovery and selection of new vaccine candidates.

P7.02.10
Development of a bioinformatic framework for the study of high-throughput antibody repertoire data

*S. Cook, V. Greiff, A. Mirsky, **S. T. Reddy**;
ETH Zurich, Basel, Switzerland.*

High-throughput antibody repertoire analysis (HTRA), which combines next-generation DNA sequencing (NGS), bioinformatics, and statistical analysis, has become a powerful way to quantitatively address fundamental questions in immunology related to antibody repertoire diversity and evolution and as a biotechnology tool for antibody engineering. On both a genetic and protein structural level, the complementarity determining regions (especially CDR3) define antibody clonality and antigen specificity.
Therefore, we developed a modular and extensible program that identifies the various CDR and framework regions within antibody variable gene NGS data using species-specific germline data (openly available on the Immunogenetics Information System, IMGT). This program is compatible with paired-end Illumina miSeq results and processes 10^6 reads in <5 minutes. Using NGS data sets from a variety of B-cell populations and species, we show that this program is comparable or better than IMGT analysis (HighV-quest) in terms of quality control, allowed input size and speed. We have used the characteristic identifiers of antibody sequences to expand bioinformatic methods to study antibody evolution using phylogenetic trees. Additionally, taking advantage of the distributional depth of NGS data, we characterized the diversity of antibody repertoires using statistical measures which take into account both clonal diversity and abundance.
Our approach to HTRA implements an improved processing and a better understanding of antibody NGS data by providing repertoire-characterizing statistical measures both of which can be capitalized upon to gain greater insight into adaptive immune responses following vaccination and infection.

P7.02.11
Heterogenous differentiation patterns in individual CD8+ T lymphocytes

***J. C. Rohr**[1,2], C. Gerlach[1], L. Perie[1,3], N. van Rooij[1], J. W. J. van Heijst[1], A. Velds[1], J. Urbanus[1], S. H. Naik[1], J. B. Beltman[1,3], H. Jacobs[1], R. de Boer[3], T. N. M. Schumacher[1];
[1]Dutch Cancer Institute, Amsterdam, Netherlands, [2]Centre of Chronic Immunodeficiency (CCI), University of Freiburg, Freiburg, Germany, [3]Utrecht University, Utrecht, Netherlands.*

Upon infection antigen-specific CD8+ T cell responses display a highly reproducible pattern of expansion and contraction that is generally assumed to reflect a uniform behavior of individual naïve T cells. To investigate this assumption we have tracked the progeny of individual CD8+ T cells by in vivo lineage tracing and demonstrate that individual T cells follow highly heterogeneous differentiation patterns. First, even for T cells bearing identical T cell receptors, clonal expansion and differentiation vary considerably. Second, T cell diversification upon primary antigen encounter leads to stable clonal dominance during recall infections. The observation that the fate of individual naïve T cells is highly discordant suggests a division of labor between the progeny of individual naïve T cells and demonstrates that reproducibility of CD8+ T cell responses is only achieved at the population level. These findings may have important implications for the rational design of vaccines to infectious diseases and cancer.

P7.02.12
Thorough characterization of TCR-pMHC binding free energy estimated by string model and Miyazawa-Jernigan matrix

***H. Tsurui**, S. Hirose;
Juntendo University School of Medicine, Tokyo, Japan.*

Estimation of TCR-pMHC binding free energy based on its structural information is an important issue to elucidate the mechanism of immunological self-image. Some strict methods to evaluate binding free energies have been reported, however, their computational costs were quite expensive. Chacraborty's group has proposed an estimating method of the binding energy based on string model and Miyazawa-Jernigan (M-J) matrix, and applied to explain the presence of super-control of AIDS (Košmrlj A. et al., PNAS 105:16671-16676, 2008, Nature 465:350-354). We generated 106 of random peptides as T cell receptor CDR3s, educated them with self-peptides selected from FANTOM library of RIKEN using position specific scoring matrix from MEME-suite, examined the reactivity against IEDB-registered epitopes, and found that no registered epitopes was recognized by

selected receptors. This estimating method predicts a larger educational epitope pool results in the increased number of hot spots for selected TCRs. However, we found that this apparent increase of recognition-specificity involved the convergence of selected TCRs to some common sequences. This paradoxical behavior of selection process derived from the physicochemical character of M-J matrix. Chakraborty's group has further proceeded their analysis and treated the thymic selection process as an extreme-value problem based on this evaluation method (Košmrlj A et al., Phys Rev Lett 103:68103, 2009, J Stat Phys 1-17, 2011). We also carried on our analysis and further characterized this evaluation method. (This work is a collaboration with Dr. Takuya Takahashi at Ritsumeikan Univ.)

Polyclonal T-cell Receptors recognise an unusually long tumour antigenic peptide complexed to HLA-B7

K. Chan[1,2,3], *S. Gras*[3], *L. Nielsen*[1], *J. McCluskey*[1], *J. Rossjohn*[3], *W. Chen*[4,2,1];
[1]*University of Melbourne, Melbourne, Australia,* [2]*Ludwig Institute for Cancer Research, Melbourne, Australia,* [3]*Monash University, Melbourne, Australia,* [4]*La Trobe University, Melbourne, Australia.*

We recently reported a novel immunodominant 13 mer epitope derived from cancer testis antigen NY-ESO-1. This peptide is restricted to HLA-B*0702 and is naturally presented by melanoma cells. Although it adopts an extensive bulge in the centre when complexed to HLA-B7, unlike other reported long peptides, the $CD8^+$ T cell response to this 13 mer is not only immunodominant but also involves broad TCR repertoire, at least 10 different Vβ families. We hypothesise that the polyclonal recognition of NY-ESO-1_{60-72}/HLA-B7 is probably a result of flexible arrangement of the bulged peptide upon being recognised by different TCRs. To date, four NY-ESO-1_{60-72}-specific $CD8^+$ T cell clones with different TCRs have been generated and functionally characterised in various *in vitro* assays. All individual full-length TCR alpha and beta chain sequences have been identified and cloned. Sequence analysis revealed that the TCRs bear different complementarity-determining region (CDR3) sequences. These TCRs have been shown to form functional surface receptor in TCR-negative human thymoma cell line, SKW-3 after retroviral transduction. High purity soluble recombinant TCRs and NY-ESO-1_{60-72}/HLA-B7 complex have been successfully produced. Gel filtration assay and Surface Plasmon Resonance analysis confirmed the interaction between purified recombinant TCRs and NY-ESO-1_{60-72}/HLA-B7 complex. Recombinant protein crystals have been successfully grown in CrystalMation screenings. High resolution X-ray diffraction dataset of 2.0 Å, 2.8 Å and 3.2 Å have been collected for three TCR-NY-ESO-1_{60-72}/HLA-B7 crystals. The knowledge acquired from this study will aid to the current understanding of the TCR-pMHC I interaction and may have important implications for future vaccine design.

Use of The Alcoholic Extract of Alfalfa Root Instead of SLO for ASO Diagnostic Test

H. Chegni[1], *M. Oshaghi*[2], *B. Gharegozlou*[2], *B. Gharegozlou*[2], *B. Gharegozlou*[2];
[1]*Iran, Mashhad, Iran,* [2]*Iran, Tehran, Iran.*

INTRODUCTION: Alfalfa (Medicago sativa) is a flowering plant in the pea family Fabaceace. Alfalfa has been used as an herbal medicine for over years. Streptolysin O (SLO) is one of the several toxic immunogenic exoenzyme produced by group A β-hemolytic Streptococci. Anti-streptolysin O (ASO) is a routine test for the diagnosis and management of acute rheumatic fever and acute glomerulonephritis. Currently, recombinant Streptolysin O antigens are used for the ASO test. This study explored the application of this extract instead of SLO.
METHODS: Roots of extraction of Alfalfa was prepared using the maceration method. At frist we determained hemolysis effect of the extract on Human Red Blood Cell (HRBC). This extract was used instead of SLO antigen in neutralization test (Macro) .The effect of extract was evaluated on reaction between SLO latex and ASO in slide method (Agglutination). Nonetheless, the antigenic properties were determined by SRID test.
RESULT: The Alfalfa Extract exhibited considerable hemolysis activity on hRBC. The ASO inhibited hemolysis activity of the extract in a specific concentration. The extract inhibit ASO, agglutination test and showed precipitation by ASO on agarous gel.
CONCLUSION :There is significant similarity of antigenic property in both Alfalfa extract and SLO. Thus, purified extract, instead of SLO, can by used for the ASO test.

Mapping the N- and O-glycome of mouse Peyer's patches

C. Cheng[1], *S. Yu*[2], *K. Khoo*[2,1];
[1]*Institute of Biochemical Sciences, National Taiwan University, Taipei, Taiwan,* [2]*Institute of Biological Chemistry, Academia Sinica, Taipei, Taiwan.*

The interaction between L-selectin on lymphocytes and carbohydrate, especially 6-sulfo sialyl Lewis X, cover on the surface of high endothelial venules mediates lymphocyte homing. However, this glycan epitope has no significant influence on lymphocytes homing to Peyer's patches. Thus, characterization of other sulfated glycan structures on Peyer's patches is critical to understand the contribution of carbohydrate to lymphocyte homing. Nevertheless, lack of antibodies could detect sulfated glycans. Therefore, total glycan are released from Peyer's patches tissue section, chemically derivatized by permethylatiton, and liquid chromatography mass spectrometric(LC-MS)-based glycomics methodologies are utilized to analyze the N- and O- linked glycan of mouse Peyer's patches. Carbohydrate carrying one or two sulfated group are identified on N- and O- linked glycan, and sulfated group are located at either galactose or N-acetylglucosamine. Moreover, the sulfated Sda like antigen is the major glycan of O-glycans on mouse Peyer's patches. Utilizing this method, we identify the glycan structure of lymphatic tissue which might interact with glycan-binding protein to cause lymphocytes homing to Peyer's patches, and might thus have critical function for innate immunity.

Disintegrin-like molecule isolated from snake venom induces endothelial cell migration and inhibits adhesion on extracellular matrix components

I. C. Lima, J. C. Silva-Santos, M. S. Della-Casa, I. L. Santos, A. Moura-da-Silva, ***P. B. Clissa****;*
Butantan Institute, São Paulo, Brazil.

Jararhagin-C (jar-C), a disintegrin-like molecule which contains an ECD sequence (Glu; Cys; Asp), was isolated from Bothrops jararaca venom. The ECD sequence can competitively binds to cell membrane integrins to disrupt platelet-collagen interaction. As endothelial cells express different integrins receptors, they represent a potential target for interaction with ECD-disintegrins. These molecules are able to induce angiogenesis, melanoma cell adhesion and wound healing. This study aimed to investigate the effects of jar-C in the adhesion and migration of human vascular endothelial cells (HUVECs) on different extracellular matrix substrates. The cell migration assay was performed on a monolayer line scraped HUVECs grown on collagen I; IV and fibronectin. After 24 hours of jar-C treatment cells were stained and analyzed by optical microscope. The inhibition of cell adhesion was evaluated incubating HUVECs with jar-C and seeding them on well plates coated with collagen I, IV or fibronectin. HUVECs were washed post-seeding and the adherent cells were quantified by MTT method. Our results show that jar-C is associated with HUVEC migration on collagen I substrate rather than collagen IV or fibronectin. By the other side, the inhibition of cell adhesion was effective on collagen IV. Both the migration process and the adhesion are modulated by the expression of integrins by binding the matrix components. There are a number of integrins that bind to collagen and serve to anchor the cells to the basement membrane and

interstitial matrix. The jararhagin-C ability to bind to α2β1is probably the responsible by the effects observed here.

Pathological Characteristic of Experimental Colorectal Cancer Model in Three Rat Strains

S. Gu[1]*, Z. Liu*[2]*;*
[1]Seirei Christopher University, Hamamatsu, Japan, [2]Southwest Hospital, Chongqing, China.

OBJECTIVE: In the present study, we found that the development of rectum-associated lymph nodules (RALN) in the experimental ulcerative colitis model induced by dextran sulfate sodium (DSS) is different in various kind of strain in rats. In order to investigate the mechanism, we examined the relationship between ulcerative colitis and rectum-associated lymph nodules in three kinds of strain [Wistar ($RT1^u$), DA ($RT1^a$) and Lewis ($RT1^l$)].
METHODS: (1) Animals: Specific pathogen-free (SPF) male rats of inbred strains Wistar ($RT1^u$), DA ($RT1^a$) and Lewis ($RT1^l$) were given drinking water containing 3 % dextran sulfate sodium (DSS). The local ethical committee approved the animal studies. (2) Tissue preparation. (3) Antibodies: Mar1 (anti macrophage specific), Mar3, ED1 (anti macrophage differention antigen specific), and ED2 (anti macrophage subset). (4) *Immunohistochemical staining. (5)* Isolation of rectum macrophages. (6) Flow cytometric analysis
RESULTS: The weak degree of ulcerative colitis was observed at 3 days in Wistar rats; at 11 days in DA and Lewis rats ($p<0.05$) after drinking water containing 3% DSS. The immuno-histochemical and Flow cytometric analysis found that the dome, lymph follicule formation and cellular components of RALN in DA and Lewis rats were different from Wistar rats during the early postnatal period and DSS administration.
CONCLUSIONS: These results suggest that there is close relationship between the pathological changes of ulcerative colitis and the development of RALN in the three strains of rats.

Ubiquitin ligase MARCH I involves peptide discrimination for MHC II complex

Y. Kozono[1]*, R. Tanizawa*[1]*, Y. C. Sasaki*[2]*, S. Ishido*[3]*, O. Kanagawa*[4]*, H. Kozono*[1]*;*
[1]Tokyo Univ. of Science, Noda, Japan, [2]The University of Tokyo, Kashiwa, Japan, [3]RIKEN Yokohama Institute, Yokohama, Japan, [4]Akashi City Hospital, Akashi, Japan.

We examined whether ubiquitin ligase MARCH I distinguish the structural fluctuation of MHC/peptide complexes. Ubiquitination of MHC II is necessary for intracellular transport from cell membrane to acidic endosomes and vice versa. However, functional properties of ubiquitination are still in question. We used dendritic cell from MARCH I KO mice to examine antigen presentation pathway and resulting MHC/peptide complex formation with peptides that bind to I-A^k with high and low affinities. In biophysical study, we observed various range of structural fluctuation of MHC/peptide complex; the degree of structural fluctuation was proportional to the sensitivity to SDS that break complex to α-chain and β-chain in acrylamide gel. We hypothesized that MARCH I detect the motion of MHC II. DC derived from wild mice showed clear elimination of low affinity peptide for binding to I-A^k, on the other hands, DC derived from MARCH I KO mice did not show such discrimination; comparable amount of MHC/peptide complex formed with both high and low affinity peptides. We next examined decay of the formed complexes; since low affinity peptide complex has shorter half-life than high affinity one with an intracellular mechanism. To our surprise, the half-life of MHC/peptide complex was almost same in MARCH I KO mice as wild type. Thus, accelerated decay of MHC/low affinity peptide should be mediated by other mechanism beside ubiqutination, or physiologically unknown ubiquitin ligases such as MARCH VIII or other families. We will discuss on MHC II sorting and DM catalysis as the function of ubiquitination.

P7.03.07
Structural analysis of the class II HLA molecule, DP5, in complex with the Cry j 1 antigen of Japanese cedar pollen

S. Kusano[1]*, M. Shirouzu*[1]*, K. Yamamoto*[2]*, T. Sasazuki*[3]*, S. Yokoyama*[1]*;*
[1]RIKEN Systems and Structural Biology Center, Yokohama-city, Kanagawa, Japan, [2]Division of Genome Analysis, Research Center for Genetic Information, Medical Institute of Bioregulation, Kyushu University, Fukuoka-city, Fukuoka, Japan, [3]Institute for Advanced Study, Kyushu University, Fukuoka-city, Fukuoka, Japan.

Japanese cedar pollinosis is a type I allergy caused by Cryptomeria japonica (Cry j, Japanese cedar). Cry j 1, one of the major Japanese cedar pollen allergens, reacts with IgE antibodies in Japanese cedar pollinosis patients. We previously analyzed the association between Japanese cedar pollinosis and class II HLA alleles, and found that the frequency of HLA-DP5 is significantly higher in the patients. Furthermore, we identified an immunodominant peptide that induces Th2 restricted by HLA-DP5, among overlapping peptides spanning the entire length of Cry j 1. However, the specific mechanism of Cry j 1 recognition by HLA-DP5 remained unknown, due to the lack of structural information.
In the present study, we determined the crystal structures of HLA-DP5 (DPA*02022 and DPB1*0501) in complex with a Cry j 1-derived nine-residue peptide (KVTVAFNQF), at 2.4 angstrom resolution. The antigen-binding groove formed by the DP5α and DP5β chains captures the nine-residue epitope. The lysine at P1 is an important anchor residue that binds in the negatively charged pocket, and we confirmed that HLA-DP5 retains the Cry j 1 binding-activity in vitro by a structure-based mutant analysis. Furthermore, we identified the characteristic residues of HLA-DP5 that are responsible for the distinct properties of the groove, by comparing the structure of HLA-DP5 and the previously reported structures of HLA-DP2 (DPA1*0103 and DPB1*0201) in complex with pDRA. The comparison revealed that the HLA-DP5/Cry j 1 complex forms several hydrogen-bond/salt bridge networks between the receptor and the antigen that were not observed in the HLA-DP2/pDRA complex.

Structures of the Pore-Forming Toxin Monalysin solved by X-ray crystallography and electron microscopy

P. Leone[1]*, C. Bebeacua*[1]*, C. Kellenberger*[1]*, O. Opota*[2]*, B. Lemaitre*[2]*, A. Roussel*[1]*;*
[1]AFMB-UMR7257 CNRS, Marseille, France, [2]EPFL, Lausanne, Switzerland.

Pore Forming Toxins (PFT) represent the largest class of bacterial protein toxins and are often important virulence factors of a pathogen. These proteins are initially produced as soluble molecules and association with a target membrane, generally via specific receptors, induces their oligomerization in a ring-like structure. Subsequent structural rearrangements of each protomer lead to the formation of a water-filed pore. Depending on the PFT, pore formation is aimed at permeabilizing the target membrane or can serve as a translocation channel to introduce other virulence factors into the target cell. The structure of several PFT has been determined, but for only one the structures of both the soluble and the pore form are available. Nevertheless, the molecular mechanisms involved in the soluble to transmenbrane form transition of PFT are still unknown.
Monalysin was recently identified as a new virulence factor secreted by the Drosophila pathogen Pseudomonas entomophila. The studies we carried out highlighted that Monalysin is a PFT involved in the ability of the pathogen to induce intestinal cell damages into the host gut. Here we present the structures of pro-Monalysin, cleaved form and inactive mutant that have been solved by X-ray crystallography or electron microscopy. On the basis of these structures a possible mechanism of action for Monalysin is presented.

Homology modeling of the extracellular region of the B cell protein CD19

M. Maloney[1], *N. Nordgren*[2], *W. Nasir*[3], *P. Nyholm*[3];
[1]*Spelman College, Atlanta, GA, United States,* [2]*Chalmers University of Technology, Gothenburg, Sweden,* [3]*University of Gothenburg, Gothenburg, Sweden.*

CD19 is a member of the immunoglobulin superfamily of proteins that is found on B cells from the earliest stages in the bone marrow until it is lost upon terminal differentiation to plasma cells. CD19 is known to have a role in signal transduction as part of a co-receptor complex containing CD21 (CR2) and CD81 (TAPA-1) that, together with the B cell antigen receptor (BCR), is involved in various pathways related to B cell development and activation. CD77, also known as Burkitt's lymphoma-associated antigen and globotriaosyl ceramide (Gb3), is a marker for germinal center stage B cells and a cellular receptor for Shiga toxin. Several studies have linked CD19 and CD77 functions and expression. Previously we identified a potential CD77-binding region on CD19 with amino acid sequence similarities to the CD77-binding Shiga toxin B-subunits. CD77 remains the only ligand for the extracellular region of CD19 described to date. In the current study, we present a structural model of the CD19 extracellular region based on homology modeling using SSEARCH, MODELLER, PROCHECK and ProSA. Shiga toxin B-subunit models were used as templates to construct the model of the proposed CD77 binding region, and immunoglobulin superfamily members and other proteins were used for additional areas of the CD19 extracellular region. The proposed CD77-binding site of this CD19 model is most similar to CD77-binding Site 1 of published Shiga toxin B-subunit structural models and contains many amino acids of the previously proposed binding region based solely on amino acid sequence similarity.

Assessing changes expression and presentation of NKG2D under the influence of serum factors in breast cancer patients

R. Roshani[1,2], *A. Khodadadi*[1], *M. Ghaforian Borujerdnia*[1], *A. Talezadeh*[1];
[1]*Jundishapur University of Medical Sciences, Ahvaz, Iran,*
[2]*Immunology Department and Cancer Research Center, Ahvaz, Iran.*

Introduction: Breast cancer is the most common cancer in women worldwide. Nk cells play an important role in tumor cells killing by NKG2D binding to the MICA proteins on tumor cells surface. accumulated soluble MICA from tumor cell surface in serum may lead to the down regulation of NKG2D expression that has been proposed to be a novel mechanism used by cancer cells to evade the immune system. In this study we assessed influence of sMICA on changes expression and presentation of NKG2D on NK cells from breast cancer patients.
Method:
In heparinised PB samples from 49 healthy and 49 breast cancer patients before surgery and chemotherapy, NKG2D expression and presentation were assessed by qRT-PCR and flow cytometry methods respectively and to determine the serum sMICA we used ELISA. The results of flow cytometry were analyzed with WinMDI software. Statistical analysis was performed with SPSS software.
Results:
In contrast to healthy volunteers, significant amounts of sMICA was detected in sera from majority of patients. The expression and presentation of NKG2D in patients was significantly lower compared to healthy individuals, with an inverse correlation to sMICA and direct correlation to tumor stage.
Conclusion:
Our study reveals that sMICA might act as an effective factor in diminishing NKG2D expression in breast cancer patients compared to healthy individuals, and sMICA can be candidate as target for elevate expression and presentation of NKG2D that directly contributing in tumor cell killing. More work is needed to determine other confounding factors in cancer patients.

How T cells engage an EBV-associated cancer epitope

A. J. A. Schauenburg[1], *J. J. Miles*[2,1], *E. Gostick*[1], *D. K. Cole*[1], *L. Wooldridge*[1], *S. R. Burrows*[2], *P. J. Rizkallah*[1], *A. K. Sewell*[1], *D. Prize*[1];
[1]*Institute of Infection and Immunity, Cardiff, United Kingdom,*
[2]*Queensland Institute of Medical Research, Brisbane, Australia.*

Epstein-Barr virus (EBV) is a flourishing microparasite presently infecting over 90% of the human population. The virus is also a global disease burden and associated with 18 different malignancies. The latent EBV protein LMP2 is a key target of the cellular immune system since it encodes a number HLA-A*0201 (A2) restricted epitopes including FLY (FLYALALLL). FLY is a promising therapeutic and prophylactic target since it is expressed on the surface of most EBV^+ malignancies and exhibits complete sequence conservation across all known virus strains. How T cells engage this important epitope has been unknown. Here, we have solved the structure of the FLY-A2 molecule on its own and in complex with the SB7 T cell receptor (TCR) and have identified key areas of T cell contact. Understanding the molecular basis of this engagement may aid in optimizing T cell recognition as well as the design of intelligent FLY mimic compounds and super-agonists for use in the clinic.

P7.03.12
Human milk immunoglobulins contain various combinations of antigen-binding sites resulting in binding polyspecificity and catalytic polyreactivity

S. Sedyh, *V. Buneva, G. Nevinsky;*
SB RAS ICBFM, Novosibirsk, Russian Federation.

In the classic paradigm, antibodies are considered as monospecific molecules that have stable structures and two or more identical antigen-binding sites. We have shown that IgG and sIgA of human milk eluted from several specific affinity sorbents under the conditions destroying strong immune complexes demonstrate high catalytic activities in hydrolysis of ATP, DNA, oligosaccharides and phosphorylation of proteins, lipids and oligosaccharides.
In preparations of human milk IgG and sIgA we have found chimeric κλ-IgGs and κλ-sIgAs, which contain both types of immunoglobulin light chains simultaneously. Chimeric κλ-IgGs were presented by all four subclasses (IgG1-IgG4). Moreover, adding of reduced glutathione and milk plasma containing no immunoglobulin to two IgG or sIgA fractions with different affinity for DNA-cellulose leads to antibodies transition from one fraction to the other. We explain this phenomenon by the possibility of HL-fragments exchange between different IgG, IgA and sIgA molecules, but not the exchange of only light or heavy chains.
Some chimeric molecules of sIgA may contain from two up to four HL-fragments to various antigens high affinity interacting with different sorbents and catalyzing various chemical reactions. Our data essentially expand the ideas explaining the phenomenon of polyspecificity and cross-reactivity of human milk antibodies. Further investigations will be focused on allocation of human milk factor that provides exchange of immunoglobulin structural components. This could lead to a method of producing bispecific antibodies.

P7.03.13
Synergistic inhibition of Her2 overexpressing tumor cells by a combination of anti Her2 monoclonal antibodies

F. Tahmasebi;
Monoclonal Antibody Research Center, Avicenna Research Institute, ACECR, Tehran, Iran.

Her2 proto-*oncogene* is critical in the biology of breast cancer and an important therapeutic target by monoclonal antibodies (MAbs). Trastuzumab (Herceptin) is the first approved anti Her2 therapeutic MAb. We prepared a panel of mouse MAbs specific for different epitopes of Her2. The anti proliferative effect of these MAbs was investigated on Her2 *overexpressing* human breast cancer cell line BT474, using radioactive thymidine incorporation assay. Our results demonstrated that while two of the MAbs (1T0&2A8) inhibited cell proliferation dose dependently, similar to Trastuzumab, four MAbs

(1F2, 1B5, 1H9 and 4C7) augmented cell proliferation. Treatment of BT474 cells with different combinations of two MAbs induced either synergistic inhibitory or stimulatory effects. Combinations of these MAbs with significant synergistic inhibitory function may improve the *therapeutic* efficacy of Her2 specific MAbs.

P7.03.14
Nicotinic receptors in nervous and immune systems:identification and functional roles

V. I. Tsetlin[1]*, I. V. Shelukhina*[1]*, I. E. Kasheverov*[1]*, Y. N. Utkin*[1]*, M. V. Skok*[2]*;*
[1]*Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry, RAS, Moscow, Russian Federation,* [2]*Palladin Institute of Biochemistry, Kiev, Ukraine.*

Nicotinic acetylcholine receptors (nAChR) are present in neuro-muscular junctions, in the brain and other tissues, including skin and the immune system cells. They are involved in normal functions ranging from muscle contraction and regulation of immune processes to cognition. nAChR malfunctioning , due to mutations, disturbances in the expression levels or to wrong interactions are associated with such autoimmune diseases as myasthenia gravis, as well as with different channelopathies, psychiatric and neurodegenerative diseases. Since nAChRs are composed of 5 identical or different subunits, the important task is identification of the individual receptor subtypes in norm and at pathologies. Due to high homology of nAChR subunits, antibodies cannot give an undoubted answer. More reliable are specific peptide and protein neurotoxins. Using Alexa-alpha-bungarotoxin, we developed a method for identification of alpha7 nAChR present both in the nervous and immune systems (J. Neurochem. 109, 1087 (2009)). We isolated or designed novel protein (J.Biol.Chem. 287, 2709(2012)) and peptide (Mar. Drugs, 9, 1698, (2011)) neurotoxins for these purposes. Snake toxins proved useful to identify neuronal-type nAChRs in immune cells (Int.J.Biochem.Cell Biol.43, 516(2011)) and to probe the involvement of alpha7 nAChRs in the Alzheimer's diseases (J. Alzheimers Dis., 25,747 (2011)) . Combination of radioactive and fluorescent derivatives of snake alpha-neurotoxins, together with mRNA analysis and application of appropriate knock-out animals, made possible identification of functionally active alpha7 nAChRs in outer membrane of mitochondria (PloSOne, 7, e31361(2012)) which might be of importance for clarifying the role of the latter in apoptosis.

P7.03.15
Rules that govern high TCR-CD3 cell surface expression

M. M. van Loenen*, R. de Boer, R. S. Hagedoorn, E. H. M. van Egmond, M. Griffioen, J. Falkenburg, M. H. M. Heemskerk;*
Leiden University Medical Center, Leiden, Netherlands.

TCR gene transfer is an attractive strategy, which enables rapid engineering of large numbers of T-cells with defined antigen-specificity. TCRs introduced via gene transfer have to compete for cell surface expression with the endogenous TCR, as well as with mixed TCR dimers. Our work has uncovered that introduced TCRs differ in their ability to compete for expression at the cell surface. Although the expression of several TCRs could be improved by codon optimization and cysteine modification, their cell surface expression was still disadvantaged in the presence of endogenous strong competitor TCRs. Therefore, TCR gene therapy might benefit from new insights into additional TCR-characteristics that govern efficient cell surface expression.
In this study, we isolated several virus-specific T-cell populations from different healthy individuals. Previously, we have shown that to some extent it can be predicted based on specificity whether virus-specific T-cells exhibit a weak or strong competitor phenotype. We hypothesized that virus-specific T-cell populations dominated by T-cells with a public TCR would be mainly of strong competitor TCR phenotype, since efficient TCR cell surface expression might benefit T-cell selection. Indeed, our results demonstrate that presence of a public TCR in some virus-specific populations coincides with a strong competitor phenotype. However, also some virus-specific T-cells with a weak competitor phenotype exhibited a dominant public TCR. These different public TCRs will be used to study the detailed interactions between the TCRα and -ß-chains as well as their capacity to efficiently capture CD3 subunits using both protein and cellular assays.

Innate immunity of the Mytilus galloprovincialis mussel and environmental pollution: Study of some parameters and interactions

Y. Bouallagui*, R. Ben Younes, R. Oueslati;*
sciences faculty of Bizerta, Bizerta, Tunisia.

The immune system of bivalves is based on innate defenses developing cell-mediated responses and on other humoral immune systems being able to resist in a polluted aquatic environment. The aim of this work is to evaluate the innate immunity at molecular level in mussels exposed to Cadmium and Chrysene (PAH). The study of the gene expression of some biomarkers such as Catalase and Superoxide Dismutase (SOD), which occur during phagocytosis in cell-mediated response, and MgBD3 (AMP) and Lysozyme (in humoral-mediated response), is of considerable interest to understand the phenomena of the ecotoxicological effects of the environmental chemical variations of these parameters. Mussels with an average length of 7 to 8 cm are exposed to different concentrations (25, 50 and 100 µg/L) of Cadmium and Chrysene in vivo for 24 hours and 7 days to quantify the gene expression levels with RT-PCR after removal of hemolymph and isolate total RNA from hemocytes. The results show that Cadmium and Chrysene modulate the expression of the studied genes in different ways depending on the type of response and contamination, and on the dose and duration of exposure. Indeed, in the case of MgBD3 and Lysozyme (humoral-mediated response) the response to Cadmium is expressed almost in the same way for both exposure durations with same contaminant, while in the case of exposure to Chrysene, Catalase and SOD (cell-mediated response) the effect differs with the exposure time for the same contaminant.

P7.05.02
The role of bidirectional activity of NWC promoter in the evolution of RAG transposon

L. Sniezewski, A. Laszkiewicz, L. Bzdzion, M. Kasztura, S. Walach, P. Kisielow, ***M. Cebrat****;*
Institute of Immunology and Experimental Therapy, Wroclaw, Poland.

NWC is a third gene in RAG (recombination activating genes 1 and 2) locus. In contrast to RAG genes which entered the genome at some point of the deuterostome evolution as a result of a horizontal transfer of a mobile genetic element, NWC gene appears to be more conserved, as its orthologs can be found in the genomes of different groups of eumetazoan and parazoan animals. It was recently shown that many transposon-derived genes that are still functional in their host genomes are localized in the immediate vicinity of the 5' end of host genes that are controlled by bidirectional promoters. Such an arrangement enables integration of the transposon, ensures its expression and protects against host-mediated epigenetic gene silencing. We have shown that the murine NWC promoter exhibits bidirectional activity which results in the transcription of RAG-2 coding exon in non-lymphoid cells and that the promoter is activated by ZFP-143 transcription factor which binds to two sites within the promoter. Similar structure and localization of the putative NWC promoters was found in other vertebrates and ongoing investigation is aimed to verify the hypothesis that the bidirectional activity of NWC promoter is an evolutionarily conserved feature that enabled integration and survival of RAG transposon in the genome of the common ancestor of jawed vertebrates.

Amyloidogenesis as protective response in invertebrates and vertebrates

M. de Eguileor[1], *R. Girardello*[1], *A. Grimaldi*[1], *D. Malagoli*[2], *L. Pulze*[1], *G. Tettamanti*[1], *E. Ottaviani*[2], *R. Valvassori*[1];
[1]*University of Insubria, Varese, Italy,* [2]*University of Modena e Reggio Emilia, Modena, Italy.*

Foreign molecule contacts from bacteria (LPS), fungi (PMA), parasites, and chemicals provoke stress stimuli inducing protective responses from acquired and/or innate immunity. In the case of innate immunity any stress event sets off a mix of responses from immune and neuroimmune systems. Animals generally show fundamental biological principles revealing conserved regulation of the involved processes. This is also true for cellular stress responses, a complex and dynamic process of restoring cellular homeostasis characterized by the same specific stages. We have previously demonstrate that cellular stress conditions are able to promote in different animal models (invertebrates and vertebrates) the same massive morphological and physiological modifications Any kind of insult mimicking a stress condition (sundry chemical, immune, neuroendocrine and inflammatory) provokes, always and in any type of cell/tissue, detectable series of events that start with ROS over expression, ACTH/α-MSH activation, and cytokine such as IL-18 production. These general overexpressions sustain a massive amyloid fibril synthesis that provides a resistant scaffold in turn driving melanin deposition. But the amyloid production is not only linked to precursor melanin activation and synthesis. In fact it is basic to guaranty a state of cellular redox equilibrium due to regulation of ROS presence, *i.e.,* amyloid fibrils production could be considered as a basic cellular compensatory response endeavouring to attenuate oxidative stress in different cell types. Moreover, the relationship between amyloidogenesis and stressors allows to surmize a new background of information on the effects of stress.

P7.05.04
Innate immunity and evolution of antioxidant defenses: the methionine sulfoxide reductase genes in the ciliated protozoan Tetrahymena thermophila

D. Ferro[1,2], *F. Cattalini*[1], *O. Coppellotti*[1], *R. Bakiu*[3], *E. Piccinni*[1], *G. Santovito*[1];
[1]*University of Padova, Department of Biology, Padova, Italy,* [2]*Institute for Evolution and Biodiversity, Westfälische Wilhelms-Universität, Munster, Germany,* [3]*Department of Animal Production, Agricultural University of Tirana, Tirana, Albania.*

Accumulative post-translational modification to proteins, mediated by the action of reactive oxygen species (ROS), is thought to be one of the major causes of aging and age-related diseases. Mechanisms have been evolved to prevent or reverse these protein modifications. While most protein damage by ROS is irreversible, methionine oxidation to proteins can be reversed by the methionine sulfoxide reductase (Msr) system, which includes MsrA (that repairs methioninesulfoxide S-enantiomer) and MsrB (that repairs the methionine-sulfoxide R-enantiomer). The action of the Msr system contribute to cellular antioxidant resistance, resulting in life span extension of the organism. Moreover, many work demonstrated that overexpression of Msrs enhances the defenses against various diseases. In particular, methionine oxidations in both inhibitor of kappa B-alpha and Ca^{2+}/calmodulin-regulated phosphatase calcineurin may alter their functions and consequently affect transcription levels mediated by NFAT and NFκB, especially in T-lynphocytes of the immune system. With the aim to explore this problem we projected some experiments using the ciliated protozoan *Tetrahymena*, as model organism, characterizing the genes codifying for Msrs. Total RNA has been purified from *T. thermophila* cells cultured in PPYG medium and the cells were harvested after three days during exponential growth. Three genes potentially codifying for MsrA were cloned and the nucleotide and aminoacid sequences of all genes were compared with orthologous of other organisms belonging from Alveolata group and used for phylogenetic analyses. Time-course of gene expression was analyzed by RT-PCR in *T. thermophila* cells grown in normal condition and after pro-oxidant exposure. (M.I.U.R. grant)

P7.05.05
Evolution of the complement system: ancient molecules and new evidences from tunicates

N. Franchi[1], *L. Ballarin*[2], *N. Parrinello*[1];
[1]*University of Palermo, Palermo, Italy,* [2]*University of Padova, Padova, Italy.*

The complement system is a key player in innate immunity but, recently, it is becoming even more evident that complement plays also important roles in adaptive immunity.
Components of the human complement system possess unique domain structures and are classified in protein families: C3, factor B (Bf), mannan-binding protein-associated serine protease (MASP), C6 and factor I (If) family.
These complement families probably derive from exon shuffling, which created the unique domain structures of each family, and gene duplication and subsequent functional divergence, which increased the number of members in each family. Accumulating information on the complement system of vertebrates indicates that these gene duplications, which played a pivotal role in establishing the classical and the lytic pathway, occurred in jawed vertebrates. In contrast, information on complement genes of invertebrate chordates is limited and, so far, only the ascidians, such as Ciona intestinalis and Halocinthia roretzi, and the cephalochordate Branchiostoma floridae have an almost complete set of the complement gene families: C3-, Bf-, MASP-, and C6-like genes.
In the present work we demonstrate the presence of C6-, C3-, MASP-, MBL- and Bf-like genes in the colonial ascidian Botryllus schlosseri and the enhanced transcription after zymosan infection, which indicates their involvement in the ascidian immunity. The observation of a transcribed C6 gene suggest that the presence of the lytic pathway predates the appearance of the vertebrates. We are now carrying out new investigation to demonstrate a complement-related lytic activity in B. schlosseri.

The determination of antibodies against human growth hormone by use electrochemical methods combined with surface plasmon resonance and the application for the analysis in human serum

N. German[1], *V. Cernysiov*[1], *A. Kausaite-Minkstimiene*[2], *J. Kirlyte*[2], *A. Makaraviciute*[2], *A. Ramanavicius*[2], *A. Ramanaviciene*[1];
[1]*Division of Immunotechnology, State Research Institute Center for Innovative Medicine, Vilnius, Lithuania,* [2]*Nanotechnas – Centre of Nanotechnology and Material science, Vilnius University, Vilnius, Lithuania.*

Optical and electrochemical methods registering antigen-antibody binding's events are widely used in clinical examinations, biochemical analyses, in other areas such as environmental pollutants and food quality control. Direct immunoassay of human growth hormone (hGH) using simple to use, rapid and cost-effective electrochemical techniques have become an important topic in bio- and immuno-analysis.
This work reports the attempt for the application of optical and electrochemical techniques on the same chip detecting interactions of the specific anti-hGH antibodies with hGH immobilized on the surface plasmon resonance (SPR)-chip surface. A novel SPR immunoassay with atomic force microscopy and electrochemical detection for the determination of hGH has been developed.
Pulsed amperometric (PA), cyclic voltammetric (CV), square wave voltammetric (SWV) and differential pulse voltammetric (DPV) were used for the detection of anti-hGH. Higher sensitivity of created immunosensor was observed using PA, CV: analytical signal registered using PA method was 2.50 times higher if compare with CV, 16.3 times higher - with SWV and 24.5 times higher - with DPV methods. Similar reproducibility of the analytical signal (0.13) was characterised for SPR, PA and CV detection. In the case of PA method the limit of detection was 75 nM, in the case of CV method - 108 nM. The electrochemical signal dependences at wide analyte concentrations (230 - 834 nM). This work demonstrates successful simultaneous exploitation of several techniques to detect the anti-hGH antibodies using direct immunoassay format on the same area of SPR-chip. Sensitive PA was chosen for the determination of anti-hGH in human serum.

P7.05.07
Characterization of the IL-17 and IL-17 receptor families in lampreys

***Q. Han**, M. Hirano, M. Cooper;*
Emory University, Atlanta, GA, United States.

Interleukin-17 family members have been identified in lampreys. These jawless vertebrates have an alternative adaptive immune system wherein variable lymphocyte receptors (VLRs) composed of leucine-rich-repeats are used for antigen recognition. Nevertheless, jawless vertebrates have T- and B-like lymphocytes that express VLRA and VLRB respectively. Prior studies in our laboratory suggested that *IL-17* transcripts (*IL-17D* orthologue) are expressed preferentially by $VLRA^+$ lymphocytes and at higher levels after activation. Conversely, $VLRB^+$ lymphocytes express *IL-17 receptor* transcripts (*IL-17RA* orthologue named *IL-17RA1*). Because lampreys represent an early phylogenetic juncture between innate and adaptive immunity, we sought to characterize the IL-17 family members and their cognate receptors in order to examine their potential roles in coordinating $VLRA^+$ and $VLRB^+$ cellular interactions. Nested PCR was used to obtain full-length cDNAs of the lamprey *IL-17D* (591-bp open reading frame) and three *IL-17R* family members with *IL-17RA* homology (*IL-17RA1*, *IL-17RA2* and *IL-17RA3*). Quantitative RT-PCR analysis indicated that the lamprey *IL-17D* orthologue is expressed highly in skin, gill and $VLRA^+$ lymphocytes, while lamprey *IL-17RA1* is expressed highly in hematopoietic tissue typhlosole, $VLRB^+$ lymphocytes and monocytes. A recombinant IL-17D-Fc fusion protein was produced and shown to bind to both monocytes and $VLRB^+$ lymphocytes, and not to neutrophils or $VLRA^+$ lymphocytes. The lamprey IL-17RA1 recombinant protein is directly associated with the IL-17D-Fc protein. These findings are consistent with the hypothesis that IL-17D produced by $VLRA^+$ lymphocytes may interact with a cognate IL-17R on $VLRB^+$ lymphocytes and monocytes to facilitate immune responses in lampreys.

Genomic analysis in inbred mice provides insights into the evolutionary history of NKG2D ligand genes

***M. Kondo**[1], J. Kasamatsu[1], Y. Sarada[1], N. Otsuka[1], T. Takada[2], A. Toyoda[2], A. Fujiyama[2], T. Shiroishi[2], M. Kasahara[1];*
[1]Department of Pathology, Hokkaido University Graduate School of Medicine, Sapporo, Japan, [2]National Institute of Genetics, Mishima, Japan.

NKG2D ligands (NKG2DLs), represented by MIC and ULBP in humans and RAET1, H60 and MULT1 in mice, are MHC class I-like molecules, the expression of which is induced by cellular stress such as transformation and infections. Engagement of NKG2DLs with NKG2D, a major activating receptor expressed on NK cells, enables NK cells to kill transformed cells and infected cells. We previously showed that the ancestors of the MIC, ULBP/RAET1/H60/MULT1, and MILL families emerged by tandem duplication within the MHC region in a common ancestor of marsupial and placental mammals (*Immunogenetics*, 2010). In the present study, we compared the genomic organization of the NKG2DL-encoding region and its adjacent region in inbred mice. This comparison showed that laboratory strains fall into two major groups with disparate repertoires of NKG2DL genes. Mouse strains with inactivated H60a ligand generally have two NKG2DL genes of the *Raet1* family, *Raet1d* and *Raet1e*, whereas those with functional H60a ligand have three *Raet1* genes, *Raet1a*, *Raet1b*, and *Raet1g.* These results suggest that some *Raet1* genes are likely allelic. Our present work revealed the complex evolutionary history of the genomic region encoding NKG2DLs.

P7.05.09
Cranial base (CB)/brain and immune system of the fetus and neonate in concert in evolutionary development

***A. Kunz**[1], C. Iliadis[2];*
[1]Harvard University (Extension), Boston, MA, United States, [2]University of Partas Medical School, Patras, Greece.

Introduction: Human CB/brain growth follows same developmental pattern as immune response maturation, 1st postnatal year; these systems' rapid extensive intra/extra uterine growth abounds despite somatic growth slowing, 4.4 months gestation. Methods: This paper explores this intertwined relationship of CB/brain and immune systems for evolutionary and ontological significance.
Results/Discussion: Human CB studies show fetal 2nd trimester anterior CB begins faster elongation rate, 1.6mm/week vs 0.9mm/week, $p<0.001$, matching midline-extension brain enlargement. A significant phylogenetic identity shift, early fusion of intrinsically controlled mid sphenoid synchondrosis, an elongation enhancement, includes crista galli/olfactory receptors. Unexpected link between immune/olfactory systems by major histocompatibility complex (MHC) transmits information about MHC genotypes/influences behavior/reinforces *new* human identity. 1st year postnatal life, human immune response maturation and CB/brain growth follow same developmental pattern. *Yet*, conserved genome plasticity of immune response is 500 million years old, when basic antigen presentation strategy by MHC polymorphism was established. Conserved gene plasticity for neo-cortex development is 57 years young; genes *RFPL1,2,3* duplication/cluster arrangement began neural expression for size/organizational changes. Life History Theory favors trade-offs for privileged CB/brain/immune systems, investment associated with increased society longevity, ongoing 125K years. Embryonic gene assembly confers vulnerability/responsiveness to environment the immature brain relies on, establishing/guiding pathways/connections. Fetal-capacity immune responsiveness begins development 8 weeks gestation; driven by environmental pathogens, infancy growth investment is then maximized by rapid development of individual specific immune repertoire, offering phylogenetically the *most* antigen binding specificities. Conclusion: Evolutionary features as central design provide insight for understanding preeminent relationships of ontological significance for CB/brain and immune systems.

A Research Coordination Network in Ecological Immunology

***L. B. Martin**[1], D. M. Hawley[2], D. R. Ardia[3];*
[1]University of South Florida, Tampa, FL, United States, [2]Virginia Polytechnic University, Blacksburg, VA, United States, [3]Franklin and Marshall College, Lancaster, PA, United States.

Ecological immunology, or eco-immunology, is one of the most rapidly growing fields of evolutionary biology. In 2010, the US National Science Foundation funded a Research Coordination Network to foster its conceptual and technical development. Since funding, the RCNE has flourished including: the spawning of several collaborations; the convening of two topical workshops in the USA (Florida and Michigan) and two in Europe (Scotland and Germany); the establishment of an email list-serv; extensive support of trainee research exchanges; and the production of a website. The group's efforts have also been influenced the Society of Integrative and Comparative Biology (SICB) to vote soon to found a new Division (Ecoimmunology and Disease Ecology). We present this poster to increase the visibility and membership of the RCNE and thus broaden and deepen immunology, from molecular to landscape scales.

P7.05.11

Functional analyses of lymphocytes and granulocytes isolated from the thymus, spiral valve intestine, spleen, and kidney of juvenile Australian lungfish, Neoceratodus forsteri

M. G. Mohammad[1]*, M. H. Golakani*[1]*, J. Joss*[2]*;*
[1]*St Vincent's Hospital Center for Applied Medical Research, Sydney, Australia,* [2]*Macquarie University, Department of Biological Sciences, Sydney, Australia.*

The Australian lungfish Neoceratodus forsteri is an evolutionary important species, data suggesting that it's the closest living relative to the tetrapods. Our current understanding of the lungfish immune system is limited. This study characterizes the immune cells separated from primary and secondary immune organs of the Australian lungfish, N. forsteri. Flow cytometry was used to conduct functional studies on immune cells extracted from the thymus, spiral valve intestine, spleen, and kidney. The different characteristics of lymphocytes and granulocytes were analyzed by utilization of viability, phagocytosis, oxidative burst, and apoptosis assays. The profile of N. forsteri thymocytes resembles those from the thymus of high vertebrates. Notably, most of the nonviable intestinal immune cells were lymphocytes. Depending on the organ, 6-25% of the total population, predominantly granulocytes from organs other than the intestine, underwent phagocytosis where the splenic cells were the most and intestinal cells the least phagocytic cells. Cells responded positively but differently to stimulation with phorbol myristate acetate (PMA) to produce radical oxygen species, an indication of their oxidative burst activity, which was mainly associated with granulocytes. Although cells were induced by dexamethasone to undergo apoptosis, such an induction did not follow a consistent pattern of dose of dexamethasone or incubation time between the different organs. In the absence of antibodies directed against lungfish immune cells, these functional flow cytometric analyses aid our understanding on the functionality of immune cells.

P7.05.12

The introduction of monoclonal antibody Institute: the region's largest student center

M. Naghavi - Behzad[1]*, M. Ghojazadeh*[2]*, A. Naghavi-Behzad*[1]*, R. Piri*[1]*;*
[1]*Students' Research Committee, Tabriz University of Medical Sciences, Tabriz, Iran,* [2]*Tabriz University of Medical Sciences, Tabriz, Iran.*

The monoclonal antibody research center was first established by Tabriz University of Medical Sciences in 2011 to provide service and research. This research center is meant to concentrate and coordinate research and production of antibodies against human and animal cells. Production of synthetic and semisynthetic monoclonal antibodies needed for research centers and companies, production of laboratorial kits for diagnostic and therapeutic purposes have played an important role in approaching Iran's national research goals.
In a short period of time, this center has produced many antibodies such as antibody against sperm surface antigen, anti-ferritin, PSA, BSA, Inhibin, different cancerous peptides and more than 68 polyclonal, enzyme-conjugated and fluorescent-conjugated products. In this research center polyclonal and monoclonal antibodies can be produced and purified. One of the other purposes of this research center is educating Iranian researchers, sharing technologies with other centers and holding research workshops. This research center is a member of European biotechnology network, so in order to cooperate with this network, besides many productive research projects, this center has held practical and theoretical workshops about monoclonal and polyclonal antibodies.

P7.05.13

The cattle germline IGHV repertoire is very limited

M. Niku[1]*, J. Liljavirta*[1]*, K. Durkin*[2]*, E. Schroderus*[1]*, A. Iivanainen*[1]*;*
[1]*, Department of Veterinary Biosciences, Helsinki, Finland,* [2]*Unit of Animal Genomics, GIGA-R & Faculty of Veterinary Medicine, Liège, Belgium.*

Ruminants are thought to have a small germline immunoglobulin gene repertoire, but the IGHV genes have been poorly known. We characterized the bovine IGHV repertoire based on the genome assemblies, raw sequencing data and targeted sequencing of several animals.
In the genomic data, 36 IGHV genes were identified and assigned to 3 subgroups. Fetal IGHV cDNA sequences, containing less somatic mutations than in adults, aligned to these genes with 99.6% average identity. Only 10 of the genes appear functional, all in subgroup IGHV1, with identical FR and CDR lengths and canonical CDR structures. Targeted sequencing yielded 17-20 different sequences homologous to the functional genes per animal (including allelic variants), indicating that the bovine genome contains 10-20 paralogous IGHV loci. Thus, the germline IGHV repertoire is very small.
The evolution of the IGHV repertoire appears highly dynamic within Cetartiodactyla. The bovine IGHV genes belong to clans I and II; no clan III genes were found even by clan-specific PCR. Of related species, sheep and elk were negative for clan III, but deer, pig and dolphin were positive. The functional subgroup in cattle was likely generated by recent duplication events. It is homologous to the murine IGHV2 (Q52), but lacks a clear human homolog.
The complex IGH locus is incorrectly assembled in current genome versions. Most IGHV genes were found in UMD_3.1 but missing from Btau_4.2. In UMD_3.1, they were distributed in BTA21 and BTA7. FISH analysis confirmed the locus on BTA21 but suggests that the BTA7 locus is an assembly error.

P7.05.14

Risk Factors Associated with the Acquisition of HIV/STIs in Female Sex Workers (FSWs) in Lagos Nigeria

N. M. Otuonye[1]*, O. Enabulele Onmoiwu*[2]*, H. Aliyu*[2]*, C. Onwuamah*[1]*;*
[1]*Nigerian Institute of Medical Research, Yaba, Lagos, Nigeria,* [2]*University of Benin, Benin City, Nigeria.*

This study assessed the risk factors that influence the acquisition of STIs/HIV infections in Nigerian FSWs. ***Methods*****:** 450 FSWs aged (15 – 35 years) were randomly selected in 3 local government areas in Lagos, Nigeria. A pre- and post-test counselling was conducted after a written informed consent was obtained. Participants provided demographic data, information on sexual behaviour, contraceptives use, number of new sexual partners within 3 months and vaginal douching. Cervical and high vaginal swabs were screened for the presence of STIs using standard microbiological methods. Quick view Chlamydia test kit was used for detection of Chlamydia antigen on cervical swabs. Blood samples were screened for HIV antibodies using ELIZA kits and Western blot tests, syphilis antibodies using RPR and TPHA kits. ***Results*****:** HIV infection (36.0%) and (31.7%) was seen in those involved in anal and oral sexual practices respectively. HIV infection in those who douched was high (32.3%) and was low (10.0%) in those who do not. HIV (21.8%) was prevalent in FSWs who had 20-30 new sex partners within 3 months. ***Conclusion:*** Anal, oral, douching, increased number of new sex partners and improper use of condom have been identified as risk factors to HIV/STIs acquisition in FSWs**.** Information on the need to access health programmes for early treatment of STIs/HIV, counseling on sexual practices, vaginal douching/proper use of condoms in order to maximize benefits should be made available, regular surveys on these risk factors would help in developing new strategies for control/ prevention of STIs/HIV diseases in FSWs.

P7.05.15
Boosting heterosubtypic neutralization antibodies in recipients of the 2009 pandemic H1N1 influenza vaccine

***C. Qiu**, Y. Huang, Y. Hu, Z. Yuan, X. Zhang, J. Xu;*
Fudan University, Shanghai, China.

BACKGROUND: A mass vaccination has been implemented to prevent the spread of 2009 pandemic influenza virus in China. Highly limited information is available on whether this vaccine induces cross-reactive neutralization antibodies against other subtypes of influenza viruses.
METHODS: We employed pseudovirus-based assays to analyze heterosubtypic neutralization responses in serum samples of 23 recipients of 2009 pandemic influenza vaccine.
RESULTS: One dose of pandemic vaccine not only stimulated effective neutralizing antibodies against cognate influenza virus 2009 influenza A (H1N1), but also raised broad cross-reactive neutralizing activities against seasonal H3N2 and highly pathogenic avian influenza virus H5N1 with lesser activity to H2N2. The cross-reactive neutralizing activities were completely abolished by IgG removal. In contrast, H1N1 vaccination alone in influenza-naive mice elicited only vigorous homologous but not cross-reactive neutralizing activities.
CONCLUSIONS: Our data suggest that the cross-reactive neutralizing epitopes do exist in this vaccine and could elicit significant cross-reactive neutralizing IgG antibodies in the presence of preexisting responses. The exposure to H1N1 vaccine is likely to modify the hierarchical order of preexisting immune responses to influenza viruses. These findings provide insights into the evolution of human immunity to influenza viruses after experiencing multiple influenza virus infections and vaccinations.

P7.05.16
R4 regulators of G-protein signaling share a common ancestry with the MHC paralogons

***J. Suurväli**[1], J. Robert[2], P. Boudinot[3], S. Rüütel Boudinot[1];*
[1]Tallinn University of Technology, Institute of Gene Technology, Tallinn, Estonia, [2]University of Rochester Medical Center, Department of Microbiology and Immunology, Rochester, NY, United States, [3]INRA, Molecular Virology and Immunology, Domaine de Vilvert, Jouy-en-Josas, France.

Regulators of G Protein Signaling (RGS) modulate a multitude of biological processes by inhibiting GPCR-mediated signaling pathways. The smallest RGS proteins, members of the R4 subfamily, are responsible for the regulation of immunological processes such as chemotaxis. In many vertebrates, genes encoding the R4 RGS proteins such as RGS1 and RGS16 are located clustered together in the same genomic regions. In this study we show that the genomic context of these genes constitutes a synteny group well conserved across tetrapods. Our findings indicate that the RGS1/RGS16 synteny group can be linked to the MHC paralogons and has been likely coevolving with them. Indeed, RGS1/RGS16 region genes can often be found on the same scaffolds as the hallmark MHC markers in the cephalochordate Branchiostoma floridae, a species with well-conserved ancestral configuration. Moreover, we show that genes of this region have immune function not only in mammals, but also in an evolutionarily distant animal - the amphibian Xenopus tropicalis.

P7.05.17
Comparative study on primary structure and function of rhesus monkey and human granulocyte-macrophage colony stimulating factor

***Z. Tao**[1,2], H. Yang[1], D. Jia[1,2], L. Wan[1], J. Cheng[1], X. Lu[1,2];*
[1]Key Lab of Transplant Engineering and Immunology, Ministry of Health West China Hospital, Sichuan University, Chengdu, Sichuan, China, [2]Regenerative Medicine Research Center, West China Hospital, Sichuan University, Chengdu,Sichuan, China.

Recent studies revealed the pivotal roles of granulocyte-macrophage colony stimulating factor (GMCSF) in inflammation and arthritis, suggesting GMCSF-neutralizing agents might be developed as novel therapeutic approaches for these immune disorders. Since the rhesus monkeys *Macaca mullata* are usually used as animal models for pathogenesis and drug discovery for human disease, it is needed to compare the human GMCSF (hGMCSF) and *M. mulatta* GMCSF (mmGMCSF). Here, a 432 bp transcript encoding mmGMCSF was amplified by RT-PCR. The predicted mmGMCSF contains 144 amino acid residues with approximately 96% identity to hGMCSF. The mature mmGMCSF differs from hGMCSF at 6 amino acid residues. MmGMCSF was expressed in freshly isolated PBMCs of monkey at low level. In contrast, Con A- and allogenic antigen-stimulation significantly increased the accumulation of mmGMCSF in the media of PBMCs. Moreover, the amount of secreted mmGMCSF was consistent with the proliferation of stimulated PBMCs. These results suggested that mmGMCSF was predominantly produced by activated T cells. The recombinant mmGMCSF produced by *E. coli* is comparable to hGMCSF in supporting TF-1 cell growth. In the presence of human interleukin 4, mmGMCSF induced the progenitor cells in monkey PBMCs to differentiate into DCs. The hGMCSF receptor protein and the neutralizing anti-hGMCSF antibody reduced the activity of mmGMCSF in supporting TF-1 cells survival. These results suggest that the recombinant mmGMCSF might be a useful tool for *in vitro* evaluation of novel hGMCSF-neutralizing agents prior to *in vivo* evaluation in the rhesus monkey model.

P7.05.18
The Drosophila immune response to Invertebrate Iridescent Virus 6

***C. C. West**, W. Theurkauf, N. Silverman;*
UMass Medical School, Worcester, MA, United States.

Although insects lack an adaptive immune response, they mount a robust innate response against many pathogens. The *Drosophila* immune response against bacteria and fungi is largely NF-κB mediated and RNA viruses initiate a strong small interfering (si)RNA response. However, very little is known regarding the response to DNA viruses. To determine which pathways respond to DNA virus infection in *Drosophila*, we have utilized Invertebrate Iridescent Virus 6 (IIV-6), to identify pathways required to protect against infection with this DNA virus. IIV-6 is an large, dsDNA virus with a nucleo-cytoplasmic replication cycle. Infected wild-type flies present an iridescent blue color and abdominal swelling in later stages of infection, before succumbing approximately thirty days post-infection. We have revealed roles for several different signaling pathways, notably the Piwi-interacting RNA (piRNA) pathway, in protection from this virus.
Canonically, the piRNA pathway functions in the germline to protect the genome from transposons, mobile genetic elements that can cause mutations and double strand breaks if uncontrolled. piRNAs are transcribed from specific genomic loci, processed, and loaded onto Piwi proteins to form an RNA-induced Silencing Complex, targeting complimentary transcripts. Additionally, these piRNAs can be amplified through a secondary pathway: the ping-pong amplification loop. We have evidence that the secondary piRNA pathway, consisting of Aubergine and AGO3, is strongly protective against IIV-6. Given the similarities between transposons and viruses, it is intriguing that this pathway is operating in an anti-viral manner against a DNA virus.

Innate and acquired immunity and apoptosis of lymphocytes and granulocytes in rabbits experimentally infected with RHDV

***M. Adamiak**[1], B. Tokarz-Deptuła[1], A. Trzeciak-Ryczek[1], J. Działo[2], B. Hukowska-Szematowicz[1], P. Niedźwiedzka-Rystwej[1], W. Deptuła[2];*
[1]University of Szczecin, Department of Immunology, Szczecin, Poland, [2]University of Szczecin, Department of Microbiology, Szczecin, Poland.

RHDV is a factor causing viral haemorrhagic disease, being a appropriate model for hemorrhagic fevers and hepatitis in humans. This paper presents an immunological picture in 30rabbits (10infected with RHDV strain-237/04, 10 infected with an antigenic variant

RHDVa-72-V/2003 and 10control) infected with RHDV. The blood was sampled from the marginal ear vein at 0 ,8, 12, 24h p.i.
The innate immunological picture was determined by the ability of adherence, absorption (absorption index, % absorbing cells), NBT test (spontaneous, stimulated, spectrophotometric, stimulation index), myeloperoxidase activity in PMN cells, the concentration and activity of lysozyme in the serum and the percentage of T-cells with receptor CD8+, while acquired immunity was determined by percentage of monostained T-cells with receptor CD5+, CD4+ and CD25+, and of B-cells with receptor CD19+. The apoptosis of lymphocytes and granulocytes was determined by the total caspase 1-9 activity.
Studies have shown that the strain 237/04 of RHDV in comparison to strain 72-V/2003-an antigenic variant (RHDVa), provides more than 40% changes in studied parameters. Those changes with the RHDV strain were recorded as increases and decreases in the 8, 12, 24h of study, and changes with RHDVa, were registered mostly as decreases in 12, 24h and rarely in 8h (CD8+). The apoptosis of lymphocytes and granulocytes in case of RHDV incorporated at 8, 12, 24h, and in case of RHDVa at 12, 24h.

P7.07.02
Tumoral necrosis factor alpha (TNF-alpha) and interleukine 1 alpha (IL-1 alpha) expression in intestinal mucosa of young alpacas (vicugna pacos) with histological diagnostic of necrotic enteritis

***C. Bardález**, A. Manchego, K. Chiok, N. Sandoval, J. More, M. Ramírez, H. Rivera;*
Universidad Nacional Mayor de San Marcos, Lima, Peru.

The aim of this study was to determine mRNA levels of pro-inflammatory cytokines TNF-α and IL-1α by real time RT-PCR in intestinal mucosa of neonatal alpacas with histological diagnosis of necrotic enteritis (n = 27). Relative quantification was performed with the 2 Delta Delta Ct method ($2^{-\Delta\Delta Ct}$), using 5 young healthy alpacas as control samples and 3 newborn alpacas as the calibrator sample. Total mRNA was extracted from each sample and subsequently real time RT-PCR was performed. It was determined that sick animals express more TNF α (13.58 times) than healthy (12.2 times) when compared with the calibrator; likewise IL-1α expression was higher in animals with necrotic enteritis (21.83) than in healthy animals (17.5 times) when compared with the calibrator. The expression levels of both cytokines in the intestinal mucosa suggest constant confrontation to proinflammatory agents in young alpacas, there being a slight increase in proinflammatory cytokines expression in animals with necrotic enteritis.

P7.07.03
Dynamics of T and B cells in lymphoid organs during the experimental infection of specific-pathogen free (SPF) layers with Fowl adenovirus (FAdV) serotype 4

***I. Best**, W. Medina, E. Choque, M. Fernández-Sánchez, M. Fernández-Díaz;*
FARVET, Chincha, Peru.

Fowl adenovirus (FAdV)-serotype 4 is involved in the etiology of inclusion body hepatitis, a disease that causes significant economic losses for the poultry industry. The aim of this study was to evaluate the dynamic changes that occur in the subsets of $CD3^+$, $CD4^+$, $CD8^+$ and B-lymphocytes among lymphoid organs after experimental infection with FadV-4.
Thirty-five SPF layers of 12-week-old were split into two groups. Group 1 (n=19) was infected with $6.25x10^9$ copies of FadV-4 while group 2 (n=16) remained uninfected (control). The percentages of $CD3^+$, $CD4^+$, $CD8^+$ and B-lymphocytes in spleen, thymus, bursa and peripheral blood were evaluated by flow cytometry at 2, 4 and 7 days post-infection (dpi). At 4 dpi, a significant decrease of $CD8^+$ T cells (median=20.18%) in spleen, B cells (median=68.39%) in bursa, and $CD8^+$ T cells (median=12.48%) and B cells (median=2.54%) in peripheral blood was observed in the infected group compared to $CD8^+$ T cells (median=27.44%, $p<0.05$) in spleen, B cells (median=96.96%, $p<0.05$) in bursa and $CD8^+$ T cells (median=18.91%, $p<0.05$) and B cells (median=10.64%, $p<0.05$) in peripheral blood from the control group. In addition, $CD45^{hi}$ population in thymus was significantly higher in the infected group (median=89.64%) than in the control group (median=66.58%, $p<0.05$). By 7 dpi, no differences in the T-cell subsets and B cells were observed between the different groups.
FadV-4 causes a rapid decay of $CD8^+$ T and B cells among lymphoid organs. Our results suggest that the thymus can be related to the T cell repopulation and immune reconstitution after disease.

P7.07.04
Immunological assessment of Aleuria Aurantia Lectin

***G. M. Bindke**[1], F. Roth-Walter[1], J. Singer[2], K. Jaeger[3], R. Brunthaler[4], K. Köhler[5], A. Willensdorfer[1], E. Jensen-Jarolim[1];*
[1]University of Veterinary Medicine Vienna, Messerli Research Institute, Comparative Medicine, Vienna, Austria, [2]Medical University of Vienna, Institute of Pathophysiology and Allergy Research, Vienna, Austria, [3]University of Veterinary Medicine Leipzig, Institute of Veterinary-Pathology, Leipzig, Germany, [4]University of Veterinary Medicine Vienna, Institute of Pathology and Forensic Veterinary Medicine, Vienna, Austria, [5]Justus-Liebig University of Gießen, Institute of Veterinary-Pathology, Gießen, Germany.

Background: We have previously shown, that Aleuria Aurantia Lectin (AAL) microparticles target murine peyer's patches in the gastrointestinal tract and can modulate an ongoing Th2-dominated response towards Th1. In this study, we further wanted to assess stability and binding of AAL to canine tonsils and intestinal sites. Moreover, the immunological properties of AAL were investigated.
Methods: AAL was incubated with Pepsin or Trypsin and stopped after different time-points, subsequently stability was assessed by SDS-PAGE following Coomassie or Silver staining. NfkB/AP1 activation upon AAL-addition was determined in human THP1 monocytic cell line, transfected with an NfkB/AP1 alkaline phosphatase reporter and quantification with Quanti-Blue. AAL-binding of paraffin-embedded canine tonsils and small intestine was analysed immunhistochemically.
Results: AAL alone was sensitive to Pepsin-digestion, when incubated longer than 15 minutes, whereas trypsin was not able to digest AAL at all. Furthermore, a modest, but concentration-depent increase in NfkB-activation was observed by adding AAL to THP1-cells. In dogs AAL-binding was predominantly observed on the apical side of epithelial cells lining canine tonsils and intestine.
Conclusion: AAL is considerably resistant to gastric digestion, is able to activate NfKb and binds to epithelial cells of tonsils, peyer's patches and intestinal villis, hence, making it suitable as an oral delivery system in canine patients.

Background: Taenia solium cysticercosis is an infection mostly endemic of developing countries in Latin America, Africa and South East Asia that affect humans and pigs. Prevalence of infection in pigs, the intermediate host for T. solium, has been used as a monitor of disease transmission in endemic areas, however, accurate and specific diagnostic tools for porcine cysticercosis remain a major goal. Aim: To identify specific antigens that can diagnose with high efficiency and specificity porcine cysticercosis. Methods: Sera from well characterized pigs, including infected and non-infected animals and infected with other common pig infections, were used to select antigens by immunoproteomics that were exclusively recognized by antibodies present in the sera from cysticercotic pigs. Results: Seven antigens well characterized using the Taenia solium genome database were identified as specific for porcine cysticercosis: None of these proteins were cross-reactive when tested with sera from pigs

infected with Ascaris spp., Cysticercus tenuicollis and hydatid cysts of Echinococcus spp or with a serum from a Taenia saginata infected cow. Comparison among orthologues indicated that the amino acid sequences of two antigens possessed highly specific regions, what makes them adequate candidates for the development of a specific diagnosis for porcine cysticercosis. Perspectives: Further studies will be conducted to evaluate the potential of the 7 selected antigens (individually or in combination) using a larger number of sera from naturally infected pigs, as well as with sera and cerebral spinal fluids from neurocysticercotic patients. Project supported by DGAPA IT201613.

P7.07.06
Monocyte chemoattractant protein-1 polymorphisms influence T cell proliferation and T subsets

***H. Chang**, H. Chaung, J. Yu, Y. Li, S. Liu, W. Chung;*
National Pingtung University of Science and Technology, Pingtung, Taiwan.

Monocyte chemoattractant protein-1 (MCP-1), a widely known pro-inflammatory cytokine, belongs to a family of secreted proteins involved in immune-regulatory and inflammatory processes. MCP-1 is produced from a wide variety of stimulated normal cells, such as mononuclear leucocytes, fibroblasts, endothelial cells, smooth muscle cells, and epithelial cells. Single nucleotide polymorphisms (SNPs) are thought to be ideally suited as genetic markers for establishing genetic linkage and as indicators of genetic diseases. MCP-1 gene variants have been known to be associated with blood pressure in ischemic heart disease, type 1 diabetes, differential susceptibility to pulmonary tuberculosis and coronary artery disease. In the present study, we characterized the MCP-1 SNPs and investigate the associations between MCP-1 SNPs and phenotypes of cell proliferation and cell surface markers on porcine peripheral blood mononuclear cells (PBMC). We firstly identified two SNPs on the MCP-1 intron 1, SNP 336 and SNP 383. Significantly lesser CD8+ and reduced cell proliferation was found in PBMC with MCP-1 SNP 336 C/C than those with 336 C/A and A/A types. In addition, lesser CD4+ cells was found in those with MCP-1 SNP 383 G/G than those with 383 G/A and A/A types while cell proliferation of PBMC with MCP-1 SNP 383 A/A was significantly lower than other two genotypes. Thus, MCP-1 SNPs may affect disease-resistance by influencing T cell proliferation and cell surface antigen expressions of PBMC.

P7.07.07
Soluble FliC fusion protein cloned from *Salmonella Enteritidis* stimulates TLR7 and TLR8 expressions

***H. Chaung**[1], Y. Lien[1], M. Wu[1], L. Hung[2], W. Chung[1];*
[1]National Pingtung University of Science and Technology, Pingtung, Taiwan, [2]SBC Vibrac Biotech Co., LTD,, Kaohsiung, Taiwan.

Flagellin, a TLR5 ligand, is the major protein component of bacterial flagella, which provide motility and allow adhesion to host mucosal tissues. Numerous studies have demonstrated that flagellin contributes to the efficacy of various novel vaccines for Yersinia pestis, West Nile virus, Plasmodium falciparum, Tetanus toxoid, and influenza. Flagellin activates TLR5-positive dendritic cells, neutrophils and epithelial cells. Mucosal administration of flagellin has been shown to induce primarily the Th2-type adaptive immune response, while also enhancing levels of mucosal and systemic IgA. Thus, flagellin may trigger the innate immunity that in turn is important for subsequent adaptive immune responses. In the present study, the full-length of flagellin was cloned from *Salmonella Enteritidis* and expressed as a soluble fusion protein (FliC). The biological activities of FliC were examined in the peripheral blood mononuclear cells (PBMC) of specific-pathogen free (SPF) pigs. Results showed that the FliC significantly stimulated gene expressions of toll-like receptor 7 (TLR7) and TLR8 and secretions of IL-4 and IL-10 in the porcine PBMC. Thus, the FliC soluble fusion protein with improving activities of porcine immune cells can be used as a potential porcine vaccine adjuvant candidate.

P7.07.08
Gentamicin-attenuated Leishmania infantum vaccine: protection of dogs against canine visceral leehmaniasis in endemic areas of southeast of Iran

***H. Daneshvar**[1], M. Namazi[2], M. Molaie[3], H. Kamiabi[1], S. Phillips[4], R. Burchmore[4];*
[1]Medical School of Kerman University, Kerman, Iran, [2]Sabzvar Medical University, Sabzvar, Iran, [3]Bahonar Vetrinay University, Kerman, Iran, [4]Biomedical and life Science,, Glasgow, United Kingdom.

An attenuated line of Leishmania infantum (L. infantum H-line) has been established by culturing promastigotes in vitro under gentamicin pressure. The safety and the ability of protection of the attenuated vaccine were conducted on dogs in the high endemic areas in the rural district of Baf in the southeast of Iran. One hundred and three dogs from non-endemic area were randomly divided 2 groups (38 dogs in vaccinated group and 65 dogs control group). The dogs were vaccinated subcoutanously with L. infantum H-line, and the prospective incidence of natural infection by this vaccine was assessed during a two-year follow-up from July 1020. The safety and protection of the vaccine in the endemic area was assayed by monitoring the clinical signs and measuring the serum specific anti-Leishmania IgG. No clinical signs of disease including anorexia, apathy, local swelling on injection site occurred and no vomit and diarrhea were developed after vaccine injection. The results show only 4% of vaccinated dogs developed CVL while 45.6% of controls developed clinical signs of disease. The gentamicin attenuated line L. infantum vaccine induced a significant and strong protective effect against canine in the field.

P7.07.09
Bm86 and Hd86 anti-*Hyalomma scupense* tick vaccine trials in cattle, efficacy and limits

***Y. Galai**[1,2], M. Ben Saïd[2], M. Gharbi[2], M. Jedidi[2], J. de la fuente[3,4], M. Darghouth[2];*
[1]Pasteur Institute of Tunis, Belvedere Tunis, Tunisia, [2]Ecole Nationale de Médecine Vétérinaire, Sidi Thabet, Tunisia, [3]Instituto de Investigación en Recursos Cinegéticos, Ciudad Real, Spain, [4]Center for Veterinary Health Sciences, Oklahoma State University, Stillwater, OK, United States.

The *Rhipicephalus microplus* recombinant Bm86-based tick vaccines have shown their efficacy for the control of several *Hyalomma* cattle ticks genera. However, *H. scupense* species, the most important tick in North Africa has never been studied. Vaccination trials using recombinant Bm86 and Hd86-based vaccines were conducted in cattle against immature and adult *H. scupense* ticks. The results showed a 59.19% reduction in the number of *scupense* nymphs engorging on Hd86 vaccinated cattle. However, cattle vaccination with Hd86 did not have an effect on *H. scupense* adult ticks infestations. In order to explain these *data*, Hd86 mRNA expression levels between these two tick developmental stages were measured. The results showed a significant reduction in the number of transcripts during feeding and, particularly, moulting to adults. The most interesting result was noted after moulting of engorged nymphs in unfed adults where the expression levels decreased significantly by 12.78 (10.77-17.39) and 9.25 (5.77-15.72) fold in unfed males and unfed females, respectively. Comparing unfed nymphs to unfed adult ticks, the *Hd*86 expression levels decreased by 13.82 (5.39-24.45) and 9.93 (2.87-22.08) fold in males and females respectively. Moreover, Bm86 vaccine didn't show any efficacy against the both stages of the *H. scupense* ticks. Amino-acids sequence variations between Bm86 and Hd86 could explain these results.

P7.07.10
Evaluation of vaccines against foot and mouth disease in the mouse model, correlation with efficacy in cattle

V. Gnazzo[1,2]*, E. Pereyra*[1,2]*, V. Quattrocchi*[1]*, I. Soria*[1,2]*, C. Langellotti*[1,2]*, C. Mongini*[2]*, V. Lopez*[3]*, E. Smitsaart*[4]*, P. Zamorano*[1,2,5]*;*
[1]Instituto Virologia CICVyA INTA Castelar, Capital Federal, Argentina, [2]CONICET, Buenos Aires, Argentina, [3]Universidad de Buenos Aires, Buenos Aires, Argentina, [4]Biogénesis Bagó, Buenos Aires, Argentina, [5]Universidad del Salvador, Buenos Aires, Argentina.

The use of mice as a laboratory animal model for assessing vaccine potency provides an attractive alternative to the use of cattle and overcomes the disadvantages of high costs and facility requirements. There is international consensus to reduce, replace, refine animal experiments.
Protection against podal generalization (PGP) and quantification of post vaccination antibodies by liquid phase blocking ELISA (lpELISA) are the official control tests in South America for assessing potency of foot-and-mouth disease (FMD) vaccines. In this report, FMD oil adjuvant vaccines were inoculated in cattle and BALB/c mice. Specific antibody titres were measured in cattle and in mice at 60 and 21 days post vaccination (dpv) respectively by lpELISA. The cut-off points for lpELISA at 60 dpv in cattle have been officially determined and are correlated with the PGP test. A statistically significant association between antibody levels in cattle and mice was shown (concordance between both methods was 92%) as supported by Fisher exact test and by Kappa index of 0.68 (good concordance). At 21 dpv, we found that IgG2b/IgG1>1 and high avidity indexes (>50%) of mice antibodies against FMDV correlated with efficacy of commercial vaccines.
In addition IFN-γ secretion and IgA mucosal level were studied in vaccinated mice although still no relationship with protection against challenge were found.
This report describes the correlation established between immune response in cattle and mice following vaccination against FMD. This alternative method is a refinement of a current test and addresses animal welfare concerns by reducing the number of animal experiments performed.

P7.07.11
Producing Anti-Somatostatin-14 in Eggs of Immunized Chickens and Evaluating Antibody by ELISA

F. Golchinfar*, R. Madani;*
Razi Vaccine & Serum Resarch Institute, Karaj, Iran.

Egg yolk is an important source of antibodies. Hens were immunized with Somatostatin-14 Human globulin conjugate, The biggest obstacle for isolation of chicken antibodies (IgY) is the removal of lipids, which are present in abundance in egg yolk. We have used a two-phase system to separate egg yolk. The use of an aqueous two - phase system with phosphate and PEG 6000, made separation of lipids and water -soluble proteins possible.
An indirect ELISA system was developed to measure anti - Somatostatin antibodies titer after their extraction. The sensitivity of ELISA was also affected by the coupling method used in the conjugation of Somatostatin and carrier protein. The results of total protein content of eggs during the immunization period showed that the protein amount of ss-14 injected group is higher than control group and the maximum level of protein content was attained at day 40, after first injection and then the amount of protein content decreased. Total protein content examined in egg yolk as indicator of total IgY amount of immunized an non immunized chicken that immunized group showed higher level of IgY content than control group after conjugated somatostatin-14 (SS-HSG) injection.

P7.07.12
Development of monoclonal antibodies against (PPR) virus

F. Golchinfar*, R. Madani, T. Emami;*
Razi Vaccine & Serum Resarch Institue, Karaj, Iran.

Peste des petits ruminants (PPR) is an acute, febrile, viral, disease of small ruminants with great economic importance. PPR and rinderpest (RP) viruses are antigenically related and need to be differentiated serologically. The use of monoclonal antibodies (Mab) in ELISA for specific diagnostic and separation PPR and RPV will be important. For this purpose six BALB/c mice were immunized with inactivated antigen from the Nijeria strain. Fusion cloning was performed 3 months later by directly using cloning plates, and by selecting the hybridoma colonies at an early stage with an inverted microscope and transferring them into 96-wells plates with a micropipette. From 300 wells nearly 56 hybridoma were found which after testing in ELISA, only 11 clones with higher titer were selected. Among them only two clones were placed for limiting dilution (1H1, 6A12). There was only one clone (6A12L1F12) that had no cross-reactivity with RPV and reacted with the N protein and was of IgG2 isotype.

P7.07.13
Participation of Treg cells in equine Recurrent Airway Obstruction

C. Henriquez*, G. Morán, B. Perez, N. Morales, H. Folch;*
Universidad Austral de Chile, Valdivia, Chile.

Recurrent Airway Obstruction (RAO) is a common allergic inflammatory disease that affects stabled adult horses. As etiological factor, environmental air borne antigens are implicated, and airway hypersensitivity types I and III, are well recognized factors of the disease. A deeper study of the disease, clearly show that other immunologic components are involved. In this work we explored the participation of the T regulatory cells (Tregs) in equine RAO.
For this purpose, a RAO susceptible herd of nine horses were exposed to *Aspergillus fumigatus* and the clinical condition monitored before and after the allergen exposure, obtaining between other samples bronchioalveolar lavage fluid (BALF) in order to evaluate the cell content the airways, and in particular the presence of Treg cells.
The results show that the Treg CD-4+, CD-25+, FoxP3+ increases in BALF obtained from healthy animals from 0.56% to 1.59% in RAO horses, if we consider as Treg population the CD-4+, FoxP3+, CD25- cells, we find that the content of this sub-population increases from 1.80% to 3.54% in normal and RAO positives animals. This increment represent represents the largest contribution to the increase of total FoxP3 cells in airways and has a direct correlation with number of neutrophils in BALF as well as with the clinical and the mucus score shown by each animal.
The role of Treg in the resolution of the disease as well as the significance of the great number of FoxP3 positives Tregs that do not show the CD-25 molecule in the membrane are discussed.

P7.07.14
Emetic potential of newly identified staphylococcal superantigens

K. Imanishi[1]*, K. Omoe*[2]*, H. K. Ono*[3]*, H. Kato*[1]*, K. Shinagawa*[2]*, J. Yagi*[1]*, A. Nakane*[3]*, T. Uchiyama*[4]*, D. Hu*[5]*;*
[1]Tokyo Women's Medical University, Tokyo, Japan, [2]Iwate University, Morioka, Japan, [3]Hirosaki University, Hirosaki, Japan, [4]Tokiwa University, Mito, Japan, [5]Kitasato University, Towada, Japan.

Staphylococcal enterotoxins (SEs) are exotoxins that cause staphylococcal food poisoning in humans. Classical types, SEA, SEB, SEC, SED and SEE have been characterized. Recently SEG, SEH, SEI, SER, SES and SET were identified as potential agents of food poisoning. In addition, new proteins (SElJ, SElK, SElL, SElM, SElN, SElO, SElP, SElQ, SElU, SElV and SElX) with similar amino acid sequences as the above SEs have been identified. SEs are also known as members of the superantigens. During the last few decades, a lot of studies have been conducted on the nature of SEs and their superantigenic activities. However, the emetic activity of those toxins has not been studied. To understand the etiologic nature of staphylococcal food poisoning extensively, emetic potential of SEls should be evaluated.
We demonstrated the emetic activity of SElK, SElL, SElM, SElN, SElO, SElP, and SElQ using primate model (cynomolgus monkeys) in which the number of vomiting, the time to the first vomit (latency period), and behavioral changes were recorded. We compared their emetic activities between classical and new SEs, and among three large groups on the basis of similarity of amino acid sequences.

Furthermore, we studied their mitogenic activities, and will discuss the relationship between emetic and superantigenic acitvities.
Additionally, we demonstrated their emetic activity in a recently established system using house musk shrews. The use of monkeys investigating SEs is severely restricted by high cost, the availability of the animals, and ethical considerations. We will discuss the usefulness of the system using house musk shrews.

P7.07.15
The technique for large-scale production of CpG DNA adjuvant and applications in avian vaccines

*H. Chaung[1], L. Hung[2], Y. Tsai[1], **Y. Lien**[1];*
[1]National Pingtung University of Science and Technology, Pingtung, Taiwan, [2]SBC Vibrac Biotech Co., LTD, Kaohsiung, Taiwan.

Research of animal vaccines is one of the most influential developing industries in the demand for the national policy regarding agricultural biotechnology industrialization. Development of adjuvants is one of the keys to development of vaccine technologies. Use of an adjuvant has proven to yield advantages improving the deficits of traditional vaccines by increasing safety and enhancing vaccine effectiveness. DNA adjuvants containing unmethylated CpG motifs have been confirmed to promote human, mammal, and even avian vaccine efficacy. Our lab has developed one species-specific, structurally stable CpG DNA adjuvant with promoting humoral and cellular immune responses in chickens. The objective of this research is to produce the CpG DNA adjuvants in a large-scale and apply the CpG DNA adjuvants in the chicken vaccines. The highest chemically purified CpG DNA plasmid contents with the 64 copies of CpG motif was achieved at the 6-10 hr under the typical fermentative conditions and the chemically purified CpG DNA plasmid with the 64 copies of CpG motif significantly stimulated gene expressions of IFN-gamma, TLR7 and TLR8 of the chicken immune cells. These technologies can be also applied for vaccine/adjuvant design, production and implementation for other animals, including mammals and even pets, and thus have the potential to drastically facilitate the development of the animal vaccine industry.

P7.07.16
Development of an ELISA for determination of potency in snake anti venoms

***R. Madani**, F. Golchinfar, T. Emami;*
Razi Vaccine & Serum Resarch Institute, Karaj, Iran.

The venom of Naja Naja Oxiana, Vipera Lebetina, Vipera Albicornouta, Echis Carinatus, Pseadocerastus Persicus and Agkistrodon Halys snakes are used to determine the potency of the polyvalent sera in neutralizing the venom. LD50 value per mouse was determined 6.5 µg. Neutralization methods for obtaining potency of anti venom are competitive ELISA (Enzyme linked immunosorbent assay) and in vivo assay (ED50). Both of these tests were performed to estimate the serum potency, in 15 samples of hyper-immune equines. Results of competitive ELISA showed that at 1/12000 dilution of serum can inhibits 50 percent of antigens. Five fold of LD50 as challenge dose of venom for lethality neutralization test was applied for all serums. Competitive ELISA was compared with current biological assay ED50. Significant correlations between ELISA titers and values of ED50 at level of P≤ 0.01 and r=0.95 was observed, that indicates competitive ELISA can estimate antibody neutralizing capacity of the serum as well as the in vivo assay. The results of present study shows C-ELISA that measures Ag-Ab complex can used as a suitable replacement method for lethal neutralizing in vivo method.

P7.07.17
Determination of lymphocytes subpopulations in peripheral blood cells of dogs with atopic dermatitis

***A. Majewska**[1], K. Dembele[2], M. Gajewska[3], T. Motyl[3];*
[1]Department of Physiological Sciences, Faculty of Veterinary Medicine,Warsaw University of Life Science-SGGW, Warsaw, Poland, [2]Department of Small Animal Diseases with Clinic, Faculty of Veterinary Medicine, Warsaw University of Life Science-SGGW, Warsaw, Poland, [3]Department of Physiological Sciences, Faculty of Veterinary Medicine, Warsaw University of Life Science-SGGW, Warsaw, Poland.

Canine atopic dermatitis (AD) is a genetically-predisposed inflammatory and pruritic allergic skin disease, with clinical features commonly associated with IgE-antibodies to environmental allergens. Th1 and Treg lymphocytes play an important role in AD, regulating immune response i.e. by inhibiting the development of allergic responses of Th2 cells. During early phases of AD Th2 response predominates and is followed by Th1 domination in chronic AD. The aim of this study was to determine the profile of lymphocyte subpopulations in peripheral blood mononuclear cells (PBMC) in dogs with AD. Twenty dogs with AD (patients of Small Animal Clinic) were included in this study. Diagnosis was made based on Willemse's and Prélaud's criteria, confirmed by serological allergy tests and intradermal skin tests. Three healthy dogs were included as controls. PBMC were isolated from blood and analyzed using flow cytometry.
The most commonly encountered positive results were against house-dust mites (over 70%), and less frequently against various pollens: grass weed, tree. Percentage of Th1 cells was higher in atopic dogs (12%) compared with controls (6.7%). The Th1/Th2 ratio equaled 3 in AD dogs, 1.3 in controls. The number of Treg lymphocytes was two times higher in atopic dogs. Tc cells population was also elevated in AD dogs vs. controls (19.5% vs. 16.8%). B cells percentage was lower in AD dogs. To summarize, dogs with AD had increased Th1 and Tc subpopulations, and decreased number of Th2 and B cells, indicating that a transition from early humoral to cell-mediated immunity occurred in the examined patients.

P7.07.18
Human anti-langerin (CD207) polyclonal antibodies detect epidermal Langerhans-like cells in the sea turtle (Chelonia mydas)

***F. A. Muñoz**[1], J. Calderon-Amador[2], A. Negrete-Philippe[3], L. Flores-Romo[4];*
[1]Universidad Autónoma de San Luis Potosí, San Luis Potosí, Mexico, [2]CINVESTAV-IPN, Ciudad de México, Mexico, [3]Xcaret, Playa del Carmen, Mexico, [4]CINVESTAV-IPN, Ciudad de éxito, Mexico.

Dendritic cells form the link between the innate and adaptative immune response, particularly on mucosal and epidermal surfaces. Langerhans cells play a key role in the skin immune response, however, no molecular marker for these cells has been identified in endangered marine reptile green turtles, thereby complicating the understanding of the pathogenesis of diseases such as fibropapillomatosis which induces internal and skin tumors in this species worldwide. Langerhans cells present different molecular markers, among them, HLA-DR, MHC-II, CD1A, and specially CD207. We demonstrate that the polyclonal anti-human langerin (CD207) antibodies strongly stained Langerhans-like cells in the suprabasal layer of epidermis in cryosections and cytospin preparation from migration assay. The morphology of these cells was round to amoeboid in normal skin and cytospin preparation, but in skin with ulcerative dermatitis, langerin+ cells aggregated around ulcers and adopted a more pleomorphic morphology. To our knowledge, this is the first identification of Langerhans-like cells with a molecular marker in a reptile species.

P7.07.19
Isolation and characterization of recombinant single chain fragment variable antibodies against Toxoplasma gondii surface antigen

***M. Nakhaei Moghadam**, M. Golchin;*
Shahid Bahonar University of Kerman, Kerman, Iran.

Toxoplasma gondii an obligate, intracellular parasite, which is widely spread in the world. The parasite is able to infect all warm-blooded hosts including human and farm animals. The infection in humans often occurs after the ingestion ofraw or undercooked meat containing tissue cysts, although the ingestion of food or water contaminated with oocysts excreted by infected cats is another major transmission route. Several methods have been applied to detect this parasite in contaminated foods. The object of present study was to isolate recombinant monoclonal antibodies against this important parasite that could be used in future in diagnostic tests. The purified Toxoplasma gondii surface antigen p30 was coated to immunotubes and used as a target for selection of antibodies from the Tomlinson I and J phage display libraries of single chain (scFv) antibodies. Clones able to recognize antigen were isolated by three rounds of binding, elution and amplification. scFv antibodies chosen from the resulting panel, their specificity were confirmed by ELISA, dot blotting and western blotting.
The study showed that several recombinant antibodies were able to bind specifically to antigen with high affinity. Therefore these isolated soluble single chain antibodies are good candidates to apply as monoclonal recombinant antibodies in diagnostic kits for detection Toxoplasma gondii in contaminated samples.

P7.07.20
Failures of immunization in animals with reference to the West Africa sub-region

M. O. Odugbo*;*
National Veterinary Research Institute, Vom, Nigeria.

In West Africa, outbreaks among livestock vaccinates of vaccine-preventable anthrax, brucellosis and clostridial diseases, have been common occurrences suggesting that no vaccine could be 100% protective. Longitudinal studies conducted over the last five years to determine active immunization against these diseases have shown in general that the antibody titres found in members of vaccinated populations were distributed on a statistically “normal” curve; a few animals having very high titres and another small group failing to respond at all, however many times the animals were re-vaccinated. This varied response is probably due to individual genetic make-up. In general we also observed that a supposedly live vaccine may be dead due to poor storage especially during transportation, or the animal may recently have been treated with an antibiotic, residues of which may be sufficient to inactivate a live bacterial vaccine. If for example more than one antigen is given at one time, the balance of antigens may be such that the response to one or more of them is overwhelmed by a greater stimulation of antibody production effected by the others. In very young animals passive immunity obtained from colostrums or through the placenta may be the cause. The implication of these failures is that where an enzootic disease such as anthrax, brucellosis or tetanus is concerned, many deaths will occur in the unprotected animals because individuals are exposed to the chance of infection over long periods of their lives.

P7.07.21
Polyspecific antigen binding by bovine immunoglobulin heavy- and light-chain variable domains

Y. Pasman*, A. K. Kaushik;*
University of Guelph, Guelph, ON, Canada.

The complementarity regions (CDR) in the variable heavy and light chain domains of immunoglobulin determine the affinity and specificity of the antigen-binding site.
Generation of an exceptionally long CDR3H (up to 61 amino acids) in the bovine heavy chain variable region (VH) provides an additional mechanism to generate antibody diversity, not found in other species to date. These long CDR3H loops, present in polyspecific IgM, originate from VDJ recombination encoded by a specific VH gene, unusually long single DH-gene and insertion of 15-18 base long conserved short nucleotide sequences at VH-DH junction. In cattle, it is thought that antigen binding is mainly a function of the variable-region VH where light chain provides only structural support. To test this hypothesis, single chain variable fragment (scFv) and single domains (Fd) from polyspecific IgM were constructed. Both purified scFv and FdVH showed polyspecific binding to structurally dissimilar antigens in an ELISA. Whether scFv and FdVH bind to multiple epitopes on an antigen or if they recognize the same epitope can now be determined. The structural-functional complexities of these antibody fragments and the role of the heavy- and light-chains in antigen binding will be discussed. [Supported by NSERC Canada]

P7.07.22
Pathogenesis of pancytopenia in canine visceral leishmaniasis: bone marrow morphological alterations and IGF-I and IL-7 mRNA expressions

F. A. Pinho*[1], S. I. Miyashiro[2], L. S. Silva[3], E. M. Ramos-Sanchez[1], F. A. L. Costa[3], H. Goto[1];*
[1]Instituto de Medicina Tropical, Universidade de São Paulo, São Paulo, Brazil, [2]Faculdade de Medicina Veterinária e Zootecnia da Universidade de São Paulo, São Paulo, Brazil, [3]Universidade Federal do Piauí, Teresina, Brazil.

Pancytopenia is an important alteration in active visceral leishmaniasis (VL) but the pathogenesis is poorly known. We examined 13 naturally *L. (L.) infantum*-infected dogs and 10 control dogs. Dogs presenting *Erlichia canis* coinfection were discarded. We performed hematological exam, myelogram and IGF-I and IL-7 mRNA expressions by Real Time PCR. All VL dogs exhibited normocitic normochromic anemia, leucopenia and/or thrombocytopenia. From 13 VL dogs 5 presented pancytopenia and 8 bicytopenia. In the myelogram we observed dysgranulopoiesis (100%), dyserythropoiesis (100%) and dysmegakaryocytosis (53.8%) and an increase in the myeloid:erythroid ratio. The precursor erythroid cell: mature erythroid cell ratio was higher in pancytopenic than in bicytopenic dogs. We also observed an increase in the mature myeloid and a decrease in the mature erythroid cells when compared with control dogs. In the differential count, we observed an increase in the number of lymphocytes in VL dogs than in controls. We observed a significant decrease of the plasma cells in VL dogs compared to control dogs. The IGF-I mRNA expression was lower but the IL-7 mRNA expression higher in VL dogs when compared with control dogs. In canine VL, the morphological analysis suggests the occurrence of dishematopoiesis with gradual disturbance in the maturation process. Furthermore, a decreased IGF-I mRNA expression may be implicated in the hematological changes mainly of erythroid series and IL-7 mRNA expression in the lymphocyte proliferation. Supported by FAPESP, CAPES, CNPq, LIM-38 (HC-FMUSP).

P7.07.23
Booster BCG vaccination modulates response against Mycobacterium bovis-PPD in dairy herds with tuberculosis

E. Ramírez*[1], C. Estrada[1], A. Ruiz[1], H. Esquivel[1], L. Higareda[1], G. López[1], L. Bojórquez[2];*
[1]CIATEJ AC., Guadalajara, Mexico, [2]PRONABIVE-SAGARPA, México, Mexico.

Vaccination with *Mycobacterium bovis* BCG and booster with protein subunit vaccine induces a significant degree of protection against bovine tuberculosis (bTB). We performed studies to determine the profile of immune response on commercial dairy herds with high bTB prevalence (30.6±9.0%) after vaccinated with BCG (5 x 10^6 CFU) and/or boosting with a subunit vaccine. We assessed gamma interferon (IFN-γ) and also (purified protein derivative [PPD])-specific Immunoglobulin G (IgG) antibody levels in serum. IFN- γ response showed a sustained increase along the time (from 1000 to 2000-4000 pg/ml) with higher peaks one month after initial vaccination (5000 pg/ml) and after the first (4000 pg/ml) and second booster (7000 pg/ml) in single tuberculin skin test reactors (TST^+). When comparing the IFN- γ in non-reactors cows, the levels were lesser, but also increased at mo 3th (2000 pg/ml; after the 1st booster) and at mo 13th (over 3000 pg/ml; after the 2nd booster). The increased response in both groups of animals, suggest the induction of a Th1 memory response in the immunized animals. We found that the IgG antibody response to this antigen was inversely correlated to the cellular immune response measured by IFN- γ production. In TST^+ the mean IgG antibody levels increased at the first month (p<0.05), although

decreased (p<0.05) along time post-vaccination (i.e., at mo 2th and 7th). We explored different cut off values for classification of test results using receiver operating characteristics curve analysis, which could enhance the power of discrimination between vaccinated and bTB infected and non-infected cattle.

Improvement in bovine haemorrhagic septicaemia vaccine potency and efficacy by aluminium nanoparticles and keyhole limpet hemocyanin, and an approach to develop a DIVA strategy

S. M. Ray*;*
Dept. of Veterinary Microbiology,ICAR Centre Of Advanced Faculty Training,LLRUVAS, Hisar,Haryana, India.

Haemorrhagic septicaemia (HS) caused by *Pasteurella multocida* B:2 serotype is a major cause of morbidity and mortality in cattle and buffaloes in India and other Asian countries. Alum adjuvanted and oil emulsion commercial vaccines for HS control suffer from poor potency, efficacy, safety and other problems. Moreover, these vaccines are unable to differentiate infected from vaccinated animals (DIVA strategy) and the HS control programme cannot be monitored effectively. The present study aimed to improve HS vaccine qualities by using aluminium nanoparticles and keyhole limpet hemocyanin (KLH) as adjuvants, and to develop a DIVA strategy by incorporating KLH. Aluminium nanoparticles and KLH were mixed with formalin-inactivated *Pasteurella multocida* B:2 P52 strain. Various controls were also used. Swiss albino mice (n=8/group) was inoculated twice at three-week interval. Two weeks after booster, mice were challenged with 50xlethal dose$_{50}$ of virulent bacteria. All the mice (n=7) immunized with nanoparticle+KLH+bacterin (group I) survived the challenge. While aluminium nanoparticles (group II), KLH (group III) and alum-precipitated bacterin (group IV) groups (n=7/group) had six, four and one survivors, respectively. Anti-bacterial antibody levels in the group I-III were significantly higher than those of group IV at every week post-immunization. Anti-KLH antibodies were produced in high titres in all KLH groups and persisted as long as those against bacterial antigens had. Anti-KLH antibodies were absent in sera samples of cattle and buffaloes. In conclusion, efficacy and potency of HS bacterin was improved by aluminium nanoparticles and KLH. KLH inclusion was also suitable for DIVA strategy for HS control programme.

TIR8/SIGIRR is expressed in tissues of adult and embryo chicken

F. Riva*, G. Manarolla, L. Turin;*
University of Milano, Milano, Italy.

The orphan receptor TIR8/SIGIRR, belongs to the TIR superfamily. TIR8 does not activate NF-kB and IRF3 and negatively modulates the inflammatory responses. It acts as antagonist for the TIR family members and triggers a negative pathway of the TIR receptor system, crucial for dampening inflammation. TIR8 was well characterized in mouse, humans and in other mammals, but it is poorly known in birds.
We investigated TIR8 distribution in adult and embryo chicken samples. The pattern of expression of chicken TIR8 in adult was ubiquitary and similar to mammals, but it resulted unique in pancreas, female reproductive tract, heterophils. Different TIR8 isoforms were detected, suggesting the occurrence of post-translational modifications or alternative splicing. Immunohistochemistry revealed TIR8 immunolabeling in the intestine, thymus and oesophageal ganglia. These results demonstrate that TIR8, although evolutionarily conserved, show species-specific peculiarities. We analyzed TIR8 expression in embryos of layer- and broiler-chicken at different incubation time-points. TIR8 was detected since the first stages of development, but it reached a remarkable expression level at day 10. TIR8 was ubiquitously expressed, but the highest expression were found in liver and kidney. This pattern was comparable to those observed in adult chickens and in mammals examined to date. No differences were observed between the two different chicken breeds despite their immunological discrepancies. These are the first findings concerning TIR8 expression in developmental stages and they contribute to better understand the reproductive physiology and transovarian pathogen transmission, together with the recent findings of TLR expression in ovary and embryos of different species.

Infection and immunity during leptospirosis disease in Golden Syrian Hamster: approaching for vaccine biological models

L. Rosario Fernandez*;*
University of Havana, Havana, Cuba.

Leptospirosis is considered by WHO the zoonotic disease most disregarded in last decades. One of the major obstacles in developing prophylactic vaccines is the absence of cross-protection among unrelated serovars and the lack of knowledge about the immune response against Leptospira spp. The main objectives of the study were to assess the existence of cross-protection among vaccine strains of different serovars and to characterize the immune response during leptospirosis in the most used animal vaccine model. The infection model reproduces the test of different doses of DL50 of several virulent leptospiras serovars. After inoculation the antibody response , cellular response, biochemical and haematological parameters and survival rates were measured. The carrier state on main organs and histopathology studies were determined after death. The results demonstrated that a cross-protection among unrelated Leptospira serovars strain is possible. Canicola strain is able to induce protection against homologous, Ballum and Copenhagen strains. Instead, Mozdok strain induced only protection against homologous challenge. The other strains showed a moderate cross-protection against heterologous challenge. It was demonstrated that elimination of the carrier state is correlated with high IgM and IgG1 antibody response. The cellular response is absent or not detected in ex vivo cultures. These results indicate that protection conferred by LPs is serovar specific in contrast to the response against external membrane proteins which is related to cross-protection among unrelated serovars. Also the humoral response is predominant during the immune response but it is not correlated to protection.

Ethoneuroimmunoendocrinology of fear-related behavior disorders in dogs and cats

M. Snitcofsky*;*
LaNyN, IBCN, Buenos Aires, Argentina.

Ethoneuroinmunendocrinology is a veterinary specialty that studies relationships between body control systems, which are communicated through common signaling molecules (neurotransmitters, cytokines, hormones); and views diseases as a result of the rupture of this systems´ balance.
Behavior disorders of dogs and cats can be analyzed from an integrative perspective, addressing the clinical presentation, diagnosis and treatment from the body-control systems´ interactions point of view. Fear-related disorders (phobias and anxiety) often occur along with immune-related chronic physical pathologies in dogs and cats, such as skin disorders (atopic dermatitis and other allergies), endocrinopathies (hypothyroidism), gastrointestinal diseases (IBD, chronic diarrea or vomiting , gastritis, gastric dilatation/ volvulus syndrome), urinary disorders (idiopathic interstitial cistitis, lower urinary tract disease), respiratory diseases (feline bronchial asthma, canine tracheal collapse), neurological diseases (hydrocephalus, epilepsy, strokes). It is not easy to distinguish which is the primary pathology (if any), or if they are comorbid pathologies.
There are several hypotheses about the joint occurrence of physical and emotional conditions: 1) Fortuit association. 2) Genetic association. 3) Gene interactions. 4) Emotional disturbances as causal factors of physical illness. 5) Physical illness as causal factor of emotional disturbance. 6) Physical illness and emotional disturbance coexist because they share molecular mediators and signaling pathways. Likely, there is a combination of all the above, which would be difficult to be studied separately.
Evidence suggests that the state of chronic stress form living with excessive fear or anxiety can have deleterious effects on health, welfare and lifespan of pets.

Ocular infectious bronchitis virus vaccination induces different immune responses in the mucosal and systemic immune compartment

***F. W. van Ginkel**, R. S. Gurjar, N. Orr, S. L. Gulley;*
Auburn University, College of Veterinary Medicine, Auburn, AL, United States.

Infectious bronchitis virus (IBV) is an economic problem in the poultry industry despite extensive vaccination. Live attenuated IBV vaccines are delivered via spray or drinking water to induce T and B cell responses in head-associated lymphoid tissues (HALT), i.e., Harderian glands and conjunctiva-associated lymphoid tissue, and spleen. HALT lymphocytes undergo an expansion phase from day 7 through 10 during the IBV-induced immune response, after which they undergo a contraction phase, which coincides with the effector phase of the T and B cell response after IBV vaccination. The IFN-gamma response to IBV is biphasic, consisting of an earlier response at the beginning of the expansion phase and a second response coinciding with the effector phase. The secondary IBV IFN-gamma response is restricted to the spleen, indicating that IBV memory cells are located in the systemic immune compartment rather than mucosa-associated lymphoid tissues. A distinct, earlier IBV-specific IgA spot-forming cell (SFC) response is observed in the spleen compared to HALT, while both display a significant SFC increase 10 days after vaccination. IBV vaccination increases IBV-specific IgA levels in plasma and tears 3-4 days earlier than IgG levels. To address whether antibody responses are affected by frequent mutations in the amino terminal portion of the IBV spike protein (S1), the target for neutralizing antibodies, an overlapping peptide array is used. Distinct B cell epitopes are recognized which are altered in variant IBV strains enabling immune escape. These data indicate distinct roles of the mucosal and systemic immune compartments in the IBV response.

Expression of TNF-alpha mRNA in canine mammary tumors as a potential marker for tumor evolution

*T. L. L. Castanheira, E. Garrido, F. S. Fernando, M. C. Rosolem, H. J. Montassier, **R. O. Vasconcelos**;*
UNESP, Jaboticabal, Brazil.

TNF-alfa is a pleiotropic cytokine, which promotes variable effects on a large number of cells. The findings on the effects of TNF-alfa on tumors are diverse and controversy, because this cytokine exerts both anti and pro-cancer activities. Thus, TNF-alfa damages tumor vasculature and has necrotic effects in tumor cells, or, it can inhibit DNA repair, promotes angiogenesis and acting as growth factor for tumor cells. Our purpose was to establish an association between a histological classification of mammary gland tumors (MGT) in dogs with TNF-alfa gene expression. Twenty nine female dogs with MGT and 5 normal dogs were selected for biopsy of mammary gland. The histopathology examination classified 3 adenomas and 26 simple carcinomas (11 tubular; 9 papillar; and 6 solid). The gene expression for TNF-alfa mRNA was measured by quantitative real-time RT-PCR. The statistical analysis was performed by Student-Newman-Keuls Test. All groups of dogs with MGT showed increased levels of TNF-alfa mRNA expression, which are significant different ($p < 0.05$) from the average level measured for the control group (mean 0.53; SD 0.48). The mean of carcinoma group (mean 575.88; SD 720.08) was higher than that found for adenoma group (mean 25.704; SD 34.15). Thus the TNF-alfa mRNA expression in MGT can be positively associated with tumor development and/or malignancy and the overexpression of this cytokine could be associated with the progression of MGT, hypothesizing that it is acting by different modulating effects in tumor microenvironment, which may lead to different tumor evolution pathways. Financial support and fellowship FAPESP (2012/09385-0; 2010/12946-8).

Novel dendrimeric peptide: Immune response and protection against Foot and Mouth Disease Virus (FMDV) induced by synthetic peptides in cattle

*I. Soria[1], V. Quattrocchi[2], C. Langellotti[1], S. Digiacomo[2], D. Buscafusco[1], B. Garcia de la Torre[3], D. Andreu[3], F. Sobrino[4], E. Blanco[5], **P. Zamorano**[2,1];*
[1]CONICET, Buenos Aires, Argentina, [2]INTA, Buenos Aires, Argentina, [3]Universitat Pompeu Fabra, Barcelona, Spain, [4]Consejo Superior de Investigaciones Científicas, Madrid, Spain, [5]Instituto Nacional de Investigación y Tecnología Agraria y Alimentaria, Madrid, Spain.

Previous work has shown that a synthetic dendrimeric peptide of FMDV containing a T epitope [3A(21-35)], and four copies of a B epitope [site A; VP1(136-154)] of serotype C protected 100% of vaccinated pigs.
The aim of the study was to evaluate the immunogenicity and protective response induced by B2T and B4T (B epitope of serotype O) peptide as FMD vaccine in cattle.
Hereford steers were inoculated twice with B2T (n=4) or B4T (n=4) by intramuscular injection with 2 mg of peptide emulsified with commercial oil adjuvant. One animal was left as unvaccinated control.
At 38 dpv, the α-FMDV IgG titers in the B4T-group were 3.5±1.0, whereas in the B2T-group were 4.1±1.0 and the predominant isotype induced in both groups was IgG1. Likewise, α-B4T antibody titers were 4.9±0.4 whereas in the B2T-group were 5.0±0.4.
At 32 dpv neutralization indexes were ≥1.8 for 3 animals in the B2T -group and for 4 animals in the B4T-group, However neutralizing antibody titers were lower than 2.
We observed positive proliferative response of PBMC of vaccinated animals, when stimulated with both peptides. IFN-γ was secreted when cells were stimulated either with virus or peptides.
At 42 dpv cattle were challenged with FMDV by nasal instillation. Two animals in both experimental groups delayed the onset of symptoms while only one animal of each group presented no foot lesions. Cattle receiving the commercial vaccine were protected against challenge. The higher level of protection was observed in animals vaccinated with peptide that presented higher cellular and humoral responses.

P7.07.31
Establishment and characterization of monoclonal antibodies against tumor-associated antigen(s)in Mc29 virus-transformed chicken hepatoma cells

***T. Zhivkova**, R. Alexandrova;*
Institute of Experimental Morphology, Pathology and Anthropology with Museum, Sofia, Bulgaria.

The tumors induced by the myelocytomatosis retrovirus Mc29 are recognized as suitable model systems in experimental oncology. The aim of our study was to develop monoclonal antibodies (Mabs) recognizing tumor-associated antigen(s) in Mc29-virus-transformed chicken hepatoma cells (cell line LSCC-SF-Mc29).
Ninety six hybridoma clones were obtained after fusion between mouse myeloma P3U1 cells and splenocytes harvested from two BALB/c mice immunized with LSCC-SF-Mc29 cells and with extract in 3M KCl from the same cells. Eight clones were found to produce antibodies that gave a positive reaction with chicken hepatoma cells (or extract in 3M KCl from these cells) in the indirect immunofluorescence test, dot-immunobinding assay and ELISA. No cytotoxic effect was found in the complement-dependent cytotoxicity test.
The intraperitoneal injection of hybridoma cells in BALB/c mice pretreated with Pristane resulted in the development of solid tumors in mesentherium which did not produce ascetic fluid.
Using SDS-polyacrylamide gel electrophoresis and Western blotting, one of the MAbs (1A6 - proved to be of subclass IgG1) was shown to visualize tumor-associated antigen with molecular weight of ~25 kDa that was expressed intracellularly as well as on cell membrane. The examined antibody did not recognize any antigen in cultured cells of various tumors in chicken, mouse, rat and human. No cross-reactivity with chicken embryonal cells was detected.
Investigations are in progress to further characterize the developed monoclonal antibodies and their corresponding antigen(s) as well as the role of these antigens in tumor growth.

Expression of the novel antigen receptor (IgNAR) in the bamboo shark and isolation of antigen-specific IgNAR domains from shark antibody repertoires

S. Zielonka[1]*, M. Empting*[1]*, P. Ockelmann*[2]*, M. Lierz*[3]*, H. Kolmar*[1]*;*
[1]Technische Universität (TU) Darmstadt, Darmstadt, Germany, [2]Klinik für Anästhesiologie, Intensivmedizin und Schmerztherapie (KAIS Forschungslabor), Frankfurt, Germany, [3]Klinik für Vögel, Reptilien, Amphibien und Fische, Justus-Liebig-Universität Giessen, Giessen, Germany.

Fish represent the oldest and most diverse group of vertebrates with over 29,000 species. Within this group, the cartilaginous fish represent the oldest extant jawed vertebrates, having evolved for more than the past 400 million years. This evolutionary ancient class already contains an adaptive immune system. Despite the fact that fundamental molecules of the immune system are similar in fish and mammals, chondrichthyans comprise a unique antibody-like molecule, named Novel Antigen Receptor (IgNAR), which is a homodimer of heavy chains devoid of light chains. Hence, the antigen-binding site is composed of only one variable domain, vNAR. Like camelid VHHs, vNAR domains have several structural and biophysical features that render them interesting molecules for biomolecular applications: vNARs are extraordinary stable proteins and have remarkable folding properties. Furthermore, due to the loss of a conventional CDR2, the vNAR domain is the smallest naturally occurring antigen binding domain which leads to greater tissue mobility and to the possibility to target more cryptic and recessed epitopes otherwise accessible only to small molecules. [1, 2]
We analyzed the vNAR repertoire and the tissue-specific expression of this antibody-like molecule of the bamboo shark (*Chiloscyllium plagiosum*). Furthermore we utilized this repertoire to generate antibody-based binding molecules against several disease-related antigens, including CD 326 (EpCAM) and EGFR *via* yeast surface display. These molecules potentially can function as tools for diagnostic applications *in vitro* and *in vivo*.
