Natural killer cells and macrophages are the major effectors of the innate immune system. Crosstalk between these two populations is still poorly understood although it is likely to have strong implications in the development of both innate and adaptive immune response. NK cells express a plethora of activating and inhibitory receptors which bind different ligands on target cells. HLA-E, a non classical MHC class I molecule, binds the inhibitory CD94/NKG2A receptor thus protecting cells from the NK killing. The expression and function of HLA-E require peptides derived from the leader sequence of HLA class I molecules. However, HLA-E molecules can also bind self or pathogen-derived peptides, whose effect on the NK response is still controversial. We show here that the expression of the HLA-E molecules is strongly up-regulated during differentiation of monocytes to macrophages along with other molecules involved in HLA class I antigen processing and presentation such as ERAP1 and ERp57 whereas, the expression of classical HLA class I molecules remains unaffected. These findings strengthen the hypothesis that HLA-E exploits the same machinery as the classical HLA-class I molecules to present self proteins. Ligands (MIC-A/B, ULBPs) for the activating NKG2D receptors are also modulated during monocyte differentiation. The influence of this strong modulation on the crosstalk between NK cells and macrophages is under investigation.

P1.06.10
Decoy receptor 3 enhances tumor progression via induction of tumor-associated macrophages

*S. K. Tai[1,2], **H. C. Chang**[3], K. L. Lan[4], C. T. Lee[3], C. Y. Yang[3], N. J. Chen[3], T. Y. Chou[5], D. C. Tarng[6], S. L. Hsieh[3,1,7];*
[1]Institute of Clinical Medicine, National Yang-Ming University, Taipei, Taiwan, [2]Department of Otolaryngology, Taipei Veterans General Hospital, Taipei, Taiwan, [3]Department and Institute of Microbiology and Immunology, National Yang-Ming University, Taipei, Taiwan, [4]Cancer Center, Taipei Veterans General Hospital, Taipei, Taiwan, [5]Department of Pathology and Laboratory Medicine, Taipei Veterans General Hospital, Taipei, Taiwan, [6]Department and Institute of Physiology, School of Medicine, National Yang-Ming University, Taipei, Taiwan, [7]Immunology Research Center, National Yang-Ming University, Taipei Veterans General Hospital, Taipei, Taiwan.

Tumor-associated macrophages (TAMs) are the major component of tumor infiltrating leukocytes. TAMs are heterogeneous with distinct phenotypes influenced by the microenvironment surrounding tumor tissues. Decoy receptor 3 (DcR3), a member of the tumor necrosis factor receptor superfamily, is over-expressed in tumor cells and is capable of modulating host immunity as either a neutralizing decoy receptor or an effector molecule. Up-regulation of DcR3 has been observed to correlate with a poor prognosis in various cancers. However, the mechanisms of DcR3-mediated tumor-promoting effect remain unclear. We previously demonstrated that DcR3 modulates macrophage activation toward an M2-like phenotype in vitro, and that DcR3 down-regulates MHC class II (MHC-II) expression in TAMs via epigenetic control. To investigate whether DcR3 promotes tumor growth, CT26-DcR3 stable transfectants were established. Compared with the vector control clone, DcR3-transfectants grew faster and attracted TAMs infiltration. We further generated CD68 promoter-driven DcR3 transgenic (Tg) mice to investigate tumor growth in vivo. Compared with wild type mice, macrophages isolated from DcR3-Tg mice displayed higher levels of IL-10, IL-1ra, Ym1, and arginase activity, while the expression of IL-12, TNF-α, IL-6, NO, and MHC-II was downregulated. Significantly enhanced tumor growth and spreading were observed in DcR3-Tg mice, and the enhanced tumor growth was abolished by arginase inhibitor nor-NOHA and histone deacetylase inhibitor sodium valproate. These results indicate that induction of TAMs is an important mechanism for DcR3-mediated tumor progression. Our findings also suggest that targeting DcR3 might help in the development of novel treatment strategies for tumors with high DcR3 expression.

P1.06.11
PTPN22 modulates macrophage polarization and susceptibility to dextran sulfate sodium-induced colitis

***H. Chang**[1,2], S. Miaw[3], W. Tseng[1], Y. Sun[3], C. Liu[3], H. Tsao[3], I. Ho[1,2,4];*
[1]Division of Rheumatology, Immunology, and Allergy, Department of Medicine, Brigham and Women's Hospital, Boston, MA, United States, [2]Harvard Medical School, Boston, MA, United States, [3]Graduate Institute of Immunology, National Taiwan University College of Medicine, Taipei, Taiwan, [4]Section of Rheumatology, VA Boston Healthcare System, Boston, MA, United States.

PTPN22, a protein tyrosine phosphatase expressed mainly in hematopoietic cells, has been linked to many autoimmune diseases. A C-to-T single nucleotide polymorphism (SNP) at position 1858 of human PTPN22 cDNA increases the risk of rheumatoid arthritis but reduces the risk of inflammatory bowel disease. However, the function of PTPN22 and how this SNP influences the risk of autoimmune diseases are poorly understood. We found that PTPN22 was located at cytoplasm and nucleus of primary macrophages. Cytoplasmic PTPN22 suppressed M1 macrophage polarization, whereas nuclear PTPN22 promoted M2 polarization. PTPN22-deficient mice developed severe colitis induced by dextran sulfate sodium and their intestinal macrophages expressed higher levels of M1 genes but lower levels of M2 genes. Furthermore, the minor T allele of the C1858T SNP was associated with attenuated expression of inflammatory cytokines in human M1 macrophages due to heightened expression of PTPN22. This T allele-associated aberrant expression of PTPN22 was partly attributed to an auto-inhibition mechanism, in which PTPN22 suppresses its own expression in M1 but not M2 macrophages. Our data not only demonstrate a critical role of PTPN22 in regulating macrophage polarization but also provide a molecular explanation for the protective effect of the C1858T SNP in inflammatory bowel disease.

P1.06.12
Triggering receptor expressed on myeloid cells-1 regulates macrophage polarization in an obstruction-induced nephritis mouse model

*T. Luo[1], K. Tseng[1], W. Tsao[1], P. Lee[1], S. Hsieh[1], A. Chiu[1], T. Takai[2], T. Mak[3], D. Tarng[1], **N. Chen**[1];*

Chronic kidney disease (CKD) is an emerging worldwide public health problem. Inflammatory cell infiltration and activation during the early stages in the injured kidneys is a common pathologic feature of CKD. Here we demonstrate that TREM-1, an important inflammatory regulator, is up-regulated in renal tissues collected from mouse obstruction-induced nephritis. TREM-1 is crucial for modulating macrophage polarization, and plays a pivotal role in mediating tubular injury and interstitial collagen deposition in obstructive nephritis. Nephritis lysates triggered a TREM-1-dependent M1 polarization ex vivo, consistent with the observation that GM-CSF-derived M1 macrophages express higher levels of TREM-1 in comparison with M-CSF-derived M2 cells. Moreover, agonistic TREM-1 crosslink significantly strengthened the inductions of iNOS and GM-CSF in M1 cells. These observations were validated by a strong clinical correlation between infiltrating TREM-1 expressing/iNOS-positive macrophages and renal injury in human obstructive nephropathy, suggesting that TREM-1 may be a potential diagnostic and therapeutic target in human kidney disease.

P1.06.13
Polarized activation phenotypes of spontaneously differentiated human monocyte-derived macrophages: role of dexamethasone

***A. Cignarella**, A. Toniolo, S. Tedesco, C. Bolego;*
University of Padova Medical School, Dept of Pharmacy, Padova, Italy.

Macrophage polarization has been observed in vivo under physiological and pathological conditions, and may represent an attractive target for pharmacological modulation. Given the lack of gold standard protocols for classic (M1) and alternative (M2) activation in vitro, we polarized human macrophages using different protocols and characterized resulting phenotypes and investigated their modulation by dexamethasone. Human monocytes were isolated from healthy donors by 2-step gradient centrifugation, and macrophages were obtained by spontaneously differentiating monocytes in RPMI 1640 with 10% FCS for 7 days. Macrophages stained positively for intracellular CD68, whereas cell surface CD68 was detected in only 10% of cells, indicating a low basal activation state. When resting macrophages were incubated with LPS/IFN-γ (M1) for 4 h, the percentage of cells expressing the M1 surface markers CD68 and CCR2 did not change. After prolonged stimulation (48 h), the number of CD68- but not CCR2-positive cells doubled, while expression of M2 markers CD206, CD163 and CX3CR1 was down-regulated compared with resting macrophages. In contrast, none of these markers were affected by alternative (M2) polarization with IL-4/IL-13 for 48 h, whereas CD206 was up-regulated after 7 days. Q-PCR phenotyping after M1 polarization for 6-48 h showed increased TNF-α, IL-1β, COX-2, IL-10, VEGF, and decreased CD206 and COX-1 transcript levels. Overnight pretreatment with 10 nM dexamethasone enhanced CD163 surface expression in resting and M2-polarized macrophages while reversing M1-induced CD163 down-regulation. We conclude that the phenotypic characterization of polarized macrophages is required and provides a basis for pharmacological macrophage targeting.

P1.06.14
Influence of the phagocytizing mononuclear system (PMS) stimulation on liver and kidney regeneration

I. Danilova[1,2]*, S. Medvedeva*[1]*, I. Gette*[1]*;*
[1]*Institute of Immunology and Physiology of UB RAS, Ekaterinburg, Russian Federation,* [2]*Institute of Medical Cellular Technologies, Ekaterinburg, Russian Federation.*

Study objective: To study the potential of liver and kidney reparative growth by means of PMS activity modulation.
The experiment was carried out on 35 outbred albino male mice with the use of modern equipment and methods of testing: morphologic, histological, morphometric and flow cytometry. The animals were treated in accordance with the Directive 86/609/EEC.
The intensification of regeneration in both organs under investigation was demonstrated both in case of local and toxic lesion in experimental models of partial hepatectomy, nephrectomy, and toxic effect of tetraclormetane under impact of immunomodulator 3-Aminophthalhydrazide. These results are clearly explained by the ability of activated macrophages to accelerate proliferation, migration and homing of hemopoietic stem cells as in response to PMS stimulation by 3-Aminophthalhydrazide the number of hemopoietic stem cells (phenotype $CD45^{low}CD117+CD38+$) increased in bone marrow, blood and liver. Multiplication of the number of this type of cells in liver can be due to both their proliferation in the organ itself and their migration from bone marrow. The results of the experiment can be of significance in substantiating new approaches in the treatment of hepatitis and renal insufficiency of various etiologies.
The work is supported by a grant of the Ural Branch of the Russian Academy of Sciences.

P1.06.15
Modulation of macrophage function by growth hormone

M. D. dos Santos Reis[1]*, Y. M. O. dos Santos*[2]*, L. F. A. Vieira*[2]*, A. R. A. Brandão*[2]*, I. M. M. N. Viana*[2]*, S. Smaniotto*[2]*;*
[1]*Oswaldo Cruz Foundation, Rio de Janeiro, Brazil,* [2]*Federal University of Alagoas, Maceió, Brazil.*

Studies have shown that macrophage activity can be modulated by neuropeptides such as the growth hormone (GH). Herein, studies were performed to determine the immunomodulatory effect of GH on macrophages. Peritoneal macrophages from GH-treated mice with 20 and 200 µg/kg for 7 days showed alterations on Mac-1, VLA-5 and VLA-6 integrins surface expression and an increase on extracellular matrix deposition. They also showed lower adherence to fibronectin (FN) and to laminin (LN), and augmented transwell cell migration toward these substrates. Besides, the peritoneal macrophages from GH-treated mice presented higher porcentage of phagocytosis and also higher phagocytic capacity than cells from control animals. To elucidate the pattern of GH action, freshly isolated peritoneal macrophages were treated *in vitro* with 20 and 200 ng/mL of GH at different times. The GH-treated macrophage cultures showed alterations in cell morphology as well as on surface expression of Mac-1 and VLA-6 integrins. Increased FN and LN deposition and decreased cell adhesion to LN substrate were also observed. Moreover, the *in vitro* GH treatment influenced the macrophage transwell migration in two distinct ways: after 6 hours there was an increase in migrating cells whereas after 12 hours there was a decrease in cell migration. Differently from the *in vivo* treatment, *in vitro* GH treatment was not able to induce the macrophage phagocytic activity. These results show that macrophage activity can be modulated directly and/or indirectly by GH and reinforce the literature data which indicate the GH as a macrophage activating-factor in the immune response.

P1.06.16
The overexpression of glucocorticoid-induced leucine zipper (GILZ) protein in macrophages enhance lifetime in mouse septic shock model

M. Ellouze[1]*, F. Capel*[1]*, O. Robert*[1]*, A. Cassard-Doulcier*[1]*, G. Perlemuter*[1,2]*, M. Pallardy*[1]*, F. Bachelerie*[1]*, D. Emilie*[1]*, V. Godot*[3]*;*
[1]*INSERM UMR-S996, University of Paris Sud, Clamart, France,* [2]*Service de Gastroenterologie, Hôpital Béclère, Clamart, France,* [3]*INSERM U995, University of Paris East Creteil, Creteil, France.*

According to the literature, the Glucocorticoid-induced leucine zipper (GILZ) protein exerts immunoregulatory activities on macrophages. For instance, the over-expression of GILZ in macrophages decreases their secretions of inflammatory cytokines upon LPS-exposure. We thus hypothesized that GILZ could contribute to the endotoxin tolerance (ET) process that comes in macrophages after prolong stimulations with endotoxins and limits inflammation.
To address this issue, we first evaluated the expression of GILZ in human monocytes which were stimulated to induced ET (tolerant-monocytes, pre-exposure to LPS for 24hrs followed by 2hrs of stimulation) and inflammatory-monocytes (a single stimulation of 2hrs). Naïve unstimulated monocytes served as controls. We observed a statistically significant decrease of GILZ expression in inflammatory-monocytes compared with their naïve counterparts. Conversely, the ET process significantly enhances GILZ expression in macrophages. High GILZ levels were significantly correlated with IL-10 production and regulatory phenotype in ET-monocytes. To explore in vivo the contribution of GILZ in macrophage functions, transgenic mice were generated with constitutive and restricted over-expression of GILZ in macrophages (CD68-GILZ transgenic mice). We then confirmed that CD68-GILZ mice have a significant prolonged lifetime in septic shock models where inflammation is responsible for death.
Our data suggest that GILZ regulates the functions of macrophages during bacterial infections and that an over-expression of GILZ protects from septic shock. We currently use an unbiased wide screening approach on peritoneal macrophages isolated from CD68-GILZ mice and their controls after LPS stimulation to link functions/pathways involved in GILZ effects. Overall, these results will improve our comprehension on macrophage regulation.

P1.06.17
CD200R-dependent regulation of monocytes is subset- and tissue specific

M. A. Falck-Hansen*;*
Kennedy Institute, London, United Kingdom.

Monocyte/macrophage regulation is crucial to avoid the potentially detrimental effects of inflammation. The CD200-CD200R pathway has been implicated to play an important role in controlling excessive myeloid cell activation (Hoek et al 2000; Snelgrove et al., 2008). Recent studies have revealed a role for CD200R expression on alternatively activated macrophage subsets (Koning et al, 2009), yet no studies have described the expression of CD200R controlling monocyte inflammation in murine models. Our in vivo data generated from FACS studies on bone marrow and PBMCs in WT C57BL/6 mice suggests CD200R is a pathway up-regulated during monocyte maturation, during the change from Ly6Chi to Ly6Clow expression ($P<0.001$) and could potentially serve as a natural slow-down mechanism for classical Ly6Chi monocyte inflammatory activity. Complementary in vitro studies using bone marrow derived macrophages, studying mRNA expression assessed by RT-PCR, have revealed the expression of CD200R pertaining to TLR stimuli after 6 hours stimulation with TLR ligands FSL-1, POLY(I:C),LPS and R848. Here we show for the first time that stimulation of TLR3, the only MyD88-independent TLR, does not down-regulate CD200R expression (P=ns), contrary to TLR2/6 ($P<0.05$), TLR4 ($P<0.01$) and TLR7 ($P<0.05$). This finding goes in accordance with previous findings describing the MyD88-dependent down-regulation of CD200R during TLR4 stimulation (Mukhopadhyay et al., 2010).

P1.06.18
Study of aminoacidic sequences of vitamin D binding proteins involved in macrophage activation

M. Fiore[1]*, S. Magherini*[2]*, M. Gulisano*[3]*, S. Pacini*[3]*, M. Ruggiero*[1]*;*
[1]*Department of Experimental Biomedical and Clinical Sciences, Firenze, Italy,* [2]*Department of Experimental and Clinical Medicine, Firenze, Italy,* [3]*Department of Experimental and Clinical Medicine, Firenze, Italy.*

Vitamin D binding protein-derived macrophage activating factor (DBP-MAF) is a powerful activator of macrophages. Polymorphisms of the gene coding for vitamin D receptor (VDR) were associated with differential responses to DBP-MAF in human monocytes. Here we examined the relationships between these vitamin D binding proteins, i.e. DBP-MAF and VDR. VDR and two isoforms of DBP share 20% identity of aminoacid (aa) sequence in the tract coded for by exons 1, 2, 3 ,4, 5, i.e. aa 1-197. An higher degree of identity (40%) was observed in the tract coded for by exons 6, 7, 8, i.e. aa 217-330. The aa in position 445 was of particular interest; VDR and isoforms 1 and 3 of the DBP show a histidine in this position, whereas the isoform 2 shows an arginine. The observation that the VDR and isoforms 1 and 3 of the DBP have the same aa, at variance with the isoform 2, suggests that this variation is implicated in the evolutionary divergence in the genes coding for these vitamin D binding proteins. In fact, isoform 2 has a lysine in position 420 at variance with isoforms 1 and 3 that have a threonine that in turn is glycosylated so that DBP-MAF can be produced from isoforms 1 and 3 but not from isoform 2. These results are consistent with the concept that all the component of the vitamin D axis, i.e. vitamin D, DBP, DBP-MAF, and VDR participate in the regulation of the immune system through macrophage activation.

P1.06.19
Characterization of the murine CD163 receptor

***L. Fischer-Riepe**, K. Barczyk, D. Holzinger, M. Wolf, J. Roth;*
Institute of Immunology, Muenster, Germany.

CD163 is a scavenger receptor exclusively expressed in monocytes and macrophages. Since CD163+ macrophages are found in the healing phase of acute inflammation and anti-inflammatory factors increase CD163 expression, CD163 is thought to be involved in resolution of inflammation. However, little is known regarding the murine CD163 (mCD163). The aim of this study was to analyze structure, expression and regulation of the murine CD163.
Extracellular domain of mCD163 was cloned in order to produce rabbit polyclonal antibody (LFR1-Ab). Regulation of CD163 expression in freshly isolated murine bone marrow cells (BMC), bone marrow-derived macrophages as well as the CD163 distribution in various organs were assessed using fluorescence microscopy and Western Blot.
LFR1-Ab specifically recognized a 170kDa protein in lysates of murine BMC and also has shown cross-reactivity with human CD163 (130kDa). The differences in molecular weight were due to strong glycosylation of mCD163. High expression of CD163 was detected in freshly isolated BMC. This was lost during in vitro culture. Stimulation of BMC with dexamethasone (DEX), but not IL-4, IL-6 or LPS and IFNγ increased CD163 expression. Similar but weaker effect was observed when bone marrow-derived macrophages were stimulated with DEX. In vivo analysis of CD163 distribution in mouse revealed the presence of CD163+ cells in all tested organs (spleen, liver, lung, intestine). However i.p. injection of DEX enhanced expression of CD163 only in the lung. CD163 is considered as a M2 marker, however we detected an increase of CD163-positive subpopulation in several experimental diseases (infection with S. aureus, L. major).

P1.06.20
Effects of biodegradable polylactic acid fibers and dexamethasone on classical and alternative activation pathways in macrophages

***M. Hämäläinen**[1], E. L. Paukkeri[1], A. Pekurinen[1], R. Nieminen[1], M. Kellomäki[2], T. L. J. Tammela[3], M. Talja[4], E. Moilanen[1];*
[1]The Immunopharmacological Research Group, University of Tampere School of Medicine and Tampere University Hospital, Tampere, Finland, [2]Department of Electronics and Communications Engineering, Tampere University of Technology and BioMediTech, Tampere, Finland, [3]Department of Urology, Tampere University Hospital and University of Tampere School of Medicine, Tampere, Finland, [4]Department of Surgery, Päijät-Häme Central Hospital, Lahti, Finland.

Fully biodegradable medical devices are under development for various applications, and addition of drug-eluting properties extends their usefulness e.g. in conditions complicated with inflammatory and fibrotic reactions. On the other hand, biodegradable material itself may trigger inflammatory responses. In the present study we investigated the effects of pure and drug-eluting biodegradable fiber on macrophage activation.
PLA96/4 (polylactide of 96% L-lactide and 4% D-lactide) fiber was found to induce a low-level inflammatory reaction in macrophages which was attenuated by dexamethasone as detected by an antibody array. Also, dexamethasone and dexamethasone-releasing PLA96/4 fibers were found to inhibit the production of IL-8, TNFα, VEGF and MCP-1 in activated macrophages.
To further study the effect of PLA96/4 fiber on macrophages, markers typical for “classical” (M1) and “alternative” (M2) macrophage activation were investigated. Macrophages were cultured on PLA96/4 fibers and exposed to LPS or IL-4+IL-13 to induce classical or alternative activation, respectively. The PLA fiber had a minor inhibitory effect on LPS-induced production of classical inflammatory mediators IL-12 and nitric oxide, and no effect on IL-6. On the other hand, PLA fiber clearly attenuated IL-4 and IL-13 induced expression of alternative activation markers arginase-1, Fizz1, Ym-1 and IL-10.
In the present study, we investigated the effects of polylactic acid on macrophage responses. PLA96/4 was found to suppress alternative type activation while only minor effects were found on classical type activation. The results are implicated in the biocompatibility of biodegradable medical devises and can be utilized in the development of improved drug-eluting materials and devises.

P1.06.21
Involvement of T-cell-Ig-mucin-3 (Tim-3) in macrophage polarization

***G. Han**, G. Chen, B. Shen, Y. Li;*
Beijing Institute of Basic Medical Sciences, Beijing, China.

T-cell-Ig-mucin-3 (Tim-3) is widely involved in the negative regulation of adaptive immunity, and its dysregulation on $CD4^+$T and $CD8^+$T cells is associated with autoimmune diseases, chronic virus infection or tumor. However, its roles in innate immunity remain unclear. We previously reported that Tim-3 promotes macrophage homeostasis by negatively regulating TLRs response (J.Immunol.2013), indicating that Tim-3 might also negatively regulate innate immunity. Here we further identified a dysregulated downregulation of Tim-3 on lamina propria macrophage in mice with ulcerative colitis (UC), which is related to a M1 shift of macrophage as marked by increased pro-inflammatory cytokines expression including IL-12, IL-6, TNF-α, and IL-1β. Blockade of Tim-3 pathway in vivo using Tim-3 antibody or soluble protein lead to enhanced the shift of M1 macrophage and exacerbated inflammation in UC. On the other hand, in mice with colonic tumor, lamina propria macrophage showed increased Tim-3 expression and increased M2-related anti-inflammatory cytokines including IL-10, TGF-β expression by macrophage. These data indicated that Tim-3 expression is closely related to the polarization of macrophage and its dysregulation significantly affects diseases progression. When the underlying mechanisms were investigated, our data showed that Tim-3 down regulation leads to increased NOS2 expression and decreased Arg-1 and Dectin-1 expression in macrophage and changed micro RNA profiles including increased mi-155, miR-27a expression. The intracellular pathways of Tim-3 mediated microphage polarization were also investigated. A better understanding of this pathway might shed new light on the mechanisms of Tim-3 regulated innate immunity.

P1.06.22
Thymic cortical dendritic macrophages (TCDMs); professional scavengers of apoptotic thymocytes in the human thymus

***A. Hayashi**[1], Y. Miki[2], Y. Gion[3], K. Takahashi[3];*
[1]Okayama Red Cross Hospital, Okayama, Japan, [2]Kagawa Prefectural University of Health Sciences, Kagawa, Japan, [3]Okayama University, Okayama, Japan.

[Aim] We previously reported the presence of the special type of macrphages showing features intermediate between macrophages and dendritic cells (DCs) in the the human thymus and named them “thymic cortical dendritic macrophages” (TCDMs) (Immunobiology

213: 837-847, 2008). Because TCDMs are so similar to DCs that they are often misinterpreted as “cortical DCs”. Here we demonstrate the distinctive macrophage-nature of TCDMs. [Materials and Methods] Frozen and paraffin sections obtained from the normal human thymus tissues were examined immunohistochemically and electron microscopically. [Results] TCDMs were identified as fascin+ large extremely dendritic-shaped cells evenly scattered throughout the cortex. TCDMs were positive for fascin, CD209, CD11c, CD68, CD163, and HAM-56, and negative for HLA-DR, CD83, CD86, CD208. Moreover, double immunostaining for fascin and CD34 indicated that approximately 50% of TCDMs intimately adhered to capillaries. At ultrastructural level, TCDMs possess wide extremely electron-lucent cytoplasm containing numerous apoptotic dense bodies, and exhibited vigorous phagocytic activity to apoptotic thymocytes. They frequently found to be attached to the basal lamina of capillary with cell-body or cytoplasmic projection. In contrast to TCDMs, DCs were distributed exclusively in the medulla. DCs were positive for fascin, HLA-DR, CD83, CD86, and CD208, and negative for CD11c, CD68, CD163, HAM-56. They did not exhibit any affinity to capillary. DCs possessed extremely irregularly shaped nuclei, numerous membrane invaginations, and did scarcely contain apoptotic dense bodies. We also found that TCDMs are useful diagnostic markers of thymoma. [Conclusion] TCDMs are not DCs but professional scavenger macrophages of apoptotic thymocytes.

P1.06.23
Tissue macrophages arise from fetal liver monocytes during late embryonic development

G. Hoeffel[1], *J. Chen*[1], *P. See*[1], *D. Low*[1], *F. Almeida*[1], *D. Hashimoto*[2], *M. Merad*[2], *M. Poidinger*[1], *F. Ginhoux*[1];
[1]*Singapore Immunology Network (SIgN), A-STAR, Singapore, Singapore,* [2]*Department of Gene and Cell Medicine and The Immunology Institute, Mount Sinai School of Medicine, New York, NY, United States.*

Macrophages (MPh) and dendritic cells (DCs) play a central role in tissue homeostasis and immunity and are thought to derive from a common adult bone marrow progenitor. However, we recently showed that microglia derive exclusively from yolk sac (YS)-derived primitive myeloid progenitors (Ginhoux et al, Science, 2010) and Langerhans cells, the DC population of the epidermis, present a dual embryonic origin and mainly derived from fetal liver (FL) monocytes (Hoeffel et al, JEM, 2012).
Accumulating evidences suggests that other macrophage populations are also independent of adult bone marrow hematopoiesis. Thus, we investigated the contribution of YS and FL hematopoiesis in adult macrophage development.
Fate mapping analysis shows that the first wave of YS-derived macrophages is only maintained lifelong in brain and epidermis. We describe here the wave of FL monocytes that colonize every tissue during late embryonic development. Gene array analysis shows a close proximity between these monocytes and tissue macrophages. Using a gene tagging system based on the S100A4 protein expression by FL monocytes, we observed their differentiation in macrophages in vivo at steady state. Tissue macrophages depletion in utero induces FL monocytes differentiation and is CSF-1R dependent. We then identified committed progenitors in the fetal liver able to regenerate tissue macrophages after in utero adoptive transfer. Our data highlight the relative importance of early and late embryonic myeloid development in the formation of key elements of the adult immune system.

P1.06.24
Fighting chronic inflammation - CD64-specific elimination of M1 macrophages

D. Hristodorov[1], *R. Mladenov*[1], *V. von Felbert*[2], *M. Huhn*[1], *R. Fischer*[1], *S. Barth*[1], *T. Thepen*[1];
[1]*Fraunhofer IME, Aachen, Germany,* [2]*University Hospital Aachen, Aachen, Germany.*

Macrophages are key players of the innate immunity and versatile cells that can adapt to microenvironmental signals resulting in distinct polarization states with altered phenotype and function. The dynamic ratio of M1 and M2 polarized macrophages is critical for the appropriate development and resolution of inflammation. In chronic diseases, this normal progression is arrested in the M1 dominant phase. Here we show the selective elimination of M1 macrophages by CD64-targeted immunotoxins both in vitro and in vivo in a transgenic mouse model of chronic cutaneous inflammation. We corroborated this using a skin biopsy from a patient with atopic dermatitis. We also show that both populations show phenotypic plasticity and that after conversion into either type, only M1 polarization results in sensitivity towards the CD64-directed immunotoxin. Targeting CD64 on the surface of M1 macrophages will facilitate the development of novel intervention strategies for most chronic inflammatory diseases.

P1.06.25
The functional fate of human monocytes after engagement of various pattern recognition receptors

D. C. Ifrim[1,2], *J. Quintin*[1,2], *L. A. B. Joosten*[1,2], *N. A. R. Gow*[3], *D. L. Williams*[4], *J. W. M. van der Meer*[1,2], *M. G. Netea*[1,2];
[1]*UMC St Radboud, Nijmegen, Netherlands,* [2]*Nijmegen Institute for Infection, Inflammation and Immunity (N4i), Nijmegen, Netherlands,* [3]*Institute of Medical Sciences, Aberdeen, United Kingdom,* [4]*East Tennessee State University, Johnson city, TN, United States.*

After priming with the human commensal *Candida albicans* or the fungal cell wall component β-glucan, monocytes respond with an increased cytokine production upon restimulation, a phenomenon termed "trained immunity". Because the vast majority of commensal microorganisms are of the bacterial or viral phyla, we sought to determine whether similar monocyte reprogramming could be induced by recognition of bacterial or viral ligands by pattern-recognition receptors. Monocytes were functionally programmed for either an enhanced (*training*) or a decreased (*tolerance*) cytokine production, depending on the type of ligand they encountered. The training effect required p38 and JNK mediated MAPK-signalling, with specific signalling patterns directing the functional fate of the cell. The long-term effects on the function of monocytes were mediated by epigenetic events, with both histone methylation and acetylation inhibitors blocking the training effects. In conclusion, our experiments identify the ability of monocytes to acquire adaptive characteristics after prior activation with a wide variety of microbial ligands. Trained immunity and tolerance are two distinct functional programs induced by the specific microbial ligands engaging the monocytes.

Intracellular chloride channel protein CLIC1 regulates macrophage functions via modulation of phagosomal acidification

L. Jiang[1,2], *K. Salao*[1,2], *H. Li*[1,2], *J. M. Rybicka*[3], *R. M. Yates*[3], *D. A. Brown*[1,2], *L. J. Brown*[4], *P. M. G. Curmi*[2], *S. N. Breit*[1,2];
[1]*St Vincent's Centre for Applied Medical Resesarch, Sydney, Australia,* [2]*University of New South Wales, Sydney, Australia,* [3]*University of Calgary, Calgary, AB, Canada,* [4]*Macquarie University, Sydney, Australia.*

Intracellular chloride channel protein 1 (CLIC1) is a 241 amino acid protein of the glutathione S transferase fold family with redox and pH dependent membrane association and chloride ion channel activity. Whilst the proteins of the 6 member CLIC family are highly evolutionarily conserved in metazoa, indicating an important role, little is known about their biology.
CLIC1 was first cloned on the basis of increased expression in activated macrophages. We therefore examined its subcellular localisation in murine peritoneal macrophages by immunofluorescence confocal microscopy. In resting cells, CLIC1 is observed in punctate cytoplasmic structures that do not colocalise with markers for endosomes or secretory vesicles. However, when these macrophages phagocytose serum opsonized zymosan, CLIC1 translocates onto the phagosomal membrane. Macrophages from CLIC1-/- mice display defective phagosome acidification as determined by imaging live cells phagocytosing zymosan tagged with the pH sensitive fluorophore Oregon Green. This altered phagosomal acidification was not accompanied by a detectable impairment in

phagosomal-lysosomal fusion. However, consistent with a defect in acidification, CLIC1-/- macrophages also displayed impaired phagosomal proteolytic capacity and reduced reactive oxygen species production. Further, CLIC1-/- mice were protected from development of serum transfer induced K/BxN arthritis.
These data all point to an important role for CLIC1 in regulating macrophage function via its ion channel activity and suggest it may be a suitable target for the development of anti-inflammatory drugs.

P1.06.27
Glucocorticoids and IL-4 synergize in M2 polarization of macrophages

***K. Jörß**, H. M. Reichardt;*
Institute of Cellular and Molecular Immunology, University of Göttingen Medical School, Göttingen, Germany.

Macrophages play an important although ambivalent role in many inflammatory conditions. This is due to the fact that they can polarize into at least two different subtypes. Classically activated M1 macrophages are induced upon IFNγ and LPS stimulation, pro-inflammatory in nature and responsible for pathogen removal. In contrast, M2 macrophages are induced by Th2 cytokines such as IL-4 and IL-13, glucocorticoids (GCs) or TGFβ, have anti-inflammatory properties and play a role during parasite infections, cancer, tolerance and tissue repair. The balance between both subtypes is believed to strongly impact the outcome of inflammatory responses. In this study we set out to characterize M2 polarization induced in murine bone marrow derived macrophages (BMDMs) upon treatment with a combination of IL-4 and the synthetic GC dexamethasone (Dex). Each reagent caused distinct alterations in macrophage morphology and adherence. Flow cytometry and expression analysis by quantitative RT-PCR revealed that IL-4 and Dex acted synergistically in the induction M2 markers such as CD136 and CD206 while M1 markers including TNFα and CD86 were down regulated. The phagocytotic activity of macrophages was enhanced by Dex but IL-4 failed to further increase this property. Collectively, our study suggests that the combined treatment of macrophages with IL-4 and Dex is a highly efficient strategy to achieve alternative macrophage polarization which could become instrumental in treating inflammatory diseases in the future.

P1.06.28
Intestinal epithelial cell-derived Semaphorin 7A negatively regulates development of colitis via αvβ1 integrin

***S. Kang**, A. Kumanogoh;*
Osaka University, Dept of Respiratory Medicine, Allergy and Rheumatic Disease, Suita, Japan.

The intestinal immune system is constantly challenged by commensal bacteria, therefore it must maintain quiescence via several regulatory mechanisms. Although intestinal macrophages have been implicated in repression of excessive inflammation, it remains unclear how their functions are regulated during inflammation. Here, we report that Sema7A, a glycosylphosphatidylinositol-anchored semaphorin expressed in intestinal epithelial cells (IECs), induces IL-10 production by intestinal macrophages to regulate intestinal inflammation. Sema7A-deficient mice showed severe signs of dextran sodium sulfate (DSS)-induced colitis due to reduced intestinal IL-10-levels. We further identified $CX3CR1^{+}MHCII^{int}F4/80^{hi}CD11b^{hi}$ macrophages as the main producers of IL-10 via αvβ1 integrin in response to Sema7A. Notably, Sema7A was predominantly expressed on the basolateral side of IECs, and its expression pattern was responsible for protective effects against DSS-induced colitis and IL-10-production by macrophages during interactions between IECs and macrophages. Furthermore, we determined that the administration of recombinant Sema7A proteins ameliorated the severity of colitis and these effects were diminished by IL-10 blocking antibodies. Therefore, our findings not only indicate that Sema7A plays crucial roles in suppressing intestinal inflammation through αvβ1 integrin, but also provides a novel mode of IL-10 induction via interactions between IECs and macrophages.

P1.06.29
SHP-1 contributes to the CD40 signaling reciprocity and controls Leishmania major infection

***T. H. Khan**;*
National Centre of Cell Science, Pune, India.

CD40, a costimulatory molecule expressed on macrophages can induce counteractive immune responses depending on the intensity of CD40 crosslinking. A strong CD40 stimulation induces preferential phosphorylation of p38MAPK and pro-inflammatory cytokine IL-12 production whereas a weaker CD40 stimulation induces preferential phosphorylation of ERK-1/2 and anti-inflammatory cytokine IL-10 production. In the experimental infection with Leishmania major, CD40-induced p38MAPK activation and IL-12 expression are suppressed whereas ERK-1/2 activation and IL-10 expression are enhanced. We concluded that the observed reciprocity was due to differential phosphorylation of these two MAPKs and we propose that this observed reciprocity can be function of a phosphatase that dephosphorylates these MAPKs differentially. Leishmania infection activates a phosphotyrosine phosphatase SHP-1, which we propose to possibly play a role in MAPK dephosphorylation and thereby influences the reciprocity in CD40 signaling. Although CD40 plays important roles in L. major infection, whether SHP-1 influences CD40 signaling and affects L. major infection or vice versa have never been examined.
In this report, we show that SHP-1 does contribute to the CD40 signaling reciprocity by differential p38MAPK and ERK-1/2 dephosphorylation. In L. major infection, SHP-1 phosphorylation and activity are increased causing reciprocal down-regulation of CD40-induced p38MAPK phosphorylation. SHP-1 overexpression renders the resistant C57BL/6 mice susceptible whereas its inhibition protects susceptible BALB/c mice to L. major infection. Thus, we demonstrate for the first time that SHP-1 contributes to the CD40 signaling reciprocity. These properties are exploited by the parasite to design the SHP-1-targeted immune evasion strategy ensuring their survival in a mammalian host.

P1.06.30
The effects of silica nanoparticles in macrophage cells

***S. Kim**, I. Choi;*
Department of Microbiology, The Institute for Immunology and Immunological Diseases, Yonsei University College of Medicine, Seoul, Republic of Korea.

Silica nanoparticles, which are applicable in many industrial fields, have been reported to induce cellular changes such as cytotoxicity in various cells and fibrosis in lungs. Because the immune system is the primary targeting organ reacting to internalized exogenous nanoparticles, we tried to figure out the immunostimulatory effect of silica nanoparticles in macrophages using differently sized silica nanoparticles. At non-toxic concentration, the intracellular Ca++ level has increased immediately after exposure to 15 nm particles, not to larger particles. ROS generation was detected significantly in response to 15 nm particles. However, all three different sizes of silica nanoparticles induced IL-8 production. 15 nm silica nanoparticles are more stimulatory than larger particles in cytotoxicity, intracellular Ca++ increase and ROS generation. But IL-8 production was induced to same levels with 50 or 100 nm particles. Therefore, IL-8 production induced by silica nanoparticles may be dependent on other mechanisms rather than intracellular Ca++ increase and ROS generation.

P1.06.31
Alternatively Activated Macrophages - Cause or Consequence in Allergic Airway inflammation?

***F. Kirstein**, N. Nieuwenhuizen, F. Brombacher;*
University of Cape Town, Cape Town, South Africa.

IL-4 and IL-13 have numerous functions in allergic diseases, including the induction of Th2 and IgE synthesis, mucus hypersecretion, airway inflammation and airway hyperreactivity. In addition, IL-4 and IL-13 induce alternative activation of macrophages through IL-4 receptor alpha (IL-4Rα). Markers of alternatively activated macrophages (AAM) are upregulated in the lungs of asthmatic patients and mice. AAM are thought to contribute to the pathogenesis of allergic asthma

by virtue of their decreased NO production and increased production of proline and polyamines, important in the synthesis of connective tissues.
However, no studies have shown clear evidence that these macrophages play a causative role in the disease. Therefore, we aimed to define the role of AAM in the pathogenesis of allergic asthma.
The IL-4Rα gene is genetically abrogated in macrophages in LysMcreIL-4Rα-/lox mice, which therefore have impaired activation of AAM. Responses of LysMcreIL-4Rα-/lox mice were examined in ovalbumin (OVA) - and house dust mite - induced allergic asthma. Although expression of markers of AAM such as Ym-1, arginase and FIZZ-1 were decreased in macrophages of LysMcreIL-4Rα-/lox mice, airway hyperreactivity, Th2 responses, mucus hypersecretion, eosinophil infiltration and collagen deposition were not significantly reduced in a OVA- and house dust mite-induced allergic asthma.
In conclusion, we find no evidence to suggest that AAMs are detrimental in allergic asthma in mice, suggesting that effector functions of other cell types are more important in the development of airway pathology. The presence of AAMs in allergic asthma may be merely associative - a consequence of elevated TH2 responses.

P1.06.32
MyD88 and Stat3 signaling are fundamental to tumor associated macrophage function

F. Kratochvill[1]*, J. E. Qualls*[1]*, L. Van De Velde*[1]*, P. Kovarik*[2]*, P. J. Murray*[1]*;*
[1]*St. Jude Children's Research Hospital, Memphis, TN, United States,* [2]*Max F. Perutz Laboratories, University of Vienna, Vienna, Austria.*

Macrophage infiltration of solid tumors correlates with poor prognosis for cancer patients. However, the tumor associated macrophage (TAM) phenotype appears complex and does not emulate the current in vitro paradigms of macrophage activation. TAMs from a variety of solid tumors from distinct organ types display a highly similar gene expression profile, suggesting a common phenotype regardless of tumor type or location. We have also collected gene expression data from TAMs impaired in IL-1 and TLR signaling (Myd88-/-) and observed a MyD88-depedent regulation of multiple secreted proteins involved in Stat3 signaling (IL-6, IL-10, G-CSF) and T cell functional differentiation (IL-23p19, IL-12p40, IL-12p35). TAMs can be further divided into inflammation resolving (R-) and non-resolving NR-TAMs. While IL1/TLR signaling affects both populations, the anti-inflammatory phenotype of Stat3 expressing R-TAMs is specifically regulated by posttranscriptional suppression of cytokine production by Tristetraprolin in a MyD88-independent fashion. Accordingly, deletion of Tristetraprolin leads to the accumulation of NR-TAMs and reduced tumor growth. We therefore suggest that the transition of NR- to tumor-supporting R-TAMs is regulated by Tristetraprolin in a Stat3-dependent manner.

P1.06.33
SHP-1/Src protein complex differentially regulates IL-12 and IL-23 cytokines in TLR4-activated signaling pathways in human macrophages

A. Kumar*, Y. Konarski, A. Busca, M. Kozlowski;*
Children's Hospital of Eastern Ontario, Ottawa, ON, Canada.

Dysregulated production of IL-12 family cytokines namely IL-12 and IL-23 may result in chronic inflammatory conditions such as rheumatoid arthritis and Crohn's disease. In spite of their critical role in inflammation and autoimmune diseases, the regulation of IL-12 and IL-23 production downstream of LPS/TLR4 is not well understood. Tyrosine phosphorylation and is one of the first events observed following LPS activation of TLR4. Recently Src protein tyrosine kinase (PTK) and SHP1 protein tyrosine phosphatase (PTP) have been implicated in the regulation of cytokine production in LPS-stimulated murine macrophages. However, the involvement of SHP-1/Src complex in LPS stimulated IL-12 and IL-23 production is not known. We hypothesized that SHP-1 and Src form a protein complex required for positive regulation of IL-12 and IL-23 production in LPS-stimulated human monocyte-derived macrophages (MDMs). Inhibition of SHP-1 function with sodium stibogluconate, resulted in decreased secretion of IL-12 and IL-23 in a dose-dependent manner in normal human monocytes and MDMs as determined by ELISA and mRNA analysis by PCR and SHP-1 silencing RNA. The inhibition of Src using SU6656 resulted in enhanced production of IL-12 and IL-23 in a dose-dependent manner as determined by ELISA , mRNA analysis and c-Src silencing RNA. Moreover, SHP-1 and Src were shown to form a protein complex by Immunofluorescence and following their immunoprecipitation and inhibition of SHP-1 prevented activation of Src (pSrc). Our results show for the first time that SHP-1 serves as a positive regulator of IL-12 whereas Src kinase negatively regulates IL-23 production in LPS-stimulated human macrophages.

P1.06.34
DMXAA, a vascular disruptive agent, is a potent inhibitor of prostaglandin synthesis

E. Kuroda[1]*, K. Ohata*[1]*, K. J. Ishii*[2,1]*;*
[1]*WPI Immunology Frontier Research Center (IFReC), Osaka University, Suita, Japan,* [2]*National Institute of Biomedical Innovation, Ibaraki, Japan.*

5,6-dimethylxantheone-4-acetic acid, DMXAA has been developed as a vascular disruptive agent for use in cancer therapy. The anti-cancer property of DMXAA was attributed to its induction of TNF-a, type-I IFN and reactive oxygen species. The as same as cytokines and ROS, prostaglandins have been known to be involved in progression of cancer, and NSAIDs are known to suppress incidence of some types of cancer. In this study, we show that DMXAA is a potent inhibitor of prostaglandin synthesis.
Macrophages are efficient producer of prostaglandins (PGs). LPS-activated murine macrophages (such as peritoneal macrophages, bone marrow-derived macrophages and macrophage cell lines) produced higher levels of PGE2. PGE2 production from macrophages was significantly suppressed by treatment with DMXAA. DMXAA suppressed production of other type of PG such as PGD2 and TXA2, and also suppressed PGE2 production from LPS-activated human PBMCs and IL-1-activated HUVEC. Levels of COX-2 and PTGES expression and phosphorylation of cytosolic PLA2 were not affected by DMXAA treatment. In addition, DMXAA did not inhibit COX activity, different from NSAIDs such as indomethacin. These results suggest that DMXAA suppress PG production via non-canonical mechanisms.
In vivo tumor models, treatment with DMXAA in E.G7 (murine lymphoma cells)-bearing mice delayed progression of tumor growth. In addition, ptges-deficient mice, whose macrophages do not produce COX-2-dependent PGE2, inoculated with E.G7 cells have delayed tumor growth, suggesting that PGE2 biosynthesis mediates tumor growth in vivo. Now, we are investigating the mechanisms of suppressive effect of DMXAA on PGE2 production.

P1.06.35
Myeloid cell expressed proprotein convertase Furin attenuates inflammation

Z. Martinez Cordova[1]*, A. Oksanen*[1]*, S. Hämäläinen*[1]*, V. Taverniti*[2]*, I. Junttila*[3]*, M. Pesu*[1]*;*
[1]*Institute of Biomedical Technology, University of Tampere, Tampere, Finland,* [2]*Department of Food Science and Microbiology, Universita` degli Studi di Milano, Milan, Italy,* [3]*School of Medicine, University of Tampere, Tampere, Finland.*

Proprotein convertase Furin converts proteolytically immature proproteins into functional end products. Previously we have shown that Furin is a key regulator of T cell mediated peripheral immune tolerance and that it is upregulated upon the activation of monocytes. The aim of this study is to assess the role of Furin in innate immunity using a mouse model with a conditional deletion for Furin in myeloid cells (LysMcre-furf/f).
LysMcre-furf/f mice remain healthy during the first year of life. Flow cytometry analysis of the immune cells populations in WT and KO mice did not reveal marked differences in the lymphocyte, macrophage and neutrophil populations. To address the consequence of Furin deficiency in myeloid cells in vivo, mice were

intraperitoneally injected with LPS and survival and serum cytokines were monitored. LPS injection resulted in significantly higher mortality of KO mice, and elevated levels of TNFa and IL-6 in serum. In contrast, IL10 cytokine levels were markedly lower. Furthermore, the in vitro experiments with peritoneal macrophages demonstrated higher production of pro-inflammatory cytokines and diminished upregulation of IL-10 upon TLR activation. TGF-β1 is a reported target for Furin as well as a downregulator of activation NFKb-p65 transcription factor. Furin deficient myeloid cells were observed to produce significantly lower levels of bioactive TGF-β1 and show hyper-activation of NFKb-p65 upon LPS stimulus.
We conclude that deletion of Furin in myeloid cells results in a proinflammatory immune phenotype, which is due at least in part to the upregulation of NFKb-p65 as result of a deficiency in TGF-β1 production.

P1.06.36
The marine natural product Honaucin A inhibits innate inflammation

S. Mascuch[1], *H. Choi*[2], *F. Villa*[3], *M. Hensler*[4], *J. Olson*[4], *V. Nizet*[4,5,6], *F. Mahdi*[7], *D. G. Nagle*[7,8], *W. Gerwick*[1,4], *L. Gerwick*[1];
[1]*Scripps Institution of Oceanography, La Jolla, CA, United States,* [2]*College of Pharmacy, Yeungnam University, Dae-dong, Gyeongsan, Republic of Korea,* [3]*Department of Chemistry, Arizona Western College, Yuma, AZ, United States,* [4]*Skaggs School of Pharmacy and Pharmaceutical Sciences, University of California San Diego, La Jolla, CA, United States,* [5]*Department of Pediatrics, University of California San Diego, La Jolla, CA, United States,* [6]*Rady Children's Hospital, San Diego, CA, United States,* [7]*Department of Pharmacognosy, School of Pharmacy, University of Mississippi, Oxford, MS, United States,* [8]*Research Institute of Pharmaceutical Sciences, University of Mississippi, Oxford, MS, United States.*

Inflammation is a hallmark of numerous diseases and represents an enormous public health and financial burden. Current drugs do not always adequately treat inflammation and often have undesirable side effects. Marine natural products represent a unique and promising source of novel therapeutic molecules. Many of these compounds exhibit a natural diversity and complexity that make them attractive from a drug screening approach as compared to synthetic libraries. In addition, possible evolutionary molecular modeling of marine natural products may have resulted in compounds with greater relevance in inflammatory pathways. The marine natural product honaucin A was isolated from the cyanobacterium *Leptolyngbya crossbyana* found overgrowing a Hawaiian coral reef. Composed of (S)-3-hydroxy-γ-butyrolactone and 4-chlorocrotonic acid connected via an ester linkage, this small molecule inhibited LPS-induced nitric oxide production in RAW 264.7 macrophages with an IC_{50} of ~4 μM. This activity was accompanied by a decrease in the production of the pro-inflammatory cytokines IL-1β, TNF-α, and IL-6. Treatment of RAW 264.7 cells with honaucin A did not result in phosphorylation of eIF2α indicating that this stress pathway was not activated, nor did the compound inhibit mitochondrial respiration in T47D breast cancer cells. In an *in vivo* ear edema model, the compound significantly inhibited swelling caused by the application of the irritant phorbol 12-myristate 13-acetate relative to a vehicle-only control. Honaucin A's potent biological activity and its relatively simple preparation by synthetic means make it a promising lead in the pursuit of new inflammatory interventions.

P1.06.37
Differential effect of cyanobacterium *Anabaena* sp. lipopolysaccharide (LPS) on rat brain microglia-derived proinflammatory and anti-inflammatory cytokines and chemokines

A. M. Mayer[1], *D. Macadam*[1], *M. L. Hall*[1], *D. Feher*[2], *P. Williams*[2];
[1]*Midwestern University, CCOM, Downers Grove, IL, United States,* [2]*University of Hawaii at Manoa, Honolulu, HI, United States.*

Cosmopolitan Gram-negative cyanobacteria may contaminate freshwater by releasing toxins, such as lipopolysaccharide (LPS) thus affecting human health. We recently reported that cyanobacterial lipopolysaccharide (LPS) elicited release of superoxide anion, thromboxane B_2, and matrix metalloproteinase-9 by rat microglia (BMG) *in vitro* (The Toxicologist CD 132 (S-1), 2013). We hypothesized that freshwater cyanobacterium *Anabaena* sp. LPS (AnaLPS) would also activate both classical and alternative activation of BMG *in vitro* and concomitant release of cytokines and chemokines. AnaLPS was prepared by hot phenol/water extraction. *E. coli* LPS (EcLPS) 026:B6 from Difco Lab, Detroit, MI was used as a positive control in these experiments. BMG were isolated from neonatal rats, and treated *in vitro* with either AnaLPS or EcLPS in a concentration-dependent manner for 18 hours at 35.9 °C. Cytokines and chemokines were determined using a Milliplex® MAP rat cytokine/chemokine multiplex immunoassay. Results were the following: EcLPS and AnaLPS stimulated statistically significant and concentration-dependent release of (a) Pro-inflammatory cytokines: IL-6>IL-1β>TNF-α; (b) Pro-inflammatory chemokines: MIP-2/CXCL2>MIP-1α/CCL3>MCP-1/CXCL2; and the (c) Anti-inflammatory cytokine: IL-10, at > than 1ng/mL and 10^4ng/mL, respectively. We conclude that after a 18 hour *in vitro* stimulation AnaLPS stimulated both "classical" and alternative" activation of rat brain microglia, but was considerably *less* potent than EcLPS in stimulating release of the pro-inflammatory cytokines and chemokines, and the anti-inflammatory cytokine IL-10. Continued investigation of the mechanism responsible for the differential response observed with AnaLPS on BMG is currently ongoing in our laboratory. Support by Midwestern University and the University of Hawaii at Manoa is gratefully acknowledged.

P1.06.38
Pulmonary surfactant protein A strengthens IL-4-mediated proliferation and alternative activation of rat alveolar macrophages

C. Minutti[1,2], *B. García-Fojeda*[1,2], *C. Casals*[1,2];
[1]*Universidad Complutense de Madrid, Madrid, Spain,* [2]*CIBERES, Instituto de de Salud Carlos III, Madrid, Spain.*

It is well established that IL-4 induces alternative activation of macrophages involving intracellular activation of STAT6. Moreover, it has recently been shown that this cytokine has a proliferative effect on macrophages. However, little is known about the effect of pulmonary surfactant protein A (SP-A), the most abundant immunomodulatory protein in the alveolar fluid, on IL-4-induced effects on alveolar macrophages (aMφ). This study was undertaken to determine whether human SP-A interferes with IL-4 immune actions on aMφ. To accomplish this, purified rat aMφ were stimulated with IL-4 in the presence and absence of SP-A. We measured arginase activity, STAT6 phosphorylation, and aMφ proliferation. We found that SP-A increased IL-4-induced arginase activity and STAT6 phosphorylation. We also found that the synergistic effect of SP-A on IL-4-mediated signaling involved PKC activation since inhibition of PKC abolished SP-A-induced reinforcement of IL-4 signaling effects. In addition, we observed that SP-A augmented IL-4-induced aMφ proliferation. We conclude that SP-A strengthens IL-4 effects on aMφ,. suggesting that SP-A might play a key role in Th2-related pathologies by enhancing IL-4 effects on aMφ.

P1.06.39
Characterization of the innate immune response in human macrophages by Mycobacterium bovis BCG

G. Molina-Olvera, *A. I. Castllo-Rodal, Y. López-Vidal;*
UNAM, México, Mexico.

Differential protection is attained against TB depending on the *Mycobacterium bovis* BCG substrain used, age and population in trial. Little information exists regarding innate immune response among BCG vaccine substrain infection of human macrophages. Innate immune response characterization of human macrophage infection with different *Mycobacterium bovis* BCG substrains would expand knowledge on protective efficacy. Macrophage cell line THP-I was infected with BCG substrains: Moreau, Danish, Mexico, Tice and Phipps. Live mycobacterium was determinated by intracellular ATP, Macrophage, nitric oxide production and cytokine profile at 0, 24 and 72h were also assessed. The number of bacteria of the BCG substrains Mexico, Moreau and Tice increased more than double at

24h of infection and declined by 72 h while BCG Phipps and Danish substrains grown slowly. Nitric oxide production at 72h by Moreau and Tice BCG infected macrophages increased 100% and 500% respectively as intracellular BCG number decrement was observed. On the other hand the BCG Phipps substrain showed able to induce higher levels of TNF, IL-12 and IL-10 at 72h production post-stimulus, suggesting a Th1 immune response and associated with a protective response in human macrophages.

P1.06.40
Regulation of macrophage complement receptor immunoglobulin (CRIg) expression by cytokines

U. Munawara[1,2], *A. Quach*[1], *N. N. Gorgani*[1,3], *C. Abbott*[2], *A. Ferrante*[1,4,5];
[1]*Department of Immunopathology, SA Pathology at Women's and Children's Hospital, Adelaide, Australia,* [2]*School of Biological Sciences, Flinders University, Adelaide, Australia,* [3]*Westmead Millennium Institute, Sydney, Australia,* [4]*Disciplines of Paediatrics and Microbiology and Immunology, University of Adelaide, Adelaide, Australia,* [5]*School of Pharmacy and Medical Sciences, Univeristy of South Australia, Adelaide, Australia.*

Complement receptor immunoglobulin (CRIg) differs in structure, tissue expression and in biological activity to the classical complement receptors, CR3 and CR4. The receptor is expressed in subpopulations of macrophages and promotes the rapid phagocytosis of bacteria and has been shown to be essential in controlling bacterial infection and preventing bacterial dissemination and overwhelming pathogenesis. Apart from its role in innate immunity, CRIg has been demonstrated to regulate T cell function in an immunosuppressive manner. However, little is known about the regulation of its expression. We examined the effects of cytokines which have pro-inflammatory, anti-inflammatory and regulatory functions. The cytokines were found to cause changes to the expression of CRIg on human monocyte derived macrophages, in a manner not akin to the expected functional roles of these cytokines. The effects were seen over a concentration range at which the cytokines cause other effects on the immune system. Changes in expression were evident at both CRIg mRNA and protein level. IFNγ, TNFα, IL-4, IL-13 and TGFβ caused a decreased expression, while IL-1β, IL-6, IL-10, LT, M-CSF and GM-CSF increased CRIg expression in macrophages. In comparison the expression of CR3 and CR4 was differently regulated by these cytokines. Dendritic cells developed in culture from monocytes under the influence of IL-4 and GM-CSF also expressed CRIg and cytokines regulated the expression of CRIg on these cells. The data show that cytokines regulate the expression of CRIg in macrophages, highlighting another point of control of innate immunity and adaptive immunity by cytokines.

P1.06.41
Ubiquitin-like protein MNSFβ covalently binds to Bcl-G and enhances lipopolysaccharide (LPS)/interferon γ (IFNγ)-induced apoptosis in macrophages

M. Nakamura*, M. Nakagawa;*
Shimane University, Izumo, Japan.

MNSFβ is a ubiquitously expressed member of the ubiquitin-like family that has been involved in various biological functions. Previous studies have demonstrated that MNSFβ covalently binds to intracellular pro-apoptotic protein Bcl-G and regulates the ERK-MAPK cascade in mouse macrophage cell line, Raw264.7. In this study, we demonstrate that MNSFβ promotes lipopolysaccharide (LPS)/interferon γ (IFNγ)-induced apoptosis of Raw264.7 macrophages. In Raw264.7 cells treated with MNSFβ small interfering RNA (siRNA), LPS/IFNγ- or NO donor S-nitrosoglutathione (GSNO)- induced apoptosis was inhibited. SiRNA-mediated knockdown of MNSFβ did not affect iNOS expression in LPS/IFNγ-stimulated Raw264.7 cells. Conversely, co-transfection with MNSFβ and Bcl-G greatly enhanced LPS/IFNγ- induced apoptosis in Raw264.7 cells, accompanied with an increased expression of p53 and a decreased Cox-2 activity. Unlike co-transfection with wild-type MNSFβ, co-transfection of a mutant MNSFβ (G74A) and Bcl-G did not result in an enhancement of LPS/IFNγ- induced apoptosis. Co-overexpression of MNSFβ and Bcl-G reduced GSNO-induced ERK1/2 phosphorylation. Furthermore, EMSA experiments revealed that MNSFβ down-regulates ERK/AP-1 signaling cascade leading to Cox-2 activation. We also observed that MNSFβ•Bcl-G promotes LPS/IFNγ-induced apoptosis of mouse peritoneal macrophages, together with a decrease in Cox-2 expression. Taken together, our data indicate an apoptosis enhancing effect of MNSFβ•Bcl-G is due in part to the down-regulation of Cox-2 activation in macrophages.

P1.06.42
T CD8+ suppressor lymphocyte-derived exosomes carrying miRNA150 impair macrophage ability to induce humoral immune response in mice

K. Nazimek*, M. Ptak, W. Ptak, K. Bryniarski;*
Department of Immunology Jagiellonian University College of Medicine, Krakow, Poland.

Introduction. Macrophages possess the ability to antigen phagocytosis, processing and presentation inducing adaptive immunity and act as effector cells in contact hypersensitivity, which in mice could be regulated by T CD8+ suppressor lymphocytes producing T suppressor factor (TsF) consisting of antigen-specific exosomes carrying miRNA150. TsF affects macrophages mediating cellular reaction. Macrophage activity can also be observed in development of humoral response to corpuscular antigen (SRBC). Therefore, our studies were aimed to determine if TsF influences the macrophage function in induction of B lymphocyte response.
Materials and methods. Thioglycollate-induced peritoneal macrophages were incubated with exosomes from either trinitrophenol-specific TsF (TNP-TsF) or negative factor (NF), fed with TNP-labelled sheep erythrocytes (TNP-SRBC) and transferred intraperitoneally into naive recipients. Seven days later sera and spleens were collected separately from each recipient and humoral response was assessed by plaque forming assay (PFA) and direct haemagglutination assay (HA) determining titers of anti-TNP-SRBC IgM and IgG antibodies, in comparison to control group of recipients of untreated macrophages fed with TNP-SRBC.
Results. The treatment of macrophages with TNP-TsF exosomes significantly reduced the number of plaque forming cells in PFA (by 34%) and changed IgM/IgG titers ratio (2/8, compared with control 0,5/9) while NF exosomes did not affect estimated parameters.
Conclusion. The impairment of macrophage activity by TNP-TsF exosomes resulted in inhibited maturation of humoral response expressed as lower number of antibody-producing B cells and decreased immunoglobulin class switching. Present study demonstrated the potential mechanism of regulation of B-cell mediated immunity via macrophages affected by antigen-specific exosomes carrying miRNA.

P1.06.43
The role of MAP kinase phosphatase-2 (MKP-2) in macrophage development and gene expression

T. Neamatallah[1,2], *J. Schroeder*[1], *R. Tate*[1], *J. Alexander*[1], *R. Plevin*[1];
[1]*Starthclyde Institute for Pharmacy and Biomedical Sciences, Glasgow, United Kingdom,* [2]*Fuculty of pharmacy, King Abdulaziz University, Jeddah, Saudi Arabia.*

Mitogen-activated protein kinase phosphatase-2 (MKP-2) is a type 1 nuclear dual specific phosphatase (DUSP4) and an important immune regulator. It specifically dephosphorylates the MAP kinases ERK and JNK to influence pro- and anti-inflammatory cytokine production. MKP-2 has recently been shown to play a significant role in controlling *Leishmania mexicana* and *Toxoplasma gondii* infections (Al-Mutairi et al., 2010 and Woods et al., in press) primarily by influencing macrophage activity. However, information on the effect of MKP-2 deletion at the molecular level on macrophage development and function is limited. Consequently, we conducted a comparative genome-wide microarray analysis on MKP-$2^{-/-}$ and MKP-$2^{+/+}$ macrophages following innate (LPS), classical (IFN-γ) and alternative (IL-4) activation. As demonstrated previously, and associated with a role for MKP-2 in antimicrobial activity, arginase-1 expression was up-regulated in MKP-$2^{-/-}$ compared with MKP-$2^{+/+}$ macrophages. Surprisingly, and in contrast, we found that the alternative activation

markers YM1 (Chi3l3) and Fizz1/Relm-α (Retnla) were significantly reduced in MKP-2$^{-/-}$ macrophages when compared with their wild-type counterparts. As both YM-1 and Relm-α have been implicated to play a major role in extracellular matrix disposition this suggests a significant role for MKP-2 in wound healing. In addition, our microarray data revealed that the expression of two genes related to macrophage differentiation and proliferation, monocyte to macrophage associated differentiation (MMD) and colony stimulating factor-2 (CSF-2) were dependent on MKP-2. MAPK inhibition also elucidated a mechanism for MKP-2 dependent gene expression. Collectively, our findings establish that MKP-2 is an essential regulator of macrophage development and function.

P1.06.44
Differential regulation of innate immunity in the lungs of smokers and non-smokers

***J. Öckinger**, M. Hagemann-Jensen, S. Kullberg, A. Eklund, J. Grunewald, J. Wahlström;*
Karolinska Institutet, Stockholm, Sweden.

Recent studies have shown that a smoking increases the risk for autoimmune diseases such as multiple sclerosis and rheumatoid arthritis. The mechanism underlying the risk increase is not known, but we hypothesized that tobacco smoke exposure could modulate the innate immune response, both systemically and in lungs. This was investigated by a comprehensive analysis of innate immune response, including TLR signaling and inflammasome activation in peripheral blood monocytes and alveolar macrophages collected through bronchoalveolar lavage (BAL) from healthy smokers and non-smokers.
Our results indicate that key components for a functional inflammasome response, including NLRP3 and pro-IL-1β are upregulated in alveolar macrophages from healthy smokers, compared to non-smokers. In contrast, in vitro stimulation with known inflammasome activators (e.g. ATP) induced a lower secretion of IL-1β in BAL-cells and peripheral blood monocytes from smokers. These results indicate a role of inflammasome activation in the regulation of smoking induced pathology, and its role in the development of autoimmune diseases will be further investigated.
Transcriptional analysis of selected TLR-dependent genes indicates that smoke exposure induces a specific expression profile, including downregulation of TNF, in light to moderate smokers. These results give further insight into the regulation of the immune response in the airways by tobacco smoke exposure, and will be follow by in-dept analysis of chromatin remodeling and transcriptional regulation of central pathways in the innate immune response.

P1.06.45
Notch Signaling Regulates Expression of Mcl-1 and Apoptosis in PPD-treated Macrophages

***T. Palaga**[1,2,3], S. Ratanabunyong[2], T. Pattarakankul[3], Y. Hadae[4], N. Sangphech[2], P. Kuenjinda[2];*
[1]Department of Microbiology, Faculty of Science, Chulalongkorn University, Bangkok, Thailand, [2]Medical Microbiology Interdisciplinary Program, Graduate School, Chulalongkorn University, Bangkok, Thailand, [3]Graduate Program in Industrial Microbiology, Faculty of Science, Chulalongkorn University, Bangkok, Thailand, [4]International Center for Biotechnology, Osaka University, Osaka, Japan.

Macrophages are cellular targets for infection by pathogens. The fate of infected macrophages plays a key role in determining the outcome of the host immune response. Apoptosis of macrophages is a protective host defense that eliminates pathogens and infected cells. In this study, we investigated the involvement of Notch signaling in regulating apoptosis in macrophages treated with tuberculin purified protein derivative (PPD). Murine bone-marrow-derived macrophages (BMM) treated with PPD or infected with *Mycobacterium bovis* BCG induced upregulation of Notch1. This upregulation correlated well with the upregulation of the anti-apoptotic gene *Mcl-1* both at the transcriptional and translational levels. Decreased levels of Notch1 and Mcl-1 were observed in BMM treated with PPD when a gamma secretase inhibitor (GSI), which inhibits the processing of Notch receptors, was used. Moreover, silencing Notch1 in cell line RAW264.7 decreased Mcl-1 protein expression, suggesting that Notch1 is critical for Mcl-1 expression in macrophages. A significant increase of apoptotic cells was observed upon treatment of BMM with PPD in the presence of GSI compared to the vehicle-control treated cells. Furthermore, overexpression of truncated Notch1 or dominant negative MAML (DN-MAML) in human monocytic leukemia cell line THP-1 affected the level of Mcl-1. Finally, analysis of the *mcl-1* promoter in human and mouse revealed a conserved potential CSL/RBP-J[[Unsupported Character - Symbol Font ]] binding site. The association of Notch1 with the *mcl-1* promoter was confirmed by chromatin immunoprecipitation. Taken together, these results indicate that Notch1 inhibits apoptosis of macrophages stimulated with PPD by directly controlling the promoter of *mcl-1*.

P1.06.46
Evaluation of the potency of CD137-activated macrophages in inhibiting tumor cell growth

***W. Pang**, H. Schwarz;*
National University of Singapore, Singapore, Singapore.

Macrophages are hematopoietic cells which play a pivotal role in immune defense. Macrophages can phagocytose pathogens and even entire cells. Also, by releasing toxic compounds including reactive oxygen intermediates or by expressing apoptosis-inducing cytokines such as tumor necrosis factor (TNF) or TRAIL, macrophages can kill bacteria and tumor cells. Macrophages express the ligand for CD137 on their cell surface which induces their activation, via reverse signaling. In this study, we aim to investigate whether CD137 ligand signaling can enhance the ability of macrophages to interfere with the growth and /or viability of cancer cells. Peripheral human monocytes were cultured for up to 10 days. Macrophage colony-stimulating factor (M-CSF) was added to differentiate the monocytes into macrophages which were then treated with recombinant immobilized CD137-Fc protein overnight before being co-cultured with MCF-7, a human breast cancer cell line, or with HeLa, a human cervical cancer cell line. Macrophages that had been pre-treated with immobilized CD137-Fc protein significantly reduced the proliferation of MCF-7 and HeLa cells, and caused a higher percentage of MCF-7 and HeLa cells with a reduced DNA content, which would be consistent with an increased incidence of apoptosis. Also, higher levels of TNF, M-CSF and IL-6 were present in the supernatants of these macrophage tumor cell co-cultures. Thus, our study shows that activation of macrophages by recombinant CD137 protein which induces reverse CD137 ligand signaling enables macrophages to suppress proliferation of cancer cells in vitro.

P1.06.47
Statins mediate protection against Mycobacterium tuberculosis infection by enhancing phagosomal maturation and autophagy

***S. P. Parihar**[1], R. Guler[1], R. Khutlang[2], D. Lang[3], M. Mhlanga[2], H. Suzuki[4], D. Marais[3], F. Brombacher[1];*
[1]International Centre for Genetic Engineering & Biotechnology, Cape Town, South Africa, [2]Council for Scientific & Industrial Research (CSIR), Pretoria, South Africa, [3]University of Cape Town, Cape Town, South Africa, [4]RIKEN, Yokohama, Japan.

Statins are effective pharmacological inhibitors of the HMG-CoA reductase, a rate-limiting enzyme for cholesterol biosynthesis, and have been shown to reduce bacteremia in statin-users.
We aimed to investigate the effect of statins on M. tuberculosis infected monocytes/macrophages isolated from statin-treated patients and uncovered the possible biological mechanisms in macrophages and mice.
Peripheral blood mononuclear cells (PBMCs) and monocyte-derived macrophages (MDMs) were isolated from patients with familial hypercholesterolemia (FH) on statin therapy. Cells were then infected with Mtb and their bacterial burden determined in comparison to cells from healthy controls. In addition, mice were treated with statins prior to aerosol infection with Mtb and disease progression in infected mice was monitored in comparison to sham-treated mice.
PBMCs and macrophages from FH patients displayed reduced M. tuberculosis burdens compared to cells from healthy non-statin users.

Statin treatment also reduced bacterial growth in both Mycobacterium-infected PBMCs isolated from healthy human subjects and murine macrophages. Statin treatment reduced mycobacterial burden in lungs and improved pathology as compared to sham-treated infected mice. Mechanistically, statins counteracted Mycobacterium-induced inhibition of phagosomal maturation and increased host-protective autophagy of infected macrophages.
Human patients on statin therapy show increased protection against Mtb infection. In addition, statin treatment led to increased protection against Mtb in infected mice as shown by reduced bacterial burdens and dissemination of bacteria to peripheral organs. Murine bone marrow-derived macrophages (BMDMs) displayed reduced mycobacterium loads following statin treatment. We found that statins inhibited bacterial growth by enhancing phagosomal maturation and autophagy in infected BMDMs.

P1.06.48
Metalloproteinase-9 production by monocytes from cutaneous leishmaniasis patients

***S. Passos**, T. Menezes, R. Costa, E. M. Carvalho, L. P. Carvalho;*
Federal University of Bahia, Salvador, Brazil.

Cutaneous leishmaniasis caused by Leishmania braziliensis is characterized by strong cell infiltrate and inflammatory response. Circulating monocytes are a heterogeneous population subdivided into classical monocytes (CD14 + CD16), intermediate monocytes (CD14 + CD16 +) and non-classical monocytes (CD14-CD16 +), and are known to migrate to inflammatory sites and secrete cytokines. TNF can mediate the pathology of CL through various mechanisms including, induction of nitric oxide (NO), increased cytotoxicity and expression of matrix metalloproteinases (MMPs). MMP-9 is a zinc-dependent enzyme that degrades type IV collagen, a component of basal membrane, and MMP-9 effect is controlled by TIMP-1 (tissue inhibitor of metalloproteinase 1). Although the factors that induce the breakdown of the basal membrane leading to the development of ulcer are unknown, it is likely that MMP-9 contributes to tissue injury in the CL. Mononuclear cells from CL patients were obtained for ex-vivo labeling of sub-populations of monocytes and MMP-9, and the frequency determined by flow cytometry. Our results showed that monocytes were major cells producing MMP-9 and all three sub-populations of monocytes from patients with early CL and CL more expressed MMP-9, when compared with those in healthy individuals. In patients with CL non-classical monocytes producer was the main source of MMP-9. Elevated levels of MMP-9 and lower levels of TIMP-1 were found in PBMC cultures from patients with cutaneous leishmaniasis. We also found that TNF induces MMP-9 production in these individuals. In conclusion, high levels of TNF in patients with cutaneous leishmaniasis contribute to MMP-9 production by monocytes.

P1.06.49
The importance of experimental milieu in regulation of macrophage activation

***M. Pekarova**[1], A. Lojek[1], H. Martiskova[1], A. Klinke[2], T. Rudolph[2], M. Maceckova[1], R. Kuchta[3], J. Kadlec[3], Z. Kuchtova[3], L. Kubala[1];*
[1]Institute of Biophysics, AS CR, v.v.i., Brno, Czech Republic,
[2]University Hospital of Cologne, Cologne, Germany, [3]Brno University of Technology, Brno, Czech Republic.

Background: Macrophages are important source of cytokines and other compounds, which recruit additional cells to sites of infection or tissue injury. Importantly, their functions might be directly controlled by the composition of milieu in their immediate vicinity. Therefore, the analysis of their function under different in vitro as well as “simulated” in vivo condition is of particular interest.
Materials and methods: Mice peritoneal macrophages were stimulated with different activators (e.g. LPS, IFN-γ, TNF-α and interleukins or their combination) under different experimental conditions (in vitro and “simulated” in vivo conditions). Consequently, the physiological functions of macrophages were assessed using different luminometric, spectrophotometric, molecular, and immunohistochemical methods.
Results: Our data demonstrate that there exists crucial difference in activation of macrophages under classical in vitro and “simulated” in vivo conditions. These abnormalities are accompanied by significant changes in inflammatory response of macrophages as well as in activation of intracellular signaling pathways.
Conclusions: The activation of mice peritoneal macrophages is dependent on the composition of milieu in their immediate vicinity and the “classically used” in vitro systems seems to be not suitable for correct analysis of their functions.

P1.06.50
The interaction of monocytes from Sjögren Syndrome patients with human salivary gland epithelial cells promotes an inflammatory microenvironment modulated by VIP

*V. Hauk[1], L. Fraccaroli[1], E. Grasso[1], A. Eimon[2], R. Ramhorst[3], O. Hubscher[2], **C. Perez-Leiros**[4];*
[1]School of Sciences. University of Buenos Aires-CONICET, Buenos Aires, Argentina, [2]Rheumatology Unit, CEMIC, Buenos Aires, Argentina, [3]School of Sciences and School of Medicine. University of Buenos Aires-CONICET, Buenos Aires, Argentina, [4]School of Sciences and School of Dentistry. University of Buenos Aires-CONICET, Buenos Aires, Argentina.

Suppressant phagocytosis by macrophages is central for tissue homeostasis maintenance. Sjögren syndrome (pSS) is an autoimmune disease characterized by progressive oral and ocular dryness with high impact in healthcare. Aberrant expression of inflammatory mediators in glandular epithelium and epithelial cell apoptosis were proposed as early events in pSS pathogenesis. Vasoactive Intestinal Peptide (VIP) is a pleiotropic, secretory and vasodilator neuropeptide with immunomodulatory effects through VPAC1/VPAC2 receptors on immune cells.
Our goal was to study the role of VIP / VPAC system in the interaction of monocytes from pSS patients with a human salivary gland epithelial cell line.
Monocytes were isolated from peripheral blood of women with pSS (Vitali C et al. 2002) (n:34) and age-matched healthy women as the control group (n:16). Mononuclear cells were analyzed by flow cytometry and RT-qPCR for phagocytosis, cytokines, chemokines and VIP receptor expression before or after coculture with a human salivary gland cell line (HSG).
pSS monocytes showed an inflammatory profile with an increased expression of VPAC2 (absent in healthy volunteers) and IL-12 expression after coculture prevented by VIP. A decreased phagocytosis of apoptotic cells was observed by pSS monocytes (pSS 23,93%±4,42 vs control 11,61%±1,52 $p<0,05$) . During coculture pSS cells promoted the expression of inflammatory (IL-6, TLR3, TLR4) and migration markers (MCP-1) on epithelial cells without inducing apoptosis markers. VIP reduced TLR3 expression.
We conclude that the interaction of pSS monocytes with gland ephitelium promotes an inflammatory microenvironment partially modulated by VIP.

P1.06.51
Contribution of microRNAs to human macrophage polarization processes

***M. Pesant**, G. Sukubo, M. Locati;*
Humanitas Clinical and Research Center, Rozzano, Italy.

Macrophages are essential components of the innate immune system and stand as the first line of defense of the organism against pathogens and virus. Macrophages can be schematically described as classically activated (M1) or alternatively activated (M2). We sought to define the microRNA (miRNA) expression profiles of human polarized macrophages and to characterize macrophage polarization-relevant miRNA targets.
MiRNA profiles from human resting (M0) and polarized macrophages (M1 and M2) were obtained with microfluidic miRNA arrays. 74 miRNAs were significantly differentially expressed among macrophage phenotypes. Hierarchical cluster analysis of these 74 miRNAs showed that M0, M1 and M2 could be discriminated by the differential expression of these miRNAs. For instance hsa-miR-135b

was strongly upregulated in M1 whereas hsa-miR-193b and hsa-miR-424 were upregulated in M2. The modulation of these miRNAs was further validated by RT-PCR in independent biological replicates. Moreover, biological pathways analysis showed that hsa-miR-135b is highly predicted to impact on the IL-4 signaling pathway, while hsa-miR-193b and hsa-miR-424 may modulate pathways associated with recognition of bacteria and virus by pattern recognition receptors (hsa-miR-193b and hsa-miR-424) and IL-15 production (hsa-miR-424). Finally, using 3'UTR luciferase assays, we validated the M2-related transcription factors c-MYC, STAT6 and KLF4 as targets of M1-associated hsa-miR-135b. In conclusion we show that macrophage phenotypes can be discriminated by the differential expression of a panel of miRNAs. The pathways impacted by some of the top-regulated miRNAs indicate a potential profound effect of these miRNAs on macrophage polarization processes and functions.

P1.06.52
Effective macrophage expression strategy

***C. Pridans**, S. Lillico, T. King, B. Whitelaw, D. A. Hume;*
Roslin Institute, University of Edinburgh, Edinburgh, United Kingdom.

Differentiation of bone marrow progenitors into macrophages requires macrophage colony-stimulating factor (Csf1) which signals via its receptor Csf1r. Expression of Csf1r within the haemopoeitic system is highest in monocytes and macrophages. MacGreen mice were created previously by placing EGFP expression under the control of the Csf1r proximal promoter and included Fms Intronic Regulatory Element (FIRE) located in the first intron. These mice have consistent expression of EGFP in the same locations as the endogenous gene. FIRE is remarkably conserved across mammalian species, including marsupials, with greater than 90% nucleotide homology between mouse and human, higher than any exons of the gene. Our laboratory has utilised both the murine Csf1r promoter and FIRE sequences in a lentiviral system to drive macrophage specific expression of EGFP in mouse, rat, sheep, pig and human cells. *In vitro* transduction of rat bone marrow cells resulted in EGFP expression only in macrophages when cells were differentiated with Csf1. This work has also resulted in the production of MacGreen sheep with the generation of rats currently underway. The broad species cross reactivity of this lentivirus makes it an attractive vehicle for gene therapy as macrophages have been implicated in numerous diseases including arthritis, atherosclerosis, lysosomal storage diseases and malignant tumours. Lentiviral vectors have already been shown to promote efficient antigen expression and presentation both *in vivo* and *in vitro* highlighting the potential use of our Csf1r-EGFP lentivirus as a vaccine that targets a wide range of cancers and infectious diseases.

P1.06.53
Altered Expression of CD200/CD200R1 Immunoinhibitory Proteins is Associated with the Dysregulated Microglial Response to Ischemic Stroke Injury in Aged Mice

***R. M. Ritzel**, A. Patel, V. Scranton, L. McCullough, F. Liu;*
University of Connecticut Health Center, Farmington, CT, United States.

Objective: The role of CD200-CD200R1 signaling in the healthy brain is important in maintaining microglia in an inactive, resting state. Recent studies investigating the imbalance of CD200-CD200R1 signaling in models of neurodegenerative disease support the hypothesis that these neuronal-glial interactions may also be important in the aged brain. The purpose of this study was to investigate the microglial response to ischemic injury in the aged brain.
Methods: Young (8 wks) and aged (20 mos) male C57Bl/6 mice were subject to sham surgery or 90min right middle cerebral artery occlusion and sacrificed at 72hrs post-reperfusion. The stroke hemisphere, spleen, and blood were harvested in separate cohorts for immunohistochemistry, Western blot analysis, and flow cytometry.
Results: Aging males had significantly smaller infarcts than young males. A significant decrease in CD200 protein expression was seen in aged brains at baseline compared to young, and further decreased after stroke in both aged and young brains. While CD200R1+ microglia significantly increased in all stroke animals, aged mice had significantly less peripheral leukocyte infiltration. The expression level of activation markers (CD80, MHCII) was significantly higher in aged microglia compared to young after stroke.
Conclusions: The aged mouse brain shows a marked imbalance in CD200-CD200R1 signaling compared to the young brain at baseline. Despite similar imbalances in expression after stroke, surprisingly, the inflammatory response appears to be more robust in the young. In summary, we observed that aged mice had higher baseline activation, leading to a muted response to injury.

P1.06.54
Age-and Location-Related Changes in the Immunoregulatory Status of Microglia

***R. M. Ritzel**, A. R. Patel, F. Liu, L. D. McCullough;*
University of Connecticut Health Center, Farmington, CT, United States.

Objective: Microglia display regional heterogeneity in the adult CNS which may contribute to region-specific responses to injury. Despite their importance to many CNS diseases, many of which manifest in the elderly population, how microglia change with aging is less understood. We examined region-specific changes in brain and spinal microglia immunophenotype across the lifespan.
Methods: Naïve young (8 wks) and aged (20 mos) male C57Bl/6 mice were sacrificed and perfused with PBS prior to brain and spinal cord harvest. Samples were processed for immunohistochemistry and into single cell suspensions for analysis by flow cytometry.
Results: The percentage and mean fluorescence intensity of microglia expressing the activation markers CD40, CD68, CD80, MHCII, CD200R1 were significantly upregulated in the aged CNS. Intracellular cytokine staining revealed age- and region-specific changes in TNF, IL1β, and IFNɣ expression. The percentage of phagocytic microglia was higher in the young brain compared to the aged brain, while spinal microglia showed low activity across the lifespan.
Conclusions: We found an age-related increase in expression of various myeloid activation markers and cytokine production that displayed regional heterogeneity. These changes were associated with an increased shift in scatter properties suggesting more dystrophic, senescent microglia and fewer ramified, resting populations in aged, as confirmed by immunohistochemistry. Aged microglia appeared dysfunctional based on phagocytic potential and enhanced pro-inflammatory cytokine production. These findings are consistent with the existence of diverse immunological phenotypes among microglia in the mouse CNS and add to our understanding of the compartmentalized functions performed by microglia in the aged CNS.

P1.06.55
Modulation of FcgammaRs expression in macrophages derived from THP-1 cells (THP-1-MΦ) polarized to inflammatory, wound-healing and regulatory phenotypes

***A. Rivera Fuentes**, E. Ortega Soto;*
UNAM, Mexico, Mexico.

Macrophages can display a high degree of phenotypic heterogeneity, depending on their anatomical location, and also as a result of activation in response to microenvironmental factors. Characterization of these diverse activation states is important because of its relevance for the induction of an effective immune response and because inappropriate activation can have pathogenic effects.
We sought to establish a cell-line model in which to study and characterize the phenotypic changes of human macrophages associated with distinct types of activation. We used THP-1 promonocytic cells, and differentiated them to a macrophage-like phenotype (THP-1-MΦ) with PMA. THP-1-MΦ cells were exposed to different cytokines, to be polarized into three subpopulations of macrophages: INFγ for inflammatory macrophages, IL-4 for wound-healing macrophages and IL-10 for regulatory macrophages. The polarization phenotype was corroborated by the expression of the surface markers CD80, CD206 and CD163 respectively. To assess the effect of polarization on FcγR expression and function, we evaluated the expression of CD64 (FcγRI) and CD32 (FcγRII), as well

as phagocytosis of IgG-coated sheep erythrocytes. INFγ polarized macrophages showed a 2.7-fold increase in CD64 expression, but a reduction of 50% in phagocytic capacity. In contrast, IL-10 treatment increased 1.7-fold the membrane expression of CD32, and three times the phagocytic capacity as compared with control cells. In IL-4 treated macrophages we observed a decrease of 30% in phagocytosis, and no statistically significant changes in CD32 and CD64. This model can be used to study phenotypic changes and plasticity in macrophage-like cells.

P1.06.56
Non-classical circulating monocytes are reduced in patients with systemic lupus erythematous (SLE) and they show regulatory functions on classical monocytes in healthy controls

*C. Burbano-Arciniegas, G. Vasquez-Duque, **M. Rojas-Lopez**; Universidad de Antioquia, Medellín, Colombia.*

Monocytes modulate inflammatory processes; recognize, remove, and present auto-antigens from apoptotic cells (AC), influencing the activity of SLE, innate and adaptive responses. Three subpopulations are recognized: classical, non-classical and intermediate. Patients with active SLE had normal monocyte counts with a reduction in the proportion of non-classical ones. Monocytes from patients with active SLE also showed reduced expression of HLA-DR, CD14 and CD16, decreased binding and phagocytosis of AC and did not up-regulate CD80 after its interaction with AC. We developed a co-cultures model to study interactions between classical and non-classical monocytes on the differentiation of classic monocytes and their interaction with autologous T lymphocytes in the presence of apoptotic Jurkat cells. Monocytes were electromagnetically sorted as non-classical and classical ones and reconstituted in different proportions. Co-cultures were made in the presence or the absence of AC evaluating the influence of non-classical monocytes and AC in the process of monocyte differentiation. AC induced up regulation of CD80 and HLA-DR in classical monocytes; however, the presence of non-classical ones prevented these increase. Co-cultures of classical and non-classical monocytes, independent of the presence of AC, showed decreased T cell proliferation and low numbers of IFN-γ+ proliferating cells. Although the presence of AC and non-classical phagocytes, affected cytokine accumulation; there was not a clear association between decreased T cell proliferation and monocyte cytokines. The evidence suggests that non-classical monocytes play a role as regulatory cells suppressing auto-reactive T lymphocytes in SLE.

P1.06.57
Isolation of mouse alveolar macrophage using mixed primary culture from lungs

*P. M. C. Silva, I. T. Brandão, A. P. Masson, W. M. Rios, R. F. Rodrigues, C. L. Silva, **R. S. Rosada**;*
Nucleo de Pesquisas em Tuberculose, FMRP/USP, Ribeirão Preto, Brazil.

Alveolar macrophages are phagocytes that present a key role on the immune response against a variety of pulmonary infectious diseases. However to study this population ex vivo in high purity manner, are necessary expensive and/or trick techniques and several animals to achieve a reasonable number of cells. Recently, Kitani and colleagues (2010) adapted a very classic and broad accepted protocol - used to isolate macrophages from brain (microglia) - to isolate liver macrophages (Kupffer cells). Surprisingly, this protocol presented similar efficacy compared to the former one. Following this rational we thought if it would work on lungs to isolate the resident macrophages.
To address that, lungs from BALB/c mice were excised and homogenized. The suspension was centrifuged at 450g for 10 minutes and pellet was resuspended with culture medium and plated on culture flask mantained at 37°C, 5% of CO2 in a humidified incubator. The medium was replace every 3 days and the day 12-14 were selected as the best time frame to recover macrophages. These macrophages grow above the concomitant formed fibroblast cell sheet and are easily detachable, through 30 minutes of orbital shaking at 120 RPM. Cell morphology observed by microscope reveals similarities with Kitani's results and flow cytometry analysis showed that more than 98,5 % was positive to macrophage markers. Further assays will verify the phagocyte ability of these cells and the mediators released by potent stimuli incubation.
We showed that mixed primary culture technique isolate alveolar macrophages efficiently, comparable to microglia and Kupffer cells isolation procedure.

P1.06.58
Mac-1 controls the pro-inflammatory phenotype of type 1 macrophages

***K. C. M. Santegoets**[1,2], M. H. Wenink[1,2], D. M. Lundvig[3], L. van Bon[1,2], A. Cambi[4], R. A. Benson[5], I. McInnes[5], W. B. van den Berg[2], F. A. Wagener[3], T. R. D. J. Radstake[1,2];*
[1]Department of Rheumatology and Clinical Immunology & Laboratory of Translational Immunology, University Medical Center Utrecht, Utrecht, Netherlands, [2]Department of Rheumatology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [3]Department of Orthodontics and Craniofacial Biology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [4]Department of Tumor Immunology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [5]Division of Immunology, Infection and Inflammation, University of Glasgow, Glasgow, United Kingdom.

Macrophages perform dichotomous tasks; they are mediators of inflammation yet are capable of suppressing immune responses and mediate tissue homeostasis. The mechanisms by which macrophages shift their phenotype is unknown. We hypothesized that accumulation of macrophages during inflammation induces a shift from a pro-inflammatory to an anti-inflammatory phenotype, aimed at dampening the immune response. Pro-inflammatory type-1 (mϕ-1) but not anti-inflammatory type-2 macrophages were highly sensitive to homotypic cell-cell contact. Increased cell-cell contact led to mϕ-1 producing lower levels of TNF, IL-1 and IL-6, while the IL-10 production was increased upon stimulation with TLR ligands or *M. tuberculosis*. To confirm this association *in vivo* a wound healing model was performed in mice. At day 4 and 6 of wound healing an increased amount of $F480^+$ macrophages was found compared to day 2. Fitting with our *in vitro* data, macrophages isolated from the wound at day 4 and 6 produced less TNF, IL-1 and IL-6 after TLR stimulation, compared to day 2. Further *in vitro* data showed that this cytokine shift depended on Mac-1 mediated cell-cell contact, signaling via p38 and the activation of COX2. Low IL-10 and high TNFα levels in high density cells were associated with an up regulation of SOCS3. Concluding, Mac-1 activation during macrophage differentiation serves as a natural inhibitory mechanism designed to dampen chronic inflammation. This places signaling via Mac-1 at a center stage in the regulation of macrophage behavior in a wide range of diseases including autoimmune diseases as well as cancer, elucidating novel therapeutic avenues.

P1.06.59
The immunomodulatory effect of propolis and chlorhexidine on cytokine production by human monocytes

***K. B. Santiago**, B. J. Conti, E. O. Cardoso, J. M. Sforcin;*
UNESP, Botucatu, Brazil.

Propolis (P) is a resinous product made by bees from several parts of plants, showing plenty of biological and pharmacological properties, with a great importance in food and in the pharmaceutical industry. Periodontal disease may occur due to an imbalance in the oral microbiota, whose agents can be transmitted. Chlorhexidine (CHX) is an oral hygiene product typically prescribed to periodontal disease patients, but its use is controversial due to side effects. This work aimed to investigate propolis, chlorhexidine and the association P/CHX on pro- and anti-inflammatory cytokine production (TNF-α and IL-10) respectively. Human monocytes were obtained from healthy donors (n=10) and incubated with propolis (0.2, 1.0), chlorhexidine (1.2, 6.0) and P/CHX (0.2/1.2, 1.0/6.0 µg/mL) or control cells for 18h. Cell viability was assessed by the MTT assay, and cytokine

production was determined by ELISA. Significant differences were determined by analysis of variance (ANOVA), followed by Dunnett's test ($p<0.05$). Treatment with P, CHX and P/CHX had no effect in monocytes viability. CHX has stimulated TNF-α production in both concentrations; on the other hand, the association P/CHX increased significantly IL-10 production. One may conclude that this association showed anti-inflammatory effects, what indicates its use in the the treatment of periodontal diseases, with no side effects.

P1.06.60
Polyporus alveolaris extract (PAE) have the ability to stimulate macrophages against tumor with unique manner

Y. Sasajima[1]*, M. Kawamura*[1]*, T. Aradate*[2]*, A. Muraguchi*[3]*, T. Katagiri*[1]*;*
[1]Dept. Biology (Faculty of Pharmaceutical Sciences) University of Toyama, Toyama city, Japan, [2]Dept. Biology (Faculty of Medical Sciences) University of Toyama, Toyama city, Japan, [3]Dept. Immunology (Faculty of Medical Sciences) University of Toyama, Toyama city, Japan.

To find the new anti-tumor reagents from natural solutions, we examined a series of plant extracts and mushroom extracts to activate the macrophage induced anti-tumor activities without over production of inflammatory monokines. We used RAW264.7 cells as effector cells (murine macrophage cell line), and we also used EL-4 or P815 (murine tumor cell line) as target cells. More than thousands of screening, finally, we found PAE from Hachinosutake (*Polyporus alveolaris*; this is a kind of the mushroom) by heated water extraction which has much possibility. The growth suppression activity against tumor cell by PAE stimulated RAW264.7 was the level that was about almost same as the LPS which was the classical well known as macrophage activator. Interestingly, anti-tumor activity of RAW264.7 by LPS stimulation used for a control disappeared under Polymyxin B coexistence, whereas the effect of PAE was not almost affected by Polymyxin B. Besides, we measured TNF-α production, nitric oxide and phosphorylation patterns of the signal in the cell. As the result, PAE stimulated RAW264.7 produced TNF-α and nitric oxide dose dependently without receiving most of the influence of Polymyxin B. We also analyzed the signal in the cell to study their production mechanism and confirmed phosphorylation of ERK, JNK and P38. As the result, all MAP kinase was phosphorylated in chronological order unlike the LPS by PAE. We are now focused on a difference of PAE receptor and TLRs on macrophage activation.

P1.06.61
Realtime analysis of monocyte migration in 3D synovial micromass tissue cultures

C. Scheinecker*, R. Byrne, K. von Dalwigk, A. Hladik, J. S. Smolen, H. Kiener;*
Medical University of Vienna, Wien, Austria.

In the synovial tissue of arthritic joints, monocyte (Mo) migration appears to be in close contact to fibroblast-like synovial cells (FLS).
Here we analyzed Mo migration under inflammatory conditions in regard to cell-cell interactions with FLS.
Human FLS were prepared from synovial tissues following joint arthroplasty. CD14+ Mo were isolated from peripheral blood. Cells were labeled with fluorescent membrane dyes and cultured in spherical extra- cellular matrix micromasses. For stimulation 10 ng/ml of tumor necrosis factor (TNF) was added. Cell migration was monitored by real-time confocal microscopy and subdivided into three phases of cell movement. Phase I (day 1-3) was characterized by the formation of the synovial lining layer. Mo in close contact with FLS appeared sessile. On average 20% of Mo displayed a mobile and seeking behavior. During phase II (day 3-7) already >95% of Mo were in contact with FLS. The majority of Mo remained sessile whereas a fraction of Mo moved with an impressive maximum speed of up to 15 mcm/min. In addition the formation of Mo cell clusters was observed. Rapid Mo migration ceased during phase III (day 7-14). TNF i) increased the frequency and size of Mo cell clusters during phase II two and ii) prolonged the mobility of Mo into phase III. This 3D synovial tissue culture system allows to monitor and analyzed subtle migration patterns of Mo in relation to the FLS lining. Ongoing experiments address molecular mechanism(s) of Mo – FLS interaction and will try to identify potential therapeutic targets

P1.06.62
The sulfation level of glycosaminoglycans in monocytes and macrophages

M. Schönberg*, U. Obeck, J. Flemmig, J. Arnhold;*
University of Leipzig, Leipzig, Germany.

Sulfation of glycosaminoglycans of components of extracellular matrix and cell surface is an important regulatory mechanism in inflammatory immune response. All sulfotransferases use 3´-phosphoadenosine 5´-phosphosulfate (PAPS) as a common sulfate donor that is produced by PAPS synthase.
In order to detect the sulfation level of monocytes/macrophages we established a CD44-hyaluronan binding assay. Monocytes were isolated from human peripheral blood of healthy volunteers. Macrophages were cultivated from monocytes at 37 °C in the presence of 100 U/ml granulocytes/macrophages - colony stimulating factor. CD44 is a cell-surface receptor that binds via heparan sulfate side chains hyaluronan, a glycosaminoglycan that is released from immune cells at inflammatory sites. Using flow cytometry approaches, the expression of CD44 was followed by antibodies against CD44, while the ability of CD44 to bind hyaluronan was assessed with FITC-labelled hyaluronan.
The additional use of a Blyscan™ dye binding assay was used to detect the sulfation level of glycosaminoglycans on the whole cell surface. To reduce stimulation of the cells by adherence, teflon-coated cell culture dishes were used. In order to simulate pro-inflammatory conditions monocytes were stimulated with TNFα.
TNFα increased the expression of CD44 on cells similar to macrophages, but shows no significant alterations of CD44 expression in monocytes. TNFα has no significant influence concerning hyaluronan binding on monocytes. The inhibitor of sulfation reactions chlorate diminished the binding of hyaluronan in a concentration-dependent manner in both TNFα- stimulated and non-stimulated cells.
This assay is a convenient tool to investigate effect on sulfation after the treatment with anti-inflammatory agents.

P1.06.63
IRF8 and IRF3 cooperatively regulate rapid interferon-β induction in human blood monocytes

P. Li[1]*, J. Wong*[1]*, C. Sum*[1]*,* ***W. Sin***[1,2]*, K. Chin*[1,3]*;*
[1]Singapore Immunology Network; Agency for Science, Technology and Research, Singapore, Singapore, [2]School of Biological Sciences; Nanyang Technological University, Singapore, Singapore, [3]Department of Physiology; National University of Singapore, Singapore, Singapore.

Type I IFN production differs in magnitude and kinetics between different cell types. Robust and rapid induction of interferon-β (IFN-β) after pathogenic stimulation is a key property that is exclusive to human blood monocytes. This disparity raised the possibility that distinct myeloid-specific transcription factor(s) may be involved in the rapid induction of IFN-β in monocytes compared with non-myeloid cell types. We found that IFN-β was produced rapidly in primary human monocytes as a result of cooperation between the myeloid-specific transcription factor IRF8 and the ubiquitous transcription factor IRF3. We provide evidence that IRF8 constitutively binds to the IFN-β promoter region, and knockdown of IRF8 in monocytes abrogated IFN-β transcription. We uncovered a requirement for IRF3, a master regulator of IFN-β production, as a previously unidentified interaction partner of IRF8. We produced a range of deletion constructs of IRF3 and IRF8 mutants, and, using co-transfection and co-immunoprecipitation, mapped the protein-protein interacting regions of IRF3 and IRF8, and found that their interaction was independent of the DNA-binding domain (DBD) and the IRF association domain (IAD) of IRF8 and IRF3, respectively. Through these and other experiments, we have been able to demonstrate that IRF8 directly synergizes with IRF3 in monocytes to facilitate faster IFN-β transcription after pathogenic stimulation.

P1.06.64
Resolving inflammation: M2 macrophages contribute to the resolution of postoperative ileus

***K. Stein**, M. Lysson, S. Wehner, J. Kalff;*
University of Bonn, Bonn, Germany.

Background: Postoperative ileus (POI) is a common complication after abdominal surgery which is mediated by a severe inflammation of the intestinal muscularis externa (ME). Monocytes, infiltrating already 3h after surgery and present up to 7 days within the ME have been shown to be the dominant immunocyte population. This long persistence indicates a contribution in the resolution of POI. Here, we characterized the infiltrating monocytes and analysed their properties in resolving POI.
Material & Methods: POI was induced by intestinal manipulation of the small bowel in mice. Expression of typical M2 macrophage markers Arginase-1, IL-10, mannose receptor 1, and Ym1 was investigated by quantitative PCR and arginase assay in ME tissue. Cytokine and surface receptor expression was analysed by flow cytometry. Additionally, FACS-separated resident and infiltrating macrophages were also characterized by gene expression analysis.
Results: Expression and secretion of Arginase 1 was significantly increased in ME tissues with a peak at 24 hours after intestinal manipulation (750-fold upregulation). $F4/80^{+}$ $Ly6C^{+}$ macrophages were identified as the main incoming cell population (70% of immunocytes) with high expression of M2 macrophage marker Arginase-1 as well as anti-inflammatory cytokine IL-10. Further classification of the alternative activated macrophages revealed a myeloid derived suppressor cell (MDSC) phenotype demonstrated by $CD11b^{high}$ $GR1^{low}$ surface expression by flow cytometric analysis.
Conclusions: $F4/80^{+}$ $CD11b^{high}$ $GR1^{low}$ macrophages are the dominant infiltrating immunocyte population in POI, showing a MDSC phenotype. Our data indicate that these cells can facilitate active resolution of POI by providing an anti-inflammatory milieu within the postoperative ME.

P1.06.65
CX3CR1+ monocytes support P. gingivalis survival

***O. Steinmetz**, S. Hoch, L. Eli-Berchoier, G. Nussbaum;*
Hebrew University-Hadassah Faculty, Jerusalem, Israel.

Two major subsets of monocytes play an important role in the innate immune response. Murine LY6C-high monocytes, termed inflammatory monocytes, are rapidly recruited to sites of infection, whereas Ly6C-negative, CX3CR1-high monocytes, termed patrolling monocytes, contribute to tissue homeostasis. *Porphyromonas gingivalis* is a gram-negative anaerobic bacterium known to be a major pathogen in periodontal disease. By manipulating the innate immune response**,** *P.gingivails* persists within a highly inflamed environment that leads to dysbiosis and eventually soft tissue and bone destruction. Surprisingly, we found that monocyte depletion using clodronate liposomes resulted in improved clearance of *P. gingivalis* following subcutaneous infection. In contrast, bacterial survival in CCR2-/- mice (characterized by defective recruitment of Ly6C-high monocytes) was enhanced, suggesting that Ly6C-high monocytes are required to clear *P. gingivalis*. Bacterial clearance was improved in CX3CR1-/- mice consistent with the effect of monocyte depletion using clodronate liposomes, suggesting that *P. gingivalis* persistence in the host depends on this monocyte subpopulation. We further demonstrated that monocyte TLR2 expression is linked to bacterial survival. Collectively, our results imply that while LY6C-high monocytes provide protection against P. gingivalis, CX3CR1-high monocytes, in a TLR2 dependent manner, support bacterial survival and ability to cause tissue destruction.

P1.06.66
Identification of RORC as regulator of polarized inflammation

***L. Strauss**[1], G. Szebeni[1], S. Morlacchi[1], M. G. Totaro[1], A. Bruno[2], D. Noonan[2], A. Anselmo[1], S. Sangaletti[3], M. Colombo[4], A. Sica[1];*
[1]Istituto Clinico Humanitas, Rozzano (MI), Italy, [2]University of Insubria, Varese (VA), Italy, [3]Fondazione Istituti di Ricovero e Cura a Carattere Scientifico Istituto Nazionale Tumori, Milano (MI), Italy, [4]Fondazione Istituti di Ricovero e Cura a Carattere Scientifico Istituto Nazionale Tumori, Rozzano (MI), Italy.

The signaling pathways that cause innate immune cells to dampen adaptive immunity and to promote tumor development remain incompletely understood. We have identified a new subset of retinoid-related orphan receptor gamma (ROR gamma) expressing myeloid cells that arise exclusively from processes of chronic inflammation. Our data indicate that ROR gamma is a negative regulator of M1 inflammation in vitro and in vivo. In particular, we observed that ROR gamma down-modulates expression of pro-inflammatory cytokines and cytotoxic functions of myeloid cells in response to TLR-agonists. Further, we observed that tumor growth (fibrosarcoma) in ROR gamma deficient mice is significantly inhibited. ROR gamma is known as a circadian regulator of glucose/lipid metabolism and insulin resistance and is a key transcription factor of Th17 cell development. Our findings link transcriptional regulators of energy metabolism to polarization of innate immunity, providing new approaches to target, cure and prevent chronic inflammatory diseases, including cancer, related to the metabolic disease cluster.

P1.06.67
Role of macrophages reaction in pathogenesis of duodenal ulcer bleeding

***O. N. Sulaieva**;*
M. Gorky Donetsk National Medical Unicersity, Donetsk, Ukraine.

Macrophages are considered as key regulator of inflammation and reparation which are tightly associated with hemostasis state. In this work we analyzed the role and mechanisms of macrophage dysfunction in patients with primary and recurrent duodenal ulcer bleeding.
Materials and methods. The morphological observation of marginal ulcer zone of 64 patients with sustained hemostasis (1^{st} group) and 28 patients with recurrent bleeding (2^{nd} group) was performed. The number and distribution of CD68 positive cells were assessed in different regions of duodenal mucosa, including villi, transitional and pericryptal zones. Additionally to this iNOS activity in peripheral blood monocytes was measured under basal conditions and after incubation with lipopolysaccharide (LPS), 5-hydroxytryptamine (5-HT) and epinephrine in NBT test.
Results. The high density of macrophages was observed in villi rather than pericryptal region of duodenal mucosa biopsy in 1^{st} group. Increased recruitment of macrophages in duodenal mucosa in transitional and perycryptal space in 2^{nd} group was associated with rising of basal activity of iNOS while monocytes response on LPS was restricted. Recurrent ulcer bleeding was associated with increase of macrophages number ($P = 0.012$). Moreover their accumulation around bottoms of crypts in biopsy of 2^{nd} group patients correlated with monocytes iNOS activity under basal conditions ($P = 0,001$), and after incubation with epinephrine ($P = 0.001$) or thrombine ($P = 0.02$), but not with 5-HT. Conclusion. Proinflammatory activation of monocytes and increase of macrophages recruitment into duodenal mucosa were associated with changes of sensitivity to humoral and coagulation factors.

P1.06.68
Effect of phytoestrogens on helper T cell and macrophage differentiation

***M. Takamoto**;*
Shinshu University Graduate School of Medicine, Matsumoto, Japan.

We previously reported that bisphenol A promoted Th2 differentiation (**Int Arch Allergy Immunol.** 132:240-247, 2003) and that prenatal BPA exposure is further effective compared to the exposure in

adulthood (**Environ Health Perspect** 116:514-9. 2008). In this paper, Th cell differentiation and M1 and M2 markers of macrophages from C57BL6 mice given soy bean-free (SF) or normal (N) chows for several generations were investigated. Splenocytes from SF mice produced less IFN-γ than those of N mice. Percentages of Th1 cells decreased in SF mice. In addition, BPA treatment before immunization suppressed differentiation of Th1 cells and IFN- γ production. These results indicate that component(s) of soy beans inhibit Th1 differentiation. BPA influences additively on the inhibitory effects of the soy bean component(s). Direct effects of bisphenol A or soy bean component(s) must not be responsible for the differentiation of Th2, macrophages differentiation was investigated. Peritoneal macrophages from SF mice expressed less M2 markers such as CD204 and CD206 than those of N mice. TLR4 expression was comparable in both SF and N. These results indicate that component(s) of soy beans might induce M2 differentiation.

P1.06.69
Immune-modifying particles inhibit inflammatory monocyte migration to the central nervous system and improve outcomes in experimental autoimmune encephalomyelitis

R. L. Terry[1,2], *D. R. Getts*[1,2], *N. J. C. King*[2], *S. D. Miller*[1];
[1]*Northwestern University, Chicago, IL, United States,* [2]*The University of Sydney, Sydney, Australia.*

Inflammatory monocytes play a significant role in the pathogenesis of most autoimmune diseases. Although the specificity of the immune response against self antigens is dictated and driven by T and/or B cells, the multifarious but non-specific factors secreted by monocyte-derived cells contributes significantly to the destruction of host tissue. Experimental autoimmune encephalomyelitis, the murine model of multiple sclerosis, is characterized by significant infiltration of inflammatory monocytes into the central nervous system (CNS). Here, they give rise to macrophage and dendritic cell populations that produce numerous factors including proinflammatory cytokines, reactive oxygen species and proteinases that contribute to neuronal damage and death. Furthermore, these cells process and present self-antigens to T cells, which further potentiates the inflammatory response by promoting epitope spreading. Thus, inflammatory monocytes have been identified as key targets for immunomodulatory therapies. However, there are few treatments available that specifically target these cells during disease. Here, we show that intravenous infusion of a novel therapeutic agent, highly negatively-charged “Immune-modifying particles” (IMP), from the onset of disease, significantly reduced inflammatory monocyte migration into the CNS by 70%, which was associated with significantly improved clinical outcomes. Furthermore, treatment of animals with IMP during remission prevented subsequent relapse. The anti-inflammatory effects of IMP resulted in the prevention of monocyte trafficking to the CNS and retention of these cells in the spleen, where they undergo apoptosis. Future studies will investigate the cytokines/chemokines involved in the redirection and retention of inflammatory monocytes in the spleen and their differentiation into M1 vs M2 effector cells.

P1.06.70
E.coli upregulates CD39 expression in RAW264.7 macrophages

G. Törő[1], *B. Koscsó*[2], *B. Csóka*[2], *L. Virág*[1], *G. Haskó*[1];
[1]*Department of Medical Chemistry, University of Debrecen Medical and Health Science Centre, Debrecen, Hungary,* [2]*Department of Surgery, UMDNJ-New Jersey Medical School, Newark, NJ, United States.*

Adenosine is a purine nucleoside signaling molecule that elicits its physiological responses by binding to and activating 4 G protein-coupled transmembrane adenosine receptors. Extracellular adenosine accumulates following the release of ATP and ADP, which are metabolized to adenosine by a cascade of ectoenzymes on the cell surface. In the first step the extracellular hydrolysis of ATP and ADP to adenosine monophosphate (AMP) is catalyzed by the ectonucleoside triphosphate diphosphohydrolase 1 (E-NTPDase1, CD39). AMP then metabolized to adenosine by 5’- ectonucleotidase (Ecto5’Ntase, CD73). Macrophages are pivotal in detecting bacteria and in initiating the host’s immune/inflammatory response. The regulation of CD39 in macrophages exposed to bacteria is poorly understood. To study this regulation we stimulated RAW264.7 murine macrophages with heat inactivated *E. coli* and specific Toll-like and NOD-like receptor agonists. *E. coli* increased CD39 mRNA and cell surface protein expression level. The selective TLR2 agonists Pam3CSK4 and FSL-1, TLR3 agonist poly(I:C), TLR4 agonist LPS, TLR5 agonist flagellin and TLR9 agonist ODN1826, but not the TLR7 agonist ssRNA40 or NOD agonists mimicked the effect of *E. coli* in upregulating CD39 expression. *E. coli* increased luciferase activity when the cells were transfected with a CD39 promoter luciferase construct. Thus, bacteria and their products can upregulate CD39 expression.

P1.06.71
Pulmonary GM-CSF regulates alveolar macrophage population size and function via a reciprocal feedback mechanism

B. C. Trapnell*, T. Suzuki;*
Cincinnati Children's Hospital, Cincinnati, OH, United States.

Pulmonary alveolar macrophages are critical to surfactant homeostasis and lung host defense. While multiple cytokines affect survival, proliferation, and functions, the mechanism(s) maintaining population size and functions of resident alveolar macrophages are poorly understood. Disruption of GM-CSF signaling by CSF2RA or CSF2RB mutations impairs alveolar macrophage functions including surfactant clearance and causes hereditary pulmonary alveolar proteinosis (hPAP) a lung disorder of surfactant accumulation. We evaluated Csf2rbKO mice as an experimental model of hPAP in humans and then conducted preclinical safety and efficacy studies evaluating intrapulmonary administration of functional macrophages (pulmonary macrophage transplantation or PMT) in mice. The key features of hPAP in children with recessive CSF2RA or CSF2RB mutations were faithfully reproduced in Csf2rbKO mice. PMT was well-tolerated and effectively resolved hPAP after only one administration. PMT synchronously normalized the increased GM-CSF observed and expanded the number of functional alveolar macrophages to levels similar to those of normal mice. PMT using Csf2rbKO-derived, lentiviral vector Csf2rb-corrected macrophages was equally effective as PMT with normal macrophages., M-CSF expression by alveolar macrophages was increased in Csf2rbKO mice and promoted their survival but not normal functions and was repressed by restoration of GM-CSF signaling. Results demonstrate that PMT is well-tolerated, efficacious and durable as therapy of hPAP in Csf2rbKO mice, and identified a novel, reciprocal feedback mechanism by which pulmonary GM-CSF regulates alveolar macrophage accumulation and functions. These results have therapeutic implications for hPAP and provide a novel experimental approach for studying macrophages in vivo.

P1.06.72
Effect of CCL1 depletion on the tumoricidal monocyte generation in cultures of peripheral blood monocytes derived from patients with hepatocellular carcinoma (HCC)

A. Asai[1], ***Y. Tsuchimoto***[1], *H. Ohama*[1], *S. Fukunishi*[1], *Y. Tsuda*[1], *A. Fukuda*[1], *M. Kobayashi*[2], *K. Higuchi*[1], *F. Suzuki*[2];
[1]*Osaka Medical College, Takatsuki, Osaka, Japan,* [2]*The University of Texas Medical Branch, Galveston, TX, United States.*

A majority of peripheral blood monocytes in advanced HCC patients has been classified as M2b monocytes, which are inhibitory on host antitumor immunities. In this study, we tried to convert macrophages (monocytes) from M2b macrophages (HCC patient monocytes) to M1 macrophages (tumoricidal macrophages) on the basis of CCL1 knockdown. CCL1 released from M2b macrophages has been characterized as an essential chemokine for the maintenance of their M2b macrophage properties. $CD14^+$ monocytes with M2b macrophage properties were isolated from peripheral blood of advanced HCC patients by Ficoll-Hypaque sedimentation and magnetic beads. $CD14^+$ monocytes (1×10^6 cells/ml) were treated with 6 μg/ml of CCL1 antisense oligodeoxynucleotides (ODN) for 48 hrs. These cells were, then, stimulated with CpG DNA (10 μg/ml, 24 hrs) for the M1 macrophage induction. Cells harvested were assayed

for their (1) tumoricidal activities against cultured HCC cells and (2) IL-12-producing capabilities by flow cytometry and immunochemical staining. In the results performed under the CpG DNA stimulation, advanced HCC patient peripheral blood monocytes were shown to be IL-12$^-$IL-10$^+$ monocytes without any tumoricidal activities. However, IL-12$^+$IL-10$^-$ monocytes were induced by CpG DNA in cultures of advanced HCC patient peripheral blood monocytes previously treated with CCL1 antisense ODN. Also, these IL-12$^+$IL-10$^-$ monocytes induced by CpG DNA from advanced HCC patient monocytes killed HCC cells that were syngeneic to the monocytes. These results indicate that, in advanced patients, macrophage-mediated host's antitumor immunities are controllable, in part, through the depletion of CCL1, an essential chemokine for the prolongation of M2b macrophages.

P1.06.73
Regulation of complement receptor immunoglobulin (CRIg) expression in human macrophages by protein kinase Cα

K. Usuwanthim[1], *Y. Ma*[1], *N. N. Gorgani*[1,2], *C. Hii*[1], *A. Ferrante*[1,3,4];
[1]*Department of Immunology, SA Pathology, Women□s and Children□s Hospital, Adelaide, Australia,* [2]*Westmead Millennium Institute, Sydney, Australia,* [3]*Disciplines of Paediatrics and Microbiology and Immunology, University of Adelaide, Adelaide, Australia,* [4]*School of Pharmaceutical and Medical Sciences, University of South Australia, Adelaide, Australia.*

Members of complement, Toll-like and scavenger receptors as well as C-type lectins are amongst the groups of genes that initially recognize opsonized-pathogen or pathogen-associated molecular patterns. Recently a new gene (VSIG4) has been added to this list and its product termed complement receptor Ig (CRIg) represents a novel complement receptor with properties distinct from those of classically known complement receptors. CRIg also inhibits the adaptive immune response; suppressing lymphocyte responses. We have been studying the mechanisms by which CRIg expression is regulated in inflammation. Results show that PKC activation depresses CRIg expression and PKC inhibition increase expression in human macrophages. We have now used PKCα specific shRNA to examine the role of this PKC isozyme in CRIg expression in human monocyte derived macrophages (MDM). The macrophages were nucleofected with plasmid containing shRNA for PKCα. The lack of PKCα in the cells was demonstrated by western blot. The specificity of the knock down was demonstrated by a normal expression of PKCζ in these cells and visa versa. PKCα-deficient MDM showed markedly increased CRIg mRNA and protein expression but decreased CR3 expression. This was associated with an increase in phagocytosis of complement-opsonised particles. The findings are conducive with arachidonic acid causing a decrease and dexamethasone an increase in CRIg expression/phagocytosis, in relation to stimulation and inhibition of PKC activation. The data showed that PKCα-deficient MDMs have significantly decreased TNF and IL-6 production. The findings suggest that PKCα promotes inflammation by decreasing CRIg expression but increasing CR3 expression and production of pyrogenic cytokines.

P1.06.74
Modulation of phagocytosis in Mononuclear Phagocyte Cells by IL-21: Involvement of Spleen Tyrosine Kinase (Syk)

F. Vallières*, D. Girard;*
INRS-Institut Armand-Frappier, Laval, QC, Canada.

The biological significance of the IL-21/IL-21R system in human monocytes/macrophages is not well documented, and the expression of IL-21R is unclear and has been disputed. In this study, we showed that human monocyte-like THP-1 cells, GM-CSF monocyte-derived macrophage and M-CSF monocyte-derived macrophage expressed the two IL-21R components, CD132 (γc) and IL-21Rα, on their cell surface, as assessed by flow cytometry. Moreover, IL-21 was found to enhance FcR-mediated phagocytosis in all these cells. The ability of IL-21 to enhance FcR mediated phagocytosis was not associated with an increased expression of both IL-21R components at the cell surface, and IL-21 did not act in synergy with IL-15. IL-21 activated spleen tyrosine kinase (Syk), as evidenced by its ability to increase Syk phosphorylation. Using a pharmacological approach to inhibit Syk activity, and an antisense technique to downregulate Syk protein expression, we demonstrated the importance of Syk in IL-21-induced phagocytosis. We conclude that IL-21 possesses important biological effects in mononuclear phagocyte cells and that Syk is a novel molecular target of IL-21 that was previously unknown. Therefore, future development of therapeutic strategies targeting the IL-21/IL-21R system should consider that monocyte and macrophage cell physiology may be affected by this system.

P1.06.75
Characterization of central macrophages in Anemia of Inflammation (AI): African trypanosomiasis as a model system

L. Vansintjan[1,2], *B. Stijlemans*[1,2], *S. Philipsen*[3], *P. J. M. Leenen*[4], *P. De Baetselier*[1,2];
[1]*Laboratory of Cellular and Molecular Immunology, Vrije Universiteit Brussels, Brussels, Belgium,* [2]*Laboratory of Myeloid Cell Immunology, VIB, Brussels, Belgium,* [3]*Department of Cell Biology, Hematopoiesis research group, Erasmus MC, Rotterdam, Netherlands,* [4]*Department of Immunology, Erasmus MC, Rotterdam, Netherlands.*

Background: Anemia of Inflammation (AI), or Anemia of Chronic Disease (ACD), is the most prominent form of anemia in hospitalized patients, affecting quality of life and resulting from an imbalance between erythrophagocytosis and erythropoiesis. Multiple mechanisms contribute to its pathogenesis, including iron restriction, direct erythropoietic suppression and shortened erythrocyte survival. A common parameter in AI is a persistent pro-inflammatory immune response of the host, whereby macrophages and their activation state play a key role. In the regulation of erythropoiesis, the enigmatic central macrophages are thought to be essential as part of erythroblastic islands.
Results: By scrutinizing African trypanosomiasis in mice as a model of infectious disease associated with AI, we could discriminate within the F4/80+ER-HR3+ macrophage population 4 distinct subsets (CD11b-/lowLy6C-/low, CD11b-/lowLy6C+, CD11b+Ly6C+Fo-SGL+ and CD11b+Ly6C-/low). Using an in vitro erythropoiesis assay we could establish that CD11b+Ly6C+Fo-SGL+ cells represent the best candidates to function as central macrophages, since these cells are able to aid in the maturation of erythroblasts. Furthermore, they express crucial adhesion molecules (VCAM-1, CD49d, CD169 and CD36) favoring erythroblastic island formation. Moreover, the gene expression levels of crucial iron-homeostasis-associated genes such as CD71, hmox-1, fpn-1 and fhc suggest that this population rather exports iron during infection in contrast to other myeloid cells. Interestingly, by comparing Trypanosome-infected wild-type and mice exhibiting different degrees of anemia, we observed that there was an inverse correlation between the CD11b+Ly6C+Fo-SGL+ population size and anemia development. Therefore, this population requires further investigation to unravel its exact role in AI development.

P1.06.76
The immunomodulatory activity of glycerophosphoinositols

M. Vessichelli[1], *P. Italiani*[2], *S. Mariggiò*[1], *P. Zizza*[1], *V. Evangelista*[3], *D. Boraschi*[2], *D. Corda*[1];
[1]*Institute of protein biochemistry (IBP), CNR, napoli, Italy,* [2]*istituto di teconologie biomediche (ITB), CNR, Pisa, Italy,* [3]*Consorzio Mario Negri Sud, Santa Maria Imbaro, Chieti, Italy.*

Glycerophosphoinositols are multifunctional and widespread phosphoinositide metabolites produced by phospholipase A_2IVα (PLA_2IVα). We proved that immune cells strictly regulate PLA_2IVα, providing a fine modulation of intracellular glycerophosphoinositols in response to pro-inflammatory agents such as lipopolysaccharide. The immunomodulatory activity of glycerophosphoinositols has been evaluated in an *in vitro* model of innate immunity/inflammation on human primary cells. Peripheral blood monocytes have been sequentially exposed in culture to CCL-2, LPS, TNF-α, IFN-γ, IL-10 and TGF-β in a period of 48 h, to mimic the microenvironmental changes characterizing the onset, the development and the eventual resolution of inflammation. Upon exposure to LPS, TNF-α and IFN-γ monocytes become activated in inflammatory direction, release pro-inflammatory cytokines and undergo pyroptosis.

Glycerophosphoinositol (GroPIns), added exogenously, attenuated the inflammatory phenotype preserving cellular viability, decreased both expression and release of the pro-inflammatory cytokines IL-1β, IL-6 and TNF-α, and reduced the expression of cyclooxygenase 2 and $PLA_2IV\alpha$, both involved in the biosynthesis of eicosanoids. GroPIns mainly affected the onset of inflammation, corroborating its role in counteracting the pro-inflammatory signalling from LPS. Conversely, GroPIns increased the expression of two inhibitors of IL-1, the IL-1 receptor antagonist (IL-1Ra) and IL-1 receptor II (IL-1RII). The genes modulated by GroPIns are common transcription target of NFκB. Indeed, GroPIns, decreased the LPS-induced NFκB binding to κB-promoter and modulated the expression of the IκB-α gene, the canonical transcription target of NFκB. These data support the hypothesis of an anti-inflammatory function of GroPIns which is probably due to a modulation of NFκB transcriptional function.

Salmonella autophagy

T. Wang[1], *C. Chiu*[1,2];
[1]*Graduate Institute of Biomedical Sciences, Chang Gung University College of Medicine, Taoyuan, Taiwan,* [2]*Molecular Infectious Diseases Research Center, Chang Gung Memorial Hospital, Taiwan, Taoyuan, Taiwan.*

happy ~Salmonella Typhi caused Typhoid fever, a systemic inflammatory response syndrome (SIRS) in humans but S. Typhimurium causes only gastroenteritis. When infecting humans, S. Typhi uses Vi capsule to evade host immune system and survive in macrophages to circulate in bloodstream. After proliferating in bone marrow, liver, and spleen, S. Typhi reenters into bloodstream, causing SIRS, and intestine, causing hemorrhage and perforation. S. Macrophages are the important reservoir for S. Typhi during the infection. The interaction of macrophages with S. Typhi and S. Typhmurium was studied. S. Typhi, rather than S. Typhimurium, induced less inflammation when infecting epithelial cells by virtue of Vi. But when infecting THP-1 macrophages in MOI=100, we found that within an hour S. Typhi with or without Vi caused more cell death than S. Typhimurium. It was confirned to be caspase-1-mediated pyroptosis. The IL-1β secretion induced by S. Typhi was also significantly higher than S. Typhimurium. We constructed a mutant library of S. Typhi to search early cell death related genes. We found that SPI-1 mutants induced less cell death as well as caspase-1 activation than the parent s

P1.06.78
Regulation of myogenesis by differentially activated macrophages during human skeletal muscle regeneration

H. Yacoub-Youssef[1,2], *M. Saclier*[1], *A. Mackey*[3], *L. Arnold*[4], *J. Chelly*[1], *R. Mounier*[1], *M. Kjaer*[3], *B. Chazaud*[1];
[1]*Institut Cochin, Paris, France,* [2]*Institut Pasteur, Tunis, Tunisia,* [3]*Centre for Healthy Ageing, Copenhagen, Denmark,* [4]*INSERM, U945, Paris, France.*

Macrophages exert either beneficial or deleterious effects on tissue repair, depending on their activation/polarization state. They are crucial for adult skeletal muscle repair, notably by acting on myogenic precursor cells. However, these interactions have not been fully characterized. Here, we explored both in vitro and in vivo, in human, the interactions of differentially activated MPs with muscle precursor cells (MPCs) during adult myogenesis and skeletal muscle regeneration. We showed in vitro that through the differential secretion of cytokines and growth factors, proinflammatory macrophages inhibited MPC fusion while anti-inflammatory macrophages strongly promoted MPC differentiation by increasing their commitment into differentiated myocytes and the formation of mature myotubes. Furthermore, the in vivo time course of expression of myogenic and macrophage markers was studied in regenerating human healthy muscle after damage. We observed that regenerating areas containing proliferating MPCs were preferentially associated with macrophages expressing pro-inflammatory markers. In the same muscle, regenerating areas containing differentiating myogenin positive MPCs were preferentially coupled to macrophages harbouring anti-inflammatory markers. These data demonstrate for the first time in human that macrophages sequentially orchestrate adult myogenesis during regeneration of damaged skeletal muscle. These results support the emerging concept that inflammation, through macrophage activation, controls stem cell fate and coordinates tissue repair.

P1.06.79
The role of a novel DEAD-box protein in LPS-induced NLRP3 inflammasome activation

C. Yang, *S. Hsu, Y. Lai, L. Hsu;*
Institute of Molecular Medicine, National Taiwan University, Taipei, Taiwan.

Innate immune response is the first host response when host encounters pathogens or senses danger signals released from damaged tissues. Recently, a novel system named the inflammasome, a multiple protein complex for caspase-1 activation, has been characterized. Activation of the inflammasome can lead to the cleavage of pro-inflammatory cytokines IL-1β and IL-18 into their active forms. It has showed that the inflammasome plays a critical role in host defense against bacterial and viral infection in vivo. Deregulation of inflammasome, however, is linked to many diseases, such as cancer, autoinflammatory diseases, and diabetes.
We recently identified a novel DEAD box-containing protein in our yeast two-hybrid screening for regulation of the NLRP3 complex. We thus continue to study the functional role of this DEAD-box containing protein in NLRP3 inflammasome activation and its molecular mechanism. Depletion of this novel DEAD box-containing protein in THP-1 macrophages and bone marrow derived macrophages (BMDMs) largely enhanced caspase-1 activity and IL-1β production solely upon LPS challenge, suggesting that this DEAD-box protein is involved in the regulation of NLRP3 inflammasome. We also found that this DEAD-box protein suppressed IL-1β maturation and caspase-1 activation after LPS/ATP challenge in J774A.1 macrophages and BMDMs. In addition, we demonstrated that this novel DEAD-box protein associated with NALP3/ASC in a co-immunoprecipitation assay. Together, our results strongly suggest that this novel DEAD-box containing protein negatively regulates NLRP3 inflammasome activation.

P1.06.80
Necrotic cells induce $CD14^-/CD68^+$ peritoneal exudate cells to proliferate and differentiate into macrophage-like cells

X. Yuan[1], *X. Li*[1], *Q. Zhang*[1], *C. Zhang*[1], *D. Li*[2];
[1]*The Affiliated Hospital of Dalian University, Dalian, China,*
[2]*Immunology Department of Harbin Medical University, Dalian, China.*

In a previous study, we noticed that some ascitic cells isolated from melanoma patients survive, proliferate, and differentiate into **giant** phagocytes after the other cells died. Similar phenomena were observed in the primary cultures of ascitic cells collected from mice inoculated with H22 hepatoma cells in the peritoneal cavity, as well as in the primary cultures of mouse lung and liver cells. In the present study, the relevance between cell proliferation and dying cells, and the biological characteristics of the differentiated cells were studied. The results indicate that necrotic cells induce non-attached abdominal exudate cells to proliferate and differentiate into **giant** phagocytes; however, apoptotic cells had no such effect. Morphologic studies revealed that the large phagocytes were abundantly covered with spherical and elongated protrusions, laminations, and cell surface vesicles. In addition, numerous phagosomes, secondary lysosomes, and mitochondria were observed inside each cell. Moreover, necrotic cells enhance the expression of CD14, CD68, CD80, and CD86, and the differentiated cells expressed high levels of CD68 and CD86. Our results indicate that necrotic cells induce non-attached abdominal exudate cells to proliferate and differentiate, and the differentiated cells possess characteristics similar to macrophages.

P1.06.81
The Effect of Polyporus umbellatus(Chinese medicine)on LPS-induced Viability and Cytokine Expression in RAW264.7 cells

X. Zeng*;*
Immunology Laboratory of Chinese Medicine, The Second Affiliated Hospital of Guangzhou University of, Guangzhou, China.

Polyporus umbellatus is a medicinal fungus with mild taste and neutral property. The investigations of immunological action of *Polyporus umbellatus* focus much more on ingredients than the compound of *Polyporus umbellatus*. The mechanism researches on toxicity attenuation and efficacy potentiation effects of *Polyporus umbellatus* in recent years reveal that the interaction among the various ingredients from *Polyporus umbellatus* probably account for the bidirectional regulation of *Polyporus umbellatus* prescription on immunity. To investigate the immune regulatory function of *Polyporus umbellatus* by studying its impact on LPS-induced expression of cytokines (IL-1β, IL-6 and IL-10) in RAW264.7 cells, based on our previous studies. Results**:** In comparison to LPS group, LPS-induced expression of IL-1β, IL-6 and IL-10 in RAW264.7 cells was inhibited by *Polyporus umbellatus* in a dose-response manner. IL-10 mRNA was promoted by 0.05μg/mL *Polyporus umbellatus* while inhibited by 0.5 and 5μg/mL.*Polyporus umbellatus* is capable of attenuating stimulation of LPS on RAW264.7 cells by suppressing the expression of cytokines like IL-1β and IL-6 as well as elevating the anti-inflammatory cytokine IL-10. The correlation between the dose of Polyporus umbellatus and IL-10 expression indicates the bidirectional regulatory effect of *Polyporus umbellatus* on LPS-induced expression of cytokines in RAW264.7 cells.

P1.06.82
Suppression of PTRF inhibits TLR4 signaling: a novel regulator of sepsis

Y. Zheng*, X. Liang, S. Wei, H. Moon, Y. Jin;*
Brigham and Women's Hospital, Harvard Medical School, Boston, MA, United States.

Rationale: Sepsis and sepsis associated end-organ failure are devastating syndromes. Understanding the detailed molecular mechanisms of sepsis potentially uncovers novel targets for therapy. PTRF is a newly discovered protein which may carry divergent cellular functions.
Objectives: to dissect the role of a novel protein, PTRF, in TLR4 mediated sepsis using mouse models in vitro and in vivo.
Methods: Cecal ligation and puncture (CLP) was used as the sepsis model in vivo to determine mortality and end-organ damage. Macrophages were adopted as the cellular models in vitro to conduct mechanistic studies.
Measurements and results: PTRF +/- mice survived better and suffered less organ damage after CLP. Further, less nitric oxide production and iNOS biosynthesis were observed in plasma, macrophages and/or vital organs from PTRF +/- mice. Using our acute sepsis models induced by CLP, we found that iNOS-/- mice carried the similar survival benefits comparing with the PTRF +/- mice. Further, similar as in the in vivo models, PTRF deficiency also resulted in decreased iNOS expression and NO/ROS production in vitro. Mechanistically, LPS enhanced the co-localization and interaction between PTRF and TLR4 in the lipid rafts. Deletion of PTRF prohibited the formation of TLR4 /Myd88 complex after LPS. Consistently, lack of PTRF impaired the TLR4 downstream signaling represented by decreased p-JNK, p-ERK and p-p38, which are upstream signals of iNOS mRNA transcription.
Conclusion: PTRF is a crucial regulator on TLR4 signaling in the development of sepsis.

P1.07.01
Diverse role of *Plasmodium falciparum* haemozoin towards anti-malarial innate response

S. Adukpo*[1,2], A. F. Feßer[1], T. Velavan[1];*
[1]Institute for Tropical Medicine, Eberhard-Karls University, Tubingen, Germany, [2]Noguchi Memorial Institute For Medical Research, Accra, Ghana.

Malaria continues to kill hundreds of thousands of children, pregnant women and non-immune adults each year. Understanding the cellular and molecular mechanisms during onset of malaria infection still remains an elemental issue in immunology. During early stages of infection, cells involved in innate immunity play a predominant role in controlling or modulating immune responses. Of which, cells of the myeloid lineage and natural killer cells are of greater interest. The interaction of these host innate immune cells with the parasite results in secretion of cell signaling protein molecules and reactive oxygen species (ROS) leading to parasite death and clearance. We investigated the effect of parasite's food vacuole containing haemozoin produced by *Plasmodium falciparum* on peripheral blood mononuclear cells (PBMCs) and neutrophils. We co-cultured parasite's food vacuole containing haemozoin, merozoites with parasite's food vacuole containing haemozoin and merozoites devoid of parasite's food vacuole or haemozoin with PBMCs or neutrophils and measured ROS production over time by Chemiluminescence. Co-culture of opsonized merozoites with and without parasite's food vacuole containing haemozoin revealed a significant lower ROS levels generated by neutrophils compared to parasite's food vacuole containing haemozoin ($p<0.05$). With similar concentrations, the non-opsonized parasite's food vacuole containing haemozoin induced a swift ROS production than opsonized one. Taken together, our preliminary results indicate that immune antibodies may not be important in parasite's food vacuole or haemozoin uptake by neutrophils and subsequent generation of ROS.

P1.07.02
Modulation of Moraxella catarrhalis and nontypeable Haemophilus influenzae phagocytosis by neuropeptides NPY and CGRP

D. Augustyniak*[1], J. Nowak[1], A. Jankowski[2];*
[1]Department of Pathogen Biology and Immunology, University of Wroclaw, Wroclaw, Poland, [2]Department and Clinics of Pediatrics, Immunology and Rheumatology of Developmental Age, Medical University of Wroclaw, Wroclaw, Poland.

Colonization of respiratory tract is the first step in the infectious process. Since mucosal surfaces of the upper respiratory tract are richly innervated, human-restricted respiratory pathogens such as Moraxella catarrhalis and nontypeable Haemophilus influenzae are potentially exposed to the action of released neuropeptides including neuropeptide Y (NPY), and calcitonin-gene related peptide (CGRP).
The study was designed to verify neuropeptide-mediated modulation of human neutrophils (PMNs) phagocytosis against studied bacteria by determination of two critical phagocytic steps: bacterial uptake and respiratory burst response.
The phagocytic uptake of antibody-opsonized and non-opsonized FITC-labeled bacteria was measured using FACs. Reactive oxygen species (ROS) formation by phagocytosing PMNs was measured using luminol-dependent chemiluminescence assay (CL).
We found the bimodal modulatory action of neuropeptides that was observed in distinct types of pathogen recognition (opsonic versus nonopsonic). The phagocytic uptake of both opsonized mucosal pathogens by PMNs was markedly improved in the presence of NPs. The uptake remained unchanged in the presence of nonopsonized bacteria. In the case of ROS production only CGRP significantly intensified the respiratory burst of PMNs triggered by phagocytosable nonopsonic M. catarrhalis. The observed stimulating effect of CGRP was not preserved for opsonized bacteria. The contradictory action of NPs on engulfment and ROS response seems to be determined both by the nature of pathogen recognition and the physiological status of PMN donor.

The results suggest that physiologic concentrations of CGRP and NPY are modulators of PMNs uptake and respiratory burst in response to M.catarrhalis and H.influenzae and may be valuable innate components of immunity.

P1.07.03
Understanding innate immune functions of peripheral blood monocytes

D. H. Banda[1], *K. C. Jambo*[1], *D. G. Russell*[2], *R. S. Heyderman*[1,3], *H. C. Mwandumba*[1,3];
[1]*Malawi Liverpool Wellcome Trust Clinical Research Programme, Blantyre, Malawi,* [2]*Cornell University, New York City, NY, United States,* [3]*Liverpool School Of Tropical Medicine, Liverpool, United Kingdom.*

Background: Monocytes play an important role in host immunity as precursors of tissue macrophages.Macrophages are involved in phagocytosis and killing of pathogens.The innate immune functions of monocytes prior to differentiation into tissue macrophages and the impact of HIV on these functions are not well described.We assessed phagocytic,oxidative burst and proteolytic functions of blood monocytes obtained from healthy,asymptomatic HIV-uninfected and HIV-infected adults.
Methods: We recruited 45 HIV-uninfected,34 chronically HIV-infected and 7 acutely HIV-infected individuals.We isolated peripheral blood mononuclear cells (PBMCs) and measured their phagocytic, oxidative burst and proteolytic capacity using fluorochrome-conjugated reporter beads and flow cytometry.For phagocytosis,silica beads conjugated with streptavidin-IgG and streptavidin-horseradish peroxidise (HRP) were used to assess internalisation via Fc and mannose receptors respectively.Oxidative burst and proteolysis were measured using reporter beads carrying a fluorogenic reporter and a calibration fluorochrome.When the beads are internalized by monocytes,they gain fluorescence intensity proportional to the degree of activity in the phagosomal compartment.
Results: There was a significant difference in internalisation of beads via the mannose-receptor between HIV-uninfected volunteers compared with acutely HIV-infected adults (72.3% vs. 50.1%; p=0.01), but not via the fc-receptor across all groups (HIV- 65.0% vs.Chronic HIV+ 61.5% vs. Acute HIV+ 62.9%; p>0.05).There was no significant difference in oxidative burst (0.82 vs. 0.76; p>0.05) and proteolysis (1.64 vs. 1.24; p>0.05) in HIV-uninfected volunteers compared to chronically HIV-infected adults.
Conclusion: This suggests that peripheral blood monocytes from acutely-HIV-infected adults have impaired mannose-receptor-mediated phagocytosis.This may adversely affect host defence against pathogens internalised via this route.

P1.07.04
Downregulation of dendritic cells functions by Neutrophil Extracellular Traps

L. S. Barrientos[1], *V. Marin-Esteban*[1], *L. de Chaisemartin*[1,2], *C. Sandré*[1], *R. Gorges*[1], *C. Gueguen*[3], *L. Mascarell*[3], *S. Kerdine-Römer*[1], *M. Pallardy*[1], *S. Chollet-Martin*[1,2];
[1]*INSERM UMR-S 996, Chatenay-Malabry, France,* [2]*APHP Hopital Bichat-Claude Bernard, Paris, France,* [3]*Stallergenes, Antony, France.*

Neutrophils are key components of the innate response via several mechanisms, in particular the production of Neutrophil Extracellular Traps (NETs), chromatin fibers associated with granule and cytoplasmic proteins that play important roles in antimicrobial defenses but seem also involved in some auto-immune and inflammatory diseases.
Our aim was to investigate whether NETs could interact with dendritic cell (DC) maturation and modulate adaptive immunity.
We first developed a model to induce, isolate and characterize NETs from human blood neutrophils. Calcium ionophore A23187 was chosen to induce NETs and the restriction enzyme Alu I allowed the recovery of heterogeneous-sized fragments of NETs. The presence of dsDNA and proteins was shown and, using western-blotting, NET major proteins (lactoferrin, histone 3, citrullinated histone 3) could be quantified. Finally, these isolated-NET were active as they were able to kill bacteria.
The co-culture of isolated-NETs preparations with DC alone did not induce DC maturation as measured by phenotypic modifications and cytokine productions. By contrast, NETs induced a significant decrease of lipolysaccharide) LPS-induced expression of CD86, CD83, CD80, CD40 and HLA-DR, as well as TNF, IL12-p70, IL23, IL8, IL6 and IL-10 release. This downregulation of LPS-induced DC maturation led to a decrease of T lymphocyte proliferation (allogenic model) and is associated with a markedly reduction of IFN-gamma and IL17 while promoting IL5 and IL13.
Our data suggest that, in our model, the NETs produced during inflammation can participate to the regulation of DC activation and maturation in order to potentially limit excessive immune responses.

P1.07.05
Immunological prognosing of complications of locomotors trauma

O. V. Berdugina[1], *K. A. Berdugin*[2];
[1]*Ural scietyphic research institute of physiopulmonology, Ekaterinburg, Russian Federation,* [2]*Ural scietyphic research institute of traumatology and orthopedics, Ekaterinburg, Russian Federation.*

Immunological status is investigated at 382 patients with damages and diseases of the locomotors system (obverse skeleton, backbone, long bones and large joints). Changes of basic immunological parameters at the noncomplicated current after operation were characterized in the whole line of similar features. In early term after operation we discover attributes of inflammation reaction - came to light developed neutrophils leucocytosis, were observed dysimmunoglobulinaemia, dynamics acute phase reactants changed. By the end of month of supervision basic immunological parameters were normalized. The occurrence of complications was characterized by increase of leukocyte number, first of all, at the expense of population's lymphocytes and eosynophils and decrease of monocytic quantity, oppression of a phagocytic link, decrease of functional activity of immunocompetent crates. Inflammation reaction to operative intervention were characterized by the greater duration and less expressed changes of concentration of acute phase reactants of fibers in comparison with the not complicated current after operation period. Thus, using of immunological tests in an estimation of damages of a skeleton allows predicting complications and in timing to carry out correction of a condition of the patient and by that to avoid or, when it is impossible, to defer development of complication.

P1.07.06
Monocyte subsets and immunopathology in Leishmania braziliensis infection

R. Costa, S. Passos, E. M. Carvalho, ***L. P. Carvalho****;*
Federal University of Bahia, Salvador, Brazil.

Cutaneous leishmaniasis (CL) is an inflammatory parasitic disease characterized by the presence of ulcerated lesion on the skin. Patients with CL due to Leishmania braziliensis produce high levels of TNF, cytokine that contribute to tissue damage and ulcer development. Mononuclear cell infiltrate are found in lesions of CL patients, with presence of T and B lymphocytes, and mononuclear phagocytes. Recently, three populations of monocytes have been described based on expression of CD14 and CD16: Classical (CD14+CD16-), intermediate (CD14+CD16+) and non-classical (CD14dimCD16+) monocytes. Here, peripheral blood mononuclear cells were obtained from healthy controls, CL patients in pre-ulcerative phase and CL patients with skin ulcer. Monocyte subsets characterization was performed by flow cytometry. We observed that the frequency of intermediate and non-classical monocyte populations was increased in individuals on pre-ulcerative phase and CL patients with skin ulcer. Expression of MHC class II was increased in intermediate monocytes, suggesting that these cells might better present antigen to T cells. Also, classical and intermediate monocytes produced more TNF than the non-classical ones in response to soluble Leishmania antigen and LPS. CCR2 is the ligand for CCL2, a chemokine known to play important role in immune response against Leishmania. The levels of CCL2 were increased in both, lesion and peripheral blood from CL patents, and CCR2 was more expressed in

classical and intermediate populations. Altogether, our data show differences among monocyte subsets in CL. While classical and intermediate monocytes produce more TNF, non-classical ones are more frequent in lesions of these patients.

P1.07.07
Modulation of Chitinases and CLPs during Macrophage Differentiation and Polarization

*M. Di Rosa, **M. Di Rosa**, M. Malaguarnera, C. De Gregorio, G. Malaguarnera, L. Malaguarnera;*
University of Catania, Catania, Italy.

Enzymatically active chitinases chitotriosidase (CHIT-1) and AMC-ase; as well as CLPs YKL-40, YKL-39 have specific patterns of association with immune response. Serum levels of chitotriosidase and YKL-40 mainly reflect the activation status of macrophages, and in particular lipid-laden macrophages. While chitotriosidase is a specific marker for lysosomal storage disorders, overexpression of YKL-40 was found in numerous of tumors, chronic and acute inflammations and during fibrosis progression. We compared the Chitinases variations during the differentiation and polarization of human macrophages. Gene expression analysis was investigated by real-time PCR from mRNA of human monocytes obtained from buffy coat of healthy volunteers, polarized to classically activated macrophages (or M1), whose prototypical activating stimuli are Interferon-gamma and lipopolysaccharide, and alternatively activated macrophages (or M2) obtained by interleukin-4 exposure. We found that CHIT-1 and YKL-40 were significantly modulated throughout monocyte-to-macrophage differentiation and polarization. In contrast, AMC-ase, YKL-39 showed slight modulation in the diverse stage of macrophages differentiation and/or polarization. In conclusion our results show that the expression of CHIT-1 AMC-ase, YKL-40 and YKL-39 is differentially regulated throughout monocyte-to-macrophage differentiation and polarization. Our finding suggests that whereas the immune function of AMC-ase and YKL-39 is restricted and selective, CHIT-1 and YKL-40 are protagonists in innate and acquired immunity.

P1.07.08
Analysis of temporally-resolved phagosome proteomes following uptake via key phagocytic receptors

***B. D. Dill**[1], M. Gierlinski[2], M. Guo[1], M. Trost[1];*
[1]MRC Protein Phosphorylation Unit, University of Dundee, Dundee, United Kingdom, [2]Data Analysis Group, University of Dundee, Dundee, United Kingdom.

Macrophages operate at the forefront of innate immunity, and their discrimination of pathogenic versus "self" particles is critical for a number of responses including antigen presentation, efficient pathogen killing, and cytokine induction. Recent studies have investigated modulation of downstream effects dependent on activation of key receptors during phagocytosis, including IgG and TLR receptors. In this work, phagosome proteomes were tracked over three timepoints to elucidate developmental differences among phagosomes taken up by well-studied receptors. Polystyrene beads conjugated to ligands representing bacterial membrane and fungal cell wall components, immune opsonins, or apoptotic cell markers were inoculated to murine bone marrow-derived macrophages (BMMs) for 30 minutes, and phagosomes were isolated after 0, 30, or 150 minutes and processed for proteomic analysis. For accurate quantitation among conditions and across the timecourse, stable isotope labelling and use of a common pooled internal control was used as a reference for all measurements. Analysis of resulting high-resolution mass spectrometric data resulted in the identification of over 1800 proteins and quantification of over 1500 proteins. Gene ontology enrichment analysis indicates increased representation of functional groups over the three timepoints, correlating with accumulation or loss of protein groups during maturation. Additionally, a mixture of subtle and distinct differences was detected between certain ligand-phagosomes, indicative of different rates of maturation and degradative capacity. For example, decreased levels of Ripk1 and Rab-19 were detected in 30'/0 LPS-bead phagosomes. Together, data support the concept of phagosome autonomy, where phagosomal fate is dependent on triggering of specific receptors during phagocytosis.

P1.07.09
Effects of aging on phagocytic activity and nitric oxide production of peritoneal macrophages from elderly mice in response to *Candida albicans*

***T. P. Gardizani**, K. H. Pinke, H. G. Lima, V. S. Lara;*
Bauru School of Dentistry - University of Sao Paulo, Bauru, Brazil.

Macrophages are an essential component of innate immunity, including their participation in the phagocytosis process and nitric oxide production. An altered function of these cells with aging may play a key role in the defense mechanisms, including infectious diseases. In this work, we use young (2-3 months old - control) and aged (18-20 months old) C57BL/6 mice to study, *in vitro*, the influence of aging on the fungicidal activity of the resident peritoneal macrophages by analyzing the phagocytosis and the production of nitric oxide in response to different proportions of dead (1 macrophage: 1 yeast, 1:2, 2:1) and viable (1 macrophage: 1 yeast, 1:5, 5:1) *Candida albicans*, for 30 and 120 minutes. Macrophages from elderly mice are able to phagocytose *C. albicans* similar to young mice, although the elderly cells can store more dead fungi (≥ 5 yeasts) when compared to the matched control. However, the production of nitric oxide by peritoneal macrophages in response to *C. albicans* was lower in aged mice compared with young mice. These data indicate that the senescent mice have the ability to store more dead fungi than young in order to kill the infectious agent, but fails, due to inhibition of the production of microbicidal substance, nitric oxide. Thus, these cells would serve as disseminator's vehicles, favoring the dispersion of the pathogen into the body and protecting the yeasts from other mechanisms of the innate immune response.

P1.07.10
Functional analyses and cytochemical staining of leucocytes from lumpsucker (*Cyclopterus lumpus* L.), including IgM$^+$ cells

***G. T. Haugland**[1], A. Rønneseth[1], K. Ulven[1], N. Vestvik[2], H. I. Wergeland[1];*
[1]University of Bergen, Bergen, Norway, [2]Aqua Kompetanse, Flatanger, Norway.

Lumpsucker, *Cyclopterus lumpus* L., is a species of marine fish belonging to the order Scopaeniformes. They are found in cold waters of the Artic and North Atlantic oceans. We have performed functional studies like phagocytosis and respiratory burst to evaluate its innate immune responses by use of flow cytometry. We found that the phagocytic capacity and ability of isolated leukocytes from head kidney, spleen and peripheral blood were very high and cells with different morphology phagocytized beads rapidly. Regarding killing/degrading mechanisms, both oxygen-dependent (respiratory burst and myeloperoxidase) and oxygen-independent mechanisms (enzymes) were proven. We have differentiated between ten different subtypes of leukocytes based on morphology and cytochemical staining and cell types like lymphocytes, monocytes/ macrophages, dendritic cells and polymorphonuclear granulocytes (basophil, eosinophil and neutrophil) were identified. Further, we have characterized a polyclonal antibody against IgM using flow cytometry, immunostaining and immunoblotting. To our knowledge, the present study represents the first analyses of lumpsucker immunity and also the first immunological study within the order Scopaeniformes.

P1.07.11
The differences in innate immune responses of Atlantic salmon, Atlantic cod and lumpsucker

***G. T. Haugland**, A. Rønneseth, H. Wergeland;*
University of Bergen, Bergen, Norway.

In comparative studies, the fish immune system can provide important knowledge and contribute to an increased understanding of the evolution of the vertebrate immune system. The teleosts are the

first group of vertebrates with both innate and adaptive immunity. This group is highly diverse concerning both the composition of the immune system and the responses to pathogens. We have studied the innate immune responses in salmon, cod and lumpsucker, representing three different phylogenetic orders. Leucocytes were isolated from peripheral blood, head kidney (primary and secondary lymphoid tissue in fish) and spleen (lymphoid organ in fish). The innate immune responses, phagocytosis and respiratory burst, were analysed by flow cytometry and immunofluorescence microscopy. Further, enzymes involved in microbial degradation were visualized by cytochemical staining. Interestingly, we found that the immune cells and responses upon pathogen challenge were highly different in these species.

P1.07.12
The effects of anabolic steroids on dendritic cells

*L. M. Cosgrave[1,2], E. W. Brenu[2], **T. K. Huth**[2], B. Gray[1], S. M. Marshall-Gradisnik[2];*
[1]Faculty of Healthy Sciences & Medicine, Bond University, Gold Coast, Australia, [2]National Centre for Neuroimmunology & Emerging Diseases, Griffith Health Institute, Griffith University, Gold Coast, Australia.

To date, there is limited information on the effects of Anabolic Androgenic Steroids (AAS) on antigen presentation function of dendritic cells (DC). Co-stimulatory molecules CD80 and CD86 are important during antigen presentation as they associate with CD28 on T cells which is important for T cell survival. Various factors including AAS may alter these processes, particularly at high levels. The objective of this study was to investigate the effects of a commonly used AAS, testosterone cypionate (TC), on DC antigen presentation over time *in vitro*. Ten healthy male university students (mean age = 22.9 ± 0.7SD) were recruited for this study. Blood samples from the participants were incubated with or without 3µM of TC and PMA for 4, 12 and 24 hours. Following incubation, the samples were fluorescently labelled with CD80, CD86, CD3, CD14, CD19, CD20, CD56 and CD11c to facilitate preferential identification of DCs from other cells. Flow cytometry analysis determined the expression of CD80/CD86 surface markers on stimulated and unstimulated DC. A repeated measures ANOVA identified significance where $p<0.05$.TC treated samples demonstrated a significant increase in CD80 expression over time for both stimulated and unstimulated DCs. CD86 expression in unstimulated samples was significantly decreased. However, TC treated samples had significantly higher expression of CD86 compared to controls at 12 and 24 hours post incubation. These studies have highlighted the effects of testosterone on DCs which may have important implications in individuals who administer different types of AAS for recreational purposes.

P1.07.13
Inflammation driven functional differentiation of human macrophages *in vitro*

***P. Italiani**[1], E. M. C. Mazza[2], S. Bicciato[2], C. Gemelli[2], A. Grande[2], I. Cifola[3], C. M. Battaglia[4], P. Giungato[1], D. Boraschi[1];*
[1]Institute of Biomedical Technologies (ITB)-National Research Council (CNR), Pisa, Italy, [2]Deptartment of Life Sciences, University of Modena and Reggio Emilia, Modena, Italy, [3]Institute of Biomedical Technologies (ITB)-National Research Council (CNR), Milano, Italy, [4]Department of Medical Biotechnology and Translational Medicine, University of Milano, Milano, Italy.

Monocytes/macrophages are key players in all phases of physiological and pathological inflammation. To understanding the regulation of macrophage functional differentiation during inflammation, we have designed an *in vitro* model of human inflammation that recapitulates the different phases of the reaction (recruitment, initiation, development, and resolution), based on human primary blood monocytes exposed in culture to sequential changes of microenvironmental conditions. All phases of the inflammatory response were profiled by transcriptomic analysis. Broad distinct clusters of genes were identified that are differentially regulated during the different phases of inflammation. The gene sets identified by GSEA revealed that the inflammatory phase was enriched in inflammatory pathways while the resolution phase comprised pathways related to metabolism and gene rearrangement. By comparing gene clusters differentially expressed in monocytes *vs*. M1 and *vs*. M2 macrophages extracted from a meta-database, it was shown that cells in the *in vitro* model resemble M1 during the inflammatory phase and M2 during resolution. A set of genes of the IL-1 family was validated for expression by real-time PCR and protein production by ELISA. In two experimental set-ups (representing bacterial- and viral-induced inflammation, respectively), IL-1 and IL-18 expression and production strongly correlated with inflammation, while their inhibitors IL-1Ra and IL-18BP were expressed and produced starting from the late phases of inflammation.
Thus, this *in vitro* kinetical model of human inflammation allows an accurate description of the development of the inflammatory reaction and can help in identifying regulatory mechanisms in physiological conditions and in pathological derangements.

P1.07.14
Alveolar macrophage innate immune function in HIV-infected African adults

***K. C. Jambo**[1], D. H. Banda[1], D. G. Russell[2], R. S. Heyderman[1,3], H. C. Mwandumba[1,3];*
[1]Malawi-Liverpool-Wellcome Trust Clinical Research programme, Blantyre, Malawi, [2]Microbiology and Immunology, Cornell University, College of Veterinary Medicine, Ithaca, NY, United States, [3]Department of Clinical Sciences, Liverpool School of Tropical Medicine, Liverpool, United Kingdom.

Background: HIV-infected individuals are at high risk of lower respiratory tract infections (LRTIs). Alveolar macrophages (AM) and T cells are the predominant cell types in the alveoli. We have previously demonstrated that antigen-specific bronchoalveolar CD4+ T cell responses to common respiratory pathogens are impaired in HIV-infected adults. The effect of HIV on AM function is, however, still poorly understood.
Methods: We recruited 45 HIV-uninfected and 34 asymptomatic HIV-infected healthy Malawian adults. We obtained AM by bronchoscopy and bronchoalveolar lavage. The function of AM was measured using novel flow cytometry based bead assays. HIV-infected AM were detected using a novel flow cytometry-based FISH assay that involves probing target HIV mRNA using a pool of 48 fluorophore-labeled oligonucleotides.
Results: The phagocytic ability and oxidative burst function of AM was not significantly different between HIV-infected and HIV-uninfected adults (phagocytosis, 62.0% vs. 70.2%, $p>0.05$; Oxidative burst, 1.31 vs. 1.34, $p>0.05$). AM from HIV-infected adults had reduced proteoytic function than those from HIV-uninfected adults (1.25 vs. 1.52; $p=0.04$). We found that 1.7%[0.7-3.8] of AM were HIV infected and these infected cells were predominantly 'small' AM. Furthermore, we found that HIV-infected small AM had reduced phagocytic ability (62.4 vs 45.5%, $p=0.03$).
Conclusion: The findings demonstrate that proteolytic function is impaired in AM from HIV-infected adults and that a group of "small" AM dominate in harbouring HIV and have impaired phagocytic function. The findings suggest that some AM innate functions are impaired in HIV-infected individuals and this may in part render HIV-infected adults more susceptible to LRTIs.

P1.07.15
The influence of T4 phage preparations on the activation of human monocytes in vitro

***G. Korczak-Kowalska**[1,2], P. Wierzbicki[2], K. Bocian[1], D. Kłosowska[2], M. Zarzycki[1], J. Borysowski[2], M. Pacek[2], B. Weber-Dąbrowska[3], A. Górski[2,3];*
[1]University of Warsaw, Faculty of Biology, Department of Immunology, Warsaw, Poland, [2]Medical University of Warsaw, Department of Clinical Immunology, Warsaw, Poland, [3]Ludwik Hirszfeld Institute of Immunology and Experimental Therapy, Polish Academy of Science, Wrocław, Poland.

Bacteriophages (bacterial viruses) are increasingly considered as a means of treating antibiotic-resistant bacterial infections. A number of

studies have revealed that bacteriophages, apart from killing bacteria, can also directly interact with immune cells, including phagocytic cells. However, there are practically no data on the potential mechanisms that might underlie the interactions between phages and phagocytic cells. The main objective of the study was to evaluate the effects of T4 phage preparation on the expression of CD80, CD86, and CD40 on monocytes and their production of IL-6, and TNF-α, two important proinflammatory cytokines, in vitro. The study was performed on peripheral blood mononuclear cells (PBMCs) from healthy blood donors. The expression of CD80, CD86, and CD40 molecules was measured by flow cytometry on CD14+ cells after 20-h cultures in the presence or absence of bacteriophage preparations. Separate experiments were performed to determine the percentage of CD80+, CD86+, and CD40+ cells in unstimulated and LPS-stimulated monocyte populations. Flow cytometry was carried out on a FACS-Calibur (Becton Dickinson) using Cell Quest software. Although T4 phage lysate significantly increased the expression of CD80 and CD40 molecules on unstimulated monocytes, this effect was not observed in LPS-activated cells. T4 phage lysate increased also the synthesis of proinflammatory cytokines by unstimulated monocytes, but not by LPS-activated cells. This suggests that monocytes activated during bacterial infection should not respond to phage preparations which confirm our earlier data on safety of phage therapy.

P1.07.16
12/15-lipoxygenase mediates GC-induced anti-inflammatory mechanisms in monocytes

Y. Kusche[1]*, L. Klotz*[2]*, H. Wiendl*[2]*, J. Roth*[1]*, K. Barczyk*[1]*;*
[1]*Institute of Immunology, Münster, Germany,* [2]*Department of Neurology-Inflammatory Disorders of the Nervous System and Neurooncology, Münster, Germany.*

Glucocorticoids (GC) are commonly used in the treatment of many chronic inflammatory diseases. Our previous studies have shown that GC treatment does not suppress monocyte functions but induces a distinct anti-inflammatory phenotype in these cells. Similarly the treatment of LPS-stimulated monocytes with GC leads to re-programming of the cells towards a specific population involved in resolution of inflammation. Microarray analysis has shown up-regulated expression of anti-inflammatory and pro-resolution 12/15-lipoxygenase (12/15-LOX) in GC- and LPS/GC-treated monocytes.
The aim of our studies was to determine lipoxygenase-dependent effects in GC-treated monocytes. Bone marrow-derived monocytes from wild-type (wt) and 12/15-LOX-/- mice were stimulated with GC and/or LPS. GC induced a much more pronounced reduction of adhesion to plastic surface in wt monocytes as compared to 12/15-LOX-/- cells. Conversely migration was enhanced in GC- and LPS/GC-treated monocytes isolated either from wt or 12/15-LOX-/- mice. GC induced protection from cell death as well as the inhibition of ROS production were much more pronounced in wt cells as compared to 12/15-LOX-/- monocytes. Phagocytosis of carboxylated-modified latex-beads (mimicking apoptotic cells) was increased in GC-treated monocytes. However, this effect was much weaker in GC-treated monocytes isolated from 12/15-LOX-/- mice. In contrast, no significant differences between wt and 12/15-LOX-/- monocytes were observed in phagocytosis of latex beads
Our results indicate that inhibition of ROS production, protection from cell death, migration and adhesion of GC-treated monocytes are at least partially mediated by 12/15-LOX.
Specific targeting of the 12/15-LOX-pathway may be a promising strategy to block undesirable inflammation with fewer side effects.

P1.07.17
Synthetic immunomodulatory peptides IDR-HH2, IDR-1002 and IDR-1018 regulate neutrophil functions

F. Niyonsaba[1]*, L. Madera*[2]*, K. Okumura*[1]*, H. Ogawa*[1]*, R. E. W. Hancock*[2]*;*
[1]*Juntendo University Graduate School of Medicine, Tokyo, Japan,* [2]*University of British Columbia, Vancouver, BC, Canada.*

Although antimicrobial peptides or host defense peptides were originally hypothesized to act as antimicrobial agents, they also have been shown to broadly modulate the immune responses. We recently developed a series of novel synthetic immunomodulatory peptides, termed innate defense regulators (IDRs), which are conceptually based on a natural host defense peptide, bovine bactenecin. We showed that IDR-1 and IDR-1002 protect the host against bacterial infections through the induction of chemokines. The objective of this study was to investigate the effects of the IDRs on various functions of human neutrophils. Here, we demonstrated that IDR-HH2, IDR-1002 and IDR-1018 modulated the expression of neutrophil adhesion and activation markers. Moreover, these IDRs enhanced neutrophil adhesion to endothelial cells in a β_2 integrin-dependent manner and induced neutrophil migration. The IDR also promoted chemokine production via MAPK activation, increased the release of the neutrophil-generated human α-defensins and LL-37, and augmented neutrophil-mediated killing of *Escherichia coli*. Notably, the IDRs significantly suppressed LPS-mediated neutrophil degranulation, the release of reactive oxygen species and the production of the inflammatory cytokines tumor necrosis factor-α and interleukin-10, consistent with their ability to dampen inflammation. Taken together, our findings indicate that immunomodulatory peptides IDR-HH2, IDR-1002 and IDR-1018 regulate a range of neutrophil functions, and provide novel evidence regarding the contribution of the IDR peptides to the innate immune response through the modulation of neutrophil functions. The results described here may aid in the development of IDRs as novel anti-infective and immunomodulatory agents.

P1.07.18
Role of Circadian Rhythm in cell metabolism and macrophage function

J. Oliva*, B. Pineda Olvera, O. Rojas Espinosa, F. Sánchez García; ENCB-IPN, Mexico, Mexico.*

Thermoregulation, wakefulness, feeding, sleep, and other vital functions are influenced by circadian rhythms, regulated by timing activation of positive and negative oscillator proteins. In murine models, the absence or deregulation of any of these proteins may lead to metabolic syndrome. It has also been shown that NK cell cytotoxic activity is higher during day-light and that macrophage pro-inflammatory cytokines production in response to LPS follows a circadian-dependent pattern. Here, we present some evidence that mitochondrial dynamics and glucose metabolism are dependent on circadian rhythm and try to relate this with macrophage anti-microbial activities.
Aim: To analyze the metabolic and functional behavior of macrophages at defined stages of a circadian cycle.
Methods: Peritoneal macrophages and J774 A.1 cells were circadian rhythm-synchronized by serum-depletion followed by high serum shock in order to analyze Per-2 and Rev-Erb gene expression (circadian clocks), mitochondrial dynamics, glycolysis rate and Glut-3 expression (as metabolic traits), as well as endocytosis of S. thyphimurium and bacterial survival (macrophage functional activity) at defined time points spanning a whole circadian cycle (24h) plus 12h.
Results and conclusion: Mitochondria shifted from fusion to fission forms in the first 20h post-synchronization and back to fusion over the next 12h. Glut-3 expression was lower in the first 12h post-synchronization as compared to the next 12h, whereas the glycolysis rate was higher in the first 4h post-synchronization thus indicating circadian-related metabolic changes. Endocytosis and bacterial killing by macrophages seem to be related with these metabolic traits.

P1.07.19
Respiratory Syncytial Virus Fusion protein stimulates neutrophil extracellular traps formation

B. N. Porto*, R. S. Czepielewski, A. P. D. Souza, C. B. C. Bonorino, R. T. Stein;*
Pontificia Universidade Católica do Rio Grande do Sul, Porto Alegre, Brazil.

Respiratory Syncytial Virus (RSV)-induced acute bronchiolitis is the most prevalent disease in children under 2 years old, which causes a huge impact in hospitalizations and costs to the health system. RSV is a single stranded RNA virus, whose genome encodes up to 11

proteins. The Fusion (F) protein is present at the virion surface and mediates the virus-target cell fusion. RSV F protein activates TLR-4 receptor, inducing cytokine secretion. Neutrophils activated by a wide range of microorganisms form neutrophil extracellular traps (NETs), which are composed of decondensed DNA and antimicrobial proteins. Our hypothesis is that F protein activates TLR-4 on neutrophils, inducing NETs formation. Human neutrophils were stimulated with F protein (1µg/mL), LPS (100ng/mL), PMA (25nM) or medium alone for 3 h at 37°C with 5% CO_2. After that, cells were fixed with 4% paraformaldehyde and stained with Hoechst 33342. Images were taken in Olympus IX51 fluorescence microscope. Alternatively, NETs were quantified in culture supernatants using Quant-iT dsDNA kit. RSV F protein induced NETs, as visualized by fluorescence microscopy, similarly to LPS and PMA. F protein, LPS and PMA induced a 2-fold increase in NET release compared to control. We are currently investigating the effect of DNase on F protein-induced NET formation and the role of TLR-4 in this process. RSV F protein is able to stimulate NET formation, and the excess of NET production in the lungs of children with bronchiolitis caused by RSV may worse the pathology, since these DNA traps induce endothelial injury and impair lung function.

P1.07.20
An inactive chromatin configuration at the *IL-10* locus in human neutrophils

N. Tamassia[1]*, M. Zimmermann*[1]*, F. Bazzoni*[1]*, G. Natoli*[2]*, M. A. Cassatella*[1]*;*
[1]*University of Verona, Dep. of Pathology and Diagnostic, Verona, Italy,* [2]*European Institute of Oncology (IEO), Dep. of Experimental Oncology, Milan, Italy.*

The ability of human neutrophils to express IL-10, a key cytokine whose function is to limit and terminate the inflammatory responses by regulating the expression of pro- and anti-inflammatory mediators, is currently controversial in the literature. In our hands, in fact, stimulation of highly purified populations of human neutrophils with diverse pathogen-associated molecular patterns (PAMPs), including Toll-like receptors (TLR) and C-type lectin receptor (CLR) agonists, or damage-associated molecular patterns (DAMPs), including serum amyloid protein A (SAA), do not trigger any mRNA expression or production of IL-10, differently from autologous monocytes and from studies of other groups. To identify the molecular basis of IL-10 expression in human phagocytes, we evaluated the chromatin modification status at their IL-10 genomic locus. By chromatin immunoprecipitation (ChIP) assays, we analyzed posttranslational modifications of histones associated with genes that are active, repressed or poised for transcriptional activation, including H3K4me3, H4Ac, H3K27Ac and H3K4me1 marks. Differently from autologous IL-10-producing monocytes, none of the marks under evaluation was detected at the IL-10 locus of resting or activated neutrophils. By contrast, elevated H3K4me3, H4Ac, H3K4me1 and H3K27Ac levels were detected at syntenic regions of the IL-10 locus in mouse neutrophils. Altogether, data demonstrate that human neutrophils, differently from either monocytes or mouse neutrophils, cannot switch on the IL-10 gene because its locus is in an inactive state, likely reflecting a neutrophil-specific developmental outcome. Implicitly, data also definitively settle a currently unsolved issue on the capacity of human neutrophils to produce IL-10.

P1.07.21
Ouabain affects human monocyte activation and function

M. P. C. Teixeira*, V. M. Rumjanek;*
Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil.

Ouabain is a steroid that is capable of binding to Na^+-K^+-ATPase, inhibiting Na^+ and K^+ transport and triggering several cell signaling pathways. Despite the fact that the mechanisms of action and physiologic roles of ouabain are not well establish, some effects of ouabain in the immune system have been described, such as the inhibition of mitogen-induced proliferation of lymphocytes, the modulation of pro-inflammatory cytokines release by mononuclear cells and the decrease of CD14 expression by monocytes. However, its impact on monocyte activation and function has not been addressed so far. Thus, the aim of the present work was to examine if ouabain was able to modulate the expression of different surface molecules related to monocyte activation, as well as their endocytic activity and cytokine production. For that, mononuclear cells from healthy volunteers were separated by Ficoll-Hystopaque density gradient and cultured for 24 hours in the presence or absence of 10^{-7}M of ouabain, a concentration found in the plasma of patients treated with ouabain in clinical setups or in individuals under acute stress. Our results show that ouabain-treated monocytes expressed increased amounts of activation markers such as CD69, HLA-DR, CD80 and CD86. Moreover, ouabain induced an increase in the endocytosis of Dextran-FITC particles and in the production of IL-1, TNF-α and IL-10 by monocytes. Collectively, these results suggest that ouabain impacts monocyte activation and modulates monocyte functions, implying that this steroid could possibly act as an immunomodulator of these cells. This work was supported by CAPES, CNPq and FAPERJ.

Test-system for observing heat shock protein 70kDa (Hsp70) effect on reactive oxygen species production by immune cells

N. Troyanova*, R. Mirzoev, A. Sapozhnikov;*
IBCh RAS, Moscow, Russian Federation.

One of the most important aspects of the ROS biological activity is associated with the damaging effect on pathogens. But elevated ROS level can also lead to tissue damage. However, not all the mechanisms of ROS production regulation in cells are well investigated. We speculate that heat shock protein 70kDa (Hsp70) extracellular form may be one of the endogenous suppressors of the excessive ROS production by phagocytes.
The aim was to determine antioxidant potential of Hsp70.
Initially we have shown that 10 min heat stress treatment of the murine bone marrow cells with 60 min recovery at 37oC, prior to phorbol-12-myristate-13-acetate (PMA) activation, significantly reduced the intensity of the following ROS production compared with the control. Already after 5 min incubation in presence of Hsp70 we observed significant reduction of PMA-induced oxidative burst amplitude. The minimal concentration of Hsp70 required for the decrease of ROS production was strongly dependent from the incubation time and prolonged incubation decreased the effective Hsp70 concentration to 0.1 µg/ml. Strong dose-dependent effect of HSP70 was observed in the case of prolonged incubation. Besides effects on oxidative burst, Hsp70 reduces the level of spontaneous ROS production by the cells, which could be important in the process of aging regulation. In addition to the murine bone marrow model, the effect of HSP70 on oxidative burst was also demonstrated on human monocytes cell line THP-1. So, the antioxidant dose- and time-dependent effect of exogenously supplied Hsp70 on spontaneous and induced ROS production was shown using different cell models.

Functional limitations of plasmacytoid dendritic cells limit type I interferon, T cell responses and virus control in early life

E. Belnoue*, P. Fontannaz, C. Tougne, A. Rochat, A. Bergthaler, P. Lambert, D. Pinschewer, C. Siegrist;*
University of Geneva, Geneva, Switzerland.

Infant mortality from viral infection remains a major global health concern: viruses causing acute infections in immunologically mature hosts often follow a more severe course in early life, with prolonged or persistent viral replication. Similarly, the LCMV-WE strain causes acute self-limiting infection in adult mice but follows a protracted course in infant animals, in which LCMV-specific $CD8^+$ T cells fail to expand and control infection. By disrupting type I IFNs signaling in adult mice or providing IFN-α supplementation to infant mice, we show here that the impaired early life T cell responses and viral control result from limited early type I IFN responses. We postulated that pDCs, which have been identified as one major source of immediate-early IFN-I, may not exert adult-like function *in vivo* in the

early life microenvironment. We tested this hypothesis by studying pDC functions *in vivo* during LCMV infection and identified a coordinated downregulation of infant pDC maturation, activation and function: despite an adult-like *in vitro* activation capacity of infant pDCs, the expression of the E2-2 pDC master regulator (and of critical downstream antiviral genes such as MyD88, TLR7/TLR9, NF-kB, IRF7 and IRF8) is downregulated *in vivo* at baseline and during LCMV infection. This suggests that the limited T cell-mediated defense against early life viral infections is largely attributable to or regulated by infant pDC responses, and provides incentives for novel strategies to supplement or stimulate immediate-early IFN-α responses**.**

P1.08.02
The role of Dendritic Cells and Monocytes in Chronic Fatigue Syndrome/Myalgic Encephalomyelitis

E. W. Brenu[1,2]*, T. K. Huth*[1,2]*, S. K. Hardcastle*[1,2]*, L. Cosgrave*[2]*, D. R. Staines*[3,2]*, S. M. Marshall-Gradisnik*[1,2]*;*
[1]School of Medical Sciences, Griffith University, Gold Coast, Australia, [2]The National Centre for Neuroimmunology and Emerging Diseases, Griffith Health Institute, Griffith University, Gold Coast, Australia, [3]Queensland Health, Gold Coast Public Health Unit, Robina,, Gold Coast, Australia.

Bidirectional communication between the adaptive and innate immune system is necessary for optimal immune function. Irregularities in innate immune cell function may affect cellular processes in the adaptive system and vice versa. In Chronic Fatigue Syndrome/ Myalgic Encephalomyelitis (CFS/ME) a dysfunctional immune system has been described and this is characterised by reduced cytotoxic function in Natural Killer (NK) cells and CD8+T cells, altered neutrophil respiratory burst and equivocal levels in cytokine secretion. Dendritic cells (DCs) and macrophages are innate immune cells with highly versatile functions as they have a role in the development and function of almost all immune cells. Hence, the objective of this study was to determine the role of monocytes and DCs in CFS/ME patients. 20 CFS/ME patients (age=51.8±1.74 years) and 30 controls (age= 53.19±1.35years) were recruited for the study. Inclusion into the CFS/ME group was based on the Centre for Disease Prevention and Control (CDC 1994) criteria for CFS/ME. 10mL of whole blood was collected from all participants. Samples were stained with a cocktail of monoclonal antibodies containing HLA.DR, CD123, CD33, CD16 and CD11c. Samples were analysed on the flow cytometer to determine the levels of total monocytes, total DCs, myeloid DCs and lymphoplasmacytoid DCs. ANOVA was the statistical analysis used to analyse all data collected. Compared to the other immune cells, monocytes were significantly elevated in the CFS/ME patients in comparison to the controls. These results suggest further highlight the role of impaired immune function in the pathogenesis of CFS/ME.

P1.08.03
Lag-3 expression and role in human plasmacytoid dendritic cells biology

C. Camisaschi[1]*, A. De Filippo*[1]*, V. Beretta*[1]*, F. Rini*[1]*, M. Tazzari*[1]*, F. Arienti*[1]*, F. Triebel*[2]*, L. Rivoltini*[1]***, C. Castelli***[1]*;*
[1]Fondazione IRCCS Istituto Nazionale dei Tumori, Milano, Italy, [2]Immutep S.A., Faculté de Pharmacie, Chatenay-Malabry, France.

In the last decade several studies provided evidence that pDC infiltrate several types of human solid tumors. However, the role of tumor-associated pDC remains controversial.
LAG-3 is a CD4-related, activation-induced cell surface molecule expressed by various cells of the human lymphoid compartments and binds to MHC class II with high affinity. Data presented here demonstrate that LAG-3 is expressed on the cell surface of a subset of mature human circulating pDC. Interestingly, *in vitro*, LAG-3+ pDC migrate toward melanoma cell lines and *in vivo* in the tumor invaded LN of melanoma patients; here they display an activated phenotype and express TRAIL molecule. Based on these observations, and on the evidence that pDC up-regulate the basal expression of LAG-3 upon TLR-9 triggering, we hypothesize a functional role of this molecule in the pDC biology. Accordingly, LAG-3 stimulation on pDC, through MHC-II interaction, leads to their activation. pDC co-cultured with target cells, expressing HLA-DR molecule, selectively release cytokines such as IFN-α, TNF-α and IL-6 but not IL-1β and TNF-β, which are only secreted upon stimulation by CpG-A. Notably, while IFN-α and TNF-α release is lower than CpG-A, IL-6 production is far higher. Based on our findings, LAG-3 is likely involved in modulating the final functional outcome of pDC activation resulting from microenvironmental stimuli. A better understanding of the LAG-3 direct role on human pDC, with regard to its contribution in modulating pDC immunogenic vs. tolerogenic response, could have significant therapeutic implications in the treatment of cancer.

P1.08.04
Distinct modulation of human myeloid and plasmacytoid dendritic cells by anandamide in multiple sclerosis

V. Chiurchiu[1,2]*, M. Cencioni*[1]*, E. Bisicchia*[1]*, M. De Bardi*[1]*, C. Gasperini*[3]*, G. Borsellino*[1]*, D. Centonze*[1,4]*, L. Battistini*[1]*, M. Maccarrone*[1,5]*;*
[1]Santa Lucia Foundation, Rome, Italy, [2]University of Teramo, Teramo, Italy, [3]San Camillo Hospital, Rome, Italy, [4]University of Rome, Tor Vergata, Rome, Italy, [5]Campus Bio-Medico, University of Rome, Rome, Italy.

The immunopathogenesis of multiple sclerosis (MS) has always been thought to be driven by chronically activated and autoreactive Th-1 and Th-17 cells. Recently, also dendritic cells (DC) are now believed to highly contribute to antigenic spread as well as to maturation of adaptive immunity, and have been linked with disease progression and exacerbation. Yet, the role of DC in MS pathogenesis remains poorly understood. Here we report that in MS myeloid dendritic cells (mDC) produced higher levels of IL-12 and IL-6, whereas plasmacytoid dendritic cells (pDC) accounted for lower levels of IFN-α compared to healthy donors. Given the recent involvement of the endocannabinoid system in MS and its role in modulating immune functions, we found that the main endocannabinoid anandamide (AEA) significantly inhibited cytokine production from healthy mDC and pDC, as well as their ability to induce Th-1 and Th-17 lineages. Moreover, we found that in MS only pDC were unresponsive to AEA-induced cytokine inhibition and that this specific cell subset expressed higher levels of AEA-hydrolyzing enzyme FAAH. Overall, our data disclose a distinct immunomodulatory effect of AEA in mDC and pDC from MS patients, which may reflect an alteration of the expression of FAAH, thus forming the basis for the rational design of new endocannabinoid-based immunotherapeutics targeting a specific cell subset.

P1.08.05
NF-kB/RelA subunit plays the critical roles on the functions of plasmacytoid dendritic cells to thymus

T. Doi*, S. Mise, T. Fukazawa;*
RIKEN BRC, Tsukuba, Japan.

Plasmacytoid dendritic cells (pDCs) are a subtype of dendritic cells and thought to play the important roles in immune systems. However the functions in lives remain to be resolved. Those cells are present in a lot of tissues in whole bodies, especially in bone marrows, spleens and thymi. pDCs are thought to be present originally in bone marrows and transfer to thymi. Nuclear factor kappa B (NF-kB)/RelA subunit is one member of NF-kB family consisting of five members; RelA, RelB, c-Rel, p50 and p52 and plays the critical roles in multiple loci and multiple mechanisms. Mice lacking RelA are embryonic lethal due to tumor necrosis factor (TNF) cytotoxicity and therefore cannot be analyzed. We generated mice deficient of RelA and TNF both to obtain live mice lacking RelA. We previously demonstrated a lot of phenotypes that those mice exhibited. One of the phenotypes is the immune deficiency. We also found that pDCs were absent in thymi, although those cells were present in bone marrows and spleens. It remains so far to be elucidated what roles pDCs play in thymi and how pDCs work in thymi for immune system of whole bodies, although the population of pDC is minor. We are analyzing mice lacking RelA and TNF focused on (1) the mechanismof transfer to thymi, (2) the functions in thymi, of pDCs.

P1.08.06
Diminished Memory T-cell Expansion due to Delayed Kinetics of Antigen Expression by Lentivectors

***K. Furmanov**, A. Hovav;*
Heberew University, Jerusalem, Israel.

Memory CD8+ T lymphocytes play a central role in protective immunity. In attempt to increase the frequencies of memory CD8+ T cells, repeated immunizations with viral vectors are regularly explored. Lentivectors have emerged as a powerful vaccine modality with relatively low pre-existing and anti-vector immunity, thus, thought to be ideal for boosting memory T cells. Nevertheless, we found that lentivectors elicited diminished secondary T-cell responses with inferior protective capacity than that observed after priming. This was not due to the presence of anti-vector immunity, as limited secondary responses were also observed following heterologous prime-boost immunizations. By dissecting the mechanisms involved in this process, we demonstrate that lentivectors trigger exceptionally slow kinetics of antigen expression, while optimal activation of lentivector-induced T cells relays on durable expression of the antigen. These qualities hamper secondary responses, since lentivector-encoded antigen is rapidly cleared by primary cytotoxic T cells that limit its presentation by dendritic cells. Indeed, blocking antigen clearance by cytotoxic T cells via FTY720 treatment, fully restored antigen presentation. Taken together, while low antigen expression is expected during secondary immunization with any vaccine vector, our results reveal that the intrinsic delayed expression kinetics of lentiviral-encoded antigen, further dampens secondary CD8+ T-cell expansion.

P1.08.07
Migratory behavior of dendritic cells during the development of lupus

***M. A. Gleisner**[1], N. Crisóstomo[1], C. Fuentes[1], P. Reyes[2], M. Rosemblatt[1,2,3], M. R. Bono[1];*
[1]Universidad de Chile, Santiago, Chile, [2]Universidad Andres Bello, Santiago, Chile, [3]Fundación Ciencia & Vida, Santiago, Chile.

Analyses of lupus-prone congenic mice (NZWxNZB)F1 (BWF1) during the development of the disease have pointed out an important role of the spleen microenvironment since dendritic cells (DCs), that are essential for B and T cell function, accumulate in this tissue. We hypothesized that changes in DC biology may play a critical role in the pathogenesis of the disease. We found that most part of spleen DCs in lupic mice are of plasmacytoid origin and possess an overactivated phenotype. In this study we performed homing experiments demonstrating that lupic and pre-lupic DCs migrate preferentially to the spleen compared to DCs from control mice. In order to understand why pDC localize preferentially to the spleen in the course of the disease we evaluated the expression levels of chemokines and their receptors by macroarrays on DCs and stromal cells from spleens of lupic, prelupic and control mice. We observed significant differences in chemokine receptor pattern in DCs and stromal cells from lupic mice compared with control mice. Interestingly, we found that pDC of lupic mice do not express CCR9 receptor suggesting that these cells are unable to migrate to the thymus to promote central tolerance as it has been recently suggested. On the other hand, we are currently investigating whether DCs accumulation in spleen makes them resistant to apoptosis. In summary, our results show that the migratory behaviour of DCs from lupus prone mice BWF1 could contribute to the pathogenesis of lupus.

P1.08.08
Differentially activated respiratory plasmacytoid and CD11b-high dendritic cells accumulate during sublethal Klebsiella pneumonia infection

***H. Hackstein**[1], S. Kranz[1], A. Wachtendorf[1], G. Michel[1], J. Lohmeyer[2], G. Bein[1], N. Baal[1], S. Herold[2];*
[1]Clinical Immunology and Transfusion Medicine, University of Giessen, D-35385 Giessen, Germany, [2]Internal Medicine, University of Giessen, D-35385 Giessen, Germany.

Klebsiella pneumoniae is a leading cause of severe hospital-acquired respiratory tract infections and death but little is known regarding the modulation of respiratory dendritic cell (DC) subsets. Plasmacytoid DC (pDC) are specialized type 1 interferon producing cells and considered to be classical mediators of antiviral immunity. By using multiparameter flow cytometry analysis of respiratory DC subsets during murine respiratory Klebsiella pneumonia infection we show that pDCs and CD11b^{hi} DC were markedly elevated in the post acute pneumonia phase when compared to mock-infected controls. pDC identification during bacterial pneumonia was confirmed by extended phenotyping for 120G8, mPDCA-1 and Siglec-H expression and by demonstration of high Interferon-alpha producing capacity after cell sorting. Cytokine expression analysis of ex vivo-sorted respiratory DC subpopulations revealed elevated Interferon-alpha in pDC, elevated IFN-gamma, IL-4 and IL-13 in CD103^{+} DC and high IL-19 and IL-12p35 in CD11b^{hi} DC subsets in comparison to monocytic DC indicating distinct functional roles. Antigen-specific naive CD4^{+} T cell stimulatory capacity of purified respiratory DC subsets was analysed in a model system with purified ovalbumin T cell receptor transgenic naive CD4^{+} responder T cells and respiratory DC subsets, pulsed with ovalbumin and matured with Klebsiella pneumoniae lysate. CD103^{+} DC and CD11b^{hi} DC subsets represented the most potent naive CD4^{+} T helper cell activators. These results provide novel insight into the differential activation of respiratory DC subsets during Klebsiella pneumonia infection. The detection of increased respiratory pDC numbers in bacterial pneumonia may indicate possible novel pDC functions with respect to lung repair and regeneration.

P1.08.09
Analysis of the characterization of bone marrow derived dendritic subsets

***K. Hashimoto**[1], T. Kawasaki[1], T. Yamamoto[2], K. Takahashi[1], M. Kojima[1];*
[1]Chiba Institute of Technology, Faculty of Engineering, Department of Life and Environmental Sciences, Narashino City, Chiba, Japan, [2]Graduate School of Medicine,Chiba University, Chiba, Japan.

Studies of dendritic cells are important to understand antigen processing and presentation in innate and acquired immunity. Several reports have discussed different procedures induced different types of dendritic cells. In vitro culture system, the factor to characterize each dendritic cell is a different types of cytokines those are added to immature dendritic cells. Bone marrow derived dendritic cells (BMDC) are useful experimental tool because those cells have relatively homogeneous property and can be collected a certain amount of the number. Using mice system, it has been indicated that BMDC induced with GM-CSF and IL-4 showed more mature phenotype than that induced with GM-CSF only or GM-CSF and IL-15. As the characters of each BMDCs are still unclear, we have induced three different types of BMDC subset with different cytokine conditions. BMDCs induced by GM-CSF, GM-CSF and IL-4 or GM-CSF and IL-15, were compared the proliferation capacities. BMDC induced by GM-CSF and IL-15 showed the most vigorous proliferation activity, whereas BMDC induced by GM-CSF and IL-4 showed the most mature type character. To confirm the antigen uptake capacity, we used different size of antigens. Moreover, susceptibility to pathogen infection was analyzed to evaluate the most useful antigen presenting cell. We concluded that BMDCs induced by GM-CSF and IL-4 are not the most useful antigen presenting cells, although the method to induce them is well known.

P1.08.10
Increased tubulointerstitial recruitment of human CD141^{hi} CLEC9A^{+} and CD1c^{+} myeloid dendritic cells in fibrotic kidney disease

A. J. Kassianos[1,2], *X. Wang*[1,2], *S. Sampangi*[1,2], *K. Muczynski*[3], *H. Healy*[1,2], *R. Wilkinson*[1,2];
[1]*Queensland Health, Brisbane, Australia,* [2]*Royal Brisbane and Women's Hospital, Brisbane, Australia,* [3]*University of Washington, Seattle, WA, United States.*

Dendritic cells (DC) play critical roles in immune-mediated kidney diseases. Little is known, however, about DC subsets in diseased human kidneys, with previous studies restricted to limited pathologies and using only immunohistochemistry. In this study, we developed novel protocols for extracting renal DC subsets from a wide range of human kidney diseases and characterised them quantitatively and phenotypically by 10-colour flow cytometry. We detected significantly elevated numbers of total DC (CD45^{+} lineage^{-} HLA-DR^{+}), CD11c^{+}CD141^{hi} and CD11c^{+}CD1c^{+} myeloid DC (mDC) subsets in diseased biopsies with interstitial fibrosis compared to diseased biopsies without fibrosis and healthy kidney tissue. In contrast, CD11c^{-}CD123^{hi} plasmacytoid DC numbers were significantly higher in the fibrotic group compared to healthy tissue only. Numbers of all DC subsets also correlated with loss of kidney function. CD141^{hi} DC expressed CLEC9A, whilst the majority of CD1c^{+} DC lacked expression of CD1a and DC-SIGN, suggesting these mDC subsets may be infiltrating tissue counterparts of CD141^{hi} and CD1c^{+} blood DC. Immunohistochemical analysis revealed CLEC9A^{+} and CD1c^{+} cells restricted to the renal tubulointerstitial compartment. Notably, DC expression of costimulatory and maturation molecule CD86 was significantly increased in both diseased cohorts compared to healthy tissue. Consistent with an inflammatory environment, significantly higher levels of chemokine IL-8 were detected in the dissociation supernatants of diseased biopsies with fibrosis than both non-fibrotic diseased biopsies and healthy tissue. Collectively, our data indicate that activated mDC subsets recruited into the tubulointerstitium may play a critical role in the development of interstitial fibrosis and thus, progression to chronic kidney disease.

P1.08.11
Human dendritic cell subpopulations show distinct behavior in their interaction with the pathogenic mould Aspergillus fumigatus

J. Kungl[1], *T. Breitschopf*[1], *S. Krappmann*[2], *H. Einsele*[1], *J. Loeffler*[1];
[1]*Institute of Molecular Biology/Infectiology, Medical Clinic and Policlinic II, University Clinic Wuerzburg, Wuerzburg, Germany,* [2]2*Institute of Clinical Microbiology, Immunology and Hygiene, Friedrich-Alexander-University Erlangen-Nuernberg and University Clinic of Erlangen, Erlangen, Germany.*

Activities of dendritic cells (DCs) such as phagocytosis, expression of co-stimulatory molecules and cytokine release are required for the successful clearance of various pathogens. We investigated the interaction between different A. fumigatus morphotypes and subpopulations of human DCs (myeloid DCs (mDCs), plasmacytoid DCs (pDCs) and monocyte derived DCs (moDCs)).
MDCs, pDCs and monocytes were isolated from the peripheral blood of healthy volunteer donors using antibody bound magnetic MicroBeads. Monocytes were differentiated into moDCs over 6 days with IL-4 and GM-CSF. DCs were co-incubated with resting conidia or germlings and afterwards analyzed by time-lapse video microscopy, scanning electron microscopy, plating assays, flow cytometry, transwell assays and multiplex ELISA.
Co-incubation with fungal morphotypes did not result in pDC maturation and there was an absence of phagocytic activity and only limited cytokine secretion. The rare and random contacts of pDCs with fungal cells during live-imaging proved that pDCs do not recognize A. fumigatus. In contrast, mDCs and moDCs were able to recognize and to respond to fungal morphologies. Although, mDCs did not kill conidia or phagocytose fungal morphotypes as well as moDCs, they matured and secreted comparable amounts of cytokines; making them both potential T cell stimulators and recruiters of neutrophile granulocytes.
In conclusion, our in vitro data elucidate the distinct interaction between DC subpopulations and A. fumigatus, which indicate their different roles in the pathogenesis of invasive aspergillosis and may be important to decide on using moDCs or mDCs for future immunotherapy approaches.

P1.08.12
CCR2^{+} monocyte-derived antigen-presenting cells from the genital tract promote Th1 and Th17 immunity after HSV-2 infection

S. Lee*, H. Yang, M. Kweon;*
International Vaccine Institute, Seoul, Republic of Korea.

Monocytes are a distinct cell subset that mediates innate and adaptive immunity in mucosal sites. However, the role of monocyte-derived APCs (MD-APCs) is not fully understood. Here we explored the *ex vivo* function of monocytes isolated from the genital tract after infection with herpes simplex virus 2 (HSV-2) which causes genital ulceration. The monocytes (CD11b^{+}Gr1^{+}MHC class II^{+}) exist in the vaginal tissue from Depo-Provera treated naïve female mice. This subset intrinsically acts as APCs by inducing antigen-specific T cell proliferation at a level comparable to that of conventional dendritic cells. Interestingly, the monocyte- subsets significantly accumulated in the genital tissues after HSV-2 infection and the recruited monocytes secreted inflammatory cytokines (i.e., IL-6 and TNF-α) and chemokines (i.e., MCP-1 and RANTES) upon recognizing the infection. The monocyte-derived APCs induced CD4^{+} T cells to generate numerous cytokines such as IFN-γ (Th1) and IL-17A (Th17) in an antigen-specific manner, as compared with other CD11b^{+} myeloid cells. The phenotype of MD-APCs was Ly6C^{high}, Ly6G^{low}; in addition, MD-APCs expressed co-stimulatory molecules such as CD40, CD80 and CD86. MD-APCs were located beneath the vaginal epithelium and migrated there in a CCR2-dependent, but CXCR2-independent manner. In summary, CD11b^{+}Gr1^{+}MHC class II^{+} monocytes obtained from the mouse genital tract performed as APCs to generate Th1 and Th17 CD4^{+} T cell responses in during HSV-2 infection.

P1.08.13
Interleukin-22 binding protein (IL-22BP) is constitutively expressed by a subset of conventional dendritic cells and is strongly induced by retinoic acid

J. C. Martin[1,2], *G. Bériou*[1], *M. Heslan*[1], *C. Chauvin*[1], *L. Utrianen*[3], *A. Aumenier*[3], *C. Scott*[3], *A. Mowat*[3], *V. Cerovic*[3], *S. Houston*[3], *M. Leboeuf*[4], *F. Hubert*[1], *C. Hémont*[2], *M. Merad*[4], *S. Milling*[3], *R. Josien*[1,2];
[1]*INSERM UMR_S 1064, Nantes, France,* [2]*Laboratoire d'Immunologie, CHU Hôtel Dieu, Nantes, France,* [3]*Institute of Infection, Immunity, and Inflammation, College of Medical, Veterinary and Life Sciences, University of Glasgow, Glasgow, United Kingdom,* [4]*Department of gene and cell medicine and the department of medicine, Mount Sinai school of medicine, New York City, NY, United States.*

Interleukin-22 (IL-22) is mainly produced at barrier surfaces by T cells and innate lymphoid cells. By acting on its membrane receptor, IL-22 promotes antimicrobial immunity, inflammation and tissue repair of epithelial cells. These properties make IL-22 an important player in the maintenance of barrier surface integrity. However, dysregulated IL-22 actions lead to deleterious inflammation and is involved in diseases such as psoriasis, intestinal inflammation, and cancer. These two faces of IL-22 emphasize the importance of IL-22 regulation. Interestingly, IL-22 has a soluble inhibitory receptor, called IL-22BP, which acts as a crucial regulator of IL-22. We show both in rats and mice that, in the steady state, the main source of IL-22BP is a subset of conventional dendritic cells (DCs) in lymphoid and non-lymphoid tissues. IL-22BP expression was detected both at the mRNA and protein levels in rat splenic CD4+ DC. qPCR experiments revealed an even stronger expression by the same DC subset in both mesenteric lymph nodes and gut draining lymph. In mouse, high expression of IL-22BP was also specifically found in mouse CD103+ CD11b+ intestinal lamina propria DC. In humans, monocyte derived DC (MDDC) expressed IL-22BP whereas monocytes did not. IL-22BP expression was strongly induced in a retinoic acid (RA)-dependent manner in MDCC. Taken together, our results indicate that IL-22BP is constitutively produced by a subset of cDC and that RA positively regulates IL-22BP expression. Our data suggest that RA-producing intestinal DC may actively participate in the regulation of IL-22 in the gut by producing high levels of IL-22BP.

P1.08.14
Human 6-sulfo LacNAc$^+$/CD16$^+$ dendritic cells are distinct from Tie-2$^+$ monocytes

A. Micheletti[1], *C. Costantini*[1], *F. Calzetti*[1], *W. Vermi*[2], *M. A. Cassatella*[1];
[1]*Department of Pathology and Diagnostics, Division of General Pathology, University of Verona, Verona, Italy,* [2]*Department of Molecular and Translational Medicine, Section of Pathology, University of Brescia School of Medicine, Brescia, Italy.*

6-sulfo LacNAc$^+$ dendritic cells (slanDCs) represent a distinct population of circulating and tissue pro-inflammatory DCs. Given their high CD16 and low CD14 expression by flow cytometry, slanDCs overlap with the heterogeneous population of the CD14^{low}CD16$^+$, non-classical monocytes, which also include the Tie2-expressing monocytes (also known as TEMs; Blood. 2007; 5276-85). TEMs have been shown to generate a perivascular cell population endowed with a prominent pro-angiogenic potential in a variety of human and mouse primary tumors, including human carcinomas. To clarify whether slanDCs and TEMs could eventually represent the same cell population, we analyzed if slanDCs express Tie-2 at both protein and mRNA level, in addition to other TEM markers. We found that even though circulating slanDCs, similarly to TEMs, stain positive for CD16, CD33, CD13, CD11b and CD11c, but negative for CCR2 and CD62L, they completely lack Tie-2, both at RNA and protein level, as assessed by means of flow cytometry, western blot and immunohistochemical analysis. Additional experiments proved that slanDCs are different from TEMs also for their behavior, since, at variance with TEMs, slanDCs are not perivascular in tissues and are not found in primary tumors. By contrast, slanDCs are selectively posed at the interface between epithelial cells and the nearby lymphoid compartments in mucosal lymphoid tissues, where, again, they result Tie2-negative. Taken together, these data demonstrate that human slanDCs are distinct from TEMs by a number of parameters.

P1.08.15
Distinct subsets of dendritic cells regulate the outcome of colonic inflammation

A. B. Mohammad Muzaki, ***C. Ruedl****;*
Nanyang Technological University, Singapore, Singapore.

Intestinal dendritic cells (DCs) are crucial in establishing tolerance towards food and commensals but, at the same time, they are fundamental in directing appropriate immune responses to pathogens. However, it is still not clear what are the roles of different DC subsets in regulating gut homeostasis in health and disease.
In order to get further insights into this, we have recently generated three transgenic mouse strains that allow us to ablate in vivo specifically different subsets of intestinal DCs (Siglec-H-, Clec9a-, Clec4a4-DTR strains). They allow us to study the roles of distinct intestinal DC subsets (SiglecH$^+$CD11c^{int} DCs, CD103$^+$CD11b$^-$ CD11c^{high} and CD103$^+$CD11b$^+$ CD11c^{high}) in acute DSS-mediated colitis. After a single round of 3% DSS treatment, a mild colitis was observed in wild type and in DT treated Siglec-H DTR mice suggesting that absence of pDCs does not increase the severity of intestinal inflammation. In contrast the DT injected Clec9A DTR mice, where CD103$^+$CD11b$^-$CD11c^{high} DCs are efficiently ablated showed much exasperated inflammation. This could be visualized by a more pronounced body weight lost, increased fecal blood as well as enhanced colonic infiltration of neutrophils and inflammatory Cx3CR1^{int} monocytes. On the other hand, the mice with CD103$^+$CD11b$^+$CD11c^{high} DC ablation did barely show any colitis signs under the same DSS regiment suggesting their pro-inflammatory nature. Our results strongly suggest a unique regulatory function of the CD103$^+$CD11b$^-$CD11c^{high} DC subset in controlling intestinal inflammation.

P1.08.16
Analysis of the expression of the inhibitory receptor ILT4 on dendritic cells from systemic lupus erythematosus (SLE) patients

A. E. Monsivais Urenda*, P. Guerra de Blas, E. Zárate Hernández;*
Universidad Autónoma de San Luis Potosí, San Luis Potosí, Mexico.

Dendritic cells (DC) are a subpopulation of leukocytes specialized in the capture and process of antigens and its presentation to T lymphocytes. There are two major subsets of DCs, myeloid or classic DCs (mDC) and plasmacytoid DC (pDC). DCs have been recognized to play a pivotal role in the development and maintenance of immune tolerance. In this regard, the tolerogenic effect of DC seems to depend on different factors, as the presence of immune-regulatory cytokines, certain tissue factors, and the nature of the antigen as well as the receptors expressed on their cell surface. The regulatory ILT's/CD85 receptors are associated with a tolerogenic effect of mDCs and previous studies have indicated the important role of these receptors on the pathogenesis of autoimmune diseases. The inhibitory receptor ILT4/LILRB2 is expressed in myeloid cells and it has been related with the tolerogenic phenotype of DC. In this work, we analyzed the expression of ILT4 in circulating pDC and mDC by polychromatic flow cytometry. pDC and mDC were detected in the basis of the expression of linage markers, HLA-DR, CD11c, BDCA1 or BDCA4. We studied fourteen patients with SLE and ten healthy volunteers. We observed that ILT4 is expressed in high levels on both subpopulations of DC (media of positive cells- pDC: 77%; mDC: 76%) from healthy volunteers. In contrast, the expression of ILT4 was significantly diminished in both pDC`s and myeloid DC's (mDC's) from SLE patients. Our results suggest that ILT2 participates in the defective immune-regulation observed in patients with SLE.

P1.08.17
Human conventional CD1c+ Dendritic Cells produce IL-12 and induce potent CD8+ T cell priming

G. Nizzoli*;*
INGM, Milan, Italy.

BDCA-3+ dendritic cells are thought to be the human equivalents of murine CD8α+ DC, which cross-prime CD8+ T-cell responses and secrete high amounts of IL-12. We compared human myeloid DC expressing CD1c or BDCA-3 and plasmacytoid DC for cytokine production and surface receptor expression in peripheral blood and lymphoid tissues, and assessed their capacities to induce cytotoxic T cell responses.
We found that mDC1, but not other DC or monocyte subsets could secrete high amounts of IL-12p70. IL-12 production by mDC1 was tightly controlled, as it required combinational Toll-like receptor (TLR) stimulation and was fine-tuned by lymphocyte-derived stimuli. Conversely, mDC2 produced high levels of IFNlambda in response to TLR-3 stimulation alone. pDC secreted IFNalpha αvδ expressed lower levels of MHC class-I and -II, CD40 and CD86 than myeloid DC. Moreover, they poorly cross-presented soluble antigens to CD8+ T cells. In contrast, both mDC1 and mDC2 could cross-present efficiently, but required different combinations of TLR ligands. Nevertheless, all DC subsets induced secondary expansions of CD8+ memory T-cells upon licensing by CD4+ T-cells. Furthermore, following appropriate TLR stimulation and help by CD4+ T cells, all DC primed naive CD8+ T-cells. However, while mDC1 induced high levels of Granzyme B via IL-12, mDC2 and pDC induced preferentially Granzyme A.
Our results show that CD1c+ mDC1 are a relevant source of IL-12 for naïve T cell priming, and that specific pathogen-derived stimuli and CD4 help can instruct different DC subsets to induce cytotoxic T-cell responses.

Tumor cell-derived Ag cross-presentation in human DC induced by NK cells: Mechanisms and specialization of the BDCA-3+ DC subset

V. Ollion[1], *F. Deauvieau*[1], *A. Doffin*[1], *E. Verronese*[1], *I. Durand*[1], *J. Marvel*[2], *H. Vie*[3], *C. Caux*[1], *J. Valladeau-Guilemond*[1];
[1]*Centre de Recherche en Cancérologie de Lyon, INSERM 1052, CNRS 5286, Lyon, France,* [2]*Université de Lyon, IFR 128, INSERM U851, Lyon, France,* [3]*INSERM U892, Nantes, France.*

Dendritic cells (DC) cross-present antigen (Ag) to initiate T cell immunity against most infectious and tumors. A more detailed understanding of the mechanisms involved is thus a major challenge for immunologists.
Natural killer (NK) cells have emerged as key modulators of multiple DC functions. We showed that human NK cells also promote cross-presentation of tumor cell derived Ag by DC, independently of their cytotoxicity. Instead, we highlighted a critical role for IFN-γ and TNF-α production by NK cells in this cross-presentation function.
Furthermore, we studied the impact of IFN-γ and TNF-α in the regulation of Ag processing machinery, in particular Ag degradation which is known to impact on cross-presentation efficacy. It seems that IFN-γ and TNF-α do not act on endosomal degradation but may be involved in other key Ag processing steps.
Finally, recent issues have shown that human blood and lymph node BDCA-3+ DC are specialized for cell-associated Ag cross-presentation compared to CD11b+ DC. Thus we set up purification and *in vitro* generation protocols to obtain those myeloid DC subsets. After a better characterization of their extensive phenotype and TLR response, we observed a high Ag cross-presentation induced by NK cells specifically in the BDCA-3+ DC subset.
In conclusion, our findings point toward a novel role for NK cells bridging innate and adaptive immunity that could allow to better harness Ag specific cellular immunity in immunotherapy.

P1.08.19

IL-21 promotes plasmacytoid dendritic cell-NK cell cooperation through the production of granzyme B

V. Salvi[1], *W. Vermi*[1], *A. Cavani*[2], *S. Lonardi*[1], *T. Carbone*[2], *P. Seeger*[1], *D. Bosisio*[1], *F. Facchetti*[1], *S. Sozzani*[1];
[1]*Dept Molecular and Translational Medicine, University of Brescia, Brescia, Italy,* [2]*Laboratory of Experimental Immunology, Istituto Dermopatico dell'Immacolata-Istituto di Ricovero e Cura a Carattere Scientifico, Rome, Italy.*

Plasmacytoid dendritic cells (pDC) are at the interface of innate and adaptive immunity and regulate immune functions at multiple levels. Granzyme B (GrB) is one of the most abundant pDC transcripts, though the mechanisms of regulation and the biological role of this protein are largely unknown. Here we report that among the Th1 and Th17 cytokines investigated, IL-21 was the only one able to induce the expression and secretion of GrB. Conversely, TLR-induced maturation of pDC inhibited GrB expression through the production of type I IFN. IL-21 expression was strongly upregulated in systemic lupus erythematosus (LE), an autoimmune disease characterized by pDC and NK cell infiltration and epithelial cell damage. In LE, pDC co-localize in large extent with NK cells. In vitro, supernatants of IL-21-activated pDC promoted autologous keratinocyte killing by both resting and activated NK cells and this action was inhibited following GrB immunodepletion. These results outline the mechanisms of GrB regulation in pDC and propose a role for GrB in pDC and NK cell biological interaction.

P1.08.20

Intestinal Aldh1a2$^+$CD103$^+$CD8a$^+$ DCs preferentially induce Th1 cells but not Tregs

B. Yang[1,2], *E. Lee*[1], *J. Kim*[1], *M. Jang*[1], *C. Hong*[1], *M. Song*[1], *A. Kumanogoh*[3], *Y. Sung*[1], *C. D. Surh*[2], *M. Jang*[1];
[1]*Division of Integrative Biosciences and Biotechnology, Pohang University of Science and Technology (POSTECH), Pohang, Republic of Korea,* [2]*Academy of Immunology and Micobiology, Institute of Basic Science (IBS), Pohang, Republic of Korea,* [3]*Laboratory of Immunopathology, WPI Immunology Frontier Research Center, Osaka, Japan.*

Intestinal CD103$^+$ DCs express retinoic acid (RA)-producing enzyme Aldh1a2 and efficiently promote generation of Foxp3$^+$ Treg cells. These DCs promote expression of gut homing receptors, such as CCR9 and integrin $\alpha_4\beta_7$, on T cells via a RA-dependent mechanism, but are thought to be largely incapable of inducing Th1 cells. However, Th1 cells are abundant in the intestine and IL-12p40 promoter is highly activated in the small intestine under steady-state conditions. Here, we have further divided the CD103$^+$ DC population in the lamina propria (LP) into two different subsets based on CD11b and CD8α expression and found that one of these subsets may be responsible for inducing the Th1 response. Specifically, CD103$^+$CD11b$^-$CD8α$^+$ LP-DCs preferentially produce IL-12 (p35/p40) and IL-12p40 whereas CD103$^+$CD11b$^+$CD8α$^-$ LP-DCs secrete IL-23 (p19/p40) upon stimulation with TLR agonists. Consistent with this, CD103$^+$CD11b$^-$CD8α$^+$ LP-DCs preferentially induce Th1 cells whereas CD103$^+$CD11b$^+$CD8α$^-$ LP-DCs induce Th17 cells. Interestingly, CD103$^+$CD11b$^-$CD8α$^+$ LP-DCs have lower efficiency to induce Foxp3$^+$ Treg cells compared to CD103$^+$CD11b$^+$CD8α$^-$ LP-DCs although both populations imprint gut homing CCR9$^+$ T cells in vitro. Taken together, these findings suggest that Aldh1a2$^+$CD103$^+$CD11b$^-$ CD8α$^+$ LP-DCs play an important role in generation of gut-tropic Th1 cells.

P1.08.21

Independence of ICOS-L expression on IL-10 production by DC and its impact on T cell subsets in respiratory tract infection

X. Gao, *J. Yang, X. Yang;*
University of Manitoba, Winnipeg, MB, Canada.

The association of ICOS-L expression and IL-10 production by dendritic cells (DCs) has been commonly found in many infectious disease models. DCs with high ICOSL expression and IL-10 production are reportedly more efficient at inducing regulatory T cells (Treg). To test whether IL-10 production and ICOS-L expression has a causal relationship, we examined ICOS-L expression by DC in IL-10 knockout (KO) mice following *Chlamydia muridarum* (Cm) lung infection. In addition, we also examined the development of T cell subsets, including Treg, Th17 and Th1 cell, in the condition of IL-10 deficiency and its relationship with ICOSL/ICOS signaling following infection. Surprisingly, we found that DCs from IL-10 KO mice exhibited significantly higher ICOS-L expression than WT DCs. Moreover, we found that the IL-10 KO mice showed lower Treg but higher Th17 and Th1 responses. Further analysis of Th17 and Th1 cells showed that only the Th17 response was dependent on ICOS signaling. Consistently, most of the Th17 cells were ICOS+, while most of the Th1 cells were ICOS- following Cm infection. Furthermore, neutralization of IL-17 in IL-10 KO mice significantly exacerbated lung infection. These results suggest that ICOSL expression on DCs is independent of IL-10. They further suggest that ICOS-L expression on DCs in the presence or absence of IL-10 co-stimulation may respectively promoting Treg or Th17 response, without having significant impact on Th1.

House dust mite-sensitized myeloid dendritic cells induce reduction of allergen-specific murine airway inflammation

L. Aragão-França[1], *F. Costa*[1], *D. Athanazio*[1], *N. Alcântara Neves*[2], *L. Pontes de Carvalho*[1];
[1]*Research Center Gonçalo Moniz- FIOCRUZ, Salvador, Brazil,* [2]*UFBA, Salvador, Brazil.*

Allergies affect about 20 to 30% of the world population and its prevalence, as well as the severity of their symptoms, has been increasing in recent decades. *Blomia tropicalis* (Bt) has been implicated as one of the most important causative agents of allergic diseases in many latin-american countries, been related to asthma, atopic dermatitis and rhinitis. Dendritic cells (DCs) in a state of partial maturation have a tolerogenic profile, being able to induce immunological tolerance. In this work, the effect of intraperitoneally injected myeloid DCs that had been *in vitro* sensitized with a Bt extract (BtE) was evaluated in an experimental respiratory allergy model. In allergic models, allergen-specific T helper type 2 (Th2) cells produce key cytokines that regulate the synthesis of allergen-specific IgE and control tissue eosinophilic airway inflammation and airway remodeling. These parameters were evaluated in mice that were intraperitoneally immunized with aluminium hydroxide-adsorbed BtE and intranasally challenged with soluble BtE. The previous inoculation of BtE-sensitized DCs significantly reduced the total number of leukocytes and the number of eosinophils in bronchoalveolar lavage fluid and reduced the production of IgE serum. In addition, reduced lung inflammatory infiltrate was observed in animals that had been treated either with BtE-sensitized DCs or with ovalbumin-sensitized DCs. Those results indicate that the use of tolerogenic DCs should be further investigated as a possible therapeutic strategy for the control of allergen-triggered airway inflammation.

P1.09.02
E-cadherin contribution for Langerhans cell differentiation

H. Azuma[1], *N. Mayumi*[1], *E. Watanabe*[1], *Y. Norose*[1], *E. Watari*[1], *S. Kawahara*[2], *T. B. H. Geijtenbeek*[3], *H. Takahashi*[1];
[1]*Nippon Medical School, Department of Microbiology and Immunology, Tokyo, Japan,* [2]*Nippon Medical School, Department of Dermatology, Tokyo, Japan,* [3]*University of Amsterdam, Academic Medical Center, Department of Experimental Immunology, Amsterdam, Netherlands.*

Human skin contains the following two distinct DC subsets: (i) Langerhans cells (LCs), expressing Langerin but not DC-specific intercellular adhesion molecule-3-grabbing non-integrin (DC-SIGN), are predominantly localized in the epidermis; and (ii) dermal DCs, expressing DC-SIGN but not Langerin, are observed mainly in the dermis. By focusing on LC localization in the epidermis, we have recently reported that E-cadherin expressed by epidermal keratinocytes (KCs) is crucial for differentiation of LCs induced from peripheral blood monocytes (PBMOs) [Eur. J. Immunol. 43:280-280, 2013]. Monocytes differentiated into LC-like cells in the presence of IL-4, GM-CSF, and TGF-β1 expressed not only Langerin but also DC-SIGN. Notably, co-culturing of these LC-like cells with KCs expressing E-cadherin or recombinant E-cadherin strongly decreased expression of DC-SIGN and further induced a phenotype similar to purified epidermal LCs. Moreover, pretreatment of LC-like cells with anti-E-cadherin-specific antibody completely abolished their Langerin expression, indicating the requirement of E-cadherin-E-cadherin interactions for the differentiation into Langerin+ cells. These findings suggest that E-cadherin expressed by KCs provide environmental cues that induce differentiation of LCs in the epidermis. Based on these findings, we examined whether we could induce similar type of LCs from CD34+ human hematopoietic progenitor cord blood cells by co-culturing KCs or recombinant E-cadherin and compared their phenotypic features and functions with PBMO-derived LCs. These results may provide the new analytical tools for investigating various dermal diseases such as atopic dermatitis and psoriasis vulgaris.

P1.09.03
Novel inducible immortalized dendritic cell line with entire properties of primary cells

J. Bandola[1], *C. Richter*[1], *S. Thieme*[1], *M. Laugsch*[1], *K. Anastassiadis*[2,3], *S. Brenner*[1,2];
[1]*University Clinic Carl Gustav Carus Dresden, Dresden, Germany,* [2]*CRTD TU Dresden, Dresden, Germany,* [3]*BIOTEC TU Dresden, Dresden, Germany.*

As the sentinels between innate and adaptive immunity, dendritic cells maintain the balance of pathogen defense and tolerance to self proteins. Studies with these professional antigen presenting cells are mainly limited by their low numbers in vivo and their difficult maintenance in vitro. During last years, the potential and the important role of dendritic cells in orchestrating the adaptive immune response were examined in more detail. Elaborate investigations of dendritic cells for immunotherapies need standardized, reproducible experimental conditions. In our study, we generated conditionally immortalized dendritic cells with classical dendritic cell properties and a stable long term phenotype. We differentiated bone marrow cells from transgenic mice expressing an inducible SV40 large T-antigen into dendritic cells. When immortalized by dexamethasone and doxycycline, these cells were stable in long-term culture. In the absence of both factors (de-induction), dendritic cells displayed properties of primary cells, characterized by expression of classical dendritic cell surface markers CD11c, CD11b, MHCII, CD40 and CD86. Furthermore, de-induced LPS-activated dendritic cells secreted IL-1β, IL-6, TNFα and IL-12. De-induced, Ovalbumin-loaded dendritic cells polarize $CD4^+$ T cells into Th1, Th17 and Th2 cells, indicating their correct antigen presenting property. Consistent with intratracheal application of Ovalbumin-loaded primary dendritic cells into mice, the application of de-induced dendritic cells resulted in recruitment of lymphocytes to the lungs. In summary, we successfully expanded dendritic cells using conditional immortalization. The generated dendritic cells demonstrate the characteristic immunophenotype of primary dendritic cells and will facilitate further studies on immunomodulatory properties of dendritic cells.

P1.09.04
Age-associated shift in rat dendritic cell T-helper polarizing capacity

B. Bufan[1], *Z. Stojić-Vukanić*[1], *N. Arsenović-Ranin*[1], *D. Kosec*[2], *I. Pilipović*[2], *M. Peri□ić*[2], *J. Đikić*[3], *G. Leposavić*[3];

Almost all cellular components of innate and adaptive immunity undergo age-related remodeling. The findings on age-related changes in human and mouse dendritic cells (DCs) are conflicting, whereas there is no data on the influence of aging on rat DCs. In attempt to fill this gap, freshly isolated splenic conventional OX62+ DCs from 3- (young) and 26-month-old (aged) Albino Oxford rats were examined for subset composition, cell surface expression of activation markers (CD80, CD86 and CD40 and MHC II molecules) and endocytic capacity using flow cytometric analysis (FCA). In addition, splenic OX62+ DCs isolated from rats of both ages were cultured in the presence or in the absence of LPS. These cells were examined for the activation marker and TNF-α, IL-6, IL-12, IL-23, TGF-β1, IL-10 expression using FCA, and RT-PCR and ELISA, respectively. Moreover, the allostimulatory capacity of OX62+ DCs and allogeneic CD4+ T cell cytokine (IFN-γ, IL-4 and IL-17) production in MLR was quantified using FCA and ELISA, respectively. It was found that aging: i) in OX62+ DCs population leads to a shift in CD4+:CD4- cell ratio towards CD4- cells and ii) influences OX62+ DCs maturation capacity (judging by activation marker expression and efficiency of endocytosis) by affecting action of intrinsic (TNF-α and IL-10) and extrinsic regulatory factor expression. Furthermore, in LPS-matured OX62+ DCs from aged rats TNF-α, IL-12, IL-23 and IL-6 expression was increased, while IL-10 expression was diminished. Moreover, in MLR, OX62+ DCs from aged rats exhibited enhanced Th1/Th17 driving force and diminished allostimulatory capacity.

P1.09.05
Junctional Adhesion Molecules and Dendritic Cell Migration

*S. Roh, **S. Byeon**, C. Yoon, Y. Bae;*
Sungkyunkwan University, Suwon, Gyeonggi-do, Republic of Korea.

Dendritic cells (DC) are well-established migratory professional antigen presenting cells (APC) with the capacity of transendothelial migration (TEM). However, the mechanism underlying DC TEM has not yet been elucidated. Among JAM family molecules (JAM1, 2, 3, 4, and L), JAM-Like (JAML) has been reported to be involved in neutrophil and monocyte TEM. In the present study, we found that JAML is also involved in the TEM of mouse bone-marrow derived dendritic cells (BMDC), but not in the TEM of human monocyte-derived DC (MODC). BMDC efficiently transmigrated in response to chemokines *in vitro* and *in vivo*. Treatment with anti-JAML antibody or JAML knock-down significantly reduced the TEM activity of BMDC in a dose-dependent manner. Furthermore, the analysis of BMDC binding to TNF-α-preactivated bEND.3 monolayer revealed that the interaction between the JAML of BMDC and the coxsackie and adenovirus receptor (CAR) of endothelial cells plays an important role in TEM of BMDC. These findings suggest that JAML and CAR play an important role in the TEM of BMDC. In contrast, human MoDC do not express JAML protein, but have normal TEM capacity. MoDC express only JAM1 among the JAM family. In the TEM assay using HUVEC (Human Umbilical Vascular Endothelial Cells) monolayer, anti-JAM1 antibody efficiently inhibited the TEM capacity of MoDC. Pre-treatment of HUVEC with anti-JAM1 antibody also reduced the TEM activity of MoDC. Our present findings suggest that the expressions of JAM family molecules and JAM-mediated TEM of DC are likely dependent on the DC subtypes and/or species.

P1.09.06
CD300 molecules as regulators of dendritic cell responses

***G. J. Clark**, R. Gasiorowski, P. Fromm, D. N. J. Hart;*
ANZAC Research Institute, Sydney, Australia.

The human CD300 family consists of six immunoregulatory membrane molecules that are expressed by leucocytes of which four, CD300b, d, e and f, are restricted to cells of the myeloid/ dendritic cell (DC) lineage. Ligands for CD300a-f include lipids such as phosphatidylserine, phosphatidylcholine and cardiolipin. We and others have shown that CD300 molecules regulate a broad range of cellular activity including differentiation, viability, cytokine and chemokine secretion, phagocytosis and chemotaxis. In transfectants CD300 molecules can form heterodimers. Human peripheral blood monocyte and DC sub-populations have specific functions, and many of these are regulated by CD300 molecules. The potential to form different CD300 heterodimers, adds further potential to their role in modulating DC function. We used in house produced mAb and commercially available mAb to document CD300a-f expression on human blood DC populations in response to a variety of inflammatory stimuli. The CD300a and CD300a/c mAb bound all DC populations. mAb to CD300d,e&f did not bind to the $CD141^+$ and pDC populations and the CD300f mAbs also failed to bind to $CD1c^+$ DC. DC mRNA analysis validated individual CD300 molecule expression and potential heterodimers. Exposure to different activators (TLR ligands, Retinoic acid) altered the pattern of CD300a-f expression. The finding that not all CD300 molecules appear on the plasma membrane at all times adds further complexity to CD300 mediated regulation. Changing their membrane levels can dramatically change CD300 mAb targeted DC functions. The data emphasizes CD300 molecules as important players in balancing DC stimulatory and tolerogenic outcomes.

P1.09.07
Human monocyte-derived dendritic cells required direct contact with natural killer cells to induce a Th1 profile of response

***M. A. Clavijo Salomón**, R. N. Ramos, G. G. Romagnoli, B. Zelante, J. A. M. Barbuto;*
University of Sao Paulo, Sao Paulo, Brazil.

Natural killer (NK) cells can promote the maturation of dendritic cells (DCs), but their role in the differentiation of monocytes into DCs remains unclear. Here, we investigated if human NK cells, through direct contact or by their products, affect Mo-DCs differentiation *in vitro*. $CD14^+$ monocytes were purified from healthy donors' blood and co-cultured with isolated NK cells ($CD56^+CD3^-$) in the presence of IL-4 and GM-CSF, in a transwell® system or in direct contact. At day 5, TNF-α was added and 48h later Mo-DCs were harvested, phenotyped and co-cultured with CFSE-labeled allogeneic T lymphocytes. After additional 5 days lymphoproliferation was determined and cytokines in supernatants quantified by CBA (BD™). Mo-DCs differentiated in contact with NK cells (NK-Mo-DCs) up-regulated the expression of HLA-DR, CD80, CD86, CD83, CCR7 and CD11c, were more potent stimulators of lymphocyte proliferation and induced a Th1-like cytokine secretion profile (IL-2, IFN-γ and TNF-α) when compared to the control group. In contrast, Mo-DCs differentiated only in the presence of NK cells' products down-regulated the expression of the mentioned molecules, were less stimulatory of lymphocyte proliferation, and induced an increase in IL-10 production. In both situations, the effect was independent of the NK cell donor. These results suggest that NK cells, through direct cell contact or through their products, may have opposite effects on Mo-DCs differentiation, and particularly NK-Mo-DCs contact seems to be required to induce a polarized Th1-like profile. This phenomenon could have potential implications for immunotherapeutic approaches based on Mo-DCs. Supported by FAPESP # 2009/54599-5, 2011/05331-0 and 2012/23478-0.

P1.09.08
Cytokine production by human dendritic cells treated with Brazilian propolis

***B. J. Conti**, K. B. Santiago, E. O. Cardoso, J. M. Sforcin;*
UNESP, Botucatu, Brazil.

Dendritic cells (DC) are professional antigen presenting cells (APCs) and play an essential role in the initiation and modulation of immune responses. DC may generate either immunity or tolerance by expressing costimulatory molecules and producing pro- or anti-inflammatory cytokines. Propolis is a resinous product, made by honey bees from various plant parts, and has attracted the attention of researchers because of its biological properties, highlighting its immunomodulatory effects. Thus, this work aimed to investigate propolis modulatory effect in vitro, evaluating TNF-α and IL-10 production by human DC. Human monocytes were obtained from healthy donors and incubated with IL-4 and GM-CSF for 7 days for DC differentiation. Then DC were incubated with different concentration of propolis (2.5, 5, 10, 20µg/mL) and LPS (5µg/mL) for 24 hours. A possible cytotoxicity was assessed by the MTT assay, and cytokine production was determined by ELISA. Significant differences were determined by analysis of variance (ANOVA), followed by Dunnett's test ($p<0.05$). Data showed that cell viability was not affected after incubation with propolis and LPS. Propolis treatment did not affect TNF-α production by DC stimulated with LPS. On the other hand, propolis increased IL-10 production at lower concentrations. One may conclude that propolis displayed an immunomodulatory action in cytokine production depending on concentration, exerting an anti-inflammatory action.

P1.09.09
Chitosan/plasmid CD40 DNA nanoparticles for gene delivery to Dendritic cells

***S. Daneshmandi**[1], A. Pourfathollah[1], M. Forouzandeh-Moghaddam[2];*
[1]Dept of Immunology, Tarbiat Modares University, Tehran, Iran, [2]Dept of Biotechnology, Tarbiat Modares University, Tehran, Iran.

In this study we evaluated synthesis and characterization of Co-stimulatory plasmid of DC40 gene in complex with chitosan nanoparticles due to transfer to dendritic immune cells. Material and Methods: chitosan were depolymerized to 10 KD oligomers using NaNO2 and Ionotrapic gelation method were done for chitosan/plasmid CD40 nanocomples formation in N/P=3-6, pH=7.2. Evaluation of particle size, polydispersity index, and zeta potential of the nanoparticles were performed by zetasizer nano particle analyzer. Dendritic cells were drived form Balb/c mice bone marrow. After transfection, DC phenptype using flowcytometery and DC functions in MLR test were evaluated. Results: SEM microscopy showed the

particles were about 300 nm in size and spherical in shape. Agarose gel electroforesis showed more than 95% integration if CD40 DNA to chitosan nanoparticles and DNA protection. DC matuaration were enhanced in nanocomplex exposed DCs but CD40 level was not different comparing with LPS matured DCs. Lymphocyte responces in MLR was not different with DCs that were matured with LPS. Conclusion: The goal of this study was to show that nonviral gene transfection to DCs. While these method is a safe technology for transfer of genes to DCs but the selected gene as CD40 will increase in mature DCs compared to iDCs and provided nanocomplex can not exceed form this maturation. Use of targeting molecules on this complex and appropriate nonviral transfection of complex will provide a good approach for many immune responses applications.

P1.09.10
The tetraspanin CD37 promotes dendritic cell migration

M. C. Demaria[1], *K. H. Gartlan*[1,2], *J. Wee*[1,3], *M. J. Hickey*[3], *M. D. Wright*[1];
[1]*Department of Immunology, Monash University, Melbourne, Australia,* [2]*Burnet Institute, Melbourne, Australia,* [3]*Centre for Inflammatory Diseases, Monash University, Melbourne, Australia.*

Tetraspanins are a family of integral membrane proteins that function by forming tetraspanin-enriched microdomains (TEMs), thus organizing the cell surface. TEM formation allows tetraspanins to function in critical processes including cell adhesion and migration. Immune system aberrations are observed in tetraspanin deficient mice. T cells and dendritic cells (DC) derived from CD37-/- mice display hyperproliferative and hyperstimulatory phenotypes, respectively. However, interestingly these mice are unable to generate an effective T cell response in vivo, following antigenic challenge, including irradiated tumors. Here we present evidence to support the hypothesis that a defective migratory capacity of CD37-/- DC may be the underlying basis of this inadequate response. Adoptively transferred CFSE labelled wild-type (WT) OT-I T cells are inefficiently primed in vivo in CD37-/- mice, indicative of poor antigen presenting capability within these mice. Immunisation of WT mice with OVA peptide pulsed CD37-/- bone marrow derived DC (BMDC) generates a defective T cell response, however CD37-/- mice elicit a sufficient T cell response when primed with OVA peptide pulsed WT BMDC. This suggests an inability of CD37-/- DC to migrate effectively to the LN to prime T cells. We demonstrate through a range of models, including two-photon confocal microscopy and competitive migration assays that CD37-/- DC migrate poorly. This migratory defect is not dependant on reduced integrin expression as CD37-/- BMDC display normal integrin levels. As tetraspanins can regulate integrin outside-in signalling and cytoskeletal rearrangement, we show that CD37-/- BMDC are impaired in their ability to spread and form actin protrusions.

P1.09.11
CD14 and NFAT mediate lipopolysaccharide-induced skin edema formation in mice

M. Di Gioia, *I. Zanoni, R. Ostuni, S. Barresi, A. Broggi, B. Costa, R. Marzi, F. Granucci;*
University of Milano-Bicocca, Milano, Italy.

Inflammation is a multistep process triggered when innate immune cells - for example, DCs - sense a pathogen or injured cell or tissue. Edema formation is one of the first steps in the inflammatory response; it is fundamental for the local accumulation of inflammatory mediators. Injection of LPS into the skin provides a model for studying the mechanisms of inflammation and edema formation. While it is known that innate immune recognition of LPS leads to activation of numerous transcriptional activators, including nuclear factor of activated T cells (NFAT) isoforms, the molecular pathways that lead to edema formation have not been determined. As PGE2 regulates many proinflammatory processes, including swelling and pain, and it is induced by LPS, we hypothesized that PGE2 mediates the local generation of edema following LPS exposure. Here, we show that tissue-resident DCs are the main source of PGE2 and the main controllers of tissue edema formation in a mouse model of LPS-induced inflammation. LPS exposure induced expression of microsomal PGE synthase-1 (mPGES-1), a key enzyme in PGE2 biosynthesis. mPGES-1 activation, PGE2 production, and edema formation required CD14 (a component of the LPS receptor) and NFAT. Therefore, tissue edema formation induced by LPS is DC and CD14/NFAT dependent. Moreover, DCs can regulate free antigen arrival at the draining lymph nodes by controlling edema formation and interstitial fluid pressure in the presence of LPS. We therefore suggest that the CD14/NFAT/mPGES-1 pathway represents a possible target for antiinflammatory therapies.

P1.09.12
Role of the Hypoxia-Inducible Factor-1alpha and Akt on hypoxia-induced migratory program in dendritic cells

I. Filippi[1], *C. Aldinucci*[1], *A. Pucci*[1], *S. Sozzani*[2], *F. Carraro*[1], *A. Naldini*[1];
[1]*University of Siena, Siena, Italy,* [2]*University of Brescia, Brescia, Italy.*

Dendritic cells (DCs) are the most potent antigen-presenting cells and, during their life cycle, are exposed to different oxygen tensions. One of the essential functions of DCs is to migrate from/into sites characterized by a low oxygen environment. Therefore, their migratory properties may be affected by such environment with important consequences in immune response regulation, inflammation and tumour microenvironment. In the present study, we show that short-term hypoxia positively activates a migratory program in human monocyte-derived DCs regardless of the applied chemotactic stimuli. To directly study the role of HIF-1alpha, the master regulator of hypoxia-induced adaptative responses, we inhibited HIF-1alpha expression by RNA interference in DCs and thereafter a chemotactic assay was performed. Of interest, hypoxia did not enhance cell migration in immature DC silenced for HIF-1alpha, when compared with the normoxic control. In contrast, chemotaxis was still increased in mature DCs silenced for HIF-1alpha exposed to hypoxia versus normoxia. In an attempt to explain this unexpected results we evaluated several pathways involved in cell migration and we observed that hypoxia significantly enhances the phosphorylation of Akt, a protein which is associated with DC migration and maturation. Indeed, hypoxia-induced cell migration was abolished by specific Akt pathway inhibitors, also in mature DCs silenced for HIF-1alpha, indicating that Akt could be an alternative pathway to be activated in hypoxic DCs. Our results may contribute to further understand the modality by which hypoxia may affect DC migration with important implications in the regulation of the immune response.

P1.09.13
Ceramide formation is involved in Lactobacillus acidophilus-induced IFN-β response in dendritic cell

E. Fuglsang, *L. Henningsen, H. Frøkiær;*
University of Copenhagen, Department of Veterinary Disease Biology, Copenhagen, Denmark.

The sphingolipid ceramide is known to play a role in lipid raft fusion and receptor clustering in the plasma membrane (PM). Upon bacterial encounter, dendritic cells (DCs) endocytose the bacteria and initiate a bacteria-specific downstream signaling event. We hypothesized that conversion of sphingomyelin to ceramide by acid sphingomyelinase (ASMase) at the outer leaflet of the PM is a key event in endocytosis of gram-positive *Lactobacillus acidophilus* and the subsequent induction of IFN-β in DCs and, as the gram-negative *Escherichia coli* does not induce appreciable amounts of IFN-β, the ASMase activity would affect endocytosis and the ensuing cytokine response of *L. acidophilus* and *E. coli* differently. SMase or an inhibitor of ASMase and acid ceramidase, chlorpromazine (CPZ) was added to DCs prior to stimulation with either of the bacteria. Endocytosis of fluorescent bacteria +/- FITC-dextran was measured by flow cytometry and gene expression and cytokine response of IFN-β and IL-12 was measured by qPCR and ELISA, respectively. Addition of SMase increased the uptake of *L. acidophilus* and *L. acidophilus*-induced IL-12/IFN-β but showed no effect on the uptake of *E. coli* though decreasing IL-12 induced by *E. coli*. SMase also showed to down-regulate Pam_3CSK_4-induced macropinocytosis of both bacteria. Addition of CPZ increased actin-dependent uptake of dextran and increased *Il-12/Ifn-β*

expression induced by *L. acidophilus*, thus further substantiating the key role of ceramide and thus, phagocytosis, in *L. acidophilus*-induced IL-12/IFN-β.

P1.09.15
T300A variant of autophagy ATG16L1 gene is associated with decreased antigen sampling and processing by dendritic cells in paediatric Crohn's disease

C. Strisciuglio[1], E. Miele[2], M. E. Wildenberg[3], A. Camarca[4], M. Barone[2], A. Staiano[2], R. Troncone[2], ***C. Gianfrani***[4];
[1]Department of Pediatrics and E.L.F.I.D, University Federico II of Naples, n, Italy, [2]Department of Pediatrics and E.L.F.I.D, University Federico II of Naples, Naples, Italy, [3]Department of Gastroenterology and Hepatology and Tytgat Institute for Intestinal and Liver Research, Academic Medical Center, Amsterdam, Netherlands, [4]Institute of Food Sciences-CNR, Avellino, Italy.

The single nucleotide polymorphism (SNP) T300A of the Crohn's disease-(CD) associated gene ATG16L1is responsible for decreased autophagy. This study aimed to investigate the effects of this SNP on the uptake and processing of antigens by dendritic cells (DC), as well as in the interaction between DC and intestinal epithelium, in paediatric CD patients. We enrolled children that homozygously carry the protective (wild type, n=7), the risk allele (risk, n=13) of ATG16L1, or were heterozygous (het, n=13). The peripheral blood monocyte-derived DC were analysed for phenotype, antigen sampling and processing by flow cytometry, while the capability of DC to form transepithelial protrusions was determined by confocal microscopy. DC generated from wild type patients showed higher bacterial sampling and antigen processing compared to risk patients. Additionally, after exposure to either bacterial particles, or to the antigen DQ-OVA, the wild type DC showed a significant increase in the expression of the HLA-DR and CD86 when compared to risk DC. Interestingly, also het patients showed an impairment in bacterial uptake and expression of activation marker when compared to the wild type. In the Caco2/DC co-colture, the formation of transepithelial protrusions were less numerous in risk DC compared to wild type and the antigen uptake was decreased. In conclusion, DC of paediatric CD patients carrying the T300A allele showed a marked impairment of antigen uptake and processing, and defective interactions between DC and intestinal epithelium. Collectively, our results suggest that an autophagy defect is associated with an impairment of intestinal innate immunity in paediatric CD.

P1.09.16
CD137 ligand generated dendritic cells are more potent than classical dendritic cells in inducing an antigen-specific T cell response

Z. Harfuddin;
National University of Singapore, Singapore, Singapore.

Dendritic cells (DC) are professional antigen-presenting cells that are essential in regulating and orchestrating T cell-based immunity. This property has prompted intense research in the use of DC-based immunotherapy. Nevertheless, DC vaccination is still in its infancy and improvements in terms of DC preparation, antigen-loading and increasing their immunostimulatory capacity are required. Here, we describe a potent and novel type of DC generated by CD137-ligand reverse signaling into peripheral monocytes.
The ligand for CD137 (CD137L) is expressed on peripheral human monocytes and delivers a potent activating signal via reverse signaling. Treatment of monocytes with a recombinant CD137 protein that induces reverse signaling through CD137L reduces typical macrophage characteristics such as phagocytosis and CD14 expression. However, distinct DC characteristics including endocytosis, costimulatory molecule expression and the ability to stimulate proliferation of allogenic naïve T-cells are induced. CD137L-generated DC (CD137L-DC) can be further matured which leads to an increase in DC marker expression such as CD83, CD86 and HLA-DR. This in turn enables a stronger activation of allogeneic T-cells. We also tested the ability of CD137L-DC to initiate antigen-specific T-cell activation in an autologous setting. Using cytomegalovirus (CMV) pp65 peptides, we show that matured CD137L-DC are able to activate pp65-specific T-cells more potently than classical DC. More importantly, these T cells are able to induce a stronger antigen-specific killing of HLA-matched target cells as compared to T cells activated by classical DC. These in vitro data show that CD137L-DC are potent antigen-presenting cells and should be evaluated for human immunotherapy.

P1.09.17
Inflammation in the periphery and dendritic cell progenitors in the bone marrow

P. H. Hart*, R. L. X. Ng, N. M. Scott, D. H. Strickland;*
Telethon Institute for Child Health Research, Perth, Australia.

Immune cells in inflamed peripheral tissues require constant replacement by cells from the bone marrow. CD11c+ cells (dendritic cells, DCs) cultured from bone marrow of mice with inflammation of the skin, airways or peritoneal cavity, have poor priming ability when transferred into naïve mice, and create reduced antigen-specific memory responses. Inflammation-associated prostaglandin E2 is involved directly or indirectly as the cyclooxygenase inhibitor, indomethacin, prevents the development from bone marrow of poorly priming DCs. Use of different culture conditions suggests that the developmental pathway of an early DC committed cell is altered by prostaglandin E2-associated tissue inflammation. To investigate DC development *in vivo*, bone marrow-ablated mice were engrafted with bone marrow cells from control mice and mice with skin or airways inflammation. Sixteen weeks after bone marrow cell transfer, immune responses largely dependent on DC function were poor in recipients engrafted with cells from mice with tissue inflammation. When an inflammatory antigen was painted onto skin, the inflammatory response was negligible. T lymphocytes from all chimeric mice had similar proliferative capabilities. An effect of prostaglandin E2 on very early progenitors, possibly haemopoietic stem cells, is suggested. Further, when pregnant mice were UV-irradiated (which induced skin inflammation), the bone marrow of the progeny contained altered DC progenitors and suggests an epigenetic effect of tissue inflammation on these cells. The effect of tissue inflammation on DC development may be an important homeostatic process. However, this effect is removed by use of drugs (eg steroids) that prevent prostanoid production.

P1.09.18
Immune dysregulation in sickle cell disease

B. Hrinczenko[1], *H. Mahtani*[2], *H. Rogers*[3], *R. Cleveland*[4], *L. Kass*[4], *P. Triozzi*[3];
[1]Michigan State University, East Lansing, MI, United States, [2]University of Alabama at Birmingham, Birmingham, AL, United States, [3]Cleveland Clinic, Cleveland, OH, United States, [4]Case Western Reserve University, MetroHealth Medical Center, Cleveland, OH, United States.

Acute painful vaso-occlusive crises and recurrent infections are frequent complications of patients with sickle cell disease (SCD). Chronic activation of monocytes producing pro-inflammatory cytokines may play a role in immune dysregulation, susceptibility to infection, activation of vascular endothelium, and vaso-occlusion in SCD. The pathophysiology of SCD may be influenced by activated and/or immature monocytes. We compared activated monocytes in SCD with normal monocytes in healthy persons, analyzing CD4, CD14, CD16, and HLA-DR antigen expression using flow cytometry and morphologic assessment of monocytes with Wright and alpha-naphthyl butyrate esterase (ANBE) stains. SCD patients showed absolute monocytosis with decreased CD4+, CD4+HLA-DR+ and CD4+CD14+ monocyte expression and increased CD14(dim)+CD16+ expression. Monocytes in SCD showed immature morphology, including a high N/C ratio, indented nuclei, decreased cytoplasmic vacuolation and ANBE activity. We also examined the function of dendritic cells in SCD. Peripheral blood dendritic cells (PBDC) were purified from patients with SCD and from healthy donors. Monocyte-derived DC (MoDC) from patients and donors were generated *in vitro* with granulocyte/macrophage colony stimulating factor (GMCSF) and interleukin-(IL-)-4. Compared to healthy donors, PBDC from SCD patients showed reduced expression of HLA-DR, CD80, CD86, and

CD40; reduced stimulatory capacity to mixed lymphocyte reactions; and reduced production of IL-12 in response to lipopolysaccharide and to CD40 ligand. Similar reductions were observed in MoDC from SCD patients. These results indicate that alterations in dendritic cell function are present in SCD patients. Alterations in both monocytes and dendritic cells in SCD may contribute to deficiencies in immune response and susceptibility to infection.

P1.09.19
Characterization of Monocyte-Derived Dendritic Cells able to induce an E6/E7-specific, HLA I-restricted, cytotoxic activity

M. Iuliano[1], *G. Mangino*[1], *S. M. Zangrillo*[1], *V. M. Chiantore*[2], *G. Fioruccl*[2,3], *G. Romeo*[1,3];
[1]*Sapienza University of Rome, Latina, Italy,* [2]*Istituto Superiore di Sanità, Rome, Italy,* [3]*National Research Council, Rome, Italy.*

The adoptive transfer of cancer Ag-specific effector T cells in patients can result in tumor rejection, thereby illustrating the immune system potential for cancer therapy. Viruses involved in tumorigenesis are useful targets because viral proteins are not expressed in normal cells and their expression is required to maintain the malignant phenotype. Between oncoviruses, high risk human papillomavirus (HPV) has a well-characterized transforming propriety and it has been associated with squamous cell carcinoma of the ano-genital and oral tracts. Cutaneous genotypes are, instead, associated with some forms of non-melanoma skin cancer. Transforming ability of HPV is based on the function of E6 and E7 viral oncoproteins, which interact and inactivate pRB and p53 oncosuppressors, respectively. For these reasons vaccines targeting oncogenic E6 and E7 are ideal candidates to elicit strong immune responses without generating autoimmunity.
Here we report results obtained using a protocol based on human monocyte-derived dendritic cells (MDDC) and/or Langerhans cells (MDLC) incubated *in vitro* with necrotic keratinocytes expressing both E6 and E7 oncoproteins derived from mucosal (HPV16) or cutaneous (HPV38) genotypes. We observed the capability of MDDCs i) to uptake necrotic material from transformed keratinocytes; ii) to upregulate the expression of class I HLA and CD86 co-stimulatory molecule following uptake and iii) to specifically prime *in vitro* cytotoxic T lymphocytes against E6/E7-expressing keratinocytes.
We also provide preliminary evidences indicating the ability of necrotic keratinocytes to alter the microRNA profile in immature MDLC compared to prototipical stimuli as bacterial lipopolysaccharide.

P1.09.20
Inhibition of nitric oxide production and pro-inflammatory cytokines by several medicinal plants

F. Kalantar*, Z. Amirghofran, S. Malek-Hossein, H. Golmoghaddam, M. Shabani;*
Immunology, Shiraz, Iran.

BACKGROUND: A number of medicinal plants have been used to treat various immunological diseases. Nitric oxide (NO) has an important regulatory role in the various types of inflammatory processes.
OBJECTIVE: To investigate the NO modulatory activity of the extracts of several medicinal plants native to Iran including Dracocephalum kotschyi, Linum persicum, Dionysia termeana, Salvia mirzayanii, Ferulago angulata and Euphorbia cheiradenia. Methods: The methanolic extracts of the plants were prepared and examined for their effects on the NO production by lipopolysaccharide-stimulated mouse macrophages. The level of TNF-α and IL-1β pro-inflammatory cytokines in the macrophage culture were detected using enzyme-linked immunosorbent assay.
RESULTS: All the extracts at concentration of 50 µg/ml demonstrated a significant decrease in NO production ($p<0.001$) after a 24-hour treatment. This inhibitory effect was also seen after 48 hours. Among the extracts, L. persicum was the strongest extract in reducing the NO production at 1 µg/ml after both 24 and 48-hours (nearly 100% inhibition, $p<0.001$). S. mirzayanii extract with 66.2 ± 8% inhibition at 50 µg/ml, showed the mildest effects in 48 hour culture. In cytokine release determination, the extract of L. persicum significantly inhibited both TNF-α and IL-1β cytokines production by stimulated macrophages ($p<0.001$). D. kotschyi, D. termeana and F. angulata decreased secretion of IL-1β from the cells.
CONCLUSION: These results indicate the presence of anti-inflammatory and macrophage inhibitory substances in these plants.

P1.09.21
Soluble TNFRp75 regulation of TNF-TNFRp55 dependent dendritic cell activation controls protective immunity against *Mycobacterium tuberculosis*

R. S. Keeton*, N. Allie, N. Hsu, P. Randall, M. Jacobs;*
University of Cape Town, Cape Town, South Africa.

Tumour necrosis factor alpha (TNF) signalling is critical for host protective immunity against *M. tuberculosis* infection. TNFRp55 and TNFRp75 both bind TNF however the role of particularly TNFRp75 dependent immune function has been poorly defined. This study demonstrates superior control of *M. tuberculosis* infection by $TNFRp75^{-/-}$ mice with increased survival and enhanced bacilli clearance. $TNFRp75^{-/-}$ mice demonstrated increased pulmonary recruitment of activated dendritic cells. Moreover, IL-12 dependent migration of dendritic cells to lung draining lymph nodes of infected $TNFRp75^{-/-}$ mice was significantly higher than WT counterparts and was associated with enhanced frequencies of activated *M. tuberculosis* specific IFNγ-expressing $CD4^+$ T-cells. Shedding of TNFRp75 in WT mice correlated with significantly reduced bioactive TNF and IL-12p40 expression during *M. tuberculosis* challenge. Indeed, neutralisation of TNFRp75 in infected WT dendritic cell cultures increased both bioactive TNF and IL-12p40 production to equivalent levels observed in $TNFRp75^{-/-}$ cultures, directly implicating TNFRp75 shedding with the regulation of dendritic cell activation. Further, TNF-TNFRp55 mediated dendritic cell activation as opposed to signalling through TNFRp75 is required for *M. tuberculosis* specific Th1 immune responses. Thus, TNFRp75 significantly down-modulates protective immune function, reducing host resistance and survival after aerosol *M. tuberculosis* infection. Targeting TNFRp75 may therefore be therapeutically beneficial for improvement of disease outcome.

P1.09.22
SHIP-1 Expression maybe involved in the endocytic functions of early bone marrow-derived dendritic cells but not myeloid derived suppressor cells

Y. Kong[1], *M. Fuchsberger*[1], *S. Xiang*[1], *M. Hibbs*[1], *V. Apostolopoulos*[2], *M. Plebanski*[1];
[1]*Monash University, Melbourne, Australia,* [2]*Burnet Institute, Melbourne, Australia.*

Dendritic cells (DCs) are often targeted in vaccine studies and immunotherapies. Granulocyte/macrophage colony-stimulating factor (GM-CSF) can generate DCs from bone marrow (BM), although it is commonly used in conjunction with other cytokines such IL-4 to produce mature DC cultures. Herein, early GM-CSF-derived DCs from murine bone marrow were evaluated in new detail, including their endocytic capacity over time. The early GM-CSF derived DCs expressed lower levels of co-stimulatory molecules and had higher endocytic capacity for nano-(40nm) and microparticles (500nm) when compared to GM-CSF+IL4-derived DCs. Surprisingly, endocytic capacity for nanoparticles decreased steeply as they matured over time, whereas microparticle uptake was largely maintained. Further investigation revealed that early GM-CSF-derived DCs take up nanoparticles via caveolae-mediated endocytosis and microparticles via phagocytosis. Myeloid derived suppressor cells (MDSCs) are also generated from the bone marrow in the presence of GM-CSF. The pattern of uptake by MDSCs was completely different from early DCs, with evidence for the use of alternative uptake pathways. Consistent with uptake via caveole, abrogation of Src homology-2 domain-containing inositol 5-phosphatase 1 (SHIP-1) expression in early GM-CSF-derived DCs dramatically reduced uptake of nanoparticles but not microparticles, and enhanced TNF and CCL2 secretion and reduced TGFβ levels. These findings shed new light on the function of early GM-CSF-derived DCs and MDSC, and the potential of early DC cells as targets in therapeutic applications.

P1.09.23
Tofacitinib, a JAK inhibitor, induces tolerogenic phenotype in human dendritic cells

***S. Kubo**, K. Yamaoka, S. Iwata, M. Kondo, Y. Tanaka;*
University of Occupational and Environmental Health,Japan, Fukuoka, Japan.

Objective: Tofacitinib, a Janus Kinase (JAK) inhibitor has shown striking clinical benefits in rheumatoid arthritis. Although JAKs are known for their importance in lymphocyte development and function, their role in human dendritic cells (DCs) remains unclear. This study was undertaken to elucidate the role of JAKs in DCs using tofacitinib.
Methods: Human monocyte-derived DCs were generated and matured with lipopolysaccharide (LPS) in the presence of tofacitinib. Cytokine production and surface marker were assessed. After elimination of tofacitinib, allogeneic-mixed lymphocyte reaction was performed with CD4+CD45RA+ naive T cells.
Results: The presence of tofacitinib during maturation with LPS inhibited DC clustering and reduced expression of CD80 and CD86 but not HLA-DR. Production of type1 IFN, TNF-α, IL-6 and IL-1β reduced, but that of TGF-β was not affected. These effects did not depend on the cell toxicity. Pretreatment with cyclohexamide or blockade of type1 IFN-receptor resulted in suppression of CD80 and CD86. Among the transcription factors involved in regulation of co-stimulatory molecules, IRF7 was the only one that was suppressed. Co-culture of tofacitinib-treated DCs with naïve CD4+ T cells reduced T-cell proliferation and IFN-γ production. Additionally, tofacitinib markedly increased the expression levels of indoleamine 2, 3-dioxygenase (IDO).
Conclusions: Tofacitinib inhibits the positive loop of type-I IFN and the subsequent expression of co-stimulatory molecules with increased IDO, leading to attenuation of T-cell stimulatory capacity. Our results indicate that tofacitinib induces transformation to tolerogenic DC subsets. The results describe a novel mode of action for tofacitinib and the pivotal role of JAKs in DCs.

P1.09.24
Estrogen receptor signaling and X-chromosome complement both independently contribute to the enhanced TLR-7-mediated responses of woman plasmacytoid dendritic cells

***S. Laffont**[1], N. Rouquié[1], C. Seillet[1], J. Plumas[2], C. Aspord[2], J. Guéry[1];*
[1]INSERM U1043, CPTP, Toulouse, France, [2]INSERM U823, EFS Rhônes-Alpes, La Tronche, France.

Human plasmacytoid dendritic cells (pDCs) play a major role in innate immunity through the production of type I IFNs after Toll-like receptor (TLR) engagement by pathogens. Woman pDCs exhibit enhanced TLR-7-mediated responses as compared to man, which may account for sex-based differences in autoimmune and infectious diseases. To further characterize the mechanisms underlying this sex-based difference in pDC innate functions, we investigated the respective contribution of X chromosome dosage versus sex hormones using a humanized mouse model in which male or female NOD-SCID-ß2m$^{-/-}$ mice were transplanted with human progenitor cells (HPCs) purified from either male or female donors. We showed that the frequency of IFN-α- and TNF-α-producing pDCs in response to TLR-7 ligands was enhanced in female mice as compared to male, suggesting that endogenous estrogens positively regulated TLR responses in pDCs in agreement with our recently published work (Seillet et al., Blood 2012 119:454). Indeed, using an in vitro model of Flt3L/IL-7-driven human pDC differentiation from HPCs, we demonstrated that blockade of ER-signaling during pDC development inhibited TLR-7 and TLR-9-mediated IFN-a production by human pDCs from either sex. Lastly, by comparing the innate functions of female or male human pDCs that develop in HIS mice, we observed that female pDCs have an enhanced TLR-7-mediated IFN-α response as compared to male ones, irrespective of the sex of the recipient mice in which they developed. Taken together, these results indicate that cell-intrinsic ER-signaling and X chromosome complement both independently contribute to the enhanced TLR-mediated responses of woman pDCs.

P1.09.25
Bovine lactoferrin induces CCL1 production in myeloid cells

***D. Latorre**[1], P. Puddu[2], P. Valenti[3], S. Gessani[2];*
[1]Institute for Research in Biomedicine, Bellinzona, Switzerland, [2]Istituto Superiore di Sanità, Rome, Italy, [3]Sapienza, University of Rome, Rome, Italy.

Lactoferrin (LF) is now recognized as a key element in mammalian immune system for its pivotal role in host defence against infection and excessive inflammation.
We previously demonstrated that bovine LF (bLF) exerts a potent anti-inflammatory activity by skewing monocyte differentiation into monocyte-derived dendritic cells (MD-DCs) with impaired capacity to undergo activation and to promote Th1 responses.
In this study we show that the exposure of both MD-DCs and their monocyte precursors to bLF induces CCL1 production, even though with differences in the protein amount. Interestingly, in freshly isolated monocytes CCL1 mRNA expression levels are significantly enhanced at 2 hours and more markedly at 4 hours after bLf-treatment, suggesting a direct role of bLF on CCL1 mRNA transcriptional activation. Furthermore, cells continue to produce this chemokine even upon medium replacement 18 hours post bLF-treatment indicating CCL1 production as a result of permanent changes induced in bLF-treated DC precursor cells.
The analysis of the role of TLR2 and TLR4, and their co-receptors CD14 and CD36, on bLF-mediated CCL1 production, indicates that blocking each of these receptors significantly influences soluble factor secretion with cell-specific differences.
Finally, CCL1 is not implicated in the bLF-mediated inhibition of MD-DCs activation since blocking its biological activity does not rescue their LPS-mediated up-modulation of CD83 and IL-12 production, as well as their ability to induce T cell proliferation.
Understanding the biological role of the bLF-induced CCL1 production in both monocytes and MD-DCs could provide further evidence for mechanisms underlying LF immunomodulatory activity.

P1.09.26
Baicalin from *Scutellaria baicalensis* impairs Th1 polarization through the inhibition of dendritic cell maturation

*M. Kim, **J. Lee**;*
Chosun University, Gwangju, Republic of Korea.

Baicalin from *Scutellaria baicalensis* is a major flavonoid constituent found in the traditional Chinese medicinal herb Baikal skull cap. It has been widely used for the treatment of various diseases, such as pneumonia, diarrhea, and hepatitis. Recent studies have demonstrated that baicalin possesses a wide range of pharmacological and biological activities, including anti-inflammatory, anti-microbial, anti-oxidant, and anti-tumor properties. Specifically, its anti-inflammatory activity has been estimated in various animal models of acute and chronic inflammation; however, its effects on dendritic cells (DCs) maturation and immuno-stimulatory activities are still unknown. In this study, we attempted to determine whether baicalin could influence DCs surface molecule expression, antigen uptake capacity, cytokine production, and capacity to induce T-cell differentiation. Baicalin was shown to significantly suppress the expression of surface molecules CD80, CD86, major histocompatibility complex (MHC) class I, and MHC class II as well as the levels of interleukin-12 production in lipopolysaccharide stimulated DCs. Moreover, baicalin-treated DCs showed an impaired induction of the T helper type 1 immune response and a normal cell-mediated immune response. These findings provide important understanding of the immunopharmacological functions of baicalin and have ramifications for the development of therapeutic adjuvants for the treatment of DCs-related acute and chronic diseases.

P1.09.27
notch ligand delta-like 4-pretreated dendritic cells alleviate allergic airway responses by enhancing IL-10 production

*H. Huang[1], G. Hsiao[2], C. Fan[3], C. Lin[4], S. Leu[5], B. Chiang[6], **Y. Lee**[5];*
[1]Graduate Institute of Medical Sciences,College of Medicine, Taipei Medical University, Taipei, Taiwan, [2]Department of Pharmacology, College of Medicine, Taipei Medical University, Taipei, Taiwan, [3]Department of Parasitology, College of Medicine, Taipei Medical University, Taipei, Taiwan, [4]Graduate Institute of Medical Sciences, College of Medicine, Taipei Medical University, Taipei, Taiwan, [5]Department of Microbiology and Immunology,College of Medicine, Taipei Medical University, Taipei, Taiwan, [6]Graduate Institute of Clinical Medicine, College of Medicine, National Taiwan University, Taipei, Taiwan.

Dendritic cells (DCs), as professional antigen-presenting cells (APCs), induce T cell activation and promote T cell differentiation by antigen stimulation. It is known that Notch ligand delta-like 4 (Dll4) on APCs is associated with stimulation of a Th1-type response. However, the regulatory roles of Dll4 in the activation and function of DCs have not been clearly elucidated. In this study, we demonstrated that activation of Dll4-pretreated bone marrow-derived DCs via ovalbumin (OVA) stimulation expressed a high level of IL-10. In contrast, the proinflammatory cytokines decreased in Dll4-pretreated DCs with either LPS or OVA stimulation. Compared to fully mature DCs, lower levels of MHC class II CD40 and higher levels of CD80 and CD86 molecules were expressed on these DCs. Dll4 Notch signaling also enhanced Notch ligand mRNA expressions of Dll1, Dll4, and Jagged1 in DCs. Dll4-modified DCs exhibited a reduced capacity to stimulate the proliferation of OVA-specific $CD4^+$ T cells but strongly promoted large amounts of IL-10 production in these activated T cells. After adoptive transfer of OVA-pulsed plus Dll4-pretreated DCs in OVA-immunized mice, OVA challenge induced lower OVA-specific IgE and higher IgG_{2a} antibody production, lower eotaxin, KC, IL-5, and IL-13 release in bronchial alveolar lavage fluid, attenuated airway hyperresponsiveness, and promoted higher IL-10 and IFN-γ production in the spleen. Taken together, our findings shed light on a new role of Dll4 in the phenotype and function of DCs and provide a novel approach for manipulating Th cell-driven deleterious immune diseases.

P1.09.28
LAMP-2, a novel endocytic receptor on human monocytes derived dendritic cells (MDDC).

***D. Leone**;*
Medical University of Vienna, Vienna, Austria.

Lysosome-associated membrane protein-2 (LAMP-2) is a type 2 membrane-protein that is commonly used as lysosome and late endosomal marker and with essential roles in chaperone mediated autophagy and antigen presentation. It is also present on the cell-surface although its role there is uncertain. We focus on the role of LAMP-2 as a receptor on freshly isolated monocytes and iDCs with possible implication in antigen presentation.
LAMP-2 was detected on the surface of immature MDDC both by FACS and confocal microscopy, its expression increased after maturation with IFN-γ LPS. The monoclonal anti-LAMP-2 antibody (H4B4) bound to LAMP-2 on the surface of MDDC and was rapidly and specifically internalized when compared to control antibodies in the presence of Fc blockade. Also the Fab fragment alone is internalized as well. Uptake was absent in MDDC from an individual with genetic LAMP-2 deficiency, Danon-disease. As expected, MDDC LAMP-2 and HLA-DR localized to partially overlapping compartments in iDC but there was no co-localization with HLA-DM. However, confocal microscopy showed that H4B4 transits into a HLA-DM positive compartment 1 hour after ligating LAMP-2 on the cell surface. Co-localization is no longer detectable after 3 hours. Finally, stimulation of immature MDDCs with H4B4 promote activation in the presence of IFN-γ indicated by up-regulation of CD80/CD83.
This data suggest that cell surface LAMP-2 can act as endocytic receptor for internalization of extracellular molecules without cross-linking. H4B4 mimics natural ligands and traffics to the MIIC co-incident with DC maturation evidenced by up-regulation of CD80/83.

P1.09.29
Role of muscarinic activation in regulation of human dendritic cells maturation process

***M. G. Lombardi**[1], G. Salamone[2], P. Martinez Pulido[1], M. S. Gori[2], L. Ariolfo[1], J. Pimentel[1], M. E. Sales[1];*
[1]Laboratorio de Inmunofarmacología Tumoral CEFYBO-CONICET, Fac de Medicina , UBA, CABA, Argentina, [2]IMEX-CONICET, Academia Nacional de Medicina, CABA, Argentina.

We demonstrated the presence of muscarínic receptors M_3, M_4 and M_5 receptors, and choline acetyltransferase and acetylcholinesterase enzymes in human dendritic cells (DC). Given that the maturation process of the DC has a central role in the immune response, we investigated the effect of cholinergic stimulation on the expression of maturation markers and the proinflammatory cytokines. DC were differentiated from positive selected $CD14^+$ cells isolated from peripheral blood mononuclear cells and cultured with IL-4 and GM-CSF. Then cells were treated with the cholinergic agonist carbachol (Carb,10^{-8}M) for 1h followed by additional 24h in the absence (immature (iDC)) or presence (mature (mDC)) of LPS (0.5mg/ml). We observed that Carb increased the expression of HLA-DR and CD86, as well as the production of IL-12 (Carb:575±10; baseline:374±15 pg/ml) and TNF-α (Carb:6733±1167, baseline: 3667±629) in mDC (n=3, $P \leq 0.01$). Both effects were reduced in the presence of the muscarinic antagonist atropine (10^{-7}M). Nitric oxide synthase (NOS) isoforms are involved in the signaling pathway of M3 and M5 receptors and their product, nitric oxide, is an inflammatory mediator and an immune response regulator. We have shown by Western blot that iDC as well as mDC expressed NOS1 and NOS3 and had similar basal release of NO_2^-(uM) (iDC:2.99±0.96; mDC:1.98±0.51). Carb treatment increased the levels of NO_2^- in iDC. We concluded that cholinergic stimulation regulates the expression of phenotypic markers of maturation and production of proinflammatory cytokines in human DC. iDC also respond to the cholinergic agonist, increasing their nitric oxide production, which could be a key factor in the maturation process.

P1.09.30
Growth phase-dependent immune response to *Staphylococcus aureus*

***L. D. Lund**[1,2], Y. Souwer[2], H. Frokiar[1], E. C. de Jong[2];*
[1]University of Copenhagen, Department of Veterinary Disease Biology, Frederiksberg C, Denmark, [2]Academic Medical Centre, University of Amsterdam, Department of Cell Biology and Histology, Amsterdam, Netherlands.

Staphylococcus aureus cause a wide range of human diseases, varying from minor skin infections to bacteremia associated with high morbidity and mortality. The bacteria express and secrete diverse proteins, polysaccharides and toxins during different stages of growth. It is unknown how growth phases of bacteria affect the initiation of the adaptive immune response. In this study, we hypothesized that professional antigen-presenting dendritic cells (DCs) respond differently to *S. aureus* in exponential and stationary phase (EP and SP), and hence to different T-cell responses. Human monocyte-derived DCs were cultured with *S. aureus* NCTC-8325-4 in EP or SP and analyzed for maturation status, cytokine production, and T-cell polarizing capacity. EP and SP bacteria equally induced maturation of the DCs. However, EP bacteria induced a higher expression of cytokines, including IL-12p70 and IL-23. Cocultures of autologous naive CD4+ T-cells with DCs and EP *S. aureus* resulted consistently in higher development of Th1 cells compared to cocultures with SP. Analysis of autologous memory T-cells revealed the same findings as seen with naive T-cells. In addition, EP also was able to drive a higher Th17 and Th1/Th17 response, compared with the SP bacteria. Collectively, these results reveal a growth phase dependent immune response to *S. aureus*. The immune response against the SP is almost absent compared to the EP, which suggests that the immune response has evolved to fight only *S. aureus* when it is growing rapidly, and thus preventing the bacteria from spreading, while allowing the presence of resting bacteria.

P1.09.31
ESAT-6 and HspX improve the effectiveness of Bacille Calmette-Guérin to induce human Dendritic Cells-dependent T cells and Natural Killer cells activation

***L. Marongiu**, M. Donini, L. Toffali, E. Zenaro, S. Dusi;*
University of Verona, Verona, Italy.

The limited efficacy of BCG vaccination is partly due to a missing expression of critical immunogenic proteins. We analyzed whether early-secreted-antigenic-target-protein-6 (ESAT-6) and 16-kDa-heat-shock-protein (HspX) Mycobacterium tuberculosis (Mtb) antigens improve the ability of BCG to activate human DC.
Addition of single HspX or ESAT-6 to BCG-treated DC did not influence cytokine release, whereas addition of both the antigens significantly improved pro-inflammatory cytokine, but not IL-10 secretion by DC. Moreover, DC incubated with BCG in presence of both ESAT-6 and HspX were able to elicit IFN-γ release by co-cultured CD4+ lymphocytes or NK. The above-mentioned effects of the antigens were inhibited by IL-12-blocking antibodies. A specific TLR2-blocking antibody decreased IL-12 release by DC stimulated with BCG, ESAT-6 and HspX, as well as IFN-γ secretion by CD4+ lymphocytes co-cultured with these cells. Furthermore, HspX and ESAT-6 improved the capacity of BCG-treated DC to induce the expression of the memory phenotype marker CD45RO by naïve CD4+ T cells.
Our results indicate that ESAT-6 and HspX cooperation enhances the BCG ability to stimulate human DC, that become able to induce an effective Th1 and NK response through TLR2-dependent IL-12 secretion. Therefore ESAT-6 and HspX represent good candidates for improving the effectiveness of vaccination with BCG.

P1.09.32
Dendritic cell CCAAT/ enhancer binding protein delta modulates Th17/Treg responses in an IL-10 dependent manner

***M. G. Mohammad**[1], V. W. W. Tsai[1], S. N. Breit[1], P. E. Sawchenko[2], D. A. Brown[1];*
[1]St Vincent's Hospital Center for Applied Medical Research, Sydney, Australia, [2]Laboratory of Neuronal Structure and Function, The Salk Institute for Biological Studies, La Jolla, CA, United States.

CCAAT/enhancer binding protein delta (CEBPD), a bZIP-transcription factor, is an emerging regulator of innate immune responses and therefore might influence adaptive immune responses. However, it hasn't been examined in the context of central nervous system (CNS) inflammation and T-cell activation. This study aimed to determine the role of CEBPD in experimental autoimmune encephalomylitis (EAE) a T-cell mediated CNS autoimmune disease. CEBPD was upregulated at the protein and RNA level in peripherally derived DCs and astrocytes in the EAE affected CNS and animals lacking CEBPD had significantly less disease. Follow on BM chimeric experiments showed that it was CEBPD expression in peripherally derived immune cells that mediated differences in EAE severity. To identify cells other than DCs that expressed CEBPD throughout disease we developed an intracellular staining method to detect CEBPD protein expression. There was no CEBPD expression in peripherally derived CNS immune cells, other than in DCs. To detect functional changes in DC activity we examined Th-lymphocytes phenotype throughout the course of EAE and showed a significant reduction in Th17:Treg ratio when DC CEBPD was missing. The same was observed in an in vitro model of T-cell development directed by DCs that lacked CEBPD. These DCs also had significantly increased IL10 mRNA expression. Further, blocking IL-10 signaling completely compensated for the lack of CEBPD expression in DCs both in vitro and in vivo. These studies identify CEBPD as an important DC factor in regulating inflammatory response through directing T-lymphocyte development and promoting autoimmunity.

P1.09.33
Study of leukemic cell products and IL-1β as modulators of human dendritic cells

***J. M. Motta**, A. Sperandio, M. T. L. Castelo-Branco, V. M. Rumjanek;*
Federal University of Rio de Janeiro, Rio de Janeiro, Brazil.

Although dendritic cells (DCs) play an important role in controlling tumors as antigen-presenting cells, they might be modulated by tumor-derived products. It was shown that leukemic cell products down regulate DC differentiation through the induction of IL-1β. The aim of this study was to compare the influence of leukemic cell products and exogenous IL-1β on DC development and function. For this, K562 cell line was used as a model of chronic myeloid leukemia to obtain the supernatant (SN K562). Monocytes from healthy donors were separated and cultured, for 5 days, in the presence of IL-4 and GM-CSF and also SN K562 or with exogenous IL-1β. After these 5 days, some cells were cultured with TNF-α for a further 2 days. Flow cytometry analyses and ELISAs were performed after 5 days and 7 days of culture. Our results showed that, in the presence of SN K562, CD14, CD16, CD68 and CD80 expressions were higher than in the control; otherwise CD1a and CD83 expressions were lower. Similarly, IL-1β modulated all these molecules, with exception of CD16 and CD68 that were not altered by its addition. Furthermore, K562 cells did not produce IL-10, yet both the addition of the supernatant and exogenous IL-1β induced IL-10 secretion by monocytes stimulated to differentiation and activation into DCs. Finally, these results suggest that both leukemic cell products and IL-1β alter DC development, inducing a suppressive phenotype. Moreover, IL-1β induction seems to be an important mechanism used by leukemic cells to inhibit DCs.

P1.09.34
Evaluation of the effect of the 14kDa protein isolated from aged garlic extract on dendritic cells

***H. Namdar Ahmadabad**[1], M. Zuhair[1], M. Nezafat Firizi[2];*
[1]Tarbiat Modares university, Tehran, Iran, [2]Tehran University of Medical Sciences, Tehran, Iran.

Garlic is used all over the world for treatment of different diseases. A wide range of biological activities of garlic has been verified in vitro and in vivo. One of major proteins of garlic which has been isolated and purified is the 14 kDa protein. This protein has been shown to have immunomodulatory effects. In this study, the effect of the 14 kDa protein isolated from aged garlic extract (AGE) was investigated on maturation and immunomodulatory activity of dendritic cells (DC). Proteins were purified from AGE by biochemical method; the semi-purified 14 kDa protein was run on gel filtration Sephadex G50 and its purity was checked by SDS-PAGE. DC were isolated from spleen of BALB/c mice by Nycodenz centrifugation and their adhesiveness to plastic dish. 14 kDa protein from AGE was added to overnight culture of DC medium and the expression percentage of CD40, CD86, and MHC-II was evaluated by flowcytometric analysis. Also, proliferation of T cells was measured by allogenic mixed lymphocyte reaction (MLR) test. The purified 14 kDa protein isolated from AGE increased the expression of CD40 molecule on DC, but it did not influence CD86 and MHCII molecules. Furthermore, no significant differences were noticed between DCs pulsed or unplused with 14 kDa protein on the MLR assay.

P1.09.35
IL-1 and IL-1 Receptor Antagonist Genes Polymorphism in ACPA Positive Rheumatoid Arthritis Patients

***N. Ouikhlef**[1,2], I. Allam[1,2], N. Raaf[1,2], A. Abdessamed[3,4], N. Bahaz[1,4], A. Tahiat[1,2], K. Cherguelaine[1,2], A. Ladjouze[3,4], R. DjiDjik[1,2], M. Ghaffor[1,2];*
[1]Beni-Messouss Hospital, Algiers, Algeria, [2]Immunology Unit, Algiers, Algeria, [3]Ben-Aknoun Hospital, Algiers, Algeria, [4]Department of Rheumatology, Algiers, Algeria.

Background & objectives: Rheumatoid arthritis (RA) is the most common systemic autoimmune disorder where environmental, hormonal and genetic factors contribute to the disease. In recent years, studies have shown that the genetic risk may include IL-1 and

IL-1receptor antagonist (IL-1Ra), cytokines which play a critical role in the pathogenesis of RA. There have also been a major development in the field of immunity focused on antibody reactivity to proteins modified by citrullination, highly specific marker of RA, which has redefined RA phenotypes, demonstrating major differences in genetic and environmental risk factors, and thus probably in molecular pathogenesis too, between RA patients with and without the presence of antibodies to citrullinated proteins (ACPA). ACPA-positive RA patients show a disease course considerably more severe than that of ACPA-negative patients. The aim of our study was to evaluate the association between a genetic IL-1 polymorphism with susceptibility and clinical aspects of RA.
Materials and methods: In this case-control study, blood samples from 100 Algerian RA patients and 127 matched healthy controls were used to study the IL-1RA and IL-1B polymorphism. ACPA was detected using an ELISA anti-CCP-3 generation test.
Results: There was no difference in the frequency of different alleles between patients and healthy controls. However, a positive correlation between IL-1RN*1/IL-1B-511T/IL-1B+3953C haplotype and ACPA production was detected (RA/ACPA+: 31.28 vs RA/ACPA-: 6.66, P= 0.011, OR= 4.693).
Conclusion: Our findings indicate that IL-1B and IL-1RA polymorphism was not a susceptibility marker in RA in our population, but it could be associated with ACPA+RA.

P1.09.36
CD40-ligand signal response diversity through dendritic cell state modification

L. Pattarini[1]*, A. Cappuccio*[1]*, E. Volpe*[2]*, V. Soumelis*[1]*;*
[1]*Institut curie, Paris, France,* [2]*Fondazione Santa Lucia, Rome, Italy.*

Immune cells potentially encounter multiple signals sequentially, each signal affecting their transcriptional state. To what extent their transcriptional state modifies the response to a following signal is not known. We used human primary dendritic cells, which by nature sequentially respond to innate and adaptive signals, to measure the effect of innate signals on the response to adaptive signals. First, we stimulated human blood dendritic cells with the innate signals LPS, Thymic Stromal Lymphopoeitin (TSLP) or medium as a control in order to generate three distinct transcriptional states in DCs. To uncouple the transcriptional effect of the state modifiers from the response to a subsequent signal, we stimulated or not the cells with the adaptive signal CD40L. Differential analysis of large-scale transcriptomic data showed that 89% of the genes modified by CD40L depended on the cell state. Each cell state primed the regulation of different factors by CD40L, among them IL6, TNFalpha and Cxcl10. We identified genes, such as TNFSF15 and CD70, specifically induced only by the combination of TSLP and CD40L, indicating that their regulation requires temporal integration of signals. Additionally, pathway analysis suggested that cell state determines biological and immune functions regulated by CD40L.
Therefore, differences in dendritic cell state translate into quantitative differences in the response to a subsequent adaptive signal.

[4]*Department of Medical Biochemistry and Biophysics, Karolinska Institutet, Stockholm, Sweden.*

The demand for controlling T cell responses via ex vivo generated dendritic cell (DC) vaccines initiated a quest for reliable and feasible DC modulatory strategies that would facilitate cytotoxicity against tumors or tolerance in autoimmunity or allergy.
We studied endogenous mechanisms in developing monocyte derived DCs (MoDCs) that can induce inflammatory or suppressor programs during differentiation. Such mechanisms can lead to functional heterogeneity of the cells and can influence the efficiency of DC therapies. We characterized a powerful autocrine regulatory pathway in developing MoDCs that, in a cell concentration-dependent manner, strongly interferes with inflammatory DC differentiation.
MoDCs developing in sparse cultures have superior ability to produce inflammatory cytokines, to induce TH1 polarization and to migrate towards the lymphoid tissue chemokine CCL19. On the contrary, MoDCs originated from dense cultures produce IL-10 but no inflammatory cytokines upon activation. DCs from high-density cultures maintained more differentiation plasticity and can develop to osteoclasts. The cell culture density-dependent pathway was independent of PPARγ, a known endogenous regulator of MoDC differentiation. Instead, it acted through lactic acid, which accumulated in dense cultures and induced an early and long-lasting reprogramming of MoDC differentiation.
Our results may indicate a strongly context-dependent nature of the in vitro MoDC model system, due to DC functions being already polarized in early stages of differentiation by cell culture density, but these results also provide the possibility for efficient and remarkably simple way of DC manipulation.

P1.09.38
CD1c$^+$ DCs are superior at stimulating Th2 cytokine production upon grass pollen stimulation compared to circulating basophils and pDCs

F. Rydnert[1]*, K. Lundberg*[1]*, L. Greiff*[2]*, M. Lindstedt*[1]*;*
[1]*Department of Immunotechnology, Lund University, Lund, Sweden,*
[2]*Department of Otorhinolaryngology, Head & Neck Surgery, Skåne University Hospital, Lund, Sweden.*

Background: Dendritic cells (DCs) are a heterogeneous group of antigen-presenting cells (APCs) and subpopulations have been identified. However, their role in allergic immune responses is not fully clarified. Additionally, basophils are suggested to be superior allergen-presenting cells in allergic responses against e.g papain in mice.
Objective: The present study aimed at elucidating the functional role of CD1c$^+$ myeloid DCs (mDCs) and CD123$^+$ plasmacytoid DCs (pDCs) in human allergic rhinitis and also to examine whether basophils operate as APCs in human allergic responses.
Method: PBMC was isolated from boosted grass pollen allergic donors. CD1c$^+$ and CD123$^+$ DCs, as well as monocyte-derived DCs (moDC) and basophils, were co-cultured with autologous CD4$^+$ effector memory T cells and pulsed with grass pollen (Phleum pratenase, Phl p). After 7 days, intracellular IL-4 and T cell proliferation were measured with flow cytometry and [^{3}H]-thymidine incorporation, respectively.
Results: Phl p stimulation of CD1c$^+$ DCs induced IL-4 producing T cells at similar levels as moDCs. Interestingly, the frequency of T cells producing IL-4 was higher upon co-culture with Phl p-pulsed CD1c$^+$ DCs as compared to pDCs as well as basophils, and Phl p-pulsed CD1c$^+$ DCs also stimulated a higher T cell proliferation. Further on, basophils induced neither IL-4 production nor T cell activation after Phl p stimulation.
Conclusion: Together, these results suggest that CD1c$^+$ DCs are superior, as compared to other primary APCs, at activating Th2 cells in grass pollen allergic individuals.

P1.09.39
Absence of Estrogen Receptor Alpha Reduces the Number and Function of Bone Marrow derived PDCA1+ cells in Lupus Prone Mice

J. L. Scott*, G. S. Gilkeson, M. Cunningham, O. Naga;*
Medical University of South Carolina, Charleston, SC, United States.

Systemic Lupus Erythematosus (SLE) is a chronic autoimmune disease that affects women at a 9:1 ratio compared to men. Using a Lupus-prone mouse model, we have shown that estrogen receptor alpha (ERα) deficient mice have increased survival and less renal disease compared to wild type mice. We hypothesize that ERα deficiency improves SLE by reducing the innate immune system's response to Toll Like Receptor (TLR) Ligands. To study the innate

immune response our research focuses on the dendritic cell (DC). PDCA1+ DCs make up less than 5% of bone marrow derived myeloid dendritic cells (mDC) from B6 mice. Using the same mDC culture conditions, PDCA1+ cells accounted for 60% of mDCs from lupus-prone NZM 2410 mice. However, PDCA1+ DCs from NZM 2410 mice lacking ERα accounted for only 35% of mDCs. PDCA1 is a marker for plasmacytoid dendritic cells (pDCs), a major producer of type I interferon (IFN), which is a critical cytokine in the pathogenesis of SLE. Functionally, ERα deficient mDCs expressed lower levels of IFN response genes in response to TLR7 and 9 ligands compared to wild type cells. To further characterize these cells, a Flt3L driven pDC culture system was used to obtain pDCs. Using this culture system, ERα deficient bone marrow from NZM 2410, MRL/lpr, SLE1,3, and B6 mice had significantly decreased numbers of PDCA1+ cells. This data indicates that ERα plays a role in altering the number and function of PDCA1+ cells cultured under both mDC and pDC culture conditions.

P1.09.40
Endogenous production of activin A acts as negative regulator of NK-DC functional interactions

P. Seeger[1], *D. Bosisio*[1], *S. Parolini*[1], *R. Badolato*[2], *A. Gismondi*[3], *A. Santoni*[3], *S. Sozzani*[1];
[1]*Department of Molecular and Translational Medicine, University of Brescia, Brescia, Italy,* [2]*Department of Clinical and Experimental Sciences, University of Brescia, Brescia, Italy,* [3]*Department of Molecular Medicine, La Sapienza University, Rome, Italy.*

The interaction of natural killer (NK) cells with dendritic cells (DC) is known to influence both innate and adaptive immune responses. Although it is known that NK cells and DC reciprocal activation occurs through the release of both soluble factors and membrane protein interactions, the characterization of the different molecules involved deserves further attention. Here we report that in NK-DC cocultures, among a set of 84 cytokines investigated, activin A was the second highest induced gene, with CXCL8 being the most upregulated one. Activin A is a member of the TGF-beta superfamily and was previously shown to possess both pro- and antiinflammatory activities. In NK-DC cocultures, the induction of activin A required cell contact and was dependent on the presence of proinflammatory cytokines (i.e. IFN-γ, TNF-α and GM-CSF) as well as on NK cell-mediated DC killing. In NK-DC cocultures, inhibition of acitivn A by follistatin, a natural inhibitory protein, resulted in the upregulation of proinflammatory cytokine release (i.e. IL-6, IL-8, TNF-α) and in the increase of DC maturation. In conclusion, our study suggests that the production of activin A during NK-DC interaction represents a relevant negative feedback mechanism that might function to prevent excessive immune activation.

P1.09.41
CD8α+ DCs can be induced in the absence of transcription factors Id2, Nfil3 and Batf3

C. Seillet[1], *J. T. Jackson*[1], *K. A. Markey*[2], *G. R. Hill*[2], *K. P. A. MacDonald*[2], *S. L. Nutt*[1], *G. T. Belz*[1];

Dendritic cells (DCs) are heterogeneous cells in which distinct DC subsets, with specialized functionalities, are established through the expression of lineage-specific transcription factors. CD103+ and CD8α+ dendritic cells (DCs) are important for cross-presentation of antigens and for the induction of effector CD8+ T cell responses against pathogens. Development of these DC subsets is thought to require the transcription factors Irf8, Id2, Nfil3 and Batf3 although how this network is regulated is poorly defined. We have addressed the nature of the differentiation blocks observed in the absence of these factors and found that while all four factors are required for CD103+ DC development, only Irf8 is essential for CD8α+ DC. CD8α+ DCs can emerged in the absence of Id2, Nfil3 and Batf3 in short-term bone marrow reconstitution. Strikingly, these 'induced' CD8α+ DCs exhibit several hallmarks of classical CD8α+ DCs, found in steady state, including the expression of CD24, Tlr3, Xcr1, Clec9A and the capacity to cross-present soluble, cell-associated antigens and viral antigens even in the absence of Batf3. Collectively, these results uncover a previously undescribed pathway by which CD8α+ equivalent DCs, found immediately following transplantation, can bypass cues provided by the Id2-Nfil3-Batf3 pathway, but Irf8 was essential determinants for their differentiation.

P1.09.42
β2 adrenergic receptor-mediated IL12p70 suppression in LPS-activated dendritic cells is IL-10- and PKA-independent

M. C. S. Takenaka*, J. T. Maricato, V. M. Nascimento, M. G. Guereschi, L. P. Araujo, A. S. Basso;*
UNIFESP, São Paulo, Brazil.

The β_2 adrenergic receptor (β_2AR) agonist inhibits IL12p70 and enhances IL10 in LPS-activated dendritic cells (LPS-DCs). We proposed to investigate the signaling pathways involved in the β2AR-mediated modulation of IL12p70 production by LPS-DCs. We used BMDCs from WT or IL10-/- mice. Immature DCs (iDCs) were treated with fenoterol (β_2AR agonist) and then activated with LPS for 18h. In some experiments, cells were pre-treated with H89 (PKA inhibitor) and then stimulated as mentioned above. The cytokine production was analyzed by ELISA. Following β_2AR signaling, we evaluated intracellular cAMP levels and PKA-induced CREB phosphorylation (pCREB) in iDCs. The pIBα was quantified by Western Blot and translocation of NFB (p65) was analyzed by immunofluorescence in LPS-DC treated with fenoterol. Fenoterol activated the canonical β_2AR signaling in iDC, leading to an increase in intracellular cAMP levels and to PKA-mediated pCREB. H89 did inhibit pCREB after β_2AR signaling in iDCs, but did not prevent β_2AR-mediated alterations in IL12p70 and IL10 production by LPS-DCs. Next, we asked if β_2AR-mediated increase in IL10 could be the reason by which IL12p70 production is inhibited in LPS-activated DCs. Just as observed in WT mice, β_2AR signaling inhibited LPS-induced IL-12p70 production in IL10-/- DCs. Finally, we verified if fenoterol impairs the activation of NFB(p65) in LPS-DC. We observed that β_2AR signaling induced a decrease of pIBα and nuclear translocation of NFB(p65) in LPS-DC. We concluded that in LPS-DCs, β2AR-mediated suppression of IL12p70 production is IL10-independent and also PKA-independent; however it is associated with inhibition of NFB translocation.

P1.09.43
Monocyte-derived dendritic cells pre-treated with TLR-3 and TLR-7 agonists express functional stability and Th17 polarization capacity in response to tumor conditioned media from colorectal cancer patients

S. Vasilijic[1,2], *D. Vucevic*[1,2], *I. Rajkovic*[2], *Z. Kostic*[3,2], *S. Jankovic*[4], *D. Mikic*[5,2], *M. Colic*[2];
[1]*Institute for Medical Research, Military Medical Academy, Belgrade, Serbia,* [2]*Faculty of Medicine of the Military Medical Academy, University of Defense, Belgrade, Serbia,* [3]*Clinic for General Surgery, Military Medical Academy, Belgrade, Serbia,* [4]*University Children's Hospital, Belgrade, Serbia,* [5]*Clinic for Infectious and Tropical Diseases, Military Medical Academy, Belgrade, Serbia.*

TLR ligands are widely used maturation agents for preparation of monocyte-derived dendritic cells (MoDCs). We assumed that MoDCs pre-treated with TLR agonists might gain resistance to the immunosuppressive effects of the tumor microenvironment. Therefore, MoDCs were pre-treated with TLR-3 (polyI:C) and TLR-7 (7-thia-8-oxoguanosine) agonists (TLR-pretreated MoDCs) for 4h, washed and stimulated overnight with tumor conditioned medium (TCM) from cultured colorectal cancer tumors.
Exposure of TLR-pretreated and corresponding control MoDCs to TCM resulted in the reduction of $CD86^+$ $HLA\text{-}DR^+$ cells. However, control MoDCs responded to TCM with up-regulation of these molecules, while the CD86 expression was unchanged in TLR-pretreated MoDCs. Consequently, TCM-treated control MoDCs, but not MoDCs treated with TLR agonists and TCM showed higher allostimulatory potential. In response to TCM, both cell groups showed up-regulation of IL-23, IL-6 and TNF-α. Control MoDCs and TLR-pretreated MoDCs secreted more IL-10 and IL-12p70, compared to TCM untreated cells, respectively. However, more than 50-fold increased production of IL-23 was detected in TLR-pretreated MoDCs

exposed to TCM and this finding correlated with several folds higher production of IL-17 in coculture with $CD4^+$T cells. Considering production of IL-10 and IL-6, the stimulatory effect of TCM was more potent in the group of control- than TLR-pretreated MoDCs. The opposite was observed for IL-12p70 and TNF-α.
These results suggest that pre-treatment with TLR-3 and TLR-7 agonists might be useful for preparation of MoDCs that could respond in the colorectal cancer microenvironment with a stabile function and potent Th17 polarizing capacity.

P1.09.44
Agonistic anti-4-1BB mAb promotes the maturation and activation of hypoxic dendritic cells

***Q. Wang**, C. Liu, Z. Dong, C. Guo, L. Zhang;*
Shandong University School of Medicine, Jinan, China.

Hypoxia resident in solid tumor and inflammatory tissues links closely with immune function. Maturation and activation of dendritic cells (DCs) are essential to drive immune response in hypoxic microenvironments. 4-1BB has been implicated involved in regulation of DC function, but its effects on hypoxic DCs remain unclear. In this study, we stimulated 4-1BB on murine hypoxic DCs using agonistic anti-4-1BB mAb and examined the phenotypic and functional changes of these DCs. We showed hypoxia had little influence on differentiation of DCs, but suppressed their maturation and activation via down-regulation of pro-inflammatory cytokines, MHC class II and co-stimulatory molecules. Compared with normoxic DCs, hypoxic DCs showed a slightly decreased expression of 4-1BB. Treatment of hypoxic DCs with anti-4-1BB mAb dramatically up-regulated the expression of pro-inflammatory cytokines including IL-6, IL-12 and TNF-α; the expression of matrix metalloproteinase 9 related to migration also increased in these DCs. Although anti-4-1BB mAb moderately up-regulated co-stimulatory molecules CD80, CD86 and MHC class II molecules on hypoxic DCs (remain lower compared to normoxic DCs), these DCs still showed limited ability to stimulate allogeneic $CD4^+$T cell proliferation compared with normoxic DCs. All together, we demonstrate that anti-4-1BB mAb partially restores the maturation and activation of hypoxic DCs by promoting their phenotypic maturation, inflammatory cytokines production and migration ability, thereby enhancing the immune function of DCs in hypoxic microenvironments.

P1.09.45
The equivalents of human blood and spleen DC subtypes can be generated in vitro from human CD34+ stem cells in the presence of Flt3L and TPO

***L. Wu**[1], A. Proietto[2], D. Mittag[2];*
[1]Tsinghua University School of Medicine, Beijing, China, [2]Walter and Eliza Hall Institute, Melbourne, Australia.

Dendritic cells (DCs) are immune cells specialized to capture, process and present antigen to T cells in order to initiate an appropriate adaptive immune response. The study of mouse DC has revealed a heterogeneous population of cells that differ in their development, surface phenotype and function. These differences are being exploited in the targeting of immunotherapies to particular DC subsets with promising outcomes. Less is known about the DC heretorgeneity in the human system, due to their rarity in human blood, and the difficulty in accessing human lymphoid tissues. The study of human blood and spleen has shown the presence of two subsets of conventional DC including the CD1b/c+ and CD141+CLEC9A+ conventional DC (cDC) and a plasmacytoid DC (pDC) that is CD304+CD123+. Studies on these subpopulations have revealed phenotypic and functional differences that are similar to those described in the mouse. In this study, the three DC subsets have been generated in vitro from human CD34+ precursors in the presence of fms-like tyrosine kinase 3 ligand (Flt3L) and thrombopoietin (TPO). The DC subsets so generated, including the CD1b/c+ and CLEC9A+ cDCs and CD123+ pDCs, were largely similar to their blood and spleen counterparts with respect to surface phenotype, Toll-like receptor and transcription factor expression, capacity to stimulate T cells, cytokine secretion and cross presentation of antigens. This system may be utilized to study aspects of DC development and function, not possible in vivo.

P1.09.46
Stat6 in dendritic cells negatively regulate IL-10 production and enhance arthritis

***K. Yamaoka**[1], S. Kubo[1], M. Kondo[1], K. Maeshima[2], K. Nakano[1], K. Oshita[3], Y. Tanaka[1];*
[1]University of Occupational and Environmental Health, Japan, Kitakyushu, Japan, [2]Internal Medicine 1 Faculty of Medicine, Oita University, Oita, Japan, [3]Pharmacology Research Laboratories I, Research Division, Mitsubishi Tanabe Pharma Corporation, Yokohama, Japan.

Stat6 is a transcription factor activated by JAK3 and is expressed on dendritic cells (DCs) in the synovium of rheumatoid arthritis patients in relation with disease activity. Previously, we reported that JAK3 negatively regulate IL-10 production in DCs. Stat6-/- DCs was evaluated the role of JAK3-Stat6 in IL-10 regulation in DCs and its involvement in inflammation. Development of Stat6-/- splenic DCs was comparable to that of wild-type (WT) mice. In fact, IL-10 production was increased in response to toll-like receptor ligands, while TNF-α and IL-6 were at comparable level with those of WT DCs, which was an identical phenotype with JAK3-/- DCs. Accordingly, LPS injection to Stat6-/- mouse resulted in increased serum IL-10 with TNF-α and IL-6 at comparable level with WT and immunostaining of the spleen revealed increased IL-10 positive cells. Genetic background did not alter the phenotype, firmly establishing that the overproduction of IL-10 by Stat6-/- DCs was a consistent phenomenon. To investigate the pathological role of Stat6 in DCs with arthritis, collagen antibody-induced arthritis (CAIA) was performed. Arthritis score was significantly suppressed and serum IL-10 concentration was increased in Stat6-/- mice and histopathological analysis revealed significantly suppressed joint destruction in Stat6-/- mice. Our results with Stat6-/- DCs confirmed that JAK3-Stat6 pathway negatively regulate IL-10 production in DCs and enhances inflammation. Therefore, the anti-inflammatory effect of the JAK inhibitor showing prominent effect on rheumatoid arthritis has the possibility of inducing IL-10 production by DCs.

P1.09.47
PU.1 regulates CCR7 expression in dendritic cells

***T. Yashiro**[1,2], M. Hara[1], K. Okumura[1], C. Nishiyama[1];*
[1]Atopy Research Center, Juntendo University School of Medicine, Bunkyo-ku, Tokyo, Japan, [2]Research Fellow of Japan Society for the Promotion of Science, Tokyo, Japan.

Dendritic cells (DCs) are professional antigen presenting cells that reside in peripheral tissue and survey the body for pathogens. Upon activation by contacting to antigens, DCs undergo a maturation process and migrate to lymphoid organs, where they prime naive T cells. CCR7 plays a key role in migration of DCs.
Several studies including ours have demonstrated that PU.1, which belongs to Ets family transcription factor, is indispensable for DC developments and functions. In this study, we investigated whether PU.1 regulates the expression of CCR7 in DCs.
PU.1 knockdown by small interfering RNA (siRNA) in bone marrow-derived DCs (BMDCs) decreased the expression of CCR7. PU.1 silencing also attenuated the CCR7 ligand-dependent migration. Reporter assays using luciferase constructs containing the CCR7 promoter revealed that multiple Ets motifs localized around transcription start site is involved in transcriptional activation. Furthermore, a chromatin immunoprecipitation assay using an anti-PU.1 antibody exhibited that PU.1 bound to the proximal region of the CCR7 promoter in BMDCs. Our results demonstrate that PU.1 transactivates the expression of CCR7 gene by interacting with its promoter. Importantly, in human monocyte derived DCs, PU.1 bound to the CCR7 promoter, suggesting that these mechanisms are conserved in both human and mouse.
Taken together, PU.1 plays a pivotal role in the DC migration by positively regulating the CCR7 expression.

P1.09.48
Specialized role of skin dendritic cell subsets in induction of antigen-specific cellular and humoral immunity following intradermal vaccination

***M. Zaric**, O. Lyubomska, C. Scott, R. Donnelly, A. Kissenpfennig;*
Queen's University Belfast, Belfast, United Kingdom.

The efficacious delivery of antigens to antigen-presenting cells, in particular to dendritic cells (DCs), and their subsequent activation remains a significant challenge in the development of effective vaccines. In this study, we used polymeric dissolvable microneedle arrays (MNs) laden with antigen encapsulated nanoparticles to target murine skin DCs network and to investigate the capacity of different skin DC subsets to present antigen to antigen specific $CD4^+$ and $CD8^+$ T cells. We demonstrated that all dermal DC subsets could cross-present nano-encapsulated antigen but not as efficiently as Langerhans cells (LCs), that constituted the major subset capable of cross-presentation. We confirmed a critical role for LCs in the immunization process when depletion of LCs dramatically reduced the proliferation of antigen specific $CD8^+$ T cells *in vivo*. LCs were also necessary for IFN-γ production among antigen specific $CD4^+$ T cells, while Langerin- dermal DCs were required for the generation of antigen specific Th2 cells. We also investigated the role of LCs, Langerin+ and Langerin- dermal DCs for IgG1 and IgG2a antibody induction, confirming differential polarization of T helper cells by different skin DC subsets. Furthermore, we explored the contribution of skin DC subsets for the generation of antigen specific anti-tumor and anti-viral immune responses following MN immunization *in vivo* and found that depletion of LCs significantly reduced protective effects in both disease models. Therefore, we show that selective targeting of antigen to specific skin DC subsets, in particular to LCs through dissolvable MNs might provide a promising technology for improved vaccination efficacy.

P1.09.49
Unique features of sublingual mucosal dendritic cells after antigen application

***C. Zhang**, T. Ohno, M. Azuma;*
Molecular Immunology, Tokyo Medical and Dental University, Tokyo, Japan.

The sublingual mucosa (Slm) is utilized as the site for sublingual immunotherapy (SLIT) that induces tolerance against allergens. However, the involvement of oral mucosal DCs (OMDCs) in tolerance mechanisms has not been elucidated. Here we compared the distribution and dynamics of OMDCs between Slm and buccal mucosa (Bm) after topical antigen painting.
Based on the histological examination of CD207 and MHC class II expression, we evaluated three types of DCs; a) CD207+(MHCII+) epithelial LCs, b) MHCII+ submucosal (sm) DCs c) CD207+ smDCs after FITC painting. The distribution of resident LCs and smDCs was clearly less in the Slm, however, the number of MHCII+ smDCs was markedly increased at 6 h after FITC painting, suggesting newly recruitment of monocyte-derived DCs. At 24h, most DCs in the Slm were disappeared, whereas substantial numbers of DCs still existed in the Bm. OVA painting onto Slm showed similar but less and slower responses. The repeated antigen painting onto Slm induced a rapid exhaustion of resident OMDCs and recruitment of round-shaped CD11b+ DCs/macrophages. In a cedar pollen-induced pollinosis model, SLIT also induced exhaustion of resident DCs and appearance of CD11b+ DC/Mϕ. Our results suggest that these unique dynamics of sublingual OMDCs may contribute to tolerance induction of sublingual immunotherapy.

TLR4 and DC-SIGN receptors recognized Mycobacterium scrofulaceum promoting semi-activated phenotype on Bone Marrow Dendritic Cells

*M. Cruz[1], **A. I. Castillo-Rodal**[1], A. Schcolnik[1], L. Bonifaz[2], Y. López-Vidal[1];*
[1]UNAM, México, Mexico, [2]IMSS, IMSS, México, Mexico.

The incidence of Non-Tuberculous Mycobacteria (NTMs) infections in both immunocompetent or immunocompromised individuals has been increasing. NTMs infections have been reported to interfere with acquired protection induced by BCG vaccination while Dendritic Cells (DCs) plays an important role in immune responses to Mycobacterium complex pathogens but some of them partially stimulate the maturity of the DCs. There have been several reports about the activation in mice Bone Marrow Dendritic Cells (BMDCs) by *Mycobacterium avium*, but there are not previous reports about the stimulation of another NTMs by similar path until now. We show that *M. avium* and *M. scrofulaceum* have both comparable ability in the induction of a semi-mature phenotype of DCs, which was assessed by confocal microscopy, in where the cytoskeletal architecture of DCs presented spikes or pseudopodia very limited and smaller accompanied by a decrease in cell migration in both cases. We also found that TLR-4 and DC-SIGN have an important role in the phenotypic activation of BMDCs by *M. scrofulaceum*, in where PD-L2 expression was induced 5.3-fold when compared with controls. Regarding to cytokines, IL-10 presented a two-fold increase while IFN-γ, TNF-α and IL-12p40 showed a significant decrease, as well as CD40, CD80 and CD86 had low expression when compared to BCG stimulated DCs. This result reveals that *M. scrofulaceum* stimulated semi-mature BMDC and that response differs from *M. avium* or BCG.

P1.10.02
NOD2 signaling promotes the Treg/Th17 imbalance and contributes to type 1 diabetes pathogenesis

***F. R. C. Costa**, M. C. S. Françozo, J. S. Silva, D. C. Sartori;*
University of São Paulo, Ribeirão Preto, Brazil.

Type 1 diabetes (T1D) is an autoimmune disease that precipitates when immunological tolerance to self tissues fails, resulting in the autoimmune destruction of pancreatic beta cells in genetically predisposed individuals. Despite extensive studies about the progression and effector mechanisms in the pathogenesis of T1D, little is known about the initial steps of the disease. In this regard, NOD-like receptors (NLRs), which are intracellular receptors responsible for the recognition of pathogen associated molecular patterns (PAMPs) and damage associated molecular patterns (DAMPs), appear as an interesting target in the context of this initial interaction between beta-cells and the innate immune response. Therefore, we investigated the role of NOD2 in the pathogenesis of T1D. For that, NOD2 deficient mice and their wild-type (C57BL/6) counterparts were inoculated intraperitoneally with streptozotocin (STZ/40mg/Kg) for 5 consecutive days and both clinical and immunological parameters were assessed. Our results demonstrate that NOD2 deficient mice developed a less severe hyperglycemia. Also, NOD2 deficiency caused a decrease of Th17 and TC17 cells without interfering on the Treg cell population in the PLNs. In parallel, we observed an increase in the immunomodulatory cytokines IL-4 and IL-10 in the pancreas of these mice. Together, these results suggest that the NOD2 receptor induces a Th17 proinflammatory phenotype and thus, possibly contributes to the pancreatic islet damage during T1D onset.

P1.10.03
Role of TREM1-DAP12 in renal inflammation during obstructive nephropathy

*I. Stroo[1], A. Tammaro[1], F. Blank[1], L. Butter[1], N. Claessen[1], T. Takai[2], M. Colonna[3], J. Leemans[1], S. Florquin[1], **M. Dessing**[1];*
[1]Academic Medical Center, Amsterdam, Netherlands, [2]Institute of

Development, Aging and Cancer, Sendai, Japan, [3]Washington University School of Medicine, St. Louis, MO, United States.

Tubulo-interstitial injury is a common finding in the chronically diseased kidney and is characterized by ongoing inflammation and fibrosis leading to renal dysfunction and end-stage renal disease. Inflammatory response can be triggered by TREM-1 (triggering receptor expressed on myeloid cell) activation and requires association with transmembrane adapter molecule DAP12 (DNAX-associated protein 12) for cell signaling. TREM1-DAP12 pathway has a cross-talk with intracellular signaling pathways of several Toll-like receptors (TLRs) and is able to amplify TLR signaling. So far, several studies have shown that TLRs play a role in obstructive nephropathy but the contribution of TREM1-DAP12 herein is unknown. We investigated the contribution of TREM1-DAP12 in obstructive nephropathy by subjecting wild-type (WT), TREM1/3 double KO and DAP12 KO mice to murine unilateral ureter obstruction (UUO) model. We showed that in kidneys from WT mice, DAP12 and especially TREM1 mRNA levels were highly elevated upon UUO. Compared to WT mice, DAP12 KO mice displayed less renal MCP-1, KC and TGF-β levels and less influx of macrophages during progression of UUO, whereas TREM1/3 double KO mice displayed less renal MCP-1 level. Renal fibrosis developed similar in WT, TREM1/3 double KO and DAP12 KO mice. We conclude that DAP12, partly through TREM1/3, is involved in renal inflammation during progression of UUO.

P1.10.04

A shortcut mechanism of innate immune defense by a solitary PRR

J. L. Ding[1]*, B. Ho*[2]*;*
[1]National University of Singapore, Department of Biological Sciences, Singapore, Singapore, [2]National University of Singapore, Department of Microbiology, Singapore, Singapore.

The accepted paradigm about an innate immune response is a multi-stepped process - from recognition of the invading microbe by pathogen-recognition receptors (PRRs) to signal transduction, to the production of antimicrobial effectors by the immune cells. Contrary to this belief, we found that a PRR can act singly via a direct shortcut process, bypassing multiple cascades of reactions. We showed that the extracellular hemoglobin (Hb) acts as a solitary frontline defense PRR, directly recognizing pathogens and eliciting powerful antimicrobial potencies. This innate immune response phenomenon is evolutionarily entrenched for 500 million years, from the limulus to humans. While the invading microbe cleaves the cell-free hemoglobin to extract an iron-rich meal for its survival and further invasion, the host exploits the intruding microbe's proteases and PAMPs to produce toxic reactive oxygen species (ROS) that effectively kills the pathogen. In this process, the hemoglobin structure-function is rapidly reprogrammed to expose multiple dual antimicrobial activities and its redox reactivity is subsequently suppressed by plasma antioxidants, thus protecting the host from ROS-induced cytotoxicity. Furthermore, we demonstrated that the monocytes efficiently import the redox active Hb via a (a) novel endocrine loop of CD163 receptor recycling and (b) paracrine communication with vascular endothelial cells.

P1.10.05

Orchestration of tissue repair by the humoral pattern recognition molecule PTX3: linking microbe and matrix recognition

A. Doni[1]*, M. Sironi*[1]*, T. Musso*[2]*, C. Castagnoli*[2]*, M. Gobbi*[3]*, S. Valentino*[1]*, S. Tartari*[1]*, B. Bottazzi*[1]*, C. Garlanda*[1]*, A. Mantovani*[1,4]*;*
[1]Humanitas Clinical and Research Center, Rozzano, Italy, [2]Dept. Public Health & Microbiology, University of Turin, Turin, Italy, [3]Mario Negri Institute, Milan, Italy, [4]Dept. Medical Biotechnology & Translational Medicine, University of Milan, Milan, Italy.

Innate immunity includes a cellular and a humoral arm. Long pentraxin 3 (PTX3) is a fluid phase pattern recognition molecule and a key component of the humoral arm of innate immunity. PTX3 is normally produced in response to microbial recognition or inflammatory signals by different immune or stromal cells. In the early phase of skin wound healing, Pentraxin 3 (PTX3)-deficiency was associated with increased fibrin deposition and persistence, and thicker clots. At later phases, increased collagen deposition was observed in *Ptx3*-deficient mice. A similar phenotype was observed after liver injury. *Ptx3*-deficient macrophages and fibroblasts showed defective pericellular fibrinolysis *in vitro*. PTX3 bound fibrinogen/fibrin and plasminogen at acidic pH. The second exon-encoded N-terminal domain of PTX3 recapitulated the interactions observed with the whole molecule. Thus, a prototypic component of humoral innate immunity, PTX3, plays a non-redundant role in the orchestration of tissue repair and remodeling. We suggest that matrix and microbial recognition are commune, ancestral features of the humoral arm of innate immunity.

P1.10.06

Dectin-1 exerts opposing roles in the activation of macrophages from resistant and susceptible mice to Paracoccidioides brasiliensis infection

C. Feriotti*, V. L. G. Calich;*
University of Sao Paulo, São Paulo, Brazil.

Dectin-1 is a non-classical, C-type lectin receptor which binds predominantly to β-glucans, carbohydrates on the outer layer of cell wall of several fungi, including *Paracoccidioides brasiliensis* (Pb). The mechanisms of innate immunity that govern the interaction of this fungal pathogen with dectin-1 receptors are still unknown. This study aimed to investigate the role of dectin-1 in the interaction between Pb yeast cells and macrophages from susceptible and resistant mice. The phagocytic and fungicidal activities as well as NO and cytokines production were determined in laminarin-treated and untreated B10. A and A/J macrophages infected or not with Pb yeasts. The mRNA expression of NOS2, ARG-1 and SOCS3 genes was assessed by RT-PCR. The presence of laminarin resulted in increased phagocytosis, fungicidal activity, and NO production by B10.A macrophages. In contrast, all these activities were decreased in laminarin-treated A/J macrophages. In addition, A/J macrophages showed a prominent production of TGF-β, IL-10, IL-6 and TNF-α, whereas B10.A cells presented increased levels of IL-12, and IL-10. Furthermore, laminarin-treated macrophages of B10.A mice up regulated NOS2 and SOCS3 mRNA expression whereas ARG1 mRNA was up regulated in A/J macrophages. Thus, Dectin-1 activation appears to induce a "M1-like" differentiation of B10.A macrophages but a "M2-like" behavior of A/J cells. This is in agreement with our previous results demonstrating that a prevalent pro-inflammatory innate immunity results in suppressed T cell immunity and susceptibility, whereas an initial tolerogenic innate response followed by a tightly regulated adaptive immunity leads to resistance to *P. brasiliensis* infection .

P1.10.07

Induction of antimicrobial peptides in primary cultures from diabetic foot ulcers with 1,25-dihydroxyvitamin D3 and L-isoleucine

I. E. Gonzalez*, V. Trujillo, A. Montoya, A. Enciso, K. Rincon, E. Avila, B. Rivas, B. Rivas-Santiago;*
Unidad de Investigación Médica de Zacatecas, Instituto Mexicano del Seguro Social, Zacatecas, Mexico.

Background: It is estimated that more than 356 million people worldwide have diabetes mellitus type 2 (DM2) and between 15 to 25% of these patients will develop diabetic foot ulceration (DFU) during their lifetime. A diminished immune response is a major factor in the development of severe infection in DM2 patients, which allows pathogens colonize those wounds that frequently became resistant to antibiotics. Therefore, new approaches for drug development or adjuvant to improve the current therapy are urgently needed. Antimicrobial peptides (AMPs) such as defensin and cathelicidin are versatile molecules of easy induction that have a strongly antimicrobial activity.
Objective: The aim of this study was to determine the efficacy of 1,25 (OH)2 D3 and L-isoleucine to induce Human β-defensin (HBD-2) and cathelicidin (LL-37) in primary skin cell culture from DFU.
Methods: 15 biopsies from DFU grade 2 according to Wagner´s classification and 15 biopsies from healthy donors were cultured and stimulated with 1,25 (OH)2 D3 and L-isoleucine. Flow cytometry, real

time PCR and ELISA were performed to measure HBD-2 and LL-37 expression.
Results: Primary cell cultures from DFU stimulated in vitro with 1,25 (OH)2 D3 overexpressed DEFB4 and CAMP gene expression and preliminary results showed a tendency to increases of HBD-2 and LL-37 in the culture supernatants.
Conclusion: 1,25 (OH)2 D3 is an inductor of HBD-2 and LL-37 in keratinocyte's cultures, which suggests their potential therapeutic use on the treatment of diabetic foot ulcers.

P1.10.08
Deficient antiviral responses to influenza in primary bronchial epithelial cells of chronic obstructive pulmonary disease

A. Hsu[1], *K. Parsons*[1], *I. Barr*[2], *P. Hansbro*[1], *P. Wark*[1];
[1]*The University of Newcastle, Newcastle, Australia,* [2]*World Health Organisation Collaborating Centre for Reference and Research on Influenza, Melbourne, Australia.*

AIM: People with chronic obstructive pulmonary disease (COPD) are more susceptible to influenza infection leading to acute exacerbations with excess mortality. The mechanisms underlying this observation in COPD however are unknown. Our aim was to assess the antiviral responses in primary bronchial epithelial cells (pBECs) from COPD and healthy control subjects to influenza infection.
METHODS: Primary BECs from healthy non-smoking volunteers and subjects with COPD were infected with human influenza A/H3N2, A/H1N1, and a low pathogenic avian influenza A/H11N9 at MOI of 5. Influenza haemagglutinin (HA), RIG-I, interferon (IFN) -β, and IFN-λ1 protein was measured by western blotting. RIG-I-initiated signalling complex antiviral stress granule and IFN-β enhanceosome was measured by confocal microscopy. Viral replication was measured by plaque assay.
RESULTS: Influenza viruses replicated more efficiently in COPD pBECs. The viruses entered COPD pBECs more efficiently than healthy control cells, and this was dependent on PI3 kinase, which showed increased expression in COPD. COPD pBECs also showed impaired IFN responses to infection. RIG-I, the primary viral RNA sensor and initiator of IFN responses, was minimally expressed in COPD cells, leading to impaired formation of IFN signalling complex antiviral stress granule and IFN-β enhanceosome. This resulted in reduced IFN protein induction and correlated with enhanced viral replication in the COPD pBECs compared to healthy control cells.
CONCLUSION: COPD pBECs have increased susceptibility to influenza viral entry, and have inherent deficiencies in innate antiviral responses, which in combination lead to more severe infection.

P1.10.09
Zinc-Finger Antiviral Protein Mediates RIG-I-Like Receptor-Independent Antiviral Response to Murine Leukemia Virus

H. Lee[1,2], *J. Komano*[3], *T. Saitoh*[1,2], *S. Akira*[1,2];
[1]*Laboratory of Host Defens, WPI Immunology Frontier Research Center, Osaka University, Osaka, Japan,* [2]*Department of Host Defense, Research Institute for Microbial Diseases, Osaka University, Osaka, Japan,* [3]*Department of Infection Disease, Osaka Prefectural Institue of Public Health, Osaka, Japan.*

Innate immunity is induced after the recognition of viral RNAs by pattern-recognition receptors (PRRs) and is the first line of the host defenses against a variety of RNA viruses. Although Toll-like receptor 7 (TLR7) recognizes the genomic RNA of extracellular murine leukemia virus (MLV) to mediate the antiviral response, the RNA-sensing PRR that recognizes the MLV in the cytosol is not fully understood. Here, we show that zinc-finger antiviral protein (ZAP) is a cytosolic viral RNA sensor, inducing the degradation of the MLV transcripts by the exosome, an RNA degradation system, on RNA granules. Although loss of the RIG-I-like receptors (RLRs), which recognize various RNA viruses in the cytosol and induce the type I interferon (IFN)-dependent antiviral response, does not alter the replication efficiency of MLV, loss of ZAP greatly enhances the replication efficiency of MLV. ZAP localizes to RNA granules, where the processing-body and stress-granule proteins assemble. The CCCH-type zinc-finger domains of ZAP, which are RNA-binding motifs, mediate its localization to the RNA granules. ZAP recruits the MLV transcripts and an exosome component to the RNA granules leading to degradation of MLV transcripts. Although ZAP was known as a regulator of RLR signaling in human cells, ZAP does not regulate the RLR-dependent production of type I IFN in mouse cells. Thus, ZAP is a novel member of the cytosolic viral RNA-sensing PRR family that induces elimination of RNA viruses independently of TLR and RLR family members.

P1.10.10
Potential role of caveolin-1 in regulation of immune cell activation

M. Maceckova[1], *M. Pekarova*[2];
[1]*Department of Experimental Biology, Masaryk University, Brno, Czech Republic,* [2]*Institute of Biophysics, AS CR, v.v.i., Brno, Czech Republic.*

Caveolae are small plasmatic membrane invaginations, located mostly on surface of endothelial cells and adipocytes. They form a special group of lipid rafts compound of cholesterol, sphingolipids, and caveolin molecules simultaneously. Their unique function includes signal transduction, therefore caveolae plays a vital role in the regulation of almost all cellular processes. Caveolae are rich in proteins called caveolins, which serves as their basic structural units. Currently, three genes are known encoding three isoforms of caveolin: caveolin-1, -2, and -3. While caveolin-1 and -2 are abundant especially in adipocytes, endothelial cells, fibroblasts and smooth muscle cells, caveolin-3 is expressed mainly in striated muscle cells. Although their function is studied for many years, their relationship to the development of both local and systemic inflammation and related diseases had not yet been elucidated. Therefore, this study focuses on examining regulation of caveolin expression in various cell types (particullary in the in vivo and ex vivo systems). Importantly, our data showed that the expression of caveolins significantly differ in individual cell types in isolated peritoneal inflammation induced in mice in vivo. While the endothelial cell expression of caveolin-1 increases, in macrophages isolated from the peritoneum was observed reversed trend. In murine aorta we also found out that caveolin-1 is preferentially expressed in vascular lumen endothelial cells. For other types of immune cells was observed different expression of caveolins, while all three isoforms was confirmed only in mice peritoneal macrophages.

P1.10.11
Unbiased screen to identify novel host factors involved in the innate immune recognition of Streptococcus pneumoniae

B. Maier[1,2], *H. Stöckl*[3], *S. Knapp*[1,2];
[1]*CeMM, Research Center for Molecular Medicine of the Austrian Academy of Sciences, Vienna, Austria,* [2]*Department of Internal Medicine 1, Laboratory of Infection Biology, Medical University of Vienna, Vienna, Austria,* [3]*Institute of Immunology, Medical University of Vienna, Vienna, Austria.*

The Gram-positive bacterium Streptococcus pneumoniae is the leading agent to cause pneumonia, which is the most common cause of death by an infectious disease worldwide. Pneumococci colonize the upper respiratory tract and lead to severe diseases like pneumonia, meningitis and sepsis. Several structures of invasive clinical strains of S. pneumoniae are known to trigger innate immune responses, e.g. pneumococcal lipoteichoic acid, which is sensed by TLR2, pneumolysin, recognized by TLR4, and others that are less well known. In the current study, we aim to identify new mechanisms of innate immune recognition of S. pneumoniae to better understand how this pathogen is eliciting an immune response in innate immune cells.
We use a genetic screening method that is based on a haploid human cell line isolated from a chronic myeloid leukemia patient. Due to its haploidy a pool of full gene knock-outs can be generated by random mutagenesis. We could show that these cells harbor phenotypic characteristics of myelo-monocytic cells, and respond to S.pneumoniae as well as TLR stimulation with the secretion of the inflammatory cytokine IL-8. Currently we are establishing a reporter cell line for IL-8 secretion following S.pneumoniae stimulation that could be used as readout for the genetic screen. By complementing

this screen with purified bacterial molecules and mutagenized bacterial strains, we expect that this approach will allow us to comprehend the complex interplay between bacterial molecules and host cells in an unbiased manner.

P1.10.12
C-type lectin receptor Mincle recognizes amphiphilic acylglucoside derived from *Helicobacter pylori*

M. Nagata[1], *M. Shimamura*[2], *E. Ishikawa*[1], *T. Nabeshima*[2], *S. Yamasaki*[1];
[1]*Division of Molecular Immunology, Medical Institute of Bioregulation, Kyushu University, Fukuoka, Japan,* [2]*Graduate School of Pure and Applied Science & Tsukuba Research Center for Interdisciplinary Materials Science, University of Tsukuba, Ibaraki, Japan.*

Mincle (Macrophage-inducible C-type lectin) is a C-type lectin receptor induced on macrophages by several stresses. We and other groups have shown that Mincle broadly recognizes a wide variety of ligands such as damaged cells, fungus, yeast and mycobacteria. In this research, we explored new pathogenic ligands and examined the function of Mincle in the defense mechanism against the pathogen.
We found that Mincle recognizes amphiphilic acylglucoside (AAG) derived from *Helicobacter pylori*. AAG activated macrophages to produce inflammatory cytokines such as TNF and MIP-2 (CXCL2), whereas these productions were impaired in macrophages derived from Mincle-deficient mice. Thus, Mincle is a receptor essential for recognition of AAG.
It is reported that AAG activates NKT cells in a CD1d-restricted fashion. We found that the production of IFNγ induced by AAG is suppressed in splenocytes from Mincle-deficient mice. This result suggests that signaling through Mincle leads to augmentation of the activation of NKT cells.
Given that IFNγ is known to prime macrophages, these results suggest that TCR on NKT cells and Mincle on myeloid cells may cooperatively contribute to augment immune responses in response to *H. pylori* through a positive feed-back loop.

P1.10.13
Natural IgG is not non-reactive: it plays a vital role in innate immune response

S. Panda*, J. L. Ding;*
National University of Singapore, Singapore, Singapore.

The function of natural antibodies, which pre-exist in neonates and uninfected individuals, has remained a biological enigma since decades of their discovery. However, our findings reveal that natural IgG, which constitutes a majority of the serum natural antibodies, plays a major protective role in innate immunity. We describe through a variety of in vitro and ex vivo techniques, a novel shortcut mechanism wherein natural IgG collaborates with specific interaction partners to recognize a diverse array of pathogens, and elicits vital frontline innate immune defense through receptor-mediated phagocytosis. This process is non-specific to antigens. To support our preliminary findings, in vivo studies using knockout mice which lack natural IgG, showed that these mice were susceptible to infection unless reconstituted with natural IgG. Overall, our findings shed light on the fundamental mechanistic role of natural IgG during infection that alters the general perception of the existence and biological function of natural antibodies.

P1.10.14
Antibodies against dengue NS1 and prM proteins increase the sensitivity of dengue diagnosis and differentiate Japanese encephalitis infection

G. S[1], *S. John Vennison*[1], *R. Paramasivan*[2], *K. Dhananjeyan*[2], *V. Thenmozhi*[2], *B. Tyagi*[2];
[1]*ANNA UNIVERSITY-BIT CAMPUS, TIRUCHIRAPPALLI, India,*
[2]*Centre for Research in Medical Entomology (ICMR), Madurai, India.*

Co-circulation of flaviviruses and sequential infections are common in developing and under-developing countries.Though cross-reactivity due to shared antigenic determinants among flavivirus subgroups have been observed commonly , cross-reactivity among different members of subgroups is rare.During the laboratory diagnosis of dengue infection using MAC-ELISA, it is necessary to rule out possible cross reactions of co-circulating flaviviruses such as Japanese encephalitis virus. In the present investigation, the usefulness of dengue virus NS1 and prM antibodies in diagnosing and differentiating dengue virus infection from Japanese encephalitis was assessed. The limitation for using NS1 specific IgM detection for dengue diagnosis increased beyond the acute phase of illness and detection of antibodies against dengue NS1 and prM proteins able to differentiate dengue from Japanese encephalitis infection in ELISA. The cross reactivity of IgM response in dengue diagnosis needs to be taken in to account especially in tropical and sub-tropical areas where there two or more flaviviruses co-circulate in one area and sequential infections are common.

P1.10.15
Cloning and characterization of cytosolic DNA in tumors

Y. Shen*, S. Gasser;*
National University of Singapore, Singapore, Singapore.

We have evidence that cytosolic DNA accumulates in response to DNA damage and is also present in tumor cells. To characterize the cytosolic DNA, we developed different strategies to clone single-stranded and double-stranded cytosolic DNA. Detailed analysis of the cloned DNA showed that the cytosolic DNA is derived from genomic DNA. Around 40% of the cloned DNA fragments corresponded to intronic sequences. Endogenous retroelements were found in over half the cloned sequences. To confirm the cloned DNA is present in the cytosol, we established a fluorescent in situ hybridization (FISH) method. FISH analysis confirmed the cytosolic localization of the cloned DNA. Cytosolic DNA is recognized by different DNA sensors which induce type I interferon secretion and regulate NKG2D ligands expression. We provide evidence that cytosolic DNA is interacting with different components of the DNA sensor pathway. In summary, our data suggest that genomic DNA accumulation in the cytosol of tumor cells and may contribute to immune responses by activating DNA sensors.

P1.10.16
Expression and role of the long pentraxin PTX3 in lymphatic endothelial cells

M. Sironi[1], *A. Doni*[1], *F. Pasqualini*[1], *S. Valentino*[1], *I. Laface*[1], *M. Nebuloni*[2], *C. Garlanda*[1], *B. Bottazzi*[1,3], *A. Vecchi*[1], *A. Mantovani*[1];
[1]*Humanitas Clinical and Research Center, Rozzano, Italy,* [2]*Pathology Unit, L.Sacco Dept. of Clinical Sciences, University of Milan, Milan, Italy,* [3]*Dept. Medical Biotechnology & Translational Medicine, University of Milan, Milan, Italy.*

Long pentraxin PTX3 is a soluble pattern recognition molecule which plays complex non redundant roles in vivo, ranging from the organization of a hyaluronic acid-rich extracellular matrix to female fertility and innate immune response to certain pathogens. PTX3 is produced in response to microbial recognition or inflammatory signals by different immune or stromal cells, however gene profiling efforts unexpectedly revealed that PTX3 is constitutively expressed by lymphatic endothelial cells (LECs) both in man and in the mouse. Immunohistochemistry and confocal analysis confirmed the presence of PTX3 in human and murine normal tissues around lymphatic but not blood vessels. A morphometric analysis of lymphatic vessels was performed by whole mounting in wild type and *ptx3-/-* mice. Results indicated that length, volume and cell area of lymphatic vessels in colon submucosa were increased in *ptx3-/-* mice compared to wild type. *Ptx3-/-* mice showed a reduced accumulation of Evans Blue dye in the draining popliteal lymph node at early times (15-30 min.) after injection into the foot pad, while no differences were observed between wild type and *ptx3-/-* mice one hour after injection. Preliminary data in *ptx3-/-* mice also indicated a reduced ability of dendritic cells to travel to draining lymph nodes under inflammatory conditions. Taken together these data indicate that PTX3 plays a non-redundant role in shaping and functionality of lymphatic vessels.

P1.10.17
Inhibition of interferon α expression with small interference RNA increases adenoviruses-GFP transduction and transgene expression in Huh7 cells

A. A. Sobrevilla Navarro[1], *A. S. Sandoval Rodríguez*[1], *J. J. García Bañuelos*[1], *P. Sanchez Hernández*[2], *L. D. Hernández Ortega*[1], *J. Gaona Bernal*[3], *J. Armendáriz Borunda*[1,4], *A. M. Salazar Montes*[1];
[1]*Institute of Molecular Biology in Medicine and Gene Therapy,CUCS, University of Guadalajara, Guadalajara Jalisco, Mexico,* [2]*Laboratory of Immunology,CUCS, University of Guadalajara, Guadalajara Jalisco, Mexico,* [3]*Laboratory of virology.Deparment of microbiology and parasitology, UNAM, Mexico,* [4]*OPD Hospital civil de Guadalajara, Guadalajara, Mexico.*

Introduction: Recombinant adenoviruses (rAd) are the mostcommonly vectors used in clinical trials of gene therapy. Systemic administration of rAd presents high tropism for liver. However, host´s immune response against rAd orchestrated by Interferons type 1 (α and β) limits the therapeutic gene expression and prevents new administrations. Aim: To evaluate the effect of IFNα inhibition by a small interfering RNA (siRNA) on rAd-GFP transduction and transgene expression in Huh7 cell line. Methods: Huh7 cells are cultured in DMEM, 5% FBS at 37 °C and 5%CO2 and then transfected with 70 nM of siRNA-IFNα. 6h later culture was exposed to 1.0 x 10^9 vp/ml of rAd-GFP for 24 hrs. Expression of IFNα1 and TNFα were determined by qRT-PCR. Cell transduction was analyzed by fluorescent analysis cell sorting (FACS) and qPCR. GFP expression was determined by western blot and qRT-PCR. Results: 70 nM of siRNA-IFNα1 inhibited 96% of IFNα1 gene expression ($p < 0.001$) and 65% of TNFα($p<0.05$) respect to control siRNA-irrelevant. Transduction and transgen expression were increased in cells treated with siRNA-IFNα1 compared to control. Conclusions: Inhibition of IFNα by siRNA-IFNα1 permits a higher transgene expression (GFP) indicating the crucial role of IFNα on adenoviruses elimination in transducted cells. This strategy could be useful in clinical trials directed to liver diseases, where adenoviruses are used as vectors for therapeutic genes; achieving an increased expression of these genes leading to better results in liver diseases resolution.

P1.10.18
ApoH an innate immune sensor and hunter that captures and scavenges infectious pathogens

S. Tigrett[1], *G. Dubois*[2], *E. Lucarz*[1], *I. Stefas*[1], ***F. Veas***[2];
[1]*ApoH-Technologies, Montpellier, France,* [2]*University Montpellier 1 - IRD, Montpellier, France.*

Apolipoprotein H (ApoH), or β2-glycoprotein I (50-kDa) circulates in blood at high concentrations (200 µg/mL). Apo-H is mainly produced in mammal's liver, but is also expressed, in a lesser extent, in other organs, including prostate, kidneys, small intestine, brain, and heart. ApoH is a pleitropic multifunctional protein, notably playing diverse physiological roles. The most well known is its role in autoimmune diseases, hemostasis, atherogenesis and angiogenesis, as well as the host defense against bacteria. Despite this, many physiological functions remain unknown. ApoH is composed of five similar domains. The fifth domain is lysin-rich containing an aromatic residue. ApoH binds negatively charged compounds and, in some unexplained cases, this activity induces anti-phospholipid antibodies. Peptides from the domain V exhibit antimicrobial activities. In addition, we have shown that ApoH is not able to capture commensal microorganisms. In contrast, it catches, with high affinity (~10-100 nM), a large variety of pernicious pathogens including: Gram+ and Gram- bacteria (ex. *Mycobacterium*, MRSA); parasites; enveloped or non-enveloped viruses (ex. Endogenous retroviruses, Hantaviruses, Rotaviruses, Dengue, HBV). ApoH capture these pathogens *via* certain forms of their conserved antigens, including: HBV-HbsAg, HIV-1/Env, HERV-K/ENV HERV-W/Env and Gag, LPS, Sbi, SFAS, IUT-A, PAP-G3, CNF1 from *E. coli* and CCRB and MECA from *Staphylococcus aureus* (and MRSA). ApoH induces pathogens removal through macrophages. But, in certain cases, to escape this response pathogens could use ApoH to enhance infection. ApoH is an innate immune sensor to scavenge microbes and modulate immune and inflammatory responses induced by pernicious pathogens.

P1.10.19
DAI (DLM-1/ZBP1) promotes lupus nephritis by activating calcium pathway

S. Xiong[1,2], *W. Zhang*[2], *W. Xu*[1];
[1]*Institutes of Biology and Medical Sciences, Soochow University, Suzhou, Jiangsu Province, China,* [2]*Institute for Immunobiology, Fudan University, Shanghai, China.*

DNA-dependent activator of IFN-regulatory factors, also referred to as DAI/DLM-1/ZBP1, functions as a cytoplasmic DNA sensor and activates innate immunity. We previously found that activated lymphocyte-derived apoptotic DNA (ALD-DNA) immunization could mediate pathological macrophage M2b polarization and lead to lupus nephritis. However, the specific DNA sensor(s) and mechanisms involved in the ALD-DNA-induced M2b polarization in SLE remain still unknown. Here, we reported that DAI expression was significantly increased both in lupus mice and in SLE patients, and play an important role in ALD-DNA-induced M2b polarization. By further exploration, we found that ALD-DNA notably induced DAI dimerization/oligomerization, subsequently activated downstream NF-κB and IRF3 by calcium pathway and consequently caused macrophage M2b polarization. More importantly, blockade of DAI or selective knockdown of DAI in macrophages could efficiently ameliorate SLE manifestations in mice by blunting M2b polarization and inflammation. So in lupus nephritis, DAI could function not only as a DNA sensor, but also as a regulator of ALD-DNA-induced macrophage M2b polarization. This study provided the possible mechanisms underlying ALD-DNA-induced macrophage M2b polarization, and made DAI as a potential therapeutic target for SLE and other macrophage mediated autoimmune disease.

P1.10.20
Functional Analyses of Recombinant Mouse hepcidin-1 in Cell Culture and Animal Model

Y. Yaghoub, *N. Keyhanvar;*
Golestan University of Medical Science, Gorgan, Iran, Gorgan, Iran.

Hepcidin as innate immune element plays an important role in iron metabolism. Human hepcidin-25 and mouse hepcidin-1 are major regulators of *iron metabolism in human and mouse respectively.* Using baculovirus expression system, we have produced the recombinant mouse hepcidin-1. The expression yield of it was obtained about 25 µg/ ml when cell culture media were supplemented with protease inhibitor cocktail. Functional assays indicated that recombinant mouse hepcidin-1 and synthetic human hepcidin-25 have similar effect on ferroportin expression as a target molecule in J774A cell line and peritoneal macrophages. However, recombinant mouse hepcidin-1 has lower effect than synthetic human hepcidin-25 in reducing iron level in blood circulation ($p < 0.01$)

***Neuinflam9/Toxo1* regulates the innate immune response after nerve injury and susceptibility to autoimmune neuroinflammation in rat**

N. Abdelmagid[1], *F. Al Nimer*[1], *J. Öckinger*[1], *R. Lindblom*[1], *X. Zhang*[1], *S. K. Bedri*[1], *A. Saoudi*[2], *G. Fournié*[2], *T. Olsson*[1], *M. Jagodic*[1], *F. Piehl*[1], *M. Diez*[1];
[1]*Karolinska Institute, Stockholm, Sweden,* [2]*Université de Toulouse, UPS, Centre de Physiopathologie de Toulouse Purpan (CPTP), Toulouse, France.*

The activation of CNS resident cells is a common theme in different neurological disorders exhibiting innate immune responses through activating toll-like receptors signaling pathways. To identify the genes predisposing CNS disorders through innate responses regulation, we performed a genome-wide linkage scan for expression of innate immune molecules after a standardized nerve injury in a rat F2 (BNxLEW.1N) intercross. We identified multiple expression

quantitative trait loci (eQTLs) responsible for the regulation of several toll-like receptors (TLRs) and interferon regulatory factors (IRFs). Among these were the previously identified *Neuinflam9* QTL on rat chromosome 10, which overlaps with *Toxo1* regulating resistance to *Toxoplasma gondii*, here found to also regulate the expression of *Tlr2* and *Irf7*. The influence of *Neuinflam9,* on the expression of these innate immune molecules after nerve injury was verified in two different BN.LEWc10 congenic lines (lineages B and E). The congenic BN.LEWc10-E also demonstrated resistance to experimental autoimmune encephalomyelitis strongly suggesting that the same gene(s) that regulated expression of innate immune molecules also regulates predisposition to autoimmune disease in the CNS. Identification of the gene(s) underlying these QTLs may reveal common pathways regulating innate immune activation in the CNS and identify new therapeutic targets for neuroinflammatory disorders.

P1.11.002

The Toll-IL-1R member Tir8 modulates post-transplant kidney ischemia/reperfusion injury by inhibiting resident leukocyte expansion

*P. Cassis, **S. Aiello**, N. Azzollini, S. Solini, G. Remuzzi, M. Noris; Mario Negri Institute for Pharmacological Research, Ranica, Italy.*

Ischemia/reperfusion injury (IRI), occurring after transplantation, activates TLRs/IL-1R on inflammatory leukocytes amplifying adaptive immune response. In a mouse model of renal artery clamp deficiency of Tir8, a IL-1R/TLR negative regulator, aggravated post-ischemic acute renal failure in association with intrarenal leukocyte accumulation.
We investigated the role of TIR8 in modulating post-transplant IRI and inflammatory response in mouse model of syngeneic kidney transplant. Donor and recipient C57BL/6 mice were congenic for CD45 leukocyte antigen to allow discriminating between intragraft recipient and donor leukocytes. Wild-type (wt-group n=5) or $Tir8^{-/-}$ ($Tir8^{-/-}$-group, n=5) donor kidneys were exposed to 30 min cold ischemia before transplant. Transient impairment of graft function was found at 1day post-transplant in wt-group (BUN: 1day 53±19, 30day: 27±3mg/dl). At variance the $Tir8^{-/-}$-group showed irreversible severe graft dysfunction (BUN: 1day 95±23, 30day: 67±23 mg/dl, P<0.05 vs wt-group).
Both at 10 and 30 days post-transplant lower numbers (P<0.05) of intragraft leukocytes were found in the wt-group (20±9/field, 61±18/field, respectively) vs the $Tir8^{-/-}$-group (104±17/field, 117±24/field, respectively). At 10 days the majority of leukocytes were of donor origin both in the wt and the $Tir8^{-/-}$ groups (79±8%, 78±2%, respectively). At 30days, in the wt-group the majority of intragraft leukocytes were of recipient origin (63±6%) while 63±2% of intragraft leukocytes were of donor origin in the $Tir8^{-/-}$-group.
These results indicate that TIR8 modulates post-transplant IRI possibly by suppressing expansion and activation of resident leukocytes within the kidney graft.

P1.11.003

Hematopoietic but not endothelial cell MyD88 contributes to host defense during gram-negative pneumonia derived sepsis

***A. A. Anas**[1], M. H. P. van Lieshout[1], S. Florquin[1], B. Hou[2], A. L. DeFranco[3], C. van t. Veer[1], A. F. de Vos[1], T. van der Poll[1];*
[1]Academic Medical Center, Amsterdam, Netherlands, [2]Chinese Academy of Sciences, Beijing, China, [3]UCSF, San Francisco, CA, United States.

Introduction: MyD88 is the common adapter of most Toll-like receptors (TLRs). MyD88 deficiency results in impaired host defense during infection. Knowledge of the contribution of different cell types to MyD88-mediated antibacterial defense is limited. The aim of our study was to determine the role of myeloid and endothelial cell MyD88 during murine *Klebsiella* pneumonia and sepsis.
Methods: We used the Cre-lox system to generate mice deficient for MyD88 in myeloid (LysM-MyD88-/-) or endothelial cells (Tek-MyD88-/-). Mice were intranasally inoculated with *Klebsiella pneumoniae* and euthanized after 24 hours for analyses or followed in a survival experiment.
Results: Both LysM-MyD88-/- and Tek-MyD88-/- mice showed a markedly accelerated lethality accompanied by a strongly enhanced bacterial outgrowth and dissemination after induction of *Klebsiella* pneumonia. In vitro studies with primary cells from Tek-MyD88-/- mice revealed that these mice were not only MyD88 deficient in endothelial but also in hematopoietic cells: TNF-a secretion in whole blood stimulated *ex vivo* with *Klebsiella* LPS or heat killed *Klebsiella* was even more strongly reduced than in LysM-MyD88-/- mice, while alveolar and peritoneal macrophages from both groups were impaired in a similar manner. Therefore, we transferred bone marrow from control mice in irradiated Tek-MyD88-/- mice to generate mice with a specific deletion of MyD88 in endothelial cells; these mice demonstrated an antibacterial defense that was restored to the level of control mice, indicating that endothelial cell MyD88 is not important for protective immunity.
Conclusion: Hematopoietic but not endothelial cell MyD88 contributes to host defense during gram-negative pneumonia derived sepsis.

P1.11.004

Activation and regulation of Toll-like receptors by infestation with Rhipicephalus sanguineus ticks

***E. Anatriello**[1,2], L. C. Ribeiro[3,3], I. Bueno[2,2], M. S. L. Nascimento[3,3], L. A. Sacramento[3,3], C. J. Oliveira[4,4], J. S. da Silva[3,3], I. K. F. d. Santos[3,3], B. R. Ferreira[2,2,2];*
[1]School of Nursing, University of São Paulo, University of São Paulo, Ribeirão Preto, Brazil, [2]School of Nursing, University of São Paulo, Ribeirão Preto, Brazil, [3]School of Medicine, University of São Paulo, Ribeirão Preto, Brazil, [4]Institute of Biological and Natural Sciences, Federal University of Triângulo Mineiro, Uberaba, Brazil.

1. Purpose/Objective: We have shown that tick saliva of Rhipicephalus sanguineus can supress the function of macrophages, lymphocytes and modulate differentiation, maturation, migration and function of DCs stimulated with ligands for TLRs. We observed that saliva of tick induced a high expression of TLR2 on DCs surface in vitro. Our goal is to check if the saliva is also able to modulate the expression of TLRs on DCs in vivo, and investigated if MyD88 disturb tick-infestation success on mice.
2. Material and Methods: We examined the expression of TLRs on DCs from the spleen and lymph nodes on days 3 and 7 of twice tick-infested mice. Additionally C57Bl/6 and MyD88(-/-) mice were infested with ticks and the biological parameters of tick were evaluated.
3. Results: Using flow cytometry, we observed that the expression the TLR1, 2, 5, 6 on DCs cells was significantly increased in both days analysed (p<0.05, t test) when compared with the non-infested group. Regarding the analysis of the tick-infestation we observed that there was an increase in the number of ticks that fed and the egg mass weight on MyD88-/- mice (p<0.05) compared with C57Bl/6 mice. Other biological parameters of ticks are still being analyzed.
4. Conclusions: These results suggest the importance of the MyD88 for the success of the tick infestation and that the augmented expression of some TLRs on DCs can modulate the host immune response. Consequently, this study can contribute to new perspectives for the control of the ticks
Supported by FAPESP.

P1.11.005

Combined Action of Nucleic Acid-Sensing Toll-Like Receptors and TLR11/TLR12 heterodimers imparts host resistance to Toxoplasma gondii

***W. A. Andrade**[1], M. C. Souza[2], E. R. Martinez[3], K. Nagpal[4], S. Ghosh[5], D. T. Golenbock[4], R. T. Gazzinelli[1,4];*
[1]Federal University of Minas Gerais, Belo Horizonte, Brazil, [2]University of São Paulo, Ribeirão Preto, Brazil, [3]Universidad Autonoma de Mexico, Mexico City, Mexico, [4]University of Massachusetts, Worcester, MA, United States, [5]Columbia University, New York, NY, United States.

One third of the human population in the world is chronically infected with *Toxoplasma gondii.* While the majority of infected individuals are asymptomatic, toxoplasmosis is a major cause of congenital disease, abortion, and a life threatening opportunistic disease in immunocompromised individuals. Early activation of the innate immune system and cytokine production (i.e. IL-12 and IFN-) by myeloid cells is required for establishment of protective immunity to *T.*

gondii infection. ‘‘Triple-defective’’ (3d) mice carrying a mutation in UNC93B1, a chaperone for the endosomal Nucleic Acid-Sensing (NAS) Toll-like receptors TLR3, 7 and 9, are highly susceptible to *T. gondii* infection. However, none of the single or even the triple NAS-TLR-deficient animals recapitulated the 3d susceptible phenotype. Investigating this further, we found that while parasite RNA and DNA activate innate immune responses via the NAS-TLRs TLR7 and TLR9, TLR11 and TLR12 working as heterodimers are required for sensing and responding to *Toxoplasma* profilin. Consequently, the triple TLR7/TLR9/TLR11-deficient mice are highly susceptible to *T. gondii* infection, recapitulating the phenotype of 3d mice. Humans lack functional TLR11 and TLR12 genes. Consistently, human cells produce high levels of proinflammatory cytokines in response to parasite derived RNA and DNA, but not to *Toxoplasma* profilin, supporting a more critical role for NAS TLRs in human toxoplasmosis.

Role of TIR8/SIGIRR in regulating TLR and IL-1R like-dependent platelet activation

A. Anselmo[1], *C. Soldani*[1], *S. Gentile*[1], *M. Bacci*[1], *A. Voza*[1], *M. Nebuloni*[2], *L. Mendolicchio*[1], *A. Mantovani*[1], *F. Riva*[2], *C. Garlanda*[1];
[1]*Humanitas Clinical and Research Centre, Rozzano, Italy,* [2]*University of Milano, Milan, Italy.*

TIR8, or single Ig IL-1R-related molecule, SIGIRR, is a member of the IL-1R like (ILR) family, which acts as negative regulator of TLR and ILR signalling, playing non-redundant roles in tuning inflammatory responses in different pathological conditions.
Platelets express functional TLRs, which are involved in sepsis-induced thrombocytopenia, binding of bacteria, neutrophil extracellular trap production and platelet activation via P-selectin and active GPaIIbIII upregulation. In addition, IL-1RI has been shown in platelets.
We investigated the expression of TIR8/SIGIRR and other ILR regulated by TIR8 in platelets, and defined the potential involvement of TIR8/SIGIRR in TLR- and ILR-dependent platelet activation. We confirmed IL-1RI expression and showed for the first time TIR8/SIGIRR, IL-18R and IL-33R expression in human and murine platelets and megakaryocytes. Functional studies showed that stimulation with TLR and ILR ligands (LPS, IL-1β and IL-18) induced upregulation of P-selectin and active GPIIbIIIa and calcium mobilization. Platelet TIR8/SIGIRR expression was downregulated upon LPS stimulation or in patients with Systemic Inflammatory Response Syndrome compared to healthy donors. Finally, functional studies showed that Tir8-deficiency in mice was associated to platelet hyperactivity in basal conditions and upon stimulation with LPS, IL-18 and IL-1β, as demonstrated by increased P-selectin and active GPaIIbIII upregulation, calcium mobilization and neutrophil/platelet aggregation.
Thus, TIR8/SIGIRR is a regulator of platelet activation in inflammatory conditions induced by TLR and ILR family ligands. The modulation of TIR8/SIGIRR expression in platelets in severe inflammatory conditions suggests that it might represent a novel diagnostic or therapeutic target in prothrombotic conditions associated to inflammatory diseases.

Interaction of Bordetella pertussis filamentous hemagglutinin with human TLR2: identification of the TLR2-binding domain

H. Asgarian-Omran[1,2], *A. Amirzargar*[3], *S. Zeerleder*[4,5], *M. Mahdavi*[6], *G. van Mierlo*[4], *S. Solati*[4], *M. Jeddi-Tehrani*[6], *H. Rabbani*[6], *L. Aarden*[4], *F. Shokri*[1,6];
[1]*Department of Immunology, School of Public Health, Tehran University of Medical Sciences, Tehran, Ir, Tehran, Iran,* [2]*Department of Immunology, Faculty of Medicine, Mazandaran University of Medical Sciences, Sari, Iran, Sari, Iran,* [3]*Department of Immunology, School of Medicine, Tehran University of Medical Sciences, Tehran, Ir, Tehran, Iran,* [4]*Department of Immunopathology, Sanquin Research Institute, Amsterdam, The Netherlands, Amsterdam, Netherlands,* [5]*Department of Hematology, Academic Medical Center, Amsterdam, The Netherlands, Amsterdam, Netherlands,* [6]*Monoclonal Antibody Research Center, Avicenna Research Institute, ACECR, Tehran, Iran, Tehran, Iran.*

Filamentous hemagglutinin (FHA) is a major adhesion and virulence factor of Bordetella pertussis and also a main component of acellular pertussis vaccines. Interaction of FHA with different receptors on human epithelial and immune cells facilitates entrance and colonization of bacteria as well as immunomodulation of the host immune response. Three overlapping segments of the FHA gene were cloned in a prokaryotic expression vector and the recombinant proteins were purified and applied along with the native FHA protein to assess their potential Toll-like receptor (TLR) stimulatory effects and to localize the TLR binding region. TLR stimulation was monitored by applying HEK293-Blue cell lines cotransfected with TLR2, 4 or 5 and a NF-κB reporter gene. Culture supernatants were checked for secretion of the reporter gene product and IL-8 as indicators of TLR stimulation. Native FHA was found to strongly stimulate TLR2, but not TLR4 or TLR5 transfected cells. Among the recombinant FHA fragments only the fragment spanning amino acid residues 1544-1917 was able to stimulate TLR2 transfected cells. Interaction of FHA with TLR2 suggests its involvement in induction of the innate immune system against Bordetella pertussis. The TLR2-binding domain of FHA may contribute to immunoprotection against pertussis infection.

P1.11.008
S100A8 and S100A9 promote hyporesponsiveness of phagocytes in polytrauma and burn patients

J. Austermann[1], *S. Fassl*[1], *B. Petersen*[1], *E. Faist*[2], *S. Zedler*[2], *T. Vogl*[1], *J. Roth*[1];
[1]*University of Muenster, Muenster, Germany,* [2]*Ludwig-Maximilian University, Munich, Germany.*

Background: Phagocytes of polytrauma and burn patients develop a hypo-responsive stage leading to secondary infections and mortality. In Gram-negative sepsis this hypoinflammation is a well-known phenomenon which is triggered by a process called endotoxin-tolerance. Endotoxin-tolerance is induced by prior exposure of endotoxins to Toll-like receptor 4 (TLR4). Since an initial microbial trigger is often missing in polytrauma and burn patients we hypothesized that this inflammatory process can additionally be modulated by endogenous activators of TLR4, like the alarmins S100A8 and S100A9.
Materials and methods: Tolerance was induced by pretreatment of phagocytes with low doses of LPS or S100A8/S100A9 prior to activation. Inflammatory response was quantified by determining cytokine release and validating corresponding mRNA-levels via RT-PCR. In vivo experiments were performed by determining survival rates of mice in a septic shock model. NF-κB activation was determined by western blot analysis. ChIP-assays were used to manifest epigenetic modifications of the TNFα-promoter.
Results: We observed highly elevated S100A8/S100A9 serum concentrations in the initial disease phase in polytrauma and burn patients which predict lethal outcome in the latter. Pre-activation of TLR4 by S100A8/S100A9 induces tolerance, accompanied by diminished secretion of proinflammatory cytokines in vitro and enhanced survival rates of mice during septic shock. NF-κB transcription factor analysis and TNFα-promoter studies revealed an increase of nuclear RelB and of methyltransferase G9a-dependent histone methylation in S100-tolerized phagocytes. Conclusions: S100A8/S100A9 induces endotoxin-tolerance in phagocytes via activation of TLR4 signaling pathways and epigenetic modification of gene expression, relevant for development of hypoinflammation in burn and polytrauma patients.

P1.11.009
Extended anti-cancer immunity by liposomes coencapsulating nucleic acid TLR-ligands and antigen

B. Bayyurt[1], *G. Gucluler*[1], *D. Bayik*[1], *E. Alpdundar*[2], *S. Yildiz*[2], *B. H. Horuluoglu*[1], *M. Ozcan*[2], *M. Gursel*[2], *I. Gursel*[1];
[1]*Biotherapeutics ODN Research Lab., Department of Molecular Biology and Genetics, Bilkent University, Ankara, Turkey,* [2]*Dept of Biological Sciences, Middle East Technical University, Ankara, Turkey.*

Nucleic acid based TLR ligands are initiating strong innate immune activation. However, their potential use in clinic due to in vivo degradation by nucleases or rapid clearance by serum protein

adsorption is hampered. Encapsulation of these labile ligands within liposome not only increases their stability and protects them from digestion but also enhances their immunostimulatory breadth. In this study, C57/BL6 mice were twice injected i.p. with free or encapsulated pI:C, CpGODN or their combinations together with ovalbumin. Two weeks after booster injection (@d=28) and every month thereafter sera were collected for eight months and OVA-specific Ig subtypes were studied by ELISA. Th1-biased immunity was calculated for each group (CpG+OVA or pIC+CpG+OVA gave the highest IgG2c/IgG1 ratio). Next, animals were inoculated with 4x106 EG7 thymoma cells expressing OVA. Tumor sizes were recorded and plotted as mm3. While all naive mice had palpable tumors by 4-5 days post inoculation, no tumor development was observed in animals vaccinated either with pI:C or D35 or their combinations with OVA in liposomes even after three weeks of post EG7 inoculation. Next, splenocytes were incubated with OVA-peptide and IFNg-producing T-cells were determined by ELISPOT. Tumor-resident, Foxp3+ cells were analyzed by FACS. Both CpG+OVA and pIC+CpG+OVA treated animals had the highest IFNg+ CD8 T-cells and the lowest number of Foxp3+ Treg cells, indicating a strong tumor-specific cytotoxicity was established by these vaccine formulations leading to complete tumor eradication 8 month post-vaccination. In conclusion, liposomes coencapsulating ssDNA or dsRNA plus antigen are promising anti-cancer vaccine candidates.

P1.11.010
R848, a Toll-like receptor 7/8 agonist, a potential therapy for allergic rhinitis patients

***G. Boghdadi**, N. Hammad, A. Amer, S. Sammour, S. Sorour;*
Faculty of Medicine, Zagazig, Egypt.

Objectives: There is a growing interest in the targeting of Toll-like receptors (TLRs) for the treatment of allergic diseases. Several new compounds are now undergoing preclinical and clinical evaluation. The study focus on TLRs7/8 ligand; resiquimod (R848) as an adjuvant to immunotherapy (IT) in AR patient and assess its effect as an immune-modulator on the pro-inflammatory and anti-inflammatory cytokines.
Material and Methods: Peripheral blood mononuclear cells (PBMCs) were obtained from 20 non atopic donors, 10 non IT atopic donors and 10 IT atopic donors. PBMCs were cultured in the absence and presence of date palm pollen allergen (Phoenix dactylifera; Pho d) and/ or R848. Interleukin (IL4), IL-10, IL-13 and interferon gamma (IFN-γ) were measured in the culture supernatants.
Results: R848 was able to significantly increase the anti-inflammatory response in atopic donors more than non atopic donors. IL-10 production was significantly reduced in R848 + Pho d stimulated cultures when compared to Pho d stimulated ones. Moreover, IFN-γ production was significantly increased in R484+ Pho d stimulated cultures when compared to Pho d stimulated ones. Nevertheless, the combination of both; R848 and Pho d provides inferior stimulus when compared to R848 alone in both atopic and non atopic donors.
Conclusion: Our data show that in vitro treatment of PBMCs with R484 hijacks the pro-inflammatory immune process triggered by TLRs7/8 to mediate anti-inflammatory response. This provides important insight into the efficacy and mode of action of TLRs7/8 ligands in AR and paves the way for their clinical application in humans.

P1.11.011
TLR4-induced activation of human monocyte cell line U937 by sickle patient's mmLDL. Possible experimental model for atherosclerosis initial phase

***B. E. Brito**[1], M. A. Duarte[1], E. L. Romano[1], M. E. Marquez[1], L. Baute[1], O. Perez-Bandez[2], N. Torrez[3];*
[1]Venezuelan Institute for Scientific Research (IVIC), Caracas, Venezuela, [2]Municipal Blood Bank-Capital District, Caracas, Venezuela, [3]Minicipal Blood Bank-Capital District, Caracas, Venezuela.

We studied the role of TLR4 in human monocytic cell U937 activation responding to in vivo minimally modified LDL (mmLDL) from patients with sickle cell disease (HbSS, n=48) compared with control (Hb AA, n=51). Free hemoglobin, hemin and iron overload, due to chronic hemolysis in these patients, promote an environment that catalyzes the production of free radicals that cause oxidative stress in the circulation. In these patients, LDL suffer oxidative modification while they circulate in the plasma. In vitro activation of U937 cells was performed with mmLDL isolated from patients. Membrane expression of CD54, Mac-1 and TLR4 on U937 cells was characterized by flow citometry. Concentration and mRNA of IL-8, MCP-1 and TNF-alpha were determined by ELISA and RT-PCR. Our results suggest that incubation for 48 h with mmLDL increased the expression of TLR4 on U937 cells surface as well as the expression of mRNA and secretion of MCP-1, IL-8 and TNF-alpha. Pre-incubation with anti-TLR4 antibody induced a significant inhibition of these cytokines concentration, suggesting that the expression of TLR4 on U937 cells surface has an important role in monocytes activation by mmLDL in patients with HbSS. We suggest that oxidative stress in hemolytic anemias can promote a minimal oxidation of LDL in circulation that would be recognized as an endogenous activating ligand for TLR4 on monocytes. This mmLDL could induce cytokines secretion which interaction with their receptors on endothelial cell surface might generate an inflammatory vessel response similar to that observed during the initial phase of an atherosclerotic process.

P1.11.012
Fungal stimulated inflammatory response of gestation associated tissues

***A. H. Bryant**, R. H. Jones, N. Melo, S. E. Owens, L. B. Davies, G. Morgan, I. M. Sheldon, C. A. Thornton;*
Swansea University, Swansea, United Kingdom.

Inflammatory mediators produced by gestation-associated tissues (amnion, choriodecidua and placenta) in response to multiple pathogen-associated molecular patterns (PAMPs) are implicated in infection-associated preterm labour. Little is known about the inflammatory response of these tissues to fungal stimuli. C-type lectin receptors (CLRs), including dectin-1, are a family of pattern recognition receptors (PRRs) involved in host recognition of fungal pathogens.
Expression of transcripts for antifungal PRRs by healthy term amnion, choriodecidua and placenta was examined by PCR. The response of each tissue (n = 4) to live and inactivated *C. albicans* (10^6cells/ml) and to the dectin-1 PAMPs (depleted zymosan, curdlan; both 100ug/ml) was determined by measuring IL-6, IL-8 and IL-1β using ELISAs. Biochemical inhibitors were used to elucidate signalling pathways.
All gestation-associated tissues expressed transcripts for dectin-1, dectin-2, MINCLE, DC-SIGN and mannose receptor. Live *C. albicans* induced significantly increased IL-6 production in placenta and choriodecidua , but not amnion; IL-8 production was only induced in placenta. Inactivated *Candida* had no significant effect in any tissue. Curdlan and depleted zymosan significantly increased IL-6 production in amnion, choriodecidua, and placenta, although significant IL-8 production only occurred in curdlan stimulated placenta and IL-1β production only occurred in curdlan stimulated placenta and choriodecidua. Inhibition of reactive oxygen species (ROS) production with butylated hydroxyanisole abrogated curdlan-induced IL-1β production.
The placenta, choriodecidua and amnion can mount an inflammatory response to fungal stimuli including ROS-dependent activation of the inflammasome by curdlan for IL-1β production in the placenta and choriodecidua.

P1.11.013

Triggering receptor expressed on myeloid cells (TREM)-1 and -2 in bronchoalveolar lavage fluid in pulmonary sarcoidosis

M. Buc[1], *M. Suchankova*[1], *M. Bucova*[1], *E. Tibenska*[2], *E. Tedlova*[3], *J. Demian*[3], *I. Majer*[3], *H. Novosadova*[3], *M. Tedla*[4], *E. Paulovicova*[5];
[1]*Department of Immunology, Comenius University School of Medicine, Bratislava, Slovakia,* [2]*Medirex, Ltd, Bratislava, Slovakia,* [3]*Department of Pneumology and Phthisiology, Comenius University School of Medicine, Bratislava, Slovakia,* [4]*1st Department of Otorhinolaryngology, Comenius University School of Medicine, Bratislava, Slovakia,* [5]*Institute of Chemistry, Slovak Academy of Science, Centre of Excellence Glycomed, Bratislava, Slovakia.*

Background and objective. Pulmonary Sarcoidosis (PS) is characterized by the formation of granulomas in lungs and has been associated with infection by microorganisms. Triggering receptor expressed on the surface of myeloid cells-1 (TREM-1) is over-expressed in response to infection while TREM-2 is involved in granuloma formation. We hypothesised that these receptors are over-expressed in PS and might be useful for diagnostic testing.
Methods. Cell surface TREM-1 and TREM-2 expression in cells obtained at bronchoalveolar lavage (BAL) was measured in individuals with sarcoidosis (n = 26) and compared to that seen in individuals with other interstitial lung diseases (ILD) (n=27).
Results. TREM-1 and TREM-2 expression was significantly increased in sarcoidosis compared to other ILDs: total number of TREM-1: p=0.0039 (23.81 vs. 13.50 cells/µl), TREM-2: p<0.0001 (32.81 vs. 7.76 cells/µl); percentage of TREM-1: p=0.0002 (41.30% vs.15.70%); TREM-2: p<0.0001 (34% vs. 9.60%) and mean fluorescence of TREM-1: p=0.0005 (5.43 vs. 1.96), TREM-2: p=0.0011 (6.85 vs. 2.77). Increase in both of these receptors seems to be typical for pulmonary sarcoidosis. In discriminating sarcoidosis from other ILDs, the specificity (96%) and sensitivity (72%) of the combination of TREM-1 and TREM-2 was high.
Conclusions. Increased TREM-1 and TREM-2 cell surface expression is observed in sarcoidosis. Evaluation of BAL cell expression of both of these receptors may serve as a diagnostic marker for sarcoidosis.

P1.11.014

Increased CD4 T cell survival during in vivo OVA-LPS presentation is partly inhibited by indomethacin and recovered by PGE2 analog

J. C. Campopiano[1,2], *J. F. Jacysyn*[3], *M. Zenteno*[1,2], *T. B. da Costa*[1,4], *K. R. Bortoluci*[5,4], *G. P. Amarante-Mendes*[1,2];

Clonal activation, proliferation and differentiation into effector cells occur when CD4+ T lymphocytes recognize antigenic peptides presented by dendritic cells (DCs). DC maturation occurs through stimulation of Toll like receptors (TLRs), which increase their antigen presentation ability and affects the profile of soluble molecules. The expansion and differentiation of antigen-specific CD4+ T cells are followed by a contraction phase due to Activation-Induced Cell Death (AICD) or Activated T Cell Autonomous cell Death (ACAD) to reestablish homeostasis. Our group demonstrated that LPS stimulated-DCs protects T cells from AICD by preventing TcR/CD3-mediated FASL upregulation. The protective effect is partially mediated by PGE2. Our hypothesis is that antigen presentation in the context of infection impacts on FASL expression and survival of CD4 T cells, dependently on TLR-mediated release of PGE2. To approach our hypothesis, we used an in vivo model of adoptive cell transfer in which splenocytes from DO11.10 mice were labeled with CFSE and transferred to wild-type syngeneic BALB/c. These mice were inoculated with pOVA±LPS and pretreated with indomethacin and/or misoprostol. The addition of LPS during pOVA presentation increased specific CD4+ T cells activation and proliferation. Pretreatment of mice with indomethacin, an inhibitor of COX2, reduces the frequency of specific T cells by increasing FASL expression and apoptosis, but did not interfere with proliferation. Addition of misoprostol, which mimics PGE2, inhibits FASL and restores the survival of specific cells, suggesting that endogenous PGE2 produced in response to LPS modulates the number of specific T cells by controlling FASL expression.

P1.11.015

Optimal Immune Response Is Mediated by CD8-IFN Gamma Production and Macrophages-iNOS Expression in trigeminal ganglia, after Interactions of Toll Like Receptors in Herpes Simplex Virus -1 (HSV-1) Infection

G. P. Zolini[1], *G. K. Lima*[2], *N. Lucinda*[1], *M. G. A. Silva*[1], *S. R. Béla*[1], *L. R. V. Antonelli*[1], *N. L. Pessoa*[1], *B. C. Pizziolo*[1], *E. G. Kroon*[2], ***M. A. Campos***[1];
[1]*Instituto René Rachou, Belo Horizonte, Brazil,* [2]*Universidade Federal de Minas Gerais, Belo Horizonte, Brazil.*

HSV-1 cause cold sores, or even encephalitis. In this work, $TLR2^{-/-}$, $TLR9^{-/-}$, $TLR2/9^{-/-}$ and WT mice were intranasally infected with HSV-1, and were euthanized at the 5th day post infection (dpi) and then trigeminal ganglia (TG) and brain were collected. $TCD8^{+}$ IFN gamma cell producers (cytometry assay) were higher in TG of infected than in uninfected mice. Infected WT mice showed increase in the expression of TLR1, TLR2, TLR3, TLR6, TLR7 and TLR9 in TG (Real Time PCR), but not in brain, compared to control. The infected knockout mice had increased expression of TLR1, TLR3, TLR6, TLR7 and additionally of TLR2 (for $TLR9^{-/-}$) and of TLR9 (for $TLR2^{-/-}$) in TG, compared to non infected mice, but decreased expression when compared to WT mice. iNOS expression in TG of infected WT was higher than in TG of knockout mice, what not occurs with the expression in TG of $gp91^{phox}$ and $p22^{phox}$, although the three genes had higher expression in TG of WT and knockouts infected mice in comparison to non infected mice. In addition, intraperitoneal macrophages of WT mice produced more nitric oxide after exposition to HSV-1 than TLR knockout mice. $RAG^{-/-}$ mice were not capable to express cytokines, and $iNOS^{-/-}$ mice showed an excessive response to cytokines expression. Finally, in survival assay with WT, $CCL3^{-/-}$, $CD8^{-/-}$, $RAG^{-/-}$ and $iNOS^{-/-}$ mice, we showed the importance of the CD8 and iNOS, because $CD8^{-/-}$, $RAG^{-/-}$ and $iNOS^{-/-}$ infected mice had 100% of mortality, compared to 10% in WT infected mice.

P1.11.016

Monocyte-produced TLR2 and TLR4 but not prolactin are involved in both, late-onset autoimmune diabetes and type 2 diabetes development

P. Cejkova[1], *V. Slukova*[1], *I. Nemeckova*[1], *J. Broz*[2], *M. Andel*[2], *M. Cerna*[3];
[1]*Faculty of Science, Charles University in Prague, Prague 2, Czech Republic,* [2]*Faculty Hospital Kralovske Vinohrady, Prague 10, Czech Republic,* [3]*Third Faculty of Medicine, Charles University in Prague, Prague 10, Czech Republic.*

We aim to define a role of monocytic PRL in the induction of immune dysbalances leading to late-onset autoimmune diabetes (AD) and by detecting TLRs, key molecules of innate immunity, to identify differences that may reflect reaction of organism to bacterial and viral infection in AD, type 2 diabetes (T2D), non-diabetic patients (nonDM) and healthy individuals.
In total, 107 blood samples were collected for monocytes separation and subsequent detection of PRL, TLR2 and TLR4 mRNA by quantitative PCR and protein molecules by flow cytometry. The analyzed adult diabetic samples were as follows: T1D (19), LADA (4), T2D (9). As controls, 60 healthy subjects and 15 specimens from non-diabetic patients (nonDM) were used.
Compared to data gained from system autoimmune disorders, prolactin produced by monocytes does not seem to contribute to the ethiopathogenesis of late-onset organ-specific AD. The autoimmune condition is accompanied by lowering numbers of monocytes, particularly $CD14^{high}TLR2/4^{high}$ expressing cells (2 times less, P<0.0001), in comparison to physiological state, whereas $CD14^{low}TLR2/4^{low}$ counts in AD are increased (P=NS). This finding is surprising when taken into consideration corresponding gene expression at the mRNA level, which is lower in healthy subjects than in all diseased patients (in TLR2 31-41.4 times depending on diseased group, P<0.0001, and in TLR4 9-11 times depending on

diseased group, P<0.0001). Further, the onset after 35 years of age corresponded with 1.37 times higher counts of monocytes (P<0.05) and 1.47 times increased numbers of cells with $CD14^{high}TLR^{2;4high}$ receptor expression (P<0.05).

P1.11.017
Roles of an innate immune regulator TBK1-Associated Protein in Endolysosomes (TAPE) in the RIG-I-like receptor and DNA sensor pathways

K. Chen[1], *C. Chang*[2], *C. Huang*[3], *C. Lin*[2], *W. Lin*[2], *Y. Lo*[2], *C. Yang*[3], *A. Shiau*[1,2], *T. Tan*[3], *P. Ling*[2,4,5];
[1]*Institute of Basic Medical Sciences, College of Medicine, National Cheng Kung University, Tainan, Taiwan,* [2]*Department of Microbiology and Immunology, College of Medicine, National Cheng Kung University, Tainan, Taiwan,* [3]*Immunology Research Center, National Health Research Institutes, Zhunan, Taiwan,* [4]*Department of Medical Laboratory Science and Biotechnology, College of Medicine, National Cheng Kung University, Tainan, Taiwan,* [5]*Center of Infectious Disease and Signaling Research, College of Medicine, National Cheng Kung University, Tainan, Taiwan.*

RIG-I-like receptors (RLRs) and DNA sensors are key cytosolic sensors for recognizing viral nucleic acids to trigger antiviral immunity. The underlying mechanisms linking RLR- and DNA sensor-mediated viral recognition to antiviral immunity remain to be further explored. A previous work from the lab led to the discovery of a novel innate immune regulator called TAPE (TBK1-Associated Protein in Endolysosomes), also known as CC2D1A/Freud-1/Aki-1. TAPE is located in endolysosomes and links TLR3 and TLR4 to IFN-β activation. We further explored the potential roles of TAPE in the RLR and DNA sensing pathways. First, knockdown of TAPE impaired RIG-I- and MDA5-mediated IFN-β activation. In contrast, knockdown of TAPE failed to impair IPS-1/MAVS- and STING-mediated IFN-β promoter activation. TAPE was shown to associate with IPS-1/MAVS in a complex with RIG-I or MDA5 in mammalian cells. Genetic evidence showed that TAPE-deficient mouse embryonic fibroblasts (MEFs) were defective in RLR ligand-induced IRF3 phosphorylation and IFN-β activation. Also, TAPE knockdown or deficiency diminished cytokine induction and antiviral responses upon RNA virus infection. However, TAPE deficiency in MEFs failed to impair DNA-induced IFN-β activation. Together, our data support a crucial role for TAPE in linking RIG-I and MDA5 to type I IFN-mediated antiviral responses. Future work will determine in vivo role of TAPE in innate immunity using TAPE conditional knockout mice and explore the mechanistic mechanisms of how TAPE regulates the RLR pathways.

P1.11.018
Immunostimulatory activities of CpG-oligodeoxynucleotides in zebrafish

D. Yeh, Y. Liu, ***T. Chuang****;*
National Health Research Institutes, Miaoli County, Taiwan.

CpG-oligodeoxynucleotides (CpG-ODN) are potent immune stimuli. Their activity is dependent on the context of their nucleotide sequences, for example CpG-ODN containing GACGTT motif are more potent in activation of murine cells than CpG-ODN with GTCGTT motif, whereas the GTCGTT motif containing CpG-ODN are more active in human and different domestic animals. Toll-like receptor (TLR) 9 is the cellular receptor for CpG-ODN in mammals, and TLR21 mediates their functions in chicken. The avian genomes are luck of *TLR9*, and mammalian genomes do not contain *TLR21*, whereas both genes are presence in fishes. CpG-ODN are investigated as vaccine adjuvant and ant-microbial agent for fishes but the biological function of fish TLR9 and TLR21 have not yet investigated.
In the present study, we comparatively investigated the expression, structural relationship and function of zebrafish TLR9 and TLR21 in an attempt to address the molecular basis of the immunostimulatory activities of CpG-ODN in fishes. Our results showed that both zebTLR9 and zebTLR21 have parallel expression profiles. They are expressed in the early stages during embryonic development, and are expressed in innate immunity related organs in adult fish, as well as expressed inside cells. In addition, both zebTLRs are functional. They are responding to CpG-ODN stimulation and cooperatively mediated the immunostimulatory activities of CpG-ODN in zebrafish.

P1.11.019
New molecular tools to investigate LPS recognition

R. Cighetti[1], *V. Calabrese*[1], *G. Damore*[1], *M. Piazza*[2], *F. Peri*[1];
[1]*Università degli Studi di Milano-Bicocca, Milano, Italy,* [2]*Alpha-O Peptides AG, Basel, Switzerland.*

Toll-Like Receptor 4 (TLR4) is one of the most important receptors of innate immunity, since it is responsible for the sensing of Lipopolysaccharide (LPS) and thus of the presence of bacteria. It works in association with proteins MD-2, LBP and CD14. In our laboratory we develop small molecules based on saccharidic scaffolds that target proteins of the TLR4 pathway and act as antagonists. Their selectivity makes them hit compounds for the treatment of several pathologies related to TLR4 pathway dysfunctions, but they are also good candidates as tools to selectively modify a biochemical route with no need to genetic engineer the cells (the “chemical genetics” approach). In this communication we will show a library of molecules that were developed in our laboratory and their biological characterization to this day.
Visualizing molecular interactions in biological samples or *in vivo* would also be very useful in order to understand which processes take place during LPS sensing by the immune system. Fluorescence microscopy is an efficient method to visualize molecular interaction both *in vivo* and *in vitro*.
The immuno-fluorescent staining of a sample is achieved with the use of fluorescent-labelled antibodies. The major drawback of this method is the high price of antibody-fluorescent conjugates. Fluorescent small molecules that show a good specificity for a protein target could be used as substitutes. Also, since chemical synthesis of small molecules frequently is easier and cheaper than biological production of antibodies, the chemical approach to fluorescent staining could be a convenient alternative to antibody labeling.

P1.11.020
The Q705K genetic variant in *NLRP3* leads to inflammasome hyperactivation and contributes to invasive aspergillosis after stem cell transplantation

C. Cunha[1], *C. Galosi*[1], *M. Puccetti*[1], *F. Aversa*[2], *L. Romani*[1], *A. Carvalho*[1];
[1]*Department of Experimental Medicine and Biochemical Sciences, University of Perugia, Perugia, Italy,* [2]*Department of Clinical and Experimental Medicine, University of Parma, Parma, Italy.*

The role of inflammasome stimulation, in particular NLRP3, in antifungal immunity has been the subject of many recent investigations in both mice and humans. Stimulation of the NLRP3 inflammasome has been demonstrated to occur in response to fungi, suggesting a crucial role in antifungal resistance. To understand the cellular and molecular immune pathways by which NLRP3 inflammasome activation might affect antifungal immunity, we have analyzed the association between genetic variants in the *NLRP3* gene and susceptibility to invasive aspergillosis in hematopoietic stem cell transplanted patients. We found that a genetic variant in *NLRP3* (rs25829419, Q705K) was associated with or tended to invasive aspergillosis when present in either donors, recipients or both. Moreover, this variant also led to poorer overall survival after transplantation. Functionally, the presence of the Q705K variant in human monocytes was correlated with an increased functional activity of the NLRP3 inflammasome, as revealed by increased levels of IL-1β and IL-18 upon stimulation with *Aspergillus fumigatus*. In conclusion, our results suggest that an hyperactivation of the NLRP3 inflammasome may be detrimental to antifungal immunity and therefore contribute to susceptibility to fungal infections in immunocompromised patients.

P1.11.021
The Role of TLRs in the Dogs Immunized with the Gentamicin-attenuated L. infantum Compared with Dogs Infected with Wild-type Parasites

M. Davarpanah*;*
Kerman, Kerman, Iran.

Introduction: *Leishmania* is an intracellular pathogen that invades host immune system. *Leishmania infantum* (*L. infantum*) is a cause of

canine visceral leishmaniasis (CVL). The outcome of the disease basically relies on the balance between Th1/Th2 immune responses. How does *Leishmania* regulate host innate immune system? Still it is unanswered. The Toll-like receptors (TLRs) play very important role during inflammatory process of various diseases. Identification of leishmanial antigens that modulate toll-like receptor signaling will certainly help in the development of future vaccine. In this study we defined the role of TLRs in the dogs immunized with the gentamicin-attenuated *L. infantum* compared with dogs infected with wild-type parasites.
Material and methods: Thirty dogs (10 dogs per group) were used in this study. The peripheral blood mononuclear cells (PBMCs) were collected from dogs vaccinated with the attenuated parasites and dogs infected with wild-type. DNA will be extracted and the expression of TLR9 will be detected using RT- PCR

P1.11.022
Unbalanced cytokine production in inducible nitric oxide synthase-deficient neonate mice upon in vitro stimulation with TLR agonists

C. A. de Brito[1], *B. S. Shida*[1], *N. Z. Pereira*[2], *A. J. S. Duarte*[2], *M. N. Sato*[2];
[1]*Adolfo Lutz Institute, Sao Paulo, Brazil,* [2]*University of São Paulo, Sao Paulo, Brazil.*

Background: It has been described several differences regarding neonatal immune responses in comparison to adults. Previous data suggest TLR agonists are less effective in neonate than in adult mice to direct immune responses toward Th1. The aim of this work was to evaluate whether nitric oxide production is involved in the modulation of cytokine production by newoborn cells upon TLR stimuli. Methods: Spleen cells of ten days old and adult C57BL/6 wild type or iNOS(-/-) mice were stimulated with Pam3Cys, Poly I:C, lipopolyssacharide or CpG-ODN (type B). Supernatant was collected after 24 hours and IL-6, TNF-alpha, IL-10 and CCL-2 levels were evaluated by cytometric bead array. Results: As observed in previous results with BALB/c cells, adult C57BL/6 spleen cells secreted higher levels of IL-6 after CpG stimuli, but lower with LPS. Also, neonatal cells showed an increased IL-10 production with all agonists used. Further, an elevated production of monocyte chemotactic protein-1 (MCP-1/CCL2) - a Th2-related chemokine - was observed in culture supernatant of neonatal cells, mainly those stimulated with poly I:C or CpG. When we analyzed the cytokine production by cells from newborn iNOS(-/-) mice, LPS increased IL-6 production comparing to the same cells with medium alone, however the basal production of other cytokines were elevated and did not change with any TLR agonist. Conclusion: Altogether, we verified that the absence of iNOS causes an unbalance in TLR-mediated cytokine production in newborn mice. These findings may contribute to our knowledge about immunomodulation in early life.

Myeloid-related protein (Mrp)-8/14 contributes to protective immunity in sepsis caused by Burkholderia pseudomallei and elevated levels correlate with poor outcome

H. K. de Jong[1], *T. A. F. Weehuijzen*[1], *A. Achouiti*[1], *L. M. Kager*[1], *G. C. K. W. Koh*[2], *J. Roth*[3], *T. Vogl*[3], *T. van der Poll*[1], *W. J. Wiersinga*[1];
[1]*Center for Infection and Immunity Amsterdam (CINIMA), Center of Experimental and Molecular Medicine (CEMM) and Division of Infectious Diseases, Academic Medical Center, Amsterdam, Netherlands,* [2]*Department of Infection and tropical Medicine, Heartlands Hospital, Birmingham, United Kingdom,* [3]*Institute of Immunology, University of Muenster, Muenster, Germany.*

Introduction: Toll-like receptor-4 activating Mrp8/14 (S100A8/A9) complexes are known to function as endogenous danger proteins that promote lipopolysaccharide induced systemic inflammation; their precise function in sepsis however remains to be determined. Melioidosis, caused by the Gram-negative bacteria *Burkholderia (B.) pseudomallei* is an important cause of sepsis in SE-Asia and associated with mortality up to 40%.
Objective: By using a translational approach we aimed to characterize the expression and function of Mrp8/14 in sepsis caused by *B. pseudomallei*.
Methods: Mrp8/14 expression was determined in isolated whole blood leukocytes and plasma from patients with *B. pseudomallei* induced sepsis (n=34) and compared to healthy controls (n=33). Mrp8/14 function was investigated in wild-type and Mrp14 deficient mice (which also lack Mrp8) intra-nasally infected with *B. pseudomallei*. Mice were sacrificed post-infection to assess Mrp8/14 expression, bacterial loads, inflammation and pathology.
Results: *Mrp8* gene expression was markedly increased in all melioidosis patients corresponding with elevated Mrp8/14 plasma levels. In patients, elevated Mrp8/14 concentrations were strongly associated with mortality. In line, mice inoculated with *B. pseudomallei* showed strong increases in plasma, BALF, and pulmonary Mrp8/14 levels. Strikingly, upon infection Mrp14 deficient mice displayed decreased pulmonary bacterial loads but increased bacterial counts in the systemic compartment, which was partially reflected in differences in cytokine response and pathology.
Conclusion: Mrp8/14 levels are increased during sepsis caused by *B. pseudomallei* and correlate with mortality. Mrp8/14 complexes can contribute to protective immunity during sepsis, but their role is versatile as reflected in its compartment dependent function during experimental *B. pseudomallei* infection.

Targeting Toll-like receptors (TLRs) by specific agonists seems to be a promising in stimulation of the immunogenicity of dendritic cells (DCs). Since the functional outcome upon the activation of TLRs may be different, the aim of our study was to evaluate how different concentrations of 7-thia-8-oxo-guanosine (7-TOG), a selective TLR7 agonist, affects functional and phenotypic properties of human monocyte-derived DCs (MoDCs) and if they could be modulated by co-ligation of TLR3. Immature MoDCs were treated with different concentrations of 7-TOG (25, 100 and 250 µmol/L) alone, or together with poly (I:C) (10 ng/mL), a selective TLR3 agonist. We showed that the highest concentration of 7-TOG stimulated the differentiation, maturation and allostimulatory capability of MoDCs, which were accompanied by induction of T helper (Th)1 and Th17 immune responses. Both Th responses were significantly enhanced by additional stimulation of MoDCs with poly (I:C). Intermediate concentration of 7-TOG up-regulated the expression of CD86 and increased production of IL-1β and IL-6 by MoDCs, followed by the stimulation of Th17 immune response. The treatment of MoDCs with the lowest concentration of 7-TOG down-regulated the expression of CD40 on MoDCs and potentiated the Th2 immune response. Additional treatment of MoDCs with poly (I:C) also stimulated both Th1 and Th17 responses, whereas Th2 response was not significantly modulated. In conclusion, our results show that 7-TOG influences phenotype and functions of MoDCs in a dose-dependent manner and suggests that signaling through TLR7 may be modified by the engagement of TLR3, resulting in a different outcome of immune response.

P1.11.025
Association of TLR4-D299G polymorphism with inflammation and overexpression of TLR4-CD14 in obese mexican patients

C. O. De Loera-Rodriguez[1], *J. E. Segura-Ortega*[2], *V. Delgado-Rizo*[1], *A. Alvarado-Navarro*[1], ***M. Fafutis-Morris***[1];
[1]*Universidad de Guadalajara, Guadalajara, Mexico,* [2]*Antiguo Hospital civil de Guadalajara, Guadalajara, Mexico.*

The Aim: Associate the TLR4-D299G polymorphism with pro-inflammatory cytokines and the expression of TLR4-CD+14 in obese Mexicans.

Methods: We evaluated 210 individuals Mexican Mestizos from western Mexico, 105 normal weight subjects (N) and 105 obese patients (O). Both study groups were determined genotypic and allelic frequency of TLR4-D299G polymorphism, inflammatory profile (IL-1β, IL-6, IL-8, IL-10 and TNFα) by ELISA, the Morpho-Anthropometric profile with the anthropometric technique and the percentage of expression and fluorescence index (FI) of TLR4 and CD14 in monocytes of peripheral blood by flow cytometry.
Results: The presence of the polymorphism was 2% N subjects and 6% in O patients. The cytokines results were: IL-1β = 2.5 vs 2.0 pg/ml (p = NS), IL-6 = 28 vs 36 pg/ml (p = 0.030), IL-8 = 25 vs 27 pg/ml (NS), IL-10 = 6.8 vs 8.4 pg/ml (NS), TNFα = 15 vs 31 pg/ml (p = 0.000) N vs O respectively. The expression of TLR4 was 70%, FI 6.41, CD14 84%, FI 1.25 and the percentage of double positive was 59% in N and TLR4 expression 77%, FI 7.70, CD14 86%, FI 1.61 and the percentage of double positive was 66% in O, with p = 0.000 as statistical difference
Conclusion: The western O Mexican, have higher concentrations of pro-inflammatory cytokines (IL-6 and TNFα) and expression of TLR4 receptor and CD14 on peripheral blood monocytes, compared to N. However not found a direct association of the polymorphism with obesity.

P1.11.026
Potential role of tlr ligand in aethiopathogenesis of Tunisian endemic pemphigus foliaceus

*O. Abida[1], **R. Fakhfakh**[1], D. Bouzid[1], S. Krichen-Makni[2], N. Kharrat[3], A. Masmoudi[4], M. Abdelmoula[5], M. Ben Ayed[1], H. Turki[4], T. Sellami-Boudawara[2];*
[1]Immunology Department, Habib Bourguiba Hospital, University of Sfax, Sfax, Tunisia, [2]Anatomy and Pathology Department, Habib Bourguiba Hospital, Sfax, Tunisia, [3]Bioinformatics' Unit, Biotechnology Center of Sfax, Sfax, Tunisia, [4]Dermatology Department, Hédi Chaker Hospital, Sfax, Tunisia, [5]Maxillofacial Surgery Department, Habib Bourguiba Hospital, Sfax, Tunisia.

Pemphigus foliaceus (PF) is an autoimmune skin disease in which environmental factors are thought to participate. Recent studies suggest that microbial components use signaling molecules of the human Toll-like receptor (TLR) family to transduce signals in keratinocytes. The aim of our research was to investigate the expression of TLRs 2, 3 and 4 by keratinocytes of PF patients compared to normal keratinocytes in order to characterise the nature of the microbial factor involved in the etiopathology of PF. Biopsies obtained from 43 PF patients and 20 healthy controls were assessed by immunohistochemical analysis using specific polyclonal antibodies. The TLR2, TLR3 and TLR4 expression was significantly upregulated in PF epidermis. The significant increase of those TLRs simultaneously may merely reflect the complicated environmental conditions of rural women in the southern rural regions of Tunisia. Interestingly, we have found that the TLR4 diffuse expression was associated with the production of anti-desmoglein 1 Abs (p=0.037). This could be in line with a potential role of TLR ligand in aethiopathogenesis of Tunisian endemic PF. TLR over-expression in pemphigus skin indicates that TLRs are involved in the pathogenesis of pemphigus through stimulation by infectious or endogenous ligands.

P1.11.027
The C-type lectin receptors on dendritic cells participate in the recognition and modulatory effect of high molecular weight components of Ascaris suum extract

*B. C. Favoretto[1], P. A. Ranéia[1], J. A. Portes-Junior[1], J. F. Jacysyn[2], **E. L. Faquim-Mauro**[1];*
[1]Laboratory of Immunopathology-Butantan Institute, São Paulo, Brazil, [2]LIM-62 Faculty of Medicine-University of São Paulo, São Paulo, Brazil.

Dendritic cells (DCs) play a key role in linking innate with adaptive immunity. The interaction of pathogens with DCs is mediated by distinct receptors as the C-type lectin (CLRs), which recognize glycan structures. We previously described that high molecular weight components (PI) from *Ascaris suum* extract down-modulate the antigen-presenting cells activities. The aim of this work was to analyze the involvement of CLRs in the modulatory effect of glycan structures in PI on DCs. The PI binding to CLRs on DCs and its internalization was analyzed by flow cytometry or confocal microscopy. Immature DCs were incubated at 4° or 37°C with PI-Alexa488 or BSA-Alexa488 for 30-45 minutes and analyzed. The binding and internalization of PI were also evaluated in DCs pre-incubated with mannan, anti-CLR (DC-SIGN, MR, MGL, DEC205) MoAbs, sucrose or EGTA. The costimulatory molecules expression and IL-10 and IL-12 secretions were studied in DCs incubated with LPS, LPS+PI, LPS+PI+mannan or LPS+PI+anti-CLRs for 18h. Higher fluorescence was observed in DCs incubated with PI-Alexa at 37°C compared with the incubation at 4°C. Inhibition of PI binding and internalization was verified in DCs previously incubated with mannan, anti-CLRs, sucrose or EGTA. The inhibitory effect of PI in the costimulatory molecules expression and cytokines secretion was blocked when DCs were incubated with mannan, anti-CLRs and LPS. The results indicate the participation of the CLRs in the PI recognition by DCs and then triggering the modulation activity of these glycan structures. Financial support: CNPq and FAPESP (2011/23735-0 and 2010/10393-1).

P1.11.028
Isolation and characterization of *N*-linked glycan structures from high molecular weight components of *Ascaris suum* extract

***B. C. Favoretto**[1,2], J. F. Jacysyn[3], A. Casabuono[4], A. S. Couto[4], E. L. Faquim-Mauro[1];*
[1]Laboratory of Immunopathology-Butantan Institute, São Paulo, Brazil, [2]Department of Immunology, Institute of Biomedical Science, USP, São Paulo, Brazil, [3]LIM62-Faculty of Medicine-USP, São Paulo, Brazil, [4]Department of Organic Chemistry-University of Buenos Aires, Buenos Aires, Argentina.

C-type lectin receptors (CLRs) are part of a heterogeneous superfamily of soluble and transmembrane proteins. They are involved in the homeostasis of immune system as well as the recognition of carbohydrate structures in pathogens by immune cells as dendritic cells (DCs). We showed that high molecular weight components (PI) from *Ascaris suum* are able to modulate the DCs activity. Here, we analyzed the presence of *N*-linked glycan antigens in PI and its ability to suppress the DCs maturation. The content of *N*-linked glycan components in PI was obtained by PNGaseF treatment and analyzed by HPAEC-PAD and UV-MALDI-TOF. The down-modulatory effect of these glycan components obtained by affinity with ConA-Sepharose was analyzed in DCs incubated with LPS. The HPAEC-PAD results at neutral and acidic conditions revealed several peaks indicating the presence of *N*-linked oligosaccharide structures with high mannose contents in PI and sialic acid residues, respectively. The UV-MALDI-TOF also confirmed the presence of *N*-linked glycan components with high-mannose type sugars. The chromatography affinity with ConA showed high content of *N*-glycosylated components on PI. The flow cytometry results showed that the ConA-linked components inhibited the expression of costimulatory molecules on DCs induced by LPS compared with those observed on DCs incubated only with LPS. These results indicate that PI contains *N*-glycosylated structures and these components are able to down-modulate the DCs maturation. Financial support: CNPq and FAPESP (2011/23735-0 and 2010/10393-1)

P1.11.029
Involvement of the nucleic acid recognizing Toll-like receptors TLR7 and TLR9 in the pathogenesis of erosive arthritis

***A. Fischer**[1], C. Böhm[1], S. Herman[1], V. Saferding[1], E. Goncalves-Alves[1], M. Koenders[2], W. van den Berg[2], G. Steiner[1];*
[1]Department of Rheumatology, Internal Medicine III, Medical University of Vienna, Vienna, Austria, [2]Department of Rheumatology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.

Abundant release of endogenous nucleic acids can trigger autoimmune reactions via activation of Toll-like receptors (TLR) 7 and 9, potentially leading to autoimmune diseases. In Rheumatoid arthritis (RA), an inflammatory joint disease, the involvement of these TLRs is not clear yet. Interestingly, in rats with pristane-induced arthritis (PIA), disease can be transferred by T cells together with antigen-presenting-cells pre-activated with TLR7 or TLR9 agonists.

To analyze the role of TLR7 and TLR9 in the pathogenesis of arthritis, we induced disease in rats with the mineral oil pristane, and in C57Bl/6 mice by injection of KRN serum. Immunoregulatory oligodeoxynucleotide (ODN) sequences (IRS) antagonizing TLR7 or TLR9 were applied throughout the whole experiment. A non-inhibitory ODN was used as control. Disease severity was assessed clinically and histologically. Serum cytokine levels were measured by ELISA.
The TLR7 inhibitor and control ODN showed no effect. Antagonizing TLR9 reduced arthritis severity in PIA. IL-6 levels were diminished in TLR9-antagonized animals. These effects were only observed when applying the inhibitor before disease onset. Moreover, neither inhibitor affected arthritis severity in the serum transfer model, which is independent of adaptive immunity.
Inhibition of TLR9 reduced inflammation and bone erosion in PIA, but not in the KRN serum transfer model, reflecting the late phase of erosive arthritis.
Thus, TLR9 appears to be involved in the initiation of arthritis. Nucleic acid binding TLRs do not seem to be important in later stages of the disease. Antagonizing TLR9 in human RA may act beneficial in the early disease phase.

Training modifies the innate immune response both in the airways and in blood in horses

L. Frellstedt[1], *P. Gosset*[2], *C. Desmet*[3], *D. Pirottin*[3], *F. Bureau*[3], *I. Waldschmidt*[4], *M. Dupuis-Tricaud*[4], *P. Lekeux*[1], *T. Art*[1];
[1]*Center of Equine Sports Medicine, University of Liege, Liege, Belgium,* [2]*LI3, INSERM U1019-CNRS UMR8204, CIIL, Institute Pasteur de Lille, Lille, France,* [3]*Laboratory of Cellular and Molecular Physiologie, GIGA-Reserch, University of Liege, Liege, Belgium,* [4]*Hippolia-Cirale, Goustranville, France.*

Lower airway diseases are common problems in sports and racing horses. In humans, exercise has been associated with upper respiratory tract infections due to down-regulated expression of Toll-like receptors (TLRs), costimulatory and antigen-presenting molecules on monocytes. The objectives of this study were 1) to examine the expression of TLRs in equine bronchial epithelial cells (EBEC) and blood monocytes in untrained and trained horses; 2) to stimulate EBEC and monocytes *in vitro* with TLR ligands, in order to mimic bacterial/viral infections; 3) to compare the cytokine production of EBEC and monocytes in untrained and trained horses. Bronchial biopsies were taken from 8 horses during lower airway endoscopy at rest and 24 hours after a standardized exercise test (SET). Bronchial epithelial cells were grown *in vitro* and activated with TLR ligands. Blood monocytes were collected at rest and after the SET. TLR1-TLR9 expression was evaluated via real-time PCR and cytokine production was measured via ELISA. TLR3 and TLR4 expression was modified by training. The expression of TLR2, TLR7 and TLR8 was modified only by strenuous exercise in trained horses. Training had local immuno-suppressive effects shown by a decreased production of TNF-alpha and IFN-beta in EBEC in response to TLR2 and TLR3 ligands. Training also caused a systemic pro-inflammatory response evidenced by increased production of TNF-alpha in monocytes in response to TLR2 and TLR4 ligands. These findings suggest that training and strenuous exercise in trained subjects may result in an increased susceptibility of the lower airway to infections associated with systemic inflammation.

P1.11.031
The novel TLR7 agonist GS-9620 induces a diverse set of interferon stimulated genes

C. Frey*, A. Palazzo, J. Hesselgesser, T. Cihlar, S. Pflanz;*
Gilead Sciences, Inc., Foster City, CA, United States.

Efficient innate and adaptive immunity is necessary for initial containment and subsequent clearance of viral infections, including hepatitis viruses B (HBV) and C (HCV). Part of the initial anti-viral immune response is the interaction of single stranded viral RNA with Toll-like receptor 7 (TLR7) within the endolysosomal compartment leading to activation of plasmacytoid dendritic cells and B lymphocytes. We demonstrated that the novel TLR7-selective agonist GS-9620 induces IFN-α and other cytokines and chemokines in human PBMC *in vitro* cultures in a dose-dependent manner. Moreover, we showed that GS-9620-dependent activation networks include the upregulated expression of lymph node retention marker CD69 on lymphocytes such as B cells and T cells. Profiling the GS-9620-dependent induction of gene expression in PBMC on a whole-genome level using the Illumina bead chip revealed a gene signature consistent with an anti-viral response including the upregulation of interferon-stimulated genes (ISGs). For a select panel of ISGs (MX1, OAS1, ISG15, IFIT1 and IFIT2) and other genes (CCL8, CCL19, CD38, IL-1RN), the time- and concentration-dependent induction after the stimulation with GS-9620 was confirmed using quantitative PCR. In addition, we showed a similar pattern of TLR7 agonist-dependent ISG induction in *ex vivo* experiments using fresh human whole blood. In conclusion, the TLR7 agonist GS-9620 broadly activates anti-viral genes including ISGs. These observations confirm the antiviral potential of GS-9620 and may facilitate the identification of sensitive pharmacodynamic markers to inform the clinical development of GS-9620.

P1.11.032
NOD-like receptor activation stimulates osteoclasts

S. Y. Fukada Alves[1], *M. R. F. Holanda*[2], *T. M. Taira*[1], *F. Q. Cunha*[1];
[1]*University of São Paulo, Ribeirão Preto, Brazil,* [2]*Centro Universitário Barão de Mauá, Ribeirão Preto, Brazil.*

Many type of cells, including osteoblasts express NOD2, a member of the family of Nod-like receptors (NLRs). Nod2 is a general sensor of peptidoglycan through the recognition of muramyl dipeptide (MDP), the minimal bioactive peptidoglycan motif common to all bacteria. The activation of NOD2 in osteoblasts can induce RANKL expression which can indirectly stimulate osteoclastogenesis.
Our purpose is to determine the direct effect of MDP on osteoclasts differentiation and activation.
Bone marrow cells from C57/BL6 and NOD2-/- mice were cultured for 3 days with MCSF (30ng/ml). Adherent cells (bone marrow macrophages - BMM) was cultured for 4 more days with MCSF (30ng/ml) and RANKL (5ng/ml) and/or bacterial peptidoglycan-derived muramyl dipeptide MDP (0,01; 0,1; 1,0 ug/ml). The cells was stained to identify tartrate-resistant acid phosphatase (TRAP)-positive multinucleated osteoclast. The differentiation and activation markers were evaluated, 96h after MCSF/RANKL stimulation, by Real time PCR.
The expression of mRNA encoding Nod2 in murine BMM was increased (2~3 fold) after 24 hours MCSF/RANKL stimulation. NOD2-/- derived RANKL/MCSF-stimulated BMM presented less multinuclear TRAP+ cells (~334 cells/well) than WT derived BMM (~402 cell/well). MDP did not alter the number of multinuclear TRAP+ cells. Treatment of BMM with MCSF and RANKL for 96 hours resulted in increased mRNA expression of TRAP, cathepsin k, ATP6i and integrin beta3, as assessed by Real time PCR.
These results confirm that NOD2 activation is important to osteoclastogenesis, with increased transcription of genes important for osteoclasts progenitor cell differentiation, fusion and function.
This work was funded by FAPESP Proc. 2011/20736-6.

P1.11.033
Collapse of TLR7/TLR9 balance leads genetical background dependent phenotypes

R. Fukui*, K. Miyake;*
The Institute of Medical Science, The University of Tokyo, Minato-ku, Tokyo, Japan.

Nucleic acid sensing-TLRs (Toll-like receptors) recognize pathogen derived-nucleic acid and induce immune response. It is important for host defense, however, it is known that nucleic acid sensing-TLRs also recognize host-derived nucleic acid and induce inflammatory disease. To prevent autoinflammation, nucleic acid sensing-TLRs should be controlled by multiple stages of mechanisms.
Unc93B1 (Unc93 homolog B1) was found as an essential molecule for responsiveness of nucleic acid sensing-TLRs (Tabeta et al., 2006). This function is depend on its binding activity to nucleic acid sensing-TLRs and following trafficking from ER to endolysosomes (Kim et al., 2008). We found that Unc93B1 has another function, controlling responses of TLR7 and TLR9 reciprocally (Fukui et al., 2009).

TLR7/TLR9 balancing function of Unc93B1 depends on N-terminal of Unc93B1 and alanine mutant of 34th aspartic acid (D34A) induces TLR7 hyper-response and TLR9 hypo-response. Because of this collapse of TLR7/TLR9 balance, *Unc93B1*$^{D34A/D34A}$ mice (D34A mice) developed lethal inflammatory disease (Fukui et al., 2011). We generated several strains of D34A mice and found that their phenotypes were dependent on genetical background. For example, most all of C57BL/6 background D34A mice developed thrombocytopenia within 4 months old but no BALB/c background D34A mice developed.
We hypothesized that there are some modifier genes linking inflammation caused by collapse of TLR7/TLR9 balance to phenotypes, and started deeper analysis. In this presentation, we will show the difference of cell activation, contributions of cytokines, and pilot data of linkage analysis between these strains of D34A mice.

Toll-like receptors 2, 4 and CD14 gene polymorphisms in Tunisian kidney transplantation

Y. Gorgi[1], *H. Krichen*[1], *Y. Mechiri*[1], *I. Sfar*[1], *T. Dhaouadi*[1], *R. Bardi*[1], *M. Bacha*[2], *R. Kheder*[2], *E. Abderrahim*[2], *T. Ben Abdallah*[1];
[1]*Laboratory of Research in Renal Transplantation and Immunopathology (LR03SP01)., Tunis, Tunisia,* [2]*Nephrology Department, Charles Nicolle Hospital, Tunis, Tunisia, Tunis, Tunisia.*

Introduction: To investigate the distribution of TLR2, TLR4 and CD14 gene polymorphisms among Tunisian renal transplantation patients in relation to occurrence of acute rejection (AR) and chronic allograft nephropathy (CAN)
Methods: TLR2 (Arg753Gln), TLR4 (Asp299Gly) and CD14 (-159 C/T) were genotyped using DNA samples from 214 renal recipient by applying Restriction Fragment Length Polymorphism (RFLP) methodology. Fifty-nine patients had developed AR episodes and 24 were identified as CAN by biopsy scored according to the Banff criteria.
Results: The frequency of TLR2 G/G genotype was higher in AR patients comparing with non-AR ones (p=0.039; CI 95% OR=2.87 [1.05-4.37]). However, no differences were found in genotypes or alleles distribution according to CAN. There was no significant effect of any TLR4 or CD14 polymorphism on graft survival or acute renal rejection and CAN. Besides, no association was found between any TLR genotypes and the presence of HLA antibodies before and after transplantation. Single allele and genotype association analyses showed no significant association with the incidence of any posttransplant infections, including CMV (cytomegalovirus) infection.
Conclusion: Our present study suggests that that, set apart the immunological factors, the Arg753Gln polymorphism of TLR2 may increase the risk of acute renal allograft rejection in Tunisian patients. However, TLR4 and CD14 do not play a significant role in the pathogenesis of both AR and CAN after renal transplantation. Monitoring mRNA expression levels of TLR molecules should offer more useful information about the role of this system in acute and chronic kidney allograft injuries.

P1.11.035
Polymorphisms of Toll-like receptor 4 and CD14 genes in systemic lupus erythematosus and rheumatoid arthritis

Y. Gorgi[1], *T. Dhaouadi*[1], *Y. Haouami*[1], *I. Sfar*[1], *L. Abdelmoula*[2], *S. Turki*[3], *L. Ben Hassine*[4], *R. Zouari*[2], *N. Khalfallah*[4], *T. Ben Abdallah*[1];
[1]*Laboratory of Research in Renal Transplantation and Immunopathology (LR03SP01)., Tunis, Tunisia,* [2]*Rheumatology Department. Charles Nicolle Hospital. Tunis. Tunisia, Tunis, Tunisia,* [3]*Internal medicine Department A. Charles Nicolle Hospital. Tunis. Tunisia, Tunis, Tunisia,* [4]*Internal Medicine Department B. Charles Nicolle Hospital. Tunis, Tunisia, Tunis, Tunisia.*

Introduction: Toll-like receptor 4 (TLR4) and its co-receptor CD14 play a major role in innate immunity by recognizing PAMPs and signal the activation of adaptive responses. These receptors can recognize endogenous ligands mainly auto-antigens. In addition, TLR4 (Asp299Gly) and CD14 (C/T -159) polymorphisms (SNPs) may modify qualitatively and/or quantitatively their expression. Therefore, they could be implied in autoimmune diseases and can influence both susceptibility and severity of systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA).
Patients and methods: TLR4 (Asp299Gly) and CD14 (C/T -159) SNPs were genotyped using polymerase chain reaction (PCR) in 127 SLE patients, 100 RA patients, and 114 healthy controls matched in age and gender.
Results: CD14*T allele was significantly more frequent in SLE patients (0.456) comparatively to controls (0.355), p=0.02 OR (95% CI)=1.53 [1.04-2.24]. In RA patients, the higher frequency of CD14*T allele (0.405) failed to reach significance, p=0.28. Investigation of the TLR4 (Asp299Gly) SNP showed no significant association neither with SLE nor with RA.
Analysis of these SNPs according to clinical and biological features showed a significant higher frequency of arthritis in SLE patients with CD14*T/T genotype (92%) comparatively to those with C/C and C/T genotypes (72.5%), p=0.04. Moreover, SLE patients carrying CD14*T/T / TLR4*A/A haplotype had significantly more arthritis (91.3%) than the rest of SLE group (73%), p=0,044 and confirmed by multivariable analysis after adjustment according to age and gender, p=0.01.
Conclusion: The CD14 (-159)*T allele seems to be associated with susceptibility to SLE and arthritis occurrence.

P1.11.036
D type CpG oligonucleotide loaded EG-7 exosomes act as strong vaccine adjuvant and anti-cancer agent

G. Gucluler[1], *T. Kahraman*[1], *D. Bayik*[1], *A. Gursel*[1], *M. Gursel*[2], *I. Gursel*[1,3];
[1]*Biotherapeutic ODN Research Lab., Department of Molecular Biology and Genetics, Bilkent University, Ankara, Turkey,* [2]*Dept of Biological Sciences, Middle East Technical University, Ankara, Turkey,* [3]*Bilgen Research Center, Bilkent University, Ankara, Turkey.*

Exosomes are naturally occurring nanovesicles secreted from several cells harboring different cargoes. Upon internalization, they can regulate cell physiology as well as mediate immune response. Immunostimulatory CpG ODNs are strong candidates for clinical use against cancer, infectious diseases and allergy. Their labile nature hampers in vivo performance. In this study, we aimed to explore the immuno-therapeutic potential of exosomes as ODN-delivery nanovehicles.
Exosomes from EG-7 (OVA expressing EL-4 cells) supernatants were purified and loaded with D-ODN. In vitro immunostimulatory activity of CpG ODN-loaded vesicles as evidenced by cytokine production by ELISA and surface marker upregulation by FACS was tested on mouse splenocytes. Then, C57/Bl6 mice were immunized with D-ODN loaded EG7-exosomes. Mice sera were analyzed for anti-OVA IgG subtype-responses. OVA immunized animals post 2 months booster immunization were seeded with EG-7 cells and tumor development were followed.
In vitro stimulation assays revealed that D-ODN encapsulation into exosomes significantly increased IL6, IL12, IFNg and IFNa production to that of free ODN. CD86 and MHC-II expressions were 2-4 fold higher for D-Exo compared to free D-ODN stimulations. D-ODN loaded exosomes induced Th1-biased anti-OVA response compared to exosome treated animals. Following thymoma induction in naive and OVA-immunized mice, data indicated that >85% of treated mice lacked tumors whereas all naive animals were positive for tumor. This trend was constant for 4wks post-inoculation.
Collectively, our data suggest that D-ODN encapsulation in exosomes improve immunostimulatory activity, provide better anti-OVA immunity thereby contribute effective tumor clearance in mice.

P1.11.037
CpG Oligodeoxynucleotide/cationic peptide nanorings as immunotherapeutic agents

B. Gungor[1], *F. C. Yağcı*[2], *I. Gursel*[2], *M. Gursel*[1];
[1]*Middle East Technical University, Ankara, Turkey,* [2]*Bilkent University, Ankara, Turkey.*

Synthetic CpG containing oligodeoxynucleotides (ODNs) mimic the immunostimulatory activity of bacterial DNA and induce a strong pro-inflammatory response via Toll-like receptor 9 (TLR9) signaling. To date, most of the human clinical trials involved one type of CpG ODN (known as K-type or B-type) whereas the therapeutic potential of the

G-quadruplex forming type I interferon inducing D-type ODN (or A-type) remained unexplored due to product aggregation that complicates the pharmaceutical manufacturing of this ODN type. Herein we show that a short K-type ODN and the HIV-derived cationic peptide Tat(47-57) condense to form monodisperse nuclease resistant nanorings that replicate the high type I interferon stimulating activity of D-type ODN in human blood. The nanorings provide nuclease resistance, enhance the cellular uptake and alter the subcellular distribution of the associated CpG ODN. Consistent with their IFNa inducing activity from plasmacytoid dendritic cells, the nanorings localize to early endosomes. In conclusion, these immunostimulatory nanorings are effective D-ODN surrogates and could prove to be of value as anti-viral or anti-cancer agents and vaccine adjuvants in the clinic.

P1.11.038

Mechanisms of MyD88- and TRIF-dependent downregulation of the glucocorticoid induced leucine zipper (GILZ) in macrophages - mRNA destabilization vs. microRNAs

N. Hachenthal[1], *T. Stadter*[1], *P. Leidinger*[2], *F. Grässer*[2], *E. Meese*[2], *S. Bruscoli*[3], *C. Riccardi*[3], *A. K. Kiemer*[1], *J. Hoppstädter*[1];
[1]*Saarland University, Saarbruecken, Germany,* [2]*Saarland University Hospital, Homburg, Germany,* [3]*University of Perugia, Perugia, Italy.*

Toll-like receptor (TLR) activation induces the production of inflammatory mediators *via* NF-κB. Glucocorticoid-Induced Leucine Zipper (GILZ) is an anti-inflammatory mediator which interferes with NF-κB-mediated gene transcription in macrophages. Thus, we aimed to investigate GILZ regulation and function in primary human and murine macrophages upon TLR activation.
Treatment with TLR agonists signalling *via* MyD88, e.g. Pam_3CSK_4 (TLR1/2) or heat-killed *Staphylococcus aureus,* rapidly decreased GILZ mRNA and protein levels. In return, GILZ downregulation lead to enhanced phagocytic activity and increased induction of inflammatory mediators, as shown in GILZ knockout macrophages.
The TLR3 ligand polyinosinic:polycytidylic acid (Poly(I:C)), acting *via* the MyD88-independent TRIF pathway, displayed no ability to decrease GILZ mRNA levels. However, GILZ protein expression was reduced by Poly(I:C)-treatment, which was paralleled by sensitization towards TLR1/2- and TLR4-agonists.
MyD88-dependent GILZ downregulation involves mRNA-destabilization, whereas our data on MyD88-independent downregulation suggest translational inhibition. Herein, we report that MyD88-independent GILZ downregulation is associated with microRNA induction, as shown by dicer knockdown experiments and by using the RISC loading inhibitor ATA. A bioinformatics approach indicated miR-24 as a potential GILZ regulator. Moreover, we observed that miR-24 is induced in a MyD88-independent manner. Finally, luciferase reporter gene assays using constructs containing the 3'-untranslated region of GILZ suggested that miR-24 mediated GILZ protein abrogation by translational repression.
Conclusion: Our data indicate a dual regulation of GILZ upon TLR stimulation, which contributes to macrophage activation.

P1.11.039

Expression Analysis of Molecular Markers of Inflammation in Human Monocytic THP-1 cells Cultured with Single Walled Carbon Nanotubes Functionalized with Polyethylene Glycol (PEG-SWNT)

A. Haghparast[1,2], *M. Heidari Kharaji*[1], *M. Moghaddam Matin*[1,2], *A. Ahmadpour*[1];
[1]*Ferdowsi University of Mashhad, Mashhad, Iran,* [2]*Institute of Biotechnology, Mashhad, Iran.*

One of the key advantages of carbon nanotubes in biomedical applications is that they can be easily internalized by cells, and therefore can act as delivery vehicles for therapeutical and diagnosis purposes. The clinical applications of using carbon nanotubes in medicine will depend on the outcomes of efficacy and Immunotoxicological studies, which will provide the necessary risk-to-benefit assessments for carbon-nanotube based materials.
The objective of the present study was to evaluate the in vitro inflammatory properties of single walled carbon nanotubes functionalized with polyethylene glycol (PEG-SWNT). Human monocytic cell line THP-1 was cultured with various concentrations of PEG-SWNT in different time points and the expression of several innate immunity receptor genes as molecular markers of Inflammation was analyzed by real time quantitative PCR (qPCR). In this study the expression of several pattern recognition receptors (PRRs) including TLR2, TLR4, CD14 and adaptor protein MyD88 which are the main sensors of Inflammation was analyzed in the PEG-SWNT treated THP-1 cells.
According to our results a significant up-regulation of TLR2, TLR4, CD14 and MyD88 transcripts was observed when THP-1 cells were treated with various concentrations of PEG-SWNT. However, down-regulation of the expression of molecular markers of Inflammation was observed when the cells were treated with high concentrations of PEG-SWNT which might suggest that higher concentrations of PEG-SWNT are toxic for the cells.
In conclusion the results presented in this study show that PEG-SWNT could trigger cellular inflammatory responses as shown by the expression analysis of genes involved in innate immunity and inflammation.

P1.11.040

Characterization of antibody responses to M13 phage vaccine: MyD88-dependent and T-cell independent IgG subclass responses

S. Hashiguchi*, M. Toyonaga, Y. Shoji, T. Gotanda, K. Sugimura; Kagoshima University, Kagoshima, Japan.*

M13 phage can be administered in PBS in mice to evoke a strong primary IgG response that is dependent on MyD88 signaling (BBRC 402: 19-22, 2010). Even a single immunization with 10^{11} pfu of phage induced a long-lasting antibody response.
M13 phage injected by the intraperitoneal and subcutaneous routes induced serum IgG subclass responses to M13 phage in C57BL/6 mice dominated by IgG2c, IgG2b and IgG3 between 1 and 2 weeks of post injection. After a secondary injection of M13 phage, all four subclasses including IgG1 were detected at the same level. The same IgG subclass profiles was observed in athymic (nu/nu) BALB/c mice except the Ab level which was at least 20-fold lower than that observed in BALBc and C57BL/6 mice, indicating T-cell independent IgG class swithing. We have preiviously reported that phage-specific IgG2c, IgG2b and IgG3 responses in TLR2-, TLR4-, TLR7- or TLR9-deficient mice, except the primary IgG1 level was significantly elevated only in TLR9-deficient mice. These data suggested that the IgG1 producing cells in the secondary response in wt mice was derived from a distinct B-cell repertoire or subpopulation involved in the primary response, and IgG1 response to M13 phage is regulated by TLR9. We are currently analyzing which sensor molecules of innate immunity are involved in the recognition of M13 phage. The ability of M13 phage to induce a strong IgG response suggests a possible application of peptide-displaying phage clones as vaccine carriers for induction of therapeutic antibodies.

P1.11.041

Card9 is essential for the CEACAM3 mediated *Moraxella catarrhalis* induced NF-kappaB activation in human granulocytes

A. Heinrich[1], ***K. A. Heyl***[2], *M. M. Müller*[2], *S. Bachmann*[3], *H. Slevogt*[2];
[1]*Department of Microbiology and Hygiene, Charité - Universitätsmedizin Berlin, Berlin, Germany,* [2]*Septomics Research Center, Jena, Germany,* [3]*Institute of vegetative Anatomy, Charité - Universitätsmedizin Berlin, Jena, Germany.*

The chronic obstructive pulmonary disease (COPD) is often associated with pathological bacterial colonization of the lower airways which are normally sterile. Here *Moraxella catarrhalis* is of particular importance, colonizing the lower respiratory tract of up to 32% of COPD. The pathogenesis of COPD is characterized by neutrophilic inflammation. Although phagocytosis is considered as most important neutrophilic function, they have also been demonstrated to orchestrate immune responses via secretion of proinflammatory cytokines and chemokines, such as interleukin 8 or MIP-1α. By activating human granulocytes, both cytokines mediate the influx of neutrophils in the airways.

The pattern recognition receptor CEACAM3 (carcinoembryonic antigen-related cell adhesion molecule 3) is exclusively expressed on the surface of human granulocytes. It consists of a single extracellular Ig_V-like domain, a transmembrane domain as well as a cytoplasmic region containing an immunoreceptor tyrosine-based activation motif (ITAM). Binding of *M. catarrhalis* via its ubiquitous surface protein A1 (UspA1) to CEACAM3 has been shown to mediate phosphorylation of the two spaced tyrosine residues in the consensus sequence of the ITAM by Src family kinases followed by engulfment of the bacteria.
In this study we demonstrated for the first time, that the specific Moraxella UspA1-CEACAM3 interaction triggers an increased chemokine response of human neutrophils via the Syk/ CARD9 pathway and the Bcl10 signalosome leading to activation of canonical NF-κB. Our results offer new insight into the impact of specific pathogen-receptor interactions modulating neutrophilic cell functions.

P1.11.042
Immune complexes isolated from malaria patients activate TLR9 and promote caspase-1 activation

I. Hirako[1], *C. Gallego*[2], *H. Gravina*[3], *M. Ataíde*[3], *D. Pereira*[4], *B. Diamond*[2], *L. R. Antonelli*[1], *D. T. Golenbock*[2], *R. T. Gazzinelli*[1];
[1]*Oswaldo Cruz Foundation, Belo Horizonte, Brazil,* [2]*University of Massachusetts Medical School, Worcester, MA, United States,* [3]*UFMG, Belo Horizonte, Brazil,* [4]*Tropical Medicine Research Center, Porto Velho, Brazil.*

High levels of pyrogenic cytokines such as IL-1β, TNF-α and IFN-γ produced during infection by Plasmodium exacerbate host immune responses causing various debilitating symptoms. Previous studies suggest that TLR9 is critical for the onset of this early inflammatory response in malaria. This project focuses on how parasite DNA is carried to the inner cellular compartment and activates TLR9. We observed the presence of high circulating levels of immune complexes (ICs) and parasite DNA during acute episodes of malaria. We also detected high levels of both IgM and IgG anti-dsDNA in individuals undergoing acute malaria episodes. Furthermore, ICs from malaria patients were found to contain primarily parasite derived DNA. Evaluating the immunostimulatory activity, we observed that ICs induced high levels of TNF-α and IL-10 as well as caspase-1 activation and IL-1β release by PBMCs and purified monocytes from healthy donors. When monocytes were primed with IFNγ, stimulation with ICs resulted in a switch of cytokine profile, similar to monocytes from malaria patients that produce high levels of IL-1β and TNF-α, but low IL-10 levels. Importantly, cytokine production by PBMCs stimulated with ICs was inhibited with the TLR7/TLR9 antagonist, but not the TLR4 antagonist. Hence, ICs are important shuttles for carrying parasite DNA to inner compartment of innate immune cells, resulting in activation of nucleic acid sensing TLR9 and signaling for inflammasome assembly. Altogether, our results support the hypothesis that ICs are important components of the systemic pro-inflammatory response and pathogenesis of malaria.

P1.11.043
Identification of novel innate pattern recognition receptors for *mycobacterium tuberculosis*

E. Iizasa[1,2], *T. Myamoto*[3], *T. Uematsu*[4], *T. Ishikawa*[5], *S. Yamasaki*[5], *G. Matsuzaki*[6], *H. Yoshida*[1], *H. Hara*[1];
[1]*Department of Biomolecular Sciences, Faculty of Medicine, Saga University, Saga, Japan,* [2]*JSPS(Japan Society for the Promotion of Science) postdoctoral fellow, Tokyo, Japan,* [3]*Graduate school of Phermaceutical Sciences, Kyushu University, Fukuoka, Japan,* [4]*Division of Biomedical Laboratory, Department of Biomedical Research, Saitama, Japan,* [5]*Division of Molecular Immunology, Research Center for Infectious Diseases, Medical Institute of Bioregulation, Kyushu University, Fukuoka, Japan,* [6]*Tropical Biosphere Research Center, University of the Ryukyus, Okinawa, Japan.*

Recent studies have shown that immunoreceptor tyrosine-based activation motif (ITAM)-coupled receptors (ITAMRs) play important roles in innate immunity to certain microbes such as fungi. ITAMRs deliver signals through the ITAM-containing adaptors DAP12 or FcRγ, or through a cytoplasmic ITAM-like motif called hemITAM. We have previously shown that the adaptor protein CARD9 is essential for ITAMR-mediated innate immune responses. CARD9-deficient mice were shown to display severe susceptibility to *M. tuberculosis* (Mtb) infection. Although some C-type lectin-type ITAMRs, such as Mincle or Dectin-1, are suggested to participate in the recognition of Mtb, any single deficiency in these receptors does not severely affect anti-mycobacterial protection in mice, implicating other unknown ITAMRs involved in innate immunity to Mtb. To identify novel ITAMRs recognizing Mtb, we examined binding activity of a series of recombinantITAMR-Ig fusion proteins for *M. BCG* and Mtb, and found two novel ITAMRs, IgSFR2 and IgSFR7, that could bind to Mtb.IgSFR7 requires DAP12, whereas IgSFR2 uses both DAP12 and FcRγ for their signal transduction. Next, ligand search by using NFAT-GFP reporter cells that ectopically express these receptors revealed that a ligand of IgSFR2 is mycolic acid (MA), which is a major cell wall component of Mtb. MA-induced MCP-1 production was markedly reduced in peritoneal macrophage lacking IgSFR2. On the other hand, we found that IgSFR7 recognized at least two different components in organic solvent fractions of Mtb as ligands. We are now exploring roles of these receptors in innate immune response to Mtb.

P1.11.045
The humoral pattern recognition molecule PTX3 is a key component of innate immunity against urinary tract infection

S. Jaillon[1], *F. Moalli*[1], *B. Ragnarsdottir*[2], *E. Bonavita*[1], *M. Nebuloni*[3], *A. Markotic*[4], *A. Montanelli*[1], *C. Svanborg*[2], *C. Garlanda*[1], *A. Mantovani*[1,5];

Sacco Department of Clinical Sciences, University of Milan, Milan, Italy,* [4]*University Hospital for Infectious Diseases, Zagreb, Croatia,* [5]*Department of Biotechnology and Translational Medicine, University of Milan, Rozzano, Italy.*

Introduction: Urinary tract infections (UTIs), which remain a major public health problem, are mainly caused by uropathogenic strains of Escherichia coli (UPEC). UTIs can progress to acute pyelonephritis that gives rise to severe morbidity. Cellular innate immune receptors and mediators play an important role in defence against UTIs but the role of humoral innate immunity has not been explored. The present study was designed to investigate the role in UTI of the soluble pattern recognition molecule pentraxin 3 (PTX3), a key component of the innate immune system.
Results: UTI of mice with UPEC was associated with increased levels of PTX3 in tissues and blood that correlated with the severity of the infection. PTX3-deficient mice showed a defective capacity to control UTI and increased tissue inflammation and damage. Urothelium is identified as a new source of PTX3 and both hematopoietic cell-derived and stromal cell-derived PTX3 were required for protection against UTI. PTX3 recognized UPEC and PTX3 opsonisation amplified UPEC phagocytosis by murine and human neutrophils. In patients with UTI, disease severity correlated with PTX3 levels in urine and serum. Finally, human counterpart of our animal data were supported by genetic analysis of UTI-prone patients where PTX3 polymorphisms were associated with susceptibility to acute pyelonephritis.
Conclusion: Our results suggest that PTX3 is the first pattern recognition molecule involved and conserved in innate resistance against UTI. Thus, the cellular and humoral arm of innate immunity exert complementary functions in mediating resistance against UTI.

P1.11.046
ER stress sensitizes TLR signaling and desensitizes LPS tolerance through IRE1α-mediated activation of GSK-3β

*S. Kim[1], **Y. Joe**[1], J. Shin[2], S. Ryter[3], H. Chung[1];*
[1]University of Ulsan, Ulsan, Republic of Korea, [2]Sungkyunkwan University, Suwon, Republic of Korea, [3]Pulmonary and Critical Care Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, United States.

Tolerance to endotoxin that is triggered by prior exposure to toll-like receptor (TLR) ligands, provides a mechanism with which to dampen inflammatory cytokines. The ER stress activates GSK-3 to regulate the expression of inflammatory cytokines. Here we found that ER stress induces stimulation of IRE1-mediated tyrosine phosphorylation and serine dephosphorylation of GSK-3, which synergistically activates TLR signaling for cytokine production and obliterates endotoxin tolerance. Furthermore, activated GSK-3 increases the abundance of nuclear coactivator, RIP140 which enhances proinflammatory cytokine production and decreases anti-inflammatory cytokine production. Our results identify an unsuspected critical role for IRE1-mediated GSK-3 activation in inflammation and endotoxin tolerance.

P1.11.047
Investigation of kinase and inflammatory pathway modulation by I2PP2A inhibition in Prostate Cancer Progression

***C. Johnson**[1], F. J. Giles[1], F. J. Sullivan[2], M. Vitek[3], S. A. Glynn[1];*
[1]National University of Ireland Galway, Galway, Ireland, [2]Galway University Hospital, Galway, Ireland, [3]Oncotide, Research Triangle Park, NC, United States.

Background: Inflammation is highly implicated in prostate cancer progression. The toll-like (TLR) and Rig-like (RLR) receptor families are involved in the implementation of innate immune response. PP2A is a tumour suppressor protein, who's dysregulation in cancer promotes activation of proliferation signalling pathways. Peptide mimetics of Apolipoprotein E (apoE) have previously been shown to inhibit SET, a PP2A inhibitor, consequently increasing PP2A mediated phosphatase activity and modulating kinase activation in signalling pathways.
Aims: This study aims to investigate the role of a novel compound which modulates PP2A, and to determine its effects on innate immune receptors and downstream kinase signalling in prostate cancer cell lines while establishing the effects of inhibition of I2PP2A/SET binding to PP2A in prostate cancer cell lines.
Material & Methods: The prostate cell lines used were RWPE1 (immortalised normal), CWR22 (Androgen dependent), 22RV1 (Androgen Independent), DU145 (brain metastasis) and PC3 (bone metastasis). To explore the expression of innate immune receptors, the cell lines were treated with COG compounds for 24, 48 and 72 hours. TLR, RLR, PP2A and SET proteins were probed for by western blot and Immunoprecipitation. A Reverse Phase Protein Array was used to explore alteration in kinase activity.
Results & Ongoing Research: TLRs and RLRs are differentially expressed in prostate cancer cell lines, in addition to PP2A and SET. Toxicity assays revealed that COG compounds can inhibit cell proliferation in prostate cancer cell lines; accompanied by altered TLR expression. Ongoing studies explore the mechanism by which PP2A influences innate immune signalling in prostate cancer.

P1.11.048
Toll-like receptor (TLR)-4 and Hepatitis C Virus (HCV): a systematic review

***N. A. Kazemi Sefat**[1], G. E. Kazemi Sefat[2], S. Talebi[3];*
[1]Kerman university of medical science, Kerman, Iran, [2]Department of Genetics, School of Basic Sciences, Science and Research Branch, Islamic Azad University, Tehran, Iran, [3]Assistant Professor in research, Avicenna Research Institute (ACECR), Tehran, Iran.

Background: Hepatitis C virus induces inflammatory signals, leading to hepatitis, hepatocellular carcinomas and lymphomas. TLR4 has some roles in pathogenesis of hepatitis C, but its mechanism is controversial. To review the available literature on the Importance of TLR4 in pathogenesis of hepatitis C a systematic review of all published articles with the special MeSH terms was done.
Methods: A computerized search strategy using PubMed with MeSH Terms (Hepatitis C, hepacivirus and toll like receptor 4 as the main headings) was done.
Results: The computerized searches between years 1960-2012 yielded 39 articles of which 32 were potentially appropriate for inclusion; 5 out of 32 were on TLR4 gene polymorphisms and 27 were about its functional aspects. In 66%, TLR4's role was evaluated in immune cells, 26% in non-immune cells and in 7% both immune and non-immune cells were assessed. TLR4 up-regulation, down regulation and signaling/downstream effects were reported in 8, 2 and 8 articles respectively. From 8 articles about TLR4 up-regulation, 5 (63%) showed over-expression in immune cells and 3 in non-immune cells. TLR4 down regulation were also observed in both immune and non-immune cells. In 15% (5/32) of articles it is believed that activation of TLR4 is irrelevant of the origin or viral dose.
Conclusion: This is the first review about the Importance of TLR4 in hepatitis C. It seems that TLR4 may play different roles in different cells in HCV hepatic infection. More cell specific studies are recommended.

P1.11.049
TLR-signaling induces Type I interferon responses in microglia and astrocytes and regulates leukocyte infiltration to the CNS

***R. M. H. Khorooshi**[1], T. Holm[2], C. Tue Berg[1], R. Truong Dieu[3], D. Dræby[1], S. Lienenklaus[4], T. Owens[1];*
[1]IMM, Odense, Denmark, [2]Department of Biomedicine – Medical Biochemistry, Århus, Denmark, [3]IMM, odense, Denmark, [4]Molecular Immunology, Helmholtz Centre for Infection Research, Braunschweig, Germany.

Our goal is to understand the glial signaling that controls inflammatory responses in the central nervous system (CNS). This glial response can play both a detrimental and beneficial role. Toll like receptor (TLR) signaling is implicated in responses to pathogens or endogenous signals. They mediates immune response by inducing cytokines, including IFN-beta, a member of the type I IFN family. IFN-beta is a first-line therapeutic for multiple sclerosis. Type I IFNs signal through a common receptor, IFNAR. The aim of this study was to investigate the in vivo response of glial cells to CNS administration of TLR ligand, and to examine whether this response involves type I IFN signaling. Mice were administered TLR ligand/agonist by injection to the cisterna magna. Injection of ligand for TLR2 resulted in strong infiltration of leukocytes to the CNS. FACS sorted astrocytes expressed equivalent levels of TLR3 mRNA to microglia but lower levels of TLR2 or 4. Astrocytes were induced by TLR3 signaling to express IRF7, which regulates the induction of type I IFN. The induction of IFN-beta in CNS in response to TLR3 signaling was verified in IFN-beta reporter mice. TLR2, 3 and 4 signaling led to increased levels of mRNA for glial CXCL10. Together these results suggest the involvement of type I IFN signaling. However, unlike CXCL10 gene expression, that was dependent on IFNAR signaling, TLR2-induced leukocyte infiltration was not affected in IFNAR deficient mice. These studies point to a role for TLR signaling in the innate glial response that regulates CNS inflammation.

P1.11.050
A reticulon family protein Nogo is an active component of TLR-triggered innate immune responses in macrophages

***T. Kimura**, M. Inui, T. Takai;*
Department of Experimental Immunology, Institute of Development, Aging and Cancer, Tohoku University, Sendai, Japan.

The reticulon family is a large group of membrane-associated proteins localized primarily to the endoplasmic reticulum of most cells. The reticulon family member 4, also known as Nogo, consists of three isoforms, Nogo-A, Nogo-B and Nogo-C. Nogo-A and C are uniquely found in the central nervous system and/or skeletal muscle, and Nogo-A was originally characterized as a regulator of axonal sprouting. Nogo-B is distributed in most tissues including immune cells. However, the function of Nogo-B in the immune system remains unclear. Interestingly, recent reports indicated that Nogo binds to

Paired immunoglobulin-like receptor B (PirB), which is one of the ITIM-harboring inhibitory molecules express on the surface of B cells and myeloid-lineage cells. Since we previously found an inhibitory role of PirB in Toll-like receptor (TLR)9 signaling of B cells, we have attempted to determine whether Nogo could be involved in regulation of macrophages, a key player of pathogen recognition via TLRs. Bone marrow-derived macrophages prepared from Nogo-A/B-deficient mice (kindly provided by Dr. Stephen M. Strittmatter, Yale Univ.) showed attenuated induction of inflammatory cytokines such as IL-6 following stimulation of TLR9, TLR2/1 and TLR2/6 than those of wild-type cells. Then, we found significant delays of IκB-α degradation and of phosphorylation of MAPKs in Nogo-A/B-deficient macrophages after TLR9 stimulation. These findings suggest that Nogo plays a crucial role in activation of TLR-mediated signaling in macrophages. We speculate that Nogo is an active component in TLR signaling, in which Nogo may regulate PirB or other signaling molecules involved in the TLR pathway.

P1.11.051
Analysis of the B cell responsiveness to the TLR9 agonist CPG in malaria semi-immune versus malaria naïve individuals

Y. Kone[1]*, K. Kassoum*[1]*, A. Ongoiba*[1]*, D. Safiatou N*[1]*, D. Didier*[1]*, M. Jacqueline*[2]*, S. Portugal*[2]*, P. Susan K.*[2]*, D. Ogobara K.*[1]*, C. Peter D.*[2]*;*
[1]University of Bamako/MRTC, Bamako, Mali, [2]NIH, Bethesda, MD, United States.

In the context of Phase 1 clinical trials of the malaria vaccine candidate AMA1 we found that the novel vaccine adjuvant CPG, TLR9 agonist that activates memory B cells, enhanced the antibody and memory B cell response to AMA1 in malaria-naïve U.S. adults, but not in malaria-immune Malian adults, suggesting that chronic *P. falciparum* exposure leads to TLR9 refractoriness. To follow up on this clinical observation we are conducting a systematic ex vivo analysis in which we compare the phenotype and function of memory B cells obtained from malaria-experienced and naïve individuals. In response to CPG stimulation we measure B cell proliferation, immunoglobulin class switching, cytokine production, antibodies secretion and the expression of co- stimulatory molecules. Male and female at age of 18 or greater from malaria endemic village are equally enrolled. Adult from malaria free area are used as control. Our preliminary results showed that both naïve and memory B cells from malaria semi-immune individuals respond less to CPG stimulation compared to malaria naïve individuals. Also malaria semi-immune individuals have a greater expression of the costimulatory molecule CD86. The next step will consist of comparing the above variables among 30 infected individuals, 30 uninfected individuals from Mali and 30 naïve individuals from the USA.
The results from this study may highlight the importance of testing the efficacy of novel vaccine adjuvants in the target population and may also provide fundamental insights into how chronic *P. falciparum* exposure modulates the innate immune response.

P1.11.052
TLR9-mediated synergistic T-bet expression and its implication for antibody production

D. Kovesdi*, G. Sarmay;*
Eotvos Lorand University, Budapest, Hungary.

Chromatin-Ig complexes stimulate autoreactive B cells by co-engaging B-cell antigen receptor (BCR) and TLR9. TLR9 is an endosomal Toll-like receptor which recognizes CpG-containing DNA fragments. Its role in the production of pathologic antibodies is well established but the mechanism by which BCR and TLR9 communicate still remains to be determined.
In this work we aimed to characterize the synergistic cross-talk between BCR and TLR9 and prove T-bet as a molecular meeting point that could be responsible for the production of the pathologic antibodies of autoimmune mice.
For this purpose we tested murine lymph node B cells for receptor cross-talk after either simultaneous or single stimulation by anti-IgM or CpG-ODN. Responses were checked for synergy at protein and mRNA levels and experiments for B cell activation and isotype switching were also carried out.
We discovered that the cross-talk between BCR and TLR9 was indeed synergistic; we found enhanced gene and protein expressions and improved proliferation with more cell divisions. Although we could not get synergy for the number of IgG2a-switched B cells nor for the secretion of IgG2a so far, we strongly believe that the synergistic cross-talk between BCR and TLR9 contribute to the development of autoimmune diseases and to the production of pathologic autoantibodies.
D. Kovesdi's work in this research was realized in the frames of TÁMOP 4.2.4. A/1-11-1-2012-0001 ,,National Excellence Program - Elaborating and operating an inland student and researcher personal support system" The project was subsidized by the European Union and co-financed by the European Social Fund.

P1.11.053
RIG-I dependent cross-priming of CD8+ T-cells

M. Bscheider[1]*, **D. Kreppel***[1]*, J. Fischer*[1]*, T. Franz*[2]*, U. Kalinke*[2]*, J. Ruland*[3]*, C. Peschel*[1]*, T. Haas*[1]*, H. Poeck*[1]*;*
*[1]III. Medizinische Klinik, Klinikum Rechts der Isar, Technische Universität München, Munich, Germany, [2]TWINCORE, Center for Experimental and Clinical Infection Research GmbH, Hannover, Germany, Hannover, Germany, [3]**Institut für Klinische Chemie und Pathobiochemie, Klinikum Rechts der Isar, Technische Universität München, Munich, Germany, Munich, Germany.*

Genetic and epigenetic plasticity allows tumor cells to evade immune-mediated elimination and renders single-targeted treatments inefficient. Targeting the cytosolic RNA-helicase RIG-I elicits a potent systemic anti-tumor immune-response and induces apoptosis in tumor cells. Therefore, RIG-I activation is a promising approach in the treatment of cancer. Yet, little is known about the molecular details of RIG-I dependent anti-tumor immune responses. Here we show that engagement of murine RIG-I induces potent peptide-specific CD8+ T-cell responses in vitro and in vivo, but does not support the differentiation of CD4+ T-cells into Th1, Th2 or Th17 cells. RIG-I ligation fosters cross-priming by up-regulation of co-stimulatory molecules, secretion of type-I IFNs and induction of NF-kappa-B dependent proinflammatory cytokines. Cross-primed CD8 T-cells respond with robust IFN-gamma secretion and differentiate into highly effective CTLs. Furthermore, vaccination with RIG-I agonists significantly delays subcutaneous tumor growth in a peptide specific manner. Thus, our data (i) uncover an important role for RIG-I in cross-priming of specific CD8+ cytotoxic T-cells thereby leading to the induction of specific adaptive anti-tumor immune responses and (ii) underscore the usefulness of RIG-I ligands for immunotherapy and vaccination.

P1.11.054
Some features of cellular immunity in patients with chronic spontaneous urticaria inducing reactivation of chronic EBV infection

E. A. Sorokina[1]*, N. K. Akhmatova*[1]*, E. A. Akhmatov*[1]*, **O. V. Lebedinskaya***[2]*;*
[1]I.I. Mechnikov Research Institute for Vaccines and Sera, RAMS, Moscow, Russian Federation, [2]Acad. E.A. Wagner Perm State Medical Academy, Perm, Russian Federation.

In the pathogenesis of chronic spontaneous urticaria (CSU) viral infections, including EBV infection often play the role of triggers. The study of EBV-induced diseases is currently an important health problem, due to the spread of the pathogen, its tropism for immune system cells, a variety of clinical forms and nonspecific treatment.
To study TLRs expression in patients with CSU as a result of immunotherapy by Immunovac-VP-4 and Kagocel. To assess TLRs expression in PBMC via flow cytometry performed with monoclonal antibodies (Caltag Laboratories, USA).
We observed 28 patients with CSU associated with reactivation of chronic EBV infection. CSU patients demonstrated increased as compared to control the levels of TLR2, 4 expression by 3-4 fold exceeding the normal values, while the TLR 3, 9 expression was increased by 2-fold.

Immunotherapy by Immunovac-VP-4 was found to enhance the expression of TLR3, 9. After Kagocel therapy the TLR2, 4 expression tended to decrease. TLR3, 9 levels demonstrated the tendency to increase and approached 42,1±3,2 and 33±3,8%, respectively after the treatment. In the group receiving standard treatment, the decrease in TLR4, 3 expression was observed.
Immunotherapy by Immunovac-VP-4 and Kagocel led to adjusting for TLR2, 4, and increased TLR3, 9 receptor expression to a more pronounced extent in the group receiving Immunovac-VP-4. Immunotherapy enhanced the TLR9 action, indicating the involvement of intracellular receptor mechanism. Inclusion of immunomodulators in the therapy of patients with CSU associated with reactivation of EBV infection promotes the activation of innate immunity, while increasing the effectiveness of therapy.

P1.11.055
Influence of the PAMPs of opportunistic microorganisms on the TLRs expression

*N. P. Utkina[1], E. A. Akhmatov[2], E. A. Ilinykh[1], E. V. Sorokina[2], E. A. Lebedinskaya[1], E. C. Marakasova[2], **O. V. Lebedinskaya**[1], E. A. Kurbatova[2], N. K. Akhmatova[2];*
[1]Acad. E.A. Wagner Perm State Medical Academy, Perm, Russian Federation, [2]I. I. Metchnikov Research Institute for Vaccines and Serum, RAMS, Moscow, Russian Federation.

Currently expanded interest in exploring the possibility of regulation of innate immune mechanisms with bacterial antigens, bearing PAMPs of microorganisms, determining the signaling pathways of the immune response. Purpose: To determine the degree of expression of TLRs on spleen cells, lymphoid tissue associated with the respiratory system - BALT / NALT, the intestinal mucosa - GALT at different methods of introducing bacterial vaccine Immunovac-VP-4 (containing antigens of *S. aureus, P.vulgaris, E. colli, K. pneumonia*).
Estimate of the number of cells expressing TLRs, was performed by flow cytometry with monoclonal antibodies (Caltag Laboratories, USA). Mice were vaccinated with Immunovac-VP-4 2-fold at intervals of 3 days subcutaneously (0.2 mg), intranasal (0.5 mg) and oral (2 mg).
The same vaccine Immunovac-VP-4 causes different signaling pathways of cell activation at different methods of administration: subcutaneously increased expression of TLR4, TLR9, TLR2, which causes further cell differentiation by Th-1 and, to some extent, Th-2 ways, with non-invasive methods for the expression of TLR4 and TLR9 involves the further development of immunity by Th-1 path accordingly induction of synthesis of IFN-γ, inhibits the synthesis of IL-4, and further the development of atopy.
Thus, it can be assumed that the different degree of sensitization with different routes of administration of the same drug is predetermined at the stage of interaction of the ligand with the TLR. Subcutaneous immunization Immunovac induced expression of all 3 TLRs, whereas non-invasive methods caused a significant increase in TLR4 and TLR9 in the absence of the dynamics of TLR2.

P1.11.056
Myeloid differentiation protein 2 as the target of curcumin analog in the inhibition of endotoxin LPS-induced TLR-4 activity

***G. Liang**[1], Y. Wang[1], L. Jiang[2], X. Shan[2];*
[1]Chemistry and Biology Research Center, School of Pharmaceutical Science, Wenzhou Medical College, Wenzhou, China, [2]The First Affiliated Hospital of Wenzhou Medical College, Wenzhou, China.

Curcumin is the key constituent in the traditional herb Curcuma Longa, and has been used in diet and traditional medicine for a long time in China. Anti-inflammatory activity and inhibition of LPS signaling are some of its many activities. In spite of the favorable anti-inflammatory property of curcumin, low bioavailability limits the development of curcumin as a potential therapeutic agent. Our previous studies have demonstrated a series of non-steroidal mono-carbonyl analogues of curcumin possessing enhanced stability and improved pharmacokinetic profiles, as well as anti-inflammatory activity in vitro. Among these curcumin analogues, compound L48H37 showed strong inhibitory effects on LPS-induced TNF-α and IL-6 release and inflammatory gene expression in mouse macrophages. Further, we show that L48H37 binds to the myeloid differentiation protein 2 (MD-2), which is the LPS-binding component of the endotoxin surface receptor complex MD-2/TLR-4. Fluorescence emission of MD-2 decreases with an absorbance maximum shift after the addition of L48H37, indicating the interaction of L48H37 and MD-2. In addition, the presence of L48H37 significantly inhibited binding of MD-2 to the immobilized LPS in a concentration-dependent manner, suggesting that the binding site for L48H37 overlaps with the binding site for LPS. This results in the inhibition of MyD88-dependent and -independent signaling pathways of LPS signaling through TLR-4. Finally, the pre-treatment with L48H37 suppressed pro-inflammatory cytokine production in plasma and liver, attenuated lung histopathology, and significantly reduced mortality in endotoxemic mice. Taken together, these findings may reveal important implications of MD-2 specific inhibitors for treatment of inflammatory diseases caused by bacterial infection.

P1.11.057
Immunomodulatory effects of P-MAPA on TLR2, ROS and nitric oxide of blood mononuclear cells from canine with visceral leishmaniasis

***V. M. Lima**, L. M. Melo, L. d. Sanches, J. Perosso, K. L. O. Silva; UNESP, Araçatuba, Brazil.*

Canine visceral leishmaniasis (CVL) is caused by a protozoan *Leishmania chagasi* is an important zoonotic disease. The parasite in dogs suppress cellular immune response, and the therapeutic arsenal against LVC is limited, the new immunomodulator aggregate fosfolinoleato-palmitoleate magnesium and ammonium protein (P-MAPA) improves immunocompetence when the immune system is impaired, but their dependence on toll like receptors (TLRs) and the mechanisms involved in immune response are still unclear. To investigate the in vitro action of P-MAPA, mononuclear cells were isolated from peripheral blood from healthy dogs and dogs infected with *Leishmania* spp and cultured in the presence of P-MAPA concentrations of 0, 50, 100 and 200 µg/mL in a
humid environment at 37°C with 5% CO2 for 24h. The in vitro observation revealed that the P-MAPA significantly increased the expression of TLR2, ROS and nitric oxide in mononuclear cells from healthy dogs and *Leishmania* spp. infected dogs. These findings suggest that P-MAPA has potential as a therapeutic drug in the treatment of canine visceral leishmaniasis.

P1.11.058
Dendritic cells differentiated using GM-CSF/IL-4 or FLT3L respond differently to TLR ligand maturation signals, affecting the quality of the primed CD8+ T-cell response

***A. Lissina**[1], O. Briceno[1], E. Martinuzzi[2], E. Gostick[3], D. A. Price[3], R. Mallone[2], V. Appay[1];*
[1]INSERM UMR S 945, Infections and Immunity, Université Pierre et Marie Curie-Paris 6, Paris, France, [2]INSERM U986, DeAR Lab Avenir, Université Paris Descartes, Paris, France, [3]Institute of Infection and Immunity, Cardiff University School of Medicine, Heath Park, Cardiff, United Kingdom.

Priming of CD8+ T-cells is highly influenced by the nature of the antigen-presenting DC. Engagement of pattern recognition receptors (PRRs) expressed by DCs induces cytokine production, expression of costimulatory molecules and alters antigen processing and presentation pathways, which collectively shape the priming, expansion and polarization of the adaptive immune response. Despite the widespread use of PRR ligands as adjuvants for vaccination, the mode of action of many of these molecules, either alone or in combination, and their influence on the priming of CD8+ T-cell responses remains largely unknown. We employed the accelerated (acDC) protocol as a simple in vitro model of T cell priming, in order to i) compare the function of DCs differentiated using either GM-CSF/IL-4 or FLT3L, and ii) investigate which combinations of adjuvants (namely TLR ligands) are responsible for the induction of Melan-A-specific CD8+ T-cell responses of the highest quality. Initially, we observed that CD8+ T-cells primed using FLT3L-differentiated DCs (FL-DCs) displayed significantly higher levels of polyfunctionality compared to GM-CSF/IL-4-treated DCs (GM-DCs).

Interestingly, FL-DCs and GM-DCs also responded differently to certain TLR ligands tested. FL-DCs stimulated with TLR8 ligand ssRNA40 primed CD8+ T-cells displaying significantly higher polyfunctionality and cytotoxic potential compared to GM-DCs treated with the same adjuvant. These results suggest that FLT3L and GM-CSF/IL-4 may generate different subsets of DCs, displaying different patterns and/or levels of TLR expression. These findings have important implications for the selection of adjuvants most effective at inducing functional CD8+ T cell responses on vaccination.

P1.11.059
Synergy in cytokine production induced by combinatorial TLR activation

***Q. Liu**, J. Ding;*
National University of Singapore, Singapore, Singapore.

Toll-like receptors (TLRs) are one of the best-characterized members of pattern recognition receptors (PRRs), which recognize specific pathogen-associated molecular patterns (PAMPs) from invading pathogens. Studies in this area have mainly focused attention on single TLRs recognizing a single PAMP. However, each invading pathogen carries with it multiple PAMPs, and at any one time, a host may encounter different types of pathogens each with multiple PAMPs. Therefore, it is crucial for the host to integrate these infection signals in order to mount the most appropriate and energetically favorable immune response. Previous studies in our lab have demonstrated that combinatorial TLR activation by multiple PAMP stimulation of macrophages can induce synergistic levels of cytokine protein production. It was noted that the synergy effect is subject to both the order and time interval of multiple PAMP stimulations, indicating a crosstalk among TLR signaling pathways, which boosts the immune signaling response. However, the mechanism underlying synergistic cytokine production upon combinatorial TLR activation is poorly understood. Here, we show how the TLRs crosstalk at multiple levels and identify the potential factor(s) that induce synergy in cytokine production. Unraveling the mechanism of TLR crosstalk will shed light on the complicated network of TLR signaling, thus contributing to infection control in pathogen invasion.

P1.11.060
The cationic lipid diC14-amidine and bacterial lipopolysaccharides both activate Toll-like receptor 4 pathways via different binding regions of TLR4

***C. Lonez**[1,2], K. Irvine[1], M. Gangloff[1], B. Caroyez[2], J. Ruysschaert[2], M. Vandenbranden[2], C. E. Bryant[1];*
[1]University of Cambridge, Cambridge, United Kingdom, [2]Université Libre de Bruxelles, Brussels, Belgium.

DiC14-amidine is a cationic lipid which induces pro-inflammatory cytokine secretion in immune cells upon interaction with the Toll-like receptor 4 (TLR4)/Myeloid Differentiation factor-2 (MD-2) membrane bound-complex, the natural sensor of bacterial lipopolysaccharides (LPS) [1, 2].
The aim of the present work is to characterize the interaction between diC14-amidine and the TLR4/MD2 receptor complex. Taking advantage of the species-dependent activity of TLR4 agonists [3], we compared the TLR4 agonist activity of diC14-amidine in four different species in order to map domains in TLR4 and MD2 that are important for diC14-amidine TLR4-agonist activity. We demonstrate that, while LPS is an agonist in all species, diC14-amidine is a full agonist for human, mouse and cat receptors, but a poor agonist for horse. Using chimeric constructs made from human and horse TLR4 and single mutants, we identify two regions in the human TLR4 that modulates the agonist activity of diC14-amidine. Interestingly, these regions in TLR4 are different from the previously identified bacterial lipopolysaccharides binding domains [4].

P1.11.061
Dectin-1 induces efficient T cell immunity and prominent expansion of CD8+ IL-17+ cells in a pulmonary model of fungal infection

***F. V. Loures**, V. L. G. Calich;*
Instituto de Ciências Biomédicas, São Paulo, Brazil.

Dectin-1 is a C-type lectin receptor which binds to β1,3-glucan present in fungal pathogens and is required for fungal resistance in mice and humans. It promotes phagocytosis and produces cytokines in collaborative signaling with TLRs. However, in the paracoccidioidomycosis the mechanisms that govern interaction between hosts and the fungus Paracoccidioides brasiliensis have been scarcely studied. Objectives: The aim of our study was to characterize the role played by Dectin-1 in pulmonary paracoccidioidomycosis. Methodology: Wild-type (WT) and Dectin-1-KO mice were used. Measurement of nitric oxide and cytokines after macrophage infection with P.brasiliensis were performed. In vivo, after intra-tracheal infection, we analyzed fungal burdens, pulmonary cytokines, histopathological analysis and assessment of leukocyte subpopulations in lung inflammatory exudates. Results: We verified that Dectin-1-KO macrophages infected with P. brasiliensis presented increased fungal loads associated with impaired synthesis of NO and IL-6 associated with increased production of IL-10 and MCP-1. In vivo, Dectin-1-KO mice produced diminished levels of Th1, Th2 and Th17 cytokines. In addition, Dectin-1-KO mice developed an impaired immune response, evidenced by poorly activated CD8+ T cells to the lungs and impaired Th17 immune response. These events led to increased fungal loads in the lungs of Dectin-1KO mice and allowed a marked dissemination of the fungus to other organs. As consequence, Dectin-1KO mice were unable to control fungal growth and presented a decreased survival time. Conclusions: Our findings demonstrate that Dectin-1 receptor is important to the activation of fungicidal mechanisms and to the induction of the innate and adaptive immunity against P. brasiliensis.

P1.11.062
MSK1 and 2 inhibit LPS induced prostaglandin production via an IL-10 feedback loop

***K. F. MacKenzie**[1], M. M. W. van den Bosch[1], S. Naqvi[1], S. E. Elcombe[1], V. A. McGuire[1], A. D. Reith[2], P. J. Blackshear[3], J. L. E. Dean[4], S. C. Arthur[1];*
[1]University of Dundee, Dundee, United Kingdom, [2]Glaxosmithkline, Stevenage, United Kingdom, [3]NIH, Durham, NC, United States, [4]Kennedy Institute for Rheumatology, Oxford, United Kingdom.

Prostaglandin production is catalysed by cox-2. We demonstrate here that MSK1/2 can exert control on the induction of cox-2 mRNA by TLR agonists. In the initial phase of cox-2 induction MSK1/2 knockout macrophages confirm a role for MSK in the positive regulation of transcription. However at later time points both LPS induced prostaglandin and cox-2 protein levels were increased in MSK1/2 knockout. Further analysis found that while MSKs promoted cox-2 transcription, following longer LPS stimulation MSKs also promoted degradation of cox-2 mRNA. This was found to be the result of an IL-10 feedback mechanism with endogenously produced IL-10 promoting cox-2 degradation. The ability of IL-10 to do this was dependent on the mRNA binding protein TTP through a p38/MK2-mediated mechanism. As MSKs regulate IL-10 production in response to LPS, MSK1/2 knockout results in reduced IL-10 secretion and therefore reduced feedback from IL-10 on cox-2 mRNA stability. Following LPS stimulation, this increased mRNA stability correlated to an elevated induction of both of cox-2 protein and prostaglandin secretion in MSK1/2 knockout macrophages relative to wild type cells. This was not restricted to isolated macrophages, as a similar effect of MSK1/2 knockout was seen on plasma PGE(2) levels following intra-peritoneal injection of LPS.

P1.11.063
Functions of endogenous TLR4 ligands

Y. Maru;
Tokyo Women's Medical University, Tokyo, Japan.

We have previously proposed that Toll-like receptor (TLR) 4 recognizes not only lipopolysaccharide (LPS) derived from pathogens but also some bioactive peptides of host origin such as S100A8 and SAA3, both of which we showed facilitate lung metastasis. Here we report that a synthetic SAA3 peptide bound MD-2 directly and stimulated cell migration in a CD14-independent manner. In contrast to LPS that induces both MyD88 and TRIF-dependent signaling, SAA3 promoted only the MyD88 pathway with little endocytosis of TLR4. In pre-metastatic lungs, pulmonary recruitment of CD11b+Gr1+ cells precedes the actual tumor cell arrival. We found that the SAA3 peptide induced their recruitment in an MD-2-dependent fashion. Moreover, we have discovered two mechanisms that allow tumor cell entry into the lungs. First, SAA3 directly promotes lung permeability. Tumor burden induced segmental vascular permeability regions in the pre-metastatic lungs with a significant up-regulation of CCL2, which in turn stimulated SAA3 expression. Tumor-mediated lung permeability and metastasis were abrogated in CCR2 knockout mice. Second, S100A8 induced expression of not only SAA3 in the pre-metastatic lungs but also that of the membrane-bound ephrin-A1 in primary tumors. TGFβ in the primary tumors activated ADAM12, which in turn shed the ephrin-A1. The released soluble ephrin-A1 then stimulated its receptor EphA1 and A2 in lung endothelial cells in an endocrine manner to deteriorate vascular barrier. In conclusion, we show that an endogenous peptide ligand(s) for TLR4 exists in mammals and, by binding MD-2, facilitates extravasation of leukocytes and tumor cells in the pre-metastatic lungs.

P1.11.064
Similarities and differences of innate immune responses elicited by smooth and rough LPS

R. Marzi, *I. Zanoni, A. Broggi, R. Ostuni, M. Caccia, M. Collini, A. Venkatesh, R. Spreafico, G. Capuano, F. Granucci;*
University of Milano-Bicocca, Milano, Italy.

The lipopolysaccharide is the major component of Gram-negative bacteria outer membrane. LPS comprises three covalently linked regions: the lipid A, the rough core oligosaccharide, and the O-antigenic side chain determining serotype specificity. Wild-type LPS (sLPS) contains the O-antigenic side chain and is referred to as smooth. Rough LPS (rLPS) does not contain the O-side chain. Most wt bacteria and especially wt Enterobacteriaceae express prevalently the sLPS form. The two sLPS and rLPS forms are used almost indistinctly to study the effects on innate immune cells. Nevertheless, there is evidence that their mechanism of action may be different. Here we have identified additional differences in the signaling capacity of the two LPS species in the mouse. We have found that rLPS, diversely from sLPS, is capable of activating in dendritic cells (DCs) the Ca2+/calcineurin and NFAT pathway in a CD14-independent manner, moreover it is also capable per se of activating the inflammasome and eliciting IL-1 secretion independent of the presence of additional stimuli required instead for sLPS. The ability of rLPS of activating the inflammasome in vitro has as a direct consequence a higher efficiency of rLPS-exposed DCs in activating natural killer (NK) cells compared to sLPS-exposed DCs. However, diversely from possible predictions, we found that the different efficiencies of the two LPS species in eliciting innate responses are almost nullified in vivo. Therefore, sLPS and rLPS induce nearly similar in vivo innate responses but with different mechanisms of signaling.

P1.11.065
Multi-step regulation of STAT1 phosphorylation in response to double-stranded RNA

T. Matsumiya, *J. Dempoya, F. Xing, R. Hayakari, H. Yoshida, T. Imaizumi;*
Hirosaki University, Hirosaki, Japan.

Pattern recognition receptors which sense non-self RNA trigger to produce type I IFN. Type I IFN binds to its cognate receptor, IFNAR, resulting in the activation of STAT1. Therefore, it has long been thought that dsRNA-introduced STAT1 phosphorylation is through transactivation of type I IFN signaling. This study asked whether the phosphorylation of STAT1 is absolutely type I IFN-dependent. A synthetic dsRNA polyinosinic-polycytidylic acid (polyI:C) induces STAT1 phosphorylation in A549 human lung epithelial cells. We found the polyI:C induced STAT1 phosphorylation in a predominantly IFN-dependent manner. However, we also found that polyI:C was able to stimulate STAT1 phosphorylation in type I IFN receptor-deficient U5A cells, suggesting this phosphorylation is type I IFN-independent. Retinoic acid-inducible gene-I (RIG-I) was involved in the initial STAT1 phosphorylation in response to polyI:C; however, little contribution of RIG-I was observed in the late STAT1 phosphorylation. Taken together, our results showed comprehensive regulation in which dsRNA induces STAT1 phosphorylation, indicating importance of STAT1 with such a tight regulation in innate immune system.

P1.11.066
Hepatic TDO2-derived L-kynurenine controls acute inflammatory responses by engaging the Aryl hydrocarbon Receptor

G. Mondanelli[1], *M. Gargaro*[1], *A. Bessede*[1,2], *D. Matino*[1], *M. Pallotta*[1], *C. Vacca*[1], *H. Funakoshi*[3], *U. Grohmann*[1], *P. Puccetti*[1], *F. Fallarino*[1];
[1]*Department of Experimental Medicine, University of Perugia, Perugia, Italy,* [2]*University of Bordeaux, IMS Laboratory, Pessac, France,* [3]*3Division of Molecular Regenerative Medicine, Department of Biochemistry and Molecular Biology, Osaka University Graduate School of Medicine, Osaka, Japan.*

Tryptophan catabolism along the kynurenine pathway is an important mechanism of immune tolerance by induction of regulatory T cells (Treg). Recently, the amino acid L-kynurenine, a byproduct of tryptophan catabolism, was found to activate the Aryl hydrocarbon receptor (AhR) in CD4+ T cells, which effect contributes to the induction of adaptive Treg cells. However, the role of tryptophan catabolism in regulating innate immune responses has been unclear. Here we demonstrate that an initial exposure to lipopolysaccharide (LPS) induces a rapid increase in endogenous kynurenine in wild-type as well as indoleamine 2,3 dioxygenases (IDO1 or IDO2)-deficient mice. In contrast, LPS fails to promote protective kynurenine/AhR-dependent responses in mice lacking hepatic tryptophan 2,3 dioxygenase (TDO2), which is an early component of the acute phase protein response in inflammation. These results suggest a critical role of TDO2 in the kynurenine-driven AhR repression of early, LPS-responsive inflammatory genes. Increased levels of proinflammatory cytokines were detected in sera from TDO2-deficient mice as compared to WT mice or mice lacking IDO1 or IDO2, with the recruitment of migratory neutrophils responsible for multiorgan infiltration. However, the administration of exogenous kynurenine reverted the effect of TDO2 deficiency in the response of AhR-competent mice to LPS. In summary, our data suggest that, upon LPS exposure, TDO2-dependent production of L-kynurenine activates AhR to limit inflammation and systemic host damage. These findings also suggest new therapeutic options in controlling early inflammatory gene expression in endotoxemia.

Expression of TLR2, 3, 9, MYD88 and TRIF in Kawasaki patients before and after IVIG therapy

H. R. Mortazavi[1], *S. Aleyasin*[1], *M. Babaei*[1], *R. Amin*[1], *M. H. Karimi*[2];
[1]*Allergy Research Center, Shiraz University of Medical Science, Shiraz, Iran,* [2]*Transplant Research Center, Shiraz University of Medical Sciences, Shiraz, Iran.*

Kawasaki disease (KD) is an acute childhood vacuities with inflammation of medium-sized arteries throughout the body, particularly of the coronary arteries. Toll-like receptors are type 1 transmembrane protein which play a critical role in recognition of microbial antigen and use NF-KB signaling pathway to induce massive number of inflammatory genes. This study was designed the role of TLR2, 3, 9, MyD88 and TRIF in immunological pathogenesis of KD.

31 patients with KD and 20 age-matched febrile children due to pneumonia plus 20 healthy children were studied. Real time PCR was used to evaluate the expression of TLR2, 3, 9, MyD88 and TRIF in peripheral blood mononuclear cells.
There were no significant differences in expression levels of TLR3 and TLR9 in comparison normal group.TLR2 gene transcript level was significantly elevated in KD in comparison to normal subjects ($P<0.05$). There were a significant differences in transcript level of MyD88 and TRIF ($P=0.03$). TLR2, 3 and 9 gene transcripts have been down regulated in peripheral blood of KD following IVIG therapy compared with expression levels of TLRs before IVIG therapy in acute febrile state. Following IVIG therapy MyD88 gene transcripts were down regulated in KD patients.
Aberrant activation of TLR2 or TLR3 (cause up-regulation of MyD88&TRIF) might be one of the initiating factors of immune aberrance in KD. IVIG causes general down-regulation and inhibition of TLR pathways which suggest as a new mechanism of anti inflammatory effect of IVIG.

P1.11.068
CpG ODN ligation of TLR-9 stimulates IFN-α and antinuclear antibody production in SLE patients

S. Morteza Gholi[1], *Z. Babaloo*[1], *P. Rahimzadeh*[2], *M. Ghayedi*[2], *H. Namdari*[2], *F. Gharibdoost*[2], *M. Taghadosi*[3], *E. Salehi*[2];
[1]*Tabriz University of Medical Science, Tabriz, Iran,* [2]*Tabriz University of Medical Science, Tehran, Iran,* [3]*Mashhad University of Medical Science, Mashhad, Iran.*

As there is no direct *in vivo* data yet for TLR-9 mediated mechanism of antinuclear antibody and IFN-α production in SLE, the level of TLR-9 expression on peripheral blood mononuclear cells in 35 SLE patients and 35 healthy controls was analyzed. The effect of TLR-9 ligation in IFN-α production was also investigated. PBMCs were stained with PE-conjugated mAb against TLR-9 and the expression of mRNA TLR-9 was determined. Antinuclear antibody titer was also determined in serum. Ultimately, the IFN-α concentration was measured in supernatants of PBMCs following CpG stimulation. Based on achieved data, the percentage of TLR-9-positive PBMCs and the TLR-9 mRNA expression were significantly higher in patients. There was a significant positive correlation between ANA titer and percentage of TLR-9 positive PBMCs. Also IFN-α concentration in patients significantly increased in response to CpG stimulation. In this study we provide evidence that TLR-9 plays an important role in SLE pathogenesis.

Genetic polymorphisms in host innate immune sensor genes and the risk of Nasopharyngeal carcinoma in North Africa

K. Moumad[1,2], *J. Lascorz*[1], *M. Bevier*[1], *M. Khyatti*[2], *M. Ennaji*[3], *S. Huhn*[1], *S. Lu*[1], *L. Chouchane*[4], *M. Corbex*[5], *A. Försti*[1,6];
[1]*Department of Molecular Genetic Epidemiology, German Cancer Research Center (DKFZ), Heidelberg, Germany,* [2]*Institut Pasteur du Maroc, Casablanca, Morocco,* [3]*Laboratory of Virology, Hygiene & Microbiology, Faculty of Sciences & Technics, University Hassan II Mohammedia, Mohammedia, Morocco,* [4]*Genetic Medicine and Immunology Laboratory, Weill Cornell Medical College in Qatar, Qatar Foundation, Education City, Doha, Qatar,* [5]*Department of Public health, Institute of Tropical Medicine, Antwerp, Belgium,* [6]*Center of Primary Health Care Research, Clinical Research Center, Lund University, Malmö, Sweden.*

Nasopharyngeal carcinoma (NPC) is an Epstein-Barr virus-associated malignancy with an unusual racial and geographical distribution. The interaction between host pattern-recognition receptors and viruses profoundly influences infection dynamics. Therefore, we studied the association between single nucleotide polymorphisms (SNPs) in selected genes involved in host innate immunity (including families of toll-like receptors, C-type lectin receptors, and RIG-I-like receptors) and the risk of NPC. In total, 26 SNPs in five pattern-recognition genes (CD209, DDX58, MBL2, TLR3 and TLR9) were genotyped in 492 North African NPC cases and 373 frequency-matched controls. The most significant association adopting a dominant model was observed for a functional SNP in TLR3. The analysis showed also that SNPs within CD209 and DDX58 are associated with NPC risk. Moreover, an 18% increased risk per allele was observed for the five most significantly associated SNPs. Our results suggest that genetic variation in pattern-recognition genes is associated with the risk of NPC. These preliminary findings require replication in larger studies.

P1.11.070
The self-perpetuating mechanism of antiphospholipid antibody production depends on TLR7 activation and endosomal superoxide generation

N. Müller-Calleja*, P. Stein, A. Canisius, C. Orning, M. Radsak, K. J. Lackner;*
Universitätsmedizin Mainz, Mainz, Germany.

Objective. Antiphospholipid antibodies (aPLs) are associated with thrombosis and recurrent abortions during autoimmune pathologies. To elucidate the underlying signaling pathways leading to autoantibody secretion we analyzed the interaction between plasmacytoid dendritic cells (pDCs) and different B cell populations with special focus on the role of TLR7 and endosomal superoxide production.
Methods. We cultured aPL stimulated human pDCs together with allogeneic B cells. Upregulation of costimulatory molecules, plasma cell differentiation and memory B cell activation were determined by flow cytometry. aPL secretion was measured using appropriate ELISAs. Furthermore we immunized different transgenic mouse strains with aPL and CFA. APL titer was determined after 6 weeks in blood obtained from tail veins.
Results. We demonstrated that aPL induced upregulation of costimulatory molecules on pDCs depend on endosomal superoxide generation and TLR7 activation. Cocultured with B cells these stimulated pDCs are able to induce plasma cell differentiation and the proliferation of memory B cells secreting aPL antibodies. These *in vitro* data could be confirmed by immunizing transgenic mice with a human aPL. While wiltype mice and TLR4 deficient mice produce murine aPL, no aPL production could be detected in $TLR7^{-/-}$ or $Gp91phox^{-/-}$ mice. The latter do not express NADPH-oxidase2 and therefore are unable to generate endosomal superoxide.
Conclusion. We could demonstrate that aPL activated pDCs have the potential to induce aPL secretion by preformed memory B cells. Thereby TLR7 activation and endosomal ROS generation play a pivotal role in this self-perpetuating mechanism of autoantibody production.

P1.11.071
Dual regulation of osteopontin production by TLR stimulation in dendritic cells

T. Musso[1], *S. Scutera*[1], *V. Salvi*[2], *S. Rossi*[1], *M. Alessandria*[1], *D. Bosisio*[2], *S. Sozzani*[2];
[1]*Dept. of Public Health and Paediatric Sciences, Torino, Italy,*
[2]*Department Molecular and Translational Medicine, Brescia, Italy.*

Osteopontin (OPN), a cytokine produced, among others, by dendritic cells (DC), is involved in inflammation and defence against pathogens. Here we report that the activation of the MyD88 pathway by TLR2, TLR5 and TLR7/8 agonists, or IL-1β, induces high levels of OPN in human DC. Conversely, LPS and Poly I:C, two TLR3 and TLR4 agonists that engage the TRIF pathway, were ineffective. TLR2 agonists were the strongest OPN inducers, and OPN production was highly stimulated by TLR2-triggering bacteria (*S. aureus*), but not by TLR4-triggering *E. coli*. Co-stimulation experiments revealed that TLR3 and TLR4 agonists, beyond being inactive by themselves, sharply limited TLR2-dependent OPN production, by activating a TRIF-dependent inhibition of the MyD88-dependent OPN production. MyD88 silencing impaired TLR2-dependent OPN induction, whereas TRIF pathway blockage by chloroquine, dynasore or TRIF knockdown prevented the TLR3/4 agonist-mediated inhibition, which was independent from the endogenous production of type I IFN, IL-29, IL-10 or TGF-β. LPS and Poly I:C inhibitory activity was associated with the release of a >10 kDa protein factor(s). We also demonstrated that the higher OPN levels produced by *S. aureus*-treated DC, compared to *E. coli*-treated DC, were responsible for a markedly increased

production of IL-17 by $CD4^+$ T cells. These results highlight the biological relevance of the differential OPN induction by TLR2 and TLR4 agonists, and emphasize the importance of TLR cross-talk in OPN induction. This implies that OPN regulation by TLR signaling is critical in shaping inflammatory responses, and may modulate IL-17 production in response to pathogens.

P1.11.072
Toll-like receptor genetic polymorphism influences susceptibility and severity to tuberculosis in the Indian Population

***N. Najmi**, G. Kaur, S. Sharma, R. Mehra, N. Mehra;*
All India Institute of Medical Sciences, New Delhi, India.

Variations within TLR genes may, in part impair the ability of certain individuals to respond to the TLR ligands thus altering the susceptibility to inflammatory diseases. We investigated an association of candidate SNPs in TLR9, TLR4 and TLR2 genes with pulmonary tuberculosis. The data revealed significantly reduced frequency of TLR9 (-1237C) in patients versus controls (12% vs. 23%, p<0.0001, OR=0.45) and significantly increased frequency of *TLR4* Asp299Gly mutation in the patient group (17% vs. 8.8%, $\chi 2$= 10.7, p = 0.001, OR=2.1). Further, the homozygous mutant allele (TLR9-1237CC) was absent in patients with severe PTB infection group vs. healthy controls (5.5% vs. 0%). The TLR4 896GG mutant occurred only in patients with high bacillary load (3+) and those with far advanced lung disease. Similarly, the mutant 1196T was significantly pronounced in the homozygous state (TT) in these patients. These results suggest a possible association of TLR9 T-1237C polymorphism with protection to *M.tb* infection, while TLR4 substitutions at residues 299 and 399 are associated with susceptibility to pulmonary TB, particularly the most severe disease. TLR4 C1196T and TLR9 (T-1486C) mutations on the other hand occurred with comparable frequencies among patients and healthy controls(12.6% Vs 9% and 42% vs. 40% respectively). TLR2 polymorphism C2180T occurred at a frequency of 50% in both healthy controls as well as PTB patients, while the TLR2 (2408G/A) mutation was completely absent in the North Indian population. These results suggest that TLR2 gene does not predispose individuals to acquire tuberculosis, in this population.

P1.11.073
Association study between Toll-like receptor 4 single-nucleotide polymorphisms and bipolar disorder

***J. Oliveira**[1,2], W. Boukouaci[3], M. Bennabi[3], A. Dargél[1], B. Etain[4,1,2], C. Henry[4,1,2], F. Bellivier[4,1,2], J. Kahn[5,2], M. Leboyer[4,1,2], R. Tamouza[3,2];*
[1]INSERM U 955, Psychiatry Genetics lab, Créteil, France, [2]FondaMental Foundation, Créteil, France, [3]Immunology and Histocompatibility Department and INSERM, U 940, Saint-Louis Hospital, Paris, France, [4]University Paris-Est, Department of Psychiatry, Créteil, France, [5]Service de Psychiatrie et Psychologie Clinique, CHU de Nancy, Hôpitaux de Brabois, Vandoeuvre Les Nancy, France.

Signs of inflammation and immune dysfunctions have repeatedly been reported in bipolar disorders (BD). Moreover, early-life insults of infectious origin and reactivation of expression of the Human Endogenous Retrovirus type W have also been associated. In this context, immunogenetic background may modulate the effect of immune inflammatory responses and is thus of particular interest in this field. In fact, innate immune response molecules such as Toll-like receptor 4 (TLR4) have already been implicated in neuroinflammation and genetic variants associated with susceptibility to several inflammatory disorders. Therefore, we hypothesized that TLR4 single-nucleotide polymorphisms (SNPs) may influence susceptibility to BD. A case-control study was conducted involving 572 patients with BD type I or II and 152 healthy controls. Among BD patients, 231 were classified as early-onset, defined by an age at onset before the age of 21. Genotyping of six SNPs of TLR4 gene was performed using TaqMan®. We found an association between rs1927914 ($p < 0,05$) and rs11536891 ($p < 0,01$) and early-onset BD, influenced by the season of birth as it was only observed among non-winter born individuals. Our preliminary data suggest the existence of immunogenetic patterns of susceptibility and the importance of gene-environment interactions in BD.

P1.11.074
Schistosome-activated B cell surface toll-like receptor-4 expression correlates with CD23 and IgM expression

***D. O. Onguru**[1,2], A. V. O. Ofulla[2], L. Ganley-Leal[3], P. N. Mwinzi[1];*
[1]Kenya Medical Research Institute, Kisumu, Kenya, [2]Maseno University, Kisumu, Kenya, [3]Boston University School of Medicine, Boston, MA, United States.

Activation of adaptive immunity depends on the preceding innate immune recognition and signaling, with specific responses varying according to the involved receptors. B cell activation through toll-like receptors triggers production of pro-inflammatory cytokines and chemokines, and expression of co-stimulatory molecules by antigen presenting cells (APCs). These molecules are also important in responses to lipopolysaccharide signaling through toll-like receptor-4 (TLR4), and together with the microbial antigens presented by APCs they activate the CD4 T cells that initiate most adaptive immune responses. B cell role in resistance to *Schistosoma mansoni* reinfection has been associated with CD23 expression. We investigated B cell TLR4 in relation to CD23 expression during *S. mansoni* infections. Whole blood cells from 36 infected adult males were stained using fluorochrome-conjugated antibodies, and analyzed on a FACS Calibur (BD). B cell surface expression of CD23, TLR4, CD69 and IgM was determined using Flowjo (v. 7.5) and statistically analyzed using GraphPad Prism v.5. B cell TLR4 expression (%) was strongly associated with CD69 (p<0.0001), IgM (p<0.0004) and CD23 (p=0.0285) expression, but not MFI (p>0.05). Over 98% peripheral B cells expressed IgM but with lower MFI than TLR4 (p=0.0205). We found no association between the expression of any of these molecules with *S. mansoni* egg counts in stool. TLR4 expression was not different between B cells from praziquantel-naïve and severally-treated persons (p=0.6083), but the latter had lower TLR4 MFI (p=0.0392). TLR4 may be important in B cell recognition of schistosome antigens and the resultant CD23-mediated anti-schistosome responses involved in protection from re-infection.

P1.11.075
Toll-like receptor -2, -4 and -9 genetic variants in Mexican patients with amoebic liver abscess

***O. Partida-Rodriguez**[1], E. G. Hernandez[1], C. Maldonado[2], U. Magaña[3], O. Valenzuela[3], M. E. Nieves-Ramirez[1], E. Gonzalez[1], A. Valadez[1], P. Moran[1], C. Ximenez[1];*
[1]National Autonomous University of Mexico, Mexico City, Mexico, [2]Children Hospital of Mexico, Mexico City, Mexico, [3]University of Sonora, Hermosillo Sonora, Mexico.

Toll-Like Receptors (TLRs) recognize *Entamoeba histolytica* molecular patterns generating a series of intracellular signaling that leads to the modulation of the innate immune system. Single nucleotide polymorphisms (SNPs) in TLR genes may influence their activity. We studied associations of TLRs SNPs with susceptibility to develop amoebic liver abscess (ALA) by *Entamoeba histolytica* in Mexican individuals from the State of Sonora and from Mexico City (DF). We typed by allelic exclusion the SNPs R677W and R753Q of TLR2, D299G and T399I of TLR4, and -1237T/C and 2848G/A of TLR9. We compared SNPs frequencies of ALA patients (Sonora n=32, DF n=32) with control individuals (Sonora n=58, DF n=21). The genotype TLR9 2848G/A in ALA patients from DF showed a statistically (p=0.008) increased frequency (63.3%) when compared with controls (25.0%), with an OR of 5.18 (95% CI 1.27-22.37). We will increase sample size in order to find out if the TLR9 2848G/A can be considered as a marker of susceptibility to ALA in population from the center of Mexico. Work partially supported by PAPIIT IN206408, IN206405, PAPIME 200105 and SEP-CONACYT 79220.

P1.11.076

The role of Damage Associated Molecular Patterns (DAMPs) in the genetic susceptibility towards cigarette smoke induced neutrophilic airway inflammation

***S. D. Pouwels**, I. H. Heijink, L. E. Den Boef, M. H. Boezen, M. C. Nawijn, A. J. M. van Oosterhout;*
University Medical Center Groningen (UMCG), Groningen, Netherlands.

Damage Associated Molecular Patterns (DAMPs) that are released from necrotic epithelial cells upon exposure to cigarette smoke (CS) have been proposed to contribute to neutrophilic lung inflammation in Chronic Obstructive Pulmonary Disease (COPD). COPD is a progressive lung disease characterized by sustained neutrophilic airway inflammation caused by chronic exposure to noxious gasses and particles like cigarette smoke. Only 20% of smoking individuals develop COPD, indicating a role for genetic susceptibility. We hypothesize that the profile of DAMPs released upon CS-exposure contributes to the susceptibility to develop neutrophilic airway inflammation.
30 Inbred mouse strains were exposed to CS or air (control) in a 5-day exposure model. Subsequently, neutrophilic airway inflammation and the DAMP profile (e.g. HMGB1, HSP70, dsDNA, mtDNA) in the BAL fluid were determined in all mice by standard morphology, ELISA and qPCR. Haplotype Association Mapping (HAM), using 4 million SNPs, was performed to identify susceptibility genes for DAMP (dsDNA) release after CS exposure.
Linear regression analysis showed a positive correlation between neutrophilia and most, but not all, DAMPs. In a stepwise forward regression analysis dsDNA (p=0.013) appeared to be the best predictor for neutrophilic airway inflammation. HAM analysis of dsDNA revealed several susceptibility genes contributing to DAMP release after CS exposure including genes that are functionally mapped to cell-death pathways.
In conclusion, mice susceptible for neutrophilic airway inflammation after CS-exposure also show increased DAMP release which is associated with genes involved in the regulation of cell-death pathways.

P1.11.077

Friends of our enemy are our enemy: Bacteria modulate cancerous behavior of prostate cancer cell lines via TLR signaling

***S. Rezania**[1,2], N. Rashidi[3], O. Zarei[4], A. Kalantari[5], A. Zarnani[5,2];*
[1]Biophysics Institute, Medical University of Graz, Graz, Austria, [2]Nanobiotechnology Research Center, Avicenna Research Institute, ACECR, Tehran, Iran, [3]Immunology Department, Tehran University of Medical Sciences, Tehran, Iran, [4]Department of Pharmaceutical Biotechnology, Faculty of Pharmacy, Tabriz University of Medical Sciences, Tabriz, Iran, [5]Immunology Research Center, Tehran University of Medical Sciences, Tehran, Iran.

Background and aim: Toll like receptors (TLR) trigger inflammatory responses upon microbial sensing. Inflammation has long been associated with cancer development. The aim of the present study was to investigate impact of Gram-negative bacterial lipololysaccharide (LPS) and Gram-positive bacterial lipoteichoic acid (LTA) on cancerous behavior of prostate cancer cell lines. **Materials and methods:** Expression of TLR1-10, CD14 and MyD88 transcripts and protein expression of TLR2 and 4 was investigated by RT-PCR, flowcytometry and Western blotting, respectively. Experiments were set up to assess effects of LPS and LTA at different concentrations and times on cell proliferation, invasion, adhesion and cytokine production. **Results:** Prostate cancer cell lines differentially expressed TLR1-10, MyD88 and CD14. LNCap and DU145 failed to express TLR2 and TLR4 genes, respectively. Flowcytometeric analysis showed that none of prostate cell lines express TLR2 and TLR4 on their surface. Interestingly, prostate cell lines lacking the surface expression of TLR2 or 4 had positive expression pattern in Western blot indicating intracellular expression of these receptors. LPS and LTA treatment of DU145, significantly increased cell proliferation regardless of lacking cognate receptor for LPS. Similarly, LTA treatment increased proliferative response of LNCap. Prostate cancer cell lines differentially produced pro-inflammatory cytokines in response to LPS or LTA treatment. While invasive capacity of PC3 or DU145 was not affected by aforesaid treatments, LPS caused increased invasiveness of LNCap. Stimulation of PC3 with LPS and LTA was associated with increased cell adhesion. **Conclusion:** Bacterial-induced pro-inflammatory milieu may shape the cancerous behavior of prostate malignancies via TLR signaling.

Using recombinant lactococci constructs as a molecular tool to dissect the immunomodulating capacity of surface piliation in *Lactobacillus rhamnosus* GG

*I. von Ossowski[1], T. E. Pietilä[1], **J. Rintahaka**[1], E. Nummenmaa[1], V. Mäkinen[1], J. Reunanen[1], R. Satokari[1], W. M. de Vos[1,2,3], I. Palva[1], A. Palva[1];*
[1]Department of Veterinary Biosciences, Faculty of Veterinary Medicine, University of Helsinki, Helsinki, Finland, [2]Laboratory of Microbiology, Wageningen University, Wageningen, Netherlands, [3]Department of Bacteriology and Immunology, Haartman Institute, University of Helsinki, Helsinki, Finland.

Lactobacillus rhamnosus GG, supported by its well-documented clinical benefits, is one of the most widely used probiotics in the food and health-supplement industries. Despite this, numerous aspects of its molecular mechanisms and limitations as a probiotic remain unknown and thus are still to be explored and dissected. Given that *L. rhamnosus* GG is one of only a few such strains exhibiting surface piliation (called SpaCBA), we sought to examine whether this particular type of cell-surface appendage has a discernible immunomodulating capacity and can stimulate responses in human immune-related cells. To do this, we recombinantly engineered *Lactococcus lactis* to produce native (and pilin-deleted) SpaCBA pili that were assembled in a structurally authentic form and anchored to the cell surface, and which had still retained mucus-binding functionality. As a molecular tool, we used these recombinant lactococcal constructs to demonstrate that SpaCBA pili can contribute to the activation of Toll-like receptor 2-dependent signaling in a HEK-TLR2 reporter cell line as well as to the modulation of inflammatory cytokine production in human monocyte-derived dendritic cells. Based on these results, we offer the possibility that the recombinant-expressed and surface-anchored SpaCBA pilus, given its projected functioning in the gut environment, is a novel microbe-associated molecular pattern (MAMP)-like modulator of innate immunity. With this study, we have been able to further add mechanistic details into the molecular immunogenicity of the SpaCBA pilus, which will help lead to a clearer understanding of its role in the multifactorialness of *L. rhamnosus* GG health-related functioning in the human gut.

P1.11.079

LPR mice with TIR8 deficiency are prone to develop B-cell lymphomas

***F. Riva**[1], M. Ponzoni[2], S. Bertilaccio[2], N. Polentarutti[3], A. Anselmo[3], A. Innocenzi[2], F. Caligaris-Cappio[2], A. Mantovani[1], M. Muzio[2], C. Garlanda[3];*
[1]University of Milano, Milano, Italy, [2]Ospedale San Raffaele Scientific Institute, Milano, Italy, [3]Humanitas Clinical and Research Center, Rozzano, Italy.

The association among autoimmunity, chronic inflammation and malignancy has been described and confirmed by epidemiological studies. Notwithstanding these achievements, the molecular mechanisms underlying this association are still unknown. Several evidences suggest that patients suffering from Systemic Lupus Erythematosus, Rheumatoid Arthritis and Sjogren's Syndrome are prone to develop B-cell Non-Hodgkin's Lymphomas. We investigated the role of Tir8/Sigirr gene, already known to be associated with autoimmunity, in the development of lymphoma. Indeed, the ability to dampen signaling from IL-1R and TLR family members confers TIR8/SIGIRR the ability to act as regulator of inflammation, cancer-related inflammation and autoimmunity. In this study we describe the occurrence of B-cell lymphoma in B6lpr/lpr and B6lpr/lpr/Tir8−/− mice. Both strains developed Diffuse Large B-Cell Lymphoma (DLBCL) during their late age, but in B6lpr/lpr/Tir8−/− mice DLBCL occurred earlier (10-12 months vs 15-18 months) and were more aggressive, with significantly higher mortality (100% vs 22%, respectively in 15 months old B6lpr/lpr/Tir8−/− and B6 lpr/lpr mice). Histopathologic

analysis of spleen and lymph nodes of B6lpr/lpr/Tir8 mice documented clear-cut DLBCL areas arising within a context of atypical lymphoproliferative disorder; these results were corroborated by both molecular analysis and transplantation experiments. Clonal rearrangement was present in both strains. However, only recipients of spleen or lymph node cell suspensions collected from B6lpr/lpr/Tir8−/− mice developed DLBCL. These observations unveil a role of TIR8 in the occurrence and development of DLBCL, suggesting its potential role in targeted therapy. Moreover, the B6lpr/lpr/Tir8−/− mouse could be a model to establish and evaluate studies of novel therapeutic protocols in DLBCL.

Vav proteins mediate Syk-coupled C-type lectin receptor-induced innate immunity

S. Roth[1], *H. Bergmann*[1], *K. Neumann*[1], *V. Laux*[1], *C. Prazeres da Costa*[1], *V. L. Tybulewicz*[2], *X. Bustelo*[3], *J. Ruland*[1];
[1]*Technical University Munich, Munich, Germany,* [2]*MRC National Institute for Medical Research, London, United Kingdom,* [3]*Cancer Research Center CSIC-University of Salamanca, Salamanca, Spain.*

Fungal infections are a major cause of morbidity and mortality worldwide - especially in immunocompromised individuals. Yet, anti-fungal immune defense mechanisms are poorly understood. C-type lectin receptors (CLRs) expressed by myeloid cells recognize structures present on fungi and other pathogens as well as endogenous danger molecules. They are crucial for host protection and immune homeostasis. Following ligand binding, CLRs activate via their cytoplasmic immunoreceptor tyrosine-based activation motifs (ITAM) or by coupling to ITAM-containing signaling chains distinct intracellular signaling cascades that mediate the expression of specific cytokines. Besides the essential role of the tyrosine kinase Syk and the adaptor protein Card9 not much is known about the molecular mechanism involved in CLR triggered inflammatory responses. Here we demonstrate that specific Vav isoforms are differentially involved in cytokine responses to Dectin-1, Dectin-2, or Mincle stimulation in dendritic cells. Moreover, mice lacking certain isoforms of the Vav protein family are severely impaired in anti-fungal host defense. Thus, our results define distinct Vav isoforms as critical signaling molecules for CLR induced immune responses.

P1.11.081
Cigarette smoke modulates the oral epithelial cell innate immunity

M. Rouabhia[1], *A. Semlali*[2], *M. Alanazi*[2], *J. Chakir*[1];
[1]*Laval University, Quebec, QC, Canada,* [2]*King Saud University, Riyadh, Saudi Arabia.*

The gingival epithelium is becoming known as a regulator of the oral innate immune responses to a variety of insults such as bacteria and chemicals, including those chemicals found in cigarette smoke. Epithelial cells play an important role in the tissue innate immunity by specifically expressing certain receptors, including toll-like receptors (TLRs) that are involved in host immune response. Oral epithelial cells are most cells targeted by tobacco smoke. This may lead to innate immunity dysregulation. The purpose of this study was to investigate the effects of cigarette smoke on expression/production of Toll-like receptors (TLRs), antimicrobial peptides, and proinflammatory cytokine expression in primary human gingival epithelial cells. Following exposure to whole cigarette smoke there was an increase of TLR2, TLR4 and TLR6 expression. Cigarette smoke led to ERK1/2, p38 and JNK phosphorylation in conjunction with nuclear factor-κB (NFκB) translocation into the nucleus. TLR expression following cigarette smoke exposure was down regulated by the use of ERK1/2, p38, JNK MAP kinases, and NFκB inhibitors, suggesting the involvement of these signaling pathways in the cellular response against cigarette smoke. Cigarette smoke also promoted HBD2, HBD3, IL-1β, and IL-6 expression through the ERK1/2 and NFκB pathways. Interestingly, the modulation of TLR, HBD, and cytokine expression was maintained long after the gingival epithelial cells were exposed to smoke. By promoting TLR, HBDs, and proinflammatory cytokine expression, cigarette smoke may contribute to innate immunity dysregulation, which may have a negative effect on human health. (Funded by the NSERC, Canada, Fonds Emile-Beaulieu, U. Laval).

P1.11.082
The role of NF-κB oscillation in inflammatory responses to Salmonella infection

J. Sakai, *J. Wright, C. E. Bryant;*
University of Cambridge, Cambridge, United Kingdom.

Macrophages play an important role in the innate immune response to Salmonella infection. Macrophages detect Salmonella through Toll-like receptor 4 (TLR4), which binds to lipopolysaccharide (LPS) on the Salmonella membrane, and subsequently initiates inflammatory responses via the activation of nuclear factor-κB (NF-κB). Activated NF-κB translocates to the nucleus where it triggers the transcription of inflammatory genes. NF-κB is subsequently inactivated and shuttles back to the cytoplasm. Under a continuous LPS stimulation, NF-κB is activated again and reenters the nucleus to initiate further transcription. This suggests that inflammatory cytokine expression may be maintained by the repeated activation of NF-κB oscillating between the cytoplasm and the nucleus in response to LPS.
This study has investigated if there is a correlation between the pattern of NF-κB oscillation and TNFα expression by time-lapse microscopy using RAW264.7 cells fluorescent reporters. NF-κB oscillation was quantified as the ratio of the nuclear fluorescent intensity to the cytosolic one. The results showed that the first peak of the ratio became higher in a LPS dose-dependent manner. In addition, the number of the peaks increased with increasing LPS concentration. A strong correlation between the height of the first peak and TNFα expression could be seen while there was no correlation between the number of the peaks and TNFα expression.

P1.11.083
Characterization of SSc5D, a molecule of the Scavenger Receptor Cysteine-Rich Superfamily, as an innate immune receptor

R. Santos, *C. Bessa-Pereira, C. M. Gonçalves, A. M. Carmo;*
IBMC Porto, Porto, Portugal.

SSc5D is a member of the Scavenger Receptor Cysteine-Rich (SRCR) superfamily. This group of proteins is characterized by the presence of one or more SRCR domains, which are thought to mediate protein-protein interactions within the immune system and/or to serve as pathogen pattern recognition receptors. However, the overall function of the SRCR family is still poorly understood. Unraveling the biological and functional properties of SSc5D may thus contribute to clarification of the role of this group of highly conserved proteins. The cellular expression of SSc5D was analyzed in different types of cell by quantitative PCR and immunohistochemical staining of various tissues such as uterus, placenta, spleen, kidney, and others. Our results show that SSc5D is differentially expressed in myeloblastic, monocytic and lymphocytic cell lines, and also detected in some tissue-specific cell lines. By immunohistochemical staining, high levels of SSc5D expression in placenta were detected, most noticeably in syncytiotrophoblast cells, which can suggest a possible role in fetal immunity. In addition, we also observed high expression of SSc5D in the gastrointestinal tract, which is in agreement with the possible role of SSc5D as an innate immune receptor. Overall, our results indicate that SSc5D may act as a molecular bridge in defensive interactions established between immune cells and pathogens.

P1.11.084
Essential role of IRF3 in microbiota-contributed Tslp induction and protection against intestinal inflammation

***H. Sarashina**, H. Negishi, S. Miki, T. Taniguchi;*
Department of Molecular Immunology, Institute of Industrial Science, University of Tokyo, Tokyo, Japan.

The large intestinal epithelial cells and immune cells are exposed to a variety of pathogen associated molecular patterns (PAMPs) derived from commensal microbiota. Although recent studies suggest that constitutive activation of these cells through pattern recognition receptors (PPRs), such as Toll-like receptors (TLRs) or RIG-like receptors (RLRs), are required to keep homeostasis rather than inflammation of large intestine, the underlying gene regulatory mechanisms are not well understood. Here we demonstrated that IFN regulatory factor (IRF)3 had a critical role in the suppression of dextran sulfate sodium induced colitis. IRF3-deficient mice exhibited lethal defects in both inflammatory and recovery phases of colitis with decreased expression of thymic stromal lymphopoietin (TSLP), a cytokine known to be essential for protection of the large intestine. We further provided evidence that DNA and RNA of the large intestinal contents are critical for Tslp gene induction via IRF3 activation by cytosolic nucleic acid receptors. We also found that Tslp promoter contains ISRE sequence to which IRF3 binds and the cooperation between IRF3 and p65 synergistically induces the activation of Tslp promoter. This newly identified intestinal gene regulatory mechanism, wherein IRF3 activated by microbiota-derived nucleic acids plays a critical role in intestinal homeostasis, may have clinical implication in the treatment of colonic inflammatory disorders.

P1.11.085
Investigating the deregulation of Toll-like receptors, pro-inflammatory cytokines and cationic peptides (Human Beta Defensins) in normal and colon cancer tissue

***A. Semlali**[1], A. AL Amri[1,2], H. Saeed[1], A. Aljebreen[1], O. Alharbi[1], M. Almadi[1], N. Ali Azzam[1], N. Reddy.P[1], M. Arafah[1], M. Rouabhia[3], M. Al-Anazi[1];*
[1]King Saud University, Riyadh, Saudi Arabia, [2]Laval University, Quebec, QC, Canada, [3]Laval University, quebec, QC, Canada.

Cancer is a multi-factorial disorder with genetic and environmental components. Furthermore, evidence for the role of the natural immune system in the protection from tumor development was supported by studies involving immune-compromised patients. This control anti-tumor immune response may involve Toll-like receptors (TLRs). The TLRs are known as the principal innate immunity receptor in humans and as key components of the pathogen recognition process that mediates inflammatory responses gene. For this reason, TLRs are currently at the centre of both basic research and drug development. The aim of this study is to investigate the association of different TLRs (TLR2, TLR4, and TLR6), pro-inflammatory cytokines (IL-6, IL-1 and TNF) and Human Beta Defencins (HBD-1,HBD-2,HBD-3 and HBD-4) with colon cancer . To reach our goal we used quantitative real time PCR and immuno-histochemistry procedures to investigate the expression of these genes in normal (n = 40) and colon cancer (n = 40) Saudian patients. Polymorphism and mutation by exon sequencing in the TLRs and HBDs genes were also analyzed. Our results show that TLRs and HBDs levels decrease in colon tumor compared to normal tissues but IL-6, IL-1 and TNF alpha expression increase in tumors tissues. Down expression of the TLRs and HBDs in colon tissues is correlated to multiple mutations in the specific exons of each TLR and HBDs. Since these TLRs and HBDs are playing active role in the innate immunity, their dysregulation/gene mutation may hamper colon cell function shifting to overgrowth and cancer initiation/development

P1.11.086
Investigating the expression of Toll-like receptor-2,4 and 6 in normal and ovarian cancer tissue

*Y. Al-Anazi1[1], M. Al-Anazi[1], M. Al-Mutairi[1], M. Adar[1], M. Arafah[1], A. Warsy[1], S. Al-Daihan[1], M. Rouabhia[2], **A. Semlali**[1];*
[1]King Saud University, Riyadh, Saudi Arabia, [2]Laval University, Quebec, QC, Canada.

Ovarian cancer is estimated to be as one of the top ten cancers in Saudi Arabia. In the year 2007 the ovarian cancer accounted for 3.1% of all newly diagnosed cases among Saudi females (4,773). Genetic predisposition to ovarian carcinoma is one of the major risk factors especially in young patients. Gene mutation that may lead to ovarian cancer involves important genes including those of innate immunity causing dysregulation of defense system. Such genetic dysregulation may involve on the Toll-like recepror (TLR) genes, specifically (TLR2, TLR4 & TLR6), because these are highly expressed by one key cell involved in ovarian cancer: epithelial cell. The aim of this study is to investigate the association of different TLRs (TLR2, TLR4, and TLR6) with ovarian cancer by studying the level of gene expression of TLRs. To reach our goal we used quantitative real time PCR and immuno-histochemistry procedures to investigate the expression of TLRs in normal (n = 10) and ovarian cancer (n = 10) Saudian females. Polymorphism and mutation by exon sequencing in the TLRs genes were also analyzed. Our results show that TLR2, TLR4 and TLR6 levels decrease in ovarian tumor compared to normal tissues. Down expression of the TLR2, TLR4 and TLR6 in ovarian tissues is correlated to multiple mutations in the specific exons of each TLR. Since these TLRs are playing active role in the innate immunity, their dysregulation/gene mutation may hamper ovarian epithelial cell function shifting to overgrowth and cancer initiation/development.

Toll-like receptors (TLRs) are a group of pattern-recognition receptor that plays an important role in innate immune response against bacterial and viral infections. Among them, intracellular TLRs are localized in endolysosomal compartment and recognize foreign nucleic acids from a variety of pathogens. Recent studies have shown that TLR9 proteolytically processed in the ectodomain by multiple lysosomal cysteine proteases, such as cathepsins and asparagine endopeptidase (AEP), and this processing is required for receptor activation. Similarly TLR3 is also processed in endolysosomal compartment. However, the main proteases involved in TLR3 proteolytic processing are not fully understood. To investigate which proteases are involved in proteolytic cleavage of TLR3, we examined the expression of cathepsins, AEP and TLR3 in THP-1 cells and PMA-differentiated macrophages by western blot using anti-cathepsins, anti-AEP as well as anti-TLR3 antibodies. In addition, the effect of inhibitors of cathepsins and AEP on cleavage of TLR3 was investigated. The expression of AEP and cleaved TLR3 C-term fragment was significantly increased in macrophages compared to THP-1 cells, but the expression level of cathepsins was decreased in macrophages. Intriguingly, the molecular size of cleaved TLR3 C-term fragment in macrophages was slightly smaller than that in THP-1 cells. Furthermore, cleavage of TLR3 was inhibited when both inhibitors were treated. Therefore our results suggest that lysosomal cysteine proteases, such as cathepsins and AEP, are required for proteolytic processing of TLR3 in THP-1 cells and macrophages.

TLR7 signalling in macrophages activates IRF3 and is dependent on the adaptor TRAM

***E. Shevlin**, S. M. Miggin;*
NUI Maynooth, Kildare, Ireland.

Toll-like Receptors (TLRs) and their related signalling pathways are crucially important in the initiation of an immune response against many pathogens and are thus the focus of intense study to fully elucidate their regulation. TLR7 is an endosomal TLR that has evolved to sense viral single-stranded RNA (ssRNA). It therefore plays a vital role in the response to ssRNA viruses such as human rhinovirus and influenza against which, there are currently no treatments or vaccines with long term efficacy available. A more complete understanding of TLR7's signalling axis would therefore be advantageous in the designing of therapeutic agents targeting this important pathway. Previous studies have shown that the TIR-domain containing adaptor TRAM plays a role in TLR4 signalling by recruiting TRIF to TLR4 at the endosomal membrane to initiate IRF3 dependent type-1 interferon production. As TRAM, TLR4 and TLR7 can all localise to endosomal compartments, we investigated whether TRAM plays a role in transducing TLR7 dependent signalling also. Results from murine macrophages indicate that although TRAM plays no role in TLR7 mediated TNFα secretion, TRAM is required for maximal TLR7 mediated RANTES (CCL5) production. This process was transcriptionally regulated and was IRF3 dependent but NF-κB independent. RNA interference of human TRAM in macrophages also showed a requirement for TRAM in human rhinovirus induced RANTES, IFNβ and CXCL10 production. TRAM is therefore required for maximal TLR7 mediated, IRF3 dependent cytokine production in both murine and human macrophages.

P1.11.089
Inverse Correlation between Histamine Receptor Expression and Toll-like Receptor Activation in Peripheral Blood Mononuclear Cells from Inflammatory Bowel Disease Patients.

***S. Smolinska**[1], P. Konieczna[2], T. Lukienczuk[1], R. Olewinski[1], G. Nowak[3], M. Jutel[1], L. O'Mahony[2];*
[1]Wroclaw Medical University, Wroclaw, Poland, [2]Swiss Institute of Allergy and Asthma Research, Davos, Switzerland, [3]Clinical Military Hospital, Wroclaw, Poland.

Histamine is a key mediator in both immediate type hypersensitivity reaction and chronic inflammatory responses. Toll-like receptors (TLR) play crucial role in innate immune response because of their ability to recognize PAMPs (pathogen associated molecular patterns). The aim of the project was to assess the effects of histamine on PBMCs, stimulated with TLR-ligands, from patients with inflammatory bowel disease (IBD). Fourteen patients diagnosed with IBD (7 with Crohn's disease and 7 with ulcerative colitis) and 6 healthy volunteers were included in the study. After reverse transcription, expression of genes which encode Toll-like receptors and histamine receptors were examined using REAL-TIME PCR. PBMCs were stimulated with various TLR ligands in the presence or absence of histamine. Cytokine levels were measured in supernatants after 24 hours (IL-12, TNF-alpha, IP-10). A significant reduction in the expression of genes encoding the Toll-like receptors (TLR-1, TLR-2, TLR-4, TLR-6, TLR-9) in UC and CD patients were found in comparison to healthy volunteers. The expression of histamine receptors (H1R, H2R, H4R) were significantly lover (especially in CD group) than in the control group. In PBMCs stimulated with TLR ligands, the level of proinflammatory cytokines was higher for patients with CD and UC in comparison to healthy volunteers and also secretion of cytokines was higher in patients with CD than in patients with UC. After addition of histamine, the level of proinflammatory cytokines decreased in each group. In conclusion, patients with IBD display dysregulated expression of histamine receptors associated with altered TLR responses to microbial ligands.

P1.11.090
Plasmacytoid dendritic cells play a key role in tumor progression in LPS-stimulated lung tumor-bearing mice

***R. Sorrentino**;*
University of Salerno, Fisciano, Italy.

The anti-tumor activity of LPS was first described by Dr. William Coley. However its role in lung cancer remains unclear. The aim of our study was to elucidate the dose-dependent effects of LPS (0.1-10μg/mouse) in a mouse model of B16-F10-induced metastatic lung cancer. Lung tumor growth increased at 3 and 7 days after the administration of low dose of LPS (0.1μg/mouse) compared to control mice. This was associated with an influx of plasmacytoid dendritic cells (pDCs), regulatory T-cells (Tregs), myeloid-derived suppressor cells (MDSC) and CD8+ Tregs. In contrast, high dose LPS (10μg/mouse) reduced lung tumor burden and was associated with a greater influx of pDCs, and a stronger Th1- and Th-17 polarization. Depletion of pDCs during low dose LPS administration resulted in a decreased lung tumor burden. Depletion of pDCs during high dose of LPS treatment resulted in an increased tumor burden. The dichotomy in LPS effects was due to the phenotype of pDCs, which were immuno-suppressive after the low dose of LPS, and Th1- and Tc-polarizing cells after the high dose LPS. Adoptive transfer of T cells into nude mice demonstrated that CD8+ T cells were responsible for pDC recruitment following low dose LPS administration, whereas CD4+ T cells were required for pDC influx after the high dose of LPS. In conclusion, our data suggest differential effects of low dose versus high dose LPS on pDC phenotype and tumor progression or regression in the lungs of mice.

P1.11.091
Pam3CSK4, a TLR2 agonist, induces in vitro osteoclastogenesis RANKL-independently and resorbs calvarial and alveolar bone in vivo

***K. Suzuki**[1], T. Arimoto[2], T. Morohashi[1], N. Sakai[1], A. Karakawa[1], H. Shinoda[3], S. Yamada[1];*
[1]Department of Pharmacology, School of Dentistry, Showa University, Tokyo, Japan, [2]Department of Oral Microbiology, School of Dentistry, Showa University, Tokyo, Japan, [3]Department of Physiology, Tohoku University Graduate School of Dentistry, Sendai, Japan.

Oral bacteria are a common cause of periodontitis, in which irreversible breakdown of alveolar bone may ultimately lead to tooth loss. It is well established that bacteria interact with host cells by binding to corresponding Toll-like receptors (TLRs). Among these, LPS, a component of gram-negative bacteria and a ligand for TLR4, is the most clearly defined molecule as a potent inducer of osteoclastogenesis and bone resorption. On the other hand, the fact that TLR2, in addition to TLR4, is prominently expressed in both precursors and differentiated osteoclasts, raises the possibility that components of gram-positive bacteria are involved in periodontitis pathogenesis. To clarify the functional role of TLR2 agonist in osteoclastogenesis, we stimulated osteoclast precursors with synthetic tri-acylated lipopeptide, Pam3CSK4. Furthermore, we examined whether Pam3CSK4 and Streptococcus mutans (S. mutans) 109c, a gram-positive oral bacterium, caused bone resorption in vivo. The results showed that; i) Pam3CSK4 induced osteoclastogenesis in both RAW264.7 cells and mouse bone marrow precursor cells, without adding RANKL exogenously; whereas, LPS (Re mutant), a specific ligand for TLR4, did not, ii) Quantitative RT-PCR analysis showed that Pam3CSK4 up-regulated mature osteoclast markers, but not RANK or RANKL, iii) Both Pam3CSK4 and S. mutans 109c injected into murine calvarial periosteum and rat palatal bone were able to cause bone resorption within 7 and 9 days, respectively, in vivo. Together these results provide important findings that components of gram-positive bacteria, as well as those of gram-negative bacteria including LPS, may be a periodontal pathogen which causes alveolar bone destruction.

P1.11.092
TLR3 recognizes single-stranded RNA with incomplete stem structures

M. Tatematsu[1], *F. Nishikawa*[2], *T. Seya*[1], *M. Matsumoto*[1];
[1]*Hokkaido university, Sapporo, Japan,* [2]*National Institute of Advanced Industrial Science and Technology, Tsukuba, Japan.*

Toll-like receptor (TLR) 3 recognizes dsRNA in the endosomes and induces type I interferons and proinflammatory cytokines via the adaptor protein, TICAM-1/TRIF. TLR3 serves as a sensor for viral infection and sterile tissue necrosis, but little is known about the essential structural elements of virus- or host-derived RNAs that activate TLR3 in infection/inflammatory states. Here we demonstrate that poliovirus (PV)-derived ssRNA segments bearing dsRNA regions with internal/bulge loops are potent TLR3 agonists. Functional ssRNAs were resistant to degradation and activated mouse/human TLR3, leading to the production of type I interferons and proinflammatory cytokines. Like polyinosinic:polycytidylic acid, PV-ssRNA was internalized into cells via raftlin-mediated endocytosis and colocalized with TLR3. Interaction of PV-ssRNA with the N- and C-terminal dsRNA binding sites in the TLR3 ectodomain was required for TLR3 activation, which was inhibited by RNase III treatment. RNA uptake and the TLR3 RNA-sensing system require an appropriate topology of multiple RNA duplexes for its specific recognition and signaling. Hence, TLR3 is a sensor of extracellular viral/host RNA with stable stem structures derived from infection or inflammation-damaged cells. The expansive recognition ability of TLR3 identified here will support a broad range of physiological functions of TLR3 recently reported, such that TLR3 signaling is involved in nuclear reprogramming and intrinsic retrovirus reactivation.

Studies on the full-length human NOD-like receptor family CARD domain containing 5 (NLRC5) protein

J. A. Mótyán[1], *A. Varga*[2], *D. Varga*[2], *K. Matúz*[1], *S. Benkő*[2], ***J. Tőzsér***[1];
[1]*Department of Biochemistry and Molecular Biology, Faculty of Medicine, University of Debrecen, Debrecen, Hungary,* [2]*Department of Physiology, Faculty of Medicine, University of Debrecen, Debrecen, Hungary.*

The NOD-like receptor family CARD domain containing 5 (NLRC5) is the largest member of the NLR protein family containing an unusually high number of leucine-rich repeats (LRRs) and an untypical CARD (caspase activation and recruitment domain) effector domain. NLRC5 is an intensively studied receptor with various functions, including the capability to transactivate MHC class I and to regulate various signal transduction pathways. As a consequence of the lack of crystal structures of full-length NLRs including NLRC5, the low number of template structures for homologous modeling and the unique domain architecture of NLRC5, only few structural data are available for NLRC5.
We aimed to analyze the sequences of NLRC5 and some NLRC5 related proteins and to build a homologous model for the full-length human NLRC5. Sequence alignments resulted in the recognition of consensus patterns within the studied LRR sequences and two typical types of consensus LRR sequences were identified in the RI and NLRC5 proteins. Investigation of LRR sequences helped to identify LRRs in NLRC5 and to predict their number and position within the protein. We have constructed a homologous model for both the monomeric and a homo-heptameric full-length human NLRC5 protein having open conformations for the monomers. To determine the molecular weight of NLRC5, we expressed flag-tagged NLRC5 in cell cultures and gel-filtration of cell lysates followed by immune-detection was utilized to determine the physiological molecular size of the protein in various circumstances and to correlate the findings with the models.
This work was supported by TÁMOP 4.2.2.A-11/1/KONV-2012-0023 "VÉD-ELEM" grant.

Activation of innate immunity through the CARD9 pathway is involved in severe influenza pneumonia

T. Uematsu[1,2], *E. Iizasa*[2], *N. Kobayashi*[1], *H. Yoshida*[2], *H. Hara*[2];
[1]*Biomedical Laboratory, Department of Biomedical research, Kitasato University Medical Center, Kitamoto City, Saitama, Japan,* [2]*Division of Molecular and Cellular Immunoscience, Department of Biomolecular Sciences, Faculty of Medicine, Saga University, Saga City, Saga, Japan.*

Background: Influenza virus (IFV) infection is a frequent cause of severe pneumonia and encephalopathy, especially in infants and the elderly. It is supposed that excessive activation of innate immune responses to IFV infection is responsible for such severe pathologies. In this study, we focused on the function of the adaptor molecule CARD9, which is essential for NF-kB signaling pathway activation through RIG-I or ITAM-coupled receptors, and analyzed the role for innate immune activation through the CARD9 pathway in defense and pathogenesis in IFV infection.
Methods: C57BL6(WT) mice and *Card9*$^{-/-}$ mice were infected intratracheally with IFV (strain A/PR/8/34), and were analyzed for daily survival, and production of inflammatory cytokines/chemokines, viral titers and histology in lung tissues. IFV was brought into contact with various macrophages(MFs) and dendritic cells(DCs) derived from WT mice or *Card9*$^{-/-}$ mice *in vitro*, and production of inflammatory cytokines was measured by ELISA.
Results: *Card9*$^{-/-}$ mice showed improved survival rate, and decrease in the production of inflammatory cytokines in BAL fluid and the inflammatory cell infiltration in lungs was observed, but viral titers in the lungs did not change compared with WT mice. Inflammatory cytokine production by MFs stimulated with IFV remained unchanged, but that by conventional DCs or plasmacytoid DCs was decreased in *Card9*$^{-/-}$ mice.
Conclusions: Activation of innate immunity through the CARD9 pathway in DCs is involved in the excessive inflammation in influenza virus-infected lungs. Thus, inhibition of the CARD9 pathway would be a promising therapeutic target for treatment of severe influenza pneumonia.

P1.11.095
TLR3 as an Exacerbating Factor for Radiation-Induced Gastrointestinal Syndrome

S. Uematsu[1], *N. Takemura*[1], *S. Akira*[2];
[1]*Institute for Medical Science, The University of Tokyo, Minato-ku, Tokyo, Japan,* [2]*Lab of Host Defense, Frontier Research Center, Osaka University, 3-1 Yamada-oka, Suita, Osaka, Japan.*

High-dose ionizing radiation induces a fatal disorder of the digestive tract called gastrointestinal syndrome. We show that TLR3 is critically involved in gastrointestinal syndrome. Tlr3-/- mice showed significantly milder symptoms of gastrointestinal syndrome, including mortality, diarrhea and weight loss, than did Tlr3+/+ mice. Tlr3-/- mice showed markedly reduced radiation-induced crypt cell death and avoided villous destruction owing to re-epithelization from surviving crypts. The TLR3 signaling components TRIF and RIP1, but not IRF3 and type I interferons, were involved in radiation-induced crypt cell death. Germ-free mice showed no changes in radiation-induced crypt cell death, indicating that endogenous molecules were responsible for TLR3 activation. We detected leakage of self-RNAs from dying crypt cells following irradiation. Furthermore, large (>200 nucleotides) RNAs derived from irradiated small intestine induced crypt cell death via TLR3. Thus, TLR3 exacerbates gastrointestinal syndrome via induction of extensive crypt cell death through the recognition of self-RNAs released from dying cells.

P1.11.096
AGE-BSA induces self- and cross-tolerance in the monocytic Mono Mac 6 cell line

***F. Uhle**, I. Magel, M. A. Weigand;*
Department of Anesthesiology and Intensive Care Medicine, Justus-Liebig-University, Giessen, Germany.

The induction of tolerance is an important negative feedback mechanism to control activated innate immune cells and thereby prevent excessive inflammation. The phenomenon of self- and cross-tolerance induction has been described so far for a variety of ligands and their corresponding pattern recocgnition receptors. We were interested to assess the capability of different ligands of the Receptor for Advanced Glycation Endproducts (RAGE) to induce tolerance. An initial screening of the monocytic cell line MonoMac-6 using a variety of immune receptor agonists revealed a tolerance induction, beside others, by the RAGE ligand advanced glycation endproduct-modified bovine serum albumin (AGE-BSA), measurable by a diminished TNF-alpha secretion in response to a second stimulation. The effect was specific for AGE-modified BSA, as unmodified BSA did not mediate the effect. In contrast to AGE-BSA, the RAGE ligand HMGB-1, neither in its chemokine nor in its cytokine redox conformation, lead to an induction of tolerance. The tolerance induction was not accompanied by a decrease, but rather with a slight increase of receptor expression as assessed by quantitative RT-PCR. To exclude the possibility, that induction of apoptosis or modulation of the cell cycle might be the reason for the altered response, we assessed both using flow cytometry and found no agonist-induced changes. Interestingly, while LPS was capable to induce tolerance in minute amounts (0,1ng/ml), higher levels of AGE-BSA (≥10µg/ml) were necessary. In conclusion, we have evidence for an AGE-BSA-mediated tolerance induction in monocytic cells, but further work is necessary to decipher the underlying pathways involved.

P1.11.097
Role of the *TLR7, 8 and 9* polymorphisms in the susceptibility to HIV-1 infection in southern Brazilian patients

***J. Valverde**[1], B. dos Santos[1], V. Mattevi[2], R. Lazzaretti[3], E. Sprinz[3], R. Kuhmmer[3], J. Chies[1];*
[1]Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil, [2]Universidade Federal de Ciências da Saúde de Porto Alegre, Porto Alegre, Brazil, [3]Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil.

This study investigates the role of the*TLR7/8/9* genes in susceptibility to HIV-1 infection through the analyses of *TLR7* rs179008, *TLR8* rs3764880, *TLR9* rs5743836 and rs352140 polymorphisms. The frequency of the variant alleles was analyzed in 366 HIV-1 infected patients and 415 healthy individuals from the southernmost state of Brazil. The promoter variant from *TLR9* was genotyped using a BI-PASA technique and all others were analyzed by PCR-RFLP. Chi-square test was used to compare allelic and genotypic frequencies between patients and controls. All analyses were conducted controlling by gender and ethnic origin. Among the Euro-derived individuals, statistically significant differences were observed for genotypic and allelic frequencies of the *TLR9* promoter variant rs5743836 between patients and controls (P=0.028 and P=0.011, respectively). The CC genotype was observed at higher frequency in patients when compared to controls (P= 0.0012, OR 1.86 95% CI: 1.28-2.71) and conferred susceptibility. However, among the Afro-derived individuals, the TC genotype was less represented in patients when compared with controls (P =0.014, OR: 0.51 95% CI 0.30-0.87) and conferred protection. No statistical significant differences were observed for all other polymorphisms or for haplotypic analyses. This study reveals a fundamental role of the *TLR9* rs5743836 polymorphism against HIV-1 infection, the CC genotype conferring susceptibility among Euro-derived individuals while TC genotype conferring protection among Afro-derived individuals. Also, we observed the importance of the genetic background in analyses of susceptibility to infectious agents, pointing to the need of studies in different human admixed populations.

P1.11.098
TLR9 enhances bacterial clearance and limits lung consolidation in murine MRSA pneumonia

***A. J. van der Meer**[1], A. Achouiti[1], S. S. Zeerleder[2,3], A. F. de Vos[1], T. van der Poll[1];*
[1]Center of Experimental and Molecular Medicine, Amsterdam, Netherlands, [2]Department of Immunopathology, Sanquin Research, Amsterdam, Netherlands, [3]Landsteiner Laboratory, Academic Medical Center, Amsterdam, Netherlands.

BACKGROUND:
Methicillin-resistant Staphylococcus aureus (MRSA) is an emerging pathogen in pneumonia, associated with severe lung damage. Tissue injury causes release of Damage Associated Molecular Patterns (DAMPs), which may perpetuate inflammation. Host DNA has been implicated as a DAMP that activates inflammation through Toll-like receptor (TLR)9.
OBJECTIVE:
To evaluate the role of TLR9 in MRSA pneumonia.
METHODS:
Wild-type (WT) and TLR9 knockout (KO) mice were infected intranasally with MRSA (5E7CFU) and euthanized at 6,24,48 or 72 hours for analyses.
RESULTS:
MRSA pneumonia was associated with profound release of cell-free DNA in the airways, as reflected by a 4-log increase in nucleosome levels in bronchoalveolar lavage fluid (BALF) from 24 hours after infection onward. In BALF, TLR9KO mice showed reduced TNFα and IL-6 levels (P<0.005 and P<0.05 resp.vs WT mice) at 6 hours and reduced bacterial clearance at 6 and 24 hours post infection (both P<0.005 vs WT mice). Furthermore, TLR9KO mice had a greater influx of neutrophils in BALF at 24 and 48 hours (P<0.05 and P<0.005 resp. vs WT mice). Finally, lung consolidation was significantly increased after 24 and 48 hours in TLR9KO mice.
CONCLUSION:
TLR9 has pro-inflammatory effects during MRSA pneumonia in mice associated with enhanced bacterial clearance and limitation of lung consolidation.

P1.11.099
A TLR9/TRIF pathway induces tolerance via TGF-β and tryptophan catabolism in plasmacytoid dendritic cells

*C. Volpi[1], **G. Castellano Gonzalez**[1,2], F. Fallarino[1], U. Grohmann[1], P. Puccetti[1];*
[1]Department of Experimental Medicine and Biochemical Sciences, University of Perugia, Perugia, Italy, [2]Department of Pharmacology, School of Medical Sciences, University of New South Wales, Sydney, Australia.

Cytosine-phosphate-guanosine (CpG)-rich oligodeoxynucleotides (ODNs) stimulate Toll-like receptor 9 (TLR9)-dependent signaling and activate the innate and acquired responses of the immune system. The immunostimulatory effects of CpG-ODN are being evaluated in clinical trials as a novel therapeutic approach for treatment of human diseases. Here we show that pre-treatment in vitro of plasmacytoid dendritic cells with a low-dose (1 µg/ml) of a CpG-ODN phosphorothioate (CpG 1826) induced, as expected, immunostimulatory effects in vivo. However, pre-treatment of the same cells with a higher concentration of the ODN (10 µg/ml) induced tolerogenic effects, which allowed us to unveil a previously undescribed role for the adaptor TRIF and TRAF6 proteins in TLR9 signaling. The low-dose CpG stimulation activated the TLR9/MyD88-dependent NF-κB pathway and the production of the pro-inflammatory cytokine IL-23, whereas the high-dose CpG stimulation triggered the TLR9/TRIF pathway, leading to activation of the noncanonical NF-κB pathway, production of the anti-inflammatory cytokine TGF-β, and subsequent induction of the immunosuppressive pathway of tryptophan catabolism. Thus, opposite in vivo outcomes of TLR9 stimulation by a CpG-ODN phosphorothioate (CpG 1826) can occur as a function of dosage. Our findings may be relevant not only for an increased understanding of the complexity of TLR signaling and for an optimal exploitation of CpG-ODNs as immune adjuvants, but also for the development of nonconventional forms of CpG-based immunotherapy in human allergy and autoimmunity.

P1.11.100

Mannan-binding lectin inhibits *Candida albicans*-induced cellular responses of human THP-1 cells through toll-like receptor 2 and toll-like receptor 4

M. Wang;
Xinxiang Medical University, Xinxiang, China.

Background: *Candida albicans* (*C. albicans*), the most common human fungal pathogen, can cause fatal systemic infections under certain circumstances. Mannan-binding lectin (MBL) ,a member of the collectin family in the C-type lectin superfamily, is an important serum component associated with innate immunity. Toll-like receptors (TLRs) are expressed extensively, and have been shown to be involved in *C. albicans*-induced cellular responses. We first examined whether MBL modulated heat-killed (HK) *C. albicans*-induced cellular responses in the monocytoid cell line, THP-1 cells. We then investigated the possible mechanisms of its inhibitory effect.
Results: Enzyme-linked immunosorbent assay (ELISA) and reverse transcriptasepolymerase chain reaction (RT-PCR) analysis showed that MBL at higher concentrations (10-20 μg/ml) significantly attenuated *C. albicans*-induced proinflammatory cytokine (e.g., TNF-α) and chemokine (e.g., IL-8) production from THP-1 cells at both protein and mRNA levels. Electrophoretic mobility shift assay (EMSA) and Western blot (WB) analysis showed that MBL could inhibit *C. albicans*-induced NF-κB DNA binding and its translocation in THP-1 cells. Furthermore, MBL could directly bind to *C. albicans* in a Ca^{2+}-dependent manner and decrease TLR2 and TLR4 expressions in *C. albicans*-induced THP-1 cells.
Conclusion: All these data suggest that MBL could affect cytokine expression by modifying *C. albicans*-/TLR-signaling pathways. This study supports an important role for MBL on the regulation of *C. albicans*-induced cellular responses.

P1.11.101
Rab7 GTPase negatively regulate inflammatory cytokine and type I interferon expression in LPS-stimulated macrophages via GTP-binding dependent manner

Y. Wang[1], *J. Xie*[2], *X. Yun*[1], *W. Zhang*[1], *S. Dong*[1], *Y. Zheng*[3], *Y. Wan*[1], *J. Liu*[1], *P. Gong*[1], *S. Zhao*[1], *H. Kang*[4];
[1]*Inner Mongolia Agricultural University, Hohhot, China,* [2]*Inner Mongolia People's Hospital, Hohhot, China,* [3]*Shanghai University of Traditional Chinese Medicine, Shanghai, China,* [4]*The First Hospital Affiliated to Inner Mongolia Medical University, Hohhot, China.*

Toll-like receptors (TLRs) play a critical role in innate immunity against invading pathogens. Rab (Ras related in brain) proteins are small guanosine triphosphatases (GTPases) that are involved in signal transduction by regulating the membrane trafficking of several receptors. The relationship between Rabs and TLR signaling remains largely unknown. In this study, we found that Rab7 can inhibit lipopolysaccharide (LPS)-induced expression of interleukin (IL)-6, IL-1β, interferon (IFN)-β and interferon-inducible protein 10 (IP-10), and suppress LPS-induced activation of mitogen-activated protein kinases (MAPKs), nuclear factor κB (NF-κB), and IFN regulatory factor 3 (IRF3) signaling pathways in RAW264.7 macrophages. However, GTP-binding deficient mutant of Rab7 (Rab7T22N) failed to inhibit TLR4-triggered expression of pro-inflammatory cytokines and IFN-β and activation of MAPKs, NF-κB and IRF3. Moreover, knockdown of endogenous Rab7 expression increased LPS-induced proinflammatory cytokines, IFN-β as well as TLR4 expression in RAW264.7 macrophages. Therefore, we demonstrate that Rab7 can negatively regulate TLR4-triggered pro-inflammatory cytokine and IFN-β expression in RAW264.7 cells in a GTP-binding-dependent manner. Our results indicate that Rab7 negatively regulate LPS/TLR4 signaling by regulating the expression of TLR4.

P1.11.102
Both Toll-like receptor-2 and -4 contribute to signalling of Burkholderia pseudomallei's lipopolysaccharide

T. Weehuizen[1], *T. van der Vaart*[2], *L. Kager*[1], *S. Ngugi*[3], *J. Prior*[3], *T. van der Poll*[1,4], ***W. Wiersinga***[1,4];
[1]*Center for Experimental and Molecular Medicine, Academic Medical Center, Amsterdam, Netherlands,* [2]*University of Amsterdam, Amsterdam, Netherlands,* [3]*Defence Science and Technology Laboratory, Porton Down, Salisbury, United Kingdom,* [4]*Division of Infectious Diseases, Academic Medical Center, Amsterdam, Netherlands.*

Introduction The Gram-negative bacterium *B.pseudomallei* causes melioidosis and is a recognized biothreat agent. While enterobacterial lipopolysaccharide (LPS) signals via MD2-Toll-like receptor (TLR)-4, we have previously shown that TLR2 impairs host defence during pulmonary *B.pseudomallei* infection while TLR4 only has a limited impact. We now investigate the role of TLRs in *B.pseudomallei*-LPS induced inflammation.
Methods Purity of isolated *B.pseudomalle*i-LPS was determined with Silver-staining, Coomassie-blue and polymyxin-B. HEK-cells transfected with TLR2/CD14 or TLR4/CD14/MD2, human whole blood treated with anti-TLR2 or anti-TLR4 and both whole blood and peritoneal macrophages of wild-type (WT), TLR2 knock-out (KO), TLR4 KO and TLR2/4 double KO's were stimulated with purified *B.pseudomallei*-LPS. Additionally, WT and selected TLR KO mice were inoculated intranasally with *B.pseudomallei*-LPS.
Results Purified LPS of *B.pseudomallei* activated only HEK-TLR2 during short stimulation and both HEK-TLR2 and HEK-TLR4 cells during overnight stimulation. In human whole blood, an additive effect of TLR2 on TLR4 mediated signalling induced by *B.pseudomallei*-LPS was observed. Murine peritoneal macrophages recognized *B.pseudomallei*-LPS solely through TLR4. Both TLR4 KO and TLR2x4 double KO's, but not TLR2 KO's, displayed diminished cytokine responses and neutrophilic influx upon inoculation with *B.pseudomallei*-LPS when compared to WT mice.
Conclusion While TLR4 is the main TLR for *in vivo* signalling of *B.pseudomallei*-LPS, TLR2 recognition seems to play an additional role. Altogether these results highlight important differences between the specificity of human or murine models in terms of TLR4-MD2 and TLR2 recognition that may have important consequences for *B.pseudomallei*-LPS sensing and subsequent susceptibility to melioidosis.

P1.11.103
Toll-like receptor-5 contributes to protective immunity in Gram-negative sepsis caused by Burkholderia pseudomallei, independent of flagella presence

T. Weehuizen[1], *M. van Lieshout*[2], *J. Roelofs*[3], *T. Schuijt*[2], *T. van der Poll*[2,4], ***W. Wiersinga***[2,5];
[1]*Academic Medical Center, Amsterdam, Netherlands,* [2]*Center for Experimental and Molecular Medicine, Academic Medical Center, Amsterdam, Netherlands,* [3]*Department of Pathology, Academic Medical Center, Amsterdam, Netherlands,* [4]*Division of Infectious Diseases, Academic Medical Center, Amsterdam, Netherlands,* [5]*Division of Infectious Diseases, Academic Medical Center, Amsterdam, Austria.*

Introduction: *Burkholderia pseudomallei* is the causative agent of melioidosis, an important cause of sepsis in south-east Asia and a recognized biothreat agent. Toll-like receptors (TLRs) recognize pathogen-associated molecular patterns and initiate the immune response. TLR5, which is highly upregulated in patients with melioidosis, recognizes bacterial flagellin. We here studied the role of TLR5 and its interaction with flagellin in experimental melioidosis.
Methods: Human embryonic kidney (HEK)-TLR5 cells, murine alveolar macrophage (MH-S), murine lung epithelial cells (MLE-15) cells and bone-marrow-derived-macrophages (BMDM) derived from wild-type (WT) C57BL/6 and TLR5 deficient ($TLR5^{-/-}$) mice were incubated with wild-type *B. pseudomallei 1026*b, flagellin-deficient *B. pseudomallei MM36* or purified *Burkholderia* flagellin. Additionally, WT and $TLR5^{-/-}$ mice were intranasally challenged with *B.pseudomallei 1026b* or *MM36*. Mice were sacrificed at different time-points post-infection to assess bacterial loads, inflammation and pathology.

Results: *B.pseudomallei MM36* was less potent than *1026b* in eliciting an inflammatory response in different cells *in vitro*. *B.pseudomallei* flagellin was confirmed to signal through TLR5. $TLR5^{-/-}$ mice challenged with *B.pseudomallei 1026b* were more susceptible to infection when compared to WT mice as demonstrated by higher systemic bacterial loads and increased organ injury. Strikingly, this effect was not dependent on the presence of flagella: $TLR5^{-/-}$ mice showed a similarly impaired antibacterial defense after infection with either *B.pseudomallei 102b* or *MM36*.
Conclusion: The presence of TLR5 contributes to protective immunity during experimental melioidosis. Surprisingly, this effect seems to be unrelated to the presence of *B. pseudomallei* flagellin, suggesting a role for yet to be discovered endogenous TLR5 ligands.

P1.11.104
A comparison of Pattern Recognition Receptor requirement for human and horse strains of Streptococcus pneumoniae

***H. Williams**, G. Paterson, C. Bryant;*
University of Cambridge, Cambridge, United Kingdom.

Streptococcus pneumoniae is an important respiratory pathogen of humans and horses. Pneumolysin and autolysin are major virulence factors of *S. pneumoniae* and damage host tissue through direct effects and/or the ability to induce activation of pattern recognition receptors (PRRs) including Toll-like receptors (TLRs). In the horse functional pneumolysin and autolysin are absent due to a chromosome deletion, yet respiratory disease still occurs in these animals. How then do the horse strains of *S. pneumonia* cause disease?
The response of horse or human TLR4 to pneumolysin was characterised using an in vitro transient transfection model. Pneumolysin is an agonist at human, mouse and horse TLR4. Disruption of pneumolysin binding using TLR4 antagonists revealed that the pneumolysin interaction occurs at the same binding pocket as the TLR4 agonist lipopolysaccharide (LPS). Molecular techniques, including fluorescent single molecule imaging, will be used to further investigate the nature of the interaction. Pneumolysin interaction with the TLR4/LPS binding pocket suggests that it may activate TLR4 in a similar manner to LPS.
This study will be expanded to compare how horse, human and mutant pneumolysin- and autolysin strains interaction with PRRs using in vitro macrophage cell culture studies and mouse infection models.

P1.11.105
Molecular mechanisms regulating the synergism between IL-32γ and NOD ligands for the induction of adhesion molecules, cytokines and chemokines of eosinophils in allergic inflammation

***C. K. Wong**[1], J. Dong[1], C. W. K. Lam[2];*
[1]Department of Chemical Pathology, The Chinese University of Hong Kong, Shatin, NT, Hong Kong, [2]Macau Institute for Applied Research in Medicine and Health, Macau University of Science and Technology, Taipa, Macao.

Background: Key intracytosolic pattern recognition receptors in innate immune responses for bacterial infections are nucleotide binding oligomerization domain (NOD) like receptors (NLR). IL-32 is novel pro-inflammatory cytokine that are associated with viral and bacterial infections, and allergic asthma. We elucidated the synergistic effect of IL-32γ and NOD-mediated the activation of human eosinophils, the principal effector cells for allergic inflammation and the underlying mechanisms.
Methodology: Expression of adhesion molecules and chemokines was quantitated by flow cytometry and multiplex assay, respectively. Phosphorylation of signaling molecules and caspase-1 activity was analysed by Western blot.
Results: IL-32γ was more capable in activating eosinophils than its isotype variant IL-32α, and the internalization of IL-32γ is dispensable for this effect. IL-32γ together with NOD1 ligand iE-DAP or NOD2 ligand MDP exhibit significant up-regulation of cell surface expression of CD18 and intercellular adhesion molecule-1 on eosinophils, and the adherence of eosinophils on dermal fibroblasts/bronchial epithelial cells. Moreover, IL-32γ exhibit synergistic effect with iE-DAP and MDP on the induction of allergic inflammation-related IL-1β, chemokines CXCL8, CCL3 and CCL4, and IL-1β, IL-6, CXCL8, TNF-α, CCL3 and CCL4, respectively (all $p<0.05$). Synergism between IL-32γ and NOD depended on the activation of intracellular caspase 1, ERK, p38 MAPK and NF-κB in eosinophils.
Conclusion: The above study provides immunological mechanisms by which bacterial infection-mediated activation of NOD1,2 together with novel pro-inflammatory IL-32 in synergizing allergic inflammation via the activation of eosinophils. This work was supported by the Research Grant Committee General Research Fund, Hong Kong (Project ref. no. CUHK 476411)

P1.11.106
Up-regualtion of HuR was critical for TLR9 signaling induced repression of tumor suppressor miR-7 in human lung cancer cells

*Y. Li, Z. Liao, S. Zhu, Y. Hu, C. Chen, J. Luo, **L. Xu**;*
Department of Immunology, Zunyi Medical College, Zunyi, China.

Accumulating evidence showed that miRNAs, a major class of gene expression regulators, played critical roles in regulating the biological effects of TLR9 signaling pathway on various cells. And TLR9 signaling could alter biological character of lung cancer cells including promoting the proliferation and enhancing the metastatic potential of tumor cells. However, the underlying mechanism regulation on the expression of TLR9 signaling-associated miRNAs in lung cancer cells remains largely unknown. Our recent work showed that TLR9 signaling could enhance the progression of human lung cancer cells through repressing miR-7 expression. Here, we further reported that TLR9 signaling could induce the expression of human antigen R (HuR) in human lung cancer cells. Moreover, overexpression of HuR could reduce the expression of miR-7 in lung cancer cells. Notably, down-regulation of HuR using RNA interference restored miR-7 expression in TLR9 signaling treated lung cancer cells and impaired their enhanced growth and metastatic potential. Finally, TLR9 signaling enhanced HuR expression through Akt pathway. Our findings indicated that HuR could act as regulator in regulating TLR9 signaling associated biological effect in human lung cancer cells through a positive feedback loop, which might be helpful for the understanding of the potential role of HuR in tumor biology.
Key words: Toll like receptor-9, miR-7, Human antigen R, human lung cancer cell

P1.11.107
Choreography and molecular strategy of dendritic cell-mediated NK cell activation in lipopolysaccharide-mediated inflammatory conditions

***I. Zanoni**[1], R. Spreafico[1], C. Bodio[1], M. Di Gioia[1], C. Cigni[1], A. Broggi[1], T. Gorletta[1], M. P. Colombo[2], N. Garbi[3], F. Granucci[1];*
[1]University of Milano-Bicocca, Milan, Italy, [2]Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy, [3]Institutes of Molecular Medicine and Experimental Immunology IMMEI, Bonn, Italy.

Natural killer (NK) cells have anti-tumor, anti-viral and anti-bacterial functions, and efforts are being made to manipulate them in immunotherapeutic approaches. However, their activation mechanisms remain poorly defined, particularly in bacterial infections. Here we show that, upon E. coli or LPS exposure, dendritic cells (DCs) mediate NK cell activation directly in vitro and in vivo. This correlates with the establishment of prolonged DC-NK cell interactions in inflamed lymph nodes. Three DC-derived cytokines - IL-2, IL-18 and IFN-β - are necessary and sufficient to trigger IFN-γ release by NK cells, and IFN-β is also essential to boost NK cell cytotoxicity. IFN-β enhances NK cell activation by inducing IL-15 not only in DCs but, surprisingly, also in NK cells. Both NK cell-derived (cis-presented) and DC-derived IL-15 (trans-presented) contribute to NK cell activation.
Our results shed new light on the mechanisms underlying NK cell activation in vivo in response to E. coli and its major PAMP. A precise understanding of the biological program governing NK cell responses

might provide a framework to build next-generation immunotherapeutic strategies based on the manipulation of NK cell functions.

P1.11.108
Lithium attenuates IFN-β production and antiviral response via inhibition of TBK1/IKK-ε kinase activity

***W. Zhao**, L. Wang, L. Zhang, C. Gao;*
Department of Immunology,Shandong University School of Medicine, Jinan, China.

Lithium salt is widely used GSK3β inhibitor and effective drug for the treatment of psychiatric diseases. However, the effects of lithium in innate immune responses, especially in cellular antiviral responses are unknown. Here we show that lithium chloride (LiCl) attenuates LPS-, poly(I:C)-, and Sendai virus (SeV)-induced IFN-β production and IRF3 activation in macrophages in a GSK3β-independent manner. The ability of the lithium to inhibit IFN-β production was confirmed in vivo as mice treated with LiCl exhibited decreased levels of IFN-β upon SeV infection. In vitro kinase assay demonstrates that lithium suppresses TBK1/IKK-ε kinase activity. Consistently, lithium significantly enhanced the replication of vesicular stomatitis virus (VSV) in vitro and in vivo. Severe infiltration of monocytes and tissue damage were observed in the lungs of control mice, compared to lithium treated mice after virus infection. Our findings suggest lithium as an inhibitor of TBK1/IKK-ε and potential target for the intervention of diseases with uncontrolled IFN-β production. Furthermore, lithium attenuates host defense to virus infection and may cause severely adverse effects in clinical applications.

P1.11.109
Mutated class II transactivator activates the IL-33-upregulated Th2 differentiation via the Nod2-involved NLR signal pathway

*Z. Q. Yang[1], P. Gu[1], Z. Q. Li[1], Y. Zhou[2], L. M. Lu[2], **G. Y. Zhou**[1];*
[1]The Department of Immunology, Shanghai Jiaotong University School of Medicine, Shanghai, China, [2]Shanghai Institute of Immunology, Shanghai Jiaotong University School of Medicine, Shanghai, China.

Class II trans-activator (CIITA) is a member of the AD domain-containing NOD-like receptor (NLR) family and also functions as an initiator for the epigenetic control of MHC class II transcription. A negative dominant mutant of CIITA (mCIITA) being depleted its N-terminal shows activity of repressing class II expression by competition with its wild type counterpart. Little is known however about properties of CIITA as a NLR member. Here we show that a mCIITA-overexpressed myeloid cell line Ana-1 (Ana-1-mCIITA) was able not only to down-regulate the class II expression but also to converse immune response patterns from Th1 (IL-2^+IFN-γ^+STAT4^+) to Th2 (IL-4^+IL-5^+IL-10^+IL-13^+STAT6^+) when the Ana-1-mCIITA was collaborated with T cells, resulting in a strong suppression of the syngeneic T cell-mediated MLR. Mechanism analysis indicated that the mCIITA protein stimulated a NLR-related signaling pathway via binding of cytoplasmic Nod2 molecule, which was followed by activating RIP2, IKK-α/β and Caspase 1 for the mobilization of NF-κB and the activation of inflammasome. This ensured an enhanced expression of IL-33 gene, which promoted a skewed secretion of the Th2-related cytokines (IL-4^+IL-5^+IL-10^+IL-13^+IL-2^- IFN-γ^-). The Th2 activation was prevented by the deactivation of Nod2 gene with siRNA or by the blockage of the IL-33-related signaling using a mAb anti-IL-33 receptor. These results indicate that the Th1/Th2 balance could be regulated by the N-terminus-depleted CIITA molecule via the NLR-related signaling, a property valuable for disease controls, especially for inducing transplantation tolerance both via the repression of class II expression and the attenuation of the Th1-dominant response.

P1.11.110
Involvement of toll like receptor 2/3/4 and 9 polymorphisms in the occurrence of cervical cancer in Tunisian women

***S. Zidi**[1], H. Verdi[2], Y. Yilmaz-Yalcin[2], Y. Suer[2], E. Gazouani[3], A. Mezlini[4], F. Atac[2], B. Yacoubli-Loueslati[1];*
[1]Faculté des sciences, Manar I tunis, Tunisia, [2]Baskent university, Faculty of medicine, Laboratory of molecular genetics, Ankara, Turkey, Turkey, [3]Military Hospital of Tunis, Laboratory of Immunology, Tunis, Tunisia, Tunis, Tunisia, [4]Salah Azeiz Oncology Institute, Tunis, Tunisia, Tunis, Tunisia.

Cervical Cancer (CC) occupies the second rank among cancers in women in the developing countries.
It's well established that Human papillomavirus (HPV) is the major causative agent of CC. Most HPV infections are cleared, but a proportion of women are unable to clear this infection, resulting in cervical lesions. Although persistent HPV infection is necessary but it is insufficient for the development of CC. It directly infects cervical keratinocytes and interferes with Toll Like Receptor (TLR) signaling.
Recently, it was reported that stromal up regulation of TLRs may play a role in cervical disease progression. Among several factors affecting the gene expression; single nucleotide polymorphisms (SNPs) or microsatellite polymorphisms particularly those within the regulatory regions of genes often affect expression levels and can serve as disease modifier.
The aim of this study was to investigate whether TLR 2 (−196 to −174 del), TLR 3 (1377 C>T), TLR 4 (Asp299Gly) and TLR 9 (2848 G>A) polymorphisms might be associated with variation of CC risk in 122 Tunisian women with invasive CC and 260 women free from any chronic clinical problem and disease manifestation, as those polymorphisms have an essential role in host immune response. These polymorphisms were genotyped in subjects using PCR amplification and PCR restriction fragment length polymorphism. Results revealed that TLR3 C/C genotype (OR: 1.1453, CI: 0.691-3.054) and TLR 4 Asp/Asp (OR: 4.29, CI:1.781-10.364) are associated with higher risk of CC.

P1.12.01
The interaction of complement-activating lectins with Mycobacterium tuberculosis

***M. A. Bartlomiejczyk**, A. S. Swierzko, A. Brzostek, J. Dziadek, M. Cedzynski;*
Institute of Medical Biology, Polish Academy of Sciences, Lodz, Poland.

Mannan-binding lectin (MBL) and ficolins (M-, L-, H-ficolin) are pattern-recognition molecules forming complexes with MBL-associated serine proteases (MASP). They bind to the carbohydrate-rich surface structures of numerous microorganisms and may contribute to their clearance thanks to opsonic properties or complement lectin pathway (LP) activation. Numerous reports demonstrated MBL or ficolin deficiency to enhance the susceptibility to infections. MBL and ficolins were shown previously to interact with M. bovis BCG and/or M. avium. However, their role in tuberculosis remains unclear. High MBL serum level or its total deficiency have been suggested to be disadvantageous for the host.
Heat-killed or formalin-fixed Mycobacterium tuberculosis H37RV cells activate lectin pathway in human sera, as demonstrated in a C4-deposition assay. In adult, BCG-vaccinated healthy subjects as well as tuberculosis patients, LP activity accounted for approximately 60% of C4 total serum activation potency (resulted also from antibody-dependent complement classical pathway). In contrast, in cord serum samples, as expected, almost whole activity against MTB came from the lectin pathway. The recombinant MBL, M-ficolin, L-ficolin, and H-ficolin were shown to recognize H37RV cells. MBL, in contrast to ficolins was moreover reactive against BCG strain, M. kansasii and M. gordonae. No interaction of any of tested lectins with M. smegmatis was observed. Further investigation demonstrated that lipoarabinomannan from M. tuberculosis is one of the target structures for MBL but not for ficolins.
Acknowledgments: This work was supported by the European Union within European Regional Development Fund, through grant Innovative Economy (POIG. 01.01.02-10-107/09).

P1.12.02
Pseudo-mannosylated compounds inhibit DC-SIGN mediated HIV infection by competitive inhibition and by interfering with DC-SIGN signal

A. Berzi[1]*, N. Varga*[1]*, P. Antonazzo*[1]*, I. Cetin*[1]*, M. Biasin*[1]*, D. Trabattoni*[1]*, A. Bernardi*[1]*, M. Clerici*[1,2]*;*
[1]*University of Milan, Milan, Italy,* [2]*Don C. Gnocchi Foundation IRCSS, Milan, Italy.*

Background: DC-SIGN is involved in the initial stages of infection by HIV. DC-SIGN, by binding high mannose glycan on HIV gp120, mediates *trans* infection of CD4 T cells. HIV interaction with DC-SIGN promote immunosuppressive responses that interfere with TLRs signalling, so favouring the persistence of the virus. We synthesized pseudo-mannosylated compounds in the attempt to compete with binding of DC-SIGN to HIV gp120 and interfere with the immunosuppressive DC-SIGN signalling.
Methods: The ability of the compounds to block HIV-1 infection and their toxicity were assessed in cellular and human cervical explant models. Laboratory strain and primary isolates both R5 tropic and X4 tropic were tested. Gene expression profile after treatment of MDDCs with the compounds was evaluated.
Results: Two of the compounds abrogated almost completely the transmission of different HIV strains to CD4 T cells and the infection of cervical explants. This activity was associated with a significant increase in the production of the antiviral cytokine IFNβ and of β chemokines. The production of inflammatory cytokines (IL-6, IL-1 β, TNFα and IFNγ) was increased, whereas IL-10, CCR5 and CXCR4 expression was not modified. The toxicity of the compounds was neglectable.
Conclusion: Pseudo-manosylated compounds competitively inhibit HIV binding to DC-SIGN, blocking infection in *trans*. Furthermore, by interacting with DC-SIGN, the compounds induce immune activation and proinflammatory responses. The production of β chemokines CCL3, CCL4 and RANTES, that compete with the virus binding to CCR5 co-receptor, contributes to antiviral activity. These features make such compounds good candidates to develop new topical microbicides.

P1.12.03
Treatment with interferon beta-1a reduces alpha-2,3-sialylation of CD4+ helper T cells

J. Piel, K. Friebe, ***F. Bischof****;*
Center for Neurology and Hertie Institute for Clincal Brain Research, Tübingen, Germany.

The function of immune cells is at least in part determined by carbohydrate residues linked to proteins and lipids on the immune cell surface. We assessed whether treatment of patients with relapsing remitting multiple sclerosis (RRMS) with interferon-beta-1a alters surface glycosylation of immune cells.
Interferon beta-1a treatment lead to reduced alpha-2,3-sialylation of non-activated Helper T cells as determined by flow cytometry using cell-type specific antibodies and glycosylation-specific lectins. Alpha-2,3-sialylated residues were predominantly expressed by effector T cells, particularly by Th2 cells. 60% of Th2 cells, 17% of Th17 cells, 7% of Th1 cells and less than 5% of regulatory T cells displayed alpha-2,3-sialylated residues. Expression of alpha-2,3-sialylated residues was increased after T cell activation and T cells without alpha-2,3-sialylation displayed a reduced capacity to proliferate after polyclonal stimulation. These data collectively indicate a new mechanism of action for Interferon beta-1a in RRMS via reduction of alpha-2,3-sialylation on T cells. Alpha-2.3-sialylation could be a marker for disease activity in RRMS or responsiveness to treatment by interferon beta-1a.

P1.12.04
Jacalin has distinct immunomodulatory effects on early and late stages of experimental colon carcinogenesis

G. S. Bisson[1]*, T. H. Geraldino*[2]*, P. Modiano*[3]*, L. C. Veronez*[2]*, R. O. Lopes*[4]*, S. B. Garcia*[4]*;*
[1]*Depto. Enfermagem Materno-Infantil e Saúde Pública, EERP/USP, Ribeirão Preto, Brazil,* [2]*Programa de Pós-graduação em Imunologia Básica e Aplicada, FMRP/USP, Ribeirão Preto, Brazil,* [3]*EERP/USP, Ribeirão Preto, Brazil,* [4]*Depto. Patologia e Medicina Legal, FMRP/USP, Ribeirão Preto, Brazil.*

Inflammation can foster or inhibit cancer growth, depending on the composition of infiltrating cell population and the stage of tumor development. Colorectal cancer represents a paradigm for the connection between inflammation and cancer. Increased expression of the TF antigen is a common feature in malignant epithelia. The lectin jacalin recognizes TF antigens and inhibits the proliferation of human colon cancer cells. In this study, we examined the effects of jacalin on different stages of experimental colon carcinogenesis. C57/BL6 or Balb/c mice were given 4 intrarectal deposits of 0.1 ml solution of Methyl-N'-Nitro-N-Nitroso-Guanidine (5 mg/ml) twice a week for 2 weeks. Jacalin treatment started 2 weeks before, or 24 weeks after carcinogen administration, and the lectin was administered orally (0.5 and 5µg/animal) twice a week for respectively 10 or 4 weeks. In all stages of carcinogenesis, jacalin treatment increased apoptosis and reduced proliferation of colonic/tumor cells. In the early stages, the lectin favored the formation of an anti-inflammatory microenvironment that impaired tumor progression, as shown by the decreased number of preneoplastic lesions. Jacalin administration resulted in increased intestinal production of TGF-β and IL-10 and in reduced COX-2 expression in stromal cells. In the late stages, after tumor establishment, jacalin treatment predominantly induced the production of the pro-inflammatory cytokines TNF and IFN-γ. Although tumor morphology was unaffected, a high number of apoptotic corpuscles was observed in tumors from treated animals. These results demonstrate that jacalin exerts distinct immunomodulatory effects on different stages of colon carcinogenesis, and highlight its potential antitumor activity.

P1.12.05
The change in the glycosylation of human leukocytes in immunosuppressive environment

K. Bocian[1]*, E. Pocheć*[2]*, M. Dolińska*[1]*, G. Korczak-Kowalska*[1,3]*;*
[1]*Department of Immunology Faculty of Biology University of Warsaw, Warsaw, Poland,* [2]*Department of Glycoconjugate Biochemistry, Jagiellonian University, Krakow, Poland,* [3]*2Department of Clinical Immunology, Transplantation Institute, Medical University of Warsaw, Warsaw, Poland, Warsaw, Poland.*

Cell and organ transplantation has become a mainstay of therapy for end-stage organ failure.The global effect of immunosuppressive drugs on the immune system predisposes a patient to the development of infection,cancer. An effect of immunosuppressive drugs, crucial for the successful transplantation of organs, on glycosylation of immune cells is not known. Glycans decorate the surfaces of all of the key molecules involved in the innate and adaptive immune response. The proper functioning of immune cells in response to alloantigeny, depends on the process of glycosylation of receptor proteins. Changes in the glycosylation profile of T cell receptor may influence the induction of response against the transplant. The aim of this study was to determine the effect of mTOR inhibitor (rapamycin-RAPA) and calcineurin inhibitors (cyclosporin A-CsA and tacrolimus-Tac), used singly and in two-drug combinations, on the glycosylation of mononuclear human cells (MNCs).MNCs were induced in two-way mixed leucocytes reaction (MLR) in the environment of different regimens of immunosuppression. The surface glycosylation of MNCs was identified by flow cytometry using lectins which selectively recognite specific carbohydrate structures. We observed changes in glycosylation of the analysed cells in the presence of mTOR and/or calcineurin inhibitors. Moreover, the environment of two-drug combinations influenced the glycosylation of MLR immune cells. The immunosuppressive drugs decreased the amount of PHAL- and VVL-positive cells, but the lowest percentage of staining cell it was observed in case of CsA and Tac treated cells. The calcineurin inhibitors reduced of PNA-,UEA- and GNA-positive

glycans, while mTOR inhibitor enhanced glycans recognized by UEA lectin.

P1.12.06
Anti-Polygalacturonic acid antibodies in diagnosis and pathogenesis of rheumatoid arthritis

H. Dai[1], *X. Gao*[2];
[1]*Peking University Health Science Center, Beijing, China,* [2]*Institute of Biology and Medical Sciences, Soochow University, Suzhou, China.*

Much progress has been made in recent years on the diagnostic value, antigen specificity and pathogenic roles of autoantibodies correlated to the development of rheumatoid arthritis (RA) in humans. However, carbohydrate antigen-specific autoantibodies that may also play important roles in RA have largely been ignored. We herein report that serum levels of Abs against polygalacturonic acid (PGA, major structural component of pectin) strongly correlate with RA in humans. The measurements of PGA-specific Ab (PGA-Abs) in sera are comparable to rheumatoid factors and anti-cyclic citrullinated peptide Abs as serological diagnostic markers for RA in terms of sensitivity and specificity. Immuno-histochemical staining results indicate that the PGA moiety is specifically expressed by synovial membrane cells and chondrocytes in the joints of both humans and rabbits (but not rodents). Induction of PGA-specific Abs by subcutaneous immunization of rabbits with carrier protein-conjugated synthetic PGA leads to severe inflammatory reactions (synovial hyperplasia, small vessels proliferation and inflammatory cell infiltration) in the joints. Injection of affinity purified anti-PGA IgG into the synovial cavity of rabbits resulted in accumulation of pro-inflammatory cytokines such as TNF-α, IL-8 and IL-1β in synovial fluid and also local pathological damage. We conclude that the PGA moiety represents a major autoantigen in joints which can be targeted by autoantibodies capable of triggering arthritogenic responses in vivo.

P1.12.07
Interaction of Siglec-7 and -9 with their ligands inhibit NK cell anti-tumor immune responses

K. Frias Boligan[1], *C. Schneider*[1], *O. Chijioke*[2], *C. Jandus*[3], *C. Münz*[2], *S. von Gunten*[1];
[1]*Institute of Pharmacology, Bern, Switzerland,* [2]*Institute of Experimental Immunology, Zürich, Switzerland,* [3]*Ludwig Center of Cancer Research, Lausanne, Switzerland.*

Malignant transformation is often accompanied with aberrant surface glycosylation patterns. Tumor cells tend to produce increased levels of sialic acid containing glycoconjugates, a phenotype, which has been associated with invasion and malignancy. Glycan expression on the surface of tumor cells can modulate anti-tumor immune responses. Sialic acid binding immunoglobulin-like lectins (Siglecs) -7 and -9 are transmembrane receptors that mediate inhibitory functions, which are expressed on natural killer (NK) cells. Due to their ability to bind sialoglycans they might contribute to tumor escape during anti-tumoral immune responses. In our work we showed that engagement of these receptors inhibits NK cell-mediated cytotoxicity of target cells, as well as, NK cell degranulation and cytokine production. In vivo experiments, in a mouse model with a reconstituted human NK cell compartment, showed an increase in NK cell-mediated cytotoxicity after removal of sialic acid on the surface of the target cells. Even more, in “in vivo” and “in vitro” experiments we are able to significantly increase the lysis of an NK non-susceptible target cell line after enzymatic removal of their ligands. In this sense we suspect that sialylated glycans at the surface of cancer cells play a functional role in shielding them from immune attack. Thus, evidence that Siglecs are implicated in tumor escape, via glycan recognition on the surface of cancer cells by inhibition of NK cells, might become an important step in the future design of novel tumor immunotherapeutic strategies.

P1.12.08
Dectin-1 expressed on human pulmonary epithelial cells is an important pattern recognition receptor for the detection of nontypeable *Haemophilus influenzae*

K. A. Heyl[1], *T. E. Klassert*[1], *B. B. Singer*[2], *A. Heinrich*[3], *M. M. Müller*[1], *R. Bals*[4], *H. Slevogt*[1];
[1]*Septomics Research Center, Jena, Germany,* [2]*Institute of Anatomy, University Hospital Essen, Essen, Germany,* [3]*Department of Microbiology and Hygiene, Charité - Universitätsmedizin Berlin, Berlin, Germany,* [4]*Department of Pulmonology, University of the Saarland, Homburg Saar, Germany.*

The C-type lectin (CTL) receptor Dectin-1 recognizes β-1,3 glucans and is known to be mainly expressed on myeloid cells. The activation of Dectin-1 induces pro-inflammatory immune responses via phosphorylation of the intracellular immunoreceptor tyrosine-based activation motif (ITAM)-like domain. Dectin-1 is known to be important for the host response targeting *Aspergillus fumigatus* and *Mycobacterium tuberculosis*. Moreover it has been suggested that nontypeaple *Haemophilus influenzae* (NTHi), an important bacterial pathogen of the respiratory tract with significant importance in chronic-obstructive lung disease (COPD), interacts with Dectin-1. Given that the majority of the interactions with these pathogens occur at the respiratory epithelium in this study we explored the expression of Dectin-1 on human airway epithelium. We found that immunohistochemical staining of human lung biopsies were positive for Dectin-1 either on bronchial as well as on alveolar epithelium of almost all samples. However, when comparing the intensity of the staining of human lung biopsies with regard to COPD and smoker status of the individuals no correlation was found. Primary normal human bronchial epithelial cells (NHBE) also showed Dectin-1 expression using FACS analysis. Importantly we found that proinflammatory immune responses of bronchial epithelium to infections with NTHi were significantly triggered by Dectin-1. In further experiments using an A549 cell-line overexpressing wildtype Dectin-1 or an ITAM-like phosphorylation mutant we found that ITAM-like phosphorylation was essential for the Dectin-1-triggered response to NTHi.
Taken together our results indicate that recognition of NTHi by Dectin-1 plays a considerable role for the generation of proinflammatory immune responses of airway epithelium.

P1.12.09
Crystal structure of the tetrameric fibrinogen-like recognition domain of FIBCD1

A. K. Shrive[1], *J. B. Moeller*[2], *I. Burns*[1], *J. M. Paterson*[1], *A. J. Shaw*[1], *A. Schlosser*[2], *G. L. Sorensen*[2], *T. J. Greenhough*[1], ***U. Holmskov***[2];
[1]*Keele University, Keele, United Kingdom,* [2]*University of Southern Denmark, Odense, Denmark.*

We have solved the crystal structures of a tetrameric fragment of the C-terminal fibrinogen-like recognition domain of FIBCD1. FIBCD1 is an endocytic receptor that forms tetramers in the membrane of gut and lung epithelial cells. FIBCD1 binds acetylated components including fungal derived chitin and is therefore a pattern recognition receptor. The overall structure shows similarity in structure to the horseshoe crab innate immune protein tachylectin 5A and to the ficolins. Binding of N-acetyl mannosamine in the S1 site shows that the predominant interaction is via the acetyl group with the oxygen interacting with two main chain NH groups, the acetamide nitrogen interacting with the side chain of Tyr431 and the methyl group inserted into a hydrophobic pocket. In the native structure, a crystal contact results in one of the independent protomers binding the first GlcNAc of the Asn340 N-linked glycan on the other independent protomer, shedding light on the mode of binding to chitin itself. In addition, a sulphate ion has been modelled into the electron density at a location similar to the S3 binding site in L-ficolin, while in the native structure an acetate ion has been placed in the S1 N-acetyl binding site and a sulphate ion adjacent to this site. These ion-binding sites are ideally placed to receive the N-acetyl and sulphate groups of sulphated GalNAc residues of glycosaminoglycans. Together, these structures give insight into important determinants of ligand selectivity, demonstrating versatility in recognition and binding in general whilst maintaining conservation in N-acetyl and calcium binding.

P1.12.10

CLEC4F is a Kupffer Cells-Specific C-type Lectin Induced in F4/80-positive Cells upon Entry to Liver

S. E. Hsieh;
Genomics Research Center, Academia Sinica, Taipei, Taiwan.

CLEC4F, a member of C-type lectins, was firstly purified from rat liver extract with high binding affinity to fucose, galactose, N-acetylgalactosamine (GalNAc), and un-sialylated glucosphingolipids with GalNAc or galactose terminus. However, the biological functions of CLEC4F have not been elucidated. To address this question, we examined the expression and distribution of murine CLEC4F firstly, and investigated its function using CLEC4F knockout (*Clec4f-/-*) mice. In this report we show that murine CLEC4F was specifically expressed in liver, worm-like F4/80^{+} Kupffer cells, but was absent in other tissues and cells. During embryogenesis, unlike F4/80, CLEC4F is not detectable in yolk sac, but is expressed in fetal liver of embryonic day 11.5 (E11.5), suggesting the expression of CLEC4F is induced after cells migrating from yolk cells to liver. In addition, CLEC4F is also expressed in both residential Kupffer cells and infiltrating mononuclear cells surrounding liver abscess caused by *Listeria monocytogenes* (*L. monocytogenes*) infection. Moreover, CLEC4F interacts with alpha-galactosylceramide (α-GalCer) in a calcium-dependent manner and participates in the presentation of α-GalCer to natural killer T (NKT) cells. This suggests that CLEC4F is not only a specific marker for Kupffer cells, but also plays an important role in the regulation of hepatic NKT cells.

P1.12.11
Characterization of carbohydrate preference of SIGNR1 as pathogen uptake receptor using carbohydrate-coated liposomes

Y. Kawauchi*, N. Kojima;*
Tokai Univ., Hiratsuka, Japan.

The C-type lectin receptors (CLRs) expressed on APCs are particularly important for pathogen recognition and uptake by APCs and therefore, CLRs are potentially useful for antigen targeting. In this context, determination of most preferable carbohydrate ligands for uptake of CLRs is important. However, little is known regarding the functional carbohydrate structures of CLRs as phagocytic receptors. In this study, we examined the uptake of neoglycolipid-coated liposomes mediated by SIGNR1 to understand the carbohydrate preferences of SIGNR1 as a phagocytic receptor.
RAW264.7 cells introduced with SIGNR1 (RAW-SIGNR1) efficiently ingested with mannotriose (Man3), mannopentapse (Man5), and mannobiose (Man2) with Manα1-3Man structure. Furthermore, the cells also efficiently took up liposomes coated with terminal α1,3/4−linked fucose-containing oligosaccharides, such as Lewis A and X antigens. On the other hand, RAW-SIGNR1 barely ingested liposomes coated with Man2 with Manα1-2Man, Manα1-4Man, and Manα1-6Man structures, and those coated with terminal α1,2−linked fucose-containing blood group H oligosaccharide and Lewis B antigen. When carbohydrate preferences of SIGNR1 as a carbohydrate-binding receptor was assessed based on the binding of RAW-SIGNR1 to neoglycolipid-coated solid phases, the cells clearly bound to all of terminal mannose-containing oligosaccharides including Man2 with Manα1-2Man, Manα1-4Man, and Manα1-6Man structures, and all of the terminal fucose-containing oligosaccharides including blood group H and Lewis B oligosaccharides. These results indicate that carbohydrate preferences of SIGNR1 as a phagocytic receptor differ from those as a carbohydrate-binding molecule.

P1.12.12
The role of membrane lectins from subcellular fractions of human prostate in intracellular transformation at different pathologies

N. Kvitsinadze[1]*, I. Megrelishvili*[2]*, R. Solomonia*[1]*, E. Davitashvili*[3]*;*
[1]*Beritashvili center of experimental biomedicine, Tbilisi, Georgia,*
[2]*Center of Biotechnology, Tbilisi, Georgia,* [3]*Iv. Javakhishvili Tbilisi State University, Tbilisi, Georgia.*

Lectins are biological active glycoproteins, which characterize to bind specifically to the terminal carbohydrates. Lctins with mytogenic activity increase a proliferation of cells that may be precondition of transformation. We studied some biological properties of lectins from human prostate tissues with different diagnoses.
Gal-Lectins was obtained from human post-operational prostate with following diagnoses: benign prostatic hyperplasia (BPH), prostatic intraepithelial neoplasia (BPH+PING$_{(2-3)}$), atypic adenomatous hyperplasia (BPH+AAH). Gal-Lectins were isolated with an aid of affine chromatography. The activity of the Citochrome-C-oxidase complex was determined by change of redox status of active copper and hem.
It has been revealed the sharp increase of lectin activity in all subcellular fractions of BPH+PING$_{(2-3)}$- and BPH+AAH-diagnose prostate as compared with BPH. Gal-1 and Gal-3 have been identified in mitochondria, plasma membrane and nucleus of all tested diagnoses prostate by Western blotting analyze and studied its distribution. Gal-lectins with 60 kD molecular weight have been isolated from mitochondrial and microsomal fractions of prostate tissues. In the modal experiments (the mitochondria and microsome of bovine liver) are studied some of their biological properties. The Gal-lectins from mitochondrial and microsomal fractions of prostate tissues with complicated diagnosis have effect on peroxidation, they inhibit the redox state of Cytochrom-C-oxidase copper and Cytochrom a+a_3 heme.
The obtained data reveal participation of membrane lectins from BPH+PING$_{(2-3)}$- and BPH+AAH-diagnosis prostate in the basic metabolic disorders, which evokes the transformation in the carcinoma and indicate to carry out the prophylactic treatment for avoid the cancer.

P1.12.13
The C-type lectin receptor SIGN-R3 binds to commensal microbiota and influences immune regulation in experimental colitis

M. Eriksson[1]*, T. Johannssen*[1]*, D. von Smolinski*[2]*, A. D. Gruber*[2]*, P. H. Seeberger*[1,2]*,* ***B. Lepenies***[1,2]*;*
[1]*Max Planck Institute of Colloids and Interfaces, Potsdam, Germany,*
[2]*Freie Universität Berlin, Berlin, Germany.*

Inflammatory bowel disease is a condition of acute or chronic inflammation of the gut. An important factor contributing to pathogenesis is a dysregulated mucosal immunity against commensal bacteria and fungi. Host pattern recognition receptors (PRRs) sense commensals in the gut and are involved in maintaining the balance between controlled responses to pathogens and overwhelming innate immune activation. C-type lectin receptors (CLRs) are PRRs recognizing glycan structures on pathogens and self-antigens. Recent studies indicate a crucial role for CLRs such as Dectin-1 in the regulation of intestinal inflammatory responses.
In the present study, we examined the role of the CLR SIGN-R3 in the recognition of commensals and its involvement in intestinal immunity. SIGN-R3 is the closest murine homologue of the human DC-SIGN receptor recognizing similar carbohydrate ligands such as terminal fucose or high-mannose glycans. Here we show that SIGN-R3 binds specifically to commensal microbes. To analyze if this interaction impacted the intestinal immunity against microbiota, the dextran sulfate sodium (DSS) model of colitis was employed. Upon colitis induction, SIGN-R3$^{-/-}$ mice exhibited a more severe weight loss compared to wild-type mice. In addition, SIGN-R3$^{-/-}$ mice displayed exacerbated colitis symptoms such as diarrhea, cell infiltration into the colon, and mucosal ulceration. The increased inflammation in SIGN-R3$^{-/-}$ mice was accompanied by a higher TNF-α level in colon of SIGN-R3$^{-/-}$ mice indicating an immune regulatory role for SIGN-R3 during colon inflammation.
Our findings highlight the importance of CLRs in intestinal immunity and demonstrate for the first time an immune regulatory role for SIGN-R3 in colitis.

P1.12.14
Role of galectin-7 in psoriasis by regulating the skin inflammatory response through keratinocytes

C. Lo[1], *C. Yen*[1], *H. Chen*[1], *Y. Lo*[1,2], *H. Chen*[1,3], *F. Liu*[1,2,3];
[1]*Institute of Biomedical Sciences, Academia Sinica, Taipei, Taiwan,* [2]*Graduate Institute of Immunology, National Taiwan University, Taipei, Taiwan,* [3]*Department of Dermatology, University of California, Davis, CA, United States.*

Galectin-7 is predominantly expressed by stratified epithelia, including epidermis. This protein was found to be highly inducible by p53 and modulate epidermal homeostasis after skin injury. However, its role in regulating immune responses in the skin is unknown. In the present study, we found galectin-7 was down-regulated in human psoriatic lesions compared with non-lesional sites. We also demonstrated that knocking down galectin-7 expression in the human keratinocyte cell line HaCaT resulted in increased production of the inflammatory cytokine and chemokine including IL-6 and IL-8, in response to various immune stimuli. In addition, chemotaxis of human neutrophils, but not of lymphocytes, toward galectin-7-knockdown cells was higher than that toward parental cells. The numbers of migratory neutrophils were positively correlated with the levels of IL-6 and IL-8 produced by the cells. Moreover, galectin-7-knockdown cells exhibited dramatically enhanced Erk1/2 phosphorylation upon LPS stimulation, which was associated with LPS-induced IL-6 and IL-8 production. Inhibition of Erk MAP kinase activation using the MEK inhibitor PD98059 suppressed LPS-induced IL-6 and IL-8 secretion from HaCaT cells. Taken together, our results suggest that galectin-7 has a suppressive effect on the inflammatory response in keratinocytes and that galectin-7 gene transfer or other means of specifically inducing galectin-7 expression may be a novel therapeutic approach for psoriasis and other chronic inflammatory skin diseases.

P1.12.15
R-MC 17 antigen - a rat homologue of DEC-205 antigen?

I. Majstorovic[1], *D. Vucevic*[1,2], *V. Ilic*[3], *S. Gasic*[1], *B. Draskovic-Pavlovic*[1,2], *M. Colic*[2];
[1]*Institute for Medical Research Military Medical Academy, Belgrade, Serbia,* [2]*Medical Faculty of the Military Medical Academy, University of Defense in Belgrade, Belgrade, Serbia,* [3]*Institute for Medical Research, University of Belgrade, Belgrade, Serbia.*

We previously produced R-MC 17, IgG1 monoclonal antibody (mAb) by fusion of P3X myeloma cells with splenocytes of BALB/c mice immunized with rat thymocytes suspension enriched in non-lymphoid cells. In thymus, immunolabeling with R-MC17 was observed on cortical thymic epithelial cells (TEC), and on scattered cells with dendritic morphology in the medulla. In lymph nodes and spleen, strong R-MC17 expression was observed on dendritic-like cells (DC) throughout the T cell areas. Weak staining was observed in the follicles. In non-lymphoid tissues, staining was observed on single isolated cells in kidney (blood vessels), brain, lung, liver and gut. During ontogenesis (thymus of 16 day old rat embryos) almost all TEC were R-MC17-positive. R-MC17 mAb precipitated a protein of approximate molecular mass of 200 kDa, under non-reducing conditions, from thymus lysate. The staining pattern and biochemical analysis strongly suggest that the mAb recognize rat DEC-205 molecule. Regarding functional characterization of R-MC 17 antigen, we found that R-MC 17 mAb stimulated the engulfment of thymocytes and thymic hybridoma cells by R-TNC.1 cells (a rat epithelilal cell line with nursing characteristics) in vitro. It is interesting that, R-MC 17 mAb also significantly stimulated engulfment of DC by the R-TNC.1 cell line in vitro. The biological significance of this intriguing phenomenon remains to be elucidated. The mAb also suppressed DC-mediated T-cell proliferation. The molecular confirmation of DEC-205 as a binding molecule of R-MC17 mAb is currently in progress.

P1.12.16
Mannose receptor plays a key role in Th1 polarization of Lactobacillus acidophilus NCFM stimulated dendritic cells

R. Mathiesen, *L. Henningsen, E. Fuglsang, H. Frøkiær; University of Copenhagen, Department of Veterinary Disease Biology, Frederiksberg C, Copenhagen, Denmark.*

Several strains of Lactobacillus acidophilus have been shown to induce a high amount of antiviral and Th1 polarizing genes in bone marrow derived dendritic cells (BMDCs), which may explain why these bacteria can reduce the incidence and duration of influenza. The induction of antiviral and Th1 polarizing genes is caused by interferon beta (IFN-β), which is secreted in high concentrations upon L. acidophilus stimulation and is also partly responsible for a high IL-12 production. The mechanisms behind this high IFN-β/IL-12 induction are still unknown. In this study, we hypothesized that L. acidophilus NCFM uses receptor-mediated phagocytosis to initiate signaling in DCs and that the mannose receptor (MR) plays a key role. When adding mannan, a ligand to the mannose receptor, before adding L. acidophilus NCFM to BMDCs, the uptake of the bacterium and the induction of IFN- β /IL-12 and CD150, a marker of increased ceramide in the plasma membrane, were increased. In contrast, binding of the dectin-1 ligand zymosan, previously shown to initiate cellular shedding of the MR from the cell surface, reduced MR expression and the L. acidophilus NCFM induced IL-12 production. Our results indicate that the mannose receptor is a likely candidate to participate in the uptake of L. acidophilus either directly, by interacting with the bacterium itself or indirectly, by inducing changes in the plasma membrane that influences the endocytic mechanism of the bacteria, thus affecting cytokine induction.

P1.12.17
An interaction of H-ficolin with lipopolysaccharide contributes to aggregation, phagocytosis and killing of Hafnia alvei 1200 bacterial cells

M. Michalski[1,2], *A. S. Swierzko*[1], *J. Lukasiewicz*[3], *A. Man-Kupisinska*[3], *M. Cedzynski*[1];
[1]*Institute of Medical Biology, Polish Academy of Sciences, Lodz, Poland,* [2]*Institute of Microbiology, Immunology and Biotechnology, University of Lodz, Lodz, Poland,* [3]*Department of Immunochemistry, Ludwik Hirszfeld Institute of Immunology and Experimental Therapy, Polish Academy of Sciences, Wroclaw, Poland.*

H-ficolin (also called ficolin-3 or Hakata antigen) is a complement-activating pattern recognition molecule, possessing the fibrinogen-like domain involved in carbohydrate binding. Amongst ficolins, H-ficolin has the highest concentration in human serum, however its physiological function remains unclear. Its deficiency has been suggested to increase the susceptibility to infections. The specificity of H-ficolin is poorly characterized and currently limited to a few ligands only. We previously presented an interaction of this protein with lipopolysaccharides (LPS) of *Hafnia alvei*, being an opportunistic pathogen. In this report, we present the data concerning the involvement of H-ficolin in aggregation, phagocytosis and killing bacterial cells of *H. alvei* 1200 strain. We observed a strong agglutination of GFP-expressing bacteria, in the presence of recombinant H-ficolin and calcium. H-ficolin augmented phagocytosis of these microorganisms by macrophages. Phagocytosis rate was estimated by flow cytometry and fluorescence microscopy. More than 40% of cells contained phagocytosed bacteria, compared with less than 15% in the case of control (non-opsonized bacteria). These data were confirmed by confocal microscopy. Moreover, we showed much higher bactericidal activity of normal than H-ficolin-depleted human serum. To conclude, H-ficolin, in effect of enhancing of phagocytosis and microbicidal activity may be protective from or influence an outcome of the infection with some bacteria.

P1.12.18
Increased sialylation of a recombinant IgG mutant produced in human embryonic kidney 293 (HEK293) cells

Y. Mimura[1], *K. Ronan*[2], *L. Unwin*[2], *S. Albrecht*[2], *Y. Mizukami*[3], *M. Goodall*[4], *T. Matsumoto*[1], *R. Jefferis*[4], *P. M. Rudd*[2];
[1]*Clinical Research, NHO Yamaguchi-Ube Medical Center, Ube, Japan,* [2]*GlycoScience Group, The National Institute for Bioprocessing Research and Training, Dublin, Ireland,* [3]*Center for Gene Research, Yamaguchi University, Ube, Japan,* [4]*Division of Immunity and Infection, The Medical School, University of Birmingham, Birmingham, United Kingdom.*

The attachment of oligosaccharide, at Asn297, of the IgG-Fc heavy chain is essential for optimal binding and activation of Fcγ receptors and the C1q component of complement[1]. However, it has recently been shown that when fully processed, and bearing terminal sialic acid residues, effector functions are down-regulated, i.e. mediates anti-inflammatory therapeutic effects[2]. The sialylation level of human serum IgG-Fc is 10 - 20% whilst for recombinant IgGs produced from Chinese hamster ovary (CHO) cells sialylation is negligible. It has been shown that sialylation is markedly increased when a mouse-human chimeric IgG3 antibody, bearing a Phe/Ala243 mutation, is expressed in CHO cells[3]. However, CHO-derived IgG is α(2-3)-sialylated whilst human serum IgG is α(2-6)-sialylated. Here, we expressed an IgG1 F/A243 mutant in both human embryonic kidney (HEK) 293 and CHO cells. As expected, sialylation was increased in the F/A243 IgG1 mutant, as for IgG3, and the HEK293-derived IgG1 was α(2-6)-sialylated. Interestingly, increased addition of bisecting GlcNAc residue was also observed for the HEK 293-derived mutant. As sialic acid and bisecting GlcNAc residues are reported to have an opposite influence on antibody-dependent cellular cytotoxicity[4], the effector function profile of a fully sialylated F/A243 mutant antibodies may be of interest for development as therapeutics.

P1.12.19
C-type lectin receptor Mincle and MCL mediate acquired immunity induced by mycobacterial glycolipid TDM

D. Mori[1], *Y. Miyake*[1], *K. Toyonaga*[1], *Y. Yoshikai*[2], *S. Yamasaki*[1];
[1]*Division of Molecular Immunology, Medical Institute of Bioregulation, Kyushu University, Fukuoka, Japan,* [2]*Division of Host Defense, Medical Institute of Bioregulation, Kyushu University, Fukuoka, Japan.*

We have recently identified the C-type lectin receptors Mincle and MCL are activating receptor for trehalose 6,6'-dimycolate (TDM). TDM is a glycolipid derived from the cell wall of *Mycobacterium tuberculosis*. It is widely known that TDM possesses potent adjuvant activity, however, the molecular mechanisms underlying has been unclear. In this study, we showed that two TDM receptors, Mincle and MCL, mediate TDM-induced acquired immunity using two acquired immunity models, delayed-typed hypersensitivity (DTH) and experimental autoimmune encephalomyelitis (EAE). TDM adjuvant strongly enhanced DTH response against OVA in WT mice, whereas it was impaired in both Mincle- and MCL- deficient mice. MCL-deficient mice failed to develop EAE. In contrast, weak but substantial EAE was observed in Mincle-deficient mice, suggesting that MCL preferentially mediates EAE induced by TDM. Finally, we carried out in vivo infection experiment using *Mycobacterium bovis* bacillus Calmette-Guérin (BCG). IFNγ production from T cells in recall response to the mycobacterial antigen (PPD) was reduced in Mincle- and MCL-deficient mice. These results suggest that Mincle and MCL play an important role in the induction of acquired immunity in response to mycobacterial adjuvant, which may lead to the development of TDM receptor-based vaccines against infectious diseases.

P1.12.20
Anti-inflammatory drugs from bugs: *Mycobacterium tuberculosis* gives us a hand

E. Blattes[1,2], *A. Vercellone*[1,2], *H. Eutamène*[3,2], *C. Turrin*[4,2], *V. Théodorou*[3,2], *J. Majoral*[4,2], *A. Caminade*[4,2], *J. Prandi*[1,2], ***J. Nigou***[1,2], *G. Puzo*[1,2];
[1]*CNRS, IPBS, Toulouse, France,* [2]*Université de Toulouse, Toulouse, France,* [3]*INRA, TOXALIM, Toulouse, France,* [4]*CNRS, LCC, Toulouse, France.*

Intracellular pathogens, such as *Mycobacterium tuberculosis*, manipulate innate immunity to down regulate inflammatory responses and secure their survival inside infected hosts. Understanding the tactics used by these pathogens and identifying their functional molecules opens new avenues for development of innovative classes of anti-inflammatory molecules. *Mycobacterium tuberculosis* exposes surface lipoglycans at its cell envelope, namely mannose-capped lipoarabinomannans (ManLAM), that inhibit the release of pro-inflammatory cytokines by LPS-stimulated human dendritic cells (DCs), via targeting the C-type lectin receptor DC-SIGN. With the aim of mimicking the bioactive supramolecular structure of ManLAM, we designed and synthesized a new set of poly(phosphorhydrazone) dendrimers grafted with mannose units, called mannodendrimers, that differed by size and the number and length of their (α1→2)-oligommanoside caps. A third-generation dendrimer bearing 48 trimannoside caps (3T) and a fourth-generation dendrimer bearing 96 dimannosides displayed the highest binding avidity for DC-SIGN. Moreover, these dendrimers inhibited TNF-α production by LPS-stimulated DCs in a DC-SIGN dependent fashion. Finally, in a model of acute lung inflammation in which mice were exposed to aerosolized LPS, *per os* administration of 3T mannodendrimer was found to significantly reduce neutrophil influx via targeting the DC-SIGN murine homolog SIGNR1. The 3T mannodendrimer therefore represents a novel type of fully synthetic powerful anti-inflammatory molecule, with an original mechanism of action, that may have therapeutic applications.

P1.12.21
Galectin-3 regulates dendritic cell responses and hematopoietic cell mobilization during acute peritonitis induced by pristane

F. L. Oliveira[1], *C. Brand*[1], *D. Hsu*[2], *L. Fu-Tong*[2], *R. Borojevic*[1], *R. Chammas*[3], *M. C. El-Cheikh*[1];
[1]*Universidade Federal do Rio Janeiro, Rio de Janeiro, Brazil,*
[2]*University of California, Sacramento, CA, United States,*
[3]*Universidade de Sao Paulo, Sao Paulo, Brazil.*

Galectin-3 adjusts cell-cell and cell-extracellular matrix interactions. We demonstrated that galectin-3 incites myeloid differentiation and inhibits B lymphocyte maturation in distinct lymphoid tissues. Here, we have investigated the role of galectin-3 in dendritic cell responses and hematopoietic cell mobilization during acute peritonitis. BALB/c (WT) and galectin-3$^{-/-}$ mice (gal-3$^{-/-}$) intraperitoneally injected with pristane (immunologic adjuvant and plasmacytoma inducer) were studied 18h after the injection. Pristane induced a significant increase in peritoneal cellularity of WT and gal-3$^{-/-}$ mice, although it was observed 4-fold more cells in both mice. Cell cycle analysis of peritoneal cells of stimulated mice reinforced the recruitment hypothesis because 98.5% of WT cells and 98.8% of gal-3$^{-/-}$ cells were in G1 phase. Phenotypic and morphological analysis revealed that CD11b^{+}Gr-1^{+} granulocytes and CD11b$^{+/low}$Gr-1^{-} monocytes were intensively mobilized to peritoneal cavity (PC) of WT mice and poorly mobilized in gal-3$^{-/-}$ mice, where the peritoneal exudate was essentially composed by mononuclear cells. Peritoneal CD4^{+}CD8^{-} B220^{-} T lymphocytes and B220^{+}CD19^{+}CD4^{-}CD8^{-} B cells were indifferent to pristane, although there were 3-fold fewer B cells and reduced CD8^{+} T cells in control- and induced-gal-3$^{-/-}$ mice, respectively. Interestingly, peritoneal dendritic cells (DCs) showed distinct responses to pristane in the absence of galectin-3. Paradoxically, peritoneal CD11c^{+}CD11b^{+} myeloid DCs were more evident in WT mice and B220^{+}CD11c^{+}CD11b^{-} plasmacytoid DCs were widely detected in gal-3$^{-/-}$ mice after pristane-injection. The results suggested that galectin-3 regulates dendritic cell responses and hematopoietic cell-fate decisions during acute peritonitis induced by pristane. We considered galectin-3 as an important target to understand immune and inflammatory responses.

P1.12.22

Galectin-8 knockout mice have sex-dependent altered homeostasis of t and b lymphocytes and autoimmune features

E. Pardo[1]*, D. Valenzuela*[2]*, A. Soza*[1]*, A. González*[1]*;*
[1]Centro de Envejecimiento y Regeneración (CARE), Fac. Ciencias Biológicas. Departamento de Inmunología Clínica y Reumatología, Fac. Medicina., Pontificia Universidad Católica de Chile., Santiago, Chile, [2]Regeneron Pharmaceuticals Inc., New York, NY, United States.

Galectin-8 (Gal-8) regulates a variety of cellular activities interacting with beta-galactosides of cell surface glycoproteins. Its effects in the immune system include stimulation of apoptosis of thymocytes and activated T cells, proliferation of "naïve" T cells and differentiation of B lymphocytes into plasma cells. We have also described function-blocking autoantibodies in patients with systemic lupus erythematosus (SLE) and rheumatoid arthritis. However, the requirement of Gal-8 in immunological functions has not been studied "*in vivo*". Here we analyze the expression of Gal-8 in different organs and lymphocyte subpopulations in a Gal-8-null/LacZ knock-in mice (Gal-$8^{-/-}$). LacZ histochemistry show Gal-8 is expressed in different organs at different levels. Strikingly, only female Gal-$8^{-/-}$ mice, examined at 8-12 weeks, have increased spleen populations of CD4 and CD8 T lymphocytes and decreased population of B-lymphocytes, without differences in dendritic cells. By the age of 14 months, these female Gal-$8^{-/-}$ mice develop alopecia and splenomegaly accompanied by a significant decrease in the population of CD4 and CD8 T lymphocytes and B-lymphocytes. These mice also generate anti-ANA and anti-dsDNA autoantibodies. These features suggest an autoimmune disease such as SLE. These results reveal an important contribution of Gal-8 to the homeostasis of T and B cells, with sexual differences, such that alterations in its function might lead to autoimmunity. (Financed by Fondecyt postdoctoral project Nº 3120061, Fondecyt Nº 1100921 and CONICYT project Basal #PFB12/2007).

P1.12.23
The binding specificity of *H. pylori* LPS to DC-SIGN receptor

K. Rudnicka*, E. Miszczyk, A. Matusiak, M. Chmiela;*
Department of Immunology and Infectious Biology, University of Lodz, Lodz, Poland.

The main pathogenic feature of Gram-negative bacilli-*Helicobacter pylori* is their ability to induce chronić infections. This feature allows them to avoid and to modulate the host immune responses. *H.pylori* lipopolysaccharide (LPS) demonstrates strong immunomodulatory properties, with rather suppressive effect on immune cells. The presence of Lewis epitopes in the O-specific region of LPS, possibly enables these bacteria to omit the immune responses, resulting in the phenomenon of antigenic mimicry. In addition, specific bacterial adhesins may recognize the dendritic cell receptor DC-SIGN. The binding of *H.pylori* to the DC-SIGN receptor, may result in the host immune response inhibition, which would encourage the enhancement of the infection. The aim of this study was to assess the binding of *H.pylori* LPS (with or without Lewis epitopes) with the DC-SIGN recombinant receptor in the optimized in-house ELISA assay. The plates were coated with various concentrations of recombinant human DC-SIGN-Fc chimeric peptide (RnD Systems), and the whole cell preparations or LPS with or without Lewis determinants were added. The specificity of this interactions was evaluated by the binding-inhibition-assay, with monoclonal antibodies against Lewis determinants, fucose, or galactose. Our results indicate that both *H.pylori* LPS with and without $Le^{x/y}$ antigenic determinants mediates binding of bacteria to DC-SIGN recombinant receptor. The residues of fucose present in the structure of Lewis determinants are responsible for binding specificity of *H.pylori* LPS to DC-SIGN receptor, whereas the residues of galactose determine binding specificity of the *H.pylori* LPS without Le antigens (LPS GalE) to this receptor.

P1.12.24
Galectin-3 plays a role in murine NK cell-mediated INF-γ production

E. Kim[1]*, B. Choi*[1]*, J. Lee*[2]*, **H. Woo***[1]*;*
[1]Seoul National University, Seoul, Republic of Korea, [2]Korea Centers for Disease Control and Prevention, Cheongwon-gun, Republic of Korea.

Natural killer (NK) cells serve as a crucial first line of defense against tumors and a diverse range of pathogens in the innate immunity. Highly related to receptors recognizing tumor cells, the activation receptors trigger cytotoxicity and cytokine production. IFN-γ, secreted by NK cells, plays a critical role in suppressing pathogen challenge, both to contain the initial infection, and to promote an appropriate adaptive response. Galectin-3, a member of β-galactoside-binding animal lectin, acts as immune modulators implicated in a variety of biological functions such as inflammation, tumor metastasis, and cell apoptosis. However, the role of immune regulation of galectin-3 on NK cells is not known. In our study, galectin-3 induced IFN-γ production in murine NK cells in a dose-dependent manner. IFN-γ production of NK cells by galectin-3 was inhibited by either anti-galectin-3 antibody or NF-*k*B inhibitor, but not lactose. These indicated that active site of galectin-3 in IFN-γ generation was in N-terminal but not in lectin domain that has many other physiological function of the molecule. IFN-γ production by galectin-3 was dependent on the activation, translocation and the transcriptional control of NF-kB. Galectin-3 induced IFN- γ production was enhanced through signaling pathway of phosphorylated Erk1/2. Erk1/2 phosphorylation was synergistically increased in galectin-3 treated NK cells and MEK1/2 inhibitor abrogated the phosphorylation of Erk1/2 by galecin-3. Our results provided new insights into mechanism of NK cell activation and, also, a novel function of galectin-3 in immune reaction.

P1.12.25
The MBL paradox: is functional MBL deficiency may be advantageous

T. Zaharov*;*
Odense Universitet's childrens hospital, Odense C, Denmark.

MBL is an ancient molecule, which has probably been subject to a large number of evolutionary pressures. MBL gene polymorphisms persist at high frequencies, suggesting that they offer potential advantages to the host. Changes in IgG glycosylation secondary to the underlying disease results in MBL-associated complement activation and then contributes to chronic inflammation Thus, there exists a balance in which certain individuals benefit from the expression of high levels of the protein, whereas others may benefit from reduced levels of circulating MBL. In the present retrospective cohort study, based on the ambulant visits of paediatrics departments Central Hospital Naestved, 35 patients aged 2-5 years with many RF in prenatal anamnesis, were investigated for serum levels of MBL, HYPA/LYPB genotypes and the MBL pathway function in serum. Conclusions: There was seen correlation between MBL deficiency, HYPA/LYPB gene mutation or reduced MBL pathway function, but MBL status was either advantageous or disadvantageous when considered from the viewpoint of the severity of a particular illness. Thus, those with higher levels of MBL are better able to modulate acute faze of infections, probably through an effect on cytokine responses. In contrast, those deficient in MBL appear to better modulate inflammation via down regulations of cytokine productions and oxidative stress. For these reasons, we believe that analyses of the relevance of MBL should be extended beyond its role in infectious disease and include clinical areas such as autoimmunity and inflammatory disorders.

P1.13.01
CD16 aggregation induced by therapeutic antibody-opsonised targets impairs cytotoxic responses in human NK cells

C. Capuano[1], *M. Romanelli*[1], *C. Pighi*[1], *R. Molfetta*[2], *R. Paolini*[2], *A. Santoni*[2], *R. Galandrini*[1];
[1]*Department of Experimental Medicine, Sapienza University of Rome, Rome, Italy,* [2]*Department of Molecular Medicine, Sapienza University of Rome, Rome, Italy.*

The low affinity receptor for IgG, FcγRIIIA, CD16, is the prototype of NK activating receptors and is responsible for the Antibody Dependent Cellular Cytotoxicity (ADCC). It is well recognised that the clinical efficacy of a number of antibody-based therapeutic approaches largely relies on the ability to induce ADCC.
Here we analysed the dynamics of CD16 expression in primary human NK cells during cytolytic interactions with opsonized targets and the impact of receptor trafficking on NK cytotoxic potential. The chimeric Rituximab and the human Ofatumumab anti-CD20 therapeutic monoclonal antibodies were used to opsonize human lymphoblastoid CD20-positive cell lines.
Our findings demonstrate that the interaction with opsonized target cells induces a marked CD16 internalization associated with a reduced ADCC function in the absence receptor recycling.
Interestingly, in opsonised target-activated NK cells we observed a major impairment of the spontaneous cytotoxic response against a panel of sensitive targets. Such CD16-dependent NK cell hyporesponsiveness was largely independent from the exhaustion of cytolytic mediators or from the down-modulation of activation receptor surface expression. Further, exploring the ability of individual receptor/ligand interaction to induce the cytotoxic response, we observed that CD16-induced cross-tolerance regards different activating receptors including NKG2D, DNAM-1 and to a lesser extent NKp46 and 2B4.
Our data support the notion that stimulation via CD16 may lead to NK cell hyporesponsiveness to triggering via other unrelated signalling pathways.

P1.13.02
Streptococcus pneumoniae triggers platelet activation and platelet-leukocyte complex formation in a strain dependent and Toll-like receptor 2 independent manner

S. F. de Stoppelaar*, M. C. L. Schaap, T. van der Poll, R. Nieuwland, C. van 't Veer;*
Academic Medical Center, Amsterdam, Netherlands.

BACKGROUND: S. pneumoniae strains vary considerably in their ability to cause invasive disease, and this is associated with the capsular serotype. The S. pneumoniae capsule inhibits complement- and phagocyte-mediated immunity. Septic patients often develop thrombocytopenia, which is associated with higher mortality. Besides the role of platelets in hemostasis, platelets exert a role in the immune continuum through release of regulatory proteins, platelet-neutrophil complex formation, and secretion of antimicrobial peptides.
AIMS: To determine how S. pneumoniae activates human platelets.
METHODS: S pneumoniae serotypes used: D39, TIGR4 and 6303 and mutant unencapsulated D39. Human platelet aggregation was measured in citrate-anticoagulated platelet rich plasma by light transmission aggregometry. Platelet degranulation and platelet-leukocyte complexes were measured by flow cytometry. Platelet and neutrophil killing capacity was determined in incubation experiments with S. pneumoniae.
RESULTS: Unencapsulated S. pneumoniae induced platelet aggregation in a capsule-dependent manner; aggregation was not induced by encapsulated strains, or by direct toll-like receptor (TLR) ligands. Aggregation was inhibited by IgG receptor blocking antibody anti-FcγRII, but not by anti-TLR2. Whole blood incubation with all S. pneumoniae serotypes resulted platelet degranulation and platelet-granulocyte and platelet-monocyte complex formation. These reactions were inhibited by PGE1 but not by anti-FcγRII, anti-TLR2 and 4. Platelets had no antimicrobial effect on S. pneumoniae, nor did platelet-neutrophil complex formation enhance neutrophil killing capacity.
CONCLUSIONS: S. pneumoniae causes FcγRII mediated platelet aggregation through a mechanism that is inhibited by its capsule. All S. pneumoniae serotypes are potent inducers of platelet degranulation and platelet-leukocyte complex formation in a TLR2 independent manner.

P1.13.03
Association of FCRL3 genotypes with susceptibility of Iranian patients to rheumatoid arthritis

H. Golmoghaddam[1], *Z. Amirghofran*[1,2], *E. Aflaki*[3], *E. Kamali-Sarvestani*[1,2], *M. Shabani*[1], *Z. Esmaeilbeig*[4], *M. Rajabi*[4];
[1]*Department of Immunology , Shiraz University of Medical Sciences, Shiraz, Iran,* [2]*Autoimmune Diseases Research Center, Shiraz University of Medical Sciences, Shiraz, Iran,* [3]*Department of Internal Medicine, Shiraz University of Medical Sciences, Shiraz, Iran,* [4]*Fasa University of Medical Sciences, Fasa, Iran.*

Rheumatoid arthritis (RA) is a complex disease, the hallmark of which is synovial joint inflammation. The substantial contribution from genetic factors in susceptibility to RA has been well defined. The Fc receptor-like3 (FCRL3) gene is one of the genes that have recently shown a significant association with RA. To determine the possible role of FCRL3-169 C/T and FCRL3-110 A/G gene polymorphisms in the development of RA in Iranian patients, 320 RA patients and 302 healthy subjects were genotyped using the polymerase chain reaction-restriction fragment length polymorphism method. No significant difference was found in genotype and allele frequencies of FCRL3-169 C/T between patients and controls, whereas a positive correlation was observed between this polymorphism and clinical findings, including erosion (P=0.017) and joint deformities (P=0.019). In contrast, at position -110 A/G, the frequency of the AA genotype was significantly decreased in RA patients compared to controls (P=0.005). The frequency of the G allele was also higher in patients than in controls (P=0.007). The results of this study showed a significant association between FCRL3-110 A/G polymorphism and susceptibility to RA. We also noted a significant association between the FCRL3-169 C/T polymorphism and clinical severity in Iranian patients.

P1.13.04
Fca/mR (CD351) regulates inflammatory responses of marginal zone B cells against experimental septic shock

S. Honda[1], *K. Satoh*[1], *Y. Matsuoka*[1], *T. Matsushita*[2], *M. Fujimoto*[2], *A. Shibuya*[1];
[1]*University of Tsukuba, Tsukuba city, Japan,* [2]*Kanazawa University, Kanazawa city, Japan.*

Fca/mR (CD351), an Fc receptor for IgA and IgM, is preferentially expressed on marginal zone B (MZB) cells and follicular dendritic cells (FDC). MZB cells, located at the border between white pulp and red pulp of the spleen, play an important role in the first line defense against blood borne antigens and quickly differentiate into plasmablast producing first wave of antibodies. However, the functional role of Fca/mR on MZB cells has been unclear.
To address this issue, we injected wild-type (WT) C57BL/6 mice or Fca/mR-deficient mice with LPS. Fca/mR-deficient mice showed significantly lower serum level of pro-inflammatory cytokines such as TNF-a and IL-6 and longer survival than WT mice did. To examine which cell type expressing Fca/mR is responsible for the attenuated inflammatory responses and prolonged survival, we generated mixed bone marrow chimeric mice, in which Fca/mR expression was specifically deleted on MZB cells, by using Fca/mR-deficient mice and CD19-deficient mice. The bone marrow chimeric mice showed the same phenotype as Fca/mR-deficient mice. We also generated bone marrow chimeric mice, in which Fca/mR expression was specifically deleted on FDC, by bone marrow transplantation from WT mice into lethally irradiated Fca/mR-deficient mice. We did not observe any difference in the pro-inflammatory cytokine level and survival between WT and the bone marrow chimeric mice. These results indicated that Fca/mR on MZB cells plays an important role in inflammatory responses against experimental septic shock.

P1.13.05

Association of FCγRIIA(CD32) polymorphism with susceptibility to brucellosis

***Z. Hosseini Khah**, A. Rafiei;*
Molecular and Cell Biology Research Center, mazandaran university of medical sciences, sari, mazandaran, Iran, sari, Iran.

Background: Brucellosis is a major bacterial zoonoses of global importance caused by organisms belonging to the *Brucella*, intracellular bacteria. phagocytosis is the main host defense against *Brucell*avia IgG receptors. FCγRIIA receptor plays a centeral role in phagocytosis of IgG2-opsonized bacteria since it is the sole receptor able to interact with IgG2 antibodies. FCγRIIA exhibits allelic polymorphisms (FcγRIIa-R131 or FcγRIIa-H131) with different capacities for binding IgG2 and phagocytosis. cells expressing FcγRIIa-H131, bind more efficiently complexed IgG2 than those expressing the FcγRIIa-R131 variant. the purpose of this study was to evaluate the association of FCγRIIA polymorphisms with susceptibility to or severity of brucellosis. Subject and methods: In this study we determined FCγRIIA polymorphisms (R/R131, R/H131, H/H131) in 67 patients with brucellosis and 67 age ,sex and geographical matched healthy volunteers. FCγRIIA genotyping was performed by using a sequence-specific primer polymerase chain reaction (SSP-PCR). Result: Comparison of the FCγRIIA genotypes distribution in patients with brucellosis and controls showed a higher frequency in FCγRIIA-R/R131 homozygosity in patients than controls (47.8% vs 28.4%). Logistic regression analysis showed that there is a significant correlation between R/R131 genotype and brucellosis (OR=2.3, 95%CI=1.3-4.2, P=0.04). although the frequency of the FCγRIIA-R/R131 was higher in patients with brucellosis compared with controls, we did not find any statistically significant differences(53.8% vs 46.3%, P=0.65). as a result, there was no significant association between FCγRIIA genotype and severity of brucellosis.
Conclusion: The homozygous genotype of FCγRIIA-R/R131 in patient with brucellosis may be associated with susceptibility to brucellosis as a genetic risk factor.

P1.13.06
The role of Prohibitin (PHB) in the initial reaction of the IgE Fc receptor signal from lipid raft

***T. Ichii**[1], T. Aradate[2], Y. Mitsuhashi[3], M. Hachiya[1], N. Tani[1], Y. Yamanoi[1], M. Kanamori[3], A. Muraguchi[4], T. Katagiri[1];*
[1]Dept. Biology (Faculty of Pharmaceutical Sciences) University of Toyama, Toyama city, Japan, [2]Dept. Biology (Faculty of Medical Sciences) University of Toyama, Toyama city, Japan, [3]Dept Human Science 1, (Faculty of Medical Sciences) University of Toyama, Toyama city, Japan, [4]Dept. Immunology (Faculty of Medical Sciences) University of Toyama, Toyama city, Japan.

To find the novel regulators affect on the initial mechanism of IgE Fcε receptor signaling, we used limited proteome analyses for lipid rafts from antibody stimulated RBL-2H3 cells. Lipid raft associated protein was prepared from stimulated RBL-2H3 cells or non-stimulated cells. Then, we identified an interesting protein, Prohibitin. Prohibitin is already known to be a regulator of cell proliferation and modulator of transcriptional activity. However, currently there is no information about what is the role of prohibitin in FcεRI signaling of mast cells and basophils.
Firstly, we confirmed that the localization of Prohibitin to raft fraction on non-stimulated or stimulated cell by using immunochemical staining. On Confocal laser scanning microscopy, we found that co-localization of raft and PHB both on stimulated cells and non-stimulated cells. By using biochemical technique, we detected small part of PHB in raft fraction and major part was in heavy fraction without stimulation. Interestingly, after stimulation, PHB in the raft fraction went along with stimulation, and quantity decreased. On the other hand, by using ds-RNA, we knocked down (KD) the Prohibitin for protein level expression. As a result, the degranulation reaction was significantly enhanced compared with wild type (WT). Also, on PHB-KD RBL-2H3 cells, it affects the phosphorylation of the MAP kinase and was no tyrosine phosphorylation of 100 kD protein that induced in stimulated WT cells.
Considering with these our findings, PHB seems to act as a negative regulator for Fcε receptor signals.

P1.13.07
Engagement of the IgM Fc receptor (FcμR) with its ligand occurs in *cis* rather than *trans*

*K. Honjo, Y. Kubagawa, J. F. Kearney, **H. Kubagawa**;*
University of Alabama at Birmingham, Birmingham, AL, United States.

IgM is the first Ig isotype seen during phylogeny, ontogeny and immune responses. An IgM Fc receptor (FcμR) has recently been identified and, unlike FcRs for switched Ig isotypes, is predominantly expressed by adaptive immune cells, both B and T lymphocytes, in humans. FcμR binds pentameric IgM with high affinity (~10 nM) in Scatchard plot assays. To compare the interaction of FcμR with soluble versus membrane-attached IgM ligands, the apoptosis-prone Jurkat human T-cell line was transduced with both FcμR and GFP cDNAs or the GFP cDNA alone and the resultant cells with equivalent GFP expression were subjected to apoptosis assays using an agonistic IgM anti-Fas mAb. Control GFP^+ cells underwent apoptosis, whereas $FcμR^+/GFP^+$ cells did not. This FcμR-mediated anti-apoptotic activity was not affected by addition of 10-fold excess of FcμR-bearing but Fas-negative cells into the assay, suggesting that the predominant interaction of FcμR with the IgM Fas mAb is in *cis* on the same cell surface rather than in *trans* between neighboring cells. At least 50,000 molar excess of soluble IgM immune complexes was required for inhibiting the FcμR-mediated anti-apoptotic activity, whereas <100 molar excess of IgM mAb against CD2 on Jurkat cells did so, suggesting that FcμR has a higher affinity for the Fc portion of IgM attached to plasma membranes via its Fab region than for the Fc portion of soluble IgM immune complexes. These results suggest that FcμR can modulate the function of lymphocyte cell surface receptors/Ags that are recognized by natural or immune IgM Abs.

P1.13.08
Selective immunotherapy of lupus prone mice by biologically active peptides and simultaneous engagement of BCR and inhibitory B-cell receptors

***N. M. Mihaylova**[1], K. Nikolova-Ganeva[1], M. Nikolova[2], T. Todorov[3], A. Tchorbanov[1];*
[1]Institute of Microbiology, BAS, Sofia, Bulgaria, [2]Central Laboratory of Immunology, National Center of Infectious and Parasitic Diseases, Sofia, Bulgaria, [3]Department of Pathology, Sofia Medical School, Sofia, Bulgaria.

Autoreactive B lymphocytes play a major role in many autoimmune diseases as precursors of pathological autoantibody-producing plasma cells and as antigen-presenting cells. The appearance of pathological DNA-specific B cells in lupus is regarded as a major event in the development of the disease because of the specificity of the antibodies they produce.
Peptide-based immunotherapies offer an approach for selective target of autoreactive cells and leaving the remainder of the immune system intact. The triggering of the immunoglobulin B cell receptors (BCR) by the specific antigens ultimately induces gene expression patterns that can promote cell activation, anergy or apoptosis. Inhibitory co-receptors such as FcγRIIb and CD22 negatively regulate BCR signaling and thus prevent unphysiological overactivation of the B lymphocytes. These surface receptors on disease-associated B-lymphocytes are potential target molecules for therapeutic intervention.
We constructed several chimeric molecules by coupling different self - mimicking peptides to antibodies against FcγRIIb and CD22. The intravenous administration of the chimeras prevent the development of the symptoms of autoimmune disease in lupus-prone MRL/lpr mice - reduction of the levels of IgM and IgG anti-dsDNA antibodies, anti-Histone 1 IgG antibodies and proteinuria. The treatment protects the animals from skin lesions development, enlargement of the size of lymphoid organs and the deposition of IgG-containing immune complexes in the glomeruli. Kidneys from chimera-treated mice had a preserved histological structure.
The administration of these artificial molecules to lupus MRL/lpr mice suppress selectively the activity of disease-associated B lymphocytes and change the natural course of the spontaneous autoimmune disease.

Background: A SNP at position 131, in the FcγRIIa gene, affects the binding of the different IgG subclasses and may influence the clinical variation seen in patients with falciparum malaria. This study confirms and extends previous findings, analysing the FcγRIIa (CD32) polymorphism in relation to the IgG subclass distribution seen among two sympatric tribes living in eastern Sudan, characterized by marked differences in susceptibility to *Plasmodium falciparum* malaria.
Methods: Two hundred and fifty Fulani subjects living in an area of meso-endemic *P. falciparum* malaria infection were genotyped for the FcγRIIa-131 polymorphism. For comparison, 101 non-Fulani donors – (Masaleit, Hausa and Four) – living in the same study area, were genotyped. The levels of plasma antibodies (IgG and subclasses) to four malaria antigens (AMA-1, MSP 2 – 3D7 & FC27, Pf332-C231) were measured using indirect enzyme-linked immunosorbent assays.
Results: The FcγRIIa-H/H131 genotype was found to be significantly more prevalent in the Fulani as compared to the non-Fulani ethnic groups (36.0% for Fulani versus 17.8% for non-Fulani, adjusted OR 3.10, 95% CI 1.61–5.97, P value < 0.001). The Fulani showed lower anti-malarial IgG1 and IgG3 antibody levels as compared to the non-Fulani and higher levels of IgG2 antibodies.
Conclusion: The FcγRIIa-H/H131 genotype and H131 allele is at higher frequency in the Fulani ethnic group. The H/H131 genotype was consistently associated with higher levels of anti-malarial IgG2 and IgG3 antibodies, while the R/R131 genotype was associated with higher levels of IgG1 antibodies.

P1.13.10

Greater number of activated T cells and enlarged germinal centers in the spleen of bovine FcRn transgenic mice in the background of the enhanced immune response

Z. Schneider[1], *A. Végh*[1,2], *J. Cervenak*[2], *P. Balogh*[3], *I. Kacskovics*[1,2];
[1]*Eötvös Loránd University, Department of Immunology, Budapest, Hungary,* [2]*ImmunoGenes Kft., Budakeszi, Hungary,* [3]*University of Pécs, Department of Immunology and Biotehnology, Pécs, Hungary.*

The neonatal Fc receptor (FcRn) plays key roles in IgG and albumin homeostasis, maternal IgG transports and antigen presentation in case of IgG-opsonized antigens. We have previously shown that bovine FcRn (bFcRn) overexpression in transgenic (Tg) mice resulted in mounting robust humoral response against weakly immunogenic antigens and improving hybridoma production efficiency without any sign of autoimmunity. Further studies showed strong expression of bFcRn in peritoneal macrophages and bone marrow-derived dendritic cells (BMDCs) as well as indicated significantly improved T cell proliferation induced by BMDCs after IgG-ovalbumin immune complex phagocytosis *in vitro*.
To gain further insights of this enhanced antibody response, we immunized mice with ovalbumin and found at least twice as many activated, antigen-specific T cells in the spleen of bFcRn Tg mice compared with wild-type (wt) mice. Furthermore, germinal centers of the immunized bFcRn Tg mice were found to be double the size of those observed in wt controls after 3 days of booster injection, indicating significantly improved germinal center reactions in case of Tg mice.
To identify cell populations expressing bFcRn, we developed bFcRn-specific monoclonal antibody that does not cross react with mouse FcRn. We detected strong bFcRn expression in macrophages of splenic marginal zone, but also found bFcRn positive cells in the T cell zone and in the red pulp, possibly dendritic cells and red pulp macrophages, respectively. These new findings provide better explanations for the augmented humoral immune response in bFcRn transgenic mice.
Supported by grant K101364 from Hungarian Scientific Research Fund.

P1.13.11

Intravenous immunoglobulin treatment suppresses dendritic cell function in humans by stimulation of the IL-33-Th2 pathway

R. van Gent*, A. S. W. Tjon, H. Jadaar, M. van Hagen, L. J. W. van der Laan, P. A. W. te Boekhorst, H. J. Metselaar, J. Kwekkeboom; Erasmus MC, Rotterdam, Netherlands.*

High-dose intravenous immunoglobulin (IVIg) is used as anti-inflammatory therapy for autoimmune diseases. Studies in mice suggest that IVIg suppresses inflammation by stimulating inhibitory Fcγ-receptor (FcγR)IIb expression on myeloid cells via a cascade of IL-33-Th2 cytokine production. Here, we investigated whether IVIg monotherapy in 29 patients with hypogammaglobulinaemia or autoimmune diseases stimulates the IL-33-Th2 pathway and modulates FcγR expression on circulating leukocytes. Blood was collected before, immediately after, and 7 days after IVIg infusion. Plasma levels of IL-33 and the Th2 cytokines IL-4 and IL-13 increased following IVIg infusion ($p<0.01$ for each cytokine, day 7), while Th1 cytokine levels remained unchanged. Regression analyses suggested an IL-33-dependent induction of IL-4 ($r=0.69$, $p<0.001$) and IL-13 ($r=0.63$, $p<0.001$) production. *In vitro* experiments showed that IVIg induces IL-33 expression in human lymph node cells, and that IL-33 stimulates Th2 cytokine production by human basophils. Interestingly, expression of the activating FcγRIIa on circulating myeloid dendritic cells (mDCs), but not on monocytes, decreased upon IVIg-treatment (day 7: -30%; $p<0.05$), while FcγRIIb expression remained unchanged. Closer inspection revealed reduction of FcγRIIa expression ($p<0.01$) only upon high-dose IVIg infusion (≥0.6g/kg). This finding was corroborated by *in vitro* experiments showing that IL-4 inhibits FcγRIIa expression on blood-derived human mDCs ($p<0.01$), while FcγRIIb expression remained unchanged. Functionally, IL-4-pre-treated mDCs demonstrated reduced production of pro-inflammatory cytokines TNF-α and IL-8 upon immune-complex stimulation ($p<0.05$). Collectively, our data demonstrate that, in contrast to mice, high-dose IVIg inhibit human mDC function via the IL-33-Th2 cytokine axis by reducing FcγRIIa expression, rather than enhancing FcγRIIb expression.

FcgammaRIIA and FcgammaRIIIB polymorphisms in Brazilian systemic lupus erythematosus patients and associations with clinical manifestations

I. C. C. Vigato-Ferreira[1], *J. E. T. Toller-Kawahisa*[1], *J. A. T. Pancoto*[2], *C. T. Mendes-Junior*[1], *E. Z. Martinez*[1], *E. A. Donadi*[1], *P. Louzada-Júnior*[1], *J. E. C. Del Lama*[1], ***C. M. Marzocchi-Machado***[1];
[1]*Universidade de São Paulo, Ribeirão Preto, Brazil,* [2]*3Universidade Federal do Espírito Santo, São Mateus-ES, Brazil.*

Background: Fcg receptors (FcgR), expressed on neutrophils, play essential roles in the immune response to infection and in inflammatory processes. Recent data have provided evidence that genetic polymorphism of Fcg receptors (FcgRIIa H/R-131 and FcgRIIIb HNA-1a/-1b/-1c) is associated with immune abnormalities and risk to development of systemic lupus erythematosus (SLE). Objective: To investigate whether the distribution of FCGR2A and FCGR3B polymorphisms confers risk for disease susceptibility and clinical manifestations of patients with SLE in Brazilian population. Study design and methods: A total of 157 patients (18 male and 139

female) diagnosed at HCFMRP-USP and which fulfilled the ACR classification criteria for SLE and 160 healthy volunteers (82 male and 78 female) were included in this study. Determination of FCGR2A and FCGR3B genotypes were performed using polymerase chain reaction (PCR)-based allotyping methods with allele-specific primers. The clinical features were obtained from the official medical record. Results: In the case of FcgRIIa polymorphism, it was observed an increase in the frequency of homozygous R-131 in patients (p=0.03; OR = 2.09) compared to genotype H-131. With respect to FcgRIIIb polymorphism, no significant skewing was found between patients and controls. The following clinical associations were found: FcgRIIa-H-131 allele is associated to susceptibility to arthritis and anti-DNA antibody production (p=0.05 for both); FcgRIIIb-HNA-2a allele is associated to susceptibility to malar rash (p=0.03) and arthritis (p=0.02). Conclusion: These results demonstrate the association of FcgRIIa polymorphism with susceptibility to SLE in Brazilian. Furthermore, the FcgRIIa and IIIb polymorphisms constitute factors influencing clinical manifestations of SLE.

Can Serial Quantification of IL-1 in human peripheral blood predict Outcome of fracture healing?

***S. Ali**, A. Singh, A. A. Mehdi, R. N. Srivastava;*
K G Medical University, Lucknow, India.

BACKGROUND: Early stages of healing recruit variety of cytokines that stimulate the repair process. This project was aimed to elucidate whether these selected cytokines may have potential to predict traumatic diaphyseal delayed or non union early.
METHODOLOGY: Patients (n=102) with simple tibial diaphyseal fractures are enrolled and their blood samples were collected at definite follow ups and plasma level of cytokines was measured using the ELISA. Clinico-radiological examination was done at definite follow-ups and radiological assessment was done by RUST Scoring. Depending on the clinico-radiological parameters, patients were divided into 03 groups; A (n = 72): union achieved; B1 (n= 21): Delayed union; and B2 (n= 09): Non-union.
RESULTS: In group A and B1, mean cytokines levels of IL-1α and IL-1β showed significantly elevated expression within the mean at 4.2 days after fracture, which was increased on mean peak at 18.5 days with maximum mean level were 16.67 & 24.18 pg/mL respectively. But the mean levels of these cytokines was significantly higher in Group-A as compare to B1. The means of RUST scores of group A & B1 were 9.6 and 7.8 respectively. In Group B2, mean levels of these cytokines were poorly expressed throughout the follow-ups. The mean Rust score of 3.4 at 36 weeks of Group- B2 also seems low in comparison to Group- A and B1.
CONCLUSIONS: Plasma levels of these cytokines are closely related to early phase of fracture healing and may be taken as a diagnostic tool for earlier identification of patients at risk.

P1.14.02
IL-1β, IL-6 and TNF-α gene's expressions and receptor's mutations in ovarian cancer tissues

***M. M. Arafah**[1], M. Al-Mutairi[1], S. Al-Daihan[1], Y. Al-Anazi[1], M. Al-Anazi[1], M. Adar[1], A. Warsy[1], A. Warsy[1], M. Rouabhia[2], A. Semlali[1];*
[1]King Saud University, Riyadh, Saudi Arabia, [2]Université Laval, Québec, QC, Canada.

Ovarian cancer (OC) remains the leading cause of death among gynecological malignancies and is the fourth most common cause of cancer-related death among women. The TLRs/inflammatory signaling mechanism involving epithelial cells are well-known as an important player for the host defense. Inflammatory cytokines were reported to be modulated in different cancer pathologies that involve epithelial cells. This can be through genetic modulation. Genetic variation in the inflammatory cytokine receptor's (IL-1, IL-6 and TNF-alpha), has been shown in many diseases but not in ovarian cancer. This study was designed to compare the expression of the inflammatory cytokine genes and their receptors in the tumor and normal ovarian tissue in Saudi population. To reach such goal we used quantitative RT-PCR and immunohistochemistry procedures on normal (n = 10) and ovarian cancer (n = 10) tissues. These were supported by analyzing the polymorphism of IL-6R, IL-1R and TNFR by exon sequencing.. The results showed an over expression of IL-1, IL-6 and TNF-α in cancer as compared to normal tissues. The level of these cytokines expression is function of the severity of cancer, which supports the evidence of the cytokines role in the development and promoting the ovarian cancer. This was confirmed by exon sequencing showing different mutations in the specific exons of IL-1R, IL-6R and TNF R. Data demonstrated a possible link between gene mutations, inflammatory processes and ovarian cancer initiation/development. Further studies are needed to shed light on possible inflammatory gene silencing and ovarian cancer control.

P1.14.03
Relationship between selenium intake and inflammatory markers in newly-diagnosed patients with B-cell non-Hodgkin lymphoma

***M. Aribi**[1,2], M. Zahzeh[2];*
[1]University of Tlemcen, Tlemcen, Algeria, [2]Laboratory of Applied Molecular Biology and Immunology, Tlemcen, Algeria.

Background: Non-Hodgkin lymphoma (NHL) is the seventh most common cancer in the world. NHL develops from lymphoid cells. Selenium can modulate the expression of multiple cellular signaling pathways leading to decreased inflammatory gene expression.
Objectives: To determine the relationship between selenium intake and inflammatory markers in newly-diagnosed patients with B-cell NHL.
Materials and Methods: Newly-diagnosed patients with B-cell NHL and healthy age- and sex-matched controls were recruited at the Hematology Department of Tlemcen Medical Centre University (Algeria Northwest) for a retrospective case-control study.
Results: Dietary selenium intake was significantly decreased in patients compared controls, and was significantly correlated with high C-reactive protein (CRP) levels and serum protein electrophoresis patterns. Additionally, oxidant/antioxidant balance was altered in patients.
Conclusion: The reduction of selenium intake induces the synthesis of CRP during the acute phase response in B-cell NHL. Additionally, oxidative stress biomarkers and multi-serum proteomic models may be used for diagnosis and prognosis of the disease.

P1.14.04
Emerging roles of eosinophils and eosinophil-derived lipid mediators in the resolution of acute inflammation

***M. Arita**;*
Graduate School of Pharmaceutical Sciences, University of Tokyo, Tokyo, Japan.

Resolution of inflammation is critical to restoration of normal tissue function following an inflammatory response. We recently demonstrated that eosinophil and eosinophil-derived lipid mediators contribute to this process. In mouse zymosan-induced peritonitis, eosinophils are recruited to the inflamed loci during the resolution phase. In vivo depletion of eosinophils caused a resolution deficit, namely impaired lymphatic drainage with reduced appearance of phagocytes carrying engulfed zymosan in the draining lymph node, and sustained numbers of neutrophils in inflamed tissues. LC-MS/MS-based lipidomics of the exudates revealed that locally activated eosinophils in the resolution phase produced 12/15-lipoxygenase (12/15-LOX)-derived antiinflammatory mediators including protectin D1 (PD1). The resolution deficit caused by eosinophil depletion was rescued by eosinophil restoration or the local administration of PD1. Eosinophils deficient in 12/15-LOX were unable to rescue the resolution phenotype. These results indicate that eosinophils play a role in promoting the resolution through the 12/15-LOX-mediated pathway. Eosinophils are known to be involved in allergic diseases and host protection against parasites through the release of cytokines/chemokines, mediators, and cytotoxic products. Here we provide the first evidence that eosinophils act as specific pro-resolving cells that are recruited and switched on during the

resolution phase of acute peritonitis. Detailed characterization of eosinophil and its functional interaction with other cell types in the resolution phase will provide insights into the molecular mechanisms for resolution of inflammation.

Leucocyte recruitment to site of infection or damage is crucial for inflammatory response. Once in the tissue, differential expression of integrins, selectins and metalloproteinases (MMPs) expression is needed for leucocyte migration. Collagen Type IV, the major protein of epithelial basal membranes, is target of MMPs activity. Both integral and degraded collagen could be recognized by leucocytes for MMPs induction, but it is unknown if it could increase inflammatory cytokines production, as reported for fibrin.
Objective: Determine if collagen IV recognition by human monocytes modifies cytokine production induced by LPS.
Procedures: Human Peripheral Blood Mononuclear Cells (PBMC) were obtained by density-gradient from Buffy Coats. One million PBMC were incubated in wells covered or not with collagen type IV(ColIV), digested or not with collagenase. Cells were stimulated with lipopolysaccharide (LPS,50 ng) from E. Coli(O26:B6). After 8,12,18 and 24 h, supernatants were collected for TNFa,IL-6,IL-1b,IL-8 and IL-10 quantification by cytometric bead array. To identify cytokine producing cells, intracellular staining procedure was done with cells preincubated with brefeldin A and Monensin (10ug) for 6h, and analyzed with flow cytometry.
Results: At 8 h, incubation of MCPBs with degraded collagen and LPS increased supernatant IL-10 concentration compared with LPS activated cells non collagen exposed. For other cytokines quantified, no significant difference were detected, among conditions explored. As evidence for intracellular detection of IL-10 in CD14+ cells, monocytes were the cells responsible for this IL-10 augmentation.
Conclusion: Fragment collagen recognition could induce regulatory pathways that enhance inflammation resolution and promote tissue repair.

P1.14.06
Analysis of c reactive protein levels after an eccentric exercise

V. Barros Costa*;*
Universidade de Brasilia, Brasilia, Brazil.

The C-reactive protein (CRP) is a plasma protein produced by the liver, which mainly operates in the acute phase response that is a body's response to inflammation process or an injury. Therefore, it is very important that tests may be done to determine the concentration of CRP in the bloodstream, in order to know some kind of injury or inflammation in the body. The eccentric exercises have been studied to see if they cause changes in inflammatory markers such as CRP. Randomly it was chosen 73 elderly who were sedentary and overweight. The elderly women were subjected to eccentric strength training through the leg extension machine . The maximum load used in the practice had been determined previously and pre-training and post-training examinations were conducted to determine if there were changes in the level of CRP, and the collection post-training were conducted at intervals of 0 and 3 hours. As results of the total elderly chosen : 38 elderly (about 52,02%) showed a reduction in the concentration of CRP, 25 elderly (34,24%) showed an increase and 10 elderly (13,69 %). This work can't set the eccentric training is an alternative for elderly.

P1.14.07
Immunomodulatory properties of bifidobacteria strains

J. Bartova[1], *A. Šalakova*[2], *J. Drbohlav*[2], *P. Roubal*[2], *O. Šveda*[1], *I. Lisová*[2];
[1]*Institute of Clinical and Experimental Dental Medicine ,GUH and 1st Faculty of Medicine CHarles University, Prague, Czech Republic,* [2]*Dairy Research Institute, Prague, Czech Republic.*

The use of bacteria in therapy has a long tradition. In the last years the number of clinical studies investigating bacteria in prevention or therapy of diseases has increased. The studies are based on the finding that interaction between microorganisms and the mucosal system of the intestine has important effects on development and function of immune system and on the health of the whole organism**.**
The aim of the study was to analyze the immunomodulatory properties of probiotic bifidobacteria strains from the Collection of Dairy Microorganisms Laktoflora ®.
The question was whether all strains react with blood mononuclear cells in the same way, or if there are differences between strains of the same species in cytokine stimulation and thus the strains may have a specific effect in the prevention and in the treatment of certain diseases. For this research was seleted 15 strains of the genus Bifidobacterium: *B. animalis subsp. lactis, B. longum subsp. infantis, B. longum subsp. longum, B. dentium and Bifidobacterium sp.*
Method: Mononuclear cells isolated from peripheral blood of healthy persons were cultivated with selected Bifidobacterium strain for 3 days at 37^{o} C and 5% CO_2 . Pro-inflammatory and anti-inflammatory cytokines produced during stimulation was determined by Luminex quantitative multiplex method.
Conclusion: It was found that different strains of bifidobacteria acting on the separated blood mononuclear cells stimulate cytokine production in individual manner. These characteristics of bifidobacteria strains could be used in the prevention and treatment of certain diseases. P28/LF1/6 and RO0511

P1.14.08
Higher baseline tumor necrosis factor [TNF]-α and early postoperative interleukin [IL]-10 level are associated with postoperative sepsis in cardiac surgery: A preliminary study

M. Ben Azaiz*, R. Arbi, C. Romdhani, W. Ghothban, S. Haddad, I. Labbane, C. Kdous, S. Shnik, F. Mustapha, E. Ghazouani;*
Military Hospital, Tunis, Tunisia.

Background and aim: Sepsis after cardiac surgery under cardiopulmonary bypass (CPB) is a serious complication. Cytokines are the main and first actors in sepsis, therefore the aim of this study was to evaluate pro-inflammatory (IL1, IL-6, IL-8 and TNF-α) and anti-inflammatory (IL-10) cytokines in patients undergoing a CPB as early markers.
Methods: Patients undergoing a CPB were enrolled in a prospective clinical study. They were divided in two groups as septic and non septic patients. The levels of TNFα, IL-6, IL-8, and IL-10 were measured at four different periods (T1: induction, T2: 5 minutes after the end of CBP, T3: 4h after the end of CBP, and T4: 24h post CBP). Quantitative variables are expressed as median (Interquartile range). CRP was measured at day 1, 3, 6 and 9 after surgery.
Results: Nineteen patients were studied. Six patients presented a postoperative sepsis. Only TNF-α at T1 [266.5 UI/ml (9.93; 480) vs. 7.75 UI/ml (6.66; 11.35) in septic vs. non septic patients respectively; p= 0.041] and IL-10 at T3 [6.35 UI/ml (5.37; 6.89) vs. 5 UI/ml (5; 5.01) in septic vs. non septic patients respectively; p= 0.022] were found to be associated with postoperative sepsis. There was no significant difference among CRP measurements.
Conclusion: Monitoring of cytokines, mainly TNFα and IL-10, are more reliable markers then CRP in this procedure. Therefore, these cytokines might be new tools for management of sepsis during CPB. However, the sample size in this preliminary study was too small to allow any definitive conclusion.

P1.14.09
Early diagnostics of the slowed down bone consolidation

O. V. Berdugina[1], *K. A. Berdugin*[2];
[1]*Ural Scietyphic Research Institute of Physiopulmonology, Ekaterinburg, Russian Federation,* [2]*Ural Scietyphic Research Institute of Traumatology and Orthopedics, Ekaterinburg, Russian Federation.*

Method of external fixation - complex system allowing considerably to change principles of treatment, in par-ticular, of damages in an obverse skeleton. We study immunological status by 96 patients. On the basis of clinico-renthgenological criteria the patients were divided into two groups - with the slowed down and normal consolidation of bone in conditions of external fixing. Research of blood carried out at receipt of the patient in clinic and in dynamics after its realization (through 3, 10 day, 1-2 months). Reaction is characterized by high activity and short-lived of proc-ess. The data are received that patients with the slowed down consolidation after ostheosynthesis are revealed the spe-cific changes from the party immunological of system. In particular, after operation period the increase of the basic subpopulations leucocytes with change of their functional condition were marked. In process were involved phagocytic part of immunological system normalization of which activity were marked in one month after operation. Changes characterized humoral part (immunoglobulines, activity комплемента, circulating immunological complexes) of immunity. Inflammation reactions for operative intervention were characterized by the greater duration and less expressed changes of concentration acute phase reactants. Dynamics of IL concentration - IL-1, IL-2, IL-8, IL-10, raIL-1, TNF is established.

P1.14.10
Laboratory monitoring at hip arthroplasty

O. V. Berdugina[1], *K. A. Berdugin*[2];
[1]*Ural scietyphic research institute of physiopulmonology, Ekaterinburg, Russian Federation,* [2]*Ural scietyphic research institute of traumatology and orthopedics, Ekaterinburg, Russian Federation.*

The laboratory researches carried out in at 110 patients with degenerative and posttraumatic diseases of hip joint. On the basis of the investigated remote outcomes of operative treatment (hip joint replacement) - in terms till 4 years - all patients are divided into groups with the complicated current - sharp pneumonia, resorbtion of bone and instability of endoprosthesis - (57,3 %) and not complicated current implantation (42,7 %).
The estimation diagnostic informers of separate laboratory parameters have allowed allocating criteria of forecasting of complications before occurrence of the developed clinical picture. In particular, the change of functional activity of neutrophils and contents Ig A allows to assume an opportunity of development sharp pneumonia in terms about 11 day after operation. Monocytic and lymphocytic reaction of blood with increase of production osteoresorbtion factors of IL - 1 and TNF raises risk of osteoresorbtion formation around prosthesis in terms till 3 years. The development of sensibilisation to components of prosthesis, in a combination to an oppression phagocytic activity and decrease of serum immunoglobulines assumes formation of instability of prosthesis in terms till 2 years. Is marked, that the monitoring sharp pneumonia in early postoperation period has shown the clinical efficiency not less, than in 73,1 % of cases, bone resorbtion around prosthesis - in 72,3 %, instability of prosthesis - in 70,6 %.

P1.14.11
Effect of human recombinant interleukin-33 on collagen mRNA expression in lung fibroblasts

A. Bocharov*, N. Filimonova, N. Sheveleva;*
National University of Pharmacy, Kharkov, Ukraine.

The purpose of this study was to investigate the effect of IL-33 on the expression of collagen type I alpha 1 (COL1A1), collagen type I alpha 2 (COL1A2), and collagen type 3 alpha 1 (COL3A1) mRNA in human lung fibroblasts (HLF).
HLF were grown to confluence in RPMI-1640 medium supplemented with 10% fetal bovine serum, then cells were serum starved in media containing 0.5% dialyzed fetal bovine serum, and 24 hours later, treated with different concentrations (2 to 300 ng/ml) of recombinant human IL-33. mRNA expression levels for COL1A1, COL1A2, and COL3A1 were measured by real-time RT-PCR.
Stimulation of the lung fibroblasts with IL-33 led to a dose-dependent increase in the steady state level of COL3A1 mRNA, but not in COL1A1, and COL1A2 mRNA. The maximum effect of IL-33 on COL3A1 mRNA expression (4.3 fold increase, $p < 0.05$) was observed at 10 ng/ml. This finding suggests that IL-33 can enhance type 3 collagen gene expression, forms conditions promoting the development of fibrotic disorders.

P1.14.12
Pro and anti-inflammatory cytokines from periferal blood mononuclear cells in elderly

J. Burgos[1], *K. H. Pinke*[1], *B. Calzavara*[1], *P. Freitas-Faria*[1], *M. P. P. Nascimento*[1], *J. Venturini*[2], *V. S. Lara*[1];
[1]*Bauru School of Dentistry - University of São Paulo, Bauru, Brazil,* [2]*2Laboratory of Experimental Immunology, Department of Biological Sciences, Faculty of Science, São Paulo State University, Bauru, Brazil.*

Currently, the studies about immunosenescence demonstrate that the functions of innate immunity are more preserved than adaptive immune mechanisms. However, the two systems operate in an integrated way in the body, and an injury in one inevitably affects the other. The aim of this study was to investigate the *in vitro* production of proinflammatory (TNF-α, IL-6, IL-1β, CXCL-8 and MCP-1) and anti-inflammatory (TGF-β and IL-10) cytokines by monocytes, stimulated or not (basal) with lipopolysaccharide, from healthy young and elderly subjects. We also studied if cytokine profile is altered in these different patient groups, in the presence of lymphocytes, under the same experimental conditions. The monocytes from elderly presented higher basal production of TNF-α, MCP-1 and lower of TGF-β than young monocytes, reinforcing the systemic state of i*nflammaging.* In the presence of lymphocytes, the spontaneous production of IL-10 was higher and of TGF-β was lower than monocytes, regardless of age. After LPS-stimulation, the presence of lymphocytes resulted in decreased CXCL-8 and TGF-β and increased IL-6, IL-1β, MCP-1 and IL-10 in comparison to pure culture of monocytes, in young group. The same differences were observed with age, except for CXCL-8 and TGF-β which production was similar between monocytes and PBMC stimulated with LPS. In contrast to PBMC, monocytes of aged subjects showed alterations in cytokines production, suggesting an immunomodulator role of lymphocytes on monocytes.

P1.14.13
Acute inflammation and anemia: hepcidin and innate immunity

M. Carrabba[1,2], *M. Zarantonello*[1], *L. Duca*[2], *N. Campostrini*[3], *G. Fabio*[1,2];
[1]*Universita' degli Studi di Milano, Milan, Italy,* [2]*Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy,* [3]*Universita' di Verona - Ospedale G.B. Rossi, Verona, Italy.*

Introduction: Immunity and iron are closely linked. Many studies in vitro and in animal models have recently elucidated the links of anemia with inflammation and how the innate immunity effectively restricts iron availability to microbial invaders. Hepcidin is an IL-6 induced hormone previously identified as an antimicrobial peptide, currently recognized as the master regulator of iron homeostasis and

the key modulator of inflammation-associated anemia. Hospitalization of patients with acute illness are often complicated by the development of anemia.
Aim: This study aims to explore the association between hepcidin and acute anemia of inflammation and the role of monocytes-derived hepcidin expression in patients with acute inflammation.
Patients and Methods: Sixty consecutive patients were prospectical enrolled after admission from the emergency for acute inflammatory illness, indicated by the presence of a proven or suspected infection and elevated C-RP. Blood was drawn at day 1 and 6 after admission for the measurement of hepcidin-25, cytokines profiling, erythropoietin, GDF-15 and iron status. Monocyte-derived hepcidin mRNA was also assessed.
Results: 95% of patients were affected by acute infections (batteremia, pneumonia, urinary tract infections). High IL-6 serum levels were associated with elevated concentrations of hepcidin, low iron levels, high transferrin saturation and very high ferritin serum levels. Between day 1 and 6, 26 patients lost hemoglobin (0.5 to 2.5g/dL; p<0.001). Erythropoiesis was blunted, despite high erythropoietin serum levels. Hepcidin concentration at admission was able to predict anemia occurrence on day 6. Monocytes-derived mRNA hepcidin positively correlated with serum ferritin and negatively correlated with IL-6R (gp130).

P1.14.14
SNARE proteins in the synaptic secretion of IL-12 and in tumor-induced immunosuppression of dendritic cells

G. Chiaruttini[1], *I. Soncin*[1], *P. Larghi*[2], *T. Galli*[3], *F. Benvenuti*[1]; [1]*ICGEB, Trieste, Italy,* [2]*Institute Curie, Paris, France,* [3]*Institute Jaques Monod, Paris, France.*

Secretion of IL-12 by pathogen-instructed DCs is crucial for initiation and programming of the T cell response. We have previously demonstrated that during formation of the DC-T immune synapse DCs polarize their secretory apparatus toward the interacting T cells leading to accumulation of IL-12 vesicles at the interaction site. However, the protein responsible for trafficking IL-12 at the immune synapse and the mechanism of its synaptic release are still unknown. The family of SNARE proteins, which regulate the membrane fusion process during the intracellular trafficking of soluble mediators, has emerged as the most informative for the identification of such pathways. Thus we have investigated the role of SNAREs in IL-12 secretion by DCs. These studies led to the identification of the lysosomal-late endosomal VAMP7 as a specific regulator in the polarized secretion of IL-12 during T cell priming. Furthermore VAMP3 was found to downregulate the production of all the cytokines tested, suggesting a role in TLR9 signalling pathway. SNARE proteins were also analysed in a model of tumour-tolerized DCs, in which the pattern of secreted cytokines is skewed. We analysed DCs *in vitro* (co-culture) and *in vivo* (spleen and tumour-bearing lungs) in a model of Lewis lung carcinoma (3LL) and found that tumour-exposed DCs downregulate all the SNAREs and in particular VAMP3. These observations suggest that regulation of trafficking proteins in DCs may represent a novel pathway targeted during immunosuppression.

P1.14.15
EMF Exposure Facilitates Wound Healing Events Modulating Cytokines Expression

E. Costantini*, G. Vianale, C. D'Angelo, R. Muraro, M. Reale; University G.D'Annunzio, Chieti, Italy.*

Background: During wound repair inflammatory cytokines are upregulated sequentially leading to the activation of keratinocyte growth and migration. IL-1, secreted by the injured keratinocytes, drives both keratinocyte activation and production of TNFα that maintain keratinocytes in their activated state. Activated keratinocytes are hyperproliferative and migratory. Previous studies showed that extremely low frequency electromagnetic fields (ELF-EMF) are able to regulate cytokine expression.
Objectives: On this basis the present study aimed to investigate the potential therapeutic use of ELF-EMF, evaluating, in HaCaT cells, the expression of cytokines that orchestrates successful wound.
Methods: HaCaT cells were starved for 24 h in serum-free, then wounded with a pipette tip to create a cell-free zone. HaCaT cells were exposed at 1 mT, 50Hz and compared to unexposed control cells. Wound healing was evaluated by measuring surface area, percentage and duration of healing. Cytokines expression was evaluated by RT-PCR in EMF-exposed and non-exposed HaCaT cells.
Results: After 24 hours the scratch area covered by keratinocyte was increased in EMF-exposed compared to non-exposed samples, in accord with the observed cell proliferation induced by EMF. Moreover, in EMF-exposed HaCaT expression of IL-1, TNFa, IL-18 and MMP-2 was increased and IL-10, IL-18BP and MMP-9 was decreased.
Conclusion: The ELF-EMF-enhanced expression of cytokines responsible for HaCaT proliferation and activation suggest an increased capacity of keratinocytes to reepithelialize the margin of wound avoiding the non-healing wounds. The ability of ELF-EMF to modulate cytokines expression highlights the potential therapeutic role of ELF-EMF in wound healing processes.

P1.14.16
Interleukin-1β micro-environment promotes viability and proliferation of malignant glioma cell U87MG

N. D Nanjaiah*, H. Fathima K, P. Ramaswamy; National Institute of Mental Health and Neurosciences, Bengaluru, India.*

Glioma is one of the most common and Glioblastoma (GBM) is most malignant tumours of the central nervous system. It is notorious for its highly proliferative, infiltrative and invasive behaviour. Despite substantial progress in early diagnosis and combined modality therapy including surgical therapy, radiotherapy and chemotherapy have failed to drastically change survival. Due to the invasive phenotype and diffuse penetration of glioblastoma cells into normal regions of the brain, patients diagnosed with GBM have mean survival of 10 to 12 months even with combined modality therapy. Their exceptional ability to proliferate and infiltrate normal brain makes complete radical surgical resection virtually impossible and leading in almost all cases to tumor recurrence. In human glioblastomas, pro-inflammatory cytokine IL-1β is expressed and secreted at high concentration. Objective of the current study was to study the role of IL1β on the glioma proliferation and cell viability. The human glioma cell line U87MG was cultured in 5% CO_2 and 95% humidified atmosphere air at 37°C in Dulbecco's modified Eagle's medium (DMEM), supplemented with 10% foetal bovine serum (FBS). Cells were trypsinized and 10^5 cells were incubated with 1 ng/mL IL-1β for 24 hours in serum free media. Cell viability was measured by Trypan blue dye exclusion assay and proliferation was analysed by MTT assay. We observed significant increase in viability of cells and proliferation of glioma cells in the microenvironment of IL-1β. We conclude that IL-1β promotes cell viability and proliferation of U87MG glioma cells.

P1.14.17
Clinical relevance of Cytokines Gene Polymorphism (CGP) in recovery of hemorrhagic shock patients

L. G. Dablu*, D. N. R. Rao, K. B. Sanjeev; AIIMS, New Delhi, India.*

Introduction: Severe trauma complicated with multiple organ dysfunction syndromes (MODS) are among the leading causes of deaths in intensive care units. Alarmingly, the mortality rate, owing to multiple causes e.g. multiple organ dysfunctions (MOD) with or without sepsis, is now reported to cross the value of 50% and thus need an immediate insight to overwhelm it. The cytokine levels and their associated gene polymorphisms are now contemplated as underlying cause for the severity of trauma.
Objective: This aims to examine if there exists any link between cytokine gene polymorphisms and outburst of pro-inflammatory/anti-inflammatory cytokines in the patients with various complications (sepsis/septic shock, MOF etc.) after traumatic injury.
Methodology: A total seventy trauma patients and fifty healthy controls were recruited in the study. The allèle, génotype, and haplotype fréquences of 13 cytokines gènes have been evaluated

using PCR-SSP. Cytokine concentrations in the individual patient's sera were determined by sandwich ELISA in a serum level dynamics up to 14 days.
Results and Conclusion: In septic patients, changes in the alleles and genotype frequencies in cytokines TGF-β (codon10), IL-10(-1082) and IL-6(-174) have emerged as major cause of sepsis and MOF related mortality. Thus, immune paralysis (IL-10 over expression) and Th17 (enhanced TGF-β/IL-6) concluded as putative cause of death in this study.

P1.14.19
Acute inflammation loci influence tissue repair in mice

T. Canhamero, M. Correa, J. G. Fernandes, A. Borrego, J. R. Jensen, W. H. K. Cabrera, O. G. Ribeiro, N. Starobinas, O. M. Ibañez, ***M. De Franco****;*
Instituto Butantan, Sao Paulo, Brazil.

AIRmax (high inflammation) and AIRmin (low inflammation) mouse lines homozygous for *Slc11a1 S* alleles, produced by genotype-assisted mating, differ in ability to completely repair ear holes. AIRmax^{SS} mice showed fast ear tissue regeneration while AIRmin^{SS} mice did not show regeneration after ear punch. In this work, two-millimeter ear holes were done in these mice for the characterization of inflammatory reaction. The local inflammatory response was more intense in AIRmin^{SS} than AIRmax^{SS} mice 24 and 48h after ear punch, which was demonstrated by histomorphometric analysis, multiplex assay for inflammatory cytokines such as IL-1β, IL-6 and MIP-2 and higher levels of MPO. Global gene expression analysis demonstrated distinct over-represented biological themes between AIRmax^{SS} and AIRmin^{SS} control mice. At 24h after punch, both AIRmax^{SS} and AIRmin^{SS} showed significant up-regulated genes related to inflammation. However, angiogenesis, epidermis development and collagen catabolic process were expressed only in AIRmin^{SS}. All down-regulated genes in response to wounding in AIRmax^{SS} were represented to muscle contraction which is known to be involved in healing with scarring. Microarray results were validated by qPCR. These results suggest that the degree of inflammatory response in the early events after injury drives tissue regeneration or wound healing after ear punch.
Supported by: FAPESP and CNPq.

P1.14.20
Content of IL-15 in patients with myalgic encephalomyelitis / chronic fatigue syndrome

N. Didkovski[1,2]*, I. Malashenkova*[1,2]*, I. Zuykov*[1]*, O. Gurskaya*[1]*, J. Sarsania*[1]*, G. Kazanova*[2]*, N. Hailov*[2]*, D. Ogurtzov*[2]*;*
[1]*Institute of Physico-Chemical Medicine FMBA Russia, Moscow, Russian Federation,* [2]*National Research Center "Kurchatovskiy Institute", Moscow, Russian Federation.*

Myalgic Encephalomyelitis/Chronic fatigue syndrome (ME/CFS) is considered as a neurological disorder with a dysfunction of the immune system. Patients have cognitive impairment, depression, sleep disorders, headaches and others. Previously we have found that the majority of patients with ME/CFS associated with herpes virus infection had reduced levels of IL-2. It is important to search biomarkers of ME/CFS and new approaches for the treatment. We studied the level of IL-15 - functional agonist IL-2.
IL-15 and proinflammatory cytokines: IL-1β, IL-8, IL-12 were measured by ELISA using BCM Diagnostics Ltd. 19 patients with ME/CFS associated with chronic herpes infection at the age of 22 to 51 years had a mixed infection: HHV 7 and/or HHV 6 and/or EBV in blood samples, saliva and oropharyngeal swabs measured by PCR. The comparison group consisted of 20 patients (21 to 50 years) with genital HPV infection. The control group: 18 healthy volunteers (20 to 45 years).
Results. Levels of IL-1β, IL-8 and IL-12 were increased or had a tendency to increase in patients with ME/CFS, and in the control group. The principal difference was observed in the level of IL-15. Thus, in patients with ME/CFS the level of IL-15 was lower than in the control group - 8,66 ± 0,93 pg/ml and 16,33 ± 2,1 pg/ml, ($p<0,05$), while in the control group the level was increased to 35,72 ± 4,22 pg/ml ($p<0,01$). Data obtained on the reduced level of IL-15, which has antiapoptotic effects, suggest its involvement in the pathogenesis of ME/CFS.

P1.14.21
Phagocytosis of apoptotic or necrotic cells differentially regulates the expression of IL-12 and IL-35 subunits in human dendritic cells

K. O. Dixon*, J. O`Flynn, S. van der Kooij, C. van Kooten;*
LUMC, Leiden, Netherlands.

Uptake of apoptotic or necrotic cells by dendritic cells (DC) is considered to have differential functional consequences, contributing to tolerance or immunity respectively. An important mechanism in this, is the regulation of IL-12 production. IL-12, a heterodimer composed of IL-12p40 and IL-12p35, belongs to a larger family of cytokines which share common chains. IL-35 is a potent immunosuppressive cytokine, consisting of IL-12p35 and Ebi3, which was initially demonstrated in regulatory T cells. Recently we showed that tolerogenic DC (tolDC) maintained expression of IL-12p35 and Ebi3, in the complete absence of IL-12p40.
When comparing tolDC with control immature DC(immDCs), we demonstrated an increased and accelerated uptake of apoptotic cells, which was not observed for necrotic cells. Culture of immDCs with necrotic cells was sufficient to induce IL-12p40 secretion. In contrast, ingestion of apoptotic cells by immDCs led to a strong increased expression of both IL-12p35 and Ebi3, without affecting IL-12p40. Moreover, apoptotic cells actively inhibited the production of IL-12 by DC following maturation. When investigating tolDCs, we found that challenge with apoptotic or necrotic cells did not further increase expression of Ebi3/IL-12p35, and IL-12p40 remained absent.
We conclude that uptake of apoptotic versus necrotic cells by DCs differentially regulates IL-12 family members, and that expression of IL-35 is favoured by apoptotic cells. Cellular therapy is a promising strategy to tailor immune responses in organ transplantation. Our study demonstrates that tolDC have an increased phagocytic capacity and a tolerogenic cytokine expression profile that is not affected by uptake of either apoptotic/necrotic cells.

P1.14.22
Immunoproperties of hypothalamic proline-rich polypeptides for antibacaterial immune response

A. Durgaryan*, M. Matevosyan, A. Galoyan;*
H.Buniatian Institute of Biochemistry, Yerevan, Armenia.

Antibiotic resistance and frequent occurrence of nosocomial infections and sepsis remain a major threat for infected people and hospitalized patients. A recent increase of multiresistant methicillin-resistant Staphylococcus aureus (MRSA) strains have developed resistance to started to pose great difficulty in selecting antimicrobial agents. In recent presentation we summarize the impact of hypothalamic neuropeptide PRP-1 also known as galarmin on adaptative immune response putative factors on cytokines and chemokines level both in methicillin-sensitive S. aureus (MSSA) and MRSA infection. Effects were analyzed in terms of animals secretion level for inflammatory markers such as IL-6, IL-8, IL-1b, IL-10, and keratynocyte chemoattractant (KC), and more detailed study was carried out to assay the level of IL-6 and macrophage inflammatory protein (MIP-2, CXCL2) at delayed stages of infection (72 hours post-infection). PRP-1 was compared with its structural analogues Gx-NH2, d-15 PRP-1 and dGx-NH2 to better understand the exact biochemical and biophysical properties required for its protective effect. PRP-1 and analogues stimulates higher production of both pro- and anti-inflammatory cytokines such as IL-6, IL-10, IL-1b, TNFa and KC at early stage of infection, and for more delayed period (72 hours post-infection) had significant impact on the plasma levels of the main markers of inflammation - IL-6 and MIP-2. Received data provide further insight into the intricate cytokine activity involved in the regulation of inflammatory responses and the control of bacterial infections and allow concluding that PRP-1 and its analogues are potential immunostimulatory agents for MRSA-induced infection prophylaxis and treatment in vivo.

P1.14.23
Targeting NO-driven Inflammation in Human Melanoma via IL-1s and CXCL-10

***S. Ekmekcioglu**, K. Tanese, Y. Qin, E. A. Grimm;*
University of Texas, M.D.Anderson Cancer Center, Houston, TX, United States.

An inflammatory microenvironment is an essential component of all tumors, including melanoma. We previously reported that the expression of inducible nitric-oxide synthase (iNOS) protein in melanoma tumor cells is strongly correlated with poor patient survival ($p< 0.001$) and is unrelated to the somatic mutations of BRAF, NRAS, and KIT. Therefore, we hypothesized that nitric oxide (NO) produced by iNOS promotes the inflammatory processes associated with poor outcome, and that attenuation of NO and associated effects would be beneficial. To approach testing this, we performed an inflammatory gene PCR array on a series of stage III melanoma of known iNOS-positive and iNOS-negative melanoma patient samples. Results indicated a series of differences including several folds of increase in IL-1β and decrease in CXCL-10, suggesting IL-1β as a marker of poor prognosis, and CXCL-10 as a marker of relatively better survival. Our functional studies revealed that treating iNOS-negative/CXCL-10-positive melanoma cell lines *in vitro* with a an NO donor reduced CXCL10; in contrast the scavenging of NO from iNOS-expressing cell lines increased expression and is hypothesized to potentiate the adaptive immune response. Our study suggests that an NO-driven carcinogenic inflammatory signature of increased IL1 α/β and decreased CXCL10 be targeted for therapeutic advantage in melanoma by reducing the production of NO in melanoma tumors.

P1.14.24
Interleukin 6 and interleukin 8 in maternal serum as markers of bacterial infection and preterm delivery

*□. **P. Erić**[1], V. Jerant Patić[2], M. Bogavac[3], A. Patić[2];*
[1]Faculty of Medicine Banjaluka, Banjaluka, Bosnia and Herzegovina, [2]Institute of Public Health of Vojvodina, Novi Sad, Serbia, [3]Clinical Center of Vojvodina, Novi Sad, Serbia.

Increased rate of preterm deliveries of pregnant women with intrauterine bacterial infections has been identified. IL-6 and IL-8 might stimulate release of prostaglandin, thereby causing preterm contractions and preterm delivery.
Goal is to examine relevance of the infection in occurrence of preterm contractions, as well as to investigate if preterm delivery is linked with increased concentration of IL-6 and IL-8 in maternal serum, as well as if measured values of the interleukins could be used in detection of early intrauterine infection and preterm delivery of pregnant women with the intact membranes.
In the experimental group, 34 of 53 pregnant women, or 64,2% had cervix infection, 26 pregnant women or 49% had positive urinal-culture, while 47 meaning 88,7% of pregnant women had bacterial vaginal infection. 14 pregnant women had all positive results, meaning 26, 4%. IL-6 has been found in blood of 37 pregnant women, meaning 70%. Average value of found IL-6 was 20,6+/-18,2 pg/ml.
IL-8 has been found in blood of 41 pregnant women, meaning 77%. Average value of found IL-8 was 11,2+/-7,3 pg/ml.
In the control group, IL-6 has been found in blood of 15 pregnant women, meaning 50%. Average value of IL-6 was 7,33+/-3,72 pg/ml. IL-8 has been found in blood of 17 pregnant women, meaning 57%, and its average value was 11, 6+/-7,5 pg/ml.
Direct linkage of bacterial infection and preterm delivery has been proven by this research. IL-6, IL-8 could be used as serum biomarker of bacterial infection and preterm delivery only combined with other interleukins.

P1.14.25
Constitutive STAT-3 activation with maintained responsiveness to IL-6 in peripheral lymphocytes of obese women

*D. H. Rhodes, V. Nguyen, M. E. Sullivan, S. L. Gomez, C. Braunschweig, **G. Fantuzzi**;*
University of Illinois at Chicago, Chicago, IL, United States.

Obesity is characterized by chronic low-grade inflammation, which increases risk of type 2 diabetes, cardiovascular disease, cancer and other pathologies. Inflammation in obesity is associated with chronically elevated levels of IL-6 and leptin, both of which signal through the STAT-3 pathway. A pathogenetic role for constitutively active STAT-3 has been demonstrated in chronic inflammatory diseases and cancer, with evidence indicating that activation of STAT-3 in leukocytes significantly influences the immune response. We investigated whether obesity is associated with alterations in STAT-3 activation in peripheral blood leukocytes. Forty women were divided into groups matched by age and ethnicity based on BMI. Plasma levels of IL-6, sIL-6R, sgp130 and leptin were measured by ELISA. Heparinized whole blood was stimulated with increasing concentrations of IL-6 (0-10 ng/ml) for 10 minutes and phosphorylation of STAT-3 (pSTAT-3) in lymphocytes evaluated by flow cytometry. Plasma IL-6 and leptin levels significantly increased with increasing BMI, as expected. However, plasma sIL-6R and sgp130 were not significantly different among groups. The percentage of unstimulated lymphocytes (no IL-6 added) positive for pSTAT-3 progressively increased with increasing BMI (6.1+/-1.5, 11.0+/-1.6, 19.1+/-3.0 and 20.4+/-2.1 with BMI 50, respectively; $p<0.001$). However, obesity did not alter the ability of lymphocytes to dose-dependently respond to IL-6 with activation of STAT-3. No significant differences among BMI groups were observed for basal or stimulated pSTAT-3 in the neutrophil/monocyte population. Our data suggest that constitutively active STAT-3 in obesity with maintained responsiveness to IL-6 may participate in determining the increased risk of chronic pathologies of obese individuals.

P1.14.26
Evaluation of the immunological reactivity of blood cells in early pregnancy for predicting of pregnancy outcomes

***I. Gazieva**;*
Mother and Child Care Ural Research Institute of Russian Public Health Ministry, Yekaterinburg, Russian Federation.

The aim: to evaluate the spontaneous and mitogen-induced production of cytokines in the early pregnancy, related to its outcome. The immunological assessment of 64 women in early pregnancy (4-12 weeks) was made. The first group consisted of 48 women whose pregnancies was complicated by compensated placental insufficiency. The second group - 60 women whose pregnancy was complicated by impairment of the fetoplacental circulation and/or fetal intrauterine growth restriction. The third group included 19 women whose pregnancy was terminated by early spontaneous abortion (before 12 weeks). The comparison group included 112 women with normal pregnancy. Spontaneous and mitogen-induced cytokine production by immune cells was determined ex vivo. It was demonstrated that the pathogenesis of placental insufficiency is associated with induced Th1-dependent immune response, characterized by increased mitogen-induced synthesis of IFN-γ and accompanied by overproduction of proinflammatory mediators. Compensated placental insufficiency was assotiated with a reduction in basal synthesis of IL-2 and increased stimulated production of IL-1β, IL-1Ra, and IFN-γ. The most significant immunological changes occur in early pregnancy terminated by spontaneous miscarriage: reduction of spontaneous production of factors with a pro-inflammatory and angiogenic effect (IL-2, IL-8 and TNF-a) as well as regulatory IL-10, and increase in induced synthesis IFN-γ, accompanied by overproduction of IL-2 and IL-8. Decreased production of tolerogen IL-10 in vivo may indicate the ineffective mechanisms which protected the fetus from maternal aggressive factors by activation of its immune system. Cytokine-producing dysfunction of immune cells may play a key role in endothelial hyperactivity, causing a thrombotic complications and abortion.

P1.14.27

Cytokine's concentrations and monocyte HLA DR expression as markers defining the therapeutic strategy in contemporary behavior in patients with acute pancreatitis

M. Georgi[1], *Y. Yovtchev*[1], *A. Petrov*[1], *S. Nikolov*[1], *T. Vlaykova*[2], *K. Halacheva*[3];
[1]*University hospital/Department of surgery, Stara Zagora, Bulgaria,* [2]*Trakian University/Department of Chemistry and Biochemistry, Stara Zagora, Bulgaria,* [3]*University hospital/Department of Immunology, Stara Zagora, Bulgaria.*

Acute pancreatitis (AP) has an incidence of approximately 40 cases per year per 100,000 adults. The mortality rate among patients with severe pancreatitis may approach 30% . The development of acute pancreatitis illustrates the requirement for understanding the basic mechanisms of disease progression to drive the exploration of therapeutic options.
Cytokines play a major role in the pathogenesis of AP as underlying systemic inflammatory response, tissue damage and organ dysfunction. Therefore, the determination of their concentrations could provide both early evaluation of severity,systemic complications and dynamic assessment of initiated treatment . However, little is known about circulating concentrations of these and other inflammatory cytokines and their real impact in clinical practice.
Several studies suggest that the prognosis for acute pancreatitis depends upon the degree of intensity of multisystem organ failure generated by the systemic inflammatory response. This suggests an intricate balance between localized tissue damage with proinflammatory cytokine production and anti-inflammatory response that restricts the inappropriate movement of proinflammatory agents into the circulation. Some of these mediators are markers for disease activity, whereas other inflammatory components may actually drive the disease process as important mediators. Implication of such mediators suggests that interruption or blunting of an inappropriate immune response has the potential to improve outcome. Full understanding of these basic mechanisms involves determining not only which mediators are present, but also closely documenting the kinetics of their appearance.

P1.14.28
Macrophage migration inhibitory factor as a regulator of neonatal innate immune responses

E. Giannoni[1], *M. Weier*[1], *L. Guignard*[1], *F. C. G. J. Sweep*[2], *T. Calandra*[3], *T. Roger*[3];
[1]*Service of Neonatology and Infectious Diseases Service, Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland,* [2]*Department of Laboratory Medicine, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands,* [3]*Infectious Diseases Service, Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland.*

Background: Newborn infants are characterized by a state of immunosuppression which puts them at risk for severe infections. MIF, a pleiotropic cytokine constitutively expressed in blood and immune cells, is an important regulator of innate immune responses. Here, we addressed the role of MIF in neonatal immunity by investigating the developmental profile of MIF expression and the impact of MIF on innate immune responses of newborn monocytes.
Methods: MIF plasma levels were measured by ELISA in 32 premature and 58 term newborns, 100 children (1 month-16 years) and 20 adults. Cord blood monocytes were transfected with MIF siRNA or incubated with the MIF antagonist ISO-1. Cytokines were quantified by ELISA/Luminex in cell-culture supernatants collected 18h after stimulation with endotoxin, bacterial lipopeptide, *Escherichia coli* and Group B *Streptococcus* (GBS).
Results: Circulating MIF levels were 10-fold higher in cord blood compared to adult blood (92.4±51.2 vs 7.1±3.8ng/ml, p<0.0001) and gradually decreased during childhood. Cord blood MIF levels correlated positively with gestational age and birthweight. Newborn monocytes expressed high levels of MIF, and released MIF upon stimulation with *Escherichia coli* and GBS. Inhibition of MIF expression with MIF siRNA or MIF activity with ISO-1 reduced 1.5-5.7-fold the secretion of pro-inflammatory (TNF, IL-1beta, IL-6, IL-8, IL-12p40, IL-12p70 and IL-23) and anti-inflammatory (IL-10, IL-20 and IL-27) cytokines by newborn monocytes exposed to microbial products.
Conclusion: MIF expression is developmentally regulated, with strikingly elevated levels in newborns compared to adults. High MIF levels at birth may act to balance the pro/anti-inflammatory immune responses in newborns.

P1.14.29
TNF-alpha, IL-4 and IL-10 cytokines induces changes in HO-1 and HDC expression in cervical cancer cells

P. Gomez-Lomeli, *P. C. Ortiz-Lazareno, A. Bravo-Cuellar, G. Hernandez-Flores, J. R. Dominguez-Rodriguez, L. F. Jave-Suarez, A. Aguilar-Lemarroy;*
CIBO-IMSS, Guadalajara, Mexico.

Background: Chronic infection with human papilloma virus (HPV) has been associated as an important factor in generating cancer. E6 and E7 viral proteins are involved in cell transformation. Likewise tumor cells generate escape mechanisms as the expression of molecules that regulate the immune response. HDC and HO-1 exert anti-apoptotic functions. These enzymes may represent another mechanism of resistance in cervical cancer cells.
Objectives: We analyzed the gene and protein expression of heme oxygenase (HO-1) and histidine decarboxylase (HDC) enzymes in HPV+ HeLa and SiHa cervical cancer cell lines and HPV- C33A cancer cells treated with TNF-α, I-4 and IL-10 cytokines.
Methods: HeLa, SiHa and C33A cervical cancer cells were treated with pro and anti-inflammatory cytokines; mRNA was extracted and analyzed expression of HO1 and HDC by real-time PCR. Protein expression was assessed by flow cytometry.
Results: Cytokines treatment induces a downregulation in HDC gene expression in HPV+ cancer cells in comparison with untreated tumor cells. In HeLa and SiHa cells this gene is downregulated whereas in C33A cancer cells we observed upregulation of HDC gene. In general HDC and HO-1 protein expression was reduced in cancer cells treated with pro and anti-inflammatory cytokines.
Conclusions: HDC and HO-1 protein expression is modified when the cells were treated with cytokines. In HeLa, SiHa and C33 cancer cells the expression of these enzymes is similar, however at the gene level the behavior is different between cancer cell lines, and this could be due to the presence of HPV infection in some cancer cells.

P1.14.30
To study the contribution of activated CD4+ and CD8+T cells arisen from B-T constructs of F1 and V antigens of Yersinia pestis for the antibacterial activity as an improved vaccine

G. Gupta[1], *D. Rao*[2];
[1]*All India Institute of Medical Sciences, Jodhpur, India,* [2]*All India Institute of Medical Sciences, New Delhi, India.*

Yersinia pestis, a Gram negative bacterium, is the etiological agent of pneumonic and bubonic plague. The current efforts are aimed at evaluating whether our vaccine protocol primes memory T cells that rapidly produce IFN-γ and/or perforin in response to peptide or conjugate stimulation.
In the present study, the secretion of IFN-γ and IL-4 by splenocytes, stimulated by different constructs of B and T cell epitopes of F1 and V antigens, was measured by ELISpot assay. We also measured perforin and IFN-γ expression as a function of cell mediated immunity by flow cytometry. We observed that three B-T constructs of F1 and seven B-T constructs of V antigens produced a high number of IFN-γ secreting cells as compared to native antigen and a low number of IL-4 secreting cells. B-T conjugates of F1 and V antigens showed significantly high ($p < 0.001$) percentage of $CD4^+$ IFN-γ+ cells as compared to $CD8^+$ IFN-γ+ cells.
Our study demonstrated that IFN-γ is an effector molecule of activated $CD4^+$ and $CD8^+$T cells arisen from B-T constructs of F1 and V antigens for the antibacterial activity as an improved plague vaccine.

P1.14.31
Resiniferatoxin exhibits anti-inflammatory property by inhibits pro-inflammatory mediators in endotoxin-challenged mice

***O. Gutierrez-Coronado**, J. Viveros-Paredes, M. Miranda-Beltran, M. Perez-Vega, C. Soria-Fregozo, P. Villalobos Gutierrez;*
Universidad de Guadalajara, Lagos de Moreno, Mexico.

Different chemical structural types of natural products exhibit anti-inflammatory activity and are considered to be potential drug candidates against the inflammation-related pathological processes. Vanilloids bind to the transient receptor potential type V1 (TRPV1) channels, nonselective cation ionophores that play an important role in integration of afferent noxious signals generated by inflammatory mediators. Resiniferatoxin (RTX) is an ultrapotent capsaicin analog showed pharmacological effect including anti-inflammatory activity. BALB/c mice were exposed to LPS application (250µg/100g) in order to evaluate the anti-inflammatory activity RTX. Five different groups were used: (i) control group (none stimulus); (ii) LPS; (iii) LPS-dexamethasone; (iv) LPS- RTX (20 µg/kg) and (v) vehicle control. Plasmas samples were collected and stored at -70ºC, 180 min after the last LPS or treatment administration. The ip administration of RTX provided a significant anti-inflammatory effect. 180 min after RTX administration, the pro-inflammatory cytokines (TNF-α and IL-1β) was significantly inhibited ($p<0.005$). Reduction in the nitric oxide levels was significantly ($p<0.001$), this results demonstrate the efficacy and therapeutic potential of RTX in inflammatory process and may be promising drug for targeted inhibition inflammatory diseases.

P1.14.32
Biomarkers of cardiovascular risk in psychiatric disorders

***A. Halaris**;*
Loyola Univ Medical Center, Maywood, IL, United States.

Cardiovascular disease (CVD) and depressive illness are two of the world's leading health problems. The most common types of CVD are coronary artery disease and cerebrovascular disease. CAD is a leading cause of morbidity and mortality in the industrialized world. Depressive illness is a very common disorder afflicting an estimated 120 million people worldwide. It is the leading cause of disability worldwide. Epidemiological studies have confirmed the high co-morbidity between these two entities and the co-morbidity is bidirectional. Systems accountable for this co-morbidity include the central and autonomic nervous systems, the neuroendocrine system, the immune system, and the vascular and hematologic systems. Pathophysiologic factors include homeostatic imbalance between the sympathetic and the parasympathetic systems with loss of heart rate variability in depression, sympathoadrenal activation, HPA activation resulting in hypercortisolemia, immune system dysregulation with release of pro-inflammatory cytokines and chemokines, platelet activation and hypercoaguability. These abnormalities have been demonstrated in individuals diagnosed with major depressive disorder. Inflammation also occurs in cardiac and cardiovascular pathology independent of the presence or absence of depression. A chronic pro-inflammatory status has been documented in numerous studies of depression and may extend beyond symptom remission. Inflammation is associated with endothelial dysfunction which is a preamble to atherosclerosis and atherothrombosis. Endothelial dysfunction has been detected in depression and may be a trait marker. Thus understanding vascular biology in conjunction with psychiatric co-morbidity is critical. I will present recent data of a pro-inflammatory status in depressed patients and ANS imbalance as reflected in diminished heart rate variability.

P1.14.33
miRNAs in Sera of Tunisian Patients discriminate between inflammatory Breast Cancer and non-inflammatory Breast Cancer

*K. Hamdi[1], D. Goerlitz[2], M. Islam[2], B. Neili[1], F. Ben Ayed[3], S. Chivi[2], C. Loffredo[2], I. Jilson[2], A. Benammar Elgaaied[4], J. Blancato[2], R. Marrakchi[1], **R. Triki**[4];*
[1]Laboratory of Genetics, Immunology and Human Pathology, Faculty of Sciences of Tunis, Tunis, Tunisia, [2]Lombardi Comprehensive Cancer Center, Georgetown University Medical Center, Washington, DC, United States, [3]Department of Medical Oncology, Hannibal International Clinic, Les Berges du Lac 2, Tunis, Tunisia, [4]faculté des sciences de Tunis, Tunis, Tunisia.

The microRNA (miRNA) is key regulators of gene expression. Recent studies have shown that aberrant expression of miRNAs has been implicated in many pathological conditions such as cancer and is associated with tumor invasivity, metastatic potential and clinical features of different types of cancers especially breast cancer. Our aim is to study the alteration of circulating microRNA levels in the model of breast cancer in an attempt to characterize the phenotype of inflammatory breast cancer (IBC).
We used quantitative PCR technology to evaluate the expression of 12 miRNAs (hsa-miR-5p, hsa-miR-3p, hsa-miR-320, hsa-miR-30b, hsa-miR-29a, hsa-miR-24, hsa-miR-15a, hsa-miR-548d-5p, hsa-miR-486-3p, hsa-miR-451, hsa-miR-337-5p, hsa-miR-335) in sera from 20 IBC and 20 non-IBC patients.
We identified a set of 4 miRNAs of which expression differed between IBC and non-IBC, making these miRNAs candidate markers for the IBC subtype.
In conclusions, our observations from this pilot study suggest that the altered levels of circulating miRNAs might have great potential for defining a molecular signature of IBC.

P1.14.34
Identification, function and mechanism of novel potential cytokines and membrane molecules of immune cells

***W. Han**, P. Wang, D. Ma;*
Peking University Center for Human Disease Genomics, Department of Immunology, Key Laboratory of Medical Immunology, Ministry of Health, School of Basic Medical Sciences, Peking University Health Science Center, Beijing, China.

Cytokines and membrane molecules are major mediators of the immune system. They have essential physiological and pathological roles. More importantly, many of them have been developed to be biomedical drugs. Therefore, it will be of great significance to identify novel potential cytokines and membrane molecules. In 1998, we characterized CKLF1 with chemotactic activity on leukocytes using SSH method. Based on *CKLF*, we identified another 8 genes named *CMTM1* to *CMTM8* using bioinformatic analysis and experimental validation. *CKLF* and *CMTM1-8* constitute the novel gene family CMTM. They have important roles in the immune and male reproductive systems, and participate in tumorigenesis. *CMTM3*, *CMTM5* and *CMTM7* are novel potential tumor suppressor genes. In 2008, we carried out genome-wide bioinformatics analysis as well as literature data mining to characterize novel potential cytokines and membrane molecules. Now, for novel potential cytokines, we obtained 212 candidates numbered 1#-212#, constructed the eukaryotic expression vectors of 121 genes and verified 36 secreted proteins, several recombinant proteins including VSTM1-v2, FAM19A4, TMEM98 et al. have modulatory effects on immune cells. For the membrane molecules, we focus on the expression and function of VSTM1-v1,TMIGD2,LRRC25 and TMEM154, which have characteristic expression profile and might involve the proliferation and differentiation of immune cells.

P1.14.35
The effect of type I and III interferons on the adrenal cortex in the context of autoimmune Addison's disease

A. Hellesen[1,2], *L. Breivik*[1], *K. Edvardsen*[1], *E. Husebye*[1,2], *E. Bratland*[1]; [1]*Department of Clinical Science, University of Bergen, Bergen, Norway,* [2]*Department of Medicine, Haukeland University Hospital, Bergen, Norway.*

Autoimmune Addison's disease (AAD) is caused by immune-mediated destruction of the adrenal cortices. Although the detailed pathogenesis of AAD remains elusive, autoantibodies and T cell responses towards 21-hydroxylase (21OH) of the adrenal cortex are often observed. IFN-α, IFN-β and IFN-λ are a set of cytokines typically induced by viral infections that have been implicated in several autoimmune conditions, like autoimmune thyroiditis, rheumatoid arthritis and type 1 diabetes. Also, treatment of hepatitis C virus infections with IFNα has been reported to trigger production of autoantibodies associated with autoimmune diseases, including antibodies against 21OH. This indicates that interferons may play a role in the induction and/or maintenance of autoimmune responses. To evaluate potential pathogenic effects of interferons in relation to AAD, we performed in vitro cell culture studies on the adrenocortical carcinoma cell line H295R. In accordance with a previous report, we found that the IFN-α/β receptor (IFNAR) was expressed in H295R cells and that stimulation with recombinant IFN-α and IFN-β induced apoptosis in a dose-dependent manner as measured by LDH release. Moreover, H295R cells expressed even higher basal levels of the IFN-λ receptor than IFNAR, and were sensitive to IFN-λ-induced apoptosis. Stimulation with either IFN-α, IFN-β or IFN-λ also upregulated MHC class I expression and sensitized H295R cells to poly (I:C)-induced chemokine secretion. The induction of these interferons in the adrenal cortex, e.g. by a local virus infection, could potentially contribute to AAD in susceptible individuals by the highlighted mechanisms.

P1.14.36
Immune Senescence in an Innate Immunity Drosophila model

A. M. Hernandez*, M. Tatar;*
Brown University, Providence, RI, United States.

Changes in the immune system are considered a hallmark of aging in many living organisms including mammals. As we age, the ability to fight off invaders decreases, yet components of the inflammatory pathway are upregulated with age, leading to low-grade chronic inflammation. The Fruit fly Drosophila Melanogaster provides a useful model inwhich to study changes in the innate immune system with age. The Drosophila malpighian tubule (MT) provides an isolated ex vivo system in which to dissect the different pathways playing a role in immunosenescence. Our studies suggest that, while the aging malpighian tubule is hyper-responsive to immune challenges, its capacity to respond effectively to these challenges is diminished. This hyperstimulation response is dependent on the NF Kappa B homolog Relish. We also show that physiologycal stresses such as dessication can elicit hyperstimulation.Underlying mechanisms include alterations in protein translation, stability, or secretion, and studies are underway to elucidate between these possibilities.

P1.14.37
Inverse susceptibility to liver and lung carcinogenesis in mouse lines genetically selected for acute inflammatory response

L. R. Carvalho[1], *W. H. K. Cabrera*[1], *A. Borrego*[1], *A. M. Santos*[2], *O. G. Ribeiro*[1], *J. R. Jensen*[1], *N. Starobinas*[1], *M. De Franco*[1], ***O. M. Ibañez***[1]; [1]*Laboratory of Immunogenetics - Instituto Butantan, São Paulo, Brazil,* [2]*Pathology Department, University of Brasilia., Brasilia, Brazil.*

Hepatocellular carcinoma (HCC) is the most common liver cancer in humans and many inflammatory diseases are risk factors for its development. AIRmax and AIRmin mouse strains were selected for maximum and minimum acute inflammatory responsiveness (AIR), respectively. Urethane induced both lung tumors and HCCs, with an inverse susceptibility to lung versus liver carcinogenesis in AIRmin and AIRmax mice. Herein, we used diethylnitrosamine (DEN), widely used in experimental hepatocarcinogenesis, and found that at 240 days after DEN treatment, most AIRmax male mice had multiple and large HCC and none or few lung tumors, whereas AIRmin male mice carried small lesions in the liver but multiple lung tumors. This inverse susceptibility was also observed in females but to a lesser extent. Early production of TNF-alpha, IL-1beta and IL-6 in liver after DEN treatment was correlated with tumor development in AIRmax mice. Transcriptome analysis of livers of untreated mice showed specific gene expression profiles in each line which may play a role in their differential susceptibility to HCC. These results demonstrate that the genetic control of AIR segregated in AIRmax and AIRmin mice modulates susceptibility to different types of cancer and highlight the role of local tissue cells in the control of immune responses to tumors. Financial support: FAPESP and CNPq (Brazil).

P1.14.38
Platelet-activating factor enhances tumor metastasis via the reactive oxygen species-dependent protein kinase CK2-mediated NF-kB activation

S. Im[1], *K. Kim*[1], *K. Cho*[1], *H. Kim*[1], *H. Lee*[2], *K. Jang*[2], *H. Kim*[3]; [1]*Chonnam National University, Gwangju, Republic of Korea,* [2]*Chonbuk National University Medical School, Jeonju, Republic of Korea,* [3]*Chonbuk National University, Medical school, Jeonju, Republic of Korea.*

Platelet-activating factor (PAF), which is a potent lipid mediator involved in a myriad of inflammatory reactions, promotes tumor metastasis via the activation of the transcription factor, NF-κB. In this study, we investigated the role of the protein kinase CK2 in PAF-induced NF-κB activation and tumor metastasis given that PAF has been reported to increase CK2 activity and CK2 plays a key role in NF-κB activation. PAF increased CK2 activity, phosphorylation, and protein expression in vivo as well as in vitro. CK2 inhibitors inhibited the PAF-mediated NF-κB activation and expression of NF-κB-dependent proinflammatory cytokines and antiapoptotic factors. Pretreatment with the antioxidants, NAC, resulted in a significant inhibition in PAF-induced enhancement of CK2 activity, phosphorylation, and protein expression in vivo as well as in vitro. H_2O_2 and the known reactive oxygen species (ROS) inducers such as LPS and TNF-α enhanced CK2 activity, phosphorylation, and protein expression, which was again inhibited by antioxidant. PAF-, LPS- and TNF-α-induced increased CK2 activity, phosphorylation, and protein expression were inhibited by p38 inhibitor. PAF, LPS or TNF-α increased pulmonary metastasis of B16F10, which were inhibited by antioxidant, CK2 inhibitor or p38 inhibitor. Our data suggest that ROS activates CK2 via p38, which, in turn, induces NF-κB activation, and 2) PAF, LPS and TNF-α increase pulmonary tumor metastasis via induction of ROS/p38/CK2/NF-κB pathway.

P1.14.39
Pathophysiological roles of the CX3CL1-CX3CR1 axis in chemical-induced skin carcinogenesis

Y. Ishida[1], *M. Nosaka*[1], *A. Kimura*[1], *Y. Kuninaka*[1], *M. Kawaguchi*[1], *N. Mukaida*[2], *T. Kondo*[1]; [1]*Wakayama Medical University, Wakayama, Japan,* [2]*Kanazawa University, Kanazawa, Japan.*

We explored the pathophysiological roles of the CX3CL1-CX3CR1 axis in chemical-induced two-step skin carcinogenesis model by using CX3CR1-/- mice. Both WT (C57BL/6) and KO mice were painted with DMBA (100 μg/200 μl acetone) followed by the treatment of TPA (30 μg/200 μl acetone) for 20 weeks. In the skin of WT mice, the gene expression of Cx3cl1 and Cx3cr1 was significantly enhanced at 2 and 10 weeks after treatment. Intradermal macrophages expressed both CX3CL1 and CX3CR1 after treatment. Moreover, CX3CR1 was also expressed by T cells and endothelial cells. In order to explore the pathophysiological roles of the CX3CL1-CX3CR1 axis in skin carcinogenesis, we monitored tumor growth in both strains. About 80% of WT mice developed papillomas by 16 weeks post-DMBA/TPA treatment, whereas less than 40% of CX3CR1-/- mice developed papillomas. The numbers of papillomas were significantly lower in KO mice than in WT ones. However, in CX3CR1-/- mice, epidermal hyperplasia was markedly impaired,

compared with WT mice. Recruitment of F4/80+ macrophage and CD3+ T cells was more evident in WT than in CX3CR1-/- mice. Moreover, intratumor vessel number was significantly less in KO mice than in WT ones. In skin carcinogenesis, several inflammatory mediators such as cytokines, chemokines, and COX-2 played important roles. In the skin samples of CX3CR1-/- mice after DMBA/TPA treatment, the gene expression of Cxcl1, Cxcl2, Il1b, Il6, Tnfa, and Cox2 was significantly attenuated, compared with WT mice. These observations implied that the CX3CL1-CX3CR1 axis was crucially involved in chemical-induced skin carcinogenesis.

P1.14.40
Inflammatory and cytotoxic effect of silver nanoparticles on human endothelial cells

***J. Jang**, I. Choi;*
Department of Microbiology, College of Medicine, Yonsei University, Seoul, Republic of Korea.

Due to silver's antimicrobial properties, silver nanoparticles are used in many biomedical applications. The main objective of this study was to elucidate the cellular effects on endothelial cell include cytotoxicity and cytokine production. The size-dependent cellular effects of silver nanoparticles (5, 20, 100 nm) were evaluated using EA.hy926 cells (human endothelial cell).
Silver nanoparticles and their cellular distribution were characterized by transmission electron microscopy (TEM). Cytotoxicity was measured by the cell counting kit-8 (CCK-8) assay. To quantify relative mRNA levels of the genes of interest in target tissue, real-time PCR was performed using primer/probe sets from FastStart DNA Master SYBER green. A total of 28,000 cDNA profiles were
screened using 5 nm, 20 nm and 100 nm silver nanoparticles in a EA.hy926 cell.
5 nm silver nanoparticles (LD_{50} = 0.89 μg/ml) were more cytotoxic on EA.hy926 cells when compared that of 20nm and 100 nm silver nanoparticles after 24h exposure. We selected four genes, intercellular adhesion molecule (ICAM), IL-1ß, IL-6, IL-8, and determined their mRNA levels. mRNA levels of genes increased significantly in the 5 nm exposure group. Also, using cDNA microarray, we found that 5nm silver nanoparticles induced the expression of specific mRNA after exposure.
Therefore, we provide important data to understand and identify the effects of silver nanoparticles on the immune system.
This research was supported by Nano · Material Technology Development Program through the National Research Foundation of Korea (NRF) funded by the Ministry of Education, Science and Technology (2009-0082417).

P1.14.41
Involvement of collagen receptor DDR2 in cytokine production by dendritic cells

***D. Kim**[1], B. Poudel[1], Y. Lee[2];*
[1]Deparment of Immunology, Medical School, Chonbuk National University, Jeonju-city, Republic of Korea, [2]Department of Oriental Pharmacy, College of Pharmacy, Wonkwang University, Iksan-city, Republic of Korea.

We investigated the mechanism involving collagen receptors in the production of cytokines by dendritic cells. Collagen type I induced the phosphorylation of discoidin domain receptor 2 (DDR2) and enhanced the phosphorylation of mitogen activated protein kinase (MAPK) kinases. NF-κB binding activity was enhanced when the cells expressing NF-κB reporter were exposed to collagen I. In addition, Collagen I enhanced the IL-12 luciferase activity on DDR2 expressing cells compared to empty vector control. Moreover, when IL-12 reporter transfected cells were treated with biochemical inhibitors of c-Jun N-terminal kinase (JNK) and NF-κB, collagen-induced IL-12 promoter activity was significantly downregulated in comparison to non-treated cells. Similarly, confirmatory experiments on murine dendritic cells revealed that IL-12 promoter activity is downregulated upon NF-κB and JNK inhibitor treatment on collagen I stimulation in dose dependent manner. These results suggest that DDR2 is involved in the collagen I-induced gene expression in dendritic cells via NF-κB and JNK signaling pathway.

The prenylated flavonoids and 2-arylbenzofurans from the root barks of *Morus alba* inhibit airway inflammation

***H. Kim**[1], H. Lim[1], J. Lee[1], H. Jin[2], E. Woo[3], S. Lee[4];*
[1]College of Pharmacy, Kangwon National University, Chunchon, Republic of Korea, [2]College of Pharmacy, Chosun university, Kwangjoo, Republic of Korea, [3]College of Pharmacy, Chosun University, Kwangjoo, Republic of Korea, [4]College of Pharmacy, Seoul National University, Seoul, Republic of Korea.

It is sometimes difficult to successfully control airway inflammation including chronic bronchitis (one form of chronic obstructive pulmonary diseases). In the present study, for finding new alternative agent against airway inflammation from the herbal medicine and to establish the scientific rationale in clinical use, the root barks of *Morus alba* and its major constituents (flavonoids: kuwanone E, kuwanone G, norartocarpanone, 2-arylbenzofurans: moracin M, moracin O, moracin R, mulberrofuran G) were for the first time examined for their pharmacological activity against lung inflammation. On lipopolysaccharide (LPS)-induced airway inflammation in mice, the total ethanol extract of *M. alba* clearly inhibited bronchitis-like symptoms at 200 - 400 mg/kg/day by oral administration when judged by inflammatory cell infiltration, cytokine levels in BALF and histological observation. When the pharmacological activity of the isolated constituents were examined, the flavonoids inhibited IL-6 production in IL-1-treated lung epithelial cells (A549) and NO production in LPS-treated lung macrophages (MH-S) at concentration ranges of 50 - 100 μM. In addition, 2-arylbenzofurans also showed strong inhibitory action on the same parameters. Among the constituents, moracin M showed a highest inhibitory activity (IC_{50} < 10 μM) in IL-6 production of A549 cells and mulberofuran G exhibited strong inhibition (IC_{50} = 28 μM) in NO production of MH-S cells. Taken together, it is concluded that *M. alba* and the major prenylated flavonoid and 2-arylbenzofuran constituents have a potential for new agents to control lung inflammation including bronchitis.

Dynamic cross-talk model of innate immune response to double-stranded RNA: order emerging from noisy cell responses

*R. Bertolusso[1], B. Tian[2], Y. Zhao[2], L. Vergara[2], A. Sabree[1], M. Iwanaszko[3], T. Lipniacki[4], A. R. Brasier[2], **M. Kimmel**[1];*
[1]Rice University, Houston, TX, United States, [2]University of Texas Medical Branch (UTMB), Galveston, TX, United States, [3]Silesian University of Technology, Gliwice, Poland, [4]Institute of Fundamental Technological Research, Polish Academy of Sciences, Warsaw, Poland.

Using experimentation and mathematical modeling, we discovered an intricate and logical pattern of dependencies in the dynamics of the innate immune response (IIR) to double stranded RNA. Dynamics involves crosstalk between the two major effector arms of the IIR: the NF-κB and IRF3 transcription factors that mediate inflammation and antiviral responses respectively. We related the highly variable response of individual cells to the coordinated response of the cell population. We found that, whereas TNFAIP3 and IκBα are purely NF-κB driven genes and ISG54 expression is purely controlled by IRF3, the RANTES and IFNβ expression is dependent on both NF-κB and IRF3. Further, NF-κB /RelA is negatively regulated by the IRF3 signaling pathway, and RelA also negatively regulates IRF3 expression. The computational model can be used in future exploration of the connectivity and dynamics of the IIR. Our work supports the hypothesis that the IIR is an "emergent phenomenon" that has evolved despite highly variable responses at individual cell level.

P1.14.44
Interleukin-33 promotes proliferation of primary human lung fibroblasts

A. Bocharov, ***O. Kornilova****;*
National University of Pharmacy, Kharkov, Ukraine.

Interleukin (IL)-33 is a multifunctional cytokine that belongs to the IL-1 cytokine family and expressed by multiple organs and cell types in humans and mice. Recent studies have showed that IL-33 plays an etiological role in several fibrotic disorders and may be involved in the pathogenesis of chronic respiratory diseases, such as asthma, and pulmonary fibrosis. It has been reported that IL-33–induced cutaneous fibrosis is associated with increased fibroblast proliferation and altered expression of extracellular matrix-modifying genes. However, the role of IL-33 in regulating of functions of lung fibroblasts remains unclear. In the present study, we examined the effect of recombinant human IL-33 on proliferation of human lung fibroblasts.
Five primary lines of normal adult human lung fibroblasts were cultured for 3-7 days in the presence of increasing concentrations of IL-33 (1, 2, 10, 50, 100 and 300 ng/ml). The proliferation of human lung fibroblasts was analyzed using non-radioactive cell proliferation assay (MTT).
We have observed that normal human lung fibroblasts responded, in a dose-dependent manner, to treatment with recombinant human IL-33, by increasing proliferation rates 1.5- to 2.3 fold compared with non-stimulated control. The maximum effect of IL-33 on fibroblast proliferation was observed in cytokine concentrations range from 2 ng/ml to 100 ng/ml. These results suggest that IL-33 may play an important role in the regulation of human lung fibroblast proliferation. Human lung fibroblasts activated by IL-33 may act as effector cells not only in the pathogenesis of lung diseases but also in lung remodeling processes.

Features of the allergic drug reactions in Russian patients: perspectives of a DNA bank development

I. Kukes*, T. Borisova;*
Sechenov First Moscow State Medical University, Moscow, Russian Federation.

INTRODUCTION:
Nowadays, in various scientific world literatures discuss the possibility of association gene's polymorphisms with the development of allergic drug reactions for different groups of drugs.
MATERIALS AND METHODS:
We analyzed anamnesis of 455 patients, 352 - women (mean age 48,39; SD = 15.86) and 102 men (mean age 44,50; SD = 15,72) [p = 0.0299, t = 2.178], who had a history of various allergic drug reactions, in anamnesis, with various diseases.
RESULTS:
The analysis revealed that the most common drugs, which have resulted in the development of allergic drug reactions previously, were penicillin antimicrobials - 93 patients (20.5%), local anesthetics - 36 patients (8%), NSAIDs, and NSAIDs 34 patients (7.5%).
Also, we noted the combinations of drug groups, which have resulted in the development of allergic drug reactions previously. The combination of penicillin and cephalosporin antimicrobials, and the combination of penicillin and aminoglycosides antimicrobials found in 13 patients (3%). The combination of penicillin antimicrobials with sulfonamides found in 17 patients (4%), and combination of penicillin antimicrobials with local anesthetics found in 18 patients (4%).
CONCLUSIONS:
Nowadays researches of polymorphisms associated with drug allergy conducted on a single group of drugs. Based on this data, the research of polymorphisms of genes, which are associated with the development of an allergic reaction to the drugs, should be carried out for combinations of penicillin and aminoglycosides antimicrobials, as the same cephalosporin antimicrobials, sulfonamides, local anesthetics.

P1.14.46
HMGB1 in an experimental model of acute lung injury

C. S. Kurokawa*[1], J. R. Fioretto[1], J. P. Araújo Junior[2], R. B. Pires[1], M. A. Moraes[1], R. C. Bonatto[1], M. F. Carpi[1];*
[1]Botucatu Medical School - UNESP, Botucatu, Brazil, [2]Botucatu Bioscience Institute - UNESP, Botucatu, Brazil.

Despite recent therapeutic advances in acute respiratory distress syndrome (ARDS), its physiological and immunological aspects have not been completely understood. Recently, HMGB1, a nonhistone, chromatin-associated protein and a cytokine produced by macrophages, has been associated with sustained inflammatory response after injury or infection of tissue and lung injury. The aim of the study was to measure HMGB1 levels in rabbits with acute lung injury (ALI) induced by tracheal infusion of warm saline.
Methods: Thirty rabbits were instrumented and randomly assigned into two groups: 1) animals with no ALI (Control Group-CG; n = 15); 2) animals with severe ALI (SG Group; n = 15). The groups were ventilated during 4 hours with protective conventional mechanical ventilation (CMV). After ventilation, HMGB1 levels from bronchoalveolar lavage fluid (BAL) and plasma were measured as well as the percentage of white cell from BAL. Left lung was collected for histopathology analysis.
Results:Lung injury decreased pulmonary compliance (SG before: 1.86±0.576 > SG after: 0.67± 0.24) and oxygenation (PaO2 - SG before: 427.92 ± 89.90 > SG after: 68.18 ± 19.08). Percentage of neutrophil (p=0.001) and lung injury score were higher in SG than CG. Higher levels of HMGB1 in BAL were found in SG as compared to CG group [SG: 62 (20.30-79.41) > CG: 15.60 (13.86-25.81); p<0.035]. No statistically significant difference was found in HMGB1 plasmatic levels when groups were compared.
Conclusions:HMGB1 is released earlier in alveolar space in acute lung lesion induced by warm saline and can contribute to the pathogenesis of ALI.

Prone positioning attenuates TNF-alpha production in rabbits with lung injury under protective conventional mechanical ventilation (CMV).

C. S. Kurokawa*[1], R. B. Pires[1], J. R. Fioretto[1], S. O. Klefens[1], J. P. Araújo[2], M. A. Moraes[1], A. M. Lousada[1], R. C. Bonatto[1], M. F. Carpi[1];*
[1]Botucatu Medical School - UNESP, Botucatu, Brazil, [2]Botucatu Bioscience Institute - UNESP, Botucatu, Brazil.

Prone positioning (PP) improves arterial oxygenation, gas exchange, distribution of ventilation toward dorsal lung areas, redirection of compressive forces on lung and facilitates secretion clearance in patients with ADRS. However, the exact mechanics of PP is still under investigation. The aim of this study aims was to measure TNF-alpha levels in rabbits with experimental ARDS under CMV and PP.
Methods: Rabbits were anesthetized, intubated and assigned into three groups: 1) Control Group(CG)- animals without lung injury under CMV in supine position; 2) Prone Group (PG)- animals with lung injury under CMV in prone position; 3) Supine Group (SG)- animals with lung injury under CMV in supine position. Lung injury was induced by tracheal infusion of warm saline. The parameters evaluated were: TNF-alpha in homogenate of lung tissue, bronchoalveolar fluid (BAL) and plasma; histological and cytological analysis of lung tissue and BAL, respectively. Results: Lung injury decreased oxygenation { PaO2 - PG before[median (p25-p75)]: 451 (412- 504) > PG after: 67 (59-76), p SG after: 76 (59-87); p SG: 24,1 (8,1-55,55); p<0,05}. There is no difference of serum and BAL TNF-alpha levels, histopathological lung injury score and BAL neutrophil percentage between PG and SG. Conclusions: Prone positioning with CMV decreased TNF-alpha production in lung tissue in this experimental model.
Fapesp grants: 2011/15144-2 and 2010/19590-4

P1.14.48
A potential role for the X chromosome in the CD99 expression and proinflammatory cytokine secretion in response to TLR ligands

N. Lefèvre[1], *F. Corazza*[2], *J. Duchâteau*[2], *A. Delbaere*[3], *G. Casimir*[1];
[1]*Hôpital Universitaire des Enfants Reine Fabiola, Brussels, Belgium,* [2]*CHU Brugmann, Brussels, Belgium,* [3]*Hôpital Erasme, Brussels, Belgium.*

In order to evaluate the role of the X chromosome in innate immunity, we studied immune functions depending on X-linked genes in adults of both sexes and patients with sex chromosome aneuploidy.
CD99 expression on monocytes and lymphocytes was higher in women (XX) compared to Turner patients (X0) as well as in Klinefelter patients (XXY) compared to men (XY). CD99 expression was strongly correlated to the number of sex chromosomes, indicating a sex chromosome dose effect on the CD99 expression. In response to LPS 1 ng/mL, monocytes produced less IL-1β, IL-6 and TNF-α in Klinefelter patients compared to men as well as less IL-1β but more IL-8 in response to zymosan, a TLR_2 ligand. We also observed a lower IL-6 production by neutrophils of Klinefelter patients compared to men in response to LPS 1 ng/mL and a higher IL-8 production in response to R848, a $TLR_{7/8}$ ligand. We did not observe any difference in cytokine production between Turner patients and women, probably due to the high rate of mosaics among Turner patients. 17β-estradiol was higher in Klinefelter patients than in men although the range of difference is probably not biologically relevant. In conclusion, our study highlighted important differences in men carrying an extra X chromosome in terms of the innate immune response through expression of a diapedesis marker and secretion of inflammatory cytokines in response to TLR activation. These differences suggest a role for the X chromosome in sex-specific responses to acute inflammatory challenge, independently on hormonal impregnation.

P1.14.49
Study of immunosenescence through the production of cytokines by blood monocytes

H. G. Lima*, P. Freitas-Faria, K. H. Pinke, M. P. P. Nascimento, N. A. Vieira, V. C. Porto, V. S. Lara;*
Bauru School of Dentistry, University of São Paulo, Bauru, Brazil.

Aging is a complex process that affects a variety of physiological functions, one of the most important biological changes is termed 'immunosenescence' characterized by a functional decline in immunity leading to a progressive immunodeficiency. Currently, there is evidence to show changes in cytokine production, as well as differences in the number, function and activation of monocytes of elderly in relation to young, although some data are contradictory. It is known also that elderly subjects show an imbalance between inflammatory and anti-inflammatory networks, which results in the low grade chronic pro-inflammatory status called inflammaging. Thus, this study evaluated in vitro the cytokine production by monocytes, challenged or not with lipopolysaccharide (LPS) for 18 hours, obtained from peripheral blood of elderly and young subjects. Later, the supernatants were submitted to the enzyme-linked immunosorbent assay for determination of the pro-inflammatory cytokines tumor necrosis factor-alpha (TNF-α), interleukin-6 (IL-6), and anti-inflammatory cytokines IL-10 and transforming growth factor-β (TGF-β). Our results demonstrated that the stimulation with LPS resulted in significantly higher levels of cytokines TNF-α, IL-6 and IL-10, compared with unstimulated monocytes, regardless of age. Comparing young and elderly, the monocytes from elderly showed a lower spontaneous production of TGF-β. Thus, the elderly have not impairment in the production of TNF-α, IL-6 and IL-10 by monocytes, even after challenged with LPS. However, the low production of TGF-β may corroborate state inflammaging, predisposing old persons to numerous diseases, infectious or neoplastic.

P1.14.50
Roles of IL-22 in the innate immune of chronic hepatitis B

Y. Zheng[1], ***Z. Liu***[2], *M. Li*[2], *J. Zhang*[1], *Q. Jing*[1], *K. Feng*[1], *J. Zhang*[1];
[1]*Department of Pathology and Experimental Medicine, 306 Hospital, Beijing, China,* [2]*Department of Medical administration, 306 Hospital, Beijing, China.*

Hepatitis B is a worldwide health problem since it has affected more than 300 million individuals and the number increases gradually year by year. Therefore, it is urgent to investigate the exact pathogenic mechanism of hepatitis B virus (HBV) and find out an effective target to interfere with HBV adhering to hepatocytes and restore the function of the infected hepatocytes. In this study, we analyzed the effects of IL-22 on the immune of liver and the origins of IL-22 in patients with chronic hepatitis B, aimed to find out what roles does IL-22 play in chronic hepatitis B and what is its mechanism. ELISA used to measure the serum concentration of IL-22. Real-time PCR and Immunohistochemical staining were used to detect the expressions of IL-22, IL-22RA1 and IL-22BP in the liver. After that, confocal microscope imaging and flow cytometric analysis were used to confirm the origins of IL-22. IL-22 expression in liver was up-regulated in hepatitis B ($P<0.05$) and it mainly produced by γδT and NKT cells. However there was no significant difference in serum concentration. Conclusively, IL-22 plays important roles in the innate immune in the liver of chronic hepatitis B patients.

P1.14.51
TNF, autoantibodies and soluble receptors to TNF in health and rheumatoid arthritis

J. A. Lopatnikova*, E. A. Golikova, N. S. Shkaruba, A. E. Sizikov, S. V. Sennikov;*
Research Institute of Clinical immunology, Siberian Branch of the Russian Academy of Medical Science, Novosibirsk, Russian Federation.

Tumor necrosis factor (TNF) is an important immunoregulatory cytokine with broad action spectrum. In addition, important place occupy molecules that regulate cytokine activity: membrane-bound and soluble receptors to TNF and autoantibodies. Objectives: to determine a possible contribution of autoantibodies to TNF in rheumatoid arthritis (RA) pathogenesis.
The protocol includes a set of affinity chromatography methods and a magnetic separation procedure to obtain a fraction of specific autoantibodies to TNF. The pure fractions of autoantibodies to TNF obtaining from human serum were used as a calibration material for the determination of the absolute content of autoantibodies to TNF by ELISA.
We have shown a significant increase in contents of TNF and soluble receptors in blood serum of RA patients at the acute stage and RA patients responded to therapy in comparison with healthy donors. It has been shown the significant increase in autoantibodies contents of IgG2, IgG3 and IgG4 subclasses in blood serum of RA patients at the acute stage in comparison with healthy donors, as well as the significant increase in contents of IgG2 and IgG4 subclasses in blood serum of RA patients at the acute stage in comparison with RA patients responded to therapy.
It has been shown change of contents not only of soluble receptors and cytokine itself but also autoantibodies to TNF in blood serum of healthy donors and RA patients. In this case taking into consideration significant changes of levels of autoantibodies to TNF sub-classes we might suppose that they make a contribution to RA pathogenesis.

P1.14.52
Markers of cellular damage, inflammation and apoptosis in a model of endotoxic shock

*J. Martinez Castillo[1], D. Cid Guerrero[1], I. Vargas Rodriguez[1], S. H. Sanchez Rodriguez[1], R. M. Ramirez Santoyo[2], G. G. Guerrero M[1], **E. E. Lopez Robles**[1];*
[1]Lab de Biologia Celular. Unidad Academica de Ciencias Biologicas, Zacatecas, Mexico, [2]Departamento de Enfermedades Infecciosas. Unidad Academica de Ciencias Biologicas, Zacatecas, Mexico.

Immunological process at central nervous system (CNS) have been studied under a large number of stimuli. Preliminary results by us have indicated that cytotoxicity could be generated by certain inflammatory mediators secreted by the same brain cells in a model of endotoxic shock. However, it remains to determine in this model whether exacerbated TNFα production might affect the release of anti-inflammatory cytokines (i.e. IL-4) as well as FasL. In this work, expression of markers of cellular damage, inflammation and apoptosis was investigated. Using indirect immunofluorescence (IFI), it was found that TNFα and FasL mark intensity was significant at 60 and 120 min, but decreasing at 270 min; while caspase3 mark intensity increased during times. By ELISA assay, concentration of FasL was determined. It was 10 times greater than TNFα, reaching its maximum induction at 270 min (22082.8 pg/ml, while TNFα reached its maximum value at 60 min (844.8pg/ml). The concentration of IL-4, showed maximum value at 30 min (331pg/ml); and IL-10 at 270 min (386.47pg/ml). TNFα, FasL and caspase3 expresion detected by IFI suggest that dead of cells is caused by apoptosis, concomitant with the presence of chromatin condensation and apoptotic bodies, as observed by Wright stain. However, we cannot discard cell death by necrosis and pyknosis. Our results suggest that TNFα expression influences FasL, IL-4 and IL-10 induction since the kinetics of the concentrations of these proteins are closely related to TNFα expression.

P1.14.53
Human acidic mammalian chitinase (AMCase); molecular cloning, protein expression, and production of monoclonal antibody

***K. Lowhalidanon**, P. Meekrathok, S. Thongsom, W. Suginta, P. Khunkaewla;*
Suranaree University of Thechnology, NakhonRatchasima, Thailand.

Human acidic mammalian chitinase (AMCase), is a 50 kDa protein containing a 30 kDa N-terminal catalytic domain that can hydrolyze chitin. This enzyme belongs to family 18 glycosyl hydrolases. High abundant of this enzyme was found in gastrointestinal tract. In lung, interleukin-13 was proposed to play a key role as primary effector that induces secretion of AMCase by airway epithelial cells and macrophages. The secreted AMCase activates elevation of monocyte chemoattractant protein 1 (MCP-1) and eotaxin-1, which induce the recruitment of eosinophils, T cells, and macrophages to site of inflammation in lung epithelial cells. Nonetheless, the mechanisms underlying AMCase mediated cells recruitment and its surface receptor have not been identified. Present study, the gene encoding AMCase was isolated from the human cDNA, cloned into pQE-tri vector, and the recombinant protein was expressed in E. coli M15. The affinity-purified AMCase was further used as immunogen for monoclonal antibody (mAb) production by standard hybridroma technique. Two specific mAbs against AMCase were successfully raised and named as 4G1 and 6E5. Both monoclones belong to IgG1 isotype. Western blot analysis showed that the mAbs strongly reacted with a corresponding protein with molecular weight of about 50 kDa in human acute monocytic leukemia cell line, THP1, and peripheral blood mononuclear cells. In conclusion, the AMCase was cloned and expressed in E. Coli system. Two specific mAbs to AMCase were raised and specifically reacted to human AMCase. The generated mAbs will be used for further functional analysis of the AMCase in regulation of the immune system.

P1.14.54
CTRP4 Plays an Important Role in Endotoxin Shock

***Y. Luo**, W. Tan, Z. Ma, L. Wang, D. Na, X. Wu, Y. Chen, Y. Zhang, D. Ma, L. Wang;*
Laboratory of Medical Immunology, School of Basic Medical Science, Peking University Health Science Center, Beijing, China.

CTRP4, as the fourth member of C1q/ TNF superfamily, was discovered and named by Harvey Lodish in 2004.
In 2011, it was for the first time that our laboratory reported the function of CTRP4 to the world, and we conducted the functional studies mainly in HepG2 cells. We found that CTRP4 was a classical secretory protein. Both overexpression of CTRP4 and addition of rhCTRP4 protein with the concentration of ng/ml could increase the expression of IL-6 and activate NF-κB and STAT3 signaling pathway.
At present, we conduct our studies in immune system. Bioinformatics analysis revealed that the globular structure of CTRP4 was similar to that of C1q. Our studies found that the CTRP4 interacted with LPS directly to inhibit the interaction of LPS and its receptors in vitro, and then inhibited the release of IL-6 and TNF-α, which were induced by the stimulation of LPS. Furthermore, we generated CTRP4 transgenic mice, and we found that the mice were less hyposensitive to endotoxin shock, induced by LPS, and could survive a higher dose of LPS than wild mice. In the endotoxin shock models, CTRP4 transgenic mice had a higher survival rate with significant difference ($p<0.01$). Finally, we found that adding LPS to RAW264.7 cells could inhibit expression of endogenous CTRP4.
In summary, CTRP4 might be a new inhibitor of LPS, and it might play an important role in endotoxin shock. There are some possibilities that CTRP4 has the potential clinical application value.

P1.14.55
Endothelial cells enhances chemokines and reduces inflammatory cytokines release by human monocyte in vitro

***I. Mancilla-Herrera**[1,2], J. Alvarado-Moreno[3], S. Estrada-Parra[4], C. López-Macías[1], A. Isibasi[1], L. Arriaga-Pizano[1];*
[1]Unidad de Investigación Médica en Inmunoquímica. Hospital de Especialidades. Centro Médico Nacional Siglo XXI, IMSS, Mexico City, Mexico, [2]Escuela Nacional de Ciencias Biológicas, IPN, Mexico City, Mexico, [3]Unidad de Investigación Médica en Trombosis,Hemostasia y Aterogénesis. Hospital General Regional Dr. Carlos Macgregor Sánchez Navarro, IMSS, Mexico City, Mexico, [4]Laboratorio de Inmunología Molecular I, Departamento de Inmunología, ENCB-IPN. México D.F, Mexico City, Mexico.

During inflammatory response, recruiting monocytes interact with activated endothelium, both by soluble mediators and direct contact. However, it is unknown if inflammation related functions, as cytokines-chemokines released change after leucocyte migration through endothelium. Our aim was, using an in vitro migration model, to determine the response to inflammatory inducer of human monocyte which have or not have contact with endothelial cells (EC). METHODOLOGY: Isolated human monocytes (ME) that migrated across activated human umbilical vein endothelial cells (activated-IL-1beta ECs) were stimulated with 10 ng of E. coli lipopolysaccharide (LPS), 50 ng of peptidoglycan (PG) or 50 ng of poly I:C during 8 hours. IL-6,TNF,IL-8,IL-10,IL-1β and IL-12, CXCL8/IL-8,CCL5/RANTES,CXCL9/MIG,CCL2/MCP-1 and CXCL10/IP-10 were quantified in supernatant using cytometric beads arrays. Controls include non-migrating monocytes exposed(MS) or not(M) with supernatants of activated ECs. RESULTS: Supernantants from LPS and PG stimulated MS or ME monocytes, show reduced IL-6, IL-1β and TNF concentration compared to LPS and PG stimulated M monocytes (Normalized results from unstimulated monocytes LPS: IL-6 -M: x1.62, MS: x1.14, ME: x0.78, IL-1β-M: x1.86, MS x1.08, ME: x0.70, TNF-M: x2.20, MS x1.18, ME: x0.75, PG: IL-6-M x1.33, MS x1.07, ME: x0.91, IL-1β-M: x1.59, MS x0.87, ME: x0.70, TNF-M: x1.85, MS: x1.21, ME: x0.82). Additionally, IL-8 and MCP-1 levels increased in both LPS stimulated and non-stimulated ME monocytes (IL-8: MvsME 286.67±89.23vs 2912.97±53.00pg/mL, MCP-1: MvsME 93.035±40.23vs594.04±361.75pg/mL). CONCLUSION: Contact with endothelial cells modulates human monocytes toward a recruiting profile over cytokines mediated inflammatory response.

Pro-inflammatory cytokines analysis in HPV-positive cancer cells

G. Mangino[1], *S. M. Zangrillo*[1], *V. M. Chiantore*[2], *M. Iuliano*[1], *M. Severa*[2], *G. Fiorucci*[2,3], *E. M. Coccia*[2], *G. Romeo*[1,3];
[1]*Sapienza University of Rome, Latina, Italy,* [2]*Istituto Superiore di Sanità, Rome, Italy,* [3]*Consiglio Nazionale delle Ricerche, Rome, Italy.*

Recent data have expanded the concept that inflammation is a critical component of tumor progression. Many cancers arise from sites of infection, chronic irritation and inflammation. It is becoming clear that the tumor microenvironment is an indispensable participant in the neoplastic process, fostering proliferation, survival and migration. In addition, tumor cells have co-opted some of the signalling molecules of the innate immune system, such as selectins, chemokines and their receptors for invasion, migration and metastasis. Virus-induced tumors, like cervical high risk Papillomavirus-induced Squamous Cell Carcinomas (SCC), represent a paradigmatic example of the tight interplay between inflammatory responses and malignant transformation as inflammation is an integral part of the innate antiviral response.
To establish a tumorigenic role of inflammatory mediators in HPV-positive SCC, we analysed by real time RT-PCR the expression of inflammatory cytokines, chemokines and related molecules (i.e. IL-1α, IL-1β, IL-1RA, IL-1R1, IL-6, IL-8, MIP-1α and MIP-1β) in several HPV-positive carcinoma cell lines as well as in HPV-negative SCC (i.e. C33A). We also analysed human foreskin keratinocytes transduced by E6 and E7 from mucosal (HPV-16) or cutaneous (HPV-38) genotypes.
Our results indicate that in HPV-positive SCC the level of IL-1β mRNA is augmented compared to HPV-negative SCC. Interestingly, despite huge increase in mRNA levels, these cells didn't secrete any IL-1β. On the other hand, IL-6 mRNA appears upregulated in the same cells as well as secreted in the supernatants. Finally, we also tested the effect of the antiviral cytokine IFN-β on the levels of these pro-inflammatory mediators.

P1.14.57
IL-6, IL-6sr, TNF-α, IL-10 and IL-8 levels in patients with chronic periodontitis after periodontal therapy

P. Mastromatteo-Alberga*, M. Correnti, L. Escalona;*
Instituto de Investigaciones Odontológicas, Caracas, Venezuela.

Purpose/Objective: The aim of this study was to determine the levels of IL-6, IL-6sr, TNF-α, IL-10 and IL-8 in gingival crevicular fluid (GCG) of subjects with chronic periodontitis before and after non-surgical periodontal therapy. Methods: Clinical measurements of gingival index (GI), plaque index (PI), bleeding on probing (BOP), probing depth (PD) and attachment loss (AL) were carried out in 11 patients with chronic periodontitis before and after scaling and root planing (SRP) and 11 periodontally healthy controls. GCF samples to measure the cytokine levels were collected by sterile endodontic paper points (No 35) from one tooth per quadrant during 30 s, before and after completion of SRP therapy, and analysed by ELISA test. Results: Significant differences were observed in all clinical parameters between patients and control group before and after periodontal treatment ($p \leq 0.05$). The total amount of IL-6, IL-6sr, TNF-α, IL-10 and IL-8 was significantly higher in the periodontitis group before periodontal therapy and compared with control group ($p \leq 0.05$). Conclusion: The levels of the inflammatory mediators obtained in this study were significantly associated with the severity of periodontal disease and the values decreased significantly after treatment, however did not reach the control group values. This research was supported by CDCH PG: 10-00-7070-2007.

Deficiency of IL-10/IL-12 cytokine exacerbate systemic inflammatory responses in renal injury induced by ischemia and reperfusion

V. Nunes de Paiva[1,2], *R. M. M. Monteiro*[1,2], *R. Assumpção Larocca*[1,2], *P. Semedo*[1,2], *M. A. dos Reis*[3,4], *A. Pacheco-Silva*[5,6], *N. O. S. Câmara*[1,2];
[1]*University of Sao Paulo, Sao Paulo, Brazil,* [2]*Laboratory of Transplantation Immunobiology, University of Sao Paulo, Brazil,* [3]*Universidade Federal de Uberaba, Minas Gerais, Brazil,* [4]*Departament of Pathology, Minas Gerais, Brazil,* [5]*University Federal of Sao Paulo, Sao Paulo, Brazil,* [6]*Departament of Nephrology, Sao Paulo, Brazil.*

Renal ischemia/reperfusion injury (IRI) is the major cause of acute kidney injury in native and also in transplanted kidneys, with a complex pathogenesis that involves many components of inflammation. Recent evidences show a critical role of the CD4+ T cell, with the Th1/Th2 paradigm as a possible effectors mechanism. In order to evaluate the role of Th1/Th2 immune profile in this system, IL-12, IL-4, IL-10 deficient mice and IL-12/IL-10 double deficient mice were used. Moreover, for adoptive transfer, IL-12 KO (IL-12 KO → WT or WT → IL-12 KO) and IL-4 KO (IL-4 KO → WT or WT → IL-4 KO) chimeric mice on C57BL/6 background and their controls were also subjected to IRI. Renal function was evaluated by serum urea and renal morphometric analyses. Gene expression of IL-6, MCP-1 and HO-1 were also investigated by Q-PCR . IL-4, IL-10 and IL-12/IL-10 KO deficient animals present the highest impairment in renal function compared to controls. Conversely, IL-12 KO and IL-12 KO (IL-12 KO → WT) chimeric mice animals were absolutely protected from IRI. Gene expression analyses showed higher expression of HO-1, a cytoprotective gene, IL-6, a pro-inflammatory cytokine and MCP-1, a pro-inflammatory macrophage chemokine, in IL-4, IL-10 and IL-12/IL-10 KO deficient animals subjected to IRI after 24 hours. KC chemokine was higher in serum of IL-4, IL-10 and IL-2/IL10 KO deficient mice and IL-4 was absence in serum of IL-10 and IL-12/IL-10 KO deficient mice. Results confirm that Th1/Th2 related cytokines are critically involved in renal IRI.

HMG-CoA reductase inhibitor simvastatin improves organ dysfunction, inflammatory profile, bacterial clearance and cognitive damage after onset of sepsis

F. M. J. Oliveira*, C. F. Gonçalves-de-Albuquerque, I. M. Medeiros-de-Moraes, P. A. Reis, P. T. Bozza, F. A. Bozza, A. R. Silva, H. C. Castro-Faria-Neto;*
Fundação Oswaldo Cruz, Rio de Janeiro, Brazil.

Sepsis is a clinical syndrome characterized by systemic inflammatory response secondary to infection, which can progress to multiple organ dysfunction and death. Cognitive impairment is a significant consequence of sepsis reported among survivors. Despite research on new therapies, sepsis treatment remains based on life support and antibiotics. Cohort studies have suggested that statin uses are associated with protection from development and mortality of sepsis. Statins have pleiotropic effects and they are emerging as potent inhibitors of inflammatory processes. In this study we aimed to evaluate the effects of simvastatin in a rodent model of sepsis (Cecal Ligation and Puncture-CLP). Swiss Webster mice were submitted to CLP and 6h later they were treated with simvastatin (2mg/kg - iv). Plasma and peritoneal lavage were collected for organ damage evaluation, cytokine (ELISA) and nitric oxide (NO) (Griess method) quantification, cell migration and bacterial clearance (colony forming units-CFU) analysis. Cognitive damage was evaluated through inhibitory avoidance task. Our results showed that simvastatin decreased liver and kidney damage, and significantly reduced neutrophils numbers, CFU counts, TNF-α, MIF, IL-6 and IL1-β levels in the peritoneum. Simvastatin decreased NO levels in the bloodstream, but it enhanced NO production in the peritoneum. Additionally, simvastatin prevented the loss of aversive memory in septic mice. Our study demonstrates that simvastatin improved inflammatory profile and bacterial elimination in sepsis, preventing organ dysfunction and late consequences of sepsis. Our study indicates that statins can be considered potential candidate to future clinical studies as adjuvant therapy for sepsis.

Human mesenchymal stem cell adherence and invasivity in vitro after transfection with CD29 specific siRNA

***C. Panaitescu**, L. Marusciac, F. Bojin, V. Paunescu;*
University of Medicine and Pharmacy Victor Babes Timisoara, Timisoara, Romania.

Background: Mesenchymal stem cells (MSCs) adhere to inflammatory substrates. The aim of this study was to determine in vitro the involvement of integrin beta1 (CD29) in human MSC (hMSCs) adherence and invasivity.
Method: hMSCs were isolated from iliac crest bone marrow, the presence of specific surface markers was evaluated by flow cytometry, and their differentiation potential was determined. After hMSCs expansion, the expression of CD29 was inhibited specifically by transfection with siRNA duplexes, and the transfection efficiency was evaluated by RT-PCR, flow cytometry, flow chamber assays, and immunohistochemistry. The adherence and invasivity of the transfected hMSCs was evaluated by culture in the presence of different inflammation mediators (VCAM-1, ICAM, TNF-alpha, TGF-beta1), using a real-time cell adhesion and invasivity analyzer system.
Results: hMSCs were successfully expanded and kept in culture for up to 8 passages. The isolated cells were positive for specific surface markers (CD29, CD44, CD73, CD90, and CD105), and they differentiated into the adipogenic, osteogenic and chondrogenic lines. Flow cytometry showed an abundance of CD29 on hMSC surface (79.33±3.8%). hMSCs showed a significant decrease of CD29 expression at 72 hours post-transfection. The invasivity capacity of transfected hMSC to VCAM-1-coated surfaces was significantly decreased in comparison with control hMSCs, and in comparison with surfaces coated with ICAM, TNF-alpha, and TGF-beta1. The adherence of transfected hMSCs to VCAM-1 under shear stress conditions was also significantly decreased.
Conclusion: Specific interactions between CD29 and VCAM-1 are involved in hMSCs migration towards inflammation, which makes CD29 a possible therapeutic target in inflammatory disorders.

P1.14.61
In vitro effect of Interleukin-33 on gastric adenocarcinoma cell line (AGS) and intestinal epithelial cancer cell line (Caco-2)

***L. F. Pisani**[1], L. Pastorelli[1,2], N. Munizio[2], M. Vecchi[1,2];*
[1]Università degli Studi di Milano, Milano, Italy, [2]I.R.C.C.S. Policlinico San Donato, San Donato Milanese, Italy.

Interleukin-33, member of the IL-1 Family of cytokines, is a potent inducer of Th-2 immune responses. IL-33 induces a potent proinflammatory response, promotes protection and the return to immune homeostasis, it also has a role during fibrogenesis at the end of dysregulated wound healing. In the gastrointestinal tract, IL-33 appears to play a critical role in maintaining normal gut homeostasis, enhancing mucosal defenses against intestinal infection and trauma. Overexpression of IL-33 has been reported in the inflamed mucosa of IBD patients, where the localization below ulcerative lesions indicates the potential role for IL-33 in wound healing. The hypothesis of this study is that IL-33 has specific effects in regulating epithelial cell functions in gut and stomach, enhancing those features that are prominent in inflammatory bowel disease. AGS and Caco-2 cell lines were used for proliferation and apoptosis assays and scratch test in a wound healing setting. Cells were seeded with growing concentration of rhIL-33 (0ng/ml-10ng/ml) for 0, 6 and 24h. The proliferation assay and wound healing showed an inhibitory effect on AGS at 24h in a dose-dependent way. Apoptosis was augmented with the increase of rhIL-33 concentrations. Conversely, rhIL-33 enhanced Caco-2 proliferation at 24h in a dose dependent fashion, whereas apoptosis was inhibited. Our study investigates the potential role of IL-33 in the regulation of cell proliferation, whose perturbations may lead to uncontrolled cell growth or impaired tissue repair; these preliminary data also suggest a different function of this cytokine in a cell-type dependent setting.

P1.14.62
***In silico* design of cytokine-trap peptides for modulation of the IL-13 signalling pathway in asthma**

***N. J. Purdy**, W. Walker, J. G. L. Mullins;*
Swansea University, Swansea, United Kingdom.

Peptide therapeutics is a promising area in which treatments are being developed to mitigate the symptoms associated with many diseases, including asthma. Novel synthetic peptides designed exclusively from endogenous peptide sequences are advantageous because the potential for drug-associated side effects is minimal. IL-13 is a Th2-associated cytokine, playing a pivotal role in allergic asthma and the development of physiological responses characteristic of this inflammatory disease; mucus hyper-secretion, airway hyper-responsiveness and airway remodelling. IL-13 and IL-4 are closely related cytokines that share a heterodimeric receptor complex comprising IL-13Rα1 and IL-4Rα chains, known as IL-13R or type-II IL-4R.
We used bioinformatics and structural modelling approaches to design peptides specific for the type-II IL-13R signalling cascade to 'trap' IL-13 and attenuate its signalling. IL-13 initially binds to IL-13Rα1, followed by recruitment and binding of IL-4Rα, culminating in the formation of a functional receptor. IL-13 also binds to another "decoy" receptor, IL-13Rα2, with high affinity. Six peptides were designed based on interacting regions of IL-13, IL-13Rα1 and IL-13Rα2, identified by sequence pattern discovery and structural modelling of IL-13 cytokine and receptor complex chains.
We present the *in silico* design of IL-13, IL-13Rα1 and IL-13Rα2-based peptides and their experimental testing, through assessment of the inhibitory effect on IL-13 signalling in cell line A549 by ELISA, qPCR and flow cytometry. Preliminary results for two of the peptides are promising, displaying 10 – 30% inhibition of IL-13 signalling. When validated, this approach may provide a framework for peptide design applicable to other cytokine receptor systems and diseases.

P1.14.63
Chemokines and biomarkers of endothelial dysfunction in chronic urticaria

***I. Puxeddu**, F. Panza, F. Pratesi, D. Bartaloni, V. Rocchi, I. Del Corso, P. Migliorini;*
Pisa University, Pisa, Italy.

Background. Chronic Urticaria (CU) is a common and disabling disease characterized by recurrent itchy wheals with or without angioedema for more than 6 weeks. These symptoms are the consequence of skin mast cells degranulation with release of histamine and other vasoactive mediators. The aim of our study is to investigate the potential involvement of chemotactic mediators (CCL5/RANTES and CXCL8/IL-8) and markers of endothelial dysfunction such as soluble VCAM-1 (sVCAM-1) and ICAM-1 (sICAM-1) in the pathogenesis of CU, and their relation with disease activity. Methods. We measured the levels of CCL5/RANTES, CXCL8/IL-8, sVCAM-1 and sICAM-1 in the sera of 87 patients with CU and 61 sex- and age-matched normal healthy subjects (NHS), using ELISA assays. According to the results of the autologous serum skin tests (ASST), CU patients were classified in the ASST-positive and ASST-negative subgroups. Results. We detected significantly higher concentration of CCL5/RANTES (P<0.0001) but not of CXCL8/IL-8 in the sera of CU patients compared to NHS. The serum levels of sICAM-1 and sVCAM-1 were significantly increased in the CU patients compared to the control subjects (P=0.0121 and P=0.0043, respectively). No differences in either chemokines and soluble adhesion molecules levels were detected in the ASST-positive and ASST-negative subgroups. Positive correlation has been found between sICAM-1 and sVCAM-1 but not between them and CCL5/RANTES. Conclusions. Our study suggests the potential involvement of the C-C chemokine CCL5/RANTES and of the biomarkers of endothelial dysfunction sICAM-1 and sVCAM-1 in the pathogenesis of CU.

P1.14.64
Role of Cytokine Response in Disease Progression and Severe Clinical Outcomes in Leptospirosis

E. A. G. Reis[1], J. Hagan[1], G. S. Ribeiro[1], A. T. Carvalho[2], O. A. Martins-Filho[2], R. R. Montgomery[3], A. C. Shaw[4], A. I. Ko[4], ***M. G. Reis***[1]*;*
[1]Research Center Gonçalo Moniz, Salvador/Ba- Brazil, Brazil, [2]Research Center René Rachou, Belo Horizonte, Brazil, [3]Yale University School of Medicine, New Haven, Brazil, [4]Yale University School of Medicine, New Haven, CT, United States.

Background. Leptospirosis is a zoonotic disease caused by pathogenic spirochetes of the genus Leptospira. The role of the immune response in determining clinical outcomes is not yet well understood. We hypothesized that acute-phase serum cytokine response may play a role in disease progression, risk for death, and development of specific clinical outcomes, including severe pulmonary hemorrhage syndrome (SPHS).
Methods. We prospectively enrolled 172 patients with laboratory-confirmed mild (n=23) and severe leptospirosis (n=149) during active outpatient and hospital-based surveillance, respectively. Circulating concentrations of pro- and anti-inflammatory cytokines were measured using Cytometric-Bead-Array. Logistic regression was used to evaluate the association between cytokine concentrations and clinical outcomes.
Results. Concentrations of IL-1β, IL-2, IL-4, IL-6, IL-8, IL-10, IL-17A, and TNF-α were significantly higher (P<0.05) in hospitalized patients with severe disease compared to outpatients with mild disease. Among hospitalized patients, levels of IL-6 (P<0.0001), IL-8 (P=0.0049), IL-10 (P<0.0001), and IFN-γ (P=0.0195) were significantly higher in fatal cases compared to severe nonfatal cases. High levels of IL-6 and IL-10 were independently associated (P<0.05) with fatal outcome after adjustment for age and days of symptoms. Finally, among fatal cases, IL-6 levels were higher among those who had SPHS compared to those who did not (P=0.0519).
Conclusion. Our findings suggest that severe cases of leptospirosis are differentiated from mild disease by the presence of a cytokine storm process, and that IL-6 and IL-10 may play an immunopathogenic role in the development of life-threatening clinical outcomes in human leptospirosis.

P1.14.65
IL-33 signaling modulates the development of adriamycin-nephropathy

V. O. Reis*, J. Nogueira-Neto, B. C. Vivanco, A. C. Keller;*
Federal University of São Paulo, São Paulo, Brazil.

Adriamycin(ADM)-nephropathy (AN) is an experimental model that mimetic the clinical manifestations of human focal and segmental glomerulosclerosis (FSGS), a leading cause of chronic kidney disease. Because different works associated FSGS with Th2 immune responses, we hypothesized that IL-33, a differentiation factor for Th2 lymphocytes, could be implicated in disease pathogenesis. In order to determine the involvement of IL-33 in AN pathogenesis, we took advantage of mice deficient in the IL-33 receptor, T1/ST2. Methods and Results: BALB/c WT or ST2-/- mice received, by a single tail vein injection, 10mg (ADM)/Kg. The renal function was determined by the proteinuria /creatininuria ratio. Proteinuria was evident at day 4 post-ADM and progressed in a time-dependent manner. In the ST2-/- mice, the proteinuria ratio was 2 fold increased in comparison to wild-type group, indicating a more severe disease. In concordance, western blotting analysis of the renal tissue revealed in ST2-/- mice a more significant decrease in the levels of Nephrin, which was associated with an increase in the expression of phospho-Nephrin, in comparison to WT group. This phenomenon was associated with higher levels of phospho-AKT, JNK-1 and PAI-1, connecting a higher proinflammatory response with a more important loss of podocyte structural proteins. Conclusion: taken together our data show that the severity of AN increases in the absence of T1/ST2 receptor, suggesting a regulatory role for IL-33 signaling during FSGS pathogenesis.

P1.14.66
Degradation of IL-1 beta by the Human Papilloma Virus: novel mechanism of innate immune escape

B. B. Rincon-Orozco*;*
German Cancer Research Center, Heidelberg, Germany.

Infections with human papillomaviruses (HPVs) are involved in the development of anogenital cancer. HPVs evade the innate immune response of their host by dysregulating immunomodulatory factors such as cytokines, thereby creating a microenvironment favoring malignancy. One key player in the immune surveillance is interleukin-1 beta (IL-1β) which mediates inflammation, and links innate and adaptive immunity.
Here, we describe a novel mechanism how high-risk HPV16 abrogates IL-1β processing and secretion in a NALP3 inflammasome-independent manner. We analyzed IL-1β regulation in immortalized keratinocytes that harbor the HPV16 E6 and/or E7 oncogenes as well as HPV-positive cervical tumor cells. While in primary and in E7-immortalized human keratinocytes the secretion of IL-1β was inducible upon inflammasome activation, E6-positive cells did not respond. Western blot analyses revealed a strong reduction of basal intracellular levels of pro-IL-1β that was independent of NALP3 inflammasome, autophagy or lysosomal activity. Instead, we show that pro-IL-1β is degraded in a proteasome-dependent manner in E6-positive cells which is mediated via the ubiquitin ligase E6-AP and p53. Conversely, in E6- and E6/E7-immortalized cells pro-IL-1β levels were restored by siRNA knock-down of E6-AP and recovery of functional p53. In the context of HPV-induced carcinogenesis, these data suggest a novel post-translational mechanism of pro-IL-1β regulation which inhibits IL-1β secretion in virus-infected cells. Clinical relevance of our results was confirmed in HPV-positive tissue samples, where a gradual decrease of IL-1β towards cervical cancer is observed. Hence, IL-1β attenuation by HPV16-E6 oncoprotein is apparently a crucial step in viral immune evasion and initiation of malignancy.

P1.14.67
Nitric Oxide tightly regulates Dendritic Cells life cycle and cytokines release under inflammatory conditions

C. Ripamonti*[1,2], S. Baldassarri[1], C. Storini[3], D. Miglietta[3], M. Foti[1,2];*
[1]University of Milano-Bicocca, Milano, Italy, [2]Genopolis Consortium, University of Milano-Bicocca, Milano, Italy, [3]Nicox Research Institute, Via Ariosto 21, Bresso, Milano, Italy.

Nitric oxide (NO) is an important effector molecule that is involved in immune regulation and host defence. It has been previously reported that NCX 2057, a chemical compound bearing a nitric oxide (NO)-donating moiety linked to the natural antioxidant ferulic acid, shows marked anti-inflammatory properties in lipopolysaccharide (LPS)/interferon-γ-stimulated RAW 264.7 macrophages and in a model of chronic brain inflammation. Dendritic cells (DCs) are the most potent APCs of immune system and are link between innate and adaptive immunity. It is known that NO is able to regulate DCs functions such as apoptosis and antigen presenting activity. Here, we investigated the anti-inflammatory role of NCX 2057, which releases NO with a slow kinetics, on LPS stimulated DCs. NCX 2057 inhibits NO production in LPS-activated DCs by the modulation of the iNOS expression. NCX 2057 exhibits an anti-inflammatory activity on DCs through the down-modulation of genes (IL6, IL12b and IL1b, ISG15) of the inflammatory signatures developed in our laboratory. The inflammatory genes modulated were further confirmed by ELISA assay. We observed a significant reduction of IL-6 production in presence of NCX 2057, but a slight reduction of IL-1beta and TNFα compared to controls. As previously reported for other NO-donors, NCX 2057 inhibits LPS-induced cells death in a dose dependent manner, with a significant reduction at 50uM. The anti-apoptotic effect of NCX 2057 seems to have a role in DCs-induction of T cells proliferation**.** The data highlight a role of NCX 2057 as anti-inflammatory compound, modulating DCs during LPS-induced activation.

P1.14.68
Correlation of magnesium levels with inflammatory markers in thiazide induced hypomagnesemic rats

***S. Sadiq**, A. Naveed, T. Ahmed, S. Khan;*
National University of Sciences and Technology, Islamabad, Pakistan.

Among cardiovascular diseases, cause of one third deaths worldwide, hypertension is playing major role in cerebrovascular disease, ischemic heart disease and cardiac and renal failure. The most prevalent type of hypertension affecting 90-95% of hypertensive patients is Primary hypertension. A thiazide-type diuretic is usually prescribed as first-line pharmacotherapy. Use of hydrochlorthiazide, although vital in the management of hypertension can have several unfavorable effects such as electrolyte disorders (hyponatremia, hypokalemia and hypomagnesemia), hyperlipidemia, hyperuricemia and impairment of glucose metabolism in addition to depletion of volume. Hypomagnesaemia is associated with considerable morbidity also influencing inflammatory response by affecting the endothelial proliferation due to an up regulation of interleukin-1 (IL1) and sVCAM-1, pro inflammatory cytokines, CRP. The objectives of the study was to evaluate the effects of Magnesium Supplementation on inflammatory markers (CRP s-VCAM 1) in thiazide administered rats. Ninety male Sprague Dawley rats of age 90 to 120 days were selected, divided into three groups of control, Hydrochlorthiazide administered control and Hydrochlorthiazide +Magnesium administered experimental group. Blood samples were taken and levels of inflammatory markers were determined by ELISA and those of serum Magnesium. The results showed levels of inflammatory markers (sVCAM-1 and CRP) are increased in HCTZ administered group thus having a negative correlation with serum magnesium levels whereas levels of these parameters decreased in HTCZ + Mg2+ administered group thus showing that magnesium supplementation helped in normalizing the derangements in inflammatory markers.

P1.14.69
Anti-inflammatory, immunostimulatory and antiviral effects of Coffee fruit (Coffea arabica)

***F. B. Saldaña Morales**, I. A. Lozada Requena, D. F. Zegarra Ruiz, S. R. Dávila Paico, M. A. Cabello Napuri, J. L. Aguilar Olano;*
Universidad Peruana Cayetano Heredia, Lima, Peru.

Chlorogenic and quinic acid are found in coffee fruit. Previous studies have demonstrated that polyphenols possess anti-inflammatory, immunostimulatory and antiviral properties. Therefore, due to their increased amount in coffee fruit these immunological activities were evaluated.
LD50 and IC50 assays were performed to assess the toxicity of the coffee fruit extract (CFE). Anti-inflammatory activity was evaluated by pro-inflammatory models, CBA and histological techniques. Immunostimulatory activity was assayed by T cell proliferation with MTT and antiviral activity was supported by T cell subpopulations analysis by flow cytometry.
LD50 value was 13.8g/kg while the IC50 value obtained was 2.9mg/ml. Anti-inflammatory activity assessed with carrageenan-induced paw edema model exhibited a dose-dependent inflammatory inhibition for CFE (1136.4mg/kg, 39.5% vs. Indomethacin, 44.8%). LPS-stimulated PBMC supernatants showed a decreased secretion of TNFα for CFE (1136.4mg/kg). Additionally, air pouch model demonstrated decreased cellular infiltration for CFE (1136.4mg/kg, $0.78x10^6$cells vs. positive control, $6.75x10^6$cells) and inflammatory exudates showed decreased production of IL6, TNFα and MCP-1. T cell proliferation assays demonstrated an immunostimulatory activity for CFE (500ug/ml). After viral simulation with Poly I:C stimulation, CFE (1000ug/ml) increased the percentage and activated cytotoxic T cells (CD8/CD44+/+). These results were statistically significant ($p<0.05$).
CFE showed anti-inflammatory properties on cellular and humoral levels supported by histological techniques. CFE decreased the secretion of pro-inflammatory cytokines such us IL6, TNFα and also MCP-1, thus diminishing cellular infiltration. Conversely, under viral simulation, CFE stimulated T cell proliferation and increased the percentage and activated cytotoxic T cells. Therefore, these results could attribute coffee fruit immunomodulatory and antiviral properties.

P1.14.70
Proinflammatory Effect of the P2X7 Receptor during Sepsis

***P. T. Santana**, C. F. Benjamim, C. Takiya, C. Caruso-Neves, R. Coutinho-Silva;*
UFRJ, Rio de Janeiro, Brazil.

Background: Sepsis is characterized by an imbalanced inflammatory response, leading to organ damage, shock and death. P2X7 receptor (P2X7R) activation induces proinflammatory events and may be associated to sepsis.
Aims: To analyze the role of P2X7R in modulating the inflammatory response observed in cecal ligation and puncture (CLP) induced sepsis.
Methods: CLP was induced (2 punctures of 21G) in C57BL/6 and P2X7KO mice. After 48 h, CFUs were counted at 37°C in agar plate. Seven-day survival curve was determined. Inflammatory neutrophil and macrophage populations were counted by flow cytometry (anti-CD11b, Ly6G antibodies). Cytokines (IL-1β, IL-6, IL-17, TNF-α, and TGF β) and NO were dosed in the peritoneal wash and blood (IL-1β) by ELISA and Griess method, respectively.
Results: P2X7KO animals were partially protected from sepsis showing 30% higher survival and reduced bacteremia after CLP. In the peritoneal lavage Ly6G+ cells increased only in WT animals and CD11b+ cells increased in both septic groups. Cytokines such as IL-1β, IL-17 and TGF- β beta were reduced in P2X7KO animals after sepsis induction.
Conclusion: The absence of the P2X7R attenuates the inflammatory response and protects against. Thus more studies may contribute to the development of new therapeutic strategies.
Financial Support: CNPq, FAPERJ, PRONEX, InPETAM-CNPq

P1.14.71
Role and correlation of inflammatory cytokines, angiogenic markers and insulin growth factors in post treatment (neoadjuvant chemoradiation) disease mapping in advanced stage carcinoma of uterine cervix

***M. Sharma**[1], R. Khan[2], M. Aggarwal[1], A. Sharma[1];*
[1]Maulana Azad Medical College, New Delhi, India, [2]All India Institute of Medical Sciences, New Delhi, India.

Background: Carcinoma of uterine cervix accounts for most common malignancy in Indian women. Inflammation is a critical component of tumour progression and many cancers arise from sites of infection & inflammation. Angiogenesis and Insulin-like growth factors promotes tumour cells survival, proliferation and metastasis. Currently chemo-radiation is mainstay of treatment. Post treatment (Neoadjuvant Chemotherapy) disease mapping using these markers in carcinoma cervix patients needs to be explored.
Material and Methods: 40 patients of cancer cervix stage IIIb were recruited. 20 healthy women were taken as controls. Circulatory levels of TNF-α, IL-8, VEGF, Ang-2 and IGF-I & II, were measured before and after chemoradiation, using ELISA and correlated with therapeutic response. mRNA levels were quantitated using Q-PCR and data was statistically analyzed.
Results: Levels of all theses molecules were significantly ($p<0.001$) higher in patients than in controls. After treatment their levels were significantly ($p<0.001$) declined. Out of 40 patients, 33 were complete responders and 7 were non-responders when they were clinically assessed. On comparison of before and after treatment levels of these molecules complete responders showed significant decline whereas non responders showed insignificant decrease in their levels.
Conclusions: Higher levels of angiogenic factors indicate role played by them in disease progression aiding angiogenesis. It may be possible that these angiogenic factors function via up-regulation of inflammatory cytokines and IGFs. These markers may serve as useful tools in post treatment disease mapping which otherwise may not provide true picture with available imaging methods.

P1.14.72

S100A8 and S100A9 induce the expression of cytokines and regulate the NLRP-3 inflammasome via ROS-dependent activation of NF-κB

J. C. Simard[1]*, A. Cesaro*[2]*, M. Tardif*[2]*, F. Antoine*[1]*, P. A. Tessier*[2]*, D. Girard*[1]*;*
[1]*INRS Institut Armand-Frappier, laval, QC, Canada,* [2]*Centre Recherche CHUL, Québec, QC, Canada.*

S100A8 et S100A9 are members of the Myeloid-Related-Proteins (MRP) sub-family, representing up the 30% of neutrophil cytosolic proteins. These proteins are released upon cell damage or cell activation, acting as danger signal for the organism by signaling, at least partially, through toll-like receptors. High extracellular concentrations of S100A8 and S100A9 are found in sera from patients suffering from various chronic inflammatory disorders. In this study, we have investigated the role of S00A8 and S100A9 on cytokine production in peripheral blood mononuclear cells. First, using an antibody array assay approach, we show that S100A8 and S100A9 induce the expression of inflammatory analytes, including TNF-α, IL-6, IL-8, Gro-α and MIP1α/β. Results were confirmed using specific ELISA for IL-6 and IL-8. Next, using an antisens strategy and a pharmacological inhibition approach for NF-κB, we show that S100A8 and S100A9 induce secretion of IL-6 and IL-8 via translocation of NF-κB. We next investigated the potential activation of the NLRP-3 inflammasome and observed an increase in the expression of the pro-IL-1β and the NLRP-3 proteins in S100A8- and S100A9- induced cells. Furthermore, pretreatment with S100A8 and S100A9 increased the IL-1β production and caspase-1 processing after stimulation with ATP, a known inflammasome activator. Inhibition experiments revealed the importance of NF-κB and ROS in the expression of pro-IL-1β and NLRP-3 as well as in IL-1β secretion. Taken together, our results show the importance of S100A8 and S100A9 in the secretion of inflammatory cytokines, especially in the production of IL-1β controlled by the NRLP-3 inflammasome.

P1.14.73
Mice selected for maximal inflammatory response display a higher lung inflammation induced by Tityus serrulatus scorpion venom

P. G. Lara[1]*, T. R. Narcizo*[1]*, A. F. Machado*[1]*, V. D. Aiello*[2]*, L. A. Benvenuti*[2]*, F. C. V. Portaro*[3]*, O. A. Sant'Anna*[3]*, N. Starobinas*[1]*, O. G. Ribeiro*[1]*,* ***M. Spadafora-Ferreira***[1]*;*
[1]*Laboratory of Immunogenetics, Butantan Institute, São Paulo, Brazil,* [2]*Laboratory of Pathology, Heart Institute (InCor), São Paulo University Medical School, Brazil, São Paulo, Brazil,* [3]*Laboratory of Immunochemistry, Butantan Institute, São Paulo, Brazil.*

Tityus serrulatus venom (TsV) may induce cardiac failure and pulmonary edema, leading to death by scorpionism. TsV induces activation of a systemic inflammatory cascade with the release of different mediators including cytokines. The aim of this study was to evaluate TsV activity in the lung of mice genetically selected for high (AIRmax) or low (AIRmin) acute inflammatory response and observe if genetic factors are involved in this response. A subletal dose of TsV was inoculated in mice and after different periods, lungs were collected, for histopathological analysis, myeloperoxidase (MPO) quantification, cellular phenotyping and cytokine and chemokine quantification. Perivascular cellular infiltrate, haemorrhage and edema were observed in the lung of TsV-treated mice after venom injection, with higher intensity in AIRmax compared to AIRmin mice. No cardiac alterations were observed. MPO activity showed that TsV induces a significant higher migration of neutrophils in AIRmax compared to AIRmin mice. Phenotypic analysis of lung cellular populations of TsV-treated mice showed that AIRmax presented significantly more neutrophils ($Ly6G^+CD11b^+$ cells) and macrophages ($F4/80^+CD11b^+$ cells) when compared to their controls and to AIRmin. Moreover, AIRmin mice displayed an increase in $Ly6G^+CD11b^+$ and $F4/80^+CD11b^+$ cells later after venom administration compared to AIRmax. Lungs of AIRmax TsV-treated mice presented higher levels of the pro-inflammatory cytokines IL-1β, IL-6 and TNF-α and the chemokines MCP-1, MIP-1β and RANTES, compared to AIRmin. Our results demonstrated that TsV induced higher acute pulmonary inflammatory response in AIRmax mice, suggesting that the response to scorpion venoms is modulated by genetic factors.

P1.14.74
Melaleuca alternifolia and its main component, terpinen-4-ol, inhibit the production of IL-1β, IL-6, IL-4 and IL-10 by activated monocytes

D. P. Spolidorio*, M. N. Nogueira, T. Bedran, M. F. Correia, L. Barbosa, C. Rossa Junior;*
Dental School of Araraquara - UNESP, Araraquara, Brazil.

The antimicrobial activity of oil of Melaleuca alternifolia (TTO) is well established, however the mechanisms of modulation of inflammatory and anti-inflammatory cytokines properties are still unclear. The present study investigated in vitro, the capacity of TTO and its main component, terpinen-4-ol, in the modulation of interleukin-1 beta (IL-1β), interleukin-6 (IL-6), interleukin-4 (IL-4) and interleukin-10 (IL-10). Initially, we determined the cytotoxicity of oil in U937 monocytes differentiated into macrophages with 40ng/mL Phorbol 12-myristate 13-acetate (PMA) for scanning the mitochondrial activity reduction assay methyl tetrazolium (MTT). The ability of TTO and terpinen-4-ol in modulating the production of cytokines such as IL-1β, IL-6, IL-4 and IL-10 after stimulation with LPS of *Porphyromonas gingivalis* (TLR2 agonist) and *Escherichia coli* (TLR4 agonist) was determined by ELISA assays. Data normality by the Shapiro-Wilk test ($p < 0.05$). In the assessment of cytotoxicity was used ANOVA with Tukey post test. In assessing cytokine production was used in the t-test. The TTO and terpinen-4-ol, were effective in decreasing the amount of these cytokines: IL-1β, IL-6 and IL-10. The TTO had no effect on IL-4 since the terpinen-4-ol significantly reduced levels of IL-4. Thus, it was concluded that the TTO and terpinen-4-ol can suppress the production of inflammatory mediators and anti-inflammatory in human monocytes activated.

P1.14.75
Inflammatory responses to low volume high load and high volume medium load protocols during dynamic leg press exercise

J. K. Stenholm[1]*, S. Walker*[1]*, G. Paulsen*[2]*, K. Häkkinen*[1]*, W. J. Kraemer*[3]*, M. Hämäläinen*[4]*, K. Vuolteenaho*[4]*, E. Moilanen*[4]*, A. A. Mero*[1]*;*
[1]*Department of Biology of Physical Activity, University of Jyväskylä, Jyväskylä, Finland,* [2]*Norwegian School of Sport Sciences, Oslo, Norway,* [3]*Human Performance Laboratory, Department of Kinesiology, University of Connecticut, Storrs, CT, United States,* [4]*The Immunopharmacology Research Group, University of Tampere School of Medicine, and Tampere University Hospital, Tampere, Finland.*

One bout of resistance exercise triggers an aseptic inflammatory response which involves leukocytosis and stimulation of pro-inflammatory cytokines (Freidenreich & Volek 2012). The purpose of the present study was to identify differences in the acute immune response between low volume high load (gains in maximal strength, MAX) and high volume medium load (gains in muscle mass, HYP) resistance exercise protocols. In a cross-over design twelve healthy men participated in bilateral press exercise consisting of 5 sets of 10 RM and 15 sets of 1 RM. The inter-set rest period was three minutes for MAX and 2 minutes for HYP. Venous blood samples were taken at baseline, immediately after and 15 (P15) and 30 (P30) minutes after the exercise. Basic blood count was analyzed using Sysmex KX-21N (TOA Medical Electronics Co., Ltd., Kobe, Japan). Concentrations of IL-6 and monocyte chemotactic protein-1 (MCP-1) in serum samples were determined by enzyme-linked immunosorbent assay (ELISA) with commercial reagents. Both exercises induced acute significant leukocytosis ($p<0.001$). Leukocytosis was significantly higher after HYP ($p<0.01$). Significant lymphopenia was observed only after HYP ($p<0.01$). IL-6 and MCP-1 concentrations increased significantly immediately after both exercises and remained elevated in HYP at P30. The acute MCP-1 response was significantly higher in HYP. Hypertrophic resistance exercise triggered significantly stronger inflammation response. As expected, manipulation of the rest period and load in resistance exercise alters the inflammatory response. This should be taken into account when planning resistance training e.g. periodization for peak performance as well as for special populations e.g. the elderly.

P1.14.76
Cytokines profile in a social defeat animal model of depression and effects of a novel anti-asthenic drug ladasten

***A. V. Tallerova**, L. Kovalenko, O. Kuznetsova, A. Durnev, S. Seredenin;*
Zakusov State Institute of Pharmacology Russian Academy of Medical Science, Moscow, Russian Federation.

Based on evidence, including the findings of clinical depression studies and animal models, the cytokine hypothesis of depression, was formulated. Ladasten® (N-(2-adamantyl)-N-(para-bromophenyl)-amine), an anti-asthenic drug with immunomodulatory, psychostimulatory and anxiolytic activities, was registered in Russia in 2008. The aim of the present study was to investigate the cytokine profile in an animal model of depression, and examine the effects of ladasten treatment .
Mice subjected to social defeat stress for 3 (T3), 15 (T15) and 30 (T30) days developed a depressive-like phenotype. Ladasten (30 mg/kg,i.p.) was administered for 5 days after the stress-days. Serum cytokines were measured using a multiplex immunoassay by flow cytometry. The forced swim test (FST) was used to evaluate the depression state of the mice.
T15 and T30 group mice from FST exhibited significantly shorter latency to the first float period by 29 and 44%, and longer time of immobility by 15 and 20%. T15, T30 ladasten-treated groups behaved as control mice. T3 was accompanied by a significant increase in IL-6 (7.9-fold), IL-17 (16.3-fold), IL-4 (6.0-fold). T15 was the peak level of IL-6 (46.5-fold), but the levels of cytokines at T30 were not different from controls. Thus, administration of ladasten prevented the expression of inflammatory cytokines in response to social defeat stress. In ladasten-treated mice, the cytokine levels were similar to unstressed mice. These findings support the notion that pro-inflammatory cytokines play an important role as mediators of the stress response. Targeting this pathway may represent a novel therapeutic approach for the treatment of depression, and ladasten could be considered as a potential drug candidate.

P1.14.77
sICAM-1 and sUPAR as Immune Markers for Treatment Response in Ethiopian TB-Patients with and without HIV Co-Infection

***W. Tamene**[1], D. Kassa[2], Y. Alemayehu[1], G. Gebremicheal[1], A. Alemu[1], T. Messele[3];*
[1]Ethiopian Health and Nutrition Research Institute, Addis Ababa, Ethiopia, [2]Ethiopian Health And and Nutrition Research Institute, Addia Ababa, Ethiopia, [3]African Society for Laboratory Medicine, Addis Ababa, Ethiopia.

Background: Soluble Intercellular Adhesion Molecule 1 (sICAM-1) and soluble Urokinase Plasminogen Activator Receptor (sUPAR) were among potential host immune markers for TB patients. This study aimed to assess the prospective of sICAM-1 and sUPAR as treatment response markers in TB patients with or without HIV in Ethiopia.
Methods: For this particular study, 34 TB+HIV-, 23 TB+HIV+ cases and 52 healthy controls participants were selected from GC6-74 cohort project conduct from 2005 to 2010 aimed to assess biomarkers of TB in relation to HIV/AIDS in Africa. Plasma levels of sICAM-1 and sUPAR were measured using Quantikine sICAM, R &D systems (USA) and suPARnostic, ViroGetes (Denmark) ELISAs, respectively at baseline and 6 months after TB treatment.
Results: Mean sICAM-1 levels at baseline were 393.8±251.1ng/ml in TB+HIV- and 698±588.4ng/ml in TB+HIV+ cases, while 195.9±125.6ng/ml in controls groups. There was decline to 250.6±147.9ng/ml and 135.6 ± 176.6ng/ml in TB+HIV- and TB+HIV+ cases, respectively after TB treatment. The mean sUPAR levels at baseline were 10.1±5.9ng/ml in TB+HIV- and 18.0±14.2ng/ml in TB+HIV+ cases and 4±2.8ng/ml in healthy controls. sUPAR levels declined to 5.3±2.7ng/ml and 9.5±7.0ng/ml in TB+HIV- and TB+HIV+ cases, respectively after TB treatment. The declines in the level of both markers after treatment were statistically significant (P-value= 0.05).
Conclusion: Significantly higher levels of sICAM-1 and sUPAR were observed in patients than controls group before TB treatment; while the levels declined significantly after 6 months treatment. This shows the potential of sICAM-1 and sUPAR as treatment response markers in TB patients irrespective of their HIV status.

P1.14.78
State of adaptive mucosal immunity among immunocompromised patients with allergic rhinosinusitis.

***N. Tataurshchikova**;*
PFUR, Moscow, Russian Federation.

Survey of immunocompromised patients with allergic rhinosinusitis reveals significant breaches in the system of adaptive mucosal immunity among these patients. Changes in the local cytokine response with violation of IL-4, IL-8, γ-interferon, α-TNF, and violation of serum fractions cytokine state are accompanied by the activation of an opportunistic infection on "allergic" mucosal. A key role in the formation of pathology among these patients plays herpetic infection.
Major disturbances in the mucosal immune system, that are clearly seen in a case of immunocompromised patient with rhinosinusitis are disturbances in the system of anti-viral defense. Violations of interferon status are easily spotted during the evaluation of local interferone response on mucosal among patients with allergic rhinosinusitis.
A common case for this group of patients is the case of IgA fractions content change.
Lack of change or insignificant changes in the phagocytic immune system, cell system, a unit responsible for the immune defense system, are fully compensated by opposite changes in local immunity among patients with allergic rhinosinusitis.
Continuous-recurrent nature of the underlying disease, complicated by infectious syndrome clinic, the presence of treatment-resistant opportunistic infection among this group of patients is the result of ineffective approaches to the treatment of mucosal immune system among immunocompromised patients with allergic rhinosinusitis.

P1.14.79
High sensitivity C-reactive protein and insulin levels in obese and non-obese patients with polycystic ovarian syndrome

***S. S. Uppal**, A. Naveed, A. Majeed;*
National University of Sciences and Technology, Islamabad, Pakistan.

The purpose of this study was to compare the levels of hs-CRP and insulin levels in obese and non-obese patients of PCOS. The study design was Cross-sectional and comparative study. A total of 72 patients having Polycystic Ovarian Syndrome (PCOS) were selected, who had been diagnosed as per Rotterdam diagnostic criteria. Blood sampling was done for glucose, insulin and high sensitivity C-reactive protein (hs-CRP) in fasting state. Insulin Resistance (IR) was calculated by homeostatic model for assessment of insulin resistance (HOMA-IR) method. The obese PCOS women had significantly higher levels of insulin, HOMA-IR and hs-CRP levels as compared to the overweight and normal weight PCOS women. The overweight PCOS women had significantly higher insulin, HOMA-IR and hs-CRP levels as compared to the normal weight PCOS women. Our results revealed that obese PCOS patients had increased rate of IR and low grade inflammation as compared to the non-obese PCOS women. Therefore it was concluded that BMI is an important factor, that plays crucial role in the etiology and the complications associated with PCOS.

P1.14.80
HMGB1 is a major mediator of pathology in mice surviving sepsis

***S. I. Valdes-Ferrer**[1], M. Rosas-Ballina[1], B. Lu[1], P. S. Olofsson[1], J. Roth[1], D. J. Antoine[2], U. Andersson[3], K. J. Tracey[1];*
[1]Feinstein Institute for Medical Research, Manhasset, NY, United

States, [2]MRC Centre for Drug Safety Science, Molecular and Clinical Pharmacology, University of Liverpool, Liverpool, United Kingdom, [3]Departments of Women's and Children's Health, Karolinska Institute and Karolinska University Hospital, Stockholm, Sweden.

Severe sepsis is a life-threatening complication of infection and tissue injury. Survivors have reduced quality of life, cognitive impairment, and five-year mortality of 80%. The pathophysiology is largely unknown, with no specific treatment available. High-mobility group box 1 (HMGB1) is a cytokine known to mediate sepsis pathogenesis by causing endothelial dysfunction, inflammation and organ damage. We hypothesized that persistently elevated levels of HMGB1 mediate immune dysfunction in sepsis survivors.
In BALB/c mice, sepsis was induced by cecal ligation and puncture (CLP) and survivors were followed for 12 weeks. Circulating HMGB1 and inflammatory cytokines were determined weekly. Cell phenotype was determined by flow cytometry. Mass spectrometric analysis was used to characterize the redox state of HMGB1.
Splenomegaly and leukocytosis were observed in mice surviving sepsis for four weeks. Levels of HMGB1 were elevated for eight weeks after CLP. IL-6 and CXCL-1 were only transiently increased in the first two weeks. No increase was observed in TNF, IL-1β, or IFN-γ. Splenocytes from sepsis survivors had an augmented response to LPS ex vivo. Treatment of CLP-survivors with an anti-HMGB1 antibody reversed splenomegaly, leukocytosis and reverted splenocyte sensitization. Administration of exogenous HMGB1 to naïve mice replicated the immunophenotype observed in sepsis survivors. Analysis of circulating HMGB1 from sepsis survivors demonstrated a stepwise increase of reduced all-thiol isoform (chemoattractant) during the first 3 weeks, followed by the disulphide isoform (cytokine-inducing) 4-8 weeks after CLP. Our findings suggest that sustained increase in circulating HMGB1 is crucial in inducing immune changes observed in sepsis survivors.

P1.14.81
Association of polymorphism of TNF-alpha receptors genes with expression levels of membrane-bound receptors and serum levels of soluble receptors

***F. F. Vasilyev**, S. V. Sennikov, J. A. Lopatnikova, A. N. Silkov;*
"Research Institute of Clinical Immunology", Russian Academy of Medical Sciences Siberian Branch, Novosibirsk, Russian Federation.

Tumor necrosis factor alpha (TNF) is a pleiotropic cytokine, the biological effects of which are mediated by interaction with specific membrane-bound receptors (TNFRs). Biological activity of TNF depends on TNFRs expression levels on cells, which in turn can be regulated by allele polymorphism. Levels of TNFRs expression were determined by flow cytometry using QuantiBRITE PE calibration beads. Serum levels of soluble TNFRs were measured using enzyme-linked immunosorbent assay. Single nucleotide polymorphisms (SNPs) of TNFRI and TNFRII were genotyped by polymerase chain reaction–restriction fragment length polymorphism. In the study sample (n=150 healthy individuals), carriers of the T allele in rs4149570 of the *TNFRI* gene showed significantly lower level of soluble TNFRI (TT vs GG, p=0.006). Number of membrane-bound TNFRI on $CD14^+$ cells of CC genotype carriers in rs4149569 of *TNFRI* gene was significantly lower than that of GC genotype carriers (p=0.012). Healthy individuals with a CC genotype in rs590368 of the *TNFRII* gene had the lower percentage of $CD14^+$ cells bearing membrane-bound TNFRII (CC vs CT, p=0.015). The results of this study provide evidence of association between SNPs in *TNFRI* and *TNFRII* genes and expression levels of membrane-bound TNF receptors types I and II on mononuclear cells and soluble TNFRI levels in serum of 150 healthy individuals. Thus, allele polymorphism of TNFα receptors genes is a one of the mechanisms influencing TNFα system, functioning through the formation of individual variability of the expression of membrane-bound receptors.

P1.14.82
Comparison of cytokine production in human lymphocytes and human tissue culture THP 1 stimulated by metallic ions

***Z. Venclikova**[1], J. Bartova[1], J. Belacek[2];*
[1]The Institute of Clinical and Experimental Dental Medicine, General University Hospital, First Faculty of Medicine, Prague, Czech Republic, [2]The Institute of Biophysics and Informatics, General University Hospital, First Faculty of Medicine, Prague, Czech Republic.

Introduction: Physiological interaction of foreign materials (including metallic ions) with oral mucosal tissue can lead to oral tolerance induction. However, a minority of humans induce an intense reaction to metal dental reconstruction. Cytokines produced during the interaction of lymphocytes and macrophages play an important role in activation and regulation of immune response. Aim and methods: Our study aimed at exploring cytokine production in lymphocytes of mercury and nickel hypersensitive patients (verified with a test of lymphocyte proliferation) and in a monocyte-macrophage cell line of human origin THP 1. In all cases, the cells were cultivated for five days with an addition of mercury and nickel salts. Cytokines in culture media were determined by Ray Bio® Human Inflammation Antibody Array III and compared with results of control group cells, cultivated without addition of metallic salts. Results: Lymphocytes of hypersensitive patients predominantly produced pro-inflammatory cytokines, for example IL-1 alpha, IL-11, IL-17, IFN-gamma, TNF-beta, sTNFRI, sTNFRII and TIMP-2. These cytokines were observed in both cases of metallic salts stimulation. On the other hand, cell culture THP 1 predominantly produced anti-inflammatory cytokines after stimulation with both metallic salts. The results suggested that in the case of hypersensitivity diagnosis, to follow the reaction of both lymphocytes and monocyte-macrophage cells should be recommended.
This study was supported by a grant from Czech Ministry of Health, IGA NT/12206-4.

P1.14.83
TNF and IL-10 in a bitter-sweet battle in taste buds

*P. Feng, J. Chai, L. Huang, **H. Wang**;*
Monell Chemical Senses Center, Philadelphia, PA, United States.

Taste buds are chemosensory structures widely distributed on the surface of the oral cavity and larynx. Taste cells, exposed to the oral environment, face great challenges in defense against potential pathogens. While immune cells are rarely found in taste buds, our recent studies suggest that some immune-response-associated molecules are expressed at higher levels in taste cells than in nontaste tongue epithelial cells. It remains unclear how protective responses are regulated in taste buds. In this study, we investigated the expression of the pro-inflammatory cytokine TNF and the anti-inflammatory cytokine IL-10 in the posterior taste tissues. Both TNF and IL-10 were found exclusively in subsets of type II taste cells, the receptor cells for sweet, bitter and umami tastes. Further analysis revealed that TNF was co-expressed with the sweet and umami receptor T1R3, but not with the G-protein Gustducin (mostly bitter receptor cells). In contrast, IL-10 was co-expressed with Gustducin, but not with T1R3. Meanwhile, there were few taste cells co-expressed both cytokines. These data suggest that these two cytokines are produced by different populations of taste cells in the posterior taste tissues: TNF by sweet and umami cells and IL-10 by bitter cells. Furthermore, TNF receptors were expressed in all taste cells at differential levels, while IL-10 receptors were preferentially expressed in T1R3+TNF+ cells, suggesting that TNF could act on all taste cells under inflammatory conditions, while IL-10 may preferentially target TNF-producing-taste cells to limit TNF production. This study revealed a novel regulatory mechanism of inflammation in taste buds.

P1.14.84
The role of Notch signaling in IL-12 production in murine macrophages

***W. Wongchana**[1], B. A. Osborne[2], N. Boonyatecha[1], N. Sangphech[1], T. Palaga[1];*
[1]Chulalongkorn University, Bangkok, Thailand, [2]University of Massachusetts, Amherst, MA, United States.

Macrophages are innate immune cells which play crucial roles in both innate and adaptive immune responses. Signaling through interferon (IFN)γ receptor together with Toll-like receptor (TLRs) such as LPS in macrophages leads to secretion of various pro-inflammatory cytokines including IL-12. Previous studies showed the involvement of Notch signaling in regulation of biological activities of TLR activated macrophages such as expression of cytokines, IL-6, TNF-a and IL-12. However, the involvement of Notch signaling pathway in IL-12 production has not been fully elucidated. In this study, we investigated the role of Notch signaling in regulating expression of the IL-12 especially focusing on the p40 subunit. We found that using a pharmacological inhibitor (GSI) to suppress Notch signaling in IFNγ/LPS-activated macrophages derived from wild type mice decreased il12p40 mRNA levels and IL-12p40/70 secretion. We found that nuclear translocation c-Rel, one of key factors to control il12p40 transcription, was inhibited and Erk1/2 activation was compromised by GSI treatment. However, activated macrophages derived from Cre+/-Notch1flox/flox mice did not show a reduction in the level of il12p40 mRNA nor the protein level whereas activated macrophages derived from Cre+/-CSLflox/flox mice phenocopied that of the GSI treatment. Treatment with GSI in activated Cre+/-Notch1flox/flox macrophages resulted in the reduction of IL12p40/70 secretion similar to GSI treatment in wild type macrophages or Cre+/-CSLflox/flox macrophages. Currently, silencing expression of CSL by siRNA is under investigation for its effect on IL-12 production. Taken together, Notch1, but not CSL or gamma secretase activity is dispensable for IL12p40/70 production.

P1.14.85

Cortex Magnolia Officinalis extract prevents gastric ulcer by stimulating CB2 gene expression and reducing IL-6 and TNF-alpha productions in stomach tissue

M. Wu[1]*, H. Chaung*[1]*, M. Hsieh*[1]*, C. Chen*[2]*, H. Chiu*[2]*;*
[1]*National Pingtung University of Science and Technology, Pingtung, Taiwan,* [2]*Chang Gung Memorial Hospital, Kaohsiung, Taiwan.*

A variety of factors including stresses, acid, Helicobacter pylori, NSAIDs and ethanol have been known to be involved in the pathogenesis of gastric mucosal injury and gastroduodenal ulcer disease. This study investigated the effects of water extracts of Curcumae Radix and Cortex Magnoliae Officinalis, on cell activities of gastric mucosa cell in vitro and protective effects on gastric mucosal injury in vivo. Results showed that Curcumae Radix and Cortex Magnoliae Officinalis extracts in vitro specifically promoted the cell viability and decreased the production of reactive oxygen species (ROS) of the gastric epithelial cells in the acidic medium as compared with those of control cells. In the animal model of Shey's ulcer ligation, the Cortex Magnoliae Officinalis extracts stimulated the gene expression of the cannabinoid receptor type 2 (CB2) and decreased the productions of tumor necrosis factor-alpha (TNF-alpha) and interleukin 6 (IL-6) of gastric tissue and thus, significantly decreased the gastric ulcer index in the pylorus-ligated animals. Thus, Cortex Magnoliae Officinalis extracts may protect the gastric mucosal tissue from the acidified injury by enhancing gastric epithelial cell survival rates and decreasing ROS, TNF-alpha and IL-6 productions in the injured gastric tissue.

P1.14.86

An essential role for eosinophils in neutrophil accumulation in response to eotaxin

P. P. Xavier-Elsas[1]*, R. A. Luz*[1]*, L. C. G. Arcanjo*[1,2]*, A. C. Faria*[1]*, M. C. Gaspar-Elsas*[3]*;*
[1]*Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil,* [2]*Universidade Federal Fluminense, Faculdade de Medicina, Programa de Pós-graduação em Patologia., Niteroi, Brazil,* [3]*Fundação Oswaldo Cruz - IFF, Rio de Janeiro, Brazil.*

The roles of eosinophils in defense against infection, unlike their contribution to allergic inflammation, remain controversial. The 5-lipoxygenase (5-LO) pathway is required for the recruitment of eosinophils to the peritoneal cavity of allergic mice by both antigen and eotaxin. The relevance of this requirement to host defense is unknown. We evaluated whether eosinophil recruitment by eotaxin in nonallergic mice: a) required 5-LO; b) contributed to innate immunity. Wild-type (BALB/c; PAS) and mutant (5-LO-deficient ALOX; eosinophil-deficient GATA-1-mutants) mice were injected i.p. with eotaxin, eosinophils or both, and leukocyte accumulation was quantified up to 24h. Recruitment of eosinophils by eotaxin in BALB/c (50 ng/cavity) was significant at 4h, 12h and 24h, and accompanied by recruitment of neutrophils and macrophages in numbers respectively 8.2 and 9.9-fold larger. These effects were abolished by eotaxin neutralization and 5-LO-pathway blocker MK886. In ALOX (but not PAS) mice, eotaxin recruitment was abolished for eosinophils and reduced by≈55% for neutrophils. In GATA -1 mutants, eotaxin recruited neither neutrophils nor macrophages. Transfer of purified eosinophils from BALB/c donors, or from ALOX donors, into GATA-1 mutant recipients, i.p., restored eotaxin recruitment of neutrophils, and showed that the critical step dependent on 5-LO is the initial recruitment of eosinophils by eotaxin, not the secondary attraction of neutrophils. Eosinophil-dependent recruitment of neutrophils in naive BALB/c mice was associated with increased binding of bacteria. This points to an indirect mechanism through which eosinophils contribute to innate immunity in nonsensitized mice.

P1.14.87

Interleukin-1 signaling prevents bacteremia in enteric infection with *Citrobacter rodentium*

H. Yang, ***M. Kweon****;*
International Vaccine Institute, Seoul, Republic of Korea.

Attaching and effacing pathogens, including enterohemorrhagic *Escherichia coli* (EHEC) in humans and *Citrobacter rodentium* (*C. rodentium*) in mice, raise serious public health concerns. Here we demonstrate that interleukin-1 receptor (IL-1R) signaling is indispensable for protection against *C. rodentium* infection in mice. Oral challenge with *C. rodentium* ($5x10^9$ CFU) showed severe loss of body weight and high mortality in IL-$1R^{-/-}$ mice at 7-14 days post infection (dpi) while IL-1R intact wild-type (WT) mice restored from mild symptoms within three weeks. The hemorrhage and thickened cecum and colon were observed in IL-$1R^{-/-}$ mice, and higher levels of inflammatory cytokines such as IL-6 and MCP-1, but not IL-22 and IL-23, were determined in IL-$1R^{-/-}$ mice than in WT mice at 10 dpi. Moreover, an enlarged spleen with neutrophil infiltration and bacteremia in systemic tissues (i.e., spleen and peripheral blood) were found in IL-$1R^{-/-}$ mice but not in WT mice. Interestingly, extracellular *C. rodentium* resided in $CD18^{high}Ly6C^{+}Ly6G^{+}$ neutrophils and $CD18^{high}Ly6C^{+}Ly6G^{-}$ monocytes from cecum and colon of IL-$1R^{-/-}$ mice, but no bacteria were found in those cells from WT mice. These results suggest that the IL-1 signaling plays a pivotal role in bactericidal activity of phagocytes and inhibits bacterial dissemination from mucosal tissues to bloodstream.

P1.14.88
IL-27 affects helper T cell responses via regulation of PGE2 production by macrophages

*Y. Sato[1,2,3], H. Hara[1], S. Suzuki[2], T. Kaisho[3], **H. Yoshida**[1];*
[1]Dept. Biomolecular Sciences, Faculty of Med., Saga Univ., Saga, Japan, [2]Dept. of Molecular & Cellular Biology, Kobe Pharma Research Institute, Nippon Boehringer Ingelheim Co., Ltd., Kobe, Japan, [3]Laboratory of Immune regulation, Immunology Frontier Research center, Osaka University, Osaka, Japan.

IL-27 is a heterodimeric cytokine that regulates both innate and adaptive immunity. IL-27 acts as an immune suppressor by the induction of Tr1 type T cells, which produce IL-10 and inhibit effector T cells. IL-27 also suppresses function of macrophages and dendritic cells by regulation of cytokine secretion. On the other hand, effects of IL-27 on regulation of inflammation via mediators other than cytokines remain poorly understood. To address this issue, we examined immunoregulatory effects of conditional medium of bone marrow-derived macrophages (BMDMs) from *WSX-1* (*IL-27Ra*) KO mice to find enhanced IFN-g and IL-17A secretion by $CD4^+$T cells over that of control BMDMs. EP2 and EP4 antagonist inhibited this enhancement, suggesting possible involvement of prostaglandins. PGE_2 secretion and *COX-2* expression by BMDMs from *WSX-1* KO mice was increased compared to control macrophages in response to LPS. To explore how IL-27/WSX-1 signal regulate COX-2/PGE_2 production, murine *WSX-1*-expressing Raw264.7 cells (mWSX-1-Raw264.7) were established. mWSX-1-Raw264.7 showed phosphorylation of both STAT1 and STAT3 in response to IL-27 and produced less amounts of PGE_2 and COX-2 compared to parental Raw264.7. Finally, siRNA knockdown study was performed toreveal siSTAT1, but not siSTAT3, resulted in increased production of PGE_2 and COX-2. In addition, BMDMs from *STAT1* KO mice showed higher *COX-2* expression than those from control mice. Collectively, our result indicated that IL-27/WSX-1 regulated PGE_2 secretion via STAT1-COX-2 pathway in macrophages and affected helper T cells responses in a PGE_2-mediated indirect fashion.

P1.14.89
High Concentration Of Interleukin-23 And Soluble Vascular Endothelial Cadherin In Sera Of Patients With Behcet disease

***H. R. Zare**[1,2], M. Habibagahi[1], F. Ghatei[1];*
[1]Medical Of Shiraz University, Shiraz, Iran, [2]Medical School, Shiraz University of Medical Sciences, Shiraz, Iran.

Introduction and Aims: Behcet's disease (BD) is a chronic multisystem vasculitis disease that can affect any organ and usually is combined with hyperactivation of neutrophils. Involvement of inflammatory cytokines such as Interleukin (IL)-12 in BD has been shown. However, IL-12 shares a p40 subunit with IL-23 which has additional inflammatory effects apart from IL-12. IL-23 increases neutrophils' transmigration therefore could contribute in BD induction or progression. Moreover, endothelial cells express vascular endothelial cadherin adhesion molecule (VE-cadherin), which plays critical roles in angiogenesis and endothelial integrity. VE-cadherin may shed into the circulation as soluble (sVE-cadherin) which inflammatory cytokines can increase this process. We therefore assessed the correlation between IL-23 concentration and amount of sVE-cadherin in sera of Behcet patients.
Methods: We enrolled 44 healthy persons and 53 cases of BD with different disease activities and examined their serum concentrations of IL-23 and sVE-cadherin using commercial ELISA kits (Bendermed Systems, Austria).
Results: A significant correlation was found between the concentrations of these two factors only among patients. Comparing sVE-cadherin mean concentration in patients and controls showed a significant difference, this difference for IL-23 was negligible. Results showed higher IL-23 levels in sera of patients with uveitis. Moreover, there was a meaningful correlation between IL-23 content and disease activity.
Conclusion: These results extend the biological effects of IL-23 in BD and introduce sVE-cadherin as a potential new biomarker in BD pathogenesis.

P1.15.01
Malaria-induced NLRP12/NLRP3-dependent caspase-1 activation mediates inflammation and hypersensitivity to bacterial superinfection

***M. A. Ataide**[1], W. A. Andrade[1], D. S. Zamboni[2], D. Wang[3], M. Ribeiro[1], M. Souza[2], F. S. Martins[1], K. Fitzgerald[3], D. T. Golenbock[3], R. T. Gazzinelli[1];*
[1]Federal University of Minas Gerais, Belo Horizonte, Brazil, [2]University of São Paulo, Ribeirão Preto, Brazil, [3]University of Massachusetts, Worcester, MA, United States.

Cyclic paroxysm is a hallmark of malaria, being associated with high levels of the pyrogenic cytokine, IL-1β. Here we report that mice infected with P. chabaudi show a signature for expression of inflammasome-related genes, and that caspase-1 activation was dependent on IFNγ-priming, MyD88 activation, ASC, P2X7R, NLRP3 and NLRP12, whereas expression of pro-IL-1β required MyD88, IFNγ and TNF receptor. Importantly, therapeutic intervention with an IL-1 receptor antagonist prevented bacterial-induced septic shock in the hypersensitive rodent malaria model. We also report a significant increase in the frequency of circulating CD14+CD16-Caspase-1+ and CD14dimCD16+Caspase-1+ monocytes, which was associated with pronounced production of IL-1β by peripheral blood mononuclear cells from febrile malaria patients. Furthermore, we demonstrated that the inflammasomes from these patients contained either NLRP12 or NLRP3 oligomerized with ASC. Thus, NLRP12/NLRP3-dependent activation of caspase-1 is a key event in mediating systemic inflammation and hypersensitivity to secondary bacterial infection during malaria.

Molecular differences of NLRP3 inflammasome activation in LPS-activated human monocyte-derived macrophage subtypes

*M. M. Budai[1], J. Danis[1], Á. Becsei[1], A. Varga[1], L. Csernoch[1], J. Tőzsér[2], **S. Benkő**[1];*
[1]Department of Physiology, Faculty of Medicine, Medical and Health Science Center, University of Debrecen, Debrecen, Hungary, [2]Department of Biochemistry and Molecular Biology, Faculty of Medicine, Medical and Health Science Center, University of Debrecen, Debrecen, Hungary.

IL-1beta is a "master" cytokine that has indispensable roles in orchestrating effective innate and adaptive immune responses. It is produced in an inactive precursor form that is cleaved to active cytokine by protein complexes called Nlrp3 inflammasomes. While our knowledge on the general mechanisms involved in Nlrp3 inflammasome function and on its regulation is rapidly increasing, it is also getting clear that the actual outcome of the activation (like IL-1beta production) strongly depends on the cell type and on the presence or absence of various intracellular or extracellular modulators. Depending on their localization macrophages can develop into a wide range of phenotypes. Macrophages differentiated in the presence of GM-CSF (GM-MFs) develop inflammatory phenotype, while cells differentiated in the presence of M-CSF (M-MFs) possess anti-inflammatory characteristics and function in wound healing and tissue repair. Our results show that following LPS treatment GM-MFs produce high IL-1beta, while M-MFs produce low IL-1beta with a different time- and concentration kinetics. We found significant differences in basal and LPS-induced expression of Nlrp3, procaspase-1 and ASC between the two MF types. We found that LPS-treated GM-MFs are able to release ATP and produce IL-1beta, while M-MFs require ATP supplementation for IL-1beta secretion. We have also found expression differences in the proteins responsible for ATP release, recognition and degradation as well as in the activation of key signal transduction pathways. Furthermore, we will show that different nucleosides have strong and differential regulatory effects of NLRP3 inflammasome function. P1.15.03
Acidosis drives DAMP-induced IL-1β secretion via a caspase-1-independent pathway

*M. E. Edye, G. Lopez-Castejon, S. Allan, **D. Brough**;*
University of Manchester, Manchester, United Kingdom.

Inflammation in the absence of infection is sterile and contributes to the worsening of disease. The pro-inflammatory cytokine interleukin-1β (IL-1β) is a mediator of sterile inflammatory responses, and is known to drive the worsening of brain injury in numerous experimental models. In the brain IL-1β is synthesised by microglia as an inactive precursor (pro-IL-1β). Cleavage of pro-IL-1β to a mature secreted form follows stimulation of the activated cell by Damage Associated Molecular Patterns (DAMPs), endogenous disease or injury associated molecules. DAMPs are sensed by the pattern recognition receptor NLRP3, whose activation results in the formation of an inflammasome, the activation of caspase-1 and the cleavage of pro-IL-1β. To-date, studies on the inflammasome in vitro have all been conducted under standard culture conditions. However, during disease there are profound changes in the intercellular milieu, and how DAMPs signal under these conditions is not known. Acidosis is a common consequence of disease and so we investigated whether acidosis influenced DAMP-induced IL-1β release. When LPS-primed glial cells were stimulated with DAMPs under acidic conditions (pH 6.2) the predominant IL-1β form secreted was 20kDa in size rather than the 17kDa caspase-1-dependent species. Lactic acidosis, induced by the addition of 25mM lactate to the culture also induced the release of 20kDa IL-1β. This 20kDa product was produced independently of the NLRP3 inflammasome and caspase-1 but could be inhibited by the cathepsin D inhibitor pepstatin A. These data suggest that under disease relevant culture conditions, DAMPs induce the secretion of IL-1β independently of the inflammasome.

P1.15.04
The impact of Butyrate on the NOD-like receptor pyrin domain-containing protein 6 (NLRP6)-inflammasome in humans

***K. Brunner**, M. Enea, S. Holly, K. Nigel, B. Mona;*
Institute of Child Health, UCL, London, United Kingdom.

A recent study using a knock-out (KO) mouse model has suggested a specific interaction between the NLRP6-inflammasome and the intestinal microbiome. KO mice presented a higher susceptibility to chemically induced colitis compared to their wild-type controls. Interestingly this phenotype was transferable upon cohousing before treatment. The investigators suggest that a shift in the commensal microbial community (dysbiosis) and a decreased expression of IL-18 at baseline could be responsible for this phenomenon. The role of NLRP6-mediated immune regulation in human health and disease is still unknown (Elinav et al., 2011).
Aim of this study was to examine if bacterial structural components (microbial associated molecular pattern, MAMPs) and bacterial by-products (butyrate) affect NLRP6 and IL-18 gene expression in the intestinal epithelium.
Time and dose-dependent effects of MAMPs, infection (Campylobacter jejuni) and sodium butyrate on intestinal NLRP6 and IL-18 gene and protein expression were analysed by quantitative real-time PCR, Elisa and Western blotting.
Butyrate led to a major increase in epithelial IL-18 and NLRP6 gene expression whereas the presence of other inflammasome components such as NLRP3 and Caspase-1 were not affected.
Butyrate-producing commensal bacteria have been associated with health benefits for the host including increased epithelial barrier function and protection against colorectal cancer (Fung et al., 2012). Our study indicates a putative novel role for butyrate-mediated modulation of the inflammasome that may have an impact on the onset of inflammatory driven diseases. Further studies are needed to investigate the association between the NLRP6 inflammasome and the microbiome.

P1.15.05
Activation of the NLRP3 inflammasome promotes the pathogenic Th1/Th17 responses in type 1 diabetes murine model

***D. Carlos**, J. N. U. Yaochite, F. R. C. Costa, S. G. Ramos, F. Q. Cunha, D. S. Zamboni, N. O. Camara, J. S. Silva;*
University of São Paulo, Ribeirão Preto, Brazil.

Introduction: Autoimmune diseases including type 1 diabetes (T1D) are thought to have a pathogenic dual Th1/Th17 response, but the underlying mechanisms of innate immunity driving the activation and polarization of these subtypes is not fully understood.
Objective: Thus, we addressed the role of the NLRP3 inflammasome in the T-cell mediated response during the development of experimental T1D.
Methods: Nlrp3 deficient mice and their wild-type (C57BL/6) were inoculated intraperitoneally with 40mg/Kg of streptozotocin for 5 consecutive days. Mice inoculated with vehicle (sodium citrate) were used as control mice. The pancreatic lymph nodes (PLNs) were removed to assess the myeloid and lymphoid cell frequency and number by flow cytometry. The pro and anti-inflammatory cytokine levels were determined in pancreatic tissue homogenates by ELISA assay.
Results: Initially, our results demonstrate that Nlrp3 deficient mice developed lower hyperglycemia and reduction of 50% in the disease incidence compared to wild-type mice. In agreement, mice lacking Nlrp3 had less inflammatory infiltrate (insulitis) and reduced IL-1β production in the pancreatic islets. In parallel, they exhibited augmented number of mast cells in the PLNs and significant increase of the IL-4 production in the pancreatic tissue. In addition, the Nlrp3 deficiency caused a decrease in IL-17 (Th17) and IFN-γ (Th1) producing CD4 T cell population in PLNs. Conclusion: These results suggest that NLRP3 inflammasome activation promotes the pathogenic Th17/Th1 response skewing and possibly contributes to pancreatic islet damage and T1D development in mice.

P1.15.06
Caspase-1 and MyD88 are involved in adaptive immune response induced by cytosolic flagellin

***T. B. da Costa**[1,2], C. L. Freitas[3,2], V. M. Gonçalves[3,2], K. R. Bortoluci[3,2];*
[1]University of São Paulo, São Paulo, Brazil, [2]CTC-Mol - Centro de Terapia Celular e Molecular, São Paulo, Brazil, [3]Federal University of São Paulo, São Paulo, Brazil.

TLR activation in dendritic cells leads to its maturation and production of proinflammatory cytokines, providing favorable conditions for the activation and differentiation of naïve T cells. Flagellin is a highly effective adjuvant for humoral and CD4 T cell responses. It is recognized by TLR5 and by cytosolic NLRs members NAIP5/NLRC4. TLR5 activates inflammatory genes through MyD88 pathway whereas NLRC4 and NAIP5 assemble multiprotein complexes called inflammasomes, leading to caspase-1 activation. Besides the well-described adjuvant properties of flagellin, little is known about the mechanisms through which TLR5 and inflammasomes act during the shaping adaptive of immune responses. Thus, we analyzed the role of inflammasome activation in the maturation of dendritic cells and activation of T cells. Purified flagellin in its free form was able to stimulate BMDCs via TLR5 and MyD88. Cytosolic flagellin induced upregulation of costimulatory molecules independent on TLR5, NLRC4 and Caspase-1, but also dependent on MyD88. In addition, cytosolic flagellin- stimulated OVA-pulsed BMDCs induced the production of IFN-γ by OT-II splenocytes, which was independent on TLR5 and dependent on caspase-1 and MyD88. From these data we can infer that in addition to TLR signaling, inflammasomes might be shaping the flagellin-induced immune response through Caspase-1 and MyD88.

P1.15.07
A novel, Cyclosporine A (CyA)-sensitive P2RX7 SNP haplotype linked to survival of immature antigen presenting cells (APC) in autoinflammation

***S. Dagenbach**, A. Altmann, M. Lorenz, H. Hohmann, K. Foehr, E. M. Schneider;*
Section Experimental Anesthesiology, University Hospital Ulm, Germany.

Adenosine-3-phosphate (ATP) is a major danger associated molecular pattern (DAMP) released by trauma. Concentrations of >1mM stimulate P2XR7 and trigger the inflammasome. We enriched in vivo activated antigen presenting cells (APC) from patients at the onset of septic shock and autoinflammatory diseases. Genotyping of functional single nucleotide polymorphisms (SNPs) of P2RX7 revealed a higher frequency of haplotypes bearing SNP489 C>T and SNP 1513 A>C in patients. ATP stimulated IL-1β secretion was lower in the mutated genotype than in wild-type (wt) and so was the ATP-induced ion flux signal (p=0.0004). When ATP was co-administered with Cyclosporine A (CyA), the ion flux of SNP489/1513 mutated cells was upregulated (p=0.03), but never reached the activity of wt cells. ATP did not stimulate but rather decrease both spontaneous and staurosporine (STS) induced caspase-3/7 release in cultured APC. This effect was more pronounced when CyA was added to ATP. Generally, STS-induced caspase-3/7 release was lower in P2RX7 mutant- than in wt cells (p<0.002). In summary, we describe the properties of a novel P2RX7 SNP haplotype in in-vivo activated APC of patients with autoinflammatory diseases. This haplotype has both a reduced ion channel activity, IL-1β-secretion and caspase activation. The phenotype encoded by this haplotype may explain persistence of chronic inflammation by impaired activation of counterregulatory pathways in vivo.

P1.15.08
Deregulation of NLRP3 inflammasome is involved in progression of hepatocellular carcinoma

***L. Han**, Q. Wei, K. Mu, T. Li, Y. Zhang, W. Huai, X. Jia;*
Department of Immunology, Jinan, China.

The nucleotide-binding domain, leucine rich family (NLR), pyrin containing 3 (NLRP3) inflammasome, has been shown to orchestrate multiple innate and adaptive immune responses, however little is known about its role in cancer. This study is to investigate the role of NLRP3 inflammasome in the development and manipulation of hepatocellular carcinoma (HCC),a typical inflammation-induced cancer. Three cohorts of patients were investigated in this study for the expression of NLRP3 inflammasome components in liver cells. Our data showed expression of all of the NLRP3 inflammasome components was either completely lost or significantly down-regulated in human HCC, and loss of NLRP3 inflammasome components was significantly correlated with advanced stages and poor pathological differentiation. Reconstitution of NLRP3 inflammasome in HCC cells had antitumor effects and significantly reversed malignant behaviors of these cancer cells. Our data offered the basis for potential immunological cancer therapy by reconstitution of NLRP3 inflammasome in HCC patients.

Mistletoe lectin-mediated mmunostimulatory effect implicates the activation of NLRP3 inflammasome

***P. Hedge**[1,2,3], A. Friboulet[2], J. Bayry[4,3,5], S. V. Kaveri[4,3,5];*
[1]Institut National de la Santé et de la Recherche Médicale, Unité 872, Paris, France, Paris, France, [2]CNRS UMR 6022, Université de Technologie de Compiègne, France, Compiègne, France, [3]Centre de Recherche des Cordeliers, Equipe 16- Immunopathology and therapeutic immunointervention, Université Pierre et Marie Curie – Paris 6, UMR S 872, Paris, Paris, France, [4]Institut National de la Santé et de la Recherche Médicale, Unité 872, Paris, France, PARIS, France, [5]Université Paris Descartes, UMR S 872, Paris-75006, Paris, France.

Inflammosomes are the molecular complexes that are activated upon cellular stimulation that trigger the maturation and secretion of pro-inflammatory cytokines like IL-1β, thereby driving innate immune defence mechanisms. NLRP3 inflammasome plays an important role in the regulation and stimulation of anti-cancer immune response. Several cancer chemotherapeutics efficiently promote the anti-tumor immunity by activating the NLRP3 inflammasome. Mistletoe lectins are one of the important bioactive molecules present in the therapeutic preparations of Viscum album (VA) which are used as complementary therapy in cancer. They exert anti-tumor activities which involve the cytotoxic properties, induction of apoptosis, inhibition of angiogenesis and several other immunomodulatory mechanisms. They also exert immunostimulatory effect by inducing maturation and activation of human dendritic cells thereby enabling them to stimulate tumor-specific CD8 T cell response; however the underlying cellular and molecular mechanisms are not clear. In this study, we hypothesized that mistletoe lectins present in Viscum album preparations induce the activation of NLRP3 inflammasome in human dendritic cells thereby activating them for the secretion of pro-inflammatory cytokine IL-1β. We demonstrate that, treatment with mistletoe lectin-containing VA preparations alone can induce a moderate secretion of mature IL-1β, however along with the TLR4 stimulation they significantly up-regulate the secretion of mature IL-1β. We are currently dissecting the mistletoe lectin-mediated activation of inflammasome at different regulatory levels of caspase-1 and purinergic signaling pathways. Our results thus demonstrate a novel molecular regulatory mechanism by which mistletoe lectin-containing Viscum album preparations exert immunostimulatory effect.

P1.15.10
Fine mapping of the mouse *Irm1* locus controlling interleukin-1beta production

*J. R. Jensen[1], A. Galvan[2], W. H. K. Cabrera[1], O. G. Ribeiro[1], M. De Franco[1], N. Starobinas[1], R. Piazza[3], M. Dugo[2], T. A. Dragani[2], **O. M. Ibañez**[1];*

Irm1 (Inflammatory response modulator 1) in chromosome 7 is a major locus regulating the acute inflammatory response through modulation of IL-1beta production by circulating leukocytes, after lipopolysaccharide and ATP stimulation of the Nlrp3 inflammasome. In order to fine map this locus, we carried out genome-wide linkage analysis of 879 informative single nucleotide polymorphisms (SNPs) in a new and larger F2 intercross population (n=693 compared with the previous analysis with 280 mice) of outbred mouse lines selected for the intensity of acute inflammatory response (AIRmax x AIRmin). We confirmed the mapping of the Irm1 locus (the LOD score increased from 9 to 72) and the 1-LOD confidence interval decreased from 14 to 3.5 Mb. Deep-sequencing of this chromosomal region was carried out in 8 F2 mice with extreme high IL-1beta production and 8 extreme low responder F2 mice. Interval of the locus region was restricted to about 420 kb where 10 protein-encoding candidate genes map. Functional assays will be carried out in order to characterize the role of genetic variants evidenced in this region to the differential modulation of IL-1beta levels in AIRmax and AIRmin mice.

P1.15.11
ASC inflammassome mediates IL-1β production and host resistance to Paracoccidioides brasiliensis

***N. Ketelut-Carneiro**, F. A. Rocha, G. K. Silva, D. S. Zamboni, J. S. Silva;*
University of Sao Paulo, Ribeirao Preto, Brazil.

An efficient recognition of the fungus *Paracoccidioides brasiliensis* by the host's innate immune system is essential for protection against paracoccidioidomycosis (PCM), a systemic human mycosis highly prevalent in Latin America. The NOD like receptors (NLRs), unlike TLRs, are intracellular pattern recognition receptors that form a molecular platform, called inflammasone, which activates caspase-1 and induces the production of active IL-1β and IL-18. Here, we evaluated the importance of inflammasome in the experimental PCM. We showed that *P. brasiliensis* triggers the secretion of IL-1β in murine bone marrow-derived macrophages (BMMs) and that its release in the active form requires the activation of caspase-1 and the involvement of the ASC inflammasome, since we found high caspase-1 activation and IL-1β production in BMMs from WT mice, but not from $ASC^{-/-}$ mice. To understand the role of inflammasome regarding protection to *P. brasiliensis* infection, WT, $ASC^{-/-}$ and caspase-$1^{-/-}$ mice were intravenously infected with Pb18 strain. We verified that the knockouts mice displayed higher mortality index and fungal loads in the lung after 30 days of infection compared with WT mice. The increased susceptibility is related with reduced amounts of IFN-γ in the same period of infection. Moreover, the histological analysis of the lung revealed that in the absence of caspase-1 there was significant increased in the amount of fungus after the infection on the 15th day after infection. However, this is not followed by impaired compact and well defined granulomas formation, revealing a new signaling pathway implicated in the regulation of pulmonary antifungal defenses.

P1.15.12
ATP-mediated inflammasome activation is efficiently inhibited by acetylcholine

***M. Kuellmar**[1], A. Hecker[1], S. Wilker[1], S. Atanasova[1], A. Zakrzewicz[1], M. Meixner[1], A. Kaufmann[2], W. Kummer[3], W. Padberg[1], V. Grau[1];*
[1]Laboratory of Experimental Surgery, Giessen, Germany, [2]Institute for Immunology, Marburg, Germany, [3]Institute for Anatomy, Giessen, Germany.

The release of IL-1beta by mononuclear phagocytes is tightly controlled. Lipopolysaccharide induces synthesis of pro-IL-1beta. A second danger signal such as ATP triggers inflammasome activation resulting in cleavage and secretion of mature IL-1beta. Acetylcholine is known for its anti-inflammatory effects on the innate immune system. In this study, we test the hypothesis, that acetylcholine dampens ATP-mediated activation of the inflammasome.
Human monocytic U937 cells were primed with lipopolysaccharide for 3 hours. In addition, mononuclear blood leukocytes from healthy human donors and from blood vessels of renal rat allografts undergoing acute rejection were investigated. Cells were stimulated with BzATP or nigericin in the presence or absence of cholinergics and inhibitors of NO-synthases. The release of IL-1beta was measured by ELISA.
Acetylcholine and nicotine efficiently inhibited BzATP-induced release of IL-1beta from U937 cells and primary blood leukocytes. Mecamylamine, strychnine, alpha-bungarotoxin and inhibitors of NO-synthases reversed this effect. Nicotinic agonists did not inhibit IL-1beta release induced by nigericin. Activated leukocytes from allografts, which are known to synthesize acetylcholine, did not release IL-1beta unless acetylcholine esterase was added together with BzATP. As revealed by RT-PCR, alpha-9 subunits of acetylcholine receptors and NO-synthases 1-3 were expressed.
We describe a novel anti-inflammatory mechanism of acetylcholine. Acetylcholine inhibits ATP-mediated inflammasome activation. Our pharmacological data suggest that P2X7 receptors, alpha-9 nicotinic receptor subunits and NO-synthases are involved in the signaling cascade. We suggest that this novel anti-inflammatory pathway is active in renal allografts during acute rejection, where endogenous leukocytic acetylcholine prevents IL-1beta secretion into the blood stream.

P1.15.13
Activation of NLRP3 inflammasome is associated with the progression of Alzheimer's disease

***F. La Rosa**[1], M. Saresella[1], E. Calabrese[1], I. Marventano[1], F. Piancone[1], D. Trabattoni[2], M. Biasin[2], M. Clerici[1];*
[1]Don Gnocchi Foundation, Milan, Italy, [2]University of Milan, Milan, Italy.

Inflammatory mediators are responsible for the neuroinflammation observed in Alzheimer's disease (AD),a phenomenon that might be the culprit of disease or, possibly, a reaction to pathology. In particular IL-1β and its key regulator, the inflammasome protein complex, are strongly suggested to play a role in this disease. To better investigate the possible involvement of the inflammasome in AD we stimulated with lipopolysaccaride (LPS) for 4 hours and β-Amyloide peptides (Aβ) for 21hours PBMC of 20 individuals with a diagnosis of mild cognitive impairment (MCI)(MMSE score>24), 20 Alzheimer's disease (AD) patients with either moderate(MMSE score 19-23), and 10 severe (MMSE score<19) Alzheimer's disease (AD) patients, and evaluated by RT-PCR the expression of 84 genes involved in the inflammasome pathway.
Proinflammatory cytokines-expressing immune cells were measured by FACS analyses in the same individuals upon stimulating cells with antigenic β-amyloid peptides.
Results showed that a number of genes including inflammasome components (AIM 2, NLRP3 and NPLR-9), downstream signaling (IRF-2 and RAGE) and effector molecules (IFNγ, IL12, IL1β, IL6, TNFα and PTGS2) are different regulated in AD compared to MCI individuals, with the highest degree of upregulation seen in patients with the lower MMSE scores. Proinflammatory cytokines, (IL-1β, TNFα, IL-6 and IFNγ), expressing β-amyloid peptides-stimulated immune cells were upregulated in severe AD compared to AD and MCI individuals; These results suggest an involvement of the inflammasome pathway in AD-associated neuroinflammation. Therapeutic strategies targeting NPLR3 modulation could be useful in the therapy of AD.

P1.15.14
Cytosolic flagellin induces caspase-1/11-independent lysosomal cathepsins-mediated cell death that correlates to the control of S. typhimurium

***S. L. Lage**[1], C. B. Lima[1], E. P. Amaral[2], K. C. Matteucci[1], M. M. Rodrigues[1], M. R. D'Império-Lima[2], G. P. Amarante-Mendes[2], K. R. Bortoluci[1];*
[1]Federal University of São Paulo, São Paulo, Brazil, [2]University of São Paulo, São Paulo, Brazil.

Cytosolic flagellin is sensed by NAIP5/NLRC4 inflammasomes leading to caspase-1 activation. Caspase-1 is responsible for IL-1β/IL-18 processing and secretion and inflammatory cell death, named pyroptosis. Regardless of the well-established role of pyroptosis as an effector mechanism to clear intracellular infections, its molecular regulation remains to be solved. We demonstrate that purified flagellin from *Bacillus subtilis* delivered directly into macrophages cytosol by transfection lipid vesicles leads to NLRC4, ASC and caspase-1/11-dependent IL-1β secretion but cell death still occurs in the absence of either of these molecules as assessed by fluorescence microscopy according to ethidium bromide (EtBr) incorporation and loss of vital acridine orange (AO) staining. Also, flagellin-induced cell death strongly correlates to the control of *S. typhimurium* by wild-type and caspase-$1/11^{-/-}$ macrophages. Cytosolic flagellin-induced caspase-1/11-independent cell death displayed some apoptotic features, such as cell shrinkage and formation of membrane blebs. Nevertheless, unlike actinomycin D-induced apoptotic cell death, cytosolic flagellin-induced caspase-1/11-independent cell death does not require caspase activation and results in the loss of membrane integrity and release of the known damage signal IL-1α. Finally, cell death induced by cytosolic flagellin seems to rely of lysosomal pathways in which cathepsins B and D

have a redundant role. These results demonstrate that cytosolic flagellin induces a novel pro-inflammatory caspase-independent lysosomal-dependent form of cell death that could be considered an additional effector mechanism to restrict flagellated bacterial infections.

P1.15.15
Selective inhibition of the NLRP3 inflammasome by targeting to promyelocytic leukemia protein

M. Lai[1]*, Y. Lo*[1]*, Y. Huang*[1]*, Y. Wu*[1]*, C. Tsai*[1]*, S. Jiang*[2]*, H. Shih*[3]*;*
[1]*Inst Mol Biol, Academia Sinica, Taipei, Taiwan,* [2]*National Laboratory Animal Center, Tainan, Taiwan,* [3]*Inst Biomedical Sciences, Academia Sinica, Taipei, Taiwan.*

The functional activities of the tumor suppressor promyelocytic leukemia protein (PML) are mostly associated with its nuclear location. In the present study, we discovered an unexpected role of PML in NLRP3 inflammasome activation. In PML-deficient macrophages, the production of IL-1beta was strongly impaired. The expression of pro-IL-1beta, NLRP3, ASC, and procaspase-1 was not affected in PML-knockout macrophages. PML deficiency selectively reduced the processing of procaspase-1. We further showed that PML is required for the assembly of the NLRP inflammasome in reconstitution experiment. All PML isoforms were capable of stimulating NLRP3 inflammasome activation. In PML-knockout macrophages, the generation of reactive oxygen species and release of mitochondrial DNA were decreased. The involvement of PML in inflammasome activation constitutes an important activity of PML and reveals a new mechanism underlying the inflammasome activation. In addition, downregulation of PML by arsenic trioxide suppressed monosodium urate (MSU)-induced IL-1beta production, suggesting that targeting to PML could be used to treat NLRP3 inflammasome-associated diseases.

P1.15.16
Caspase-1-dependent iNOS activation require NF-κB and acts as a non-redundant effector mechanism agaisnt *S. typhimurium*

C. B. Lima*, S. L. Lage, G. P. A. Mendes, K. R. Bortoluci;*
Institute of Biomedical Sciences, São Paulo, Brazil.

Introduction: Flagellin recognition is shared by transmembranic TLR5 and cytosolic Nlrc4 and Naip5 innate receptors. Although both TLR5 and Naip5/Nlrc4 pathways are known to be involved in the clearance of infections, little is known about the anti-pathogen effector mechanisms operated through each of them. In this sense, we have recently described a novel pathway for iNOS activation by Naip5/Nlrc4 inflammasomes in response to cytosolic flagellin in peritoneal macrophages (PM).
Methods and Results: Extending our findings, here we found that NF-κB
was required for caspase-1-mediated iNOS activation in response to cytosolic flagellin, since iNOS activation was abrogated in the presence of a selective IκB-α degradation inhibitor, PDTC. Caspase-1-induced pyroptosis has been described as the main effector mechanism against *S. typhimurium.* However, at late time points of infection, when the frequency of cell death was similar in both, wild type (WT) and caspase-$1^{-/-}$ PM, we found a higher CFU number inside of remaining caspase-$1^{-/-}$ PM when compared to WT PM ones. Using a selective inhibitor of iNOS, aminoguanidine (AG), we found that iNOS expression and NO production contribute to the control of *S. typhimurium.* Moreover, flagellin was required for caspase-1-mediated iNOS activation in MP, showing that it could represent a non-redundant additional effector mechanism along with cell death to the control of *S. typhimurium.* **Conclusion:** Our results indicate that NF-κB is required for caspase-1-mediated iNOS activation in response to cytosolic flagellin and it activation contributes to the control of *S. typhimurium* infection. **Financial support:** CAPES; CNPq, FAPESP.

P1.15.17
NLRP3 inflammasome controls the cellular response to DNA damage during oxidative and genotoxic stress

G. Licandro, H. L. Khor, O. Beretta, J. Lai, H. Derks, P. Ricciardi-Castagnoli, ***A. Mortellaro****;*
*Singapore Immunology Network (SIgN), Agency for Science, Technology and Research (A*STAR), Singapore, Singapore.*

The NLRP3 inflammasome is a cytoplasmic protein complex, which mediates inflammatory responses to a broad array of signals by driving caspase-1 activation and promoting the secretion of pro-inflammatory cytokines IL-1β and IL-18. It is unclear whether NLRP3 participates in other cellular processes. This study was undertaken to identify new NLRP3-regulated pathways induced by monosodium urate (MSU) crystals in DCs. Using a transcriptomic approach, we initially found that NLRP3-/- DCs responded to MSU with differential expression of genes involved in DNA damage response and apoptosis. Upon exposure to MSU or other ROS-mobilizing stimuli (rotenone, gamma-radiation), DNA fragmentation was markedly ameliorated in NLRP3-/- and caspase-1-/- DCs compared with WT DCs. Moreover, NLRP3-/- DCs showed a significant reduction in oxidative damage of DNA mediated by ROS. A significant decrease of the expression of several genes involved in double-strand and base-excision DNA repair was observed in WT DC. Suboptimal cellular DNA repair capacity in WT DC resulted in activation and stabilization of p53 in vitro and in vivo, which resulted in increased cell death compared to NLRP3-/- cells. These data provide evidence for the novel involvement of the NLRP3 inflammasome in DNA damage responses induced by cellular stress.

P1.15.18
Intracellular Shigella remodels its LPS to dampen the innate immune recognition and evade inflammasome activation

I. Paciello[1]*, A. Silipo*[2]*, L. Lembo-Fazio*[1]*, G. Noel*[1]*, V. Ciancarella*[1]*, A. Zychlinsky*[3]*, A. Molinaro*[2]*, M. Bernardini*[1]*;*
[1]*Sapienza Università di Roma, Rome, Italy,* [2]*Università Federico II di Napoli, Naple, Italy,* [3]*Max Planck Institute, Berlin, Germany.*

Lipopolysaccharide (LPS) is a potent bacterial effector triggering the activation of the innate immune system following binding with the complex CD14, MD-2 and TLR4. The LPS of the enteropathogen *Shigella flexneri* is a hexa-acylated isoform possessing an optimal inflammatory activity. Symptoms of shigellosis are produced by severe inflammation due to the invasion process of *Shigella* in colonic and rectal mucosa. Here we addressed the question of the role played by the *Shigella* LPS in eliciting a dysregulated inflammatory response of the host. We unveil that (i) *Shigella* is able to modify the LPS composition, e.g. the lipid A and core domains, during proliferation within epithelial cells; (ii) the LPS of intracellular bacteria (iLPS) and that of bacteria grown in laboratory medium (eLPS) differ in the number of acyl chains in lipid A, iLPS being the hypo-acylated; (iii) the immunopotential of iLPS is dramatically lower than that of eLPS; (iv) both LPS forms mainly signal through the TLR4/MyD88 pathway; (v) iLPS down-regulates the inflammasome-mediated release of IL-1β in *Shigella*-infected macrophages; and (vi) iLPS exhibits a reduced capacity to prime PMNs for an oxidative burst.
We hypothesized that the two forms of LPS might govern different steps of the invasive process of *Shigella*. In the first phases the bacteria, decorated with hypo-acylated LPS, are able to lower the immune system surveillance, while in the late phases *shigella* harboring immunopotent LPS are fully recognized by the immune system which can then successfully resolve the infection.

P1.15.19
Molecular mechanisms of caspase-11-mediated NLRP3 inflammasome activation

V. Rathinam[1], *S. Kailasan Vanaja*[2], *L. Waggoner*[1], *A. Sokolovska*[3], *C. Becker*[3], *L. Stuart*[3], *J. Leong*[2], *K. Fitzgerald*[1];
[1]*University of Massachusetts Medical School, Worcester, MA, United States,* [2]*Tufts University School of Medicine, Boston, MA, United States,* [3]*Massachusetts General Hospital, Boston, MA, United States.*

Caspase-11 is the central inflammatory caspase responsible for NLRP3 inflammasome-dependent maturation of caspase-1 and the subsequent production of inflammatory cytokines IL-1 and IL-18 in enteropathogenic bacterial infections. Caspase-11 also functions to facilitate pyroptosis (inflammatory cell death). While the effector functions of caspase-11 have been well known, the proximal signaling events that trigger caspase-11 activation remained unknown. Here, we have identified a novel innate immune pathway that licenses caspase-11 activation. A systematic investigation of inflammasome activation by enterohemorrhagic *Escherichia coli* (EHEC) and *Citrobacter rodentium*, two model Gram-negative enteropathogens, revealed a role for TLR4 and TRIF in caspase-11-mediated responses as macrophages lacking TLR4 or TRIF failed to activate caspase-11 and as a result process caspase-1 and secrete IL-1β and IL-18. By engaging TLR4-TRIF, EHEC and *C. rodentium* activate caspase-11 via the type I interferon (IFN-β) signaling. IFN-β was found to regulate caspase-11 activation by up-regulating caspase-11 expression in an autocrine/paracrine manner. Remarkably the transcriptional induction of caspase-11 by IFN-β was both necessary and sufficient to promote caspase-11 auto-activation suggesting a model wherein transcriptional induction of pro-caspase-11 is coupled to its auto-activation. Once activated via the TLR4-TRIF-IFN-β pathway, caspase-11 ultimately synergizes with the NLRP3 inflammasome to coordinate caspase-1 dependent production of active IL-1β and IL-18. The IFN-β-caspase-11 axis is specifically required for NLRP3-caspase-1 inflammasome activation by Gram-negative but not Gram-positive bacteria. Overall, the identification of TRIF-type I interferon as a key regulator of caspase-11-dependent NLRP3 activation provides new insights into the integration of TLR and NLR pathways during Gram-negative infections.

P1.15.20
NLRP3-driven IL-1β production by *Cryptococcus neoformans* infection

P. H. V. Saavedra[1], *K. G. Magalhães*[1], *M. Capparelli*[1], *D. S. Zamboni*[2], *A. H. Tavares*[1], *A. Casadevall*[3], *A. L. Bocca*[1];
[1]*University of Brasília, Brasilia, Brazil,* [2]*University of São Paulo, Ribeirão Preto, Brazil,* [3]*Albert Einstein College of Medicine, Bronx, NY, United States.*

Cryptococcus neoformans is an encapsulated human pathogenic fungus that affects primarly immunocompromised individuals. It has a prominent capsule that is an important virulence factor, which is involved in immune response evasion and fungal dissemination. In the present study we investigated whether *C. neoformans* was able of triggering inflammasome activation and the role of its capsule in this event. The acapsular mutant of *C. neoformans*, but not the wild type, induced high levels of IL-1β secretion. In parallel, caspase-1 was activated upon infection with acapsular but not with WT *C. neoformans*. IL-1β secretion induced by *C. neoformans* was assessed in WT, *Asc*$^{-/-}$, *Casp1*$^{-/-}$, *Nlrp3*$^{-/-}$ and *Nlrc4*$^{-/-}$ bone marrow-derived macrophages, showing IL-1β secretion to be dependent on NLRP3 inflammasome. In addition, inflammasome components were dispensable for *C. neoformans* uptake or killing. The mechanisms underlying IL-1β processing and release were dependent on reactive oxygen species (ROS), lysosomal destabilization, potassium efflux and Syk tirosine kinase signaling. We also demonstrate that IL-1β signaling is not required to restrict intracellular yeast, but limited the rate of infection by an unknown mechanism. Together, our data show that acapsular *C. neoformans* activates the NLRP3 inflammasome and IL-1β secretion in a caspase-1 dependent manner and that the mechanisms involved in this event rely on ROS, lysosomal damage, potassium efflux and Syk signaling, leading to restriction of infection rate. Furthermore, our results show that the encapsulated *C. neoformans* is able to dimish inflammasome activation.

P1.15.21
Inflammation triggered by oncogene KRas in pancreatic tumor cells

I. Siddiqui[1], *F. Marchesi*[1], *S. Pesce*[1], *M. Erreni*[1], *A. Mantovani*[1], *H. M. Kocher*[2], *P. Allavena*[1];
[1]*Clinical and Research Institute Humanitas, Milan, Italy,* [2]*Queen Mary University of London, London, United Kingdom.*

Pancreatic ductal adenocarcinoma (PDAC) has one of the worst prognoses among all cancers and current therapeutic approaches are limited and largely ineffective. PDAC is almost invariably associated with mutations in the KRas gene, which is essential for its maintenance. However, how KRas mutations promote pancreatic carcinogenesis is not fully understood. KRas drives cancer-associated inflammation and its contribution to tumor development and possibly to Epithelial to Mesenchymal transition (EMT) needs to be elucidated. In order to address this, we transduced with oncogenic KRasG12V the normal immortalized human pancreatic cell line HPDE and obtained various cloned sub-lines with distinct epithelial and mesenchymal features. Here, we report that differential expression of KRas activity results in different cellular phenotypes: “epithelial” with higher expression of E-cadherin and “mesenchymal” with increased expression of Vimentin, loss of E-cadherin and enhanced expression of transcription factor responsible Twist and Zeb2 for EMT. Significant amounts of pro-inflammatory cytokines (IL-6 and IL-8) are secreted from all clones, whereas IL-beta and PTX-3 are produced more in mesenchymal clones. By using IL-1 receptor antagonist, we observed higher suppression of IL-6, IL-8 and PTX-3 in epithelial clones, whereas significantly lower degree of suppression was observed in mesenchymal clones. This suggests that cells with EMT phenotype are less dependent on IL-1 for production of inflammatory mediators, indicating a link between oncogenic KRas induced inflammation and EMT. Future studies involving silencing of IL-1 or IL-6 receptors and in vivo growth in immune deficient mice may reveal important aspects of inflammatory mediators in tumor progression and EMT.

P1.15.22
Uric acid-induced NLRP3 inflammasome contribute to diabetic kidney injury

K. Su-Mi[1], *K. Jeong*[1], *S. Lee*[1], *T. Lee*[1], *C. Ihm*[1], *S. Lim*[2], *J. Moon*[1];
[1]*Division of Nephrology, Department of Internal Medicine, Kyung Hee University, Colleage of Medicine, Seoul, Republic of Korea,* [2]*Department of Pathology, Kyung Hee University, Colleage of Medicine, Seoul, Republic of Korea.*

Background: Although hyperuricemia is frequently found in a diabetic nephropathy, the definite cause and effect between hyperuricemia and kidney injury have not well investigated yet. Recently, reports showed IL-1β secreting NLRP3 inflammasome in cytoplasm plays a role as a sensor of the innate immune injury in metabolic disease. Therefore, we investigated the cause and effects of hyperuricemia and kidney injury in diabetic nephropathy to demonstrate the role of NLRP3 inflammasome in uric acid-induced kidney injury in diabetes.
Methods: We designed four animal groups as following; 1) LETO (Long Evans Tokushima Otsuka); 2) OLETF (Otsuka Long Evans Tokushima Fatty); 3) OLETF + HFD (high fructose diet) for 16 weeks; 4) OLETF + HFD + allopurinol (10mg/dL). HK-2 cells and THP1 cells were cultured and stimulated with uric acid.
Result: OLETF + HFD group showed a higher serum uric acid, urinary albumin creatinine ratio and the expression of NLRP3 and IL1β than OLETF group. Immunohistochemical staining of CD68^{+} cells showed significant increase in HFD group compared to OLETF group. Allopurinol attenuated HFD induced hyperuricemia and NLRP3 activation-related renal inflammation. Uric acid-induced NLRP3 activation and IL-1β secretion in THP1 cells were also observed. THP1 and HK-2 co-culture confirmed that IL-1β, secreted by THP1, plays a pivotal role in activating IL-1R1, MyD88 and IRAK4 signaling in HK-2 cells. This up-regulated IL-1R1 resulted in NF-κB activation in HK-2 cells.
Conclusion: According to these results we can conclude that hyperuricemia activates NLRP3 inflammasome of macrophage and contribute in renal injury by secretion of IL-1β.

P1.15.23

Transcriptional regulation of the anti-inflammatory NLRP12/Monarch-1 by NF-kB

S. Tuncer[1], *C. Camperio*[1], *G. Camilli*[1], *N. Porciello*[1], *E. Piccolella*[1], *M. Fiorillo*[1], *R. Sorrentino*[1,2];
[1]*Department of Biology and Biotechnology "Charles Darwin", Sapienza University, Rome, Italy,* [2]*Instituto Pasteur, Fondazione Cenci Bolognetti, Sapienza University, Rome, Italy.*

NLRP12 (NLR family, pyrin domain containing 12) is a NLR (Nucleotide-binding domain and leucine-rich repeat containing) protein which is expressed predominantly in cells of myeloid origin. It has been described as a negative regulator of both canonical and non-canonical NF-kB activation. Accordingly with its inhibitory function, NLRP12 expression is down-regulated following activation by TLR agonists or exposure of cells to inflammatory cytokines, whereas the expression of most NLR proteins is typically induced. It is hypothesized that the downregulation of NLRP12 expression is necessary for an appropriate immune response. After the removal of inflammatory stimuli, the expression level of NLRP12 should be restored to prevent excessive inflammation. To test this hypothesis, we focused on the control of NLRP12 expression at the transcriptional level. We asked if a NF-kB-driven negative feedback mechanism causes the down-regulation of NLRP12 transcription. We will show our recent findings about the modulatory effects of NF-kB on the NLRP12 promoter. Moreover, work is in progress to analyze the modulation of NLRP12 protein expression during inflammation and differentiation of myeloid cells.

P1.15.24
The role of autophagy in macrophage-derived foam cells after Salmonella enterica serovar Typhimurium infection

T. Wang*;*
Graduate Institute of Biomedical Sciences, Chang Gung University College of Medicine, Taoyuan, Taiwan.

Mycotic aneurysm are bacteria infected cardiovascular diseases. The mortality rate is extremely high without surgical treatment. Salmonella Typhimurium, which belongs to the type of non-typhoid, can cause gastroenteritis, bacteremia, and at times mycotic aneurysm. Foam cells are major immune cells in mycotic aneurysm. In our hospital, we found the most common pathogens isolated was nontyphoid Salmonella. We want to characterize the immune response in foam cells during Salmonella infecetion. We used Salmonella Typhimurium strain, SL1344 to infect macrophages cell line THP-1 cells and foam cells, using ELISA to analysis IL-1βsecretion and Western blot to detect activated caspase-1 and LC3-I and II which can trace autophagy activation. Foam cells derived from THP-1 cells by treating oxidized LDL. ELISA data shows more secretion of IL-1 β inTHP-1 cells after SL1344 infection, but after SL1344 infection and NH4Cl treatment, there were not significant difference between foam cells and THP-1 cells. In Western blot data, Salmonella infection or NH4Cl treatment, foam cells can activate more autophagy than THP-1 cells. And active caspase-1 in foam cells were more than in THP-1 cells after NH4Cl treatment and SL1344 infection. We suggest in foam cells, the hyper-activation of autophagy in foam cells may cause inflammasome degradation after Salmonella infection.

P1.16.01
Transcript levels of complement regulatory proteins (CD35 and CD59) in rheumatoid arthritis patients and their relationship with disease activity and prognosis

D. Anand[1], *U. Kumar*[2], *M. Kanjilal*[2], *S. Kaur*[2], *N. Das*[1];
[1]*Deptt. of Biochemistry, All India Institute of Medical Sciences, New Delhi, India,* [2]*Deptt. of Medicine, All India Institute of Medical Sciences, New Delhi, India.*

Objectives: Complement regulatory proteins (CRPs) protect the host from tissue injury mediated by activated complement system. In rheumatoid arthritis (RA) exaggerated complement activation is the key event, due to which CRPs CD35 and CD59 may influence the disease pathology and prognosis. Therefore, we aimed at elucidating the leukocyte-CD35 (L-CD35) and L-CD59 transcript levels and the relationship of these two CRPs with the disease activity of RA patients.
Methods: 66 controls and 45 RA patients were recruited for this study. Out of 45 RA patients, 11 patients volunteered for the longitudinal study. L-CD35 and L-CD59 transcript levels were determined by real-time PCR and correlated with Circulating immune complexes (CIC) levels and Disease Activity Score-28 (DAS28).
Results: Transcript levels of L-CR1 ($p < 0.05$) and L-CD59 ($p < 0.01$) were lowered in patients as compared to controls. In longitudinal study, L-CR1 transcript levels ($p < 0.05$) increased in patients which responded to treatment which correlated with lowered CIC levels ($p < 0.05$) and DAS28 scores ($p < 0.05$) at W24 as compared to W0. No significant difference was observed for L-CR1 transcript levels in non-responder group and for L-CD59 transcript levels in responder and non-responder group at W24 as compared to W0.
Conclusions: This is the first study to assess the L-CR1 and L-CD59 transcript levels in RA patients. The findings indicate an intimate relation of L-CD35 transcript levels with the disease activity and prognosis in RA patients, and thus suggest L-CD35 transcript as a potential disease marker in RA.

P1.16.02
Anti-mitochondria antibodies type 2 and neurological manifestations: Report of 5 cases

I. Ayadi*, L. Laadhar, M. Kallel Sellami;*
Immunology laboratory La Rabta, Tunis, Tunisia.

Introduction: Anti-mitochondria antibodies type2 (AMA2) are often described as a specific marker of primary biliary cirrhosis(CBP).AMA2 associated with neurological symptoms were rarely described in the literature.
Objective: Clinical and biological features of patients with AMA2 and neurological manifestations.
Patients and methods: From January 2010 to March 2011 we recorded all cases with neurological manifestations and AMA2.
In all cases, AMA2 were detected fortuitously when screening sera for ANA on Hep-2 cells (granular cytoplasmic fluorescence).
AMA2 were confirmed by indirect immunefluorescence on tissue rat sections and/or immunodot using the subunit E2 of pyruvate dehydrogenase as antigen (Euroimmun).
Results: There were 5 patients, all of them were women. The average age was 50 years. Neurologic signs were weakness and impairment of speech in 1 case, functional neurological deficit in 2 cases, a pyramidal syndrome with myelitis in 1 cases and cerebellar syndrome associated a mood disorder in the last case. Anti-gp 210 antibodies were associated with AMA2 in 1 case. Hepatic assessment, available in 2 cases, showed a cholestasis suggestive of PBC.
Conclusion: Neurological manifestations associated with cholestasis are rare. However this association should evoke PBC. Physiopathologic mechanisms of this association are not yet elucidated.

P1.16.03
Immunotoxicity of work environment exposure in some welders: implications for occupational health

B. Banjoko*;*
Obafemi Awolowo University, Ile-Ife, Nigeria.

Background: The welding process generates fumes of toxic metals oxides and ground level ozone. Exposure to these complex mixtures may have deleterious effect on metabolic functions including the immune system.
Methods: To investigate this live of thought, fifty welders and Forty controls were recruited for the study. Interviewer styled questionnaire was administered for information on work history and biodata. Urine was estimated for welding related toxic metals, namely chromium, Iron, Lead, manganese, zinc, nickel and lead using AA.
Serum obtained from whole blood was used for the estimation of IgG, IgA, IgM, IgE and C3 by turbidmetic method and WBC of whole blood by haematology analyzer.
Results were input into the computer and statistical analysis was done using Student T-test, Mann-Whitney U and Pearson correlation.

Results: There was significantly increased concentration of all the toxic metals analysed in welders compared to the control with a pronounced increased value in iron concentration P = 0.0002, There was also significant reduction in levels of WBC (P = 0.004), IgA P = 0.001, IgM P =0.001, C3, P = 0.012 but not in IgG P = 0.128 and IgE P = 0.115. There was positive correlation between level of iron and reduced concentration of the immune markers.
Conclusion: The welders studied are at increased risk of respiratory tract infections due to the depression in the immune system particularly IgA and in case of infections, like Mycobacterium tuberculosis, severity could be supported by reduced C3 and increased body iron levels.

P1.16.04
Hereditary C1 esterase inhibitor deficiency in Tunisia: a seven years laboratory experience

***A. Ben Hmid**, H. Jouini, Y. Zerzeri, J. Sassi, L. Laadhar, M. Sallemi, S. Makni;*
Immunology departement La Rabta Hospital, Tunis, Tunisia.

Introduction: Hereditary C1 esterase inhibitor (C1-INH) deficiency is characterized by occurrence of subcutaneous and submucosal swellings in any parts of the skin, the respiratory and gastrointestinal tracts, called hereditary angioedema (HAE). The epidemiological, clinical and biological characteristics of C1 INH deficiency were reported in many series in Europe and USA. In Tunisia data are not available. Here we report our laboratory experience to define the frequency, the clinical and biological aspects of C1 INH deficiency.
Materials and methods: From May 2005 to August 2012, we enrolled all cases sent for suspicion of C1-INH deficiency. Complement investigations included (i) C3 and C4 measurement (ii) functional activity of the classical pathway (CH50), (iii) C1 INH antigenic and functional assays; Type I HAE is defined by low plasma levels of a C1-INH protein. Type II is characterized by dysfunctional C1-INH.
Results: Twelve patients among 150 analysis were diagnosed as C1-INH deficiency. Ten were type I HAE and two were type II. Four patients were diagnosed in a context of a familial investigation. C1-INH deficient patients were 6 men and 6 women with a median age 21years and 41years respectively. The main clinical features were skin and mucosal swellings (5 patients), and chronic urticaria in 2 patients. Ten out of 12 cases had low levels of C4 and CH50.
Conclusion: C1-INH deficiency seems to be rare in Tunisia compared to European and other Maghrebin series. Improvement of knowledge to the various forms of HAE is needed to assess our real prevalence of C1-INH deficiency.

P1.16.05
Humoral Immunity in the healthy population of the central region of Cuba

*L. C. Bequer Mendoza, T. Gómez Hernández, L. Salazar Torres, L. Perez de Alejo Rodriguez, V. Hernández Moreno, L. Molina Hernández, **O. Perez**;*
Unidad de Investigaciones Biomédicas. Universidad de Ciencias Médicas de Villa Clara., Santa Clara. Villa Clara, Cuba.

In order to study the humoral immune response in healthy population of the central region of Cuba we establish reference values of immunoglobulins IgG, IgM and IgA and C3 and C4 complement proteins in three different and interesting moments in life from the immunological point of view (birth, childhood and adulthood) in apparently healthy population of the province of Villa Clara, Cuba. METHODS: With serum samples from 200 individuals were formed 3 study groups comprised 80 new born, 60 children and 60 adults. In each case were 50% female and 50% male. Using nonparametric tests found no significant differences between gender at each group was taken as a single sample. The values of reference were established for the immunological parameters according to age, taking the central interval (95%) delimited by the 2.5th and 97.5. RESULTS: It was observed that new born had lower serum complement proteins, while children showed slightly higher serum concentrations than adults. The immunoglobulins were significantly different in each study group. CONCLUSIONS: This work is unique in the region as it also characterizes the humoral immunity, and provides reference values to facilitate further studies to make decisions about possible prognosis and treatment of patients exhibiting immunological symptoms.

P1.16.06
Whole exome sequencing in a Finnish family with hereditary angioedema with normal C1 inhibitor

***L. J. Bouchard**[1,2], H. Jarva[1], A. Laukkanen[3], M. J. Savolainen[4], S. Meri[1];*
[1]Department of Bacteriology and Immunology, Haartman Institute, University of Helsinki, Helsinki, Finland, [2]Department of Dermatology, Skin and Allergy Hospital, Helsinki University Central Hospital, Helsinki, Finland, [3]Department of Dermatology, Kuopio University Hospital, Kuopio, Finland, [4]Department of Internal Medicine, Clinical Research Center, University of Oulu, Oulu, Finland.

Hereditary angioedema (HAE) is an autosomal dominant disease characterized by episodic, local swelling of the submucosal, dermal or subcutaneous tissue. HAE is divided into type I and II HAE with low or functionally defective serum C1 inhibitor, respectively. Both forms are caused by mutations in the C1 inhibitor gene. In addition, there is a group of patients with symptoms typical of HAE, but normal C1 inhibitor. Mutations in coagulation factor XII have been identified in 20% of these patients. The aim of our study is to find a mutation predisposing to the described symptoms in families of Finnish descent. For this purpose we collected five patients from four different families. They presented with symptoms typical of HAE, normal C1 inhibitor levels, functional activity and C4. These patients did not respond to treatment with high dose antihistamines, corticosteroids or adrenalin. Two of the patients are mother and daughter from the same family in which the late grandmother and cousins from the mother's side also had similar symptoms. We sequenced the coding and regulatory regions of the factor XII gene in these patients. We found only previously identified gene polymorphisms that were also present in control subjects. Thus, genetic causes other than those in C1 inhibitor or FXII may cause angioedema. Since the predisposing cause for the same phenotype is probably heterogeneous, we chose the patients from the family affected in three generations for whole exome sequencing. The analyses are underway and may reveal a new genetic cause for hereditary angioedema.

P1.16.07
Effect of immune complex and cytokines on expression and modulation of neutrophil complement regulatory proteins in SLE

***N. Das**[1], B. Biswas[1], U. Kumar[1], V. Arora[2], A. Kumar[3];*
[1]All India Institute of Medical Sciences, New Delhi, India, [2]University of Pennsylvania, Philadelphia, PA, United States, [3]Fortis Health Care Ltd., New Delhi, India.

Modulation of neutrophil DAF, MCP, CD59 & CR1 transcripts in SLE and their close correlations with SLE disease activity had been documented. To gain further insight, we studied effects of serum opsonized heat aggregated immunoglobulins (sHIgG), IFN-γ, TNF-α, IL4 and, IL10 on the expression and, modulation of these proteins in SLE.
Neutrophils isolated from the venous blood of patients and controls were treated in vitro with different effecters. The transcript levels of different complement regulatory proteins in treated and untreated cells were determined by real time PCR, data were compared between patients and controls.
sHIgG down-regulated the levels of CR1 transcript but up-regulated the levels of MCP and DAF with no significant effects on CD59 expression both in controls and patients. CR1 correlated negatively with MCP, DAF, & CD59. Levels of all these proteins were upregulated by IFN-γ and were down regulated by TNF α. IL4 and IL10 significantly up regulated MCP and DAF, respectively. The upregulation by all the effecters ranged from 1.5 -4 fold and down regulation ranged from .25-.8 fold as compared to the untreated cells. Mostly, the modulation was more marked in patients compared to controls. Observations were statistically significant ((P<.05-0.001, Mann-Whitney test).
Our study documents modulation of neutrophil complement regulatory proteins by cytokines and hence, suggests close interplay of

cytokines with functional attributes of complement in health and diseases like SLE where complement proteins have disease modulating roles. Further studies are needed to confirm our findings and their translational implications.

P1.16.08
Contribution of C5a measurement to explain some clinical biological discrepancies in monitoring of lupus

K. Djenouhat[1]*, A. Tahiat*[2]*, M. Boucelma*[3]*;*
[1]*Institut Pasteur of Algiers, Algiers, Algeria,* [2]*CHU Béni Messous, Algiers, Algeria,* [3]*CHU Bab El Oued, Algiers, Algeria.*

Introduction: Besides the search for anti-dsDNA, complement investigations and measurement of CH50, C3 and C4 specially, have long been considered as good parameters for monitoring lupus (SLE). Very few works explores the degradation products of complement in this disease. Aim: The objective of our study is to determine the role of C5a assay in explaining some discrepancies clinical biological of lupus.
Patients and methods: Our study included 142 patients with SLE based on the American College of Rheumatology (ACR) criteria. Patients were stratified according to state's activity of disease. Classical exploration of complement was done. C5a was detected by an enzyme-linked immunoassay kit (Quiedel, USA) in sera of patients in clinical relapse with normocomplementemia only.
Results: Positive correlation between complement variation and SLE disease activity (r=0.69; P=0.0001) was detected in 81.5% (97/120) of SLE sera. Clinical biological discordance was found in 23 patients, among them 10 were in remission and showed deceased of complement C4 with or without C3. However 13 patients were in relapse and normocomplementemia, 5 among these 13 patients have very increased level of C5a.
Conclusion: Normal level of C3 with increased level of C5 would support the involvement of a new pathway for generation of C5a independently of classical, alternative and lectin ones. The presence of thrombin seems to be the major parameter to generate C5a as reported recently.

P1.16.09
Complement activation in patients with systemic lupus erythematosus without nephritis

A. Tahiat[1]*,* ***K. Djenouhat***[1]*, M. Boucelma*[2]*, M. C. Abbadi*[1]*;*
[1]*Department of Immunology, Institut Pasteur d'Algérie, Algiers, Algeria,* [2]*Department of Internal medicine, Bab el Oued teaching hospital, Algiers, Algeria.*

INTRODUCTION: The complement system has long been known to be activated in exacerbations of systemic lupus erythematosus (SLE), particularly reflecting nephritic activity. The aim of this study was to evaluate the association between disease activity and complement activation in SLE patients with mild disease and with no renal involvement.
METHODS: We studied 42 SLE patients (36 females, 6 male) without nephritis. Levels of serum complement C3 and C4 were measured by nephelometry. Total complement haemolytic activity was measured with assays specific for the classical pathway (CH50). Terminal SC5b-9 complement complex (TCC), as an activation product from the final common pathway, was quantified by ELISA.
RESULTS: Lupus flares were observed in 11 patients (26%). Decreased CH50 was found in 13 (31%) patients but was not associated with increased complement activation. Slightly to moderately decreased C4 (0.05-0.10 g/l) was found in five patients and severely decreased C4 (<0.05 g/l) in three patients. Three patients had decreased C3 in conjunction with positive anti-C1q antibodies and low C4 concentrations. Complement activation products (TTC) were either normal or slightly elevated. None of the variables tested (C3, C4, CH50 and SC5b-C9) correlated with disease activity.
CONCLUSION: Our data suggest that complement tests are of limited value in routine examination of SLE without nephritis.

P1.16.10
MASP2 and MBL: Dynamics and Intrathecal synthesis

A. J. Dorta-Contreras[1]*, B. Padilla Docal*[1]*, A. Arias Morales*[1]*, O. Pérez*[2]*, H. Reiber*[3]*, J. C. Jensenius*[4]*;*
[1]*Labcel, Medical Sciences University Havana,, Havana, Cuba,* [2]*Finlay Institute, Havana, Cuba,* [3]*Neurochemistry Laboratory, University Göttingen, Göttingen,, Germany,* [4]*Department of Biomedicine, University of Aarhus, Aarhus, Denmark.*

Background: There is an increasing interest to look for the possible participation in lectin pathway components in the immune response in CNS. Methods: MASP2 and MBL were assayed in 20 control samples of CSF and serum with an ELISA, coated with anti MASP2 and MBL antibodies. Albumin-, immunoglobulin- CSF/serum quotients, oligoclonal IgG and cell count were used to characterize the patient groups. Groups comprised firstly, control patients without organic brain disease with normal CSF and normal barrier function and secondly, patients without inflammatory diseases but with increased QAlb, with a blood CSF barrier dysfunction. Results: MASP2 concentration in CSF was at least two-fold higher than expected for a molecular-size-dependent passage from blood and CSF MBL was at least five-fold 2) in a QMASP2 vs QAlb regression line 9/20 cases showed an intrathecal fraction and QIgM/QAlb quotient diagram (Reibergram) 9/13 cases showed an intrathecal fraction in some cases over 80% of total CSF MBL concentration 3) The higher inter-individual variation of MASP2 concentrations in CSF of the control group (CV = 55%) compared to the MASP2 concentrations in serum (CV = 40%) indicate that MASP2 is mostly a blood protein and the smaller inter-individual variation of CSF MBL of the control group compared to serum MBL concentration indicate an independent source of CSF MBL 4) The absolute MASP2 and MBL concentration in CSF increases with increasing QAlb. Conclusions: MASP2 in CSF is predominantly blood-derived. MBL dynamics indicate that only the leptomeningeal proteins shower a linear increase with decreasing CSF flow rate.

P1.16.11
Human skin-derived mast cells express complement C3 and C5

Y. Fukuoka*, M. Hite, A. Dellinger, L. B. Schwartz;*
Virginia Commonwealth University, Richmond, VA, United States.

This study examines whether complement factor C3 or C5 is synthesized by the cultured human skin-derived mast cells and whether their synthesis is regulated by cytokines. C3 and C5 mRNAs were expressed and baseline protein levels/10^6 cultured mast cells measured by ELISA were 0.9 and 0.8 ng, respectively, and detected by flow cytometry and Western blotting. Both proteins were located in the cytoplasm outside of secretory granules assessed by confocal microscopy. Similar mRNA and protein levels were also found in freshly purified skin-derived mast cells as the cultured mast cells. C3 accumulated in mast cell culture medium over time and by 3 days reached a concentration of 9.4 ± 8.0 ng/ml, whereas C5 levels were not detectable. Three-day incubations of mast cells with IL-1α, IL-1β, IL-17, IFNγ or IL-6 did not affect C3 protein levels in culture medium, whereas incubations with TNFα, IL-13 or IL-4 enhanced levels of C3 1.7- to 3.3-fold. Importantly, treatment with TNFα together with either IL-4 or IL-13 synergistically enhanced C3 (but not C5) production in culture medium by 9.8 or 7.1 fold, respectively. This synergy was blocked with neutralizing anti-TNFα Ab, soluble TNFR, or an inhibitor of NF-κB, or by attenuating the IL-4/13 pathway with Jak family or Erk inhibitors. This study shows for the first time that human mast cells can produce and secrete C3, while beta-tryptase can act on C3 to generate C3a and C3b, raising the likelihood that mast cells engage complement to modulate immunity and inflammation in vivo.

P1.16.12
Probiotic spores: a missing link between innate immunity and nutritional health

E. Saball[1]*, M. Salvarrey*[1]*, J. Moreno*[1]*, N. Abraham*[1]*,* ***R. R. Grau***[2]*;*
[1]*Facultad de Bioquímica y Farmacia,FCByF-UNR. Área Inmunología, Rosario, Argentina,* [2]*Facultad de Bioquímica y Farmacia,FCByF-UNR-CONICET. Área de Microbiología, Rosario, Argentina.*

Spores of the human-friendly bacterium Bacillus subtilis represent a new generation of probiotics due to their high stability and additional utilization as non-refrigerated antigen-delivery vaccines. An interesting premise for probiotics is their capacity to modulate the immune system. The Complement System (C) is a major effector of innate response and is under the control of three different pathways of activation (Classic, CP; Alternative, AP; and Lectin pathway, LP). However, the understanding of the probiotic effect on C is waiting. Using a battery of bacterial genetic techniques, in combination with specific methods to evaluate C activation, we demonstrate that B. subtilis is capable of activating the three C pathways without MAC formation. This activation is under the control of the master transcriptional regulator of biofilm development SinR. Using different genetically-constructed B. subtilis mutants, we uncovered each component of the biofilm involved in C regulation. B. subtilis mutants deficient in the synthesis of exopolysaccharide (EPS) and the antimicrobial and antibiotic-repellent proteins TasA and BslA, respectively, were severely affected in C activation. Furthermore, we demonstrate a specific role for each biofilm component on each C activation-pathway. TasA was essential and specific for CP-activation whereas BslA and EPS were essential and specific for the activation of the AP and LP, respectively. Overall, our results show for the first time how different components of the bacterial biofilm (which colonize the human mucosa) modulates the activity of C and contribute to a better understanding of the beneficial effects of probiotics on innate immunity at molecular level.

P1.16.13
Hereditary complement C8 deficiency in a Turkish family found in a girl with recurrent meningitis and her asymptomatic sister

N. Gulez[1]*, F. Genel*[1]*, L. Skattum*[2]*, L. Truedsson*[2]*;*
[1]*Dr. Behcet Uz Children Hospital, Izmir, Turkey,* [2]*Clinical Immunology and Transfusion Medicine, Lund, Sweden.*

The complement system plays important roles in both the innate and the adaptive immune defence and also acts as a bridge between these arms of immunity. C8 is one of the five terminal complement components required for the formation of the membrane attack complex and composed of three polypeptide chains. Complete absence of C8 Complete absence of C8 results in increased susceptibility to gram-negative bacteria especially Neisseria species. Two functionally distinct C8 deficiency states (C8 alpha-gamma and C8 beta deficiency) in all together thirteen patients have been described until now. The patient, a seven years old girl was admitted to hospital with high fever and diffuse, purple-coloured skin lesions. Her symptoms gave the diagnose meningococcal meningitis. She had also earlier been diagnosed with the same disease when she was 5 years old. A sister to the patient had died from meningitis at 3 years of age. She has also one older and one younger sister. There is no consanguinity between her parents. The laboratory analyses of the classical pathway measured as complement hemolytic activity (CH50) and C8 concentration revealed no activity and absence of C8, respectively. Analysis of serum from her younger sister showed the same results, while her older sister's CH50 and C8 levels were found normal. Thus, our patient and her younger sister were diagnosed with hereditary C8 deficiency. The genetic analyses have not been completed yet. We here report the first cases of C8 deficiency in Turkish patients.

P1.16.14
Complement component C3 variant (R102G) and the risk of neovascular age realated macular degeneration in a Tunisian population

I. Habibi[1]*, I. Sfar*[1]*, A. Chebil*[2]*, F. kort*[2]*, R. Bouraoui*[2]*, R. Limaiem*[2]*, S. Ayed*[1]*, T. Ben Abdallah*[1]*, L. El Matri*[2]*, Y. Gorgi*[1]*;*
[1]*Research Laboratory of renal Transplantation immunology and Immunopathology (LR03SP01), University T, Tunis, Tunisia,* [2]*Oculogenetic research unit, department B of ophthalmology, Hedi Rais Institute of Ophthalmology, Tunis, Tunisia., Tunis, Tunisia.*

Purpose: To explore the association between the polymorphism(S/F) R102G in the complement component 3 (C3) gene and age-related macular degeneration (AMD) in a Tunisian population.
Methods: The molecular study was performed by PCR-SSP in 135 control subjects free of any eye disease (Fundus normal) and 91 patients with exudative AMD. The CH50 activity and quantification of C3 and C4 have been made by technical home method and nephelometry respectively.
Results: The prevalence of C3 F allele polymorphism was significantly higher in AMD patients compared to controls OR: 2.051, IC95% [1.29-3.26], p=0.002. However, no correlation between this allelic variant and the type of neovascularization. Similarly, there is no association between this polymorphism and the presence of functional and / or quantitative hypocomplementemia.
Conclusions: The C3 F allele of the gene could be a susceptibility factor for AMD in the Tunisian population. However, it does not seem to influence the clinical profil of the disease.

P1.16.15
The Yersinia pestis Outer Membrane Protein Ail Recruits C4b-Binding Protein Leading to Factor I-Mediated Inactivation of Covalently and Non-covalently Bound C4b

D. K. Ho[1]*, M. Skurnik*[1]*, A. Blom*[2]*, S. Meri*[1]*;*
[1]*University of Helsinki, Helsinki, Finland,* [2]*Lund University, Malmö, Sweden.*

The outer membrane protein Ail of Yersinia pestis mediates several virulence functions, including serum resistance. It is highly expressed at 37oC and indispensable in a rat model of infection. The Ail protein from the closely related enteropathogen Y. pseudotuberculosis functionally recruits C4b-binding protein (C4BP), the primary fluid-phase inhibitor of the classical and lectin pathways of complement. Here, we demonstrate that Y. pestis Ail also binds C4BP as well as C4 and C4b in a non-covalent manner. C4BP bound to Ail can act as a cofactor to the serine protease factor I (fI) in the cleavage of fluid-phase C4b. Employing a panel of C4BP alpha-chain mutants, each deficient in a single complement control protein domain (CCP), we observed that the absence of CCPs 6 and 8 reduced binding to Ail. Immunoblot analysis of normal human serum (NHS)-treated bacteria revealed minimal C4b alpha'-chain complexes with the bacterial outer membrane targets. The addition of the anti-C4BP monoclonal antibody MK104 to NHS restored the emergence of C4b-alpha' chain target complexes, suggesting that C4b binds covalently to targets on the Y. pestis surface. C4b bound to Ail non-covalently is also cleaved in a C4BP and fI-dependent manner, leaving the C4c fragment bound to Ail. The addition of MK104 to NHS also prevented the cleavage of non-covalently bound C4b. Collectively, these data suggest that when C4BP is bound to Ail, fI can cleave and inactivate C4b that has bound covalently to bacterial surface structures as well as C4b that has bound non-covalently to neighboring Ail molecules.

P1.16.16
Neutralizing complement resistance improves cell-mediated killing (CDCC) of HER2 positive breast cancer cells by Trastuzumab and Pertuzumab

S. Mamidi, S. Höne, ***M. Kirschfink****;*
Institute of Immunology, Heidelberg, Germany.

The therapeutic potential of anti-cancer mAbs is hampered by the ability of malignant cells to acquire resistance to complement, primarily by the over-expression of membrane complement regulatory

proteins (mCRPs) such as CD46, CD55 and CD59. Trastuzumab and Pertuzumab are anti-HER2 monoclonal antibodies approved for the treatment of HER2-positive breast cancers, which exert only minor complement-mediated cytotoxicity (CDC). Upon opsonisation of tumor cells with the C3 split product iC3b, complement receptor 3 (CD11b/CD18) on NK cells and macrophages mediates complement-dependent cellular cytotoxicity (CDCC). Here, we investigated whether treatment of HER2 positive tumor cells with trastuzumab and pertuzumab not only leads to direct destruction by CDC but also induces CDCC and if silencing of mCRPs with siRNA enhances cell-mediated cytotoxicity.
Small interfering RNAs (siRNAs), which are chemically stabilized by 2´-O-methyl sugar modifications, were encapsulated in liposomes (AtuPLEX) for delivery to Her2/neu high expressing BT474 breast tumor cells to knockdown synthesis of CD46, CD55 and CD59.
Upon mCRPs knock down, CDC was significantly increased when BT474 tumor cells were treated with both trastuzumab and pertuzumab. Complement-induced apoptosis and caspase activation was augmented if mCRPs were neutralized in tumor cells. Incubation of tumor cells with both antibodies also led to increased C3 deposition (opsonization), and further augmented tumor cell killing by M1 and M2 macrophages. Furthermore, incubation of mCRP neutralized BT474 cells with PBL or NK92 cells further augmented cell-mediated cytotoxicity.
Thus, the combination of both trastuzumab and pertuzumab induces CDCC and neutralization of complement regulators further enhances their anti-tumor effects

P1.16.17
Dissecting the modular nature of properdin using recombinant thrombospondin repeats TSR4 and TSR5

L. Kouser[1], *M. Abdul-Aziz*[1,2], *R. B. Sim*[3], *A. G. Tsolaki*[1], *U. Kishore*[1];
[1]*Brunel University, London, United Kingdom,* [2]*University of Oxford, Oxford, United Kingdom,* [3]*Kingston University, Surrey, United Kingdom.*

Properdin upregulates the alternative complement pathway by binding and stabilising the C3 convertase complex (C3bBb). Properdin is a 53kDa soluble glycoprotein and its flexible rod-like monomers form cyclic polymers (dimers, trimers and tetramers). The properdin monomer consists of six thrombospondin type I repeats (TSR) each having about 60 amino acids, which are similar or homologous to circumsporozoite and thrombospondin-related anonymous proteins (TRAP) of *Plasmodium* species, ETP100 of *Eimeria tenella*, various complement components C6-C9 and thrombopondins I and II. Using deletion constructs, TSR4 and TSR5 have been shown to be involved in C3b binding and stabilising C3 convertase, suggesting that these modules contribute significantly to properdin functions. However, individual TSR4 or TSR5, expressed in *E. coli*, failed to bind properdin ligands. Here, we have expressed in *E. coli* biologically active TSR4 and TSR5, together in tandem (TSR4+5), in *E. coli* and examined its interaction with C3b, sulfatides, Bacillus Calmette-Guerin (BCG) and apoptotic cells. The results of binding studies and modulation of the alternative pathway by recombinant TSR4+5 will be presented.

P1.16.18
Comparison of C3 and C4 with CH50 in North West of Iran

B. Mansoori[1], *A. Osali*[2];
[1]*Tabriz university of Medical science, Tabriz, Iran,* [2]*Zanjan Azad university, zanjan, Iran.*

Background and Aim: The complement system comprises a group of serum proteins and cell membrane receptors that function primarily to fight infection. These components interact in three activation pathways. The central results of activation of these pathways are to deposit the opsonic C3b on bacteria to promote phagocytosis, to lyse bacteria by the assembly of the terminal membrane attack complex and to promote inflammation. The aim of this study was to compare the rate of increase or decrease in C3 and C4 in patients is CH50.
Methods: This cross-sectional study on 281 patients referred to the Zanjan's Clinical Laboratory, measured C3 and C4 by nephelometry method, CH50 levels were measured using SRID. Then the data were analyzed by the SPSS13 Software.
Results: The results of tests on patients revealed that the female:male ratio was 1/16. The mean age of the patients was 35.31±16.21. (5.5 percent) 15 cases with high C3, (8.7 percent) 24 cases with high C4, (3.4 percent) 9 cases with high CH50. The CH50 data not showed a significant increase in patients.
Conclusions: This study showed that CH50 measurements alone cannot be the expression of the complement system function. Other measures such as the complement component like C1q, C3, C4, C5, and C9 with CH50 are recommended.

P1.16.19
Myeloperoxidase directly interacts with properdin and induces alternative pathway complement activation

J. O`Flynn*, K. Dixon, M. C. Faber Krol, M. R. Daha, C. van Kooten;*
Leiden University Medical Centre, Leiden, Netherlands.

Properdin is well known as a stabilizing factor for the alternative pathway (AP) C3 convertase, thereby promoting complement activation. More recently it has been demonstrated that properdin can also act as a pattern recognition molecule, recognizing for instance microbial surfaces or apoptotic cells, providing a platform for AP activation. Neutrophils are a major source of properdin and the AP has been implicated in many neutrophil-mediated diseases. Here we investigated the ability of properdin to interact with various neutrophil components which are released upon neutrophil priming and activation. Using purified components, properdin showed a clear dose-dependent binding with several neutrophil enzymes, including myeloperoxidase (MPO), elastase, lysozyme and cathepsin G, but not with azurocidin. However, only MPO showed the ability to induce C3 activation when exposed to serum as a complement source. Complement activation could be completely prevented by EDTA, but was not affected by MgEGTA, confirming that MPO specifically activated the AP. Activation of the complement cascade could be demonstrated both by the deposition of C3, but also resulted in deposition of C5b-9. MPO initiated AP activation was absent in properdin deficient serum. Furthermore, we could show that MPO can bind properdin directly which then induces AP C3 deposition in-vitro. In summary we show a novel mechanism by which properdin can interact directly with neutrophil components, and for MPO results in AP mediated complement activation. This unique interaction may be an important contribution to the central role for the AP in neutrophil-mediated diseases such as rheumatoid arthritis and ANCA vasculitis.

P1.16.20
Marine algae Bostrychia tenella fractions and extracts from associated endophytic microorganisms modulate the complement system

J. C. Pereira, C. G. Nogueira-Santos, T. M. C. Ogasawara, R. de Felício, H. M. Debonsi, ***L. S. Pereira-Crott****;*
Faculty of Pharmaceutical Sciences of Ribeirao Preto - University of Sao Paulo, Ribeirão Preto, Brazil.

Exotic sources of natural products such as marine environment, including marine endophytic microorganisms, have gained interest in the search for novel bioactive substances. Very few studies have explored the pharmacological potential of the marine algae Bostrychia tenella. Therefore, this study aimed to evaluate whether different fractions of this macroalgae and extracts of endophytic microorganisms isolated from it possess immunomodulatory activity on the human complement system (CS), which is recognized as one of the major effectors of the inflammatory process. CS plays an important role in various inflammatory reactions and in various pathogenic mechanisms of tissue damage. Hemolytic assays of complement activity were used for screening 20 samples. Ten samples were selected because they were able to modulate this activity in a pool of normal human serum. The 10 samples (fractions, subfractions and extracts of B. tenella and its endophytic microorganisms) were able to induce the generation of fragments of C3, which were detected by immunoelectrophoresis and Western blot. Also, we observed the formation of the membrane attack complex in enzyme immunoassay, indicating that there was total

activation of the CS. From the results obtained in Western blot for fragments of C4 and Factor B was possible to identify which pathways are activated in CS, when correlated with the results of hemolytic assays for the classical/lectin (CP/LP) and alternative pathway (AP). Thus, we conclude that the 10 selected samples have modulatory effects on human CS because they were able to activate it either by CP/LP or AP. Financial support: CAPES, FAPESP.

P1.16.21
Developmental programming of low levels of C3 and C4 complement factors by gestational chronodisruption

J. M. Sarmiento[1]*, N. Mendez*[1]*, H. Galdames*[1]*, C. Spichiger*[1]*, M. Seron-Ferre*[2]*, H. Folch*[1]*, C. Torres-Farfan*[1]*, H. Richter*[1]*;*
[1]Universidad Austral de Chile, Valdivia, Chile, [2]Universidad de Chile, Santiago, Chile.

The hypothesis of developmental origins of health and disease (DOHaD) states that exposure to adverse intrauterine environment leads to fetal maladaptation, increasing the risk for diseases in adulthood. In this context, epidemiological and animal model studies have been mainly focused in the effects of gestational undernutrition on the offspring development. Chronodisruption (a significant disturbance of the circadian rhythm of physiological parameters) along pregnancy has been associated with an increased risk of preterm delivery and low birth weight, both strong predictors of chronic diseases in adulthood. The long term goal of our research is to determine the effects of developmental chronodisruption on the immune system of the offspring. Our results of gene expression analysis by means of DNA microarray and real time RT-PCR in the fetal liver, demonstrated that exposure of pregnant rats to constant light along the second half of gestation downregulated the expression of several genes of classic and alternative complement activation pathway as well as the membrane attack complex, relative to gestation under control photoperiod. Interestingly, in a parallel cohort analyzed at postnatal day 90, we found that plasma circulating levels of C3 and C4 complement factors were significantly lower in the offspring gestated under constant light, relative to normal photoperiod ($P<0.05$). Shift work affects about one fifth of the workforce, including pregnant woman, which means that detrimental impact on health by intrauterine exposure to chronodisruption may have important public health implications.

P1.16.22
Dietary restriction and fasting downregulate complement activity via MBL-pathway

S. Shushimita[1]*, P. van der Pol*[2]*, R. W. F. de Bruin*[1]*, J. N. M. IJzermans*[1]*, C. van Kooten*[2]*, F. J. M. F. Dor*[1]*;*
[1]Erasmus University Medical Center, Rotterdam, Netherlands, [2]Leiden University Medical Center, Leiden, Netherlands.

Introduction: Preoperative dietary restriction (DR) offers robust protection against renal ischemia-reperfusion injury (IRI) in mice. However, the mechanism is unknown. We hypothesize that immunomodulation via the complement system plays a pivotal role, and investigated the impact of DR on complement activation pathways.
Materials and Methods: Male C57Bl/6 mice were fed *ad libitum* (AL), underwent 72hrs fasting (F) or 2 weeks 30% DR (n=8/group). Functional activity of the complement activation pathways (classical (CP), lectin (LP) and alternative pathway (AP)) was assessed, and mRNA studies were performed for all relevant upstream and downstream complement proteins.
Results: Significant downregulation in CP, LP activity by DR and in CP, LP and AP activity by F was observed. Activation of C3, C9, and MBL-A and -C concentrations in DR and F were significantly decreased ($p\leq0.002$) in CP, LP and AP. C1q concentration was only significantly lower in the F group ($p\leq0.0001$). The mRNA studies showed a significant downregulation in liver MBL expression in both DR and F ($p\leq0.004$) groups. However, C3 levels (both in kidney and liver) were found to be elevated in both DR ($p\leq0.03$) and F ($p\leq0.05$) groups.
Discussion: Dietary interventions downregulate complement activation pathways. The most prominent effect of DR and F was observed on the MBL pathway. To our knowledge, our data for the first time show that DR and F cause downregulation of complement activation pathways. This may be one of the mechanisms by which dietary interventions protect against renal IRI.

P1.17 Allergic mediators

P1.17.01
Parvalbumin: as a fish-allergen

S. H. Arif*;*
Jazan University, Jazan, Saudi Arabia.

Parvalbumin is a small, acidic, Ca^{2+}-binding protein found abundantly in the muscle sarcoplasm of fish, frog and other vertebrates. IgE-binding studies have shown that purified parvalbumins from several fish species were recognized by a large number of individuals allergic to fish. Therefore, fish allergy has been considered as one of the most common food allergies in the countries where, fish is a staple in the diet. However, in the present study boiled parvalbumin samples from several commonly consumed Indian fish species (*Channa* sps. and *Clarias* sps.) were run on native 10% polyacrylamide gels. The electrophoretic studies revealed that the parvalbumins remained pretty stable at boiling temperatures for about one hour. Thus, the fact that parvalbumins have remarkable thermo-stability and remain allergic to the susceptible people suggests that the immunologic-domains of the protein also remain active even after cooking. Therefore, molecule-based research would be of immense help in better understanding of the parvalbumin-allergy and diagnosis.

P1.17.02
Clock genes and eosinophil-specific mediators are expressed in a circadian manner in human eosinophils

A. Baumann[1]*, O. Froy*[2]*, S. C. Bischoff*[1]*, A. Lorentz*[1]*;*
[1]University of Hohenheim, Stuttgart, Germany, [2]The Hebrew University of Jerusalem, Rehovot, Israel.

Allergic diseases are frequently exacerbated between midnight and early morning suggesting an involvement of the biological clock. Eosinophils are main effector cells of allergic diseases and some eosinophil-specific markers such as eosinophil cationic protein (ECP) exhibit circadian variation. Thus, the aim of our study was to analyze whether the circadian clock is functional in eosinophils. Human eosinophils were isolated from peripheral blood of both non-allergic and allergic subjects and purified by magnetic cell separation. Subsequently, cells were harvested and analyzed every 3 hours around the circadian cycle. Clock gene (hPer1, hPer2, hCry1, hBmal1 and hClock) expression and expression of eosinophil-specific mediators including hEcp as well as eosinophil-derived neurotoxin (hEdn) was analyzed by real-time RT-PCR, and protein levels of ECP were measured by Western blotting. All clock genes, hPer1, hPer2, hCry1, hBmal1, and hClock are expressed and exhibit a circadian rhythm in eosinophils of both healthy and allergic persons. In addition, the expression of eosinophil-specific mediators ECP and EDN also revealed a circadian oscillation. In summary, circadian clock genes as well as eosinophil-specific mediators oscillate in human eosinophils. Thus, the biological clock controls eosinophils leading to circadian expression of their mediators and therefore may play a pivotal role in the pathophysiology of allergy.

P1.17.03
Heat shock protein 70 is potent to suppress chemotactic activity of ATP and migration of dendritic cells

***E. Bolkhovitina**, A. Sapozhnikov, M. Shevchenko;*
Shemyakin-Ovchinnikov Institute of bioorganic chemistry RAS, Moscow, Russian Federation.

Heat shock protein 70 (Hsp70) responds for ATP-dependent folding and degradation of proteins. The pool of extracellular Hsp70 possesses immunomodulatory activity. Extracellular ATP has gain attention as a key mediator of asthma. ATP has been shown to modify the recruitment and function of inflammatory cells including dendritic cells (DCs). Due to high affinity of Hsp70 to ATP that results in ATP dephosphorylation, Hsp70 might decrease ATP-mediated lung inflammation. To prove this hypothesis in the present study we tested the influence of Hsp70 on ATP-dependent chemotaxis of dendritic cells in vitro.
Bone marrow-derived DCs (BMDC) were cultivated in presence of GM-CSF for 9 days. Migration assay was carried out using 24-well Transwell chambers. To induce the chemotaxis we used 1uM of ATP or ADP. To estimate the suppressive effect 1uM of Hsp70 was added to ATP. PBS served as a control. BMDCs were added in concentration 0,5 mln cell/well and incubated at 37C. After 90 minutes migrated DCs were collected and counted. Chemotactic index was calculated as the ratio of the cells migrated in response to chemoattractants and to PBS.
ATP revealed the highest chemotactic activity compare to other stimuli. The minimal chemotactic index was observed in response to ADP. Although Hsp70 along induced slight cell migration, addition of Hsp70 to ATP in 1:1 ratio two-fold decreased the chemotactic index.
Thus, Hsp70 reduced ATP chemotactic activity and subsequently ATP-induced migration of BMDCs.
This work was supported by EAACI.

P1.17.04
Regulation of allergen-specific IgA and IL-17 responses by intestinal epithelial cell IKKβ reshapes allergic inflammation at distant sites

*A. Bonnegarde-Bernard[1], J. Jee[1], M. J. Fial[1], F. Aeffner[1], E. Cormet-Boyaka[1], I. C. Davis[1], M. Lin[1], D. Tomé[2], M. Karin[3], **P. N. Boyaka**[1];*
[1]The Ohio State University, Columbus, OH, United States,
[2]AgroParisTech, Paris, France, [3]USD, San Diego, CA, United States.

Regulation of allergic responses by intestinal epithelial cells remains poorly understood. Using a model of oral allergen sensitization in the presence of cholera toxin as adjuvant and mice with cell-specific deletion of IKKβ in intestinal epithelial cells IECs (IKKβΔIEC), we addressed the contribution of IECs to allergic sensitization to ingested antigens and allergic manifestations at distant mucosal sites and the skin. Cholera toxin induced higher proinflammatory responses and altered the profile of the gut microbiota in IKKβΔIEC mice. Antigen-specific IgE responses were unaltered in IKKβΔIEC mice, but Th1 responses and associated IgG2a Abs were enhanced. Interestingly, allergen-specific Th17 and IgA Ab responses were enhanced in IKKβΔIEC mice. Upon nasal antigen challenge, these mice developed lower levels of allergic lung inflammation, which correlated with higher levels of IgA Abs in the airways. However, IKKβΔIEC mice recruited a higher number of gut-sensitized T cells in the airways after nasal antigen challenge and developed airway hyper-responsiveness, which were suppressed by treatment with anti-IL-17A. Orally sensitized IKKβΔIEC mice were also protected against allergic inflammation in response to epicutaeous challenge. Ongoing studies are investigating the relative contribution of IgA and T helper cell subsets to the protection achieved in the skin.

P1.17.05
Regulation of human skin mast cell histamine release by PDE inhibitors

***N. Eskandari**[1], R. Bastan[2], P. Peachell[3];*
[1]Isfahan University, Isfahan, Iran, [2]Abadan University of Medical, Abadan, Iran, [3]Sheffield University, Sheffield, United Kingdom.

Mast cell and basophil are thought to be central to inflammation that has an allergic basis as allergens activate these cells in an ige-dependent manner to generate mediators such as histamine, eicosanoids and cytokines. Phosphodiestres is known to exist as multiple molecular forms of enzyme that metabolize the second messengers. studies of our own have shown that, of a variety of isoform-selective drugs, the phosphodiestres4-selective inhibitors, such as rolipram, attenuate the ige-mediated release of histamine from human basophils but not from human lung mast cells . The main aim of the present study was to characterize the type and role of phosphodiestres regulating human skin mast cells by using selective and non-selective phosphodiestres inhibitors
Cells were pre-treated for 15 min with these agents and then challenged with an optimal releasing concentration of anti ige (1:300) for a further 25 min for the release of histamine. the data show that all the selective phosphodiestres inhibitor compounds (10^{-5} m) were ineffective whereas the non-selective phosphodiestres inhibitor, theophylline (10^{-3} m), inhibited histamine release from skin mast cell (74±4% inhibition; $p<0.05$). None of the selective phosphodiestrases inhibitors had any effect on histamine release from lung mast cells whereas, in basophils, compounds with activity at phosphodiestrases 4 (rolipram, denbufylline, ro-2017, org 30029) were effective inhibitors of histamine release.
Data suggest that unlike most inflammatory cells, phosphodiestres-selective inhibitors are ineffective stabilizers of skin mast cells activity which is similar to lung mast cells.

P1.17.06
Interferon-α antagonizes IL-3-mediated immunoregulatory functions of human basophils

***B. Hagmann**, A. Odermatt, A. Eggel, C. A. Dahinden, M. Fux;*
Institute of Immunology, University Hospital, Inselspital, Bern, Switzerland.

Human basophils are major inflammatory cells in maintaining chronic allergic asthma. It has been published that interferon-α (IFN-α) improves clinical symptoms of asthma patients. In contrast, IL-3 exacerbates airway inflammation by inducing IL-4, IL-8 and IL-13 secretion from human basophils thus regulating their immunoregulatory functions. Furthermore, IL-3 exceptionally promotes survival of basophils. Here, we assessed cellular response of human basophils treated with IFN-α alone or in combination with IL-3.
Our data show that IFN-α enhances apoptosis in purified human blood basophils compared to spontaneous apoptosis of controls or IFN-γ treated cells. Furthermore, we demonstrate that both IFN-α and FasL enhance apoptosis in human basophils with similar efficiency in a rather additive than synergistic way. IFN-α inhibits IL-3-induced survival to a minor degree. Particularly however, it suppresses IL-3-induced de-novo production of IL-8 and IL-13 up to 80%. In contrast, the production of IL-4 is not affected. Analyses of signaling pathways reveal that IFN-α promotes prolonged phosphorylation of STAT1/STAT2. By using a pan-JAK inhibitor the phosphorylation of STAT1/STAT2 is inhibited and most importantly the pro-apoptotic effect of IFN-α is abolished. Although the phosphorylation of p38-MAPK in IFN-α-treated cells is comparable to non-treated cells, inhibition of p-p38 activity abrogates IFN-α-enhanced apoptosis as well.
We conclude that IFN-α-enhanced apoptosis is tightly regulated by the cooperation of JAK/STAT and p38-MAPK pathways. Our study identifies IFN-α as a novel inhibitor of IL-3-induced IL-8 and IL-13 production of human basophils. Taken together our study may explain the improved clinical symptoms of asthma patients treated with IFN-α.

P1.17.07
Serum IgE and Eosinophil level in patients Infected with giardiasis

M. Hosseinzadeh[1], *A. Khosravi*[2], *E. Sabbagh*[2], *K. Sayemiri*[2];
[1]*Tehran university of medical sciences, Tehran, Iran,* [2]*Ilam University of Medical sciences, Ilam, Iran.*

Background: Several studies have described the existence of allergic symptoms such as eosinophilia and elevated levels of IgE in patients with giardia infection. Due to discrepancy of the results of these studies, lack of recent studies showing the relationship between the Giaridsis and allergy among higher age groups, it seems essential to design and perform the currents study.
Materials and methods: Amongst patients who were infected with giardiasis and their infection was definitely diagnosed using stool exam 30 individuals were randomly selected as the case and 30 healthy individuals were also selected as the control group. Total IgE was measured using ELISA while CBC was count using Sysmax cell counter. Data were analysed using Logestic regression and Mann-whitney U test.
Results: The mean CBC among the case and control groups was 6.69 × 103 and 7.45 × 10 3 respectively. The mean Hb was 13,37 and 13.74 among the case and the control groups respectively. The difference of mean absolute neutrophil count (ANC) between the case and the control groups was statistically significant (P<0. 01). The mean IgE of all patients in all ages was 134.±12 for case and 50.57± 66 for the control group. The odd ratio for IgE of case and control group was 2.7.
Conclusion: The strong relationship of IgE and giardiasis showed a prediction value for this antibody amongst the giardiasis patients so that with increasing the probability of giardiasis the level of IgE can be increased few times.

P1.17.08
Anti-TIM-4 mAb ameliorates allergic lung inflammation by inhibiting TIM-4-mediated mast cell stimulation

F. Kamachi[1], *M. Hara*[2], *N. Harada*[3], *Y. Katsura*[3], *Y. Kojima*[4], *K. Izawa*[1,5], *C. Nishiyama*[2], *K. Okumura*[1,2], *H. Akiba*[1];
[1]*Department of Immunology, Juntendo University School of Medicine, Tokyo, Japan,* [2]*Atopy (Allergy) Research Center, Juntendo University School of Medicine, Tokyo, Japan,* [3]*Department of Respiratory Medicine, Juntendo University School of Medicine, Tokyo, Japan,* [4]*Laboratory of Biomedical Imaging Research, Juntendo University School of Medicine, Tokyo, Japan,* [5]*Division of Cellular Therapy, Advanced Clinical Research Center, The Institute of Medical Science, The University of Tokyo, Tokyo, Japan.*

T-cell immunoglobulin and mucin domain (TIM)-4 plays an essential role as the phosphatidylserine receptor in maintaining the homoeostatic function of macrophages, but the function of TIM-4 in allergic responses is not fully understood. In this study, we investigated whether TIM-4 regulates mast cell activation and allergic response. TIM-4 extracellular domain/Ig Fc region fusion protein (TIM-4-Ig) could bind to bone marrow-derived mast cells (BMMCs) and induced pro-inflammatory cytokine production, but not degranulation, by naïve and IgE/Ag-stimulated BMMCs. It was confirmed that these effects of TIM-4-Ig was induced by the interaction with leukocyte mono-Ig-like receptor 5 (LIMR5) by the findings using LMIR5 siRNA-transfected BMMCs or LMIR5$^{-/-}$ BMMCs. These results indicated that LMIR5 works as functional receptors on mast cells for TIM-4. Thus, we further investigated the effects of anti-TIM-4 mAb on a murine model of mast cell-dependent airway inflammation. Accumulation of eosinophils and production of Th2 cytokines in the lung were significantly reduced in the anti-TIM-4-treated mice. Importantly, TIM-4-trasfected cells and macrophages released a soluble form of TIM-4 (sTIM-4) through proteolytic cleavage of surface TIM-4. Moreover, high amount of sTIM-4 was detected in bronchoalveolar lavage fluids and sera in the allergic lung inflammatory mice. Given that sTIM-4 could induce pro-inflammatory cytokine production by BMMCs, it is possible that TIM-4 can be an appropriate target for the therapeutic treatment and/or the diagnostic marker of allergic diseases.

P1.17.09
Role of IL-6 in the development of dendritic cell-induced allergic inflammation

Y. Lin[1], *J. Wang*[2];
[1]*Graduate Institute of Basic Medical Sciences, College of Medicine, National Cheng Kung University Medical Center, Tainan, Taiwan,* [2]*Graduate Institute of Basic Medical Sciences, Institute of Microbiology and Immunology, Department of Pediatrics, National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University Medical Center, Tainan, Taiwan.*

IL-6, a pleiotropic inflammatory cytokine, secreted by dendritic cells (DCs) is recognized as an important factor for the development of T_H2 and T_H17 cells. However, the role of IL-6 in allergic asthma is still undefined. In this study, to understand the effect of IL-6 on *Dermatophagoides pteronyssinus* (Der p)-induced airway inflammation, mice were sensitized through the peritoneum and intratracheally challenged or instilled through the airway using Der p. Significant decreases of airway hyperreactivity (AHR), recruited eosinophils and neutrophils in the inflamed airways, and cytokine (IL-4, IL-5, IL-13, and IL-17) production of IL-6$^{-/-}$ mice were found in both models of allergic asthma. Moreover, the suppressive function of $CD4^+CD25^+$ regulatory T cells from lungs and Foxp3 expression from lung draining lymph nodes and spleens were all down-regulated in Der p-sensitized and -challenged wild-type mice, but not affected in IL-6$^{-/-}$ mice. Further exploration on bone marrow-derived DCs (BMDCs) from IL-6$^{-/-}$ mice revealed reduced expression of DC maturation markers, MHC class II and CD86, after Der p stimulation. Studies on the adoptive transfer of Der p-primed BMDCs showed a functional defect of BMDCs from IL-6$^{-/-}$ mice due to their inability to induce T_H2 and T_H17 responses and allergic airway inflammation in recipient mice. Hence, IL-6 plays important roles in regulating DC functions and subsequent T_H2/T_H17-mediated airway inflammation and AHR, and is thus a potential target for the treatment of allergic asthma.

P1.17.10
Role of the CC-chemokine receptor CCR9 as a modulator of the inflammatory process during allergic airway inflammation

C. P. Lopez-Pacheco, *G. Du Pont, G. Soldevila, E. A. García-Zepeda;*
Instituto de Investigaciones Biomédicas.UNAM, Mexico, Mexico.

BACKGROUND. Recruitment of inflammatory cells to airway epithelium is a pathological feature of allergic airway disease. It remains unclear if the chemokine-receptor CCR9 has a function as a modulator of the inflammatory process. AIM. To analyze wheather exists a potencial regulatory role of CCR9 in the inflammatory process in a murine model of allergic airway disease. METHODS. Mice were sensitized by i.p. injections of 10 µg of OVA and 10 µL of AL(OH)3 (Alum) diluted in 100 µL of PBS for each one, on days 1 and 8. Then, aerosolized OVA was administrated as local challenge (1% in PBS) for 30 min on days 15 to 20 and 34 (5% in PBS). RESULTS. There is a reduction in the eosinophils recruitment as it was observed in a differential cell count. Furthermore, we observed a significant reduction in the eosinophilic population-recruitment of CCR9 -/- mice compared to WT mice as we determined by flow cytometry. Histological and morphometric analysis demostrated a reduction in celluar recruitment in the absence of CCR9. The recruitment of different cell types was analyzed by FACS using anti-CD4 and anti-CD8 as expressing T- lymphocytes, CD19 expression was not modified in CCR9 -/- mice.These results suggest that CCR9 could be involved in the modulation of asthmatic response in airways. Interestingly, mucus production and IgE levels in CCR9-deficient mice were not affected. CONCLUSIONS. These results suggest a potential role of CCR9 as a regulator of eosinophils recruitment into inflammed airways. Further investigation is in process to corroborate these findings.

P1.17.11
Multiplex immunoassay for allergens using oligonucleotide tethering

R. S. Matson*;*
QuantiScientifics, Irvine, CA, United States.

Allergy to cow's milk affects about 2.5% of all children under age 3. While most infants overcome this allergy, milk intolerance is prevalent in most countries. Milk allergy is often associated with other food allergy, as well as, respiratory allergy.
Microplate-based multiplexed immunoassays are useful for the simultaneous measure of multiple analytes from a single sample in a single well. This allows for the creation of disease-specific panels potentially leading to a more accurate prognosis and/or diagnosis of the disease state.
The A-squared (A^2®) MicroArray System (QuantiScientifics, Irvine, CA, USA) is a microplate-based platform for quantitative multiplexed immunoassays. Arrays of oligonucleotides are covalently attached to the bottom of the plate well. Complementary strands are in turn linked to antibodies or antigens. The prepared oligo-antibody (-antigen) conjugates are pooled and applied to the wells. Through the process of hybridization self-assembly of the hybrids leads to the creation of a diagnostic multiplex panel in each well of the plate.
In this study, several milk proteins recognized as allergens were assembled into a multiplex panel using oligonucleotide tethering. Here, purified milk proteins whose epitopes are known to be associated with the allergy, as well as, crude milk allergen extracts are conjugated to oligonucleotides to create the panel. The panel included F2 crude extract, beta-lactoglobulin, alpha-lactalbumin, IgG, bovine serum albumin, lactoferrin, and 3 caseins. 13 patient serums were screened for the presence of specific IgE providing a profile and subsequent identification of principal component allergen.

P1.17.12
Microfibrillar-associated protein 4 deficiency attenuates experimental allergic airway inflammation

B. Pilecki*[1], A. T. Holm[1], A. Schlosser[1], H. Wulf-Johansson[1], J. B. Møller[1], J. Vestbo[2], C. Stevenson[3], U. Holmskov[1], G. L. Sorensen[1];*
[1]Department of Cardiovascular and Renal Research, Institute of Molecular Medicine, University of Southern Denmark, Odense, Denmark, [2]Department of Respiratory Medicine, Odense University Hospital, Odense, Denmark, [3]Inflammation Discovery, Hoffmann-LaRoche, Nutley, NJ, United States.

Microfibrillar-associated protein 4 (MFAP4) is a matricellular protein abundant in lungs and other elastin-rich tissues. It contains a fibrinogen-related domain, characteristic of many proteins engaged in innate immune responses, and an integrin-binding domain. MFAP4 is known to interact with surfactant proteins SP-A and SP-D, collectins critical for pulmonary host defence. No studies so far have addressed the possible immunomodulatory effects of MFAP4.
The aim of the current study is to investigate a potential pro-inflammatory role of MFAP4 in the murine acute model of allergic asthma.
BALB/c MFAP4 KO and WT mice were sensitized and subsequently challenged intranasally with ovalbumin (OVA) during three consecutive days. Immune cell infiltration and cytokine production were measured in bronchoalveolar lavage (BAL). Lungs were processed for histology and evaluated for signs of inflammation and airway remodeling.
OVA-treated MFAP4 KO mice exhibited significantly lowered cell counts in the BAL, corresponding to diminished numbers of eosinophils and neutrophils. Alveolar macrophages, although similar in number, were less activated in KO animals than in WT littermates. There was also a tendency towards reduced production of Th2-related cytokines IL-4, IL-5 and IL-13 in the BAL of MFAP4-deficient mice. Moreover, histological stainings revealed significant differences in lung morphology: more prominent parenchymal inflammation and more pronounced early airway remodeling events in WT mice, including increased epithelial thickness and goblet cell hyperplasia.
Obtained results show that absence of MFAP4 attenuates OVA-induced allergic airway disease. It indicates that MFAP4 may serve as a potential therapeutic target in the treatment for acute allergic asthma.

P1.17.13
S1P/SphK signalling in mast cells: relevance to airway inflammation, asthma and anaphylaxis

P. N. Pushparaj*[1], J. Manikandan[1], S. D. Kumar[2], L. A. Damiati[3], K. Gauthaman[1], M. H. Al-Qahtani[1];*
[1]Center of Excellence in Genomic Medicine Research, King Abdulaziz University, Jeddah, Saudi Arabia, [2]Lee Kong Chian School of Medicine, Nanyang Technological University, Singapore, Singapore, [3]Biology Department, King Abdulaziz University, Jeddah, Saudi Arabia.

Airway inflammation is primarily characterized by increased numbers of eosinophils, macrophages, and T lymphocytes in the airway mucosa and lumen recruited through the release of chemokines from resident structural and inflammatory cells like mast cells. The airway inflammation is driven by increased mast cell activation and Th2 cytokines/chemokines. Developing new therapies for chronic airway inflammation has been shown to be challenging. The sphingosine kinases (SphK1 & SphK2) may be the potential targets for allergic anaphylaxis, refractory asthma and chronic airway inflammation. Two isoenzymes SphK1 and SphK2 generate bioactive sphingosine-1-phosphate (S1P). Using Ingenuity Pathway Analysis (IPA) software, we have constructed the biological networks initiated through FcεRI receptor in mast cells and the intracellular molecular activation networks regulated by SphK during the activation process in allergic responses. In our preliminary in vivo studies, we have specifically silenced SPHK1 or SPHK2 in vivo, using specific siRNAs, and demonstrate that SphK1, but not SphK2, is indeed required for the effector responses triggered by Ag/FcεRI in mice models. We have used both Passive Cutaneous Anaphylaxis (PCA) and Passive Systemic Anaphylaxis (PSA) models to study the isoform specific in vivo role of SphKs which has not been well-characterized. Hence, dissecting the S1P/SphK signalling in mast cells could provide novel cues for the effective treatment and management of an extensive range of allergic disorders and asthma, which remain unmet clinical need in the world.

P1.17.14
Identification of a novel quantitative trait locus and candidate genes for airway hyperresponsiveness

C. Kanagaratham, R. Marino, P. Camateros, R. Sladek, S. Vidal, ***D. Radzioch****;*
McGill University, Montreal, QC, Canada.

The objectives of our study are to identify novel candidate genomic regions and genes associated with airway hyperresponsiveness (AHR), a heritable polygenic phenotype seen in allergic asthmatics where their airways are susceptible to bronchospasms.
To identify candidate genes for AHR, we used a unique genetic panel of 33 recombinant congenic strains (RCS) of mice originating from airway hyperreresponsive and hyporesponsive strains, A/J and C57BL/6J respectively. An informative RCS that has 85% of its genetic material originating from C57BL/6J, but has an AHR phenotype similar to A/J was used to generate F2 mice. Quantitative trait loci (QTL) analysis was done using the F2 mice and genes within the QTL containing non-synonymous or splice site coding mutations were selected as candidates. Candidate regions and genes were validated at the chromosome and gene expression levels.
One QTL containing 15 candidate genes was identified. Chromosome substitution strain mice, for the chromosome containing the candidate QTL, had an AHR phenotype similar to A/J strain and significantly different from C57BL/6J strain. Interestingly, this chromosome was not associated with other phenotypes of allergic asthma, such as atopy. Gene expression analysis revealed one candidate gene as having a two-fold increase in expression in the lungs of C57BL/6J mice compared to A/J, the informative RCS and the chromosome substitution strain.
Our approach provides a manageable list of candidate genes for AHR and can be applied to identify candidate genes for other phenotypes of asthma. Furthermore, it allows us to genetically segregate the phenotypes of asthma and study them individually.

P1.17.15

Circulating human basophils lack the features of professional antigen presenting cells

M. Sharma[1,2], *P. Hegde*[1,2], *V. Aimanianda*[3], *R. Beau*[3], *H. Sénéchal*[4,5], *P. Poncet*[6,4], *S. V. Kaveri*[1,7,8], *J. Bayry*[1,7,8];
[1]*INSERM UMRS 872, Paris, France,* [2]*Université de Technologie de Compiègne, Compiègne, France,* [3]*Institut Pasteur, Paris, France,* [4]*ESPCI ParisTech, UMR 7195 CNRS, Paris, France,* [5]*INSERM, Paris, France,* [6]*Institut Pasteur, Department of Infection and Epidemiology, Paris, France,* [7]*Centre de Recherche des Cordeliers, Université Pierre et Marie Curie – Paris 6, Paris, France,* [8]*Université Paris Descartes, UMR S 872, Paris, France.*

Recent reports in mice demonstrate that basophils function as antigen presenting cells (APC). They express MHC class II and co-stimulatory molecules CD80 and CD86, capture and present soluble antigens or IgE-antigen complexes and polarize Th2 responses. Therefore, we explored whether circulating human basophils possess the features of professional APC. We found that unlike dendritic cells (DC) and monocytes, steady-state circulating human basophils did not express HLA-DR and co-stimulatory molecules CD80 and CD86. Interestingly, basophils remained negative for these molecules following stimulation with soluble Asp f 1, one of the allergens of Aspergillus fumigatus, Bet v 1, the major birch allergen, stimulation via TLR2-ligand or even upon IgE cross-linking. Further, DC pulsed with Asp f 1 promoted the Th2 response as analyzed by the secretion of IL-4 in the DC-CD4+ T cell co-culture. Whereas, Asp f 1-pulsed basophils did not promote Th2 responses from CD4+ T cells. Together, these results demonstrate that although basophils from mice show the expression of antigen presenting and co-stimulatory molecules, human basophils from circulation show the inability to function as professional APC.

P1.17.16
Intratracheally administration Asian sand dust activates NF-kappaB in immune cells

Y. Song[1], *T. Ichinose*[2], *T. Kanazawa*[1], *Y. Yoshida*[1];
[1]*University of Occupational and Environmental Health, Japan, Kitakyushu, Japan,* [2]*Oita University of Nursing and Health Sciences, Oita, Japan.*

Asian sand dust (ASD) is derived from air pollutants in East China that migrate to Japan. ASD contains particles of SiO_2 with microbial materials, sulfate, and nitrate. As increasing flying ASD, there are concerns regarding its possible adverse health effects. Although our group has reported that ASD induces inflammatory responses in lung tissue and causes respiratory diseases in mice. It is still unclear whether ASD influence lymphoid organ. In this study, we investigated the effect on splenocytes in an ASD-administered mice model. ICR mice were intratracheally administered ASD and were sacrificed at days 1 and day 3. After administration cell number of bronchoalveoar fluids (BALF) was significantly increased after ASD administration at days 1 and 3. Spleen cells were prepared and cell lysates of splenocytes were resolved by western blotting. Immunoblotting demonstrated that phosphorylation of p65 was induced at days 3 after ASD administration but not at day 1. Furthermore, electrophoretic mobility shift assay demonstrated that ASD induced active form of NF-κB in splenocytes after ASD administration at days 3 but not day 1. In addition, ASD could increase the expression of TNF-α production after 3 days administration. Finally, ATP level in splenocytes was measured, and high level of ATP was observed after ASD administration for 3 days. These results suggest that at different time point of lung response, ASD affects peripheral lymphoid tissue, and may modulate cell survival or activity.

P1.17.17
Receptor for advanced glycation end products (RAGE) - a central mediator of allergic sensitization

M. A. Ullah[1,2], *Z. Loh*[2], *W. J. Gan*[2], *V. Zhang*[2], *J. M. Hughes*[3], *C. L. Armour*[1], *S. Phipps*[2], *M. B. Sukkar*[1,4];
[1]*Woolcock Institute of Medical Research, The University of Sydney, Sydney, Australia,* [2]*School of Biomedical Sciences, The University of Queensland, Brisbane, Australia,* [3]*Faculty of Pharmacy, The University of Sydney, Sydney, Australia,* [4]*School of Pharmacy, The University of Technology Sydney, Sydney, Australia.*

Allergic sensitization to house dust mite (HDM) is a significant risk factor associated with asthma onset and progression. Activation of innate pattern-recognition receptors (PRRs) can induce the release of endogenous tissue alarmins that modulate the magnitude of the inflammatory response. RAGE is a PRR with the unique capacity to recognise a diverse repertoire of endogenous alarmins, and can collaborate with toll-like receptor (TLR)-4 (known to 'sense' HDM), yet its role in the development of allergic sensitization to HDM and other allergens remains obscure. Here, we report that HDM-induced airway inflammation was diminished in RAGE-deficient mice. Strikingly, the early induction of HDM-induced IL-33 and IL-25 was TLR4-dependent; whereas a second 'wave' (persistent expression) of these T_H2-instructive cytokines was regulated downstream of RAGE activation. HDM sensitization also induced nuclear to cytoplasmic translocation of endogenous alarmin, high mobility group box-1 (HMGB1), and elevated levels in bronchoalveolar lavage fluid. Like innate cytokines, the early HMGB1 activation was TLR4-dependent and later on sustained via RAGE signalling. Moreover the magnitude of the T_H2 immune response was abolished when HMGB1 was neutralized, implicating the functional role of HMGB1. With evidence that RAGE is engaged secondary to TLR4, we hypothesised that it might potentially function as a common pathway down-stream of various PRRs involved in initial allergen recognition/sensing. Of note, we demonstrated that RAGE-deficient mice were also protected against cockroach-extract induced allergic inflammation and had attenuated levels of HMGB1. Together, these studies address HMGB1-RAGE signalling as a critical innate mechanism of allergic sensitization and development of airway inflammation.

P2.01 Leukocyte signalling

P2.01.01
Hydrophobic amino acid cluster in the cytoplasmic tail of interleukin-2 receptor β chain acts as a sorting signal for lysosome

Y. Amano, *K. Kojima, K. Yoshino, T. Takeshita;*
Shinshu University School of Medicine, Matsumoto, Nagano, Japan.

Lysosomal degradation of cell surface receptors contributes to regulate the expression levels of the receptors, and attenuation of signal transduction from the receptors. It is well known that ubiquitin modification of the cell surface receptors serves as a sorting signal for endocytic trafficking to lysosome. Hepatocyte growth factor-regulated tyrosine kinase substrate (Hrs) is a key molecule in this process that captures ubiquitinated receptors and sorts them to the lysosomal pathway. On the other hand, we previously demonstrated that lysosomal trafficking of interleukin-2 receptor β chain (IL-2Rβ) does not require the ubiquitin modification, although undergoing Hrs-interaction process. We also reported that hydrophobic amino acid cluster (HC) in the cytoplasmic tail of IL-2Rβ (365-FFFHL-369) is essential for its binding to Hrs and trafficking to lysosome. HC is necessary for lysosomal sorting of IL-2Rβ, but it has been unknown whether the motif is sufficient to act as a sorting signal for lysosome. To elucidate this, we constructed chimeras comprised of IL-2R α chain (IL-2Rα) fused with various fragments including HC. Because IL-2Rα has no sorting signal, after internalized, it is rapidly recycle back to plasma membrane. The IL-2Rα chimeras were sorted to lysosome, while chimeras including only HC or fragments lacking HC were not sorted. These results indicated that fragments (more than 30 residues) including HC are functional sorting signal for lysosome via interaction with Hrs.

P2.01.02

Apurinic/apyrimidinic endonuclease1/redox factor-1 (Ape1/Ref-1) is essential for IL-21-induced signal transduction through ERK1/2 pathway

*F. M. Juliana[1], H. Nara[1], T. Onoda[1], M. Rahman[1], A. Araki[1], L. Jin[1], H. Fujii[2], N. Tanaka[3], T. Hoshino[4], **H. Asao**[1];*
[1]Yamagata University, Yamagata, Japan, [2]Osaka University, Suita, Japan, [3]Miyagi Cancer Center Research Institute, Natori, Japan, [4]Kurume University, Kurume, Japan.

IL-21 is a pleiotropic cytokine that regulates T-cell and B-cell differentiation, NK-cell activation, and dendritic cell functions. IL-21 activates the JAK-STAT, ERK, and PI3K pathways. We report here that Ape1/Ref-1, which has many functions through the regulation of redox, through endonuclease activity and also through unknown mechanisms, has an essential role in IL-21-induced cell growth signal transduction. Overexpression of Ape1/Ref-1 enhances IL-21-induced cell proliferation, but it is suppressed by overexpressing an N-terminal deletion mutant of Ape1/Ref-1 that lacks the redox domain. Furthermore, knockdown of the Ape1/Ref-1 mRNA dramatically compromises IL-21-induced ERK1/2 activation and cell proliferation with increasing cell death. Activity of JAK1 and JAK3, which are the key kinases for IL-21-induced signaling, seems not to be reduced in the Ape1/Ref-1 knockdown cells. These impaired activities are recovered by the re-expression of Ape1/Ref-1 in the knockdown cells. Our findings are the first demonstration that Ape1/Ref-1 is an indispensable molecule for the IL-21-mediated signal transduction through ERK1/2 activation. We are now studying how Ape1/Ref-1 controls the ERK activation.

Notch receptors and ligands expression in human T cell development

***L. Bento-de-Souza**[1,2], J. R. Victor[1], J. B. Oliveira Filho[3], A. C. Rangel-Santos[1,3], E. Pereira-Costa[1], L. C. Bento-de-Souza[2], M. Arrais-Santos[2], E. Raniero-Fernandes[4], M. I. Seixas-Duarte[4], A. J. da Silva Duarte[1];*
[1]Laboratory of Medical Investigation in Dermatology and Imunodeficiencies LIM56, School of Medicine of University of São Paulo, Sao Paulo, Brazil, [2]Hospital do Coração-HCor, São Paulo, Brazil, [3]Human Disorders of Lymphocyte Homeostasis Unit, National Institutes of Health, Bethesda, MD, United States, [4]Laboratory of Pathology of Transmissible Diseases, School of Medicine of University of São Paulo, São Paulo, Brazil.

The thymus is a primary lymphoid organ responsible of maturing T lymphocytes. Several signaling pathways act during T lymphocytes maturation including Notch signaling pathway, comprising in receptors (Notch1-4) and ligands (DLL1-3-4, Jagged1-2). We sought to verify the expression of Notch components in human developing lymphocytes. Thymic tissue fragments were stained by immunohistochemistry and Notch receptors/ligands were quantified. Total thymocytes were sorted into CD4-8-, CD4+8+, CD4+8- and CD4-8+. RNA expression was evaluated on each population. In thymic tissue we detected all Notch components (mean of positive cells). Notch receptors and ligands proteic expression showed no significant difference.The CD4+8+ subset presented higher percentage among all sorted populations (51,82%). RNA expression showed that all Notch receptors and ligands genes were detected in lymphocytes subsets, except DLL3 gene. NOTCH1 gene was more expressed at earlier stages of development (CD4-8-), and JAG2 gene was more expressed on CD4+8+ subset. The other genes showed no difference among lymphocytes subsets. NOTCH1 gene may have a key role in the first stages of T lymphocytes development due to its higher expression in early stages, different of NOTCH2 gene which showed significant expression at later stages of thymic subsets. JAGGED2 gene may represent a consequence of TCD4+ maturation owing to its prior expression at CD4+8+ subset. Different from genes analysis, the homogeneous distribution of Notch components in thymic tissue suggests that a new approach should be considered for Notch pathway during human T lymphocytes development and maturation.

P2.01.05

Site-wide quantitative phosphoproteomics reveal non-redundant pathways regulated by IL-7 and IL-15 in memory CD8+ T cells

***M. J. Carrasco-Alfonso**[1], S. Ficarro[2], Y. Zhang[2], W. Jiang[1], J. Marto[2], J. Luckey[1];*
[1]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, United States, [2]Dana Farber Cancer Institute and Harvard Medical School, Boston, MA, United States.

Self-renewing memory CD8+ T-cells require IL-7 and IL-15, which preferentially promote survival versus cell division/growth. Although both signal through a common gamma-chain and JAK/STAT5, their non-redundant networks are unknown. Here, we compared highly purified primary memory-phenotype (CD44high) lymphocytes after IL-7 or IL-15 equipotent stimulation *ex vivo*. IL-15 was shown to greatly increase, besides proliferation and size, blast formation and migration/contact. To identify specific signaling components, the differential downstream phosphorylation events were measured. Since conventional mass spectrometry (MS) demands samples in the range of mg, we faced the challenge of robust and large-scale quantification of post-translational modifications in primary cells. This was overcome with our automated online liquid chromatography-MS/MS platform combining nanoflow electrospray ionization with a novel 3D fractionation. By enabling examination of minute protein amounts (~50 µg/condition), we efficiently (>8000 unique phosphopeptides) completed a quantitative high-throughput site-wide (Ser-/Thr-/Tyr) phosphoproteome profiling. Notably, despite the extreme biological variability that hinders these analyses, we succeeded in detecting selected peptides (mapped to 24 proteins) that in cells from independent animal pools were consistently differentially phosphorylated (by >2-fold). This led to reveal IL-15-induced signatures: 1) AKT over-activation (as confirmed by phosphorylated AKT and substrate levels after IL-15-stimulation and selective AKT-inhibition); and 2) phosphorylation of potential effectors with unexplored roles (i.e. membrane sculpting, calcium signaling and mRNA splicing) in self-renewal. The relationship between IL-15-induced phenotypes, AKT activation and candidate effectors is being determined. In conclusion, we provide a powerful approach for global phosphoproteomics of immune cell subsets and contribute to define the non-redundant effects of IL-7/IL-15.

P2.01.06

Quantifying differential T cell responses using tuneable material surfaces

***S. N. Christo**[1], B. R. Coad[2], G. T. Sarvestani[3], H. J. Griesser[2], K. Vasilev[4], R. Nordon[5], C. K. Fraser[6], M. P. Brown[6], K. R. Diener[7], J. D. Hayball[1];*
[1]University of South Australia, Adelaide, Australia, [2]Ian Wark Research Institute, Adelaide, Australia, [3]Detmold Imaging Core Facility, Adelaide, Australia, [4]Mawson Institute, Adelaide, Australia, [5]University of New South Wales, Sydney, Australia, [6]Royal Adelaide Hospital, Adelaide, Australia, [7]University of Adelaide, Adelaide, Australia.

Upon the interaction between the T-cell receptor (TCR) and its cognate ligand, activated T-cells elicit powerful anti-tumour responses and can destroy pathogen-infected host cells. It is well established that the binding affinity and the density of the stimulating TCR ligand has directly proportional consequences on the overall T-cell response. Understanding the combination of these parameters that result in optimal T-cell activation has significant applications in the field of immune monitoring of vaccines. Therefore, the purpose of this study is to develop a functionalized platform that allows controlled deposition of TCR ligand parameters for the characterization of the resulting T-cell response.
Functionalized platforms were created by covalently attaching streptavidin on solid material surfaces for immobilizing biotinylated ligands. The concentration of streptavidin on the surfaces was altered to control deposition of ligands, which included anti-CD3 f(Ab) fragments, and OVA-specific peptide-MHC monomers. When primary T-cells were then activated on the material surfaces of altered ligand density, differential expression of activation markers and early calcium flux was observed. To interrogate the early T-cell response, calcium oscillations within single cells were assessed and found to differ based on ligand density, suggesting that intracellular calcium flux may be used to differentiate T-cell outcomes. To explore this, we are developing an assay to measure and correlate early calcium flux

with late stage activation markers within individual cells. Therefore, the ability of functionalized material surfaces to 'tune' TCR ligand density can be employed in combination with altered ligand affinity for fully quantifying differential T-cell responses for clinical application.

P2.01.07
Levodopa-induced neutropenia in Parkinson's disease

C. Cordano[1], *B. Parodi*[1], *A. Uccelli*[1], *A. Schenone*[1], *L. Schembri*[2], *F. Marino*[2], *M. Cosentino*[2];
[1]*Clinica Neurologica, Università di Genova, Genova, Italy,* [2]*Centro di Ricerca in Farmacologia Medica, Università dell'Insubria, Varese, Italy.*

We report the case of a male PD patient, who came to our attention for progressive resting tremor, hypokinesia and rigidity. The patient was thus started on Levodopa-Carbidopa. At the beginning of therapy, the patient showed reduction of hypokinesia and rigidity but also a significant reduction in leukocytes count (2,470 x mm3), particularly neutrophils (0,710 x mm3), confirmed by a second control. After these findings, Levodopa-Carbidopa therapy was stopped with normalization of blood studies. Then the patient began treatment with Levodopa-Benserazide to control motor symptoms. For the second time the blood tests underscored an important neutropenia (2,40 x mm3), that forced the suspension of therapy followed by normalization of leukocyte count. To date, the patient is taking dopamine agonists with benefit and no evidence of adverse effects. By means of rt-PCR we showed that, in comparison to circulating neutrophils from healthy subjects, cells from our patient underexprressed mRNA for D2-like dopamine receptors (DR) and overexpressed mRNA for D1-like (D5) DR as well as for tyrosine hydroxylase, the first and rate-limiting enzyme in the synthesis of dopamine.
Our case shows an adverse reaction to LD that to our knowledge has not been previously reported. Normalization after LD dechallenge as well as relapse after rechallenge with LD in association with a different inhibitor of L-Dopa decarboxylase supports a strong causal relationship between LD and leukopenia. Additional studies are warranted to assess whether DR and/or TH mRNA expression in circulating neutrophils may be a marker of vulnerability to LD-induced leukopenia.

P2.01.08
Correlation between low tyrosine phosphatase activity of inhibitory SHP-1 and high proliferation in chronic lymphocytic leukemia (CLL) B-cells

P. Delfani[1], *Z. El-Schich*[2], *A. Rosén*[3], ***A. Gjörloff Wingren***[2];
[1]*Lund Institute of Technology, Lund, Sweden,* [2]*Malmö University, Malmö, Sweden,* [3]*Linköping University, Linköping, Sweden.*

The clinical course of B-cell chronic lymphocytic leukemia (CLL) is very heterogenous, with some patients presenting an indolent disease and others having a worse outcome. Biological active inhibitory molecules, such as Src homology domain-containing protein tyrosine phosphatase-1 (SHP-1), can decrease cell viability or proliferation in CLL cells. In this study, expression levels of IgM, SHP-1, ZAP70 were investigated together with SHP-1 phosphatase activity of different CLL cell lines. The intracellular phosphatase activity was assessed to evaluate a potential role of SHP-1 on cell proliferation. We show that CLL cells with high expression levels of SHP-1 also displayed high SHP-1 phosphatase activity, lower levels of ZAP70, and lower cell proliferation. On the other hand, in cells with low SHP-1 expression and phosphatase activity, increased proliferative activity was determined. To our knowledge, this is the first time that the SHP-1 phosphatase activity has been shown to correlate with proliferative activity in CLL.

P2.01.09
Functional regions in the Ankyrin Repeat Domain 54/ Liar protein which regulate nucleocytoplasmic shuttling of Bruton's Tyrosine Kinase (Btk) through a novel SH3-dependent interaction

M. O. Gustafsson, *A. Hussain, D. K. Mohammad, A. J. Mohamed, C. Smith, B. F. Nore;*
Karolinska Institutet, Huddinge, Sweden.

Bruton's tyrosine kinase (Btk) is a cytoplasmic protein kinase that belongs to the Tec family of tyrosine kinases (TFKs). It is essential for B-lymphocyte development and is involved in multiple signal transduction pathways. Abrogation of Btk signaling causes human X-linked agammaglobulinemia (XLA) and murine X-linked immunodeficiency (Xid).
We have recently employed affinity-purification of Flag-tagged Btk, combined with tandem mass-spectrometry analysis to capture and identify novel interacting proteins. The results were validated by using endogenous as well as ectopic expression of both proteins in a co-immunoprecipitation assay. We further characterized the interaction with Ankryin repeat domain protein 54, also known as Lyn-interacting ankyrin repeat protein, Liar (Gustafsson et al. Mol Cell Biol. 32:13; 2440-2453).
Liar mediated Btk shuttling was enriched for activation loop, nonphosphorylated Btk and entirely dependent on Btk's SH3 domain. Liar also showed reduced binding to an aspartic acid phosphomimetic SH3 mutant. We have now generated site-directed mutants where different regions in Liar have been removed or altered. This allows us to assign functional entities within the protein, which govern intracellular transport of Btk.
We identified a novel interaction between Liar and the Btk SH3 domain and it was not dependent on classical polyproline-rich (PPR) PXXP motifs, since the Liar ankyrin repeats does not contain such motifs. Moreover, mutagenetic analysis revealed that three of four ankyrin repeat domains of Liar are required for the interaction and nuclear shuttling of Btk.

P2.01.10
Role of the long-chain fatty acids receptor GPR40 in bovine neutrophils activation

M. A. Hidalgo[1], *J. Mena*[1,2], *C. Manosalva*[1], *D. Carroza*[1], *R. A. Burgos*[1];
[1]*Universidad Austral de Chile, Valdivia, Chile,* [2]*Universidad de Nariño, Pasto, Colombia.*

Long chain fatty acids (LCFA) bind to G-protein coupled receptors such as GPR40, a receptor with known functions in pancreas. Recently, we described the presence of GPR40 in bovine neutrophils and demonstrated that oleic and linoleic acids, two LCFA, stimulate responses such as superoxide production, granules release and MAPK phosphorylation. In this study, we investigated the function of GPR40 on bovine neutrophils activation. Neutrophils isolated from blood samples of healthy heifers were treated with GW9508, a synthetic GPR40 agonist, or linoleic and oleic acid, natural ligands of GPR40, in presence or absence of the selective GPR40 antagonist GW1100. Protein phosphorylation was analyzed by immunoblot, NF-κB pathway was assessed as IκBα levels by flow cytometry, IL8 mRNA by RT-qPCR, matrix metalloproteinase-9 (MMP9) activity by zymography and superoxide production by flow cytometry. We observed that GW1100 (10 μM) reduced the ERK1/2, p38 MAPK and Akt phopshorylation induced by GW9508 (10 μM), linoleic (100 μM) or oleic acid (300 μM). GW9508 and fatty acids significantly decreased IκBα levels, at 30 min of treatment, suggesting activation of the NFκB pathway. The reduction of IκBα levels induced by ligands of GPR40 was inhibited by GW1100. GW9508 and natural ligands increased the IL8 mRNA levels and GW1100 reduced this effect. Finally, GW1100 reduced the MMP9 activity and superoxide production induced by GPR40 ligands. We conclude that GPR40 activation modulates the function oxidative and non-oxidative of bovine neutrophils, exerting a potential role in innate immune response.

P2.01.11

Role of SLP-76, ADAP and Pyk2 on chemokine-stimulated T cell adhesion mediated by the integrin *Alpha4-Beta1*

***S. Isern de Val**, A. Dios-Esponera, J. Teixidó;*
CIB Centro de Investigaciones Biológicas-CSIC, Madrid, Spain.

Lymphocyte extravasation at sites of tissue injury or infection depends on chemokine-activated adhesion mediated by the α4β1 and αLβ2 integrins. This activation must be rapid to deliver tight cell attachment to resist the blood shear stress. The chemokine-dependent integrin activation step in lymphocytes requires an inside-out signalling that impinges on the integrin β subunit cytoplasmic domains, a key event for transmitting conformational changes to the extracellular regions that leads to increase in integrin affinity. Talin is a recipient of this inside-out signalling that promote their binding to the β cytoplasmic domains, finally stimulating the transition to high-affinity α4β1 and αLβ2 conformations. A key inside-out molecule that regulates the activation of α4β1is the guanine-nucleotide exchange factor Vav1, which associates with talin forming a key complex that controls chemokine-dependent, α4β1-mediated T cell adhesion. SLP-76 and Pyk2 are Vav1-binding proteins with the potential of influencing α4β1-mediated T cell adhesion in response to chemokine stimulation. We are investigating the role of SLP-76, its binding partner ADAP, and Pyk2, as possible regulators of this adhesion by inside-out mechanisms arising from chemokine stimulation.

P2.01.12
Regulation of apoptosis by CD45 in T cells

***B. Johnson**[1], G. Dupéré-Minier[2], D. Bernier[2], J. Bernier[2];*
[1]INRS-IAF, Montreal, QC, Canada, [2]INRS-IAF, Laval, QC, Canada.

CD45 is a transmembrane tyrosine phosphatase expressed in all leukocytes. We have previously showed that CD45- cells (HPB45.0 and JK6.6) were resistant to nuclear apoptosis, as observed by a lack of chromatin condensation and DNA fragmentation. The latter is majorly under the responsibility of the DNA fragmentation factor (DFF), an heteromeric complex of the endonuclease DFF40 and its inhibitor DFF45. Nuclear apoptosis is an important process that reduces the risk of mutated genes transfers to neighbouring cells. The aim of this study was to identify if the CD45-dependant signalisation pathways can be responsible for the lack of DNA fragmentation. HPB-ALL (CD45+) T cells and HPB45.0 (CD45-) T cells were exposed to the mitochondrial perturbing agent, tributyltin (TBT), to induce apoptosis and selected biochemical pathways were analysed by immunoblot and antibody array. The absence of CD45 expression increased the activity of downstream protein kinases such as p38, JNK, Akt and PKC-delta after apoptosis induction. However, specific protein kinases inhibitors did not restore nuclear apoptosis in CD45- cells, suggesting an intramolecular defect in the regulation of apoptosis with the lack of CD45 expression. Interestingly, the phosphorylation, 0-glycosylation and acetylation level of DFF is altered in CD45- cells. Understanding the control of DNA fragmentation is important considering that the expression of CD45 is lost in nearly 10% of patients with acute lymphoblastic lymphomas and was associated with poor prognostic.

P2.01.13
The SNARE protein VAMP7 controls T cell activation by regulating recruitment and phosphorylation of Lat subsynaptic vesicles to the TCR activation sites

***P. Larghi**[1,2], D. J. Williamson[3], J. Carpier[1,2], S. Dogniaux[1,2], K. Chemin[1,2], A. Bohineust[1,2], L. Danglot[4,5], K. Gaus[3], T. Galli[4,5], C. Hivroz[1,2];*
[1]Institut Curie, Paris, France, [2]INSERM U932, Paris, France, [3]University of New South Wales, Sydney, Australia, [4]Institut Jacques Monod, UMR 7592, CNRS, Université Paris Diderot, Paris, France, [5]INSERM ERL U950, Paris, France.

The mechanisms by which the linker for activation of T cells (Lat), a key adaptor in the T cell receptor (TCR) signaling pathway, and the TCR come together after TCR triggering are not well understood. Nevertheless, it is now known that Lat is contained in intracellular compartments that are recruited close to the TCR activation sites. We reasoned that fusion/docking of these Lat containing compartments might be important for T cell activation.
We show here, by using silencing approaches and genetically modified mice, that the vesicular soluble N-ethylmaleimide-sensitive factor attachment protein receptor (v-SNARE) VAMP7 is required for the recruitment to the TCR activation sites of Lat-containing sub-synaptic vesicles, which do not fuse with the plasma membrane. VAMP7, which colocalized with Lat on the vesicles, controls Lat phosphorylation, TCR-Lat-signaling complex formation and ultimately T cell activation.
Our findings suggest that transport, docking and perhaps fusion of Lat-containing vesicles with target membranes containing the TCR are required to regulate TCR-induced signaling.

P2.01.14
Dual phosphorylation of Btk induced by Akt/PKB kinase regulating shuttling and attenuating signaling in B cells

***D. K. Mohammad**, B. F. Nore, M. O. Gustafsson, A. Hussain, A. J. Mohamed, C. Smith;*
Karolinska Institutet, Stockholm, Sweden.

Bruton's tyrosine kinase (Btk) is a key regulator of B-cell activation and development. Mutations in the Btk-gene cause X-linked agammaglobulinemia (XLA) in humans and X-linked immunodeficiency (Xid) in mice. In the present study, we employed mass spectrometry to identify a new partner protein as a novel regulator of Btk in B-cell lines and primary B-lymphocytes. In addition, we herein demonstrate that phosphorylation of two bona fide Akt (PKB) target sites is responsible for mediating functional interaction of BTK with a new partner.
The interaction-sites on Btk were mapped to phospho-serine/threonine in the kinase-domain. Mutation of both residues to alanine abolished binding of Btk to the new identified partner, while phosphomimetic mutant conversely demonstrated enhanced interaction. The PI3-kinase inhibitor LY294002 abrogated Btk serine/threonine phosphorylation and disrupted Btk's interaction with that particular partner.
Moreover, a newly characterized Btk inhibitor, PCI-32765, interrupted Btk binding. Down-regulation of the novel partner of Btk elevated nuclear translocation of Btk, while over-expression of that particular partner resulted in the perinuclear accumulation of Btk. Finally, phosphorylation of these sites is a prerequisite for the tyrosine phosphorylation, ubiquitination and degradation of Btk by the 26S proteasome and has implications in the regulation of the B cell receptor signaling pathway.

P2.01.15
Role of SRC family kinases in the activation of ITK-SYK

***A. J. Mohammed Hamasy**, A. Hussain, D. K. Mohammad, M. O. Gustafsson, B. F. Nore, A. J. Mohamed, C. Smith;*
Karolinska Institutet, Stockholm, Sweden.

The chromosomal translocation t(5;9)(q33;q22) generating the interleukin-2 (IL-2)-inducible T cell kinase (ITK)-spleen tyrosine kinase (SYK) fusion tyrosine kinase was identified as a recurrent event in PTCL. SRC family kinases (SFKs) initiate intracellular signaling in response to ligation of many antigen receptors. This leads to recruitment of SYK, by binding of the SYK SH2 protein domain to the phospho-tyrosines (pY) on ITAM residues, and activation of SYK allowing it to phosphorylate downstream substrate. To investigate the role of the SRC family kinases in ITK-SYK activation and signaling, we used a SFK-deficient cell line, SYF, and transfected it with ITK-SYK mutants. Other cell lines that contain SRC family kinases, like COS-7 cells, were used as a control. The results show that coexpression of ITK-SYK and ITK-SYK mutants with SLP-76 in SYF cells leads to phosphorylation of SLP-76, while there is no detectable phosphorylation of ITK-SYK. We then used COS-7 cells as control, and when we cotransfected ITK-SYK and SLP-76, there was conversely detectable phosphorylation of both SLP-76 and ITK-SYK. From these results we can conclude that the activation and phosphorylation of ITK-SYK is independent of SFKs.

P2.01.16

CD137 Costimulation may compromise cytotoxic mediators of Natural Killer Cells

***S. Navabi**, A. Hosseini, M. Jaberipour, M. Doroudchi, M. Habibagahi;*
Shiraz University Medical Of Sciences, Shiraz, Iran.

Background: In spite of T cells, costimulatory effects of CD137 in NK cells have not been fully understood. In this study, we investigated the consequence of CD137-CD137L interaction on activation and functionality of human NK cells.
Methods:
MCF-7 breast cancer cells were infected in advance by non-replicative adenovirus vectors to over-express 4-1BBL transgene or GFP (as control). Human NK cells were negatively purified from peripheral blood and activated with suboptimal concentrations of IL-2 and IL-15 and cocultured with the infected tumor cells. The cytotoxic function of the NK cells was examined by CD107a mobilization and granzyme-B staining. Moreover, killing of target cells was visualized on CFSE labeled K562 cells by flow cytometry.
Result: CD137 signal in IL-2/IL-15 activated NK cells resulted in decrease in the frequency of $CD107a^{+}GrB^{+}$ cells. More NK cells turned to $CD56^{-}$ $CD16^{-}$ after exposure to CD137L. There was an increase in the frequency of $CD107a^{+}GrB^{+}$ cells in the $CD56^{+}CD16^{+}$ subpopulation compared to other subsets. However, results of CFSE cytotoxicity assays of the whole population showed no significant difference between the experimental conditions.
Conclusion: CD137-CD137L interaction may affect the activity of various sub-populations of NK cells differently as it augmented the cytotoxcity of only CD56+CD16+ subpopulation but not others.

P2.01.17
NFkB alternative pathway is activated in IgE class switching

***H. Sakamoto**, K. Tanabe, S. Inui;*
Kumamoto University, Kumamoto, Japan.

We previously established B cell specific alpha4 KO mouse and showed that alpha4 was essential for B cell activation through BCR, IL4 receptor, LPS and CD40. Mature B cells undergo class switching to IgE by IL4 and CD40 signaling. It was later found that alpha4 associated with Protein phosphatase 2Ac and regulated its enzymatic activity. Alpha4 and PP2A regulate CaMKII activity in the central nervous system to control learning and memory. Alpha4 deficient mice also showed impaired class switching with T cell dependent Ag. We therefore analyzed whether alpha4 was involved in class switching to IgE. Real Time PCR of epsilon germ line transcript revealed that IL4 and CD40 induced IgE class switching in M12, a murine mature B cell line. IL4 stimulation of M12 induced serine and threonine phosphorylation of alpha4. Although canonical and alternative NFkB activation by CD40 signal was well characterized, IL4 receptor engagement was shown to activate Stat signaling and only canonical NFkB pathway. IL4-induced class switching to IgE and alpha4 phosphorylation was inhibited by KN93, a potent CaMKII inhibitor. These results suggest that alpha4/CaMKII is involved in IgE class switching via NFkB alternative pathway.

P2.01.18
Level of CD44 expression and its function distinguishes TH17 from TH1 cells

***J. Schumann**, K. Stanko, C. Appelt, B. Sawitzki;*
Charité - Universitätsmedizin Berlin; Institute for Medical Immunology, Berlin, Germany.

CD44 is a prominent activation marker, which distinguishes memory and effector from naïve T cells. CD44 also has a role in early T cell signaling events: It is bound to lymphocyte-specific protein kinase (Lck) and can enhance TCR signaling (Taher et al. 1996). We found that the level of CD44 distinguishes TH17 from TH1 cells. We hypothesize, that CD44 serves as a co-stimulus for TH17 cells and facilitates its development.
MACS-purified CD4+ cells from C57Bl/6 mice were either stimulated with allogeneic bone-marrow-derived dendritic cells (BMDCs) from Balb/c mice or polyclonally with anti-CD3 and splenocytes. Four days later cells were analyzed by fluorescence cytometry.
Stimulation of CD4+ T cells with allogeneic BMDCs results in the formation of three distinguishable populations: CD44low, CD44intermediate and CD44high. In vitro and in vivo generated allo-reactive TH17 cells are mainly CD44high compared to TH1, which are CD44int. This effect is strengthened under polarizing conditions: TH17 polarization leads to a shift towards a CD44high-population whereas TH1 polarization diminishes the CD44high and increases the CD44int-population. Furthermore, blocking CD44 with neutralizing antibodies decreases IL17 secretion, while IFNγ is barely affected. Titration experiments revealed that low TCR and low CD28 stimulation supports TH17 rather than TH1 development. Under exactly these conditions CD44 can replace CD28 signaling and enhance TCR signaling (Föger et al. 2000). Indeed, rested CD44high cells contain already more phosphorylated Zap70 compared to their CD44int counterparts.
Our results support the notion that CD44 enhances TCR signaling strength by delivering LCK, which is required to support TH17 development.

P2.01.19
CD28 and NKG2D-mediated costimulation regulates CD8+ T cell chemotaxis through different signaling pathways

***E. Serrano-Pertierra**[1], E. Cernuda-Morollón[2], C. López-Larrea[1];*
[1]Hospital Universitario Central de Asturias, Oviedo, Spain,
[2]Universidad de Oviedo, Oviedo, Spain.

Introduction: CD28 is the prototypical costimulatory receptor in T cells, which propagates its signals through the YMNM signaling motif. NKG2D is a transmembrane receptor mainly expressed on NK cells and CD8+ T cells. It associates with DAP10, which contains a YINM motif, similar to CD28. Here we study the potential role of NKG2D as a costimulatory molecule in CD8+ T cell chemotactic response.
Material and methods: Human CD8+ T cells were assayed for their ability to migrate towards a CXCL12 gradient upon stimulation with anti-CD3, anti-CD28 and anti-NKG2D alone or in combinations. The activity of the Rho GTPases Rac1 and Cdc42 was analyzed by G-LISA. N-WASp was knocked-down using siRNA. Pharmacological inhibition of N-WASp by wiskostatin was used to analyze proteins involved in TCR signaling and cytoskeleton dynamics by western blot.
Results: Costimulation via CD28 and NKG2D inhibited cell migration. Rac1 is activated upon T cell receptor activation and costimulation through CD28 and NKG2D, whereas Cdc42 is activated only upon CD3/NKG2D activation. Knock-down of N-WASp partially abolished CD3/NKG2D-mediated impairment of T-cell chemotaxis. Vav, ERK1/2 and ERM proteins are regulated by CD3-mediated signaling, and pretreatment with wiskostatin did not affect their phosphorylation status. Costimulation of the TCR together with CD28 or NKG2D induces cofilin dephosphorylation. Administration of wiskostatin further decreased upon CD3/NKG2D activation, but not after CD3/CD28 engagement.
Conclusions: Costimulation via CD28 and NKG2D inhibits CD8+ T cell migration through different signaling pathways. CD3/NKG2D stimulation activates the Cdc42/N-WASp axis, and N-WASp is required for CD3/NKG2D-mediated inhibition of CD8+ T cell chemotaxis.

P2.01.20
Inhibition of T cell receptor signaling by CD147

***V. Supper**, H. B. Schiller, W. Paster, F. Forster, H. Stockinger;*
Molecular Immunology Unit, Institute for Hygiene and Applied Immunology, Center for Pathophysiology, Infectiology and Immunology, Medical University of Vienna, Vienna, Austria.

In the defence strategy of the body against harming pathogens, the activation of T cells is a central but tightly regulated event. To make the grade, T cells not only upregulate costimulatory but also inhibitory receptors upon antigen recognition to modulate the response. A potential new inhibitory receptor is CD147, a member of the immunoglobulin supergene-family, which is upregulated upon T cell activation. Previous studies reported that lymphocytes from CD147 knockout mice possess enhanced mixed lymphocyte reactions and a CD147 monoclonal antibody can interfere with T cell activation. These observations already pointed to a negative crosstalk of CD147

signals with the T cell antigen receptor or co-stimulatory signals. Consistent with these studies, we found that RNA interference (RNAi) with CD147 in Jurkat T cells augments the secretion of the T cell growth-factor interleukin-2 (IL-2) upon T cell activation. With the help of reporter gene assays, we show that this upregulation is at least partially due to an increased activity of the nuclear factor of activated T cells (NFAT), which resulted in an enhanced IL-2 promoter activity. However, biochemical and cellular assays revealed that the increased transcriptional activity of NFAT in CD147 silenced cells was independent from calcium mobilization or the activity of MAP kinases. By reconstituting the RNAi-mediated knockdown with various truncated RNAi-resistant forms of CD147, we identified the immunomodulatory sub-domain of CD147.
Acknowledgments: This work was supported by the GEN-AU Program of the Austrian Federal Ministry of Science and Research

P2.01.21
IL4-induced IgE class switching is regulated by NFkB alternative pathway

***K. Tanabe**, H. Sakamoto, S. Inui;*
Kumamoto University, Kumamoto, Japan.

Alpha4 was identified as a signal transduction molecule which associated with Ig-alpha, a component of B cell antigen receptor (BCR) complex. Alpha4 was ubiquitously expressed and gene targeting experiment revealed that alpha4 was essential for cell survival. B cell specific gene targeting confirmed that alpha4 was not only essential for BCR signal transduction but also for CD40, IL4 and LPS signals. At the same time, we found that alpha4 associated with a protein phosphatase PP2A catalytic subunit and regulated its enzymatic activity. Neuron specific gene targeting of alpha4 revealed that alpha4/PP2Ac associated with CaMKII to regulate learning and memory. In this study, we show that IL4 receptor signaling activates alternative as well as canonical NFkB signal transduction pathway. IL4 induced the serine and threonine phosphorylation of alpha4. Both alternative NFkB pathway and threonine phosphorylation of alpha4 were inhibited by a potent CaMKII inhibitor KN93. These results suggest that alpha4/CaMKII molecules are involved in IL4 receptor-induced NFkB alternative pathway. These molecules also regulate IgE class switching induced by IL4 and CD40. Establishment of M12 B cell transfectant which inducibly express TRAF3 will be also discussed.

P2.01.22
During human T cell activation ERK binds to a panel of promoters and regulates the transcription of target genes

***U. Ullah**[1], N. C. Sahoo[2], P. Tripathi[3], R. Lahesmaa[1], K. V. S. Rao[2];*
[1]University of Turku, Turku, Finland, [2]International Centre for Genetic Engineering and Biotechnology, New Delhi, India, [3]Central Drug Research Institute, Lucknow, India.

Extracellular signal regulated kinase 1/2 (ERK1/2) is a serine threonine kinase, which is conserved across all mammals. It has been shown to regulate proliferation, division and differentiation in many different cell types. We recently reported that upon primary human T cell activation ERK is recruited to IL-4 promoter and activates its transcription leading to Th2 differentiation (Tripathi et al., Immunol Cell Biol. 90, 676-87, 2012). It was therefore of interest to investigate the global profile of its binding throughout all the promoters of known human open reading frames during the activation of primary human $CD4^+$ T cells. We found ERK to bind to a panel of gene promoters including those of the immune system. This binding appears to be phosphorylation dependent as it was sensitive to treatment with a MEK inhibitor U0126. We also identified the consensus binding motif for ERK. Further analysis of target genes identified olfactory receptor family as the most abundant gene family arguing for a dominant role of this protein in sensory development. Expression analysis of the target genes indicate a complex relationship between ERK binding and the expression of target genes, suggesting for a context dependent role of ERK.

P2.01.23
Paracrine ATP signalling between T lymphocytes

***C. M. Wang**[1,2], F. Anselmi[1], J. Cibella[1], A. Viola[1,2];*
[1]Humanitas Clinical and Research Center, Rozzano (MI), Italy, [2]University of Milano, Milan, Italy.

Extracellular nucleotides such as adenosine-5'-triphosphate (ATP) serve as important signals in many biological processes and is released by many immune cells during an inflammatory response. The binding of T Cell Receptor to the ligand triggers a cascade of signals resulting the release of calcium from intracellular stores and the opening of Calcium Release Activated Channels to promote the subsequent activation processes. The increased concentration of cytosolic free calcium and mitochondria uptake lead to the synthesis and release of ATP by T lymphocytes. Many studies now show that autocrine ATP signalling via purinergic receptors is vital to sustain and promote T cell activation. We report that ATP can also signal in a paracrine manner between CD4+ lymphocytes and trigger calcium waves in murine ex vivo lymph node slices. Using a series of of pharmacological agents, we identified P2X4 and P2X7 as the key purinergic receptors for paracrine ATP signalling. ATP acts as a paracrine messenger to reduce the motility of lymphocytes and this may represent an additional mechanism contributing to the orchestration of cell trafficking in lymph nodes.

P2.01.24
Pleural B cells protect against pneumonia via a GM-CSF-IgM axis

***G. F. Weber**[1,2], C. S. Robbins[2], I. Hilgendorf[2], I. Theurl[2], Y. Iwamoto[2], M. Nahrendorf[2], R. Weissleder[2], F. K. Swirski[2];*
[1]Department of Surgery, Universitätsklinikum Carl Gustav Carus, TU Dresden, Dresden, Germany, [2]Center for Systems Biology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, United States.

Pneumonia is a major cause of mortality worldwide and a serious problem in critical care medicine. The host mechanisms that promote microbial recognition and clearance are essential to effective protection and operate in a broad immuno-physiological system that encompasses lung anatomy and the immune system. Although many of these recognition and clearance mechanisms have been identified, their in vivo context is still poorly understood. Here we show that the pleural cavity, a space between the lung and chest wall that aids in respiration, is an immune site harboring a crucial anti-microbial function. Using different genetic, fate mapping and rescue approaches we show that in response to airway infection, pleural space B1a B cells relocate to the lungs and secrete protective immunoglobulin-M (IgM). The process requires innate response activator (IRA) B cells which license IgM production via direct granulocyte-macrophage colony stimulating factor (GM-CSF) signaling. B1a and IRA B cells, the study indicates, are strategically located in the pleural space to provide effective early frontline defense against microbes invading the lungs. The study identifies the pleural space as the primary source of IgM in the airways; describes an important, previously unrecognized, GM-CSF-IgM axis; and positions IRA B cells as orchestrators of protective IgM immunity.

P2.01.25
The Rho Family Guanine Nucleotide Exchange Factor, FARP1 negatively regulates T cell response

***Y. Yoshida**, S. Kang, A. Kumanogoh;*
Osaka University Graduate School of Medicine, Department of Respiratory Medicine, Allergy and Rheuma, Osaka, Japan.

Rho small GTPases are known to function in the transduction of T cell receptor (TCR) signaling which is essential for survival and maturation, although the mechanisms underlying this event remains unclear. Here, we present evidence that the FERM domain-containing guanine nucleotide exchange factor, FARP1 is negatively regulates the T cell response upon the engagement of TCR. To explore the function of FARP1 in the immune system, we analyzed immune response in FARP1-deficient($FARP1^{-/-}$) mice. Interestingly, we

detected the higher level of FARP1 transcripts in the activated CD4+ lymphocytes, but not in naïve T cells. Moreover, the expression of FARP1 was induced by anti-CD3 stimulation in a dose dependent manner. FARP1$^{-/-}$ mice had normal numbers and cell surface markers for each lymphocyte subset, suggesting that FARP1 is dispensable for lymphocyte development. To investigate a role of FARP1 during T cell activation, we immunized wild-type and FARP1$^{-/-}$ mice with keyhole limpet hemocyanin in complete freund adjuvant. After 5 days, CD4^{+} lymphocytes from FARP1$^{-/-}$ mice exhibited enhanced antigen-specific T cells responses as higher amount of IFN-γ production than that of wild type. On the other hands, the proliferation of CD4^{+} lymphocytes from FARP1$^{-/-}$ mice was comparable to wild-type mice. In addition, FARP1$^{-/-}$ CD4^{+} lymphocytes showed hypereactive to produce IFN-γand IL-17 upon anti-CD3 and CD28 stimulation *in vitro*. Collectively, these results suggest that FARP1 negatively regulates the T cell-mediated immune response.

P2.01.26
Interaction between Siglec-9 and prohibitins down-regulates T cell receptor signaling

***H. Yurugi**, H. Nakada;*
Kyoto Sangyo University, Kyoto, Japan.

In this study, we provided that new markers of activated T lymphocytes, and these markers may become a new therapeutic target. First, we demonstrated that prohibitin-1 and -2 (prohibitins) were induced on the cell surface of T lymphocytes in response to activation. Furthermore, we found that prohibitins play a role as counter receptors for Siglec-9 expressed on macrophages and dendritic cells. Siglec-9 bound to prohibitins in a sialic acid-independent manner. Mutated Siglec-9 with Arg120 changed to Ala lost the binding activity, suggesting a specific ionic peptide-peptide interaction. Prohibitins were co-localized with CD3 on the surface of Jurkat cells. ERK1/2 was phosphorylated in Jurkat cells and preactivated T lymphocytes on treatment with anti-CD3 antibody immobilized beads, whereas phosphorylation of ERK1/2 was markedly diminished on treatment with anti-CD3 antibody and Siglec-9 co-immobilized beads, indicating that engagement of prohibitins with Siglec-9 inhibits ERK1/2 phosphorylation. Phosphorylation of c-Raf was also reduced, maybe due to inhibition of the c-Raf-prohibitin interaction by Siglec-9 ligation. In parallel with inhibition of the ERK cascade, IL-2 and IFN-γ production were markedly decreased in Jurkat cells and preactivated T lymphocytes, respectively. Anti-PHBs antibodies also reduced T cell receptor mediated cell signaling. Therefore, cell surface PHBs could be a target of immunoregulator to cure autoimmune diseases. In addition, PHBs were also induced on the surface of activated B lymphocytes. Thus, this interaction may be a useful immunotherapeutic target on T and B lymphocytes.

P2.01.27
PD-1 - PD-L1 interaction does not affect the ability of dendritic-like cells to activate human lymphocytes in vitro

***M. Zarzycki**, K. Bocian, G. Korczak-Kowalska;*
University of Warsaw, Warsaw, Poland.

Dendritic cells (DC) are professional antigen presenting cells and are responsible for antigen capture and T-cells activation. Recently a PD-1 (Programmed death 1) receptor was discovered which is involved in inhibition of lymphocyte activation. Two ligands for the PD-1 receptor, namely PD-L1 and PD-L2, were identified. Both are present on DC.
In this study a myeloid KG-1 cell line was used as a known model of dendritic cells. After appropriate stimulation they differentiate into so-called dendritic-like cells (DC-like cells) which exhibit many properties of DC. In previous studies we have shown that the KG-1 cells express PD-L1, but not PD-L2, in activation dependant fashion.
The aim of this study was to determine if the expression of PD-L1, ligand for PD-1 receptor, on activated KG-1 cells affects their ability to activate T lymphocytes in MLR (mixed leukocyte reaction).
KG-1 cells were stimulated with PMA and ionomycin to receive DC-like cells. Then the PD-L1 ligand on KG-1 cells was blocked by using blocking antibodies. Prepared in such way KG-1 cells were then used in MLR with human lymphocytes. The results show that the blockade of PD-1 - PD-L1 signaling didn't affect the ability of the DC-like cells to activate T lymphocytes.
Research on DC is difficult because of high costs and problematic procedure. Using a cell line, such as KG-1 line of DC phenotype, overcomes these difficulties. The presented study demonstrates that the PD-1 - PD-L1 interaction does not take part during activation of T lymphocytes by KG-1 cells in MLR.

A comparison of the biological features of prostate cancer with (PSA+,PSMA+) profile according to RKIP

***A. Ben Jemaa**[1], Y. Bouraoui[1], S. Sallami[2], Y. Nouira[2], R. Oueslati[1];*
[1]Unit of Immunology and Microbiology Environmental and Carcinogenesis (IMEC), Faculty of Sciences of Bizerte, 7021, Zarzouna, University of Carthage, Bizerte, Tunisia, [2]Department of Urology, Hospital of La Rabta, Tunis, Tunisia.

To investigate differences in the biological features of the most immunoexpressed prostate cancer (PC) profile (PSA+,PSMA+) according to the RKIP. Formalin-fixed and paraffin embedded tissue blocks from 19 PC with dominant Gleason grade ≥ 8 were studied. Expression of PSA, PSMA, RKIP, Raf-1, MEK-1, ERK-1, ERK-2, p-Akt (T308),p-Akt (S473),NF-κB p50 and NF-κBp65 were detected immunohistochemically. The most relevant results showed that loss of RKIP in the most immunoexpressed PC (PSA+,PSMA+) profile was associated with increased of PSA and PSMA expression. Intensities of immunoreactions to PSA and PSMA were higher in cancer epithelial cells negative for RKIP (12.51±1.6 and 34.95±1.92) compared to those positive for RKIP (4.68±1.11 and 28.56±0.91). In parallel, missing of RKIP expression in PC patients with (PSA+,PSMA+) profile was connected with increased of components of both Raf-1/MEK/ERK and NF-κB (p65/p50); whereas Akt is activated independently to RKIP. Although characterized by the same (PSA+,PSMA+) profile, PC phenotype missing the RKIP related to invasive potential and greater biological aggressiveness reflected in overexpression of components of Raf-1/MEK/ERK and NF-κB (p65/p50) in which Akt is activated independently to RKIP. Taking into account the PC phenotypes according to RKIP among PSA-PSMA profiles may improve distinguish from cancers that will become more aggressive; and therefore adapt the therapeutic strategies in those patients.

P2.02.02
Matrix metalloproteinase 3 activates NFκB in cell nucleus during Dengue virus infection

***J. Dai**;*
Institute of Biology and Medical Sciences, Soochow University, Suzhou, China.

Dengue virus (DENV) is a mosquito-borne virus that endangers an estimated 2.5 billion people globally. Study of the host anti-viral mechanism is important for us to understand the process of Dengue fever disease. Matrix metalloproteinase 3(MMP3), a downstream effector of JAK-STAT pathway, was found to be induced during DENV infection. Silencing MMP3 in macrophage, the DENV infection level significantly increased, while the anti-viral cytokine (eg: IFNβ,IL6) production impaired. Further experiments shown that MMP3 was translocated into cell nucleus upon DENV infection and positively influenced the activity of transcriptional factor NFκB. Immunofluorescence assay showed that MMP3 were co-localized with NFκB in the cell nucleus after DENV infection, and co-immunoprecipitation experiment suggested that MMP3 may directly interact with NFκB p65 subunit in cell nucleus. These data suggested that, during DENV infection, MMP3 may move to cell nucleus, interact with NFκB, and further enhance the transcriptional activity of NFκB to promote the anti-viral cytokine production. This will be the first time to show the novel anti-viral function of MMP3 in cell nucleus, and provide new evidence for the role of MMPs in immune modulation.This work will also contribute to the development of new anti-viral drugs based on MMPs.

P2.02.03
Tumor inflammatory environment modulates expression of PPAR-γ, inflammasome activation and triggers prostate cancer cell death in vitro

***R. S. Fontenele**, N. M. Vasconcelos, B. C. Guido, K. G. Magalhães, J. R. Corrêa;*
University of Brasília, Brasilia, Brazil.

Inflammation is one of the most well-known risk factors for the development of prostate cancer. Prostatic inflamed areas are characterized by focal epithelial atrophy and immune cells infiltration. To address the relation between the tumor cells and inflammation process, tumor environment was simulated using a conditioned medium of peripheral mononuclear blood cells that were previously stimulated by standard inflammatory inducers. All assays were performed using prostate cancer cell lines DU145 and LNCaP clone FGC. Our results showed that prostate cancer cell lines secreted IL-1β in response to inflammatory environment, indicating that these cells could trigger inflammasome activation. IL-6 and TNF-α were also quantified and no significant secretion level was observed. It was also observed constitutively expression of PPAR-γ in the cell line LNCaP that is androgen sensitive. In the other hand, DU145 an androgen insensitive cell line showed no constitutively PPAR-γ expression. When subjected to proinflammatory medium both cell lines showed increased expression of the nuclear receptor PPAR-γ. Furthermore, after 24h of stimulation both cell lines presented an increased rate of cell death although only DU145 had a decreased level of cell proliferation, as assessed by DNA fragmentation assay and CFSE staining, respectively. These results suggest that a proinflammatory microenvironment modulates secretion of IL-1β and PPAR-γ expression, which seems to trigger cell death and decrease proliferation rate in prostate cancer cell lines in vitro. Therefore, our data suggest that inflammasome and PPAR-γ could be an interesting chemotherapeutic target in prostate cancer treatment. CNPq, FapDF

P2.02.04
Glucocorticoid receptor-dependent immunomodulatory effect of ursodeoxycholic acid on liver lymphocytes in mice

***M. Kinoshita**[1], H. Miyazaki[2], H. Nakashima[1], M. Ikarashi[1], S. Seki[1];*
[1]Department of Immunology and Microbiology, National Defense Medical College, Tokorozawa, Japan, [2]Division of Traumatology, Research Institute, National Defense Medical College, Tokorozawa, Japan.

Although ursodeoxycholic acid (UDCA) has long been used for patients with chronic cholestatic liver diseases, particularly primary biliary cirrhosis, it may modulate the host immune response. This study investigated the effect of UDCA feeding on experimental hepatitis, endotoxin shock, and bacterial infection in mice. C57BL/6 mice were fed a diet supplemented with or without 0.3% (w/v) UDCA for four weeks. UDCA improved hepatocyte injury and survival in concanavalin-A (Con-A)-induced hepatitis by suppressing IFN- production by liver mononuclear cells (MNC), especially NK and NKT cells. UDCA also increased survival after lipopolysaccharide (LPS)-challenge; however, it decreased survival of mice following *Escherichia coli* (*E. coli*) infection due to the worsening of infection. UDCA-fed mice showed suppressed serum IL-18 levels and production of IL-18 from liver Kupffer cells, which together with IL-12 induces potent IFN- production from liver NK/NKT cells. However, unlike normal mice and immune-compromised burn-injured mice, exogenous IL-18 pretreatment did not increase the serum IFN- levels after *E. coli* challenge in the UDCA-fed mice. Interestingly, however, glucocorticoid receptor (GR) expression was significantly upregulated in the liver MNC, especially NK and NKT cells, of the UDCA-fed mice but not in their whole liver tissue homogenates. Silencing GR in the liver MNC abrogated the suppressive effect of UDCA on LPS-induced IFN- production. Furthermore, RU486, a GR antagonist, restored the serum IFN- level in UDCA-fed mice after *E. coli* infection. Taken together, these results suggest that IFN--reducing immunomodulatory property of UDCA is mediated by elevated GR in the liver lymphocytes in an IL-12/18 independent manner.

Polycomb repressive complex-1 is critical for peripheral B cell differentiation and germinal center responses

***F. Alberghini**[1], L. D'Artista[2], F. Mainoldi[1], F. Pisati[1], C. Carrisi[1], H. Koseki[3], M. Vidal[4], S. Casola[1];*
[1]Foundation, The FIRC Institute of Molecular Oncology Foundation, Milano, Italy, [2]IEO, Milano, Italy, [3]Developmental Genetics Group, RIKEN Research Center for Allergy & Immunology, 1-7-22 Suehiro-cho, Tsurumi, Yokohama, 230-0045 Kanagawa, Japan, Kanagawa, Japan, [4]Cellular and Molecular Biology, Centro de Investigaciones Biológicas, Consejo Superior de Investigaciones Científicas (CSIC), 28040 Madrid, Spain, Madrid, Spain.

B cell development is a step-wise, tightly regulated process whereby multipotent stem cells progressively acquire immunological competence, ultimately becoming antibody- secreting cells. Transition from one developmental stage to the next entails changes in gene expression mediated by the activity of stage-specific transcription factors and chromatin remodeling enzymes.
Polycomb group proteins (PcG) are a family of chromatin remodelers that repress targeted loci within complexes named Polycomb Repressive Complex 1 and 2 (PRC1 and PRC2). The former monubiquitinates lysine 119 of histone H2A whereas the latter trimethylates lysine 27 of histone H3. In pre- and post-natal life, PcG proteins regulate lineage specification and restrict cell identity.
Using conditional gene targeting, we studied the role of the PRC1 catalytic subunits Ring1a and Ring1b in peripheral B cell development and germinal center (GC) B cell responses.
We found that PRC1 ablation in transitional (T) B cells leads to a differentiation block at the T2 stage, resulting in decreased numbers of mature B cells. Moreover, PRC1 inactivation in GC B cells revealed an essential requirement for the complex in the generation and/or maintenance of memory and antibody-secreting cells, as shown by a reduction in antibody titers produced during both primary and recall T-cell dependent immune responses. Transcriptome analyses of PRC1-deficient splenic B cells suggest that PRC1 activity is needed to prevent diversion to other lineages and orchestrate B cell differentiation.
Identification of direct PRC1 targets in peripheral B cells will help to unravel the molecular mechanisms through which the complex controls late B cell differentiation.

P2.03.02
The rheumatoid factor in idiotypic regulation of autoimmunity

***L. Beduleva**, I. Menshikov, E. Stolyarova, O. Lobanova;*
Udmurt State University, Izhevsk, Russian Federation.

Rheumatoid factors (RFs) were defined originally by the ability to react with Fc region of IgG and useful marker for the diagnosis of rheumatoid arthritis. Further studies showed that RFs are able to bind the Fab region of IgG, and to enter into idiotypic interactions with antibodies of different specificity. Facts about RF multiplicity and heterogeneous behavior require a new look at the role of RF. Taking into account important role of idiotypic interactions in autoimmunity regulation we assumed that RFs might regulate autoimmune response through idiotypic interactions. We have investigated RF levels in rats resistant and susceptible to arthritis, encephalomyelitis, atherosclerosis and idiotypic interactions between RFs and antibodies to antigens-inductors of autoimmunity. We revealed that in the autoimmune disease-resistant rats the increase of RF level preceded antibodies appearance to given antigens, on the contrary it was not observed in autoimmune rats. Thus resistance to induction of autoimmune diseases in rats is associated with high RF production within the initiation of immune response, and low RF levels in this period may be used as a preclinical marker of autoimmune manifestations. RF containing sera compete with antigen, if sera were obtained by this antigen immunization, and nonspecifically inhibit binding of different antigen-antibodies pairs. These facts suggest that RFs are anti-idiotypic antibodies carrying individual and shared

paratopes. Individual paratope recognizes antigen-binding sites of antibodies. Shared paratope is bound to recurrent idiotype in antibodies of different specificity. Thus RFs are involved **in** negative idiotypic regulation of lymphocytes specific to antigens-inductors of autoimmune diseases.

P2.03.03
Interleukin-10 suppresses CXCL8 gene transcription in LPS-stimulated monocytes via modulation of histone deacetylases (HDACs) recruitment

***M. Castellucci**, M. Rossato, N. Tamassia, S. Gasperini, F. Bazzoni; University of Verona, Verona, Italy.*

Interleukin-10 (IL-10) is a potent anti-inflammatory cytokine, very effective at suppressing pro-inflammatory cytokine produced by myeloid cells. The mechanistic bases of the immuno-suppressive/immuno-modulating activities of IL-10 largely involve transcriptional regulation. In the last years, we demonstrated that the ability of IL-10 to modulate LPS-induced IL-1ra transcription relies on IL-10 capacity to modify the acetylated state of local promoter-associated histones. Herein, we extended this study to the mechanisms utilized by IL-10 to inhibit the pro-inflammatory CXCL8 gene transcription, particularly focusing on the epigenetic modifications at the CXCL8 promoter level.
Chromatin immunoprecipitation (ChIP) was employed to characterize the molecular events triggered by IL-10 at the level of CXCL8 gene promoter in LPS-stimulated human monocytes.
ChIP analysis revealed that IL-10 reduces the recruitment of CDK9 induced by LPS and, as a consequence, inhibits LPS-induced activation (i.e. ser-2-phosphorylation) of promoter-bound Pol II. Furthermore, we demonstrate that IL-10 acts upstream of CDK9, by triggering histone H4 deacetylation and preventing, in this manner, the subsequent recruitment of bromodomain-containig protein Brd4. Indeed, histone H4 deacetylation blockade with HDAC inhibitors, abrogates the ability of IL-10 to inhibit LPS-induced CXCL8, further suggesting the involvement of an HDAC in the CXCL8 transcriptional inhibition by IL-10. Most importantly, PBMCs from patients with alterations in the HDAC activity show a reduced responsiveness to IL-10-mediated inhibition of CXCL8, but not TNF-α, transcription triggered by LPS.
Collectively, our data unravel a novel mechanism utilized by IL-10 to inhibit LPS-induced CXCL8 transcription, likely proceeding via histone deacetylase(s) (HDAC) activation.

P2.03.04
Bacteria-induced epigenetic modifications in gingival innate immunity

***W. O. Chung**, L. Yin, J. Y. An, S. Hong, R. London, C. Spiekerman; University of Washington, Seattle, WA, United States.*

We previously reported exposure to different oral bacteria resulted in differential epigenetic modifications and in altered expression of inflammation-associated genes. The goal of this study was to investigate which bacteria-induced epigenetic modifications regulate gingival innate immunity *in vitro* and if amount of periopathogens is correlated to epigenetic status *in vivo*.
Chromatin Immunoprecipitation examined if trimethylation of histone H3 at lysine4 (H3K4Me3) and at lysine9 (H3K9Me3) interacted with promoters of innate immune genes hBD-2, CCL20 and IL-8 following exposure of gingival epithelial cells (GECs) to periopathogen *Porphyromonas gingivalis* (Pg) or to non-pathogen *Fusobacterium nucleatum* (Fn). Western analyses of total and acetylated H3 and H4 investigated differential modulation of chromatin structure by Fn vs. Pg. Unstimulated GECs were used as controls. Correlation between CXCL5 methylation level of periodontal patients and amount of periopathogens recovered was determined by Spearman correlation.
Interaction between H3K4Me3 and hBD-2, CCL20 and IL-8 promoters was suppressed with Pg, while increased with Fn. Fn decreased acetylation of H3 and H4, while Pg decreased acetylation of H4 only. Amount of Fn recovered from plaque of periodontal patients was correlated with decreased CXCL5 methylation.
Our data show bacteria-specific histone modification and suggest oral bacteria affect the accessibility of chromatin to transcription factors, subsequently affecting gene transcription. Hypomethylation of CXCL5 with increased *Fn* may cause an inappropriate over-transcription of CXCL5 in periodontal patients. This study highlights potential interplay between epigenetic modifications and oral bacteria in periodontitis, and may ultimately lead to the development of innovative treatment and diagnostic modalities.

P2.03.05
Methylation patterns near and inside of the TSLP promoter in an african descendent population of Colombia

***L. Fang**[1], A. J. Manrique[2,3], J. J. Builes[3,2], L. Hernandez[1], D. P. Aguirre[3], C. Muñoz[1], B. Martínez[1], J. Marrugo[1];*
[1]University of Cartagena, Cartagena, Colombia, [2]Instituto de Biología, Universidad de Antioquia, Medellín, Colombia, [3]GENES LTDA, Medellín, Colombia.

Rationale: Thymic stromal lymphopoietin - TSLP is a gene that affects many cell lineages and can directly or indirectly leads to various outcomes, the expression of it is detected in the airways of asthmatic patients, and correlates with disease severity. For this reason we decided to analyze the methylation patterns of the TSLP in Afro-Colombian population.
Methods: We analyze the methylation patterns close and inside of the TSLP promoter in 94 African-descent individuals of Colombian Caribbean coast. From TSLP isoform 1 precursor sequence reported by NCBI, we selected the sequence from chromosomal location chr5: 110405778 to 110413722, that containing 5'UTR and promoter regions from TSLP. Using Methprimer the parameters for prediction of CpG Islands were CpG islands >100bp, GC>50% and Obs/Exp >0.60.
Results: Methprimer analysis predicted two CpG Islands, where primers for methylation specific PCR (MSP) where designed, one in the 5'UTR region (Island 1 with 190bp) and the other one in his promoter (Island 2 with 231bp). We found, that Island 1 showed a variable methylation pattern with unmethylated, methylated and hipermethylated individuals (24.5%, 44.7% and 30.9%, respectively. While, the Island 2 was almost always hipermethylated (92.6%, n=87).
Conclusions: Although this study was performed with peripheral blood samples, the Island 1 in the 5'UTR is more informative than Island 2, and could be regulating gene expression of TSLP and may be associated with the levels of TSLP protein in serum.

P2.03.06
Tumor Necrosis Factor Gene Polymorphisms in Tunisian Patients with Non -Small Cell Lung Cancer

***S. W. A. K. Fayçal Haj Sassi**;*
Faculté de Médecine de Tunis, Tunis, Tunisia.

Lung cancer (LC) is one of the most lethal malignant disorders; it's divided into two groups: small cell lung cancer (SCLC) and non small cell lung cancer (NSCLC). In our present study we have been interested to NSCLC. Several approaches were adopted to study the etiology or pathophysiology of this disease, as recent reports which focused on the genetic susceptibility to this disease, among the many candidate genes studied, we chose the TNF in view of the major role it plays in the immune pro inflammatory and its association with increased risk of a variety of human cancers. We have investigated three polymorphisms in the promoter region of the TNFα gene (-308 G/A and -238 G/A) and TNF β +252A>G for their susceptibility to non-small cell lung cancer (NSCLC) in Tunisian population. We compared the distribution of these polymorphisms between 133NSCL patients and 174 healthy controls using a polymerase chain reaction restriction fragment length-polymorphism (PCR-RFLP) analysis. The frequencies of the two TNFα (-238 and-308) "A" alleles were significantly higher in NSCLC patients than in healthy controls respectively (p =0.01; OR= 1.92; 95% CI 1.14_3.23 and p =0.000008; OR=3.65; 95% CI 2.12_6.30), whereas the frequency of the TNF β +252 G allele was approximately similar in the two compared groups. This study support a relation between TNFα-238G/A and TNFα -308G/A polymorphisms and the susceptibility to lung cancer. Contrary to other studies, the -308 A and -238A alleles have an inductive

action on Lung cancer development and progression in our Tunisian population.

P2.03.07
Locus-specific biochemical epigenetics / chromatin biochemistry by insertional chromatin immnoprecipitation (iChIP)

***T. Fujita**, H. Fujii;*
Research Institute for Microbial Diseases, Suita, Osaka, Japan.

Comprehensive understanding of mechanisms of epigenetic regulation requires identification of molecules bound to genomic regions of interest *in vivo*. To perform biochemical and molecular biological analysis of specific genomic regions, we developed the insertional chromatin immunoprecipitation (iChIP) [1-3].
The scheme of iChIP is as follows:
i) The recognition sequence of LexA, an exogenous DNA-binding protein, is inserted into the genomic region of interest in the cell to be analyzed.
ii) The DNA-binding domain of LexA is fused with a tag(s) and a nuclear localization signal(s) and expressed in the cell.
iii) The resultant cell is crosslinked and lysed, and the crosslinked DNA is fragmented.
iv) The complexes including the LexA protein are immunoprecipitated with an antibody against the tag. The isolated complexes retain molecules interacting with the genomic region of interest.
v) Reverse crosslinking and subsequent purification of DNA, RNA, or proteins allows their identification and characterization.
We applied iChIP to identification of proteins interacting with the single-copy *Pax5* promoter in the chicken DT40 B cell line. Pax5 is known as a key factor for B cell lineage commitment. iChIP combined with mass spectrometry identified proteins interacting with the *Pax5* promoter. Knock-down of an identified protein reduced *Pax5* transcription. Therefore, the protein should be a novel regulator of *Pax5* expression. iChIP is a useful tool for identification of proteins bound to endogenous genomic regions *in vivo*.

The Research on IFN-γ,IL-4 Gene Methylation of Uighurs and Han Patients with Allergic Rhinitis in Xinjiang of China

***L. Gao**, X. f. Jiang, Q. Yang, Q. Q. Zhang, N. R. Mu, F. T. Liu, Z. Z. Lou;*
Xinjiang Medical University, Urumqi, China.

Objective To investigate the methylation level of IFN-γ,IL-4 gene in allergic rhinitis (AR) patients of Uighur and Han in Xinjiang. Methods we randomly selected sample via epidemiological survey in Yili area, which includ healthy peoples and AR patients. In this study, the genomic DNA was extracted from peripheral blood and was modified using bisulfate modification kit. Then, the methylation of DNA was analyzed by methylation specificity polymerase chain reaction (MS-PCR). Results We found that the positive rate of IFN-γ, IL-4 gene methylation in Han and Uighur AR patients was no significant differences as compared with healthy groups ($P > 0.05$). Also, there are no significant differences between Uighurs and Han AR patients ($P > 0.05$). However, the positive rate of IFN-γ, IL-4 gene methylation in Uighur healthy group was significant higher than that of Han healthy control ($P< 0.05$). Conclusion This research suggest that the low methylation of IFN-γ gene and high methylation of IL-4 in Han healthy groups may play an important role in the pathogenesis of AR in Han patients.

P2.03.09
Pronounced co-localization of immunoglobulin genes and their enhancers in transcription factories at the nuclear periphery in plasma cells

*S. Park, Y. Xiang, **W. T. Garrard**;*
UT Southwestern Medical Center, Dallas, TX, United States.

A single plasma cell is estimated to secrete its own mass in antibody molecules each day. To uncover some of the molecular secrets behind such remarkably high levels of gene expression, we have investigated the nuclear organization of transcribing immunoglobulin (Ig) genes at various stages of mouse B cell development, utilizing 3D RNA immuno-FISH and ChIP-3C-Seq technologies. After the pro-B cell stage, ~80% of Igκ and IgH genes are bi-allelically transcribed. As B cells differentiate to become better suited for high-level expression of antibody molecules, their Ig genes become progressively co-localized in transcription factories, which peaks at the plasma cell stage, with ~48% co-localization between Igκ-IgH, Igκ-IgJ, and IgH-IgJ gene pairs. Remarkably, ~26% of the plasma cell nuclei exhibit triplet Igκ-IgH-IgJ gene co-localizations in transcription factories, with ~45% of the transcribing Ig genes located within <0.5μm from the nuclear periphery. In plasmablasts we identified the trans-chromosomal interacting sequences between Ig genes in transcription factories as their enhancer elements. Moreover, plasma cells from Igκ gene E3′ knockout mice exhibit significant reductions in Ig gene co-localizations at transcription factories, nuclear periphery locales, and Ig gene transcript levels. Furthermore, Ig gene transcripts arising from genes co-localized in the nuclear interior are channeled together between dense chromatin regions from their sites of synthesis toward a subset of nuclear pores. We conclude that plasma cells have optimized coordinated transcriptional and post-transcriptional control of Ig genes by co-localizing them in transcription factories often near the nuclear periphery through their transcriptional enhancers.

P2.03.10
Testing the resource-reallocation hypothesis: influence of maternal testosterone on immune system of Japanese quail (Coturnix japonica) chicks

***Z. Kaňková**[1], M. Okuliarová[1], M. Zeman[1,2];*
[1]Department of Animal Physiology and Ethology, Faculty of Natural Sciences, Comenius University, Bratislava 4, Slovakia, [2]Institute of Animal Biochemistry and Genetics, Slovak Academy of Sciences, Ivanka pri Dunaji, Slovakia.

Immunomodulatory effects of testosterone are frequently discussed but the effects of maternal testosterone (mT) are less studied. Deposition of mT into the egg yolk is generally considered as epigenetic mechanism, enabling transfer of information from the mother to her offspring and better coping with environmental challenges after hatching. In our study we challenge the hypothesis about reallocation of resources between mT-enhanced growth and immune system in Japanese quail selected for high (HET) and low (LET) egg testosterone content since HET quail exhibit faster growth than LET quail. From day 4 after hatching, half of animals (n= 40) was subjected to protein restriction (control group 21%, restricted group 15% of protein content). Subsequently, cell-mediated immune response to phytohemmaglutinine (PHA) and acute phase response to lipopolysaccharide were examined. Acute phase response was evaluated as plasma corticosterone concentrations (Cort), heterophil/lymphocyte (He/Ly) ratio and total immunoglobulin (IgY) levels. Protein restriction negatively influenced body weight and performance in PHA-test. The increase of basal and stimulated Cort and He/Ly ratio and no changes in total IgY levels were observed. HET quail showed higher body mass and total IgY levels and lower He/Ly ratio than LET quail, while PHA index and Cort concentration did not differ between lines. No significant interaction was found between food restriction and genetic line. Therefore, it is unlikely that reallocation of resources induced by mT acts as the main mechanism affecting the immune system of offspring and a compromised immune response probably does not limit selection for high maternal androgen deposition.

P2.03.11
Heterogeneity of Polycomb repressive complexes and long-noncoding RNA dictate the regulation network of thymic T cell development

***M. Kanno**, Y. Guo, K. Weng-Sheng, A. Nobukiyo, H. Inoue;*
Hiroshima University, Hiroshima, Japan.

The thymic microenvironment principally formed by thymic epithelial cells (TECs) provides a specialized niche for T-cell development and controls thymocyte cellularity.
The epigenetic regulator Polycomb group (PcG) gene products form multimeric protein complexes (PRC1, PRC2), which maintain the repressed state of target genes during multiple rounds of cell divisions through histone modifications. We reported that different PRC1 subunit plays a crucial role in thymocyte development on different point of action, which might be due to the heterogeneity of PRCs. Bmi1, one of PRC1 subunit, acts on the repression of p19Arf but not p16Ink4a, and p19Arf deficiency completely restores the Bmi1-/- thymocyte defects in vitro. However, unlike cases with thymocytes, the deletion of p16Ink4a and p19Arf could not restore the defects in Bmi1-/- TEC, indicating a distinct role for Bmi1 in regeneration process of TECs.
Recently we and others noticed that long-noncoding RNA can bind the PRC complex, therefore, may leading to the target gene specificity. One of these is ANRIL that is anti-sense RNA encoded in INK4 locus.
In human, sequence polymorphisms in a 58-kilobase (kb) interval on chromosome 9p21 (including INK4 locus) confer a markedly increased risk of coronary artery disease (CAD), the leading cause of death worldwide. And it was shown that deletion of the orthologous 70-kb non-coding interval on mouse chromosome 4 affects cardiac expression of neighboring genes, as well as proliferation properties of vascular cells. Therefore, we will discuss the Heterogeneity of PRCs on thymopoiesis and Polycomb connection between CAD and regeneration process of thymus.

P2.03.12
Epigenetic regulation of T cell Ig mucin 3 expression in Th1 cells reveals a novel control of adaptive immunity

***C. Kuo**, F. Chou, Y. Lin, H. Sytwu;*
National Defense Medical Center, Department and Graduate Institute of Microbiology and Immunology, Taipei, Taiwan.

The T cell Ig mucin 3 (Tim-3) is expressed selectively on the terminal differentiated Th1 cells and acts as a negative regulator of the Th1 immunity. The dysregulated expression of Tim-3 on Th1 cells is linked to several autoimmune phenotypes and chronic viral infections, indicating that Tim-3 pathway regulates homeostasis of the T cell response under pathogenic condition. In this study, we investigated the epigenetic regulation of *Tim-3* and dissect the possible mechanisms of dysregulated Tim-3 expression under pathogenic conditions. By analyzing the sequences of putative *Tim-3* promoter region of human and mouse, we found that there are three conserved regions and one CpG island within the Tim-3 promoter. We identified the promoter regions of the *Tim-3* gene and explored the effects of DNA methylation on the promoter activity by using a CpG free vector for *in vitro* methylation experiment and reporter assays. Finally, treatment of 5-Azacytidine (5-Aza) enhanced Tim-3 expression on $CD4^+$ T cells under the Th1 polarization condition, which is correlated with the demethylation of the CpG island within the promoter region. Surprisingly, 5-Aza induced Tim-3 expression under a Th2 condition but not under a Th17 condition. These data suggested that the epigenetic process selectively cooperates with lineage-specific factors in the controlling of Th1 cell development, whereas under certain conditions, epigenetic control displayed different hierarchy in the control of Tim-3 expression. In conclusion, these regulatory mechanisms of Tim-3 provide novel insight into the understanding of the Th1 cell biology.

P2.03.13
DNA methylation changes in allergic patients correlate with symptom severity and reflect altered CD4+ T-cell population structure

Altered DNA methylation patterns in CD4+ T-cells indicate the importance of epigenetic mechanisms in inflammatory diseases. However, the identification of these alterations is complicated by the heterogeneity of most inflammatory diseases. Seasonal allergic rhinitis (SAR) is an optimal disease model for the study of DNA methylation because of its well-defined phenotype and etiology. We generated genome-wide DNA methylation and gene expression profiles of CD4+ T-cells from SAR patients and healthy controls using Illumina's HumanMethylation450 and HT-12 microarrays, respectively. DNA methylation profiles clearly and robustly distinguished SAR patients from controls, during and outside the pollen season. Moreover, we found that this methylation signature correlated with symptom severity. In agreement with previously published studies, gene expression profiles of the same samples failed to separate patients and controls. Separation by methylation, but not by gene expression was also observed in an in vitro model system in which purified PBMCs from patients and healthy controls were challenged with allergen. We associated these differences, not with epigenetic dysregulation in a given CD4+ T-cell subset, but with changes in the proportions of central memory T-cell populations between patients and controls. Thus, quantitative DNA methylation data can act as a sensitive proxy measure of changes in cell population structure in disease. Our data highlight the potential of epigenomics in the stratification of immune disease and represents the first successful molecular classification of SAR using CD4+ T cells.

P2.03.14
Targeted disruption of Calcium/NFAT signaling reveals a left-right determination disorder in the pharyngeal arch artery

***Y. Miyachi**;*
National Cerebral and Cardiovascular Center, Suita, Japan.

An immunosuppressant was injected into the pregnant mice in order to investigate whether the immune response is involved in differentiation during embryonic development. In saline-injected fetuses, the cardiac outflow tract (aorta) arose from the left ventricle, ascended for a short distance and then curved to the left and descended through the left side of the chest. Injection of FK506, an inhibitor of carcineurin, into the mother mouse on days 6.5, 7.5, and 8.5 of pregnancy induced an left-right (L/R) determination disorder, in which the cardiac outflow tract ascended toward the right side, formed an arch and then descended through the right side of the chest. Injection of 3.0mg/kg of FK506 increased the penetrance of the right aortic arch by 32% (ten of 31) relative to saline injection. FK506 is known to work by restricting NFAT (nuclear factor activated T-cell) dephosphorylation. An L/R determination disorder in cardiac outflows appeared when an NFATc4 siRNA was directly injected into amniotic fluid. As for the mechanism, Pitx2, which is normally expressed on the left-hand side, was found to be expressed also on the right-hand side. Furthermore, it turned out that administration of FK506 also prevented the dephosphorylation of NSFL1 cofactor p47. When an siRNA targeting p47 was introduced into amniotic fluid of FK506-treated fetuses, both of the dorsal arteries - which should normally become one - remained. The finding is that mother's immune system contributes not only to self-defense but also to remodeling processes in her fetus morphogenesis.

P2.03.15
Activation of Aryl hydrocarbon receptor (AhR) triggers epigenetic and microRNA modulation and consequent differential regulation of Tregs and Th17 cells and amelioration of Experimental Autoimmune Encephalomyelitis (EAE)

***M. Nagarkatti**, N. P. Singh, P. Nagarkatti;*
University of South Carolina School of Medicine, Columbia, SC, United States.

AhR is a member of the family of basic-helix-loop-helix transcription factors. Recent studies have suggested that AhR may regulate T cell differentiation. We examined the effect of AhR activation on micro RNA (miRNA) profile in T cells, and epigenetic modulation of Foxp3 and IL-17 genes, using a wide range of AhR agonists such as TCDD and dietary indole derivatives, indole-3-carbinol (I3C), and diindolylmethane (DIM). Upon activation of AhR, there was a

significant difference in the profiles of various miRNAs in T cells. Analysis of some of these miRNAs showed their role in regulation of Foxp3 and IL-17. AhR activation also led to significant epigenetic modulation including demethylation of Foxp3 promoter but methylation of IL-17 promoter. Addition of AhR ligands in vitro and administration in vivo triggered increased induction of Tregs but a decrease in Th17 cells. Using an EAE murine model of multiple sclerosis, we examined the effects of AhR activation on EAE symptoms. There was significant amelioration of EAE disease symptoms in mice treated with AhR ligands. I3C and DIM acted in vivo as AhR ligands inasmuch as AhR inhibitors reversed the protection afforded against EAE. Also, the effect of these compounds on Tregs and Th17 cells was not demonstrable in AhR knockout mice. Together, these data demonstrated that AhR activation regulates epigenetic modulation and can have differential effects on T cell differentiation into Tregs/Th17 leading to immune suppression. Our studies also suggest that natural dietary AhR ligands may serve as novel treatment modalities against inflammatory diseases.

P2.03.16
Epigenetic regulation of cytokine production in sepsis and endotoxin tolerance

C. Reschke[1], *D. Ibrahim*[2,3], *J. Hecht*[2,3], *H. Volk*[1,3], *G. Grütz*[1,3];
[1]*Charite - Institute for Medical Immunology, Berlin, Germany,* [2]*MPI for Molecular Genetics, Berlin, Germany,* [3]*Berlin-Brandenburg Center for Regenerative Therapies (BCRT), Berlin, Germany.*

Endotoxin tolerance (ET), defined by a transient unresponsiveness to endotoxin (LPS) following a first exposure to LPS, is a protective mechanism against excessive inflammation. However, it plays a major role in the mortality of sepsis patients suffering from secondary infections.
A previous publication demonstrated chromatin remodeling through histone modifications with a transient silencing of a class of tolerizable genes including pro-inflammatory cytokines in endotoxin-tolerant murine macrophages (Foster et al. 2007).
The aim of our study is to understand ET on the chromatin level and the impact of anti-inflammatory cytokines in human monocytes during ET induction. Therefore, human $CD14^+$ monocytes were desensitized with a first LPS treatment overnight followed by a second LPS challenge on Day 2. Histone modifications were analyzed by chromatin-immunoprecipitation (ChIP) combined with sequencing and quantitative PCR analysis.
In contrast to the findings from Foster et al., our results did not reveal any differences between endotoxin-responsive and endotoxin-tolerant genes in human monocytes for two markers of active transcription - H3K4me3 and H4ac. These modifications were still present in the promoter regions of pro-inflammatory cytokines in desensitized cells suggesting that other epigenetic changes might play a role. Therefore, we are currently analyzing histone modifications determining transcriptional repression and combining different ChIP assays of positive and negative histone markers as well as transcriptional co-regulatory proteins.
This study could help to clarify the complex picture of induction/inhibition of cytokine production in ET.

P2.03.17
Impact of Wnt pathway activation in liver infiltrating T lymphocytes

V. Schinzari[1], *C. Martire*[1], *M. Rossi*[2], *S. Brozzetti*[3], *V. Barnaba*[1];
[1]*Department of Internal Medicine and Medical Specialties, "La Sapienza" University of Rome, Rome, Italy,* [2]*G. Mennini Department of General Surgery, Division of Organ Transplantation, University of Rome "Sapienza", Rome, Italy,* [3]*Department of Surgery "Pietro Valdoni", University of Rome "La Sapienza", Rome, Italy, rome, Italy.*

Hepatocellular carcinoma (HCC), a malignancy caused mainly by chronic infection with hepatitis B virus (HBV) and/or hepatitis C virus (HCV), is a highly fatal disease.
Wnt/β-catenin pathway is frequently activated in HCC, therefore we hypothesize that Wnt ligands or activation of Wnt/β-catenin pathway in inflamed/tumor liver tissues, can establish micro-environmental conditions that influence T cells functions and phenotypes.
Recent studies indicate that Wnt/β-catenin signaling is critical for the differentiation, polarization and survival of mature T lymphocytes. In order to asses the Wnt pathway activation on T cells that infiltrate peritumoral (LIL) and tumoral liver tissues (TIL), we performed flow cytometry analysis in peripheral or intrahepatic T cells to evaluate citoplasmatic accumulation of β-catenin in patients with HCC related to HCV and HBV infection. Preliminary data show significant citoplasmatic accumulation of β-catenin in CD4+CD127hi Foxp3low T cells (Tconv) from LIL and TIL as compared to PBMC from patients or healthy donors ex vivo. The β-catenin accumulation was also evident in CD4+CD127lowFoxp3hi Treg cells derived from the same tissue districts. The effect of β-catenin accumulation on CD4 T cell proliferation and differentiation was evaluated by inhibiting GSK-3β with the pharmacological compound TWS119 in vitro. Both CD4+ Tconv and Treg cells treated with TWS119 proliferated less than untreated cells, and Tconv cells displayed cytokine production impairment. Correlation between Wnt/β-catenin pathway activation in liver cancer and T cells in inflamed or tumor tissue, is crucial to better understand the behavior of immunological effector/memory phenotypes in this pathological condition.

P2.03.18
Evidence for in vivo DNA demethylation at Interferon-γ promoter site CpG island during human endotoxemia

B. P. Scicluna*, M. Wevel, H. Belkasim, A. van der Meer, R. Lutter, T. van der Poll;*
Academic Medical Center, Amsterdam, Netherlands.

Introduction: Activation of inflammatory gene transcription is vital for host immune defense against pathogens. This response is often deleterious to the host due to exaggerated or undermined inflammatory protein production, representing common manifestations in sepsis. Modifications to histones and DNA sequence nucleotides by nuclear proteins, including methylation of cytosine residues (5-mC) at CpG islands (CGIs), support mRNA transcription initiation, repression and/or elongation. We here sought to unravel the role of DNA methylation at an interferon-γ (IFNG) promoter CGI in connection with inducible IFNG transcription in vivo. To this aim we adopted the well-established human model of lipopolysaccharide (LPS)-induced systemic inflammation.
Methods: Eight healthy subjects were enrolled for an intravenous LPS challenge (4 ng/kg). Whole-blood was collected prior to and 3, 6, 20 hours post-LPS challenge. Ex vivo LPS-stimulated whole-blood at each time point was analyzed for pro-inflammatory (TNFα, IL1ß, IL6, IL8 and IFNG) and anti-inflammatory (IL1RN and IL10) gene transcription and protein release. DNA methylation was assessed by methylation-specific PCR (MSP) of bisulfite converted DNA.
Results: In line with previous studies, we observed a significantly impaired ex vivo induction of pro-inflammatory cytokines in the 3 and 6 hour samples given the "second hit" of LPS. Anti-inflammatory cytokine release was not impaired. By MSP analysis we detected a statistically significant increase in demethylation, in parallel to a decrease in methylation, at the IFNG CGI that coincided with a repressive state of IFNG mRNA transcription ex vivo.
Conclusion: Our findings suggest LPS-induced active DNA demethylation at an IFNG promoter CGI in vivo.

P2.03.19
Differential effects of histone-deacetylase inhibition during lipopolysaccharide-induced lung inflammation in mice

A. J. van der Meer[1], *S. S. Zeerleder*[2,3], *C. van 't Veer*[1], *T. van der Poll*[1];
[1]*Center of Experimental and Molecular Medicine, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands,* [2]*Landsteiner Laboratory, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands,* [3]*Department of Immunopathology, Sanquin Research, Amsterdam, Netherlands.*

Introduction: Histone-deacetylases (HDACs) can influence gene transcription by increasing the interaction between histones and DNA. HDAC inhibitors have been implicated as possible new therapeutic agents in inflammatory diseases. The aim of this study was to determine the effect of the HDAC inhibitor suberoylanilide hydroxamic acid (SAHA) on lipopolysaccharide (LPS)-induced lung inflammation.

Methods: C57BL/6 mice received either SAHA (200mg/kg) or vehicle intraperitoneally 30 minutes before intranasal inoculation with Klebsiella LPS (1µg). Mice were euthanized 6 hours after LPS administration for analyses. MH-S cells (alveolar macrophages) were used to study the effect of SAHA at cellular level.
Results: SAHA pretreatment resulted in a 10-fold reduction in TNFα and a 4-fold reduction of IL-6 levels in bronchoalveolar lavage fluid (BALF) upon LPS instillation (both P< 0.001). In contrast, SAHA increased LPS-induced release of the CXC chemokines KC and MIP-2 in BALF (both P< 0.001). In accordance, SAHA significantly inhibited LPS-induced TNFα release, while significantly enhancing LPS-induced KC and MIP-2 secretion by MH-S cells in vitro. These effects were associated with reduced NFkB activation in the presence of SAHA, suggesting a NFkB independent mechanism of chemokine upregulation.
Conclusion: HDAC inhibition results in differential effects in the bronchoalveolar space during LPS-induced lung inflammation characterized by inhibition of proinflammatory cytokine release with concurrent enhancement of chemokine secretion.

P2.04 MicroRNAs in immune regulation

P2.04.01
miR-146, miR-21, and miR-31 expression in patients with active tuberculosis and subjects with latent tuberculosis infection

*E. Alijani[1], A. Poorfatholah[1], B. Sharifi Mood[2], A. Ahmad Zavaran Hosseini[1], **S. Ajdary**[3];*
[1]Immunology Dept., Faculty of medicine, Tarbiat Modares university, Tehran, Iran, [2]- Research center for infectious diseases and tropical Medicine, Boo-Ali hospital, Zahedan, Iran, [3]Pasteur institute of Iran, Tehran, Iran.

There is a growing amount of evidence that microRNAs (miRs) play critical roles in complex host-pathogen interaction networks. Different studies have identified a role for mir-146 in regulation of inflammatory cytokines, and for mir-21 and mir-31 in FOXP3 expression, a master regulatory gene for both development and function of regulatory T cells. Tuberculosis (TB) as a chronic infectious disease remains a world-wide public health problem around the world. 5%-10% of individuals infected with *Mycobacterium tuberculosis* will eventually develop active disease and more than 90% of the people who become infected develop a latent TB infection (LTBI). Immune effector mechanisms that lead to resistance or susceptibility to infection or clinical disease are not fully known.
In the present study the expression patterns of miR-146, miR-21, and miR-31 have been studied in patients with active TB and subjects with LTBI, and healthy individuals. Peripheral blood mononuclear cells were cultured with or without PPD. MiRs were isolated by microRNA isolation kit; and quantitation of miRs was carried out using Taqman microRNA assay kit. The expression level of miRNA was normalized to RNU24.
The results showed that the expression of miR-146, miR-21, and miR-31 were up-regulated in TB-infected individuals compared with those in healthy individuals. Moreover, miR-146, miR-21, and miR-31 expression were higher in patients with active disease compared to subjects with LTBI.
The different expression patterns of the miRs suggest that they may mediate important roles in development of appropriate immune response.

P2.04.02
MicroRNA-mediated regulation of the pattern recognition receptor PTX3

***E. Barbati**[1,2], L. Mori[1,2], L. Zammataro[3], M. Rubino[1,2], A. Mantovani[1,2], C. Garlanda[1], M. Locati[1,2];*
[1]Humanitas Clinical and Research Center, Rozzano, Milano, Italy, [2]Department of Translational Medicine, University of Milan, Milan, Italy, [3]Center for Genomic Science of IIT@SEMM, Milano, Italy.

The long pentraxin 3 (PTX3) is a soluble pattern recognition receptor transcriptionally induced by proinflammatory signals in different cell types, including monocytes and macrophages. Despite its characterized role in innate resistance and inflammation, regulation of PTX3 by microRNAs, fundamental fine-tuners of these processes, has not yet been described. Therefore, we investigated the effect on PTX3 production of microRNAs potentially targeting PTX3 itself or molecules involved in PTX3 expression and correct folding.
Among the microRNAs predicted to target PTX3 3'UTR, miR-29c and miR-181c are constitutively expressed in human primary monocytes and macrophages, whereas miR-9 is expressed in monocytes, as demonstrated by bioinformatic analysis on transcription profiles. Reporter assay experiments demonstrated that miR-9, miR-29 and miR-181c act on PTX3 mRNA. Experiments on *PTX3* promoter showed that miR-29, miR-181c and other microRNAs induced by proinflammatory signals in monocyte/macrophages (miR-146a, miR-132 and miR-155) reduced the transcriptional rate of *PTX3* gene. Finally, miR-181c inhibited the production of ERp18, a thioredoxin superfamily member required for the correct folding of PTX3, by directly targeting its mRNA. When overexpressed in the 8387 fibroblastic cell line which produces PTX3 in basal conditions and upon stimulation with inflammatory mediators (TNFα and IL-1β), these microRNAs downregulated PTX3 production, demonstrating the biological relevance of this network of post-transcriptional regulators.
All together, these data reveal a complex role of microRNAs in regulating PTX3 expression, exerted either by direct targeting PTX3 mRNA or indirectly by regulating key molecules involved in PTX3 induction.

P2.04.03
MiR-217 is an oncogene that enhances the germinal center reaction

***N. Bartolomé-Izquierdo**[1], V. G de Yébenes[1], R. Nogales-Cadenas[2], P. Pérez-Durán[1], D. F Robbiani[3], M. Cañamero[4], A. Pascual-Montano[2], A. R Ramiro[1];*
[1]Centro Nacional de Investigaciones Cardiovasculares (CNIC), Madrid, Spain, [2]National Center for Biotechnology-CSIC, Madrid, Spain, [3]The Rockefeller University, New York, NY, United States, [4]Centro Nacional de Investigaciones Oncológicas (CNIO), Madrid, Spain.

MicroRNAs (miRNAs) regulate virtually all biological processes, but little is known of their role in germinal center (GC) B cells. While the GC response is crucial to ensure a competent immune response, GC B cells are also the origin of most human lymphomas. Here we report that miR-217 is specifically upregulated in GC B cells. Gain- and loss-of-function mouse models reveal that miR-217 functions as a positive modulator of the GC response through the regulation of a DNA repair gene network. Moreover, we show that miR-217 overexpression promotes mature B cell lymphomagenesis. Therefore miR-217 provides a novel molecular link between the normal GC response and B cell transformation.

P2.04.04
The effect of tumor cell derived exosomes on mesenchymal stem cells

*A. Marton[1], M. Harmati[1], R. Katona[1], E. Gyukity-Sebestyén[1], I. Nagy[2], B. Horváth[3], C. Vizler[1], E. Duda[4,1], A. Borsodi[5], **K. Buzas**[1,6];*
[1]Biol. Research Center, Szeged, Hungary, [2]Baygen Ltd, Szeged, Hungary, [3]Baygen Ltd., Szeged, Hungary, [4]Inst. Medical Biology, University of Szeged, Szeged, Hungary, [5]BioTargeting Ltd., Szeged, Hungary, [6]University of Szeged, Szeged, Hungary.

Malignant melanoma (MM) is an especially aggressive skin cancer. The mechanism of its rapid metastasis formation, high genetic variability and effective immune escape mechanisms are not fully explained. Exosomes are among the potential mediators of communication between melanoma cells and their environment. To explore the interaction of melanoma cell derived exosomes (MDCE) and their microenvironment, we investigated their effect of mesenchymal stem cells (MSC). Mouse MSCs from adipose tissue were pretreated with B16 mouse melanoma cell derived exosomes, then the rate of spontaneous apoptosis and expression of multipotent stromal cell markers were analyzed by flow cytofluorometry. We have found marked differences in the expression CD44, integrin alpha 4, CD29 and CD106 after 7 days of induction. The ratio of late apoptotic or necrotic/early apoptototic cells decreased after MCDE treatment (0.43/1 versus 0.98/1). We sequenced the small RNA content of melanoma cell derived exosomes by SOLiD 5500xl technology, and the sequences were annotated in CLC Genomics Workbench version 5.5.1. We have found highest expression values of mir205, mir31, mir21a, mir15b respectively. To explore the potential in vivo tumor-promoting effect of exosomes, B16F1 tumor bearing mice were injected with MDCE-induced-MSCs i.v., the control mice received untreated MSC. The survival rate was 38% after pre-conditioned MSC treatment versus 85% un-induced MSCs treatment at day 42nd. Our data suggest that melanoma cell derived exosomes reeducate mesenchymal stem cells through their miRNA cargo, giving rise to a cell population that support metastasis formation.

P2.04.05
MicroRNA modulations in plasmacytoid dendritic cell hyperactivity in systemic lupus erythematosus

***V. S. Chan**[1], S. Yan[1], R. C. Y. Tam[1], N. Shen[2], C. S. Lau[1];*
[1]The University of Hong Kong, Pokfulam, Hong Kong, [2]The Shanghai Jiao Tong University, Shanghai, China.

Systemic lupus erythematosus (SLE) is a prototypic autoimmune disease that affects predominantly young females causing significant morbidity and mortality. The etiopathogenesis of SLE is not completely clear and plasmacytoid dendritic cells (pDCs) are thought to play a major pathogenic role owing to its unique ability to produce large amount of type-I interferon upon nucleic acids stimulation through the toll-like receptors (TLRs)-7/9. We previously demonstrated hyperactivity in pDCs from lupus patients when compared with healthy control subjects. Using the NZB/W F1 mouse model, we aimed to elucidate the regulatory mechanism for pDC hyperactivity in lupus development. Similar to the human setting, bone marrow–derived pDCs from symptomatic F1 mice exhibited heightened up-regulation of co-stimulatory molecules upon TLR-7 and TLR-9 ligands stimulation when compared with pre-symptomatic animals. Functional abnormalities in terms of cytokines production were also compared. The expression profiles of over 700 microRNA (miRNAs) in pDCs upon TLR7 activation were analyzed by low-density arrays and distinct miRNAs were differentially expressed by pDCs from lupus mice. On-going experiments are underway to correlate the perturbed miRNAs induction and the aberrant pDC functions in SLE using miRNA mimics and inhibitors. In summary, our study has revealed miRNA-mediated modulations that may lead to pDC functional abnormalities, thus further demonstrating its pathogenic attributes in SLE development.

P2.04.06
MicroRNA profiling in giant cell arteritis: diagnostic and prognostic potential

***S. Croci**[1], A. Zerbini[1], G. Pazzola[2], D. Nicoli[3], E. Farnetti[3], B. Casali[3], A. Cavazza[4], L. Boiardi[2], M. Parmeggiani[1], C. Salvarani[2];*
[1]Clinical Immunology, Allergology and Advanced Biotechnologies Unit, IRCCS-Arcispedale Santa Maria Nuova, Reggio Emilia, Italy, Reggio Emilia, Italy, [2]Rheumatology Unit, IRCCS-Arcispedale Santa Maria Nuova, Reggio Emilia, Italy, Reggio Emilia, Italy, [3]Laboratory of Molecular Biology, IRCCS-Arcispedale Santa Maria Nuova, Reggio Emilia, Italy, Reggio Emilia, Italy, [4]Pathology Unit, IRCCS-Arcispedale Santa Maria Nuova, Reggio Emilia, Italy, Reggio Emilia, Italy.

MicroRNAs (miRNAs) are small, non-coding RNAs that suppress gene expression at post-transcriptional level. MiRNAs have a proven role in innate and adaptive immunity and inflammatory networks. They have been shown deregulated in various autoimmune diseases emerging not only as biomarkers but also as novel therapeutic targets. No data exist on miRNA expression in giant cell arteritis (GCA), an autoimmune inflammatory vasculitis affecting large and medium-sized arteries.
The present study aimed to evaluate the diagnostic and prognostic potential of miRNAs in GCA.
Expression of 1209 miRNAs was profiled with a microRNA array (Ocean Ridge Biosciences, Palm Beach Gardens, FL) in temporal artery biopsies (TABs) from 7 GCA patients (harboring a transmural infiltrate) *versus* normal TABs obtained from 8 patients thought to have GCA instead having a different disease. MiRNAs showing a >2 fold, statistically significant differential expression with a FDR <10%, were selected for further analyses. Subsequent real-time PCRs confirmed that miR-146b-5p, -146a, -155, -150 and -21 were significantly more expressed in TABs from patients with GCA. Expression of miR-146b-5p was particularly promising in a diagnostic perspective because it was possible to set a threshold level which correctly classified TABs as diseased or normal. MiR-146a and miR-21 are negative regulators of the physiologic immune responses inhibiting respectively IRAK1 and PDCD4. No correlations were found between miR-146 and IRAK1 and between miR-21 and PDCD4 levels in TABs indicating defective mechanisms. Ongoing patients' follow up will let to determine if miRNA levels might predict response to therapy and correlate with GCA aggressiveness.

P2.04.07
MicroRNAs dysregulation in human Chagas cardiomyopathy

***L. R. P. Ferreira**[1,2,3], R. H. Santos[4], M. A. Baron[1,2,3], I. Navarro[1,2,3], P. C. Teixeira[1,2,3], N. A. Stolf[4], E. Bocchi[4], A. Fiorelli[4], J. Kalil[1,2,3], E. Cunha-Neto[1,2,3];*
[1]Laboratory of Immunology, Heart Institute (InCor), School of Medicine, USP, São Paulo, Brazil, [2]Institute for Investigation in Immunology (iii), INCT, São Paulo, Brazil, [3]Division of Clinical Immunology and Allergy, School of Medicine, USP, São Paulo, Brazil, [4]InCor, São Paulo, Brazil.

MicroRNAs (miR) are 22 nucleotide-long small RNA molecules that regulate tissue-specific mRNA and protein expression by interaction with complementary 3'UTR sequences and are involved in virtually all cellular processes. Several studies have described the fundamental role of different miR in heart development and cardiovascular disease (CD), but until now there are no data on their role in Chronic Chagas disease Cardiomyopathy (CCC), an inflammatory dilated cardiomyopathy occurring in 30% of Trypanosoma cruzi-infected individuals. We therefore analyzed the expression of eight miRs (miR-1, -133a-2, -133b, -208a, -208b, -214-3p, -146a-5p, -155-5p and -150-5p) by real-time quantitative PCR (qPCR) in myocardial tissue samples from end-stage CCC and idiopathic dilated cardiomyopathy (DCM) patients, using samples from heart donors as controls (CONT). Five miRNAs (miR-1, 133a-2, 133b, 208a, 208b) were significantly downregulated in CCC samples as compared to CONT and the miRNAs: of those, miR-1, -133a-2 and -208b were significantly less expressed among CCC than DCM samples. These three downregulated MiRs targeted multiple genes concordantly upregulated in CCC myocardium, which belong to pathways associated with progression of cardiomyopathy. We also confirmed by qPCR a negative correlation between expression of miR-1 and its target gene, cyclin D1 (cyD1), important in cardiomyocyte hypertrophy. Our results indicate that miRs may play a fundamental

role in CCC pathogenesis by controlling expression of key genes and proteins. Further in-depth studies will assess the full extent of miRs contribution to CCC.

P2.04.08
Does HCMV employ miRNA mediated regulation to counter the antiviral mechanisms to maintain long latency periods in Humans? An in silico study

***S. B. Gosipatala**, S. Saxena;*
Babasaheb Bhimrao Ambedkar University, Lucknow, India.

MicroRNAs are gaining significance, for their regulatory role in RNA directed gene expression regulation in various spectrums of biological systems such as cell development, differentiation, carcinogenesis and disease pathogenesis to prognosis. Reports pertaining to the immunoevasion role of HCMV miRNAs are beginning, this study was initiated to understand the role of HCMV miRNAs on the human antiviral mechanism such as apoptosis and autophagy. The 3'UTR regions of the genes were probed for the potential binding sites of HCMV miRNAs by RNAhybrid and RNA22 algorithms. The results revealed that genes involved in both the intrinsic and extrinsic pathway of apoptosis and autophagy contain potential binding sites for HCMV miRNAs. Further, HCMV appears to regulate these mechanisms by targeting multiple genes in any pathway with more than one miRNA, suggesting that HCMV uses miRNA mediated regulation in controlled manner. The obtained results strengthens the hypothesis that HCMV employes miRNA mediated regulation for its tissue tropism and long latency periods in humans.

P2.04.09
Anti-microRNA-378 Enhances Wound Healing Process by Up-regulating Vimentin and Integrin beta-3

***H. Li**, B. Yang;*
University of Toronto, Toronto, ON, Canada.

Background: Impaired wound healing evolves to be a major public health issue worldwide. Until recently, microRNAs has emerged as key regulators of wound healing. Methods: We developed an anti-miR-378 sponge by inserting multiple-tandem microRNA binding sites. It sufficiently blocks the process of precursor microRNA. Anti-miR-378 transgenic mice were generated and subjected to skin biopsy, causing full-thickness, excisional wounds. Wound size was measured and tissue samples were collected for immunohistochemistry study. Mouse fibroblasts NIH/3T3 was transfected with anti-miR-378 fragments and subjected to function tests. Results: Anti-miR-378 sponge could block mature miR-378 generation in vitro and in vivo. Compared to control mice, enhanced wound healing process was shown in anti-miR-378 transgenic mice. In addition, we found vimentin and integrin beta-3, modulators which are important in wound healing process, increased remarkably in transgenic mice samples. Wound scratch and transwell migration tests showed a greater mobility in anti-miR-378 transfected NIH/3T3 cells, which was due to the up-regulation of vimentin and integrin beta-3. They are confirmed as targets of miR-378, thus their expression could be rescued by anti-miR-378. Overexpression of vimentin could also contribute to fibroblasts differentiation and up-regulation of integrin beta-3 by anti-miR-378 is responsible for angiogenesis. More interestingly, further analysis of inflammatory cytokines in situ revealed a pro-inflammation pattern, which favors wound healing as well. Conclusion: Taken together, we demonstrated that knockdown of miR-378 by endogenous-integrated antisense-fragments can increase the expression of its targeted proteins, vimentin and integrin beta-3, which enhanced wound healing.

P2.04.10
Global effect of IL-10-induced modulation of miRNAs expression on cytokine production by LPS-stimulated human monocytes

***B. Mariotti**, M. Rossato, M. Castellucci, S. Gasperini, F. Bazzoni;*
University of Verona, Verona, Italy.

IL-10 negatively regulates inflammation via transcriptional and post-transcriptional inhibition of proinflammatory cytokines production. With respect to the mechanisms acting at the post-transcriptional level, we have recently identified miR-187 and miR-146b as a direct targets of IL-10, and uncovered a novel miR-187-mediated pathway triggered by IL-10 to inhibit LPS-induced TNFα, IL-6 and IL-12p40 production. Moreover, we demonstrated that IL-10 is able not only to increase the expression of LPS-induced miR-187 and miR-146b, but also to down-modulate the expression of LPS-induced miR-9, miR-155, miR-146a and miR-132. In this study, we analyzed the global contribution of IL-10-down-modulated miR-9, miR-155, miR-146a and miR-132 and of IL-10-upregulated miR-187 and miR-146b in the cytokine response of monocytes to LPS. AntagomiRs targeting each of the LPS-induced miRNAs (i.e. miR-9, miR-155, miR-146a and miR-132) together with miR-187 and miR-146b mimics were simultaneously transfected into monocytes, in order to reproduce the effect of IL-10. Cytokine production were qualitatively and quantitatively evaluated in the supernatants of transfected monocytes stimulated with LPS or left untreated. Our data show that while the overexpression and/or silencing of each individual miRNA partially modifies the levels of cytokine produced, only the combination of all miRNA inhibitors and mimics correctly replicates the effect of IL10 on LPS-induced cytokine production. Collectively, our data provide evidence for the differential role played by miRNA during the development of the inflammatory response and candidate the miRNA system as a novel mechanism through which IL-10 can tailor the overall monocyte responses to LPS.

P2.04.11
TNF influences microRNA expression during T cell activation

***V. Molnár**[1], B. Molnár-Érsek[1], E. Buzás[1], A. Falus[1], G. Nagy[1,2];*
[1]Semmelweis University, Department of Genetics, Cell-, and Immunbiology, Budapest, Hungary, [2]Department of Rheumatology, Semmelweis University, Hungary, Budapest, Hungary.

MicroRNAs (miRNAs) are recently described posttranscriptional regulators. Altered expression of miR-155 is associated with several immunological diseases, including rheumatoid arthritis (RA). MiR-181a deficiency leads to the increase in the proportion of autoreactive lymphocytes. Dysregulated expression of miR-146a was described in more cell types that are relevant in RA.
In this study, we focused on miRNAs, which may influence the activation of T lymphocytes, and assumed to be involved in the pathomechanism of RA. The aim was to find connection between the dysregulated miRNAs and the presence of proinflammatory cytokines like TNF. The expression of miRNAs was determined in anti-CD3/CD28 activated human CD4+ T lymphocytes by RT-PCR method.
The expression of miR-155 was significantly upregulated during T cell activation, and according to our data this can be attenuated by TNF pretreatment. In case of miR-181a, a downregulation was observed, and this effect was inhibited when cells had been primed with TNF before activation. The activation of T cells leads to increase the expression of miR-146a with the maximal expression at 2 hours after stimulation, and surprisingly the TNF treatment shifted this peak to 6 hours.
Among the characterized targets of these miRNAs there are some proteins of TNF signal transduction (miR-146a: TRAF6, IRAK1) and they can regulate several other key components of T cell signal transduction (miR-155: various targets in fate decisions and Treg homeostasis; miR-181a: PTPN22, DUSP6) as well. Bioinformatic analysis using predicted targets was performed to delineate the extent of involvement of these miRNAs in these pathways.

P2.04.12
The miR-17-92 cluster is regulating naive T cell homeostasis as well as effector and memory differentiation

G. C. Monnot[1], *J. C. Dudda*[1], *B. Salaun*[2], *D. Utzschneider*[3], *D. Zehn*[3], *P. Romero*[1];
[1]*Ludwig Institute Lausanne, Epalinges, Switzerland,* [2]*Glaxo Smith Kline Bio, Bruxelles, Belgium,* [3]*Service of Immunology and Allergy, Lausanne, Switzerland.*

The miR-17-92 cluster, encoding 6 different microRNAs, is upregulated upon T cell activation and has been shown to have important effects on T cell-mediated immune responses. To study its role in CD8+ T cells, we used mice expressing CRE recombinase under the control of the CD4 promoter in combination with a floxed miR-17-92 locus. In naïve mice, CD8+ T cell numbers in lymphoid organs and blood were reduced by about 50%. This was also observed in chimera mouse bearing a mix of wild type and 17-92 fl/fl bone marrow. Upon activation in vitro, early T cell proliferation was strongly impaired. In order to follow a virus-specific immune response in vivo, we infected mice with LCMV and analysed the effector and memory response from day 8 to several months after infection. We found that again virus specific and IFN-γ producing cells were strongly reduced. In order to identify intrinsic roles for miR-17-92, we adoptively transferred TCR transgenic OT-1 specific or gp-33 specific knockout CD8 T cells into wild type recipients before infection with either OVA-expressing L. monocytogenes or LCMV. At the early memory phase upon infection, knockout CD8+ T cells were skewed towards central memory cell differentiation (CD127high, CD62Lhigh, KLRG1low). Together, these results demonstrate an important role for the miR-17-92 cluster in the homeostasis and differentiation of CD8+ T cells. Future experiments will explore the potential of modulating these miRNAs for the improvement of immunotherapy with cytolytic T lymphocytes.

P2.04.13
Double stimuli by TLR7 and CD11c+ may change microRNA expression in murine plasmacytoids dendritic cells

E. Padilha*, T. Malardo, I. C. Fontoura, J. C. C. Lorenzi, B. P. Moreira, C. L. Silva, A. A. M. Coelho-Castelo;*
University of Sao Paulo, Ribeirao Preto, Brazil.

Dendritic Cells (DC) are central key in starting an immune response activating or inhibiting T lymphocytes in specific way. PAMPs as messenger RNA (mRNA) or plasmideal DNA (pDNA) are molecules able to activate DC through toll-like receptor 7 and 9, respectively. However these cells need a regulation, avoiding nonspecific response. The microRNAs (miRNA) are involved in a fine-tuned cell-response at control posttranscriptional level. Then we verified whether different miRNAs and targets are induced by mRNA or pDNA stimuli.
We used DC (anti-$CD11c^+$ or anti-mPDCA-1 magnetic beads separation) from spleen of Balb/c mice stimulated with 10µg of mRNAhsp65 or 10µg of pDNA-HSP65 and incubated per 30 minutes. The miRNA were obtained in triplicate in microarray analysis, using the Agilent platform. Our results showed just one differentially express miRNAs, miR-690 was down-regulated ($p<0,05$) with mRNA-stimuli. Moreover, after the use of anti-mPDCA-1(plasmacytoid dendritic cell especific) beads, DC was not able to show miRNA differential expression, when we use anti-$CD11c^+$ before anti-PDCA-1 we recovery the miRNA differential expression. In addition *in silico* and *in vitro* analysis suggests that prostaglandin E synthasis would be a possible target for the miRNA. Taken together, mRNAhsp65 and $CD11c^+$ stimuli may induce change in miR-690 expression and in target, which may play important role gene therapy.

P2.04.14
Anti-inflammatory function of miR-146a in human primary keratinocytes and atopic dermatitis

A. Rebane[1,2], *T. Runnel*[1,2], *A. Aab*[1,2], *B. Rückert*[1], *J. Maslovskaja*[2], *M. Zimmermann*[1], *M. Plaas*[2], *L. Kemeny*[3], *K. Kingo*[2], *C. A. Akdis*[1];
[1]*SIAF, Davos, Switzerland,* [2]*University of Tartu, Tartu, Estonia,* [3]*University of Szeged, Szeged, Hungary.*

Previously, miR-146a has been shown to regulate immune responses in different cell types. We carried out miRNA expression profiling and determined elevated expression of miR-146a in keratinocytes and skin from atopic dermatitis (AD) patients. Our results show that miRNA-146a is up-regulated by proinflammatory cytokines, such as TNF-alpha and IL1-beta, but not by IFN-gamma in primary keratinocytes. To study miR-146a functions in human primary keratinocytes, we transfected miR-146a precursors or inhibitors into keratinocytes treated with IFN-gamma, TNF-alpha or IL1-beta. These experiments reveal that miR-146a hinders the capacity of primary keratinocytes to produce several inflammation-related cytokines and chemokines, such as CCL5, IL-8 and IL-6 both in mRNA and protein level. Over-expression of miR-146a suppresses proliferation and cytokine induced apoptosis of primary keratinocytes. mRNA array and pathway analysis of miR-146a-influenced genes demonstrates that miR-146a down-regulates mRNAs encoding proteins from NF-kappaB pathway as well as proteins involved in regulation of apoptosis and proliferation. siRNA inhibition of two miR-146a targets from NF-kappaB pathway, CARD10 and IRAK1 show that both these proteins are needed for production of IL-8, however, only CARD10 influences the expression of CCL5. In addition, our preliminary results indicate that miR-146a-deficient mouse acquires similar Th2 type skin inflammation as wild type mouse in mouse AD model and that the anti-inflammatory function of miR-146a becomes more important in the chronic phase of the skin inflammation. Together, our data show that miR-146a has a strong anti-inflammatory effect in human keratinocytes and its expression level may influence the course and intensity of skin inflammation in AD.

P2.04.15
Negative regulation of Toll-like receptor 4 signaling by the IL-10-dependent miR-146b

T. A. Renzi*, G. Curtale, M. Mirolo, M. Locati;*
Istituto Clinico Humanitas, Rozzano, Italy.

Toll-like receptors (TLRs) play key roles in detecting pathogens and in initiating inflammatory responses but their activity must be tightly regulated to avoid excessive inflammation which could lead to the development of immunopathology. Our work has identified that in human monocytes, stimulation with the anti-inflammatory IL-10 induced the expression of miR-146b and was able to potentiate the effect of LPS which induces miR-146b expression only at later time points. Blocking endogenous IL-10 autocrine signaling resulted in a 40% reduction of miR-146b induction by LPS and when the JAK/STAT signaling pathway activated by IL-10 was blocked, the LPS-mediated induction of miR-146b and the production of IL-10 were significantly reduced. To gain additional insight on the role of IL-10 in the transcriptional regulation of miR-146b in monocytes, we demonstrated the recruitment of Pol II and the enrichment of STAT3 to the miR-146b promoter region after stimulation with IL-10, consistent with IL-10-mediated up-regulation of miR-146b expression. To demonstrate the role of miR-146b in the context of inflammation, we over-expressed miR-146b in the THP-1 cell line using a lentiviral-based system approach. We identified as targets the major components of the TLR pathway including TLR4, MyD88, IRAK1 and TRAF6 and observed a significant reduction in the production of several pro-inflammatory cytokines. Our results show miR-146b as an IL-10-responsive miRNA with an anti-inflammatory activity in monocytes based on multiple targeting of the TLR4 pathway and candidate miR-146b as a new feedback modulator of LPS response possibly involved in the resolution of inflammation.

P2.04.16
The role of microRNA 155 in innate immunity and arthritis

***V. Saferding**, E. Goncalves-Alves, A. Puchner, J. Smolen, K. Redlich, S. Blüml;*
Medical University Vienna, Dpt. of Rheumatology, Vienna, Austria.

Background: MicroRNA 155 (miR155) has been demonstrated to be essential for the development of collagen induced arthritis by controlling the generation of autoreactive T and B cells. However, the contribution of miR155 in innate immune cells is not known.
Materials and Methods: We analyzed activation and cytokine production of macrophages and dendritic cells (DCs) in vitro and in vivo. T-cell stimulatory capacity of DCs was measured. MiR155 deficient mice were crossed into hTNFtg mice and arthritis development was analyzed clinically as well as histologically.
Results: MiR155 deficiency did not alter the expression of costimulatory molecules or MHCII expression after stimulation of macrophages and DCs in vitro and in vivo. We also Facs-sorted DCs after stimulation with LPS in vivo and determined the production of proinflammatory cytokines such as IL-23, IL-6 as well as TNF. We did not detect differences between wt and miR155-/- mice. In addition, the T cell stimulatory capacity of wt and miR155-/- was identical. When we analyzed hTNFtg/ miR155-/- mice compared to wt mice, we did not detect differences in the clinical signs and symptoms of arthritis. Histologically, we even found slightly increased synovial inflammation in hTNFtg/ miR155-/- mice compared to wt mice.
Conclusion: In contrast to the pivotal role of miR155 in autoimmunity requiring the adaptive immune system, the role of miR155 in innate immunity seems to be limited. This is emphasized by the fact that miR155 hardly influences the course of TNF-driven arthritis, which is mainly dependent on components of the innate immune system.

P2.04.17
Association of microRNA-146a target gene IRAK-1 polymorphism with enthesitis related arthritis category of juvenile idiopathic arthritis

***S. Singh**, A. Aggarwal;*
Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India.

Purpose of the study: MicroRNAs are non-coding RNA molecules that play pivotal role in modulating the expression of multiple target genes at the post-transcriptional level. SNP in pre-miRNAs can alter miRNA expression, and polymorphism in target molecules can affect binding to target mRNA. Studies have shown there is association of *miR-146a* target *IRAK*-1 polymorphisms in autoimmune disease. Thus we studied the association between SNPs of *miRNA-146* and it's target *IRAK*-1 with susceptibility to ERA-JIA.
Methods: 115 patients with JIA-ERA were included in the study. 216 blood donors (201 male) with a mean age of 30.5 years served as controls. *miR-146a* (rs2910164) and it's target *IRAK*-1 (rs1059703) at Exon 12 region and *IRAK*-1 (rs3027898) at 3'UTR polymorphisms were done using PCR-RFLP method.
Results: Among 115 patients (103 males), the mean age at onset of disease was 11(4-17) years with mean disease duration 4.6(0.5-12) years. 21 had uveitis, 16 had positive family history, 51 had enthesitis, 57 had inflammatory back pain and all had arthritis. 88 were HLA B27 positive. The genotype frequency for *miR-146a* was similar in controls and patients. *IRAK*-1(rs1059703) genotype frequencies in controls and patients were also similar. But *IRAK*-1(rs3027898) genotype frequencies were different among control and patients [CC (59.72% vs 65.22%), CA (34.26% vs 20.87%) with 95% CI= 0.56 (0.32 - 0.96) and AA (6.02% vs 13.91%) with 95% CI= 2.12 (1.02 - 4.64)].
Conclusion: Polymorphisms at 3'UTR of *IRAK*-1 (rs3027898) with AA genotype was associated whereas polymorphism in *miRNA-146a* (rs2910164) was not associated with susceptibility to ERA-JIA.

P2.04.18
Regulated expression of microRNA-21 is involved in memory T-cell survival

***K. Smigielska-Czepiel**, A. van den Berg, P. G. Jellema, H. Maat, R. J. van der Lei, E. Brouwer, A. M. H. Boots, B. J. Kroesen;*
University of Groningen, University Medical Center Groningen, Groningen, Netherlands.

Objectives: MicroRNAs (miRNAs) are important post-transcriptional gene regulators. Immune cell-type specific miRNA expression patterns have been described. However, the specific role of single miRNAs in T cell activation is still not well known. In this study we investigated the function of miR-21 in the process of T cell activation. We report that miR-21 is a pro-survival factor in the context of memory T cell function.
Methods: Using qRT-PCR we analyzed miR-21 expression in course of anti-CD3/CD28 stimulation of naive (CD4+CD45RO-) and memory (CD4+CD45RO+)-FACS sorted human primary T cells. Viral vector harboring miR-21 inhibitor sequence served to stably inhibit endogenous miR-21. Apoptosis was assessed by measuring mitochondrial potential. Experimental analysis of T-cell specific miR-21 target genes was performed by RISC immunoprecipitation followed by gene expression analysis in Jurkat cell line.
Results and conclusions: Resting memory CD4+ T cells expressed five times more miR-21 than naive cells. Moreover, miR-21 was strongly upregulated upon TcR engagement implicating it's contribution to the activation process. MiR-21 inhibition resulted in an increased rate of spontaneous apoptosis in in vitro activated T cell cultures, especially in the memory T cell population, and induced massive spontaneous apoptosis in Jurkat cells. RISC immunoprecipitation in Jurkat cells overexpressing miR-21, followed by gene expression analysis identified several potential miR-21 target genes relevant to T cell biology. In conclusion, our data provide evidence that miR-21 is a key component in the process of T-cell activation by regulating T-cell survival signaling, especially in the memory T-cell population.

P2.04.19
Aged T cell subsets are characterized by a distinct microRNA signature

***N. Teteloshvili**, A. van den Berg, N. van der Geest, R. J. van der Lei, P. Jellema, E. Brouwer, A. M. H. Boots, B. J. Kroesen;*
University of Groningen, University Medical Center Groningen, Groningen, Netherlands.

Objective: Decline of immunological responsiveness in elderly correlates with changes in the composition of the T cell compartment. Recently, microRNAs (miRNA) have emerged as important players in the regulation of T cell development, differentiation and function. However, comprehensive insight into the contribution of miRNAs to T cell age-related changes remains elusive. The aim of this study was to investigate the age associated changes in miRNA expression within defined T cell subsets in young and old healthy individuals.
Materials and Methods: T cell subsets (naïve, memory, CD4 and CD8 cells) derived from young and elderly healthy subjects were sorted based on CD3, CD4, CD45RO and CCR7 expression. MiRNA expression patterns were determined using the agilent human miRNA microarray platform (V2) based on Sanger miRbase (release 10.1). Results were validated by miRNA-specific qRT-PCR.
Results: Hierarchical clustering showed differential expression of miRNAs mainly between naive and memory T-cell subsets. Age related differential expression was observed predominantly within the naive CD45RO- T-cell population. 17 miRNAs showed at least 2 fold up- or downregulation in aged naïve T cells. Analysis of individual samples revealed a statistically significant age related upregulation for miR-21, miR-223 and miR-451 by qRT-PCR. Moreover, age-related upregulation of miR-21 was associated with age-dependent accumulation of end-stage differentiated CD8 T cells.
Conclusion: Age-related changes in miRNA expression are found predominantly within the CD45RO- T cell compartment that converges with the accumulation of end-stage differentiated CD45RO- T cells.

P2.04.20

MicroRNA-mediated regulation of TLR4 by immunosuppressive agent increases susceptibility to bacterial infections

E. Tourneur[1,2]*, C. Chassin*[1,2]*;*
[1]Inserm ATIP-Avenir Team "miRNAs & Inflammation", Paris cedex 18, France, [2]Université Paris Diderot, Sorbonne Paris Cité, Paris, France.

Urinary tract infections (UTIs) are responsible for 7 to 10 million cases each year in the United States. They constitute a major cause of morbidity and mortality in humans, particularly in renal transplanted patients. Acute pyelonephritis (APNs) are frequent complications after renal graft and represent an independent risk factor associated with graft survival. Uropathogenic *Escherichia coli* (UPECs) cause more than 80% of the community-acquired APNs and about half of the APNs in hospitalized patients. Bacterial attachment to mucosal epithelial cells represents the initial step in the pathogenicity and TLR4-mediated recognition of UPECs by epithelial cells elicits potent inflammatory response. The consequences of long-term immunosuppressive drugs on TLR function in transplanted patients have not been yet investigated. We showed that mice treated with cyclosporine A (CsA), widely used for the prevention of graft rejection, are more susceptible to UPEC infection. Moreover, the expression of TLR4 and phosphorylated form of p65 subunit were decreased in LPS-activated epithelial cells incubated with CsA. Increasing concentrations of CsA induced a dose-dependent inhibition of the level of TLR4 mRNA concomitantly with the increase of the expression of the microRNA let-7. The inflammatory response, as well as TLR4 expression, was restored by using an anti-let-7. Taken together, these results show that CsA induces an increase of let-7 downregulating the expression of TLR4, which could explain the greater sensitivity of patients to APN after transplantation. Consequently, let-7 may represent a therapeutic target to prevent interstitial injury and progressive alteration of the kidney function of transplanted patients.

P2.04.21
Genome-wide identification of differentially expressed microRNAs in human plasma cell differentiation revealed crucial microRNAs involved

D. Tsai*, S. Wu, C. Chung, A. C. Shih, K. Lin;*
Acadamia Sinica, Taipei, Taiwan.

MicroRNAs (miRNAs) are the classes of short endogenous small noncoding RNA molecules. They regulate the expression of genes by inhibition of translation or degradation of target mRNAs via binding to the partially complementary sites in the 3'-untranslated region (3'-UTR) of target mRNAs. Recently, accumulating studies indicate that the expression of some miRNAs can be highly tissue-specific in many important cellular pathways. In this study, we focus on identification of the expression profiles of miRNAs and their target genes by genome-wide approaches, deep-sequencing of miRNAs and microarray analysis of cDNA expression, in primary human plasma cell differentiation. A total of 134 miRNAs were detected to be either up- or down-regulated after differentiation. Combined computational analysis with gene expression profile data revealed that gene ontology of miRNAs target genes is indistinguishable from that of overall gene expression. Given that plasma cell differentiation is controlled by some key transcription factors, such as BCL6, BACH2, and PRDM1, we examined the relationship between the differentially expressed miRNAs and key transcription factors. Interestingly, our analysis revealed that the expression of these key transcription factors could be co-regulated by clusters of differentially expressed miRNAs. We are examining the functional role of these miRNAs in plasma cell differentiation.

P2.04.22
Evaluation of expression pattern of miRNA146a in Pakistani rheumatoid Arthritis Patients

S. Ullah*, P. John, A. Bhatti;*
National University of Sciene and Technology, Islamabad, Pakistan.

Objectives: The objectives of the present study were to identify the role of miRNA146a in rheumatoid arthritis (RA) pathogenesis and to evaluate expression of miRNA146a and its target genes in RA patients.
Methods: In the present study, expression of microRNA146a (miRNA146a) and its target genes were analyzed using Real time PCR and Semi-quantitative Reverse transcription PCR in blood and synovial fluid of rheumatoid arthritis patients.
Results: An average of 0.7 fold increase was observed in expression of miRNA146a in blood and 14 fold in synovial fluid in rheumatoid arthritis patients as compared to healthy controls. Tumor necrosis factor receptor-associated factor 6 (TRAF6) was down-regulated and its expression correlated with miRNA146a in blood but not in synovial fluid. Interleukin-1 receptor-associated kinase 1 (IRAK-1) and Tumor Necrosis factor alpha (TNF-α) was up-regulated in both blood and synovial fluid. IRAK-1 expression did not correlate with miRNA16a in both blood and synovial fluid while TNF-α correlated with miRNA146a expression in synovial fluid only (R square = 1.4). **Conclusion:** Increased expression of miRNA146a and its statistically significant correlation with expression of TNF-α suggests that miRNA146a can be used as a potential diagnostic biomarker in rheumatoid arthritis.

P2.04.23
Functional analysis for microRNA involving in arthritis

T. Yonezawa*;*
Research Institute for Biomedical Sciences, Chiba, Japan.

microRNAs (miRNAs), which are class of post-transcriptional regulators such as short 19 to 23-nucleotide non-coding RNAs, complementarily bind seed sequences in the 3'-untranslational region of multiple target mRNAs, resulting in their suppression of translation or degradation [1]. In the former case, since the mRNA expression of the targets does not any change, transcriptomics approach, such as expression array, cannot identify the targets.
Recent studies shed light on the fine-tuning mechanism of miRNAs in myriad biological processes including development [2], tumorigenesis [3] and inflammation [4]. We have identified enhancement of mir-146a expression in synoviocyte and macrophages of rheumatoid arthritis [5], whilst suppression of them in osteoarthritis [6]. However, the targets of mir-146a and its molecular mechanisms are not still fully identified.
In this study, in order to identify the targets of them, we established cell-based screening for miRNA using luciferase tandemed full length mRNA. We also performed liquid chromatography-tandem mass spectrometry-based shotgun proteomics in gain of function models using adenovirus- and CMV promoter-mediated overexpression.

P2.04.24
Mir-34a promotes the development of Plasmacytoid dendritic cell

J. Zhang*;*
Soochow University, Institutes of Biology and Medical Sciences, Suzhou, China.

MicroRNAs are a class of small non-coding RNAs that negatively regulate gene expression, causing translational repression and/or messenger RNA degradation. They play pivotal roles in cell development, activation and some diseases occurrences such as tumor, infections and autoimmune diseases. First we established mir-34a chimerical and transgenic mice model, FACS analysis showed that over-expression of mir-34a could induce the increasing of the number of plasmacytoid dendritic cells, as well as conventional dendritic cells, either in chimerical mice or in transgenic mice. Further analysis suggests that mir-34a affected the check-point at PreDC to pDC. Brdu and Annexin V staining indicated that mir-34a did not affect the proliferation and apoptosis of PreDC and pDC, also did not

induce the activation of pDC by detection of CD80/CD86/MHCII. Luciferase assay showed that WNT1 may the target of mir-34a in pDC, indeed, western-blot showed that WNT1 was down-regulated in the BM and spleen cells from mir-34a-TG mice, compared to that in wild type cells. Moreover, over-expression of WNT1 in pDCs could rescue the phenotype of the number increasing of pDCs in mir-34a-TG mice; suggest that WNT1 is the functional target of mir-34a in pDCs. Thus, our studies suggest that mir-34a promotes the development of preDC to pDCs by targeting the expression of WNT1.

P2.05 Immune responses in aging

P2.05.01
How M. leprae Hsp65 influences the immune response in genetically selected aged mice?

E. J. Baldon[1], *E. B. Marengo*[2], *V. Bueno*[3], *M. De Franco*[4], *O. A. Sant'Anna*[1];
[1]*Immunochemistry Laboratory, Butantan Institute, São Paulo, Brazil,* [2]*Hospital Israelita Albert Einstein, São Paulo, Brazil,* [3]*Immunology Division, Federal University of São Paulo (UNIFESP), São Paulo, Brazil,* [4]*Immunogenetics Laboratory, Butantan Institute, São Paulo, Brazil.*

Heat shock proteins may trigger innate immune responses and are involved in immunosenescence and autoimmunity. We characterized some cellular and humoral alterations after intraperitoneal administration of 2.5µg *M. leprae* Hsp65 in genetically selected mice for High (H_{III}) or Low (L_{III}) antibody production (9-months-old) and in its F_1 hybrids. Aged H_{III} female injected with Hsp65 presented a survival decrease of 42% when compared to untreated group (control); no changes in IgG1 or IgG2a anti-Hsp production were observed in H_{III} and L_{III} mice. Regarding the cellular changes, aged H_{III} female Hsp65-group presented amplified frequency in $CD4^+CD154^+CD28^+$ cells (p<0.01) and reduced percentage of B and activated $CD11c^+$ cells (p<0.01) in the spleen, and increased percentage of $CD11c^+$ and $NKG1A/C/E^+$ cells (p<0.01) in the blood compared to control. Hsp65 acts like an imbalance trigger: post-injection, the aged F_1H female Hsp65-group died 2 months after the first death, as observed in aged H_{III} females; however there was no statistically significance compared with F_1H control group. Furthermore, aged F_1H and F_1L female showed amplified frequency of naïve T cells and CD11c cells in spleen (p<0.001). In conclusion, our results confirm the sex dichotomy (sex effect) of the Hsp65 interference in the immunity of aged mice, becoming evident in females. Next, we will characterize innate immune cells in peritoneal cavity after Hsp65 inoculation; in addition, the role of myeloid-derived suppressor cells will be investigated as these cells are increased during ageing process and have been associated with attenuation of experimental autoimmune diseases.

P2.05.02
Interferon signaling pathway: Intrahepatic expression of STAT 1 and interferon resistance in HCV patients

Q. Bashir*, A. Rashid, A. Naveed, R. S. A. Khan, S. Razak;*
National University of Sciences and Technology, Islamabad, Pakistan.

Hepatitis C virus (HCV) has victimized more than 210 million of the world population and about 7 million of Pakistani population. The only widely used approved therapy for the disease is pegylated interferon alpha but in Pakistan the standard combination therapy interferon plus ribavirin is preferably recommended for HCV genotype 3 (most prevalent genotype i.e., between 75-90% in Pakistan) because of its higher response rate i.e., up to 80%. There are number of viral and cellular factors causing failure to respond to standard interferon treatment. In order to evaluate the cellular factors, interferon signaling pathway was studied. The current study aimed to investigate the role of intrahepatic expression analysis of STAT1 in treatment failure taking age of the patient into consideration. The study was first approved by Institute's Ethical Committee. Liver biopsies and blood from 26 HCV patients resistant to interferon therapy were collected under sterile conditions. Serum markers i.e., liver function tests (LFTs), HCV viral load, genotyping and pre-biopsy tests were taken into consideration. The liver biopsy was then subjected to both liver histopathology status evaluation and PCR based detection of STAT1. STAT1 mRNA was detected in about 96% of the HCV patients resistant to interferon therapy. The investigation showed that STAT 1 expression is not a major factor behind interferon resistance in HCV patients and mean age of the normal and responders (to interferon treatment) group is lower than that of the non-responders.

P2.05.03
Impact of Cytomegalovirus seropositivity on the lymphocytes counts in middle age individuals: increase of CD4+CD62L-CD28- lymphocytes in a sub-group of CMV+ individuals

P. Apoil[1,2], *B. Puissant-Lubrano*[1,2], *N. Congy-Jolivet*[1,2], *M. Peres*[2], *D. Bloom*[3], *F. Roubinet*[3], ***A. Blancher***[1,2];
[1]*Faculté de Médecine Purpan, Universite Paul Sabatier, Toulouse 3, Toulouse, France,* [2]*CHU de Toulouse, Toulouse, France,* [3]*EFS Pyrénées-Méditerranée, Toulouse, France.*

The peripheral blood T, B and NK lymphocytes and their subpopulations were numerated by flow cytometry by using four antibody panels of 8 antibodies each, in 200 healthy blood donors of both genders, 18 to 68 years old, of known cytomegalovirus serology (120 CMV- and 80 CMV+).
The T lymphocytes counts are significantly increased in the CMV+ group but are not influenced by gender or age. CD4+ T lymphocytes counts are increased in women and CMV+ subjects. B-lymphocytes are increased in CMV+ individuals but not influenced by gender or age. Absolute counts of NK cells are not influenced by gender age or CMV serological status. CMV+ individuals have lower proportions of NK cells expressing NKp30, NKp46 or KIR3DL1/NKB1, and a higher proportion of HLA-DR+ NK lymphocytes.
The CMV+ subjects have lower frequencies of naive CD8+ T lymphocytes and a higher percentage of CD8+ "effector memory" and terminally differentiated "EMRA" lymphocytes which have lost CD28 and/or CD27 markers. Moreover, an increase of the CD4+ T EMRA / total CD4+ T cells ratio (above 3%, up to 27%) is observed in 25% of CMV+ individuals but in none of CMV- controls. These CMV+ individuals with a high proportion of CD4+ T EMRA might progress toward an Immune Risk Phenotype at a later age.

P2.05.04
Reduced naïve CD8+ T-cell priming capacity in elderly and HIV infected individuals

O. Y. Briceño[1], *A. Lissina*[1], *G. Afonso*[2], *E. Gostick*[3], *D. Price*[3], *C. Katlama*[4], *U. Karrer*[4], *R. Mallone*[2], *D. Sauce*[1], *V. Appay*[1];
[1]*INSERM U945, Paris, France,* [2]*INSERM U986, Paris, France,* [3]*Department of Infection, Immunity and Biochemistry, Cardiff, United Kingdom,* [4]*Institute of Medical Microbiology, University of Zurich, Zurich, Switzerland.*

Naïve CD8+ T-cells are necessary for the induction of adaptive immune responses upon priming with specific antigens. However, advanced age as well as HIV infection are known to affect T-cell production and the pool of naïve CD8+ T-cells. This deterioration may alter CD8+ T-cell priming capacity, thus making old individuals or HIV infected patients vulnerable to new or reemerging pathogens and less responsive to vaccination. Our objective is to study the effect of age and HIV infection on the priming capacities of antigen-specific CD8+ T-cell precursors, and thus the mounting of effective T-cell responses in humans.
We have developed a simple in vitro assay to assess CD8+ T-cell priming in humans. We used Melan-A as a model antigen, due to the high frequency of Melan-A specific naïve CD8+ T-cell precursors in HLA-A2 healthy donors. Using an accelerated co-cultured of dendritic cells, we analyze antigen specific CD8+ T-cells upon in vitro priming. We compared the naïve CD8+ T-cell priming capacities between healthy donors, elderly individuals and HIV infected individuals.
We found that elderly individuals and HIV infected patients have reduced priming capacities compared with healthy donors. Priming capacities were directly correlated with naïve CD8+ T-cell frequencies. Moreover, we observed that elderly individuals with

better in vitro priming capacities responded better to vaccination in vivo.
Alterations in priming capacity could explain the lack of response to new or recall antigens in elderly and HIV infected individuals. This assay could be used to predict vaccination response in humans.

P2.05.05
Is angiotensin-I converting enzyme (ACE) associated with immunosenescence?

*M. E. Ishimura, B. Viniauskas, D. Teixeira, J. Chagas, I. M. Longo-Maugeri, **V. Bueno**;*
UNIFESP, São Paulo, Brazil.

Aging has been associated with changes in the immune system which interfere with responses to infections and efficacy of vaccination. Angiotensin-I converting enzyme (ACE) plays a role in inflammation and in the generation of progenitor cells from bone marrow. Our aim was to evaluate ACE and immunological parameters in individuals from 61 to 65 years old and in adults (20-30 years old). Blood was collected for ACE activity evaluation (fluorogenic assay), ACE expression in non-lymphocytes cells (CD143+) and T lymphocytes phenotype by flow cytometry. In individuals older than 60 years (G1) we observed a higher median of plasmatic ACE activity (125 nM/min/mg) in comparison with adults (G2, 103 nM/min/mg) in opposition to ACE expression in the membrane of non-lymphocytes (G1=57.4% x G2=71.6%). The median of CD4+ T cells was higher in older individuals (G1=54.1% x G2=49.7%) whereas CD4+ naïve T cells were decreased in this population (CD4+CD45RA+CD27+, G1=40.5% x G2=48.4%). CD8+ T cells percentage was decreased in elderly individuals (G1=16.6% x G2=25.1%) and the same was observed for CD8+ naïve T cells (CD8+CD45RA+CD27+, G1=41.2% x G2=47.3%). Memory CD4+ T cells were higher in elderly individuals (G1=47.1% x G2=33.2%) and the same was observed for CD8+ T cells (G1=22.9% x G2=14.3%). Individuals older than 60 years presented decrease in naïve T cells and also in non-lymphocytes expressing ACE in opposite to the increase in memory T cells and higher activity of ACE. In conclusion, ACE modulation during aging could play a role in immunosenescence.

P2.05.06
SRC homology 2 domain-containing phosphatase-1 (SHP-1) is a negative T cell regulator of T lymphocyte responses associated with aging

***T. Fulop**[1], A. Le Page[1], H. Garneau[1], N. Allard[1], K. Tsvetkova[1], A. Larbi[2], C. Fortin[1], G. Dupuis[3];*
*[1]Research Center on Aging, Sherbrooke, QC, Canada, [2]Singapore Immunology Network (SIgN), Immunos Building at Biopolis, Agency for Science, Technology and Research (A*STAR), Singapore, Singapore, [3]Université de Sherbrooke, Dept. of Biochemistry, Immunology Programme, Sherbrooke, QC, Canada.*

With aging the immune response is decreasing. Our aim was to study the role of phosphatases in T cells in elderly under TCR/CD28 stimulation. We showed that a dysregulation of the Csk/PAG loop in activated T cells from elderly individuals favored the inactive form of phosphorylated Lck (Tyr505). Dynamic movements of these regulatory proteins in lipid raft microdomains were also altered in T cells of aged individuals. We showed that SHP-1 activity was upregulated in T cells of aged donors compared to young subjects. Pharmacological inhibition of SHP-1 resulted in recovery of TCR/CD28-dependent lymphocyte proliferation and IL-2 production of aged individuals to levels not significantly different than those of young donors. Furthermore, we report differences in the active (Y394) and inactive (Y505) phosphorylated forms of Lck in response to T cell activation in elderly donors. Our data suggest that the regulatory role of SHP-1 in T cell activation extends to its involvement in Lck-associated negative feedback in aging. Modulation of SHP-1 activity could restore altered T cell functions in aging, suggesting a powerful tool for improvement of immunosenescence. Our data suggest that the tyrosine phosphatase SHP-1, a key regulator of T cell signal transduction machinery is, at least in part, responsible for the impaired T cell activation in aging.

P2.05.07
MF59-induced ATP-signaling pathway is not impaired by immunosenescence thereby contributing to an efficient adjuvant activity in the elderly

***M. Gallotta**[1], M. Taccone[1], M. Tortoli[1], M. Vono[2,1], A. Bonci[1], D. Casini[1], S. Bertholet[1], E. De Gregorio[1], D. T. O'Hagan[1], A. Seubert[1];*
[1]Novartis V&D, Siena, Italy, [2]Dipartimento di Scienze Biomediche and Istituto CNR di Neuroscienze, Università di Padova, Padova, Italy.

MF59-adjuvanted influenza vaccine has been developed specifically for the elderly, since this age group typically responds inadequately to traditional influenza vaccines, due to immunosenescence. Several studies have been performed to identify MF59 mechanism of action in pre-clinical models. However, most of these studies have been conducted in young mice (6-8 weeks), which do not reflect the immune response of the elderly. Taking into consideration that several signalling cascades are altered during aging, we wanted to assess which MF59-activated immune events were still active in old mice (> 18 months), and performed a comparison to young mice in most of the relevant assays for MF59 activity.
We found differences in MF59-induced cytokines, with a lower pro-inflammatory response in the elderly. Yet, our results also show that MF59 still acts as adjuvant in elderly mice, enhancing immune cell recruitment, antigen-translocation to draining LNs, CD4 T cell responses and restores HI titers similar to those from young mice immunized with unadjuvanted vaccine. Further, since we recently showed that MF59 induces rapid and transient ATP-release in young mice, we tested functionality of this signalling pathway also in the elderly. Indeed, abrogation of ATP-signaling with apyrase – an ATP-hydrolyzing enzyme - completely blocks MF59-activity also in elderly mice suggesting an important role for extracellular ATP also in this age group. Understanding in elderly mice how the immune system is altered and how MF59 helps to overcome age-related limitations, will give us useful insight for future tailor-made vaccine solutions for this growing patient age group.

P2.05.08
The significance of thymic involution and the function of re-entryed T cells in thymus

***Y. Gao**, X. Pei, Y. Zhang;*
Department of Immunology, Peking university Health Science Center, Beijing, China.

During the aging, the phenomena named thymic involution show that the size of thymus is shrinking and the cellularity is decreased and the structure is disordered. Thymic involution is associated with reduced number of thymic output, meanwhile the number of T cell pool is maintained by the homeostatic expansion of T cells in the periphery. Thymic involution is the key point of immune senescence. Since the aged has worse resistance to tumor, infection and self-immune diseases, thymic involution is not thought as a benefit process to the individual. However, the reasons of thymic involution are not clear until now. Some believe that deficiency of hemopoietic stem cells is the major concern of thymic involution, but most agree with the point that the change of microenvironment is the essential reason of thymic involution. Some results suggest that peripheral T cells could go back to the thymus through some unknown mechanism, most of which are CD44hi, an activated phenotype. The function of these re-entryed T cells is not known. We find that thymic involution might be a beneficial process for individuals as increased numbers of memory T cells which is helpful to the immune response to the secondary infection with the same pathogen. These re-entryed activated T cells may play a role in thymic involution, especially of Th2 subsets.

P2.05.09
Targeting macrophages rescues age-related immune deficiencies in geriatric mice

C. Jackaman[1], *H. G. Radley-Crabb*[1], *Z. Soffe*[2], *T. Shavlakadze*[2], *M. D. Grounds*[2], *D. J. Nelson*[1];
[1]*Curtin University, Bentley, Australia,* [2]*University of Western Australia, Perth, Australia.*

Changes to innate cells, such as macrophages and myeloid-derived suppressor cells (MDSCs), during aging in healthy or tumor-bearing hosts are not well understood. We compared macrophage subpopulations and MDSCs from healthy young (6 - 8 weeks) C57BL/6J mice to those from healthy geriatric (24 - 28 months) mice. Spleens, lymph nodes and bone marrow of geriatric hosts contained significantly more M2-macrophages and MDSCs than their younger counterparts. Peritoneal macrophages from geriatric, but not young, mice co-expressed CD40 and CX3CR1 that are usually mutually exclusively expressed by M1 or M2 macrophages. Nonetheless macrophages from geriatric mice responded to M1 or M2 stimuli similarly to macrophages from young mice, although they secreted higher levels of TGF-β in response to IL-4. We mimicked conditions that may occur within tumors by exposing macrophages from young versus geriatric mice to mesothelioma or lung carcinoma tumor cell-derived supernatants. Whilst both supernatants skewed macrophages towards the M2-phenotype regardless of age, only geriatric-derived macrophages produced IL-4, suggesting a more immunosuppressive tumor microenvironment will be established in the elderly. Both geriatric- and young-derived macrophages induced allogeneic T cell proliferation, regardless of the stimuli used, including tumor supernatant. However, only macrophages from young mice induced T cell IFN-γ production. We examined the potential of an IL-2/agonist anti-CD40 antibody immunotherapy that eradicates large tumors in young hosts to activate macrophages from geriatric mice. IL-2/CD40 activated macrophages rescued T cell production of IFN-γ in geriatric mice. Therefore, targeting macrophages with IL-2/anti-CD40 antibody may improve innate and T cell immunity in aging hosts.

P2.05.11
Crucial role of Menin in the regulation of CD4 T cell immunosenescence

M. Kuwahara[1], *T. Nakayama*[2], *M. Yamashita*[3];
[1]*Kazusa DNA Research Institute, Kisarazu-shi, Japan,* [2]*Chiba University, Chiba-shi, Japan,* [3]*Ehime University, Toon-shi, Japan.*

Although altered CD4 T cell functions play an important role in immunosenescence, the molecular mechanisms remain unclear. Menin is a tumor suppressor encoded by the *MEN1* gene that is mutated in patients with multiple endocrine neoplasia type 1. We assessed the role of Menin in T cell functions and found that Menin controls senescence of CD4 T cells. *Menin*-deficient (Men KO) effector CD4 T (Th) cells normally proliferated after antigenic stimulation during the initial activation phase. However, Men KO Th cells showed a markedly reduced proliferation rate in comparison to the control wild-type (WT) Th cells from day 5 after the initial antigenic stimulation, even in the presence of exogenous IL-2. Menin KO Th cells also showed a senescence-like phenotype more rapidly than WT Th cells, based on the expression of senescence-associated β-galactosidase activity and cell cycle regulators. A prolonged activation of RelA/p65, a characteristic feature of senescent cells, was also detected in Menin KO Th cells. In addition, Menin KO Th cells expressed large amounts of pro-inflammatory cytokines, chemokines, enzymes, and angiogenic factors including *Il6*, *Opn, Ccl3, Ccl4, Ccl5, Cxcl2*, *Gzms, S100a4, Pdgfα,* and *Vegfc*. These findings suggest that Menin KO Th cells exhibited a senescent-associated secretory phenotype (SASP). Therefore, Menin KO CD4 T cells underwent premature senescence after antigenic stimulation.

P2.05.12
Gender specific immune status differences in children and adults

J. Lagereva[1,2], *S. Belyaeva*[1];
[1]*Clinical and Diagnostic Centre, Ekaterinburg, Russian Federation,* [2]*Institute of Immunology and Physiology, Ural Branch of the Russian Academy of Sciences, Ekaterinburg, Russian Federation.*

150 healthy children 7 months-18 years and 45 adults 25-45 years of age balanced by sex were studied to identify gender specific immune status differences dependent from sex hormone concentrations. As result of study it was found that up to 14 years of age the major gender-dependent difference was found among innate immunity phenomena: higher efficacy of phagocytic leucocytes was identified in males. The level of phagocytic activity was correlated with serum progesterone concentration. In older age groups: adolescents 15-18 years and adults the adaptive immunity parameters demonstrated gender-specific differences.Th1 lymphocytes absolute count was increased in male adolescents 15-18 years of age and was correlated with dehydroepiandrosterone sulfate level. Th2 lymphocytes level was significantly higher in females than in males and was correlated with estradiol concentration. IgG and IgM concentrations were higher in adolescent girls and females than in male subjects. Innate and adaptive immunity quantitative factors' gender-specific differences correlate with changes of sex hormones concentrations.

P2.05.13
Lipid laden multilocular cells in the aging thymus are phenotypically heterogeneous

L. G. P. Langhi[1], *L. R. Andrade*[1], *M. K. Shimabukuro*[1], *D. D. Taub*[2], *R. Borojevic*[1], *V. de Mello-Coelho*[1];
[1]*Instituto de Ciências Biomédicas - UFRJ, Rio de Janeiro, Brazil,* [2]*VA Medical Center, Washington, DC, United States.*

Age-related thymic involution is characterized by decreased thymopoiesis and increased white adipose tissue mainly in the septa region of the thymus. Previously, we showed lipid-laden multilocular cells (LLMC) expressing pro-inflammatory factors inside the aging thymus. Herein, we characterized the distribution, morphology and phenotype of intrathymic LLMC in middle-aged Balb/c mice. LLMC were found in subcapsular region (SC-LLMC) and deeper in parenchyma (P-LLMC), including in perivascular area (PV-LLMC). The number of SC- and P-LLMC increase in the thymus with age. Furthermore, LLMC exhibit fibroblastoid, globular or stellate morphologies in distinct regions of the thymus. Ultrastructural features noticed in LLMC includes numerous lipid droplets of different electrondensities, lipofuscin granules and autolipophagossomes. Autophagic activity was confirmed by immunofluorescence staining for beclin and perilipin (Plin) in these cells. In addition, we noticed membrane contacts between P-LLMC and thymic epithelial cells, lymphocytes or mast cells, which number increase in the thymus with age. Some P-LLMC in a juxtacrine interaction with lymphocytes presented long membrane protrusions resembling telocytes. PV-LLMC contacting thymocytes and endothelial cells were observed as well. Phenotypically, intrathymic LLMC were positively stained for PPAR-γ2 or UCP1, markers for preadipocytes or brown adipocytes, respectively. Moreover, Iba1+Plin+ macrophages, α-SMA+Plin+ or NG2+Plin+ pericytes were identified in the aging thymus. LLMC were negative for cytokeratin expression. In conclusion, intrathymic LLMC are able to interact with various microenvironmental cells and correspond to a population of distinct cell types. LLMC of different phenotypes might play distinct roles in the physiology of the aging thymus and in its involution process.

P2.05.14
Ageing impairs macrophage phagocytosis: impact of altered cellular microenvironment?

***E. Linehan**, D. C. Fitzgerald;*
Queen's University Belfast, Belfast, United Kingdom.

Ageing results in deterioration of the immune system and is associated with an increased susceptibility to infection and impaired wound healing in the elderly. Phagocytosis is an essential process in both wound healing and immune defence. We hypothesised that macrophage phagocytosis is impaired with age which may be due to age-related cellular changes in the peritoneum of aged mice. We investigated the efficiency of peritoneal and bone-marrow derived macrophages from young and aged mice to phagocytose fluorescent particles. Phagocytosis was analysed by flow cytometry and immunofluorescence microscopy. In addition, *in vivo* phagocytosis was measured by intraperitoneal injection of fluorescent particles in young and aged mice. Proportions of immune cell types in the peritoneum of young and aged mice were also characterised. Phagocytosis was significantly reduced in peritoneal macrophages from aged mice compared to young mice, both *in vitro* and *in vivo*. Interestingly, ageing did not significantly alter phagocytosis in bone marrow-derived macrophages generated from young or aged mice in our experimental system. We found a consistent decrease in the percentage of macrophages in the peritoneum of aged mice and this was accompanied by an increase in the percentage of $B220^+$ cells and $CD3^+$ cells. In conclusion, phagocytosis is impaired in macrophages from aged mice. This finding has important implications for defence against infection and tissue repair in the elderly. Future work will investigate impact of increased $B220^+$ and $CD3^+$ cells on macrophage function.

P2.05.15
The effect of anti-CMV response differs in nonagenarians and young controls: a transcriptomic analysis

***S. Marttila**[1], J. Jylhävä[1], M. Jylhä[2], A. Hervonen[2], M. Hurme[1];*
[1]Department of Microbiology and Immunology, School of Medicine, University of Tampere, Tampere, Finland, [2]School of Health Sciences, University of Tampere, Tampere, Finland.

Cytomegalovirus (CMV) is a common herpes virus; seroprevalence in the population increases with age, being 85-95% in elderly individuals. CMV seropositivity is associated with dramatic changes in the immune system, especially in the T-cell pool. The exact mechanisms of how CMV affects the immune system are yet to be identified. However, several epidemiological studies show that the strength of the anti-CMV response, quantified as the anti-CMV IgG antibody titer, is of significance in the pathogenesis. The high anti-CMV titer has for example been associated with shortened lifespan. To get information about the immunological processes associated with high anti-CMV response we now performed a genome-wide transcriptomic analysis of peripheral blood mononuclear cells (PBMCs) of 138 nonagenarians and 16 young controls (aged 19-30 years). We identified 1305 and 441 transcripts whose expression correlated ($p<0.05$) with anti-CMV titer in nonagenarians and young controls, respectively. Further, an IPA canonical pathway analysis (Ingenuity® Systems) identified 95 pathways in nonagenarians and 26 pathways in young controls that were associated with the CMV titer. Of these pathways, only 10 were common to nonagenarians and young controls. The most enriched signaling pathway categories in nonagenarians were “Cellular Growth” and “Proliferation and Development” and in the young controls the most enriched categories were “Cellular Immune Response” and “Cytokine Signaling”. From our results it appears that in the nonagenarians the CMV titer has a wide-spread effect on basic cellular functions, whereas in the young controls the main effect is the viral defense.

P2.05.16
Fetal microchimerism induces positive effects on the immune system of elderly individuals

***T. Nevalainen**[1], J. Jylhävä[1], S. Marttila[1], T. Kuparinen[1], M. Jylhä[2], A. Hervonen[2], M. Hurme[1];*
[1]Department of Microbiology and Immunology, The School of Medicine, University of Tampere, Tampere, Finland, [2]The School of Health Sciences, University of Tampere, Tampere, Finland.

After a pregnancy small numbers of cells originating from the fetus persist in the mothers, a phenomenon called fetal microchimerism (FMc). It has been suggested to be associated either with positive or negative (e.g. autoimmunity) health effects. We decided to find out whether FMc can still be detected in elderly individuals (nonagenarians) and whether it has any effect on the aging of the immune system. The study cohort consisted of 106 nonagenarians who had given birth to 0-5 sons. DNA was extracted from the whole blood and the Y chromosome specific DYS-14 multicopy gene was used for the quantification of fetal cells with quantitative PCR. 34 samples out of 106 gave positive DYS-14 signal with the mean of 18 fetal cells in milliliter of blood. The quantity of fetal cells correlated positively with the proportion of CD4(+) helper T cells ($p=0.015$, $r=0.238$) and negatively with the proportion of CD8(+) cytotoxic T cells ($p=0.046$, $r=-0.196$). In addition, whole genome transcriptome analysis indicated 635 significantly up-regulated and 1083 down-regulated genes. Further gene pathway analysis revealed 125 significantly ($p<0.05$) overrepresented pathways of which several were immunologically related such as positive regulation of T cell activation ($p=0.0001$) and regulation of lymphocyte activation ($p=0.0003$). In addition 19 pathways were significantly ($p<0.05$) underrepresented. In conclusion, the presence of male fetus derived cells in nonagenarian females seems to induce positive effects on their immune system. This phenomenon appears to be long-lasting as their last pregnancy took place several decades ago.

P2.05.17
Bone marrow T cells from the femur are similar to iliac crest derived cells in old age and represent a useful tool for studying the aged immune system

***T. Pritz**[1], K. Landgraf-Rauf[1], D. Herndler-Brandstetter[1], R. Rauf[2], J. Lair[2], R. Gassner[3], B. Weinberger[1], M. Krismer[2], B. Grubeck-Loebenstein[1];*
[1]Institute for Biomedical Aging Research, University Innsbruck, Innsbruck, Austria, [2]Department of Orthopedic Surgery, Innsbruck Medical University, Innsbruck, Austria, [3]Department of Cranio-Maxillofacial and Oral Surgery, Innsbruck Medical University, Innsbruck, Austria.

$CD4^+$ and $CD8^+$ T cells reside in the human bone marrow (BM) and show a heightened activation state. However, only small sample sizes are available from the iliac crest. Larger samples can be obtained from the femur shaft. Therefore it was the goal to compare the phenotype and function of BM T cells from different sources from elderly persons and to investigate how femur derived BM T cells can serve as a tool to gain a better understanding of the role of adaptive immune cells in the BM in old age. As expected the yield of mononuclear cells was higher from femur than from iliac crest samples. There were no phenotypic differences between BMMC from the two sources. Compared to PBMC, both BM sample types contained fewer naïve and more antigen-experienced $CD4^+$ and $CD8^+$ T cells, which, in contrast to peripheral cells, expressed CD69. Cytokine production was also similar in T cells from both BM types. Femur derived BM samples allowed the generation of T cell lines using non-specific and specific stimulation. On the one hand such lines can be used for studies on the interaction of different types of BM cells. On the other hand the generation of pp65 CMV_{NLV} specific T cell lines can be used in studies on the clonal composition of antigen specific BM T cells. In conclusion, our results demonstrate that BMMC from the femur shaft are a useful tool for studies on the role of T cells in the BM in old age.

P2.05.18
Association analysis between CTLA-4 polymorphisms and bipolar disorder

***A. Rafiei(Ph.D)**, Z. Hosseini Khah, M. Taheri, S. Hosseini, M. Vesali; Molecular and Cell Biology Research Center, Mazandaran University of Medical Sciences, Sari, Mazandaran, Iran, Sari, Iran.*

Background: The immunogenetics of bipolar affective disorder (BPD) comprises a complex area of study with growing importance. In BPD, massive immune activation might be due to immune dysregulation. The current study investigated whether is a contribution of CTLA-4 SNPs in a Caucasian population with bipolar affective disorder (BPD).
Methods: This case-control association study assessed the association of four common CTLA-4 SNPs (-318 C/T, -1661 A/G and -1722 C/T in the promoter region and +49A/G in exon 1) with BPD subjects. Genotyping was performed in 312 BPD patients and 308 healthy controls by polymerase chain reaction-fragment length polymorphism or amplification refractory mutation system analysis.
Results: The allelic and genotype frequencies of only -1661 A/G SNP were more prominence in BPD patients than that controls (0.0003 and 0.04, respectively). Multivariate logistic regression analysis was demonstrated that G allele carriage genotypes had significantly increased risk of BPD up to 1.9 fold (95% CI; 1.3- 2.7, p= 0.0008). Gender stratification was revealed CTLA-4 -1661 A/G and +49 A/G SNPs are associated with increased susceptibility to BPD only in female patients. In addition, female patients who carried -1661G allele, experienced more depressive episodes than male patients.
Conclusion: Our results suggest that CTLA-4 gene variants might be associated to increased risk of BPD, particularly, in a gender-specific manner.

P2.05.19
Survival, proapoptotic proteins and TNFR induced in senil cataract

***A. Robles-Contreras**[1], M. Arredondo-Flores[2], J. L. Oliva-Ramirez[3], C. Palacio-Pastrana[2], L. L. Arroyo[2], O. Guerrero-Berguer[2], H. J. Perez-Cano[1];*
[1]Hospital Foundation "Nuestra Señora de la Luz" Biomedical Research Center, Mexico city, Mexico, [2]Hospital Foundation "Nuestra Señora de la Luz", Anterior segment department, Mexico city, Mexico, [3]Immunoregulation lab, Escuela Nacional de Ciencias Biológicas,IPN, Mexico city, Mexico.

Purpose: Various studies in murine models have suggested alterations in apoptosis of epithelial cells of the lens to cause cataract. Apoptotic proteins have not been described in human, so we consider apoptotic proteome study of senile cataract for a greater understanding of its pathogenesis.
Methods: We performed a continuous curvilinear capsulorhexis to obtain lens epithelium, both patients with senile cataract patients as well as healthy crystalline underwent phacorefractive surgery, samples were placed in a lysis buffer. Once all samples were collected, we proceeded to perform the apoptotic protein microarray, as suggested by the vendor (R&Dsystems) adjusting to a 300mg of protein. After processing the microarray membrane were visualized with iBOX and analyzed density of each point with Vision Works LS software. Data were normalized relative to the positive control and the negative control. We considered as a biological significance more than 2-fold change.
Results: Apoptotic proteome analysis in senile cataract showed that apoptotic and anti-apoptotic proteins were differentially expressed. By analyzing the proteins with which were greater increases, we found that the profile type is found antiapoptotic and survival: clusterin, XIAP, (>7fold change, fc), (6-7fc) (5-6fc) (4-5fc), (3-4fc) (2-3fc)
Conclusions: We observed a survival proteome in general. Importantly we observed a increased expression of TNFR1SFA1, we need more studies to know if this increased is due to a inflammatory microenvironment or is due a response of the signaling of survival in the lens epithelial cells

P2.05.20
CMV infection associates to the expansion of polyfunctional CD8+CD57+ T cells in young individuals

*A. Pera[1], C. Campos[1], B. Sanchez-Correa[2], C. Alonso[1], R. Tarazona[2], **R. Solana**[1];*
[1]IMIBIC-Reina Sofia Hospital-University of Cordoba, Cordoba, Spain, [2]Dpto. Inmunología. Universidad de Extremadura, Cáceres, Spain.

CMV infection plays is a major factor involved in the development of T cell age-associated changes (immunosenescence). CMV infection is associated in elderly individuals to T cell repertoire shrinkage and clonal expansion of CMV-specific CD8+ T cells with limited functional capacities. It also has a deleterious effect on the efficacy of influenza vaccination in the elderly, suggesting that CMV chronic infection in old age restricts immunological diversity and impairs the immune system functionality. The efficiency of the T cell response is associated with the capacity of responding cells to produce several cytokines (“polyfunctionality” as a marker of quality) rather than with the percentage (quantity) of specific T cells.
The aim of this work is to study in young healthy donors the effect of CMV infection on CD8+ T cells polyfunctionality, degranulation (CD107a) and INFg and TNFa production in response to CMV proteins (pp65/IE-1) and to a nonspecific antigen (SEB).
CD8+ T cells from CMV-seropositive individuals are more polyfunctional than CD8+ T cells from CMV-seronegative, not only in response to CMV peptides, but also in response to SEB stimulation, indicating that CMV infection improves the quality of CD8+ T cells in young individuals. In addition, CD8+CD57+ T cells are expanded in CMV-seropositive young individuals. These CD8+CD57+ T cells are more polyfunctional than CD8+CD57- T cells. Therefore, CMV infection in young individuals enhances the functionality and consequently the quality of CD8+ T cells and this effect is most probably due to the expansion of polyfunctional CD8+CD57+ T cells.

P2.05.21
Association between early development of cellular immunity to cytomegalovirus and Graft-Versus Leukemia effect in pediatric transplantation

*V. Guérin-El Khourouj[1], R. Porcher[2], S. Leveillé[3], J. LeGoff[4], B. Pédron[1], A. Baruchel[3], J. Dalle[3], **G. Sterkers**[1];*
[1]Robert Debré Hospital - Laboratory of Immunology, Paris, France, [2]Saint Louis Hospital - Department of Biostatistics, Paris, France, [3]Robert Debré Hospital - Department of Haematology, Paris, France, [4]Laboratory of Virology – Saint Louis Hospital, Paris, France.

Background: A favorable impact, on graft-versus leukemia effect (GVL), from early cytomegalovirus-(CMV) reactivations after allogeneic hematopoietic-stem cell transplantation (HSCT) has been suggested. The role, in this process, for the immune response triggered by CMV remains to be addressed.
Methods: 108 children (median age 8 years) were included at HSCT following myeloablative conditioning for primary acute leukemia. HSCT were from HLA-matched related (42%) or unrelated (44%) donors. 15% of patients received cord-blood units. CMV-DNAemia was programmed weekly for at least 3 months post-HSCT. Immunity to CMV was evaluated sequentially since the first month post-HSCT using 3H-Thymidine incorporation assay (T-cell proliferation) and intracytoplasmic cytokine accumulation assay (IFNγ secretion).
Results: Median follow-up from transplant was 40 months; the cumulative incidence of recipients with CMV-DNAemia at day 120 was 31% (median time to onset: 26 days) and of recipients with anti-CMV immunity (T-cell proliferation and/or IFNγ secretion) at that time was 38% (median time to onset: 2 months). Among the 89 patients without disease at day 120 multivariate analysis revealed different risk factors for relapse according to anti-CMV immunity and CMV-reactivation (p=0.039), with the lowest risk (7%) in recipients with immunity but no reactivation and the highest risk (40%) in recipients with reactivation but no immunity (HR: 0.06, 95%CI 0.005-0.69, p=0.024).
Conclusions: An association between early development post-HSCT of immunity to CMV and GVL was observed. The mechanisms that may be involved in this process will be discussed.

Introduction: Community-acquired pneumonia (CAP) is a major cause of morbidity and mortality worldwide. Increasing age has been associated with elevated circulating levels of proinflammatory mediators.
Aim: To determine the impact of aging on the systemic inflammatory response to CAP.
Methods: 201 CAP patients were enrolled. Blood samples were obtained from 171 patients for measurement of inflammatory mediators upon presentation, and day 2, 3, 5, 10 and >30. For the current analysis only patients ≤ 50 and ≥ 80 years were included. Pneumonia Severity Index (PSI) score was calculated at presentation.
Results: This study encompassed 46 CAP patients ≤ 50 years (median 37) and 41 CAP patients ≥ 80 years (median 84). Old patients had more comorbidity, especially chronic obstructive pulmonary disease (49%). In both groups *Streptococcus pneumoniae* was the common causative microorganism. Whereas most young patients had a PSI score of I (54%), 98% of old patients had a PSI score ≥ III ($P < 0.0001$). Four old patients died versus none of the young patients ($P < 0.05$). Old patients demonstrated lower serum C-reactive protein levels on admission and during the course of their disease ($P < 0.001$). The overall serum IL-8 response was higher in older patients ($P < 0.001$), whereas the overall serum IL-1RA response was lower in this group ($P < 0.001$). Serum IL-6 was not discriminative.
Conclusions: Cytokine biomarkers of CAP severity are differentially influenced by a high age. Old CAP patients have lower CRP levels than young CAP patients in spite of more severe disease.

P2.05.23
Age-related changes in cell surface markers of BALB/C mice: A flow cytometric analysis

E. Yavuz*, S. Hasgur, E. U. Bagriacik;*
Gazi University Immunology Research and Application Center, Ankara, Turkey.

Introduction: Age-related phenotypic alterations have been indentified in lymphocytes. However, the effect of aging on lymphocyte surface markers in BALB/c mice was not studied inclusively and systematically in a single study.The aim of this study is to analyze and identify the cell surface markers of lymphocyte populations from various lymphoid organs of young and aged mice.
Material and Methods: Spleen, lymph nodes, mesenteric lymph nodes, thymus, and intraepithelial T lymphocytes were isolated from BALB/c mice. Flow cytometric analysis of lymphocytes was performed.
Results: The CD4:CD8 ratio has declined with age in thymus. In spleen, while the number of $CD4^+CD45R^+$, $CD4^+CD28^+$, $CD4^+CTLA4^+$, and $CD8^+CD28^+$, $NKpan^+$ cell populations have increased with age, TCRαβ+ and $CD62L^+$ cell counts have decreased. In lymph nodes, $CD4^+CTLA4^+$, $CD8^+CD45RB^+$, $CD8^+CD45R^+$, $CD11b^+$, and $CD11c^+$ cell numbers have increased with age but the number of $CD8^+CD28^+$, $CD4^+CD45RB^+$ cells have declined. Partially different results were seen in mesenteric lymph nodes: $CD4^+CD8^-$, $CD4^+CD25^+$, $CD8^+CD25^+$, $CD8^+CD28^+$, $CD62L^+$, and $CD11b^+$ cell counts were less in older mice. In intestinal intraepithelial lymphocytes, the number of $TCR\gamma\delta^+$ cells has decreased with increasing age while $CD4^+CD8\alpha^+$ cell count has increased.
Conclusions: The changes in cell surface markers of T cells of lymphoid organs and mucosal lymphoid tissues in BALB/c mice are crucial during aging. The number of innate immune system cells also differs between young and old BALB/c mice. These results might be important to understand the physiological process of immune senescence and immune regulatory mechanisms in the aging immune system.

P2.05.24
irradiation indeces immune modification in splenocytes

Y. Yoshida*, Y. Song, R. Okazaki, T. Kanazawa;*
Univ.Occup.& Environ. Health, Dep. Imm., Kitakyushu, Japan.

It is reported that irradiation induces shortened lifespan in mice with dose-dependent. We also previously reported that young-age irradiated mice induces shorten lifespan compared to non-irradiated mice. In addition, the number of lymphocytes in the S- and G2/M-phases was significantly increased in the irradiated mice. However, the detail mechanism is still not fully understood. In the present study, we demonstrated that irradiation at young age induces immune-modulation of splencytes in old age mice. The $p53^{+/-}$ mice were exposed to 3 Gy at 8 weeks (young age) of whole-body irradiation and were sacrificed at 54 weeks of age. Irradiation at young age but not at old age enhanced CDK2 and p21expression in the splenocytes. Western blotting demonstrated phosphorylation of IKKα, IκBα and p65 was induced by irradiation at young age. Furthermore, electrophoretic mobility shift assay demonstrated increased activated-NF-κB in the splenocytes of the mice irradiated at young age but not at old age mice. The expression of IL-6 production was increased in the splenocytes of the mice irradiated at young age. Finally, ATP level in splenocytes was measured, and high level of ATP was observed in the mice irradiated at young age both female and male mice compared to non-irradiated mice. Taken together, these results suggest that young age irradiation induced immune-modulated response in the second lymphoid organ, which relates to be activation of NF-κB, and this effect sustained until old age.

P2.05.25
Cytomegalovirus infection impacts the development of CD4 memory T cells in young individuals

Z. Zadrazil*, A. Larbi, A. Vasudev;*
Singapore Immunology Network, Singapore, Singapore.

With increasing age the immune system accumulates memory lymphocytes some of which are senescent on the expense of naive cells. Such a tendency renders the immune system incapable of optimal immune responses. Latent infections fasten this process significantly. Cytomegalovirus (CMV) has been identified as one “master” of this phenomenon. Mechanism of such an impact on the immune system remains unknown, however it has been postulated that this is simply a result of constant immune responses against the virus. We have compared the immune profile of more than 300 young individuals. Employing staining for markers of different stages of memory cells development, i.e. CD4, CD8, CD27, CD28, CD57 and CD45RA, we have found significant differences in the distribution of CD4 subpopulations between CMV+ and CMV- individuals. Surprisingly no significant differences were found in the CD8 subpopulations. In elderly, the immune system inclines towards late-stage memory cells, i.e. CD27-CD28-CD57+CD45RA+/-. We have found this is also true for young individuals infected with CMV. This suggests that CMV directly affect memory/senescent T cell generation. Understanding the mechanism could be essential. Comparing the CD4/CD8 ratio shows no difference between CMV+ and CMV-. Analysing complex data of plasma molecules will soon give us more clues about the impact of CMV on the immune system in aging.

P2.06.01
CCL17 deficiency is associated with beneficial CNS immune responses and prevents cognitive decline in a mouse model of Alzheimer's disease

*K. Neitzert[1], Ö. Albayram[1], R. Göhrs[1], I. Karaca[2], A. Ramirez[3], J. Walter[2], F. Jessen[3], W. Maier[3], A. Zimmer[1], **J. Alferink**[1,3,4];*
[1]Institute of Molecular Psychiatry, Bonn, Germany, [2]Laboratory of Molecular Cell Biology, Department of Neurology, Bonn, Germany, [3]Department of Psychiatry, University Hospital of Bonn, Bonn, Germany, [4]Department of Psychiatry, University, Münster, Germany.

The C-C chemokine CCL17 regulates leukocyte trafficking during inflammation, however, its role in Alzheimer's disease (AD) pathogenesis remains undefined. This study demonstrates that CCL17 controls amyloid β (Aβ) deposition, neuroinflammation, and cognitive decline in a mouse model for AD. CCL17 deficient APP/PS1 mice (APP/PS1-CCL17$^{E/E}$) showed reduced Aβ brain levels, and were protected against neuronal loss and cognitive deficits. Enhanced microgliosis and brain recruitment of Ly6C^{+}CCR2^{+} macrophages expressing mannose receptors associated with elevated brain IL-10 levels pointed to beneficial immune responses in these mice. In the absence of CCL17 we observed accelerated uptake of Aβ, enhanced IL-10 release by activated microglia, reduced expression of the receptor for advanced glycation end products (RAGE) and upregulated Aβ-degrading enzyme neprilysin (NEP) in the brains of APP/PS1 mice. These newly identified roles for CCL17 in regulating microglia function and memory loss suggest that targeting this chemokine may harbor therapeutic potential for the treatment of AD.

P2.06.02
T-cell immunoglobulin- and mucin-domain-containing molecule (Tim)-1 is a novel physiological ligand for P-selectin controlling activated T cell trafficking under inflammatory conditions

***S. Angiari**[1], T. Donnarumma[1], B. Rossi[1], G. Piacentino[1], S. Dusi[1], S. Xiao[2], V. K. Kuchroo[2], P. D. Rennert[3], G. Constantin[1];*
[1]Dept. of Pathology and Diagnostics, University of Verona, Verona, Italy, [2]Center for Neurologic Diseases, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, United States, [3]Dept. of Molecular Discovery and Immunobiology, Biogen Idec Inc., Cambridge, MA, United States.

T-cell immunoglobulin- and mucin-domain (Tim) molecules are transmembrane glycoproteins involved in a variety of immune processes. Tim-1 regulates T cell-mediated responses, and has structural similarities with mucosal addressin MAdCAM-1 and mucin PSGL-1. The aim of our study was to investigate a role for Tim-1 in lymphocyte trafficking under inflammatory conditions.
RESULTS. Tim-1 bound P-, E- and L-selectin *in vitro*, and Tim-1 covered microbeads rolled on P- and E-selectin under flow. T_H1 and T_H17 cells from Tim-1 mutant (Tim-1$^{\Delta mucin}$) mice lacking Tim-1 mucin domain had a reduced ability to roll on P-selectin, but not E-selectin, when compared to WT cells, suggesting that Tim-1 is a rolling receptor on T cells. Intravital microscopy studies shown that Tim-1$^{\Delta mucin}$ T_H1 and T_H17 cells had a reduced capability to interact with P-selectin *in vivo*, in thrombin-activated mesenteric venules, and to migrate in the inflamed skin in a model of contact hypersensitivity. Furthermore, in inflamed cerebral venules expressing P-selectin, that Tim-1$^{\Delta mucin}$ activated T cells displayed reduced rolling and arrest, when compared to WT cells, suggesting a role for Tim-1 in the control of primary adhesion also on activated brain endothelium. Finally, Tim-1$^{\Delta mucin}$ T_H1 cells had a reduced ability to migrate in the inflamed CNS, and induce a less sever experimental autoimmune encephalomyelitis compared to WT cells.
In conclusion, our data suggest that Tim-1 represents a novel physiological ligand for P-selectin controlling trafficking of T cells under inflammatory conditions.

P2.06.03
Expression and function of selectins during human development in utero

***K. Auvinen**[1,2], S. Jalkanen[1,2], M. Salmi[1,2];*
[1]University of Turku, Turku, Finland, [2]National Institute of Health and Welfare, Turku, Finland.

Continuous recirculation of lymphocytes between the blood and lymphoid organs is vital for adequate immune surveillance. Recirculation is mediated by molecular interactions between adhesion molecules on endothelium and their counterparts on lymphocytes. Selectins are a family of adhesion molecules responsible for initial interactions of leukocytes with endothelium. However, relatively little is known about the role of selectins before and at the birth in humans. Here we have studied the expression and function of selectins and their ligands during human ontogeny. We examined cord blood mononuclear cell rolling on and adhesion to stimulated human umbilical vein endothelial cell (HUVEC) monolayer under flow-conditions in vitro in the presence of antibodies against selectins and their counter-receptors. The expression levels of L-selectin, PSGL-1 and cutaneous lymphocyte-associated antigen (CLA) were analyzed by flow cytometry. Immunohistological stainings for endothelial selectins in different tissues during ontogeny were made. We found that the rolling of cord blood mononuclear cells was mediated by L-, E- and P-selectins like in adults. The expression levels of L-selectin, PSGL-1 and CLA were similar on adult and cord blood mononuclear cells. Endothelial selectins were expressed in fetal tissues. P-selectin was expressed already during the first trimester and E-selectin at least from the gestational week 32 onwards. We conclude that selectins are synthetized before birth and are functional thus mediating leukocyte rolling. These results have significance in understanding the mechanisms of inflammatory responses during fetal development and potentially in the use of anti-adhesive therapies.

P2.06.04
Susceptibility of Mycobacterium tuberculosis-infected CCR4 deficient mice is associated with a balance between lymphocytes and Foxp3+ regulatory cells

***T. B. Bertolini**[1], A. R. Piñeros[1], R. Q. Prado[1], A. F. Gembre[1], J. C. Alves Filho[2], V. L. Bonato[1];*
[1]Department of Biochemistry and Immunology, School of Medicine of Ribeirão Preto, University of São Paulo, Ribeirão Preto, São Paulo, Brazil., Ribeirão Preto, Brazil, [2]Department of Pharmacology, School of Medicine of Ribeirão Preto, University of São Paulo, Ribeirão Preto, São Paulo, Brazil., Ribeirão Preto, Brazil.

Introduction: The control of M. tuberculosis infection requires granuloma formation as consequence of the leukocyte recruitment, partially dependent on chemokine and chemokine receptor. The pattern of chemokine and chemokine receptor expression drives the recruitment of specific leukocyte populations, including lymphocyte subsets. Chemokine receptor 4 (CCR4) is mostly expressed in Th2 CD4+ cells and CD4+Foxp3+ cells. The aim of this study was to assessment the participation of CCR4 in response to pulmonary infection with M. tuberculosis. Methods and Results: CCR4 deficient (CCR4-/-) and wild type (WT) mice were infected with 1x105 bacilli by intra-tracheal route. Seventy days post-infection, Colony-Forming Unit (CFU) number in the lung and spleen, cell subsets and cytokine production were evaluated in the lungs of CCR4-/- and WT mice. At the chronic phase (70 days), CCR4-/- (n=14) mice were more susceptible to M. tuberculosis infection compared to WT (n=14) mice ($p<0.05$). In addition, 70-day infected CCR4-/- mice showed an increase in the total number of CD4+ and CD8+ cells, an increase in the frequency of CD8+ cells, followed by a decrease in the frequency of NK and CD4+Foxp3+ cells compared with WT mice. The lungs of infected CCR4-/- mice also exhibited a significant reduction of IL-17 and production of IFN-γ higher than those observed in infected WT mice. Conclusion: These data show that CCR4 plays a key role at the chronic phase of the infection and suggest that the balance between T lymphocytes and Foxp3+ regulatory cells may drive the resistance for tuberculosis.

Systemic lupus erythematosus is a chronic, inflammatory autoimmune disease, the development of which is characterized by a progressive loss of renal function. Such dysfunction is associated with leukocyte infiltration in the glomerular and tubulointerstitial compartments in both human and experimental lupus nephritis. Here, we investigated the role of the Ccr1 chemokine receptor in this infiltration process during the progression of nephritis in the lupus-prone New Zealand Black/New Zealand White (NZB/W) mouse model. We found that peripheral T cells, macrophages, and neutrophils but not B cells from nephritic NZB/W mice were more responsive to Ccr1 ligands than the leukocytes from younger prenephritic NZB/W mice. Acute treatment of nephritic NZB/W mice with the orally available Ccr1 antagonist BL5923 decreased renal infiltration by myeloid cells and T cells, whereas late onset BL5923 treatment reduced tubulointerstitial and glomerular injuries, delayed fatal proteinuria and prolonged animal lifespan. In contrast, systemic and renal humoral autoimmunity was unaffected in BL5923-treated mice, which likely reflected the unchanged numbers of infiltrated B cells in the kidneys. Altogether, these findings define a pivotal role for Ccr1 in the recruitment of T and myeloid cells to inflamed kidneys of NZB/W mice, which in turn contributes to the progression of renal injury.

P2.06.06
Local and systemic effects of chronic peritonitis induced by pristane in the absence of galectin-3

C. Brand[1], *F. L. Oliveira*[1], *T. P. Costa*[1], *F. E. P. L. Abreu*[1], *R. Borojevic*[1], *R. Chammas*[2], *M. C. El-Cheikh*[1]; [1]*Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil,* [2]*Universidade São Paulo, São Paulo, Brazil.*

Recent studies of our group show that galectin-3-/- (gal-3-/-) animals present larger amount of plasma cells in lymphoid organs. Furthermore, in B cell neoplasms, high concentrations of gal-3 provide greater tumor resistance and progression. An important model for induction of plasmacytomas is the injection of pristane, leading to chronic granulomatous inflammation rich in macrophages, plasma cells and peritoneal B cells. Thus, the objectives of this study were to evaluate quantitative and qualitatively peritoneal cavity and lymphoid organs, and analyze formation of oil granulomas due to stimulus of pristane. Animals were intraperitoneally injected with pristane or maintained under physiological conditions. We observed a significant increase of total cell number in peritoneal cavity of injected WT animals, in contrast to reduced cellularity of gal-3-/- animals. Kinetics of cell cycle from peritoneal cavity cells was modified and annexin-V+ cells were increased in gal-3-/- animals. Quantification of peritoneal subpopulations showed an increase in neutrophils, and decreased numbers of both B and T lymphocytes. The spleen presented large amounts of lipid droplets and CD138+ plasma cells abnormally distributed in gal-3-/- animals, forming cell clusters in splenic parenchyma. Tertiary lymphoid organs were formed in both groups, but in gal-3-/- mice less or none lymphoid structures were present in oil granulomas and annexin-V+ cells were increased compared to WT animal. The results obtained allow us to conclude that the kinetics of inflammatory cells occurs differently in the absence of galectin-3, modulating lymphoid and myeloid populations, both in peripheral regions, as peritoneal cavity, spleen and oil granulomas.

P2.06.07
CCR5-dependent T cell migration contribute to squamous cell carcinoma development

C. E. Oliveira[1], *T. H. Gasparoto*[1], *C. R. Pinheiro*[1], *K. A. Cavassani*[2], *G. P. Garlet*[1], *J. S. Silva*[3], ***A. P. Campanelli***[1]; [1]*Bauru School of Dentistry, University of São Paulo, Bauru, Brazil,* [2]*University of Michigan, Ann Arbor,, MI, United States,* [3]*School of Medicine of Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil.*

Squamous cell carcinoma (SCC) is one of the most common human cancers worldwide. Recent studies show that Treg cells have a critical role in modulating the antitumor immune responses and consequently the SCC development. Since the accumulation of Tregs at the tumor site is in part due to selective recruitment through the CCR5 and the CCR5-associated chemokines, we investigated the role of CCR5 in the SCC development. The results showed that CCR5 deficient mice are more efficient in controlling papilloma incidence than wild-type (WT) mice. In the absence of CCR5, the percentage of leukocytes in the lymph nodes and tumor was significantly increased. Moreover, the adoptive transfer of CD4+CD25+CCR5+, CD4+CD25−CCR5+ and CD8+CCR5+ T cells to CCR5−/− mice resulted in an increase of papilloma incidence. Interestingly, adoptive transfer of Treg cells induced a SCC lesion more undifferentiated than all the other groups with a higher infiltration of macrophage, dendritic cells and myeloid suppressive cells. Overall, CCR5 is a key receptor for the migration of T cells to the SCC lesions. Thus, a tight control of CCR5+ T cells migration, especially Treg cells, to the SCC lesions could be an important mechanism for avoiding tumor progression.

P2.06.08
The absence of chemokine signalling via CCR5 impairs sepsis outcome

F. V. S. Castanheira, *F. Sonego, A. Kanashiro, P. G. Czaikoski, T. M. Cunha, J. Alves-Filho, F. Q. Cunha;*
Universidade de São Paulo, Ribeirão Preto, Brazil.

Sepsis is a systemic inflammatory response that is consequence of the immune system's inability to control an infection. The survival rate during sepsis is dependent on neutrophil recruitment to the infection site, which is mediated by chemokine receptor signaling. In physiological conditions neutrophils express the CXCR family of chemokine receptors. However, it has been showed that chemokine receptors expression profile can be altered under sepsis. In this context, we investigated the possible expression of CCR5 on neutrophils and its role on sepsis. C57BL/6 and CCR5 deficient mice (CCR5-/-) were used to induce sepsis using cecal ligation and puncture (CLP) model. We showed that neutrophils from naïve C57BL/6 mice express high levels of CXCR2 and low levels of CCR5. However, after CLP, in parallel with CXCR2 internalization, neutrophils express higher levels of CCR5. Interestingly, CCR5-/- mice subject to CLP show reduced neutrophil migration to the infection site, increased neutrophil infiltration in lung, increased levels of injury markers and, as consequence, decreased survival rate when compared to C57BL/6 mice. Moreover, we demonstrated that CCR5 has an important role during neutrophil adhesion to the vascular endothelium before transmigration. In summary, we showed that chemokine receptors are modulated on neutrophils during sepsis, whereas the increase in CCR5 expression occurs at the same time that CXCR2 is internalized. Together, our data indicate that CCR5 expression during CLP may represent a protective compensatory mechanism of CXCR2 down-regulation, in order to maintains neutrophil migration to the infection focus and consequently to restrict the infection locally.

P2.06.09
Melatonin regulates the migration of granulocytes into mouse peritoneal cavity via MT2 receptor

V. Cernysiov[1,2], *M. Mauricas*[1], *I. Girkontaite*[1];
[1]*State Research Institute Centre for Innovative Medicine, Vilnius, Lithuania,* [2]*Vilnius University, Faculty of Natural Science, Vilnius, Lithuania.*

The production of melatonin occurs during the night in response to the darkness and it is inhibited by the light. The aim of our study was to investigate the effect of suppressed (caused by constant lighting) synthesis of melatonin on the migration of granulocytes into mouse peritoneal cavity. BALB/c mice were kept under normal light/dark conditions (LD) and under constant exposure to the light (LL). N-formyl-Met-Leu-Phe (fMCP) was injected into mouse peritoneum to induce migration of granulocytes. The mice were sacrifice 4 hours later and the numbers of granulocytes in peritoneal cavity were counted. The mice kept at LL had significant more granulocytes in the peritoneal cavity than LD mice. This difference was observed during the dark time only. The amount of granulocytes in peritoneum of LD and LL mice did not differ during the light time. LD mice had more granulocytes in the peritoneum in the morning than in the night (when the concentration of melatonin is higher). The injection of MT2 antagonist 4P-PDOT three hours prior fMCP caused increased numbers of granulocytes in peritoneum. rtPCR results showed that melatonin MT2 receptors are expressed in granulocytes and endothelial cells.
Our results demonstrate that melatonin via MT2 receptor negatively regulates fMCP induced granulocyte migration to peritoneal cavity.

P2.06.10
CLEVER-1 as a cell trafficking molecule

J. Dunkel[1], *P. Rantakari*[1], *M. Karikoski*[1], *O. Schulz*[2], *O. Pabst*[2], *S. Jalkanen*[1];
[1]*University of Turku, Turku, Finland,* [2]*Medical School Hannover, Hannover, Germany.*

CLEVER-1/Stabilin-1/FEEL-1 is a molecule with two known niches in the host's immune response. It is expressed by a subpopulation of macrophages, where it acts as a scavenger receptor. It is additionally expressed by lymphatic endothelial cells (LEC), inflamed blood vascular endothelial cells (BEC) and high endothelial venules (HEV), where it binds leukocytes in the transmigration phase of the extravasation cascade. Here we explored the significance of CLEVER-1 in homeostatic lymphocyte trafficking to the lymph nodes (LN) with a newly-generated CLEVER-1 knock-out mouse.
WT and KO mice were injected with poly(I:C), a synthetic TLR-3 agonist, to induce lymphopenia. Lymphocyte homing rate was evaluated by sampling peripheral blood. Both the WT and CLEVER-1 KO mice reached the most marked lymphopenia 6 hours after the poly(I:C) injection. However, earlier sampling points revealed that lymphocytes disappear from the blood at a slower rate in the CLEVER-1 KO, indicating that the lymphocyte recirculation rate is potentially slower in the absence of CLEVER-1. These findings were further confirmed with short-term homing experiments using adoptive cell transfer of labeled splenocytes intravenously. In these experiments, mice were sacrificed 2-3 hours after the transfer, LNs were collected and homed cells were quantified by flow cytometry and immunofluorescence microscopy.
These results indicate that CLEVER-1 on HEV is functionally important in regulating lymphocyte entrance into the lymph nodes.

P2.06.11
Collective organization confers chemotactic prowess to lymphoid cells

G. Malet-Engra[1], *W. Yu*[2], *A. Oldani*[1], *N. Gov*[3], *G. Scita*[1], ***L. Dupre***[4];
[1]*IFOM, Milan, Italy,* [2]*A*Star, Singapore, Singapore,* [3]*The Weizmann Institute of Science, Rehovot, Israel,* [4]*INSERM UMR1043, Toulouse, France.*

Whether lymphoid cells undergo collective migration, a biological process governing tissue morphogenesis and solid cancer invasion, is unknown. We show that both tumoral and non-tumoral lymphoid cell populations can simultaneously adopt collective and individual modes of directed migration when exposed to stable chemokine gradients. In particular, we demonstrate that, when organized as clusters, malignant B cells display a wider chemotactic sensitivity to CCL19 than individual cells. Physical modeling, considering clusters as solid objects, recapitulates cluster motility statistics and predicts that intra-cluster cell cohesion reduces noise and enhances directionality. Strikingly, lymphocyte clusters are resistant to chemorepulsion, a process observed in individual lymphocytes exposed to high chemokine concentrations. We further identify endocytosis and ERK activity as central rheostats to set directional sensing and in particular decision between attraction and repulsion in individual lymphocytes. Our data strongly suggest that clusters resist endocytosis/ERK-mediated directional switch at saturating chemokine concentration by alternating protrusive lymphocytes at the leading edge. In support of intra-cluster dynamics, high-resolution automated tracking reveals complex coordination of lymphocyte orientation, reminiscent of fish school models in which forward migration runs are periodically interrupted by transitory rotation and random phases. Thus, coordinated cluster dynamics confers distinct chemotactic properties, highlighting unexpected features of lymphoid cell migration that are potentially relevant for tissue homing and dissemination.

P2.06.12
Phenotypic characterization of CLEVER-1 knock-out mice

K. Elima[1,2], *M. Karikoski*[2], *P. Rantakari*[2], *M. Salmi*[1,2], *S. Jalkanen*[3,2];
[1]*Dept. of Medical Biochemistry and Genetics, University of Turku, Turku, Finland,* [2]*MediCity, University of Turku, Turku, Finland,* [3]*Dept. of Medical Microbiology and Immunology, University of Turku, Turku, Finland.*

Common Lymphatic Endothelial and Vascular Endothelial Receptor-1 (CLEVER-1; also known as Stabilin-1 /FEEL-1) is a large cell surface glycoprotein composed of distinct repetitive elements including several Fas-domains, EGF-like repeats, two RGD-motives, and a Link-domain. CLEVER-1 is constitutively expressed on lymphatic and sinusoidal endothelium as well as on type 2 immunosuppressive macrophages. Upon inflammation it is also induced on continuous flat-walled vascular endothelium. CLEVER-1 has been shown to support leukocyte adhesion and transmigration and to function as a scavenging receptor. In order to study the role of CLEVER-1 in vivo we have generated a knock-out mouse line for this protein. In addition, to be able to address the importance of CLEVER-1 in macrophages, we have also made a conditional knock-out mouse line for CLEVER-1 and crossed the line with mice carrying the gene for Cre-recombinase under a myeloid cell lineage specific promoter. Studies using several experimental models for inflammation and cancer are now in progress. The results obtained thus far confirm the role of this multifunctional protein in leukocyte and cancer cell trafficking and corroborate the results obtained, when using anti-Clever-1 antibodies in similar models with wild-type mice. Furthermore, during characterization of the two genetically modified mouse lines also new functions for CLEVER-1 were discovered.

P2.06.13
Studies on the human primary amine oxidase/sialic acid binding Ig-like lectin -9 and -10 interactions

H. Elovaara[1,2], *V. Parkash*[3], *R. Fair-Mäkelä*[1], *E. Bligt-Lindén*[3], *T. A. Salminen*[3], *S. Jalkanen*[1,2];
[1]*Medicity, University of Turku, Turku, Finland,* [2]*National Institute of Health and Welfare, Turku, Finland,* [3]*Biochemistry, Department of Biosciences, Åbo Akademi University, Turku, Finland.*

Leukocyte trafficking from blood vessels into inflamed tissues is essential in maintaining health. Human primary amine oxidase (hAOC3) on the endothelium is a significant player in the trafficking with a still unknown mechanism. The first hAOC3 counter molecules have been identified being sialic acid binding Ig-like lectins -9 and -10 [SIGLEC-9 and -10; Kivi et al. (2009) Blood 114:5385; Aalto et al. (2011) Blood 118: 3725]. Our objective is to characterize the

mechanisms of hAOC3 in the leukocyte trafficking by studying its interaction with SIGLEC-9 and -10.
For the interaction studies we have put up an insect cell production system and purified the protein by chromatographic methods. The binding constants for hAOC3/SIGLEC interaction were determined by a surface plasmon resonance. The mutagenesis of specific arginine residues of SIGLECs was performed to study the importance of these residues in the interaction. The effect of active site residues of hAOC3 on the SIGLEC binding is being addressed. We are also studying the activity of hAOC3 towards the recombinant SIGLECs. We will aim for detailed characterization of the interaction via the co-crystallization of hAOC3/SIGLEC complex. Finally, we will test if hAOC3/SIGLEC interaction influences SIGLEC signaling in neutrophils.
We have been able to produce a soluble extracellular part of SIGLEC-9 as well as a C2-C3-fragment of SIGLEC-10 in the insect cells. The SPR studies indicate specific binding of both SIGLECs to the immobilized hAOC3. The current status of the activity and signaling studies will be presented.

P2.06.14
A novel role for GIRK channels in the immune system

***E. S. Garty**, A. Kaminitz, A. Ben-Nun, E. Reuveny;*
Weizmann Institute of Science, Rehovot, Israel.

The physiological role of G protein coupled potassium channels (GIRK) is to translate chemical transmission to electrical signaling, mainly in excitable tissues. Using real-time PCR, electrophysiological measurements and western blot analysis we can now show novel expression of GIRK4 channels in immunological tissue from the spleen, bone marrow, lymph nodes and the peritoneal cavity. FACS analysis reveals that GIRK4 channels are expressed in B but not T lymphocytes. In B lymphocytes, GIRK4 was found to be differentially expressed in naïve mature lineages including the natural antibody secreting B-1 cells and regulatory B-10 cells. In GIRK4 null mice, relative B cell populations in the spleen, inguinal lymph nodes and the peritoneum have been found to be affected. In addition, *in vitro* CXCL13-dependant chemotactic migration assays revealed a two-fold increase in migration of B cells in GIRK4 null mice as well as in wt cells in the presence of Tertiapin-Q, a GIRK-specific channel blocker. This increase was found to be dependent on B cell trans-membrane potential. These findings are the first example of the involvement of G protein coupled ion channels in B cell function, and thus serves as a novel mechanism that translates chemical information into electrical activity in the immune system.

P2.06.15
Integrin alpha 4 differentially affect the homing of effector and regulatory T cell subsets

***S. Glatigny**[1,2], R. Duhen[1,2], C. Arbelaez[1,2], S. Kumari[1], M. Oukka[3,2], E. Bettelli[1,2];*
[1]Benaroya Research Institute, Seattle, WA, United States,
[2]Department of Immunology, University of Washington, Seattle, WA, United States, [3]Seattle Children's hospital, Seattle, WA, United States.

Experimental autoimmune encephalomyelitis (EAE) is an animal model of multiple sclerosis (MS), mediated by autoreactive myelin-specific T cells. The immune system disposes of different ways to control effector T cell populations such as myelin specific Th1 and Th17 cells. Regulatory T cells (Tregs) expressing the transcription factor Foxp3 represent the major part of this control. The neutralization of alpha 4 integrin (via Tysabri) is currently used as a second line of treatment for MS and it is thought to prevent the entry of most immune cells in target tissues. Recently, we showed that Itga4 differentially affect the homing of effector T cells and was required for the stability and the homing of the Th1 cells. Our study was designed to understand how Itga4 is controlling regulatory T cells homing and functions during EAE. We used different approaches *in vivo* to evaluate the role of Itag4 on $Foxp3^+$ regulatory T cells. We show that Itga4 is not required for the homing of regulatory T cells in the CNS during EAE and that Itga4 deficient regulatory T cells can limit disease development.
This study reveals that Itga4 differentially affects the homing effector and regulatory T cell subsets during EAE. In conclusions, our work suggests that the development of an anti-Itga4 antibody targeting T cells in particular can be beneficial to increase the suppressive functions of Tregs, to block the homing of Th1 cells and limit side effects associated with Tysabri therapy.

P2.06.16
Contribution of L-selectin to activated CD4 and CD8 T cell migration into dermal inflammation

***T. B. Issekutz**;*
Dalhousie University, Halifax, NS, Canada.

The selectins and α_4 integrins are key mediators of lymphocyte migration out of the blood. The role of L-selectin in lymphocyte homing to LNs is well established, and neutrophil migration to inflammation can be mediated partly by L-selectin. The contribution of L-selectin to T cell migration to inflammation is unknown, as is its role compared to E-and P-selectins and $\alpha_4\beta_1$. To investigate the involvement of L-selectin in migration *in vivo*, T cells were activated with anti-TCR and anti-CD28 and their receptor expression and migration to dermal inflammatory sites determined. L-selectin expression declined in the first 72 h of activation, but by 120 h increased with ~85% CD4 cells positive, and 50-80% of cells expressing E-and P-selectin ligands. L-selectin and α_4 blockade each partially inhibited homing to peripheral and mesenteric LNs, and together abolished it. Anti-L-selectin and anti-α_4 each inhibited 30-50% of the migration to interferon-γ, TNF, LPS, poly I:C and to DTH, and the combination reduced it by 80-90%. Anti-E-selectin was most effective at blocking migration to DTH, and in combination with anti-L-selectin and anti-α_4 mAb CD4 cell migration was virtually eliminated. P-selectin blockade had little effect, but further deccreased migration in combination with anti-L-selectin and abolished migration in the presence of E-selectin blockade. CD8 cell was much less inhibited than CD4 cell migration to most inflammatory sites.
Thus, L-selectin is up-regulated on activated CD4 cells, is an important mediator of migration to dermal inflammation, and together with $\alpha_4\beta_1$ and E-selectin facilitates this migration. (Supported by CIHR)

P2.06.17
Podoplanin (Aggrus)-bound CCL21 regulates adhesive migration of T lymphocytes on the cell surfaces of lymphatic endothelium

***C. Iwata**;*
University of Tokyo, Tokyo, Japan.

The surface-immobilized form of the chemokine CCL21 causes random migration of CCR7-positive lymphocytes by activating integrins in order to induce cell adhesion. In this study, we focused on adhesive migration of lymphocytes on lymphatic endothelium. First, we detected CCL21 on cell surfaces of lymphatics in murine ears and on those of cultured human dermal lymphatic endothelial cells (LEC). We found that the distribution pattern of CCL21 on the apical surfaces of LEC was "dot-shaped". Further morphological analysis revealed that CCL21 colocalized with podoplanin (also known as aggrus), a lymphatic-specific transmembrane glycoprotein, at microvilli on the apical surfaces of LEC. We confirmed the binding ability of podoplanin to CCL21, using surface plasmon resonance analysis and in situ PLA analysis. We also confirmed the contribution of podoplanin to immobilization of CCL21 on the cell surfaces, by overexpression and knockdown of podoplanin in blood endothelial cells (BEC) and LEC, respectively. Next, we investigated the significance of podoplanin-expression on microvilli formation. We found that microvilli and phosphorylated ERM (exrin-radixin-moesin) proteins were reduced by knockdown of podoplanin in LEC. We also found that mutant form of podoplanin, lacking the cytoplasmic ERM- binding domain, was not accumulated to microvilli. Finally, we examined the stimulatory role of podoplanin-bound CCL21 on the adhesive migration of T lymphocytes on lymphatic endothelium in vitro, using time-lapse image analyses.

P2.06.18
TCR-Induced Activation of LFA-1 Involves Signaling through Tiam1

***F. A. Jahan**, M. Grönholm, C. G. Gahmberg;*
University of Helsinki, Helsinki, Finland.

Binding of leukocytes to cells and surrounding molecules, leukocyte adhesion, is of critical importance for immune system and has to be strictly regulated. The most important molecule for leukocyte adhesion is the leukocyte specific ß2 integrins. The integrins need activation to become functional, but the molecular events resulting in adhesion have remain a mystery or incompletely understood. T cell activation leads to the phosphorylation of numerous proteins in the cell. In human T cells, activation through the TCR (T cell receptor) results in specific phosphorylation of the T758 on the ß2 chain of LFA-1. We now show that this phosphorylation leads to downstream binding of 14-3-3 proteins, followed by engagement of the guanine nucleotide exchange factor protein, Tiam1 and Rac1 activation. Down regulation of the signaling molecules inhibits LFA-1 activity. Activation by the chemokine stromal cell-derived factor-1a also results in T758 phosphorylation and integrin activation. Thus, TCR and chemokine activation converges on LFA-1 phosphorylation, followed by similar downstream events affecting adhesion. Ultimately this will be of importance for understanding diseases like cancers and autoimmune diseases, and for the development of methods to control inflammation.

P2.06.19
17-parameter flow cytometry: immunophenotyping cellular infiltration during flavivirus encephalitis in the mouse

*T. M. Ashhurst[1], C. van Vreden[1], M. Karimi Azardaryany[1], K. Lundsten[2], S. Allen[3], S. Dervish[3], F. Kao[3], A. Smith[3], **N. J. C. King**[1]; [1]The University of Sydney, Sydney, Australia, [2]BioLegend, San Diego, CA, United States, [3]Centenary Institute, Sydney, Australia.*

Background: Viral encephalitis is a major cause of morbidity and mortality worldwide. The pathogenesis of flaviviral encephalitis is a complex process, where the immune response elicited by the virus contributes substantially to pathological damage in the brain. As this process is still incompletely understood, there is a critical need for a detailed analysis and characterization of cellular infiltration in the infected brain, to elucidate the critical mediators of immunopathology and viral clearance.
Aims and outcomes: The aim of this investigation was to design, evaluate, implement, and standardize a 17-parameter flow cytometry panel to immunophenotype cellular infiltration in virally infected brain and lymphoid tissues.
Method: Brains, lymph nodes, and spleens were isolated from C57BL/6 mice on day-7, following intranasal inoculation with West Nile virus (WNV). Tissue was processed and stained with a mixture of 12-15 antibodies. Cells were analyzed on a 5-laser Becton-Dickinson (BD) FortessaTM, and the data analyzed using FlowJo software.
Results: The panel allowed for simultaneous identification of B cells (CD19, B220), CD4 and CD8 T cells (CD3, CD4, CD8), NK cells (NK1.1), NKT cells (NK1.1, CD3), neutrophils and other granulocytes (Ly6G, Ly6C, CD11b, SSc), monocytes, microglia, and macrophages (CD45, CD11b, CD11c, Ly6C, F4/80, MHCII), dendritic cells subsets (CD11c, MHCII, CD11b, CD8, CD4, CD103), and plasmacytoid dendritic cells (CD11c, MHCII, B220).
Conclusion: We have developed an immunophenotyping panel that allows simultaneous investigation of all major subsets of leukocytes that are relevant to immune infiltration during viral encephalitis. This will provide an excellent research tool for the future.

P2.06.20
CD69 expression and leukocyte distribution in CD69-BAC transgenic mice

***T. Laguna**, L. Notario, P. Lauzurica;*
Instituto de Salud Carlos III, Majadahonda, Spain.

Expressed on almost every leukocyte, CD69 function has been related to co-stimulation in lymphocytes, inhibition of pro-inflammatory responses and distribution of leukocytes. Here we give new clues on the complex regulation of CD69 expression and its effects in the immune system. We observed alterations in several leukocyte populations' distribution in CD69-overexpressing mice generated by BAC transgenesis. These transgenic mice exhibit higher expression of CD69 than the wt littermates in all leukocytes though the CD69 expression of the transgenic mice correlates with the endogenous levels of cell type involved. The resulting phenotype observed consists in an enhanced presence of single-positive thymocytes and reduced presence of T-cells in spleen and LNs. Regulatory T cells are also reduced respect to the wt mice in periphery, although the proportions between Tregs/non Tregs were augmented, showing a different influence of CD69 expression on the distribution between regulatory and effector T cells. B cell expression of CD69 is high in BM of tg mice, though the B subpopulations are similar to wt mice, indicating the B cell development is not affected. However, the numbers of B cells are reduced in spleen but surprisingly not in lymph nodes. In addition, cDC numbers are reduced in spleen and LNs, whereas granulocytes and NK cells numbers were not significantly altered. In sum, this CD69-overexpressing mice conforms a good model to study the effects of CD69 on leukocyte migration and distribution.

P2.06.21
Induction of cytosolic phospholipase $A_2\alpha$ is required for adipose neutrophil infiltration and hepatic insulin resistance early in the course of high fat feeding

***R. Levy**[1], N. Hadad[2], O. Burgazliev[2], V. Elgazar carmon[2], A. Rudich[2]; [1]Ben-Gurion of the Negev, beer-Sheva, Israel, [2]Ben-Gurion of the Negev, Beer-Sheva, Israel.*

While in established obesity adipose tissue inflammation likely contributes to dysfunctional fat-liver crosstalk, whether this occurs in short-term adaptation to dietary surplus is unclear. Here we set to explore if the adipose tissue infiltration by neutrophils that occurs 3-7d after initiating high-fat diet (HFD) could contribute to the early occurrence of hepatic insulin resistance and to determine the role of cytosolic phospholipase$A_2\alpha$ ($cPLA_2\alpha$) in this process. HFD for 3 days (3dHFD) caused a significant upregulation of $cPLA_2\alpha$ in peri-epididymal fat and the liver. A specific antisense oligonucleotide (AS) effectively prevented $cPLA_2\alpha$ induction and neutrophil infiltration into adipose tissue, an effect likely involving MIP-2. AS also protected against 3dHFD-induced hepatic insulin resistance. To sort out the role of adipose neutrophil infiltration in hepatic insulin resistance (independent of $cPLA_2\alpha$ induction in the liver), mice were intraperitoneally injected with anti-ICAM-1 antibodies. This effectively prevented neutrophil infiltration without affecting $cPLA_2\alpha$ or MIP-2 expression. Nevertheless, similarly to AS, 3dHFD-induced hepatic insulin resistance was prevented. Adipose tissue secretion of TNFα was increased by 3dHFD and was prevented by AS or ICAM-1 antibodies treatment. We propose that an acute, $cPLA_2\alpha$ dependent neutrophil-dominated inflammatory response of adipose tissue contributes to hepatic insulin resistance in short-term hyper-nutrition.

P2.06.22
Deficiency of the leukocyte integrin inhibitor, Del-1 exacerbates experimental autoimmune encephalomyelitis through increased Th17 cells infiltration

***J. Lim**;*
TU Dresden, Dresden, Germany.

Del-1 is an endogenous endothelial-derived inhibitor of LFA-1-mediated leukocyte adhesion (Choi et al. Science 2008). As Del-1 has high expression in brain, we assessed here its role in

neuroinflammation in experimental autoimmune encephalomyelitis (EAE), the rodent model of multiple sclerosis. We found decreased Del-1 expression in the inflamed spinal cord of mice subjected to the EAE protocol. Moreover, Del-1-deficiency in mice resulted in increased EAE severity, associated with increased inflammatory cell recruitment to the inflamed spinal cord. Immunohistochemistry showed that demyelination and axonal damage of the spinal cord was higher due to Del-1-deficiency. Recently, we proved that Del-1 suppressed IL-17-triggered inflammation (Eskan et al., Nat Immunol, 2012). Consistent with this finding, we found that the infiltration of IL-17 producing $CD4^+$ T cells (Th17 cells) was significantly increased at the onset of the disease. This resulted in enhanced infiltration of $CD45^{high}CD11b^+$ monocytes/macrophages that was up to the effector phase of EAE. Subsequent studies revealed that $IL17R^{-/-}$ deficiency reversed the aggravated EAE phenotype of Del-1-deficiency, accompanied by a decrease of leukocyte infiltration into the spinal cord. Our results suggest that Del-1 deficiency exacerbates EAE disease severity by elevating Th17 cell infiltration to the inflamed spinal cord, which implies that Del-1 could be used as a therapeutic approach for neuro-inflammatory disorders.

P2.06.23
Possible role of Myo1g in vesicular traffic of different molecules of B lymphocytes

O. López-Ortega[1,2], *J. Maravillas-Montero*[1], *G. Patiño-López*[3], *S. Shaw*[3], *L. Santos-Argumedo*[1];
[1]*Molecular Biomedicine Department, Centro de Investigación y de Estudios Avanzados del Instituto Politécnico Nacional (CINVESTAV-IPN), México DF, Mexico,* [2]*School of medicine, UNAM, México DF, Mexico,* [3]*Experimental Immunology Branch, National Cancer Institute, National Institutes of Health, Bethesda, MD, United States.*

Eukaryotic cells are compartmentalized into membrane structures that establish and maintain defined microenvironments. These structures are connected and interchange components trough a complex mechanism named vesicular traffic. The regulation of this process involves coordinated function of different molecules including members of the myosin superfamily. Class I myosins are proteins with a conserved structure that consists of three regions: head, neck and tail. There are 8 class I myosins in mammals, ranging from myosin 1a to 1h, which are molecular motors that interact both with actin fibers and plasma membrane phosphoinositides. Myosin 1g (Myo1g) binds primarily to PIP2 and PIP3, these phosphoinositides are significantly present in several types of vesicles. We detected the presence of Myo1g in membrane protrusions in B lymphocytes such as microvilli and dendrites-like structures. Also we evaluated phagocytic index of Myo1g deficient B lymphocytes, finding that Myo1g deficiency result in an increased phagocytic activity. Myo1g deficient B lymphocytes show a decrease in the surface expression of CD44 and LFA-1 during activation conditions with LPS plus IL-4 for 48 h. Myo1g deficient B lymphocytes also adhere and spread less to different substrates. As these adhesion molecules are recycled in caveolin-dependent vesicles with lipid rafts, we investigated the presence of Myo1g in lipid rafts, finding an enrichment of myo1g on these microdomains of the plasma membrane. In conclusion, we showed that Myo1g has a role in vesicular traffic in murine B lymphocytes, specifically in caveolin-dependent vesicle recycling.

P2.06.24
AChR-specific T cell trafficking in the thymus of chronic Experimental Autoimmune Myasthenia Gravis

R. Marolda*, C. Cordiglieri, P. Cavalcante, P. Bernasconi, R. Mantegazza, F. Baggi;*
Istituto Neurologico Carlo Besta Fondazione IRCCS, Milano, Italy.

The immune effector mechanisms and the target autoantigen(s) have been delineated in Myasthenia Gravis (MG), however the events that lead to loss of self-tolerance are not fully understood. The involvement of the thymus has long been reported in MG but its role remains elusive also because limited information has been obtained from experimental MG (EAMG), where thymus has been investigated without conclusive data.

We observed an enlargement of the thymus, suggestive of tissue hyperplasia, in EAMG animals at disease manifestation (wk=4) and in chronic phase (wk=10) as compared to age-matched PBS/CFA or acute EAE animals (wk=2). To better investigate this observation, from GFP+ Lewis rats we generated CD4+ T cells, specific for the immunodominant 97-116 epitope of the rat AChR, and T cell blasts were i.v. injected in EAMG animals. We showed an accumulation of GFP+ T cells in thymic medulla, but not in the cortex; this in vivo migratory pattern, observed selectively in EAMG animals, was specifically associated to AChR-responsive T cells, since OVA-specific GFP+ T cells injected in EAMG animals failed to re-circulate to the thymus.
Although thymocyte trafficking is generally considered to be unidirectional, we demonstrated that immunocompetent T cells migrate to the thymus in a pathological situation. Specific lymphocyte re-circulation to the thymus might be an important step during the onset phase of EAMG, when numerous peripheral T cells acquire an activated phenotype. Our data point to a direct link between auto-antigen activation and thymic involvement in the animal model of Myasthenia Gravis.

P2.06.25
Role of CD38 in regulating the migration of B cells in Chronic Lymphocytic Leukemia

S. Mele*, S. Devereux, A. Ridley;*
King's College London, London, United Kingdom.

Chronic lymphocytic leukaemia (CLL) is the most common leukaemia in adults and it is characterized by the proliferation of a malignant clone of B-cells. Progressive disease is defined by the infiltration of leukemic cells into lymphoid tissues where they receive pro-tumour signalling. Understanding CLL cell migration and retention within lymphoid tissues will be essential to devise new treatment strategies. High expression of the surface molecule CD38 on CLL cells is an adverse prognostic marker. Although CD38 has been linked to migratory function in CLL, its role in the migration remains unclear. In this study, we have focussed on analysing leukocyte migration using CLL cells (Mec-1 cell line) over-expressing CD38 compared to control cells. CD38 over-expression enhanced CLL cell spreading on VCAM-1 in response to the chemokine CCL21. Time-lapse microscopy analysis showed that CD38 over-expression reduced the ability of CLL cells to crawl on endothelial cells and transmigrate through an endothelial cell monolayer towards CCL21. In contrast, CLL cells over-expressing CD38 showed markedly enhanced chemotaxis towards CCL21, which correlated with increased Rac1 activity and increased calcium mobilization in response to CCL21. Taken together, our data suggest that CD38 expression alters key steps in CLL cell motility. Current studies aim to identify the critical signalling molecules regulating CD38-dependent responses in CLL.

P2.06.26
The autotaxin/lysophosphatidic acid is a regulator of lymphocyte extravasation at the high endothelial venules of lymph nodes

M. Miyasaka[1], *E. Umemoto*[2], *A. Takeda*[2], *Z. Bai*[3], *L. Cai*[4], *E. Hata*[5], *K. Tohya*[6], *Y. Komai*[7], *P. Veeraveedu*[7], *Y. Sugiura*[8];
[1]*IPBS, Institute for Academic Initiatives, Osaka University, Suita, Japan,* [2]*Laboratory of Immune Regulation, Osaka University Graduate School of Medicine, Suita, Japan,* [3]*Key Laboratory of Puer Tea Science, Yunnan Agricultural University, Kunming, China,* [4]*Key Laboratory of Bionics Engineering,, Jilin University, Changchun,, China,* [5]*Laboratory of Immunodynamics, Osaka University Graduate School of Medicine, Suita, Japan,* [6]*Department of Anatomy, Kansai University of Health Sciences, Kumatori, Osaka, Japan,* [7]*Laboratory of Single Molecule Imaging, WPI Immunology Frontier Research Center, Osaka University,, Suita, Japan,* [8]*Department of Biochemistry, School of Medicine, Keio University,, Tokyo, Japan.*

While lymphocyte extravasation from the high endothelial venules (HEVs) of lymph nodes is crucial for the maintenance of immune homeostasis, its molecular mechanism remains unclear. Here we report that lymphocyte transmigration across the basal lamina of the HEVs is regulated at least in part by autotaxin (ATX) and its end-product, lysophosphatidic acid (LPA); ATX is a HEV-associated

ectoenzyme that produces LPA from lysophosphatidylcholine (LPC), which is abundant in the systemic circulation. In agreement with selective expression of ATX in HEVs, LPA was constitutively and specifically detected on HEVs by MALDI imaging mass spectrometry. In vivo, inhibition of ATX impaired the lymphocyte extravasation from HEVs without affecting lymphocyte rolling and adhesion at HEVs, and induced lymphocyte accumulation within the endothelial cells (ECs) and sub-EC compartment; this impairment was abrogated by LPA. In vitro, both LPA and LPC induced marked increase in the motility of HEV ECs; LPC's effect was abrogated by ATX inhibition, whereas LPA's effect was abrogated by ATX/LPA receptor inhibition. In in vitro transmigration assay, ATX inhibition impaired release of lymphocytes that had been migrated underneath HEV ECs, and these defects were abrogated by LPA. Collectively, these results strongly suggest that HEV-associated ATX generates LPA locally, and LPA in turn acts on HEV ECs to increase their motility, promoting dynamic lymphocyte-HEV interactions and subsequent lymphocyte transmigration across the basal lamina of HEVs at steady state.
Drs. A. Kubo, M. Suematsu, H. Hayasaka, S. Okudaira, J. Aoki, T. Tanaka, H. Albers, and H. Ovaa have collaborated in this work.

P2.06.27
Langerhans cell penetration through the epidermal- dermal barrier

***C. Moussion**, M. Sixt;*
IST Austria, Klosterneuburg, Austria.

Upon inflammation Dendritic cells (DCs) translocate from peripheral sites of antigen uptake into the draining lymph node where they present the processed antigens to T cells. Most skin DCs reside in the dermis from where they crawl into the afferent lymphatic vessels. Langerhans cells (LCs), as they colonize the epidermis, need to cross the basement membrane (BM) of the epidermal-dermal junction before proceeding towards the lymph node. BM penetration is the prototype of a tissue invasion event, which has been extensively studied in culture but rarely addressed in a physiological setting. We establish LC invasion as a novel experimentally tractable model to study the cell biology of BM penetration, allowing us to explore physical and molecular interactions.
By inference from other cell systems DCs might require chemotactic signals, substrate adhesion via integrin receptors, actin cytoskeletal dynamics and pericellular proteolysis to act in concert in order to erode and infiltrate the BM. We explore these different aspects by employing intravital live cell imaging in conjunction with fluorescent reporters in mice harboring DCs conditionally deleted for different candidate genes to dynamically visualize invasion *in situ*. To complement the *in vivo* approach we further developed a reductionist *ex vivo* setup where bone marrow derived DCs invade decellularized skin. Such a reductionist setting provides a much higher level of experimental accessibility.
The live imaging of LCs transmigration *in vivo* and *ex vivo* allows us to uncover basic principles of cell migration that are equally relevant for immunology, embryonic development and cancer biology.

P2.06.28
Identification and Characterization of a Monocyte CXCL4 Receptor

*J. M. Fox[1], F. Kausar[1], A. Day[1], M. Osbourne[1], A. Mueller[1], T. Tsuchiya[2], S. Kanegasaki[2], **J. E. Pease**[1];*
[1]Imperial College London, London, United Kingdom, [2]YU-ECI Research Center for Medical Science, Yeungnam University, Gyeongsansi, Republic of Korea.

Activated platelets release micromolar concentrations of the chemokine CXCL4/Platelet Factor-4. The deposition of CXCL4 is implicated in the pathogenesis of atherosclerosis, inducing signaling cascades in monocytes and a distinct transcriptional profile of monocyte maturation via an unknown receptor.
Using the monocytic line THP-1 we observed that CXCL4 could induce pertussis toxin-sensitive intracellular calcium flux and migration, implicating a G protein coupled receptor (GPCR) in the transduction of the CXCL4 signal. Although CXCR3 has been reported to function as a T-cell CXCL4 receptor, THP-1 cells were unresponsive to CXCR3 ligands and CXCL4-mediated migration was also insensitive to a CXCR3-specific antagonist. By interrogating a panel of GPCR transfectants, we identified a cDNA that when expressed in a murine Pre-B cell line could confer sensitivity to CXCL4 in chemotaxis assays and confer the ability to bind a CXCL4-Fc fusion protein generated in house. Using a novel assay of real-time cell migration we observed that CXCL4 could drive the migration of freshly-isolated monocytes which was sensitive to blockade with a specific antagonist.
Identification of the monocyte CXCL4 receptor should provide a platform for the further characterization of this enigmatic chemokine.

P2.06.29
Involvement of CXCR3 and CXCR4 in natural killer cell trafficking into bone marrow during multiple myeloma growth

***A. Ponzetta**[1], G. Benigni[1], F. Antonangeli[1], G. Sciumè[2], G. Bernardini[1], A. Santoni[1];*
[1]Sapienza University of Rome, Rome, Italy, [2]NIAMS - Molecular Immunology and Inflammatory Branch, Bethesda, MD, United States.

Natural Killer (NK) cells represent an important weapon for the immune system in the defense against hematologic malignancies. In particular, NK cells have been shown to be effective against Multiple Myeloma (MM), and are thus under investigation as potential tool for cellular immunotherapy.
In this study we analyzed how NK cell trafficking capacities and effector functions are modulated during tumor growth in the BM, using a MM mouse model.
Initially, we highlighted a differential distribution of NK cell subsets within the BM, which were defined according to the expression of the maturation markers CD11b and KLRG1: at an early stage of tumor growth, the frequency of KLRG1+ NK cells increased, while the total NK cell number was slightly reduced. Furthermore, the pattern of chemokine receptor expression on NK cells was altered during MM development: indeed, when tumor growth was low, CXCR3 was downmodulated, while at later times both CXCR3 and CXCR4 were upregulated as compared to control mice.
By competitive adoptive transfer experiments, we found that while KLRG1+ NK cells similarly migrated to BM of control and tumor-bearing mice, KLRG1- NK cell homing to BM in tumor-bearing mice was impaired.
Moreover, changes in NK cells trafficking behavior were associated with alterations in CXCR3 and CXCR4 ligands expression in BM tumor microenvironment.
Taken together, our data indicate that selected NK cell subsets are retained in the BM depending on the stage of MM growth, and that this differential trafficking might be caused by alterations of chemokine receptor/ligand pairs in tumor microenvironment.

P2.06.30
Natural posttranslational modification of CXC chemokines modifies their in vitro and in vivo activity

***P. Proost**, A. Mortier, E. Moelants, T. Loos, M. Gouwy, S. Struyf, G. Opdenakker, J. Van Damme;*
Rega Institute, KU Leuven, Leuven, Belgium.

Purification of natural CXC chemokines from conditioned medium of stimulated PBMC and fibroblasts revealed multiple posttranslationally modified forms. Several modifications, i.e. proteolytic truncation and deimination of arginine to citrulline were identified on CXCL5, CXCL8 (IL-8) and CXCL10 (IP-10). The enhanced in vitro activity of N-terminally truncated neutrophil chemotactic proteins CXCL5 and CXCL8 was confirmed. Surprisingly, although intact CXCL5 had potent in vitro chemotactic activity, it failed to recruit neutrophils to the peritoneal cavity in mice. Also truncation of CXCL8 enhanced its in vivo chemotactic properties. In contrast, limited truncation of the lymphocyte chemotactic CXC chemokines CXCL9 - CXCL12 abolished their chemotactic activity. Citrullination of structural proteins by peptidylarginine deiminases (PAD) has been associated with auto-immune diseases such as rheumatoid arthritis and multiple sclerosis. Chemokines were identified as the first PAD substrates that signal in a receptor-dependent manner. PAD2 and PAD4 rapidly and site-specifically deiminate CXCL5, CXCL8 and CXCL10. Although

citrullination hardly affected the in vitro activity of CXCL8, it rendered this chemokine resistant to proteolytic cleavage and reduced its glycosaminoglycan binding properties. More strikingly, intraperitoneal injection of citrullinated CXCL5 or CXCL8 failed to attract neutrophils to the peritoneal pocket. Using a citrulline-specific chemical modification in combination with immunological detection, we observed that neutrophils rather than PBMC produce significant amounts of citrullinated CXCL8. Overall, chemokines are subject to various modifications affecting their activity. These data provide new structure-function information for chemokines in leukocyte mobilization and suggest a role for PAD in the downregulation of acute inflammation.

P2.06.31
Non-hematopoietic endothelial LSP1 orchestrates CXCL2-sensitive motile neutrophil functions in vivo

***S. M. Qadri**, M. Hossain, N. Xu, L. Liu;*
University of Saskatchewan, Saskatoon, SK, Canada.

The Ca2+- and F-actin-binding leukocyte-specific protein 1 (LSP1) is expressed not only in leukocytes but also in non-hematopoietic endothelial cells. Endothelial LSP1 was recently shown to participate in microvascular permeability increases and transendothelial migration of leukocytes during inflammation. However, the cell-specific functions of LSP1 remain elusive. Using intravital and time-lapsed video microscopy we demonstrate MIP-2/CXCL2-elicited motile neutrophil dynamics in the cremasteric microvasculature of LSP1-deficient chimeric mice. Absence of endothelial LSP1 (Lsp1−/−) resulted in significantly impaired neutrophil chemotactic directionality (chemotaxis index) in CXCL2-elicited intraluminal crawling and extravascular migration as compared to these responses in wild type (Lsp1+/+) endothelial cells. The velocity of migration of Lsp1 neutrophils in extravascular tissue was significantly lower in both Lsp1+/+ and Lsp1−/− chimeric mice as compared to that of Lsp1+/+ neutrophils in these mice. Determination of integrin expression on transmigrated neutrophils from CXCL2-triggered peritonitis in chimeric mice showed that deficiency of endothelial LSP1 mitigated the expression of α6 and β1 on neutrophils irrespective of neutrophil LSP1 expression. Furthermore, immunoblotting of lysates from whole cremaster muscles revealed blunted expression of CD31/PECAM-1 in Lsp1−/− mice as compared to Lsp1+/+ mice. In conclusion, non-hematopoietic endothelial LSP1 is a novel regulator of dynamic neutrophil motile functions during leukocyte recruitment in vivo.

Sphingosine-1-phosfate receptors are involved in cell migration in T-cell acute lymphoblastic leukemia and lymphoma

***C. V. M. Rachid**, J. P. Lemos, W. Savino, D. A. Mendes-da-Cruz;*
Oswaldo Cruz Institution, Rio de Janeiro, Brazil.

T-cell acute lymphoblastic leukemia (T-ALL) and T-cell lymphoblastic lymphoma (T-LBL) are malignant proliferations of T-cell precursors at different stages of normal development. As T-ALL/LBL lymphoblasts present similar characteristics of normal T-cell precursors, molecules involved on the migration of these cells might also be associated with migration and homing of T-ALL/LBL. In this context, the sphingosine-1-phosphate receptor 1 (S1P1), has been described as essential for mouse thymocyte migration and thymic egress. We evaluated the expression and role of S1P1 in T-ALL cell lines in response to its physiological ligand, sphingosine-1-phophate (S1P). At first, we observed that the migratory response of the cells towards S1P was directly related with their expression levels of S1P1. The cell line which express very low levels of S1P1 mRNA (HPB-ALL) do not migrate towards S1P while MOLT-4, JURKAT and CEM cells which express higher levels of S1P1 mRNA migrate towards S1P. S1P induced migration of the cell lines in different concentrations up to 100nM and inhibited cell migration at higher concentrations (500-1000nM). Interestingly, when S1P1 was blocked by W146 (S1P1 specific inhibitor), S1P-induced migration at lower concentrations was barely reduced. Conversely, S1P higher concentrations induced cell migration when S1P1 was blocked, suggesting the involvement of other S1P receptor, in the absence of S1P1 signaling. We observed that the responding cell lines also express S1P3 mRNA suggesting that this receptor may be involved, and this issue is under study. In summary, our results suggest that interactions mediated by S1P/S1P receptors can modulate cell migration of T-ALL/LBL blasts.

P2.06.33
A new mTOR-dependent, Akt-independent pathway differentiates the migratory behavior of regulatory and conventional T cells

***G. Raimondi**[1], L. C. Chen[2], B. R. Rosborough[2], A. W. Thomson[2];*
[1]Johns Hopkins School of Medicine, Baltimore, MD, United States, [2]Starzl Transplantation Institute - University of Pittsburgh School of Medicine, Pittsburgh, PA, United States.

The vitamin A metabolite all-trans retinoic acid (ATRA) is known to induce a gut-homing phenotype in activated CD4+ conventional T cells (Tconv) by upregulating the integrin α4β7 and the chemokine receptor CCR9. We report that in contrast to mouse Tconv, only about half of regulatory T cells (Treg) upregulate CCR9 when stimulated in presence of physiological levels of ATRA, even though Tconv and Treg express identical levels of retinoic acid receptor (RAR). The bimodal distribution of CCR9+ versus CCR9- Treg subsets is not associated with differences in the extent of proliferation, level of FoxP3 expression, or segregation between the populations of thymic-derived Treg (nTreg) and induced Treg (iTreg) that constitute the pool of circulating Treg. Furthermore, we report that exposure to the mTOR inhibitor rapamycin suppresses upregulation of both CCR9+ and α4β7 on Treg, an inhibitory effect that is not evident in Tconv. This suggests that ATRA-induced upregulation of CCR9 and α4β7 on Treg is dependent on activation of an mTOR signaling pathway. This mTOR involvement is independent of Akt activity, since specific inhibition of Akt or its downstream target GSK-3B did not prevent CCR9 expression. Additionally, Rictor-/- Treg (that lack mTORC2) showed unaltered ability to express CCR9 compared to WT control, suggesting the selective participation of mTORC1 or another mTOR complex. These findings reveal a novel difference between ATRA signaling and chemokine receptor induction in Treg versus Tconv, and provide a framework via which the migratory behavior of Treg versus Tconv can be differentially influenced for therapeutic purposes.

P2.06.34
Role of oxysterol EBI2 ligand pathway in inflammation

***A. Reboldi**, T. Yi, J. G. Cyster;*
Howard Hughes Medical Institute and Department of Microbiology and Immunology, University of California, San Francisco, CA, United States.

In order to mount a rapid and efficient antibody response, B cells undergo a series of dynamic movements within secondary lymphoid organs. The oxysterol 7a,25-dihydroxycholesterol (7a,25-OHC) has been recently identified as a ligand for EBI2, a G protein-coupled receptor, in regulating B cell movement along the B-T boundary and later to inter- and outer-follicular regions. 7a,25-OHC has been historically described as an intermediate in the alternate pathway of hepatic bile acid synthesis. 7a,25-OHC is synthesized from cholesterol by the stepwise actions of two enzymes, CH25H and CYP7B1: CH25H mediates hydroxylation at the 25 position, whereas CYP7B1 mediates the subsequent hydroxylation at the 7a position. 7a,25-OHC can be further metabolized by the enzyme HSD3B7, inactivating it as an EBI2 ligand. The enzymes needed for the generation and degradation of EBI2 ligand are expressed in a wide range of tissues, and in the case of CH25H, are strongly inducible by inflammatory stimuli, but their extra-hepatic function(s) remain poorly understood. Similarly, EBI2 is widely expressed across the hematopoietic lineage but its role outside the B cell compartment has been little investigated. We are currently investigating how the enzymes involved in the production of 7a,25-OHC are regulated in steady-state and inflammation in lymphoid and non-lymphoid organs, and how oxysterol abundance impacts trafficking and activation of EBI2-expressing immune cells under inflammatory conditions.

P2.06.35
CR3 and CR4 differently mediate the adherence to fibrinogen of human dendritic cells

N. Sándor[1], *C. Kriston*[2], *A. Erdei*[1,2], *Z. Bajtay*[2];
[1]*Immunology Research Group of Hungarian Academy of Sciences at Eötvös Loránd University, Budapest, Hungary,* [2]*Eötvös Loránd University Institute of Biology, Department of Immunology, Budapest, Hungary.*

CR3 and CR4 are members of the family of β2 integrins, both expressed by human monocytes, neutrophil granulocytes (PMN), macrophages and dendritic cells. They consist of a common β-chain (CD18) and a unique α chain (CD11b in CR3 and CD11c in CR4). Their similarity is very high regarding their extracellular domain; 87% respectively. This is why ligand specificity of CR3 and CR4 is very much overlapping, and their main ligands - such as iC3b, fibrinogen, ICAM-1 - are the same. They differ however, in their intracellular domain, which suggests fundamental differences between the two receptors. So far however, very little is known about the function of CD11c. We recently demonstrated that CD11b dominates iC3b mediated phagocytosis over CD11c, the latter having only a supportive role in this process. In our present work we analyzed the role of CD11b/CD18 and CD11c/CD18 in another important cellular function of β2 integrins, namely adherence to fibrinogen, a common ligand of both receptors. Fibrinogen is an acute phase protein present on inflamed endothelium as well as a component of the extracellular matrix. We studied the adhesion of primary human monocytes and monocyte-derived dendritic cells and macrophages to this protein in the presence or absence of blocking antibodies binding to CD11b or CD11c. Interestingly we found that in contrast to phagocytosis, adherence is mainly mediated through CD11c ligation. These results provide further evidence that CD11b/CD18 and CD11c/CD18 have different roles despite their structural similarites.

P2.06.36
Angiotensin II-induced vascular dysfunction depends on aortic infiltration and mutual activation of NK cells and monocytes

M. Schwenk[1,2], *S. Kossmann*[1,3], *M. Hausding*[1,3], *M. Knorr*[1,3], *M. I. Schmidgen*[3], *S. H. Karbach*[1,3,4], *A. Daiber*[1,3], *T. Münzel*[1,3], *P. Wenzel*[1,3], *C. Becker*[1,2];
[1]*Center for Thrombosis and Hemostasis (CTH), University Medical Center Mainz, Mainz, Germany,* [2]*Department for Dermatology, University Medical Center Mainz, Mainz, Germany,* [3]*2nd Medical Clinic, University Medical Center Mainz, Mainz, Germany,* [4]*Institute for Molecular Medicine, University Medical Center Mainz, Mainz, Germany.*

The recruitment of immune cells into the aortic vessel wall is crucial to angiotensin II (ATII) induced vascular dysfunction. But how the different immune cell subsets contribute to this inflammatory process is incompletely understood. Comparing vascular endothelial and smooth muscle function, superoxide formation and expression of NADPH oxidase subunits in C57BL/6, T-bet deficient Tbx21$^{-/-}$ mice, IFN-γ$^{-/-}$ mice and IFN-γ transgenic IFN-SAP mice, we found that ATII-induced vascular inflammation and dysfunction depends on the recruitment of IFN-γ producing immune cells into the aortic vessel wall. Analyzing the role of different immune cell subsets by adoptive transfer and depletion experiments identified NK cells as main IFN-γ producers in the aortic endothelium and their mutual interaction with vascular infiltrating monocytes as crucial events in ATII-induced aortic inflammation.
These results disclose IFN-γ production by vascular infiltrating NK cells as an important factor in ATII-induced vascular dysfunction and suggest NK cells and IFN-γ as a molecular target in the treatment of cardiovascular disease.

P2.06.37
Morphometric analysis of the distribution of decidua NK cells and macrophages in the neighborhood of the trophoblast invasion front

P. Sedlmayr;
Medical University of Graz, Graz, Austria.

Trafficking of leukocytes towards and accumulation in the vicinity of immobile tissue structures may be objectified by using algorithms for automated morphometric analysis of the relative densities of wandering cells. We applied a new method of quantitative image analysis to answer the question whether NK cells or macrophages accumulate in the neighborhood of the trophoblast invading the maternal decidua. We used tissue fragments from placentation sites of 1st trimester pregnancy and co-cultures of 1st trimester decidua parietalis with villous explants of the same pregnancy. Cryostat sections from those tissues were double-stained by immunohistochemistry for CD56 or CD163 versus HLA-G and analyzed by automatic quantitative image processing. Distinct cell compartments as well as cell neighborhood areas were defined and relative areal cell densities were calculated. At 1st trimester placentation sites we found a higher density of NK cells as well as of macrophages in close proximity to the invasive trophoblast. In the three-dimensional co-culture model enrichment in the neighbourhood of the trophoblast was observed for macrophages but not for NK cells. As the presented method of analysis of distribution of mobile cells in relation of immobile tissue structures not only replaces laborious counting of cells but also excludes an observer bias, we envisage further applications in other fields such as tumor immunology and inflammation.

P2.06.38
Endothelial- specific gene ablation of CD99L2 impairs leukocyte extravasation in vivo

R. Seelige, *C. Natsch, S. März, D. Jing, M. Frye, S. Butz, D. Vestweber;*
Max Planck Institute for Molecular Biomedicine, Muenster, Germany.

Leukocyte extravasation depends on a tightly regulated cascade involving receptors and adhesion molecules on leukocytes and on endothelial cells. One of the most recently identified proteins participating in this process is CD99L2, a small, highly O-glycosylated transmembrane protein with no resemblance to any known protein family.
CD99L2 is expressed on neutrophils, lymphocytes and endothelium, where it locates to the intercellular junctions. With the help of polyclonal antibodies, we could recently show that it is involved in the transmigration of neutrophils through endothelial cells in vitro as well as into inflamed peritoneum and cremaster tissue. Despite of its high expression on lymphocytes, CD99L2 was dispensable for lymphocyte extravasation.
To further elucidate the role of CD99L2 in leukocyte diapedesis and to evaluate its function independent of antibody effects, we generated CD99L2 conditional knock-out mice. By using intravital microscopy in the inflamed cremaster muscle, we were able to clarify that CD99L2 deficiency does not affect adhesion or rolling of leukocytes, but only the actual diapedesis step. Combining techniques of conditional gene deletion and bone marrow transplantation, we found that neutrophil extravasation was only decreased when CD99L2 was missing in endothelial cells, but not on neutrophils. In an in vivo model for allergic reactions, we could for the first time also reveal a role for CD99L2 during T cell transmigration. Similar to the situation for neutrophils, CD99L2 was only required for efficient T cell transmigration on the endothelial, but not the lymphocyte, site.

P2.06.39

PI3Kgamma confers resistance against Trypanosoma cruzi infection due to its important role in microbicidal activity of macrophages

***M. C. Silva**, R. Sesti, F. C. Dias, T. S. Medina, G. K. Silva, J. C. A. Filho, F. Q. Cunha, J. S. Silva, T. M. Cunha;*
School of Medicine of Ribeirão Preto - USP, Ribeirão Preto, Brazil.

The phosphatidylinositol-3-kinases (PI3Ks) are a family of lipid kinases that play a crucial role in several cellular processes including survival and proliferation. PI3Kgamma is involved in the signaling of chemotactic factors and leukocytes migration and activation. Here, we evaluated the role of PI3Kgamma during experimental infection by the protozoan parasite *T. cruzi* in C57BL/6 WT mice. We observed that *T. cruzi* infection causes an increase in the PI3Kgamma expression and activation in the mice's heart. Although there is no difference in the blood parasitemia between WT and PI3Kgamma$^{-/-}$ mice, all PI3Kgamma deficient mice died until day 25 after infection, whereas the WT remained alive after 30 days. PI3Kgamma$^{-/-}$ mice also showed greater inflammation, parasitism and lesion in the heart tissue. Interestingly, in the absence of PI3Kgamma, the heart tissue express higher levels of iNOS enzyme after infection compared with WT mice, but the expression of arginase I, that also consume the amino acid arginine thus impairing the nitric oxide (NO) production, is also higher compared with WT mice. PI3K$^{-/-}$ macrophages stimulated *in vitro* with *T. cruzi* plus IFN-gamma fail to produce NO and to kill the parasite compared with WT macrophages. Corroborating these data, the addition of ARG1 inhibitor (BEC) to macrophage culture restores the ability of PI3Kgamma$^{-/-}$ macrophages to produce NO. These results indicate that PI3Kgamma is not involved in the leukocyte migration during *T. cruzi* infection, but it helps in the microbicidal mechanisms of macrophage by mediation of NO production, which is important to kill the intracellular parasites.

P2.06.40

***Nr4a1*-dependent Ly6C^{low} monocytes monitor endothelial cells and orchestrate their disposal in the presence of nucleic acids**

L. M. Carlin[*1], **E. Stamatiades***[*1], *C. Auffray[2], R. N. Hanna[3], L. Glover[4], G. Vizcay-Barrena[4], C. C. Hedrick[3], H. T. Cook[5], S. Diebold[6], F. Geissmann[1];*
[1]CMCBI, King's College London, London, United Kingdom, [2]Inserm U838, Institut Necker, Paris Descartes University, Paris, France, [3]Division of Inflammation Biology, La Jolla Institute for Allergy and Immunology, La Jolla, CA, United States, [4]Centre for Ultrastructural Imaging, King's College London, London, United Kingdom, [5]Centre for Complement and Inflammation Research, Imperial College London, London, United Kingdom, [6]Peter Gorer Department of Imunology, King's College London, London, United Kingdom.

The functions of *Nr4a1*-dependent Ly6C^{low} monocytes have remained enigmatic. We show herein that they are highly enriched within capillary vessels and scavenge microparticles from their luminal side in a steady state. Induction of inflammation by a TLR7-dependent nucleic acid signal in the kidney cortex triggers G[[Unsupported Character - Symbol Font ]]*i*-dependent intravascular retention of Ly6C^{low} monocytes, which recruit neutrophils in a TLR7-dependent manner to mediate focal necrotic death of endothelial cells, while the monocytes remove cellular debris. Prevention of Ly6C^{low} monocyte development, crawling, or retention in *Nr4a1*$^{-/-}$, *Itgal*$^{-/-}$, and *Tlr7*$^{host-/-BM+/+}$ and *Cx3cr1*$^{-/-}$ mice, respectively, abolished neutrophil recruitment and endothelial killing. Prevention of neutrophil recruitment by monocytes in *Tlr7*$^{host+/+BM-/-}$ bone-marrow chimeras or by antibody-mediated neutrophil depletion also abolished endothelial cell necrosis. *Nr4a1*-dependent Ly6C^{low} monocytes are therefore intravascular housekeepers that orchestrate the necrosis by neutrophils of endothelial cells that signal a local threat sensed via TLR7, and the disposal of cellular debris.

P2.06.41

Simultaneous analysis of multiple fluorescent proteins and fluorochromes by a novel spectral flow cytomete

***M. Tomura**[1], K. Futamura[2], M. Furuki[2];*
[1]Center for Innovation in Immunoregulative Technology and Therapeutics Kyoto University Graduate Scho, Kyoto-city, Japan, [2]Life Electronics Development Division, R&D Department, Medical Business Unit, SONY Corporation, Tokyo, Japan.

We have been revealing immune system based of spatiotemporal regulation of immune cells in the entire body by using photoconvertible fluorescent protein (FP), Kaede and KikGR mice. Flow cytometric analysis of green and red signals of non-photoconverted and photoconverted Kaede or KikGR expressing cells with multiple fluorochrome-conjugated mAbs have been difficult and unable to increase color panels, because of the fluorescence signal overlap between FPs and fluorochromes.
We have newly developed a spectral flow cytometer (FCM) based on a novel measurement principle. Unlike a polychromatic FCM, the spectral FCM with 32 channel linear array PMT detects the fluorescence derived from every fluorescent probe. The data of acquired spectra is analyzed with a unique algorithm.
We detected spectral changes of KikGR color from green to red during photoconversion. We separated EGFP and Venus. One of the feature advantages of this instrument is that it can recognize spectral shape of each fluorescent probes and we could separate EGFP and FITC, their peaks of wavelength are almost same and only spectral shape of GFP is slightly broader than FITC. Finally, we successfully separated 11-colors including kikGR-green and -red simultaneously.
Taken together, spectral FCM allow us to detection of FPs with multicolor fluorochromes, and thus, the system which uses KikGR mice with spectral FCM is a powerful tool to investigate spatiotemporal regulation of immune cells in the entire body.

P2.06.42

The atypical chemokine receptor D6 is mobilized from recycling endosome for adaptive up-regulation and chemokine degradation through a β-arrestin1/myosinVb-dependent mechanism

***A. Vacchini**[1,2], E. M. Borroni[1,2], C. Cancellieri[1,2], A. Mantovani[1,2], M. Locati[1,2], R. Bonecchi[1,2];*
[1]Humanitas Research and Cancer Center, Rozzano, Italy, [2]Department of Medical Biotechnologies and Translational Medicine, University of Milan, Rozzano, Italy.

The atypical chemokine receptor D6 is a chemokine scavenger with a non-redundant role in the control of inflammation. D6 scavenging activity relies on its unique trafficking properties. The peculiar D6 intracellular distribution is ensured by its constitutive internalization and recycling through Rab4/Rab11-positive endosomes. Ligands induce D6 up-regulation on plasma membrane through a rapid mobilization of receptor from recycling endosomes but the mechanisms by which this adaptive up-regulation is achieved are still undefined. Here we show that in basal conditions D6/myosinVb complexes are differently associated to actin and microtubules, and perturbations of cytoskeletal dynamics dramatically affect receptor constitutive endocytosis and its correct sorting to recycling compartments. Ligand recognition per se rapidly mobilizes the intracellular pool of D6 through activation of a G protein-independent β arrestin1-dependent signaling pathway leading to actin and microtubules rearrangements at plasma membrane via myosinVb, thus upregulating receptor membrane expression and optimizing its scavenging properties. In conclusion, here we provide further evidences that the atypical chemokine receptor D6 is a β arrestin-biased signaling receptor, exerting its scavenger function through activation of a G protein-indipendent signaling pathway aimed at regulating its trafficking properties via myosinVb-dependent control of cytoskeletal dynamics.

P2.06.43
LFA-1 is critical for T-cell mediated protective immunity elicited by heterologous prime-boost vaccination strategy against a systemic parasitic infection

*F. Virgilio[1], M. Mariana R. Dominguez[1], A. V. Machado[2], O. Bruna–Romero[3], R. Ricardo T. Gazzinelli[2], M. M. Rodrigues[1], **J. C. Vasconcelos**[1];*
[1]Federal University of São Paulo, São Paulo, Brazil, [2]FIOCRUZ, Minas Gerais, Brazil, [3]Federal University of Santa Catarina, Florianópolis, Brazil.

INTRODUCTION: Heterologous prime-boost vaccination strategy using recombinant plasmid DNA followed by replication-defective human recombinant adenovirus 5 (AdHu5) is a powerful strategy to elicit specific $CD4^+$ and $CD8^+$ T cells which play a key role in protective immunity against intracellular pathogens as for example *Trypanosoma cruzi*, the causative agent of the neglected Chagas' disease. Based on evidences that recirculation after challenge is critical for T-cell mediated protective immunity, herein we tested whether certain integrins, cell adhesion molecules (CAM) and chemokines were key mediators of this process playing a critical role during immunity against infection.
RESULTS: To study the role of integrins, A/Sn mice were immunized with heterologous prime-boost vaccine (rec. plasmid DNA/AdHu5), challenged with parasites (Y strain) and treated with blocking antibodies to LFA-1 and/or VLA-4. Immunized mice treated with control Rat IgG or anti-VLA-4 antibodies controlled the parasitemia and survived the lethal challenge. In contrast, immunized mice treated with anti-LFA-1 or anti-LFA-1 and anti-VLA-4 displayed high parasitemia and all of them died after challenge. LFA-1 blockage neither diminished the frequency nor compromised the capacity of specific $CD8^+$ T cells to respond *in vitro* (IFN-γ and TNF). We performed similar experiments by vaccinating *icam-1*$^{-/-}$ or *cccr5*$^{-/-}$ mice. These mice controlled the infection at similar extension as wild type animals. CONCLUSION: We concluded that LFA-1 integrin, but not VLA-4, ICAM-1 or CCR5 play a critical role in the protective immune response generated by the heterologous prime-boost vaccination possibly by blocking T cell recirculation after challenge.

P2.06.44
TNFR2 induces IRF-1 dependent IFNβ autocrine signaling in endothelial cells to promote monocyte recruitment

***D. Venkatesh**, T. Ernandez, F. Rosetti, I. Batal, X. Cullere, F. Luscinskas, Y. Zhang, G. Stavraki, G. García-Cardeña, B. Horwitz, T. N Mayadas;*
Brigham and Women's Hospital, Harvard Medical School, Bosotn, MA, United States.

Endothelial-dependent mechanisms of mononuclear cell influx are not well understood. We discovered that acute stimulation of murine microvascular endothelial cells expressing TNFR1 and TNFR2 with soluble TNF, led to mononuclear CXCR3 chemokine generation through Interferon regulatory factor-1 (IRF-1) induced IFNβ synthesis and subsequent autocrine signaling via the IFNα/β -receptor and STAT1. Both TNFR2 and TNFR1 were required for IRF-1-IFNβ signaling. TNFR2's role in this pathway and monocyte recruitment was also evident following its overexpression and ligand independent activation in human endothelial cells. In vivo, TNFR1 was required for acute renal neutrophil and monocyte recruitment following systemic TNF treatment, while the TNFR2-IRF-1-IFNβ autocrine loop was essential only for monocyte/macrophage influx. In a chronic model of proliferative nephritis, IRF-1 and renal expressed TNFR2, but not TNFR1, were essential for sustained macrophage accumulation. Thus, our data identify a previously unrecognized pathway in endothelial cells that selectively recruits monocytes during a TNF-induced inflammatory response

P2.06.45
Role of CBAP in chemokine-induced zap70-mediated T-cell trafficking

*Y. Chiang[1], K. Ho[2], K. Ho[2], C. Sun[3], J. Chiu[4], F. Lee[2], F. Liao[3], H. Yang-Yen[5], **J. J. Yen**[3];*
[1]Institute of Microbiology and Immunology, National Yang-Ming University, Taipei, Taiwan, [2]Institute of Molecular Medicine, College of Medicine, National Taiwan University, Taipei, Taiwan, [3]Institute of Biomedical Sciences, Academia Sinica, Taipei, Taiwan, [4]Division of Medical Engineering Research, National Health Research Institutes, Chu-Nan, Taiwan, [5]Institute of Molecular Biology, Academia Sinica, Taipei, Taiwan.

Activated chemokine receptor initiates inside-out signaling to transiently trigger activation of integrins, a process involving multiple components that have not been fully characterized. Here we report that GM-CSF/IL-3/IL-5 receptor common beta-chain-associated protein (CBAP) is required to optimize this inside-out signaling and activation of integrins. First, knockdown of CBAP expression in human Jurkat T cells caused attenuated CXC chemokine ligand-12 (CXCL12)-induced cell migration and integrin α4β1- and αLβ2-mediated cell adhesion *in vitro*, which could be rescued sufficiently upon expression of murine CBAP proteins. Freshly isolated CBAP-deficient primary T cells also exhibited diminution of chemotaxis toward CC chemokine ligand-21 (CCL21) and CXCL12, and these chemokines-induced T-cell adhesions *in vitro*. Adoptive transfer of isolated naive T cells demonstrated that CBAP deficiency significantly reduced lymph node homing ability *in vivo*. Finally, migration of T cell-receptor-activated T cells induced by inflammatory chemokines was also attenuated in CBAP-deficient cells. Further analyses revealed that CBAP constitutively associated with both integrin β1 and ZAP70 and that CBAP is required for chemokine-induced initial binding of the talin-Vav1 complex to integrin β1 and to facilitate subsequent ZAP70-mediated dissociation of the talin-Vav1 complex and Vav1 phosphorylation. Within such an integrin signaling complex, CBAP likely functions as an adaptor and ultimately leads to activation of both integrin α4β1 and Rac1. Taken together, our data suggest that CBAP indeed can function as a novel signaling component within the ZAP70/Vav1/talin complex and plays an important role in regulating chemokine-promoted T-cell trafficking.

Anergy in CLL B lymphocytes: implications for the biology and the therapy of the disease

***B. Apollonio**[1,2], S. Cristina[2], M. Bertilaccio[2], E. ten Hacken[1,2], L. Scarfò[1,3], F. Stevenson[4], G. Packham[5], P. Ghia[3,2,1], M. Muzio[2], F. Caligaris Cappio[1,2,3];*
[1]Università Vita Salute San Raffaele, Milano, Italy, [2]San Raffaele Scientific Institute, Division of Molecular Oncology, Unit of Lymphoid Malignancies, Milano, Italy, [3]San Raffaele Scientific Institute, Department of Onco-Hematology, Lymphoma Unit, Milano, Italy, [4]Molecular Immunology Group, Tenovus Laboratory, Cancer Sciences Division, Southampton University Hospitals Trust, Southampton, United Kingdom, [5]Cancer Research UK Centre, Cancer Sciences Unit, University of Southampton Faculty of Medicine, Southampton General Hospital, Southampton, United Kingdom.

Chronic Lymphocytic Leukemia (CLL) is due to the clonal expansion of $CD5^+$ B lymphocytes. For many years CLL has been considered a leukemia of functionally inactive B lymphocytes. In apparent contrast, more recently it has been shown that a portion of cases is actually responsive to external stimuli including the activation though the BCR. That notwithstanding, it holds true that a sizable fraction of CLL patients are indeed characterized by the expansion of clonal B cells endowed with anergic features.
In particular, our studies demonstrated that lack of in vitro signaling capacity upon BCR triggering in a subset of CLL patients, was associated with the anergic features previously described in murine

models of B cell anergy (constitutive activation of ERK1/2 and NF-ATc1, higher basal levels of intracellular calcium, reduced expression of surface IgM and increased expression of the negative regulator receptors CD5 and CD22).
In this group of patients, chronic BCR engagement in vivo leads to the induction of a reversible biochemical anergic program that promotes survival of leukemic cells.
Constitutive ERK and NF-ATc1 activation can be efficiently targeted with small chemical compounds and cells first regain antigen responsiveness and then undergo apoptosis, thus further confirming the pro-survival role of anergy induction and possibly opening new perspectives in the clinical management of this subset of patients.

P2.07.02
Immune regulation mediated by soluble MHC-II targeting CD4+ T-cells

K. Bakela[1]*, M. Grigoriou*[1]*, P. Petroulakis*[1]*, E. Gizeli*[1,2]*, I. Athanassakis*[1]*;*
[1]*Dpt. of Biology, University of Crete, Heraklion, Greece,* [2]*Immb, FORTH, Heraklion, Greece.*

Soluble MHC-II (sMHCII) molecules are present in body fluids of healthy individuals and are considered to be involved in the maintenance of self tolerance, while they are also related to various diseases. Their concentration increases during in vivo antigen-specific tolerogenic stimulation and it was recently shown that exosome-mediated tolerance is MHC-II dependent. At the cellular level, sMHCII proteins compete with membrane MHCII for TCR binding. Soluble MHC-II proteins were isolated from serum of HSA-tolerant mice and purity was verified through ELISA, SDS-PAGE, Western blot analysis and acoustic biosensor assays using specific a-class II antibodies. SDS-PAGE revealed one band at ~60kDa which was found to be highly glycozylated. Soluble MHCII suppressed an antigen-specific immune response by reducing the number of active cells as tested by 3HTdR incorporation assays. Furthermore, sMHC-II molecules appeared to target purified CD4+ cells in contrast to CD8+ cells and K562 cells used as control in acoustic biosensor assays. In fact, they increased CTLA+/CD4+ numbers while reducing CD28+/CD4+ T-cells as tested by FACS analysis. ELISA experiments showed that sMHCII induced secretion of IL-10, while increasing the expression of CD25 surface marker in control CD4+ T-cells. Evaluation of TCR signaling in CD4+ cells indicated differential pathway activation in the presence or not of sMHCII. Finally, the results showed that sMHCII could negatively regulate antigen-specific immune response in vivo as well as in vitro by inducing immunosuppressive CTLA4+ and CD25+ T-cell populations and immunosuppressive mediators, playing thus an important role in immune homeostasis.

P2.07.03
Hepatocyte growth factor attenuates in vitro murine cytotoxic T-lymphocyte activity

M. Benkhoucha*, N. Molnarfi, G. Schneiter, R. Vuilleroy De Silly, P. Walker, P. Lalive;*
Faculty of Medicine. Department de Pathology and Immunology - CMU, Geneva, Switzerland.

Background: Hepatocyte growth factor (HGF) is a multifunctional pleiotropic cytokine recognized as a key factor in the prevention and attenuation of disease progression. We have recently reported that HGF limits CD4+ T cell-mediated autoimmune inflammation by promoting tolerogenic dendritic cells (DC) and subsequent regulatory T cells. Whether HGF modulates cell-mediated immunity driven by MHC class I-restricted CD8+ T cells remains to be determined.
Objective: Here we examined whether HGF regulates antigen (Ag)-specific CD8+ T cell responses using an established in vitro model of murine cytotoxic T lymphocyte (CTL)-mediated killing.
Methods: Pmel-1 transgenic gp100-specific CD8+ T cells were activated using Ag-pulsed Ag-presenting cells (APC) in the absence or presence of the HGF (30 ng/ml). After 5 days, cytolytic activity against EL4 or peptide-pulsed EL4 was measured in a 4-h DELFIA® release assay. Cytolitic pathways were quantified by FACS analysis.
Results: HGF treatment reduced MHC class I-restricted CTL-mediated cytolysis. FACS analysis revealed decreased levels of IFN-gamma, TNF, FAS-L, granzyme B, perforin and the degranulation marker CD107a among CD8+ T cells co-cultured with HGF-treated APC. Moreover, HGF suppressed the frequency of the CÐ62L effector memory CTL population.
Conclusion: Our findings indicate that HGF treatment limits both the generation of effector CTL from naive CD8+ T cells and their cytotoxic functions, such as granule exocytosis mediated by perforin/granzymes and the Fas/Fas ligand system. Complementary to its impact on CD4+ T-cell immunity, our findings further suggest that HGF treatment could be exploited to control CD8+ T-cell-mediated, MHC I-restricted dysfunctions.

Newcastle University, Newcastle Upon Tyne, United Kingdom.

The gene encoding a transmembrane spanning protein (NTP) was originally discovered in neuronal cells and subsequent studies have identified NTP gene expression in a range of different primary cells and cell lines, but with no reference to its function. Functional roles have been suggested in cellular interactions and regulation of cellular ion fluxes, based on homology to other proteins, yet no experimental data have developed this hypothesis in T-cells. Analysis of early gene expression in anergic, activated and resting CD4+ T-cell clones identified NTP to be differentially expressed between the different states. Expression was stable in the anergic state and fell upon activation. These data suggest that NTP may regulate CD4+ T-cell activation.
The aim of this study was to identify the role of NTP expression in immune cell subsets, focusing primarily on the CD4+ T-cells. NTP expression was investigated in the resting and activated states of CD4+ T-cells in a bid to understand how NTP may be regulated and the effects it may exert on different CD4+ T-cell states.
NTP protein expression has been identified on the surface of a variety of immune cell subsets. Culturing CD4+ T-cells *in vitro* resulted in the internalisation of NTP, creating a challenge to determine NTP function. Interestingly, CD4+ T-cell activation induced elevated NTP expression and whole blood cultures also maintained the expression of NTP. Over-expression studies in primary human CD4+ T-cells has also revealed a potential role for NTP in the regulation of T-cell function, opening up many further research avenues.

P2.07.05
T cell receptor modulation in peripheral CD8 T cells to influenza infection

P. Dash*, J. L. McClaren, P. C. Doherty, P. G. Thomas;*
St Jude Children's Research Hospital, Memphis, TN, United States.

Our understanding of complementary T cell receptor (TCR) α and β chain utilization and modulation is very limited for pathogen-specific immunity. We recently reported a method for amplifying paired T cell receptor (TCR) αβ CDR3 regions from single cells in mice and human. Using this technique, we found surprisingly, 25% of influenza-epitope-specific CD8+ cytotoxic T lymphocytes recovered directly from the pneumonic lung expressed a dominant, non-productively rearranged TCRα transcript, an effect that is never seen for TCRβ. T cells with these out-of-frame TCRα mRNAs also express an alternate, in-frame TCRα, while approximately 10% have two productive TCRα transcripts. Taking TCRα out-of-frame mRNA as a surrogate for the alternate allele expression, we found that the proportion of cells with biallelic transcription increases over the course of a response, stayed high in the memory compartment, and decreased in the recall response. However, these biallelic cells appear to expand with low efficiency. Further, cells with out-of-frame TCRα mRNA expression appear to be specifically excluded from the recall response but upregulated to the level seen in primary response in highly inflammatory conditions. Finally, mice deficient in a single alpha locus, thus lacking modulation in alpha chain, showed delayed onset

and decreased severity of Experimental autoimmune encephalomyelitis (EAE) compared to that of the WT littermate controls. Thus, allelic modulation may play a role in down regulation of TCR expression for survival advantage in highly inflammatory condition by down modulating the TCRα mRNA, a finding that has implications for immune memory and for autoimmunity.

P2.07.06
Activation induced split anergy: a mechanism for persistence of autoimmune T cells

S. Dubey[1]*, R. R. Singh*[2]*;*
[1]Amity Institute of Virology & Immunology, Amity University Uttar Pradesh, Noida, India, [2]Division of Rheumatology, David Geffen School of Medicine, University of California Los Angeles, Los Angeles, CA, United States.

T cell anergy is considered to be one of the major mechanisms for maintaining self-tolerance and restricting autoimmunity. Self-reactive T-cells from patients with autoimmune diseases such as systemic lupus erythematosus (SLE), Sjogren's syndrome and rheumatoid arthritis are believed to avoid anergy. Instead, we found that T-cells from animal models of autoimmune diseases exhibit anergy rather than resistance to it. Autoimmune T-cells, however, also display features of chronic in vivo activation characterized by enhanced activation markers (CD44hiCD62LlowCD69+), IFN-γ production and constitutive phosphorylation of multiple T-cell receptor (TCR) signalling proteins. Those autoimmune T-cells that exhibit such split responsiveness acquire an anergic phenotype but retain effector functions and evade AICD upon TCR stimulation. Thus, persistent activation of T-cells by self-antigens in autoimmune-prone subjects culminates as "activation-induced split anergy" that promotes the development, rather than avoidance, of autoimmunity. The seemingly paradoxical or split phenotype of autoimmune T-cells described above may represent different CD4+ T-cell subsets, with one subset manifesting anergy and the other subset exhibiting activation phenotype. The localization of split T-cell phenotype to one subpopulation indicates a link between anergy and activation and leads us to propose that anergy in autoimmune T-cells might occur as a consequence of chronic in vivo activation with self-antigens.

P2.07.07
Ectopic expression of IL-35Ig by dendritic cells induces IDO-related tolerance in vivo

M. Gargaro*, M. Belladonna, C. Volpi, R. Bianchi, F. Fallarino, C. Orabona, M. Pallotta, D. Matino, U. Grohmann, P. Puccetti;*
Department of Experimental Medicine, University of Perugia, Perugia, Italy.

Dendritic cells (DCs) are specialized APCs playing a central role in activating, but also in regulating, T-cell responses. In previous studies, we demonstrated that their functional plasticity can be exploited to trigger and amplify a tolerogenic state ('infectious tolerance'), here we focused on the possible modulation of immune responses by ectopic expression of IL-35 in DCs, a potent suppressive cytokine produced by T regulatory cells. We transfected immunogenic CD8- DCs with a single-chain IL-35-Ig gene construct and we found that, after P815AB antigen peptide pulsing, even a minority fraction of transfected cells inhibited the immunogenic presentation of the peptide in a skin test assay, triggering the onset of a long-lasting, specific tolerance subverting the otherwise immunogenic priming to the peptide. This suppressive effect was attributable to changes occurring in vivo in total splenocytes and in their CD11c+ DC fraction after DC/IL-35-Ig/P815AB injection, including induction of tolerogenic indoleamine 2,3-dioxygenase-1 (IDO1) and production of mediators sustaining the mechanism of infectious tolerance (via the IDO1 metabolite kynurenine, TGF-β, and IL-10). On the basis of these findings, we attempted a tolerogenic vaccination protocol to prevent autoimmune diabetes. Interestingly, on treating prediabetic NOD mice with DCs overexpressing IL-35 and presenting the IGRP peptide (one of the most relevant type 1 diabetes self-antigens), we observed delayed and less severe onset of hyperglycemia. In conclusion, DCs overexpressing ectopic IL-35Ig exert an important suppression in vivo, which, on combination with specific antigen, might represent a powerful, selective means of negative vaccination in autoimmune diseases.

P2.07.08
Abnormal transcriptional regulation of the E3 ligase Cbl-b by early growth response genes 2 and 3 in systemic lupus erythematosus patients

D. Gomez-Martin, J. Romo-Tena, K. Santana-de Anda, ***J. Alcocer-Varela****;*
Instituto Nacional de Ciencias Medicas y Nutricion, Salvador Zubiran, Mexico City, Mexico.

T cells from Systemic Lupus Erythematosus (SLE) patients display resistance to anergy induction, which has been related to the deficiency of the E3 ligase Cbl-b. This abnormal peripheral tolerance is characterized by increased IL-2 production, proliferation and expression of activation and costimulatory markers upon anergy-inducing conditions. The transcription factors Early Growth Response (Egr) 2 and 3 have been implicated in the transcriptional regulation of Cbl-b in murine models. However their role in human T cell responses has not been fully addressed. The aim of this study was to evaluate the expression of the transcription factors Egr-2 and 3 and its relationship to Cbl-b in T cells from SLE patients. We included 16 SLE patients (8 in remission and 8 with active untreated disease) and 16 healthy controls. PBMCs were isolated and $CD4^+$ cells were purified by negative selection.The expression of Egr-2, 3 and Cbl-b was analysed by qPCR and Western blotting. $CD4^+$ cells from SLE patients show increased proliferation and IL-2 synthesis after anergy induction. Moreover, upon anergy induction with ionomycin, decreased expression of *Egr-2* (0.46 vs 1.89, $p<0.001$); *Egr-3* (0.80 vs 2.55,$p<0.001$) and Cbl-b (0.52 vs 0.87, $p=0.028$) was found in lupus T cells in comparison to healthy controls. Our data suggest that the deficiency in Cbl-b expression in $CD4^+$ T cells from SLE patients, without regarding disease activity, is related to transcriptional defects, mainly, decreased Egr-2 and 3 expression, which is related to the breach in peripheral tolerance.

P2.07.09
Olfactory exposure to Tokishakuyaku-san (TJ-23) prolonged cardiac allograft survival and generated regulatory cells

X. Jin[1,2]*, M. Uchiyama*[3,1]*, Q. Zhang*[1,4]*, L. Yu*[1,2]*, M. Niimi*[1]*;*
[1]Teikyo University, Tokyo, Japan, [2]Harbin Medical University, Harbin, China, [3]Juntendo University Hospital, Tokyo, Japan, [4]Huashan Hospital of Fudan University, Shanghai, China.

Background. Herbal medicines have unique odors, and the act of smelling may have modulatory effects on the immune system. We investigated the effect of olfactory exposure to Tokishakuyaku-san (TJ-23), a Japanese herbal medicine, on alloimmune responses in a murine model of cardiac allograft transplantation.
Methods. Naïve or olfactory-dysfunctional CBA mice underwent transplantation of a C57BL/6 heart and were exposed to the odor of TJ-23 until rejection. Some naïve CBA recipients of an allograft were given olfactory exposure to Sairei-to (TJ-114), trimethylthiazoline (TMT), individual components of TJ-23, or a TJ-23 preparation lacking one component. Adoptive transfer studies were performed to determine whether regulatory cells were generated.
Results. Untreated CBA mice rejected their C57BL/6 allografts acutely, as did olfactory-dysfunctional CBA mice exposed to the odor of TJ-23 (median survival times [MSTs], 7 and 7 days, respectively). CBA recipients of a C57BL/6 heart given olfactory exposure to TJ-23 had significantly prolonged allograft survival, whereas those exposed to the odor of TJ-114, TMT (MSTs, 48, 8.5 and 8 days), one component of TJ-23, or TJ-23 lacking a component did not. Secondary allograft recipients that were given, at 30 days after transplantation, either whole splenocytes, $CD4^+$ cells, or $CD4^+CD25^+$ cells from primary recipients exposed to the odor of TJ-23 had indefinitely prolonged allograft survival.
Conclusions. Prolonged survival of cardiac allografts and generation of regulatory cells was associated with exposure to the odor of TJ-23 in our model. The olfactory area of the brain may have a role in the modulation of immune responses.

P2.07.10
Combination of anti-BTLA antibody (6B2) and anti-PD-1 antibody (PIM-2) induced indefinite survival of fully MHC-mismatched murine cardiac allograft

X. Jin[1,2], *M. Uchiyama*[3,1], *L. Yu*[1,2], *H. Bashuda*[3], *H. Yagita*[3], *M. Niimi*[1]; [1]*Teikyo University, Tokyo, Japan,* [2]*Harbin Medical University, Harbin, China,* [3]*Juntendo University Hospital, Tokyo, Japan.*

Background: Programmed death (PD)-1 and B and T lymphocyte attenuator (BTLA) had been implicated in the regulation of autoimmune and may potentially play an important role in alloimmune responses. In this study, we investigated the effect of anti-PD-1 monoclonal antibody (mAb) (PIM-2) and anti-BTLA mAb (6B2) in fully MHC-mismatched murine model of cardiac allograft transplantation.
Methods: CBA mice underwent transplantation of C57BL/6 hearts and received a single dose (100μg) of 6B2 on the day of transplantation (day 0) or four doses on day 0, 3, 6 and 9. Moreover, CBA recipients were also given one dose of combination of 6B2 and PIM-2 on day 0. Adoptive transfer was performed to determine whether regulatory cells were generated. Cell-proliferation and cytokine assessments were also performed.
Result: Untreated CBA mice rejected C57BL/6 allografts acutely (median survival time [MST], 7 days). When CBA recipients were given one and four doses of 6B2, the allograft survivals were significantly prolonged (MSTs, 46 and >100 days, respectively). Moreover, when CBA mice were given with combination for one dose of 6B2 and PIM-2, the allograft survival was indefinitely prolonged (MST, >100 days). Secondary CBA recipients given whole splenocytes from primary combination-treated CBA recipients with C57BL/6 cardiac allografts 30 days after grafting had prolonged C57BL/6 allograft survival (MST, >20 days). Proliferation of splenocytes and interferon-γ production were suppressed and interleukin-4 production was increased in combination-treated mice.
Conclusion: Combination of anti-BTLA mAb (6B2) and anti-PD-1 mAb (PIM-2) could induce hyporesponsiveness of fully MHC-mismatched cardiac allografts and may generate regulatory cells.

P2.07.11
Tolerogenic human IL-10-modulated dendritic cells as inducers of regulatory T cells: analysis of mature CD83highCCR7highHLA-DRhigh and immature CD83lowCCR7negativeHLA-DRlow DC subpopulations

F. Kryczanowsky*, E. Graulich, K. Rost, K. Steinbrink;*
University Medical Center, Dermatology, Mainz, Germany.

Human IL-10-modulated, tolerogenic dendritic cells (IL-10DC), which are capable to induce anergic regulatory $CD4^+$ T cells (iTregs), consists of two subpopulations, mature $CD83^{high}CCR7^{high}HLA\text{-}DR^{high}$ and immature $CD83^{low}CCR7^{negative}HLA\text{-}DR^{low}$. Here, we investigated both IL-10DC subsets with regard to their phenotype and tolerogenic capacity in detail. As compared to fully mature DC (mDC), the $CD83^{low}$ IL-10DC subset revealed a significantly diminished expression of CD80, CD86, ICOS-L, and CD40 accompanied by a slight upregulation of PD-L2, ILT3, and ILT4. In contrast, we observed minor changes in expression of costimulatory molecules but significantly increased levels of inhibitory molecules on $CD83^{high}$ IL-10DC, demonstrating significant differences in expression of costimulatory and inhibitory molecules between the two IL-10DC subsets. Notably, primary stimulation of naïve T cells and restimulation experiments demonstrated that both IL-10DC subpopulations, in contrast to mDC and regardless of their maturation state, induced anergic $CD4^+$ T cells as evaluated by a significantly reduced T cell proliferation and diminished Th1 and Th2 responses. In addition, both iTreg subpopulations exhibited regulatory activities and suppressed the activation of responder T cells but lost their anergic state during suppressor experiments. In conclusion, mature $CD83^{high}CCR7^{high}HLA\text{-}DR^{high}$ and immature $CD83^{low}CCR7^{negative}HLA\text{-}DR^{low}$ IL-10DC display properties of tolerogenic human DC, in particular of inducers of iTregs, which may be used as targets for the development of novel therapeutic approaches for allergies, autoimmune disease or transplant rejections.

P2.07.12
A humanized mouse model for the study of B cell tolerance in human lymphocytes

J. Lang[1], *M. Kelly*[1], *D. Nemazee*[2], *B. Freed*[3], *R. Torres*[3], *R. Pelanda*[1]; [1]*National Jewish Health, Denver, CO, United States,* [2]*Scripps Research Institute, La Jolla, CA, United States,* [3]*University of Colorado-Denver, Aurora, CO, United States.*

In most autoimmune diseases, autoreactive B cells fail to undergo negative selection (i.e., tolerance), and thus promote immune responses against self. B cell tolerance mechanisms of receptor editing, deletion and anergy have been established using genetically modified mice. The mechanisms by which human B cells undergo tolerance, however, are currently unknown because of the challenges associated with studying the human immune system. We are using hematopoietic humanized mice (hu-mice) to study mechanisms of human B cell tolerance. Hu-mice are immunodeficient mice transplanted with human hematopoietic stem cells that generate a human immune system within the mouse host. To investigate human B cell tolerance in hu-mice we generated a ubiquitous membrane-tethered *human* Ck-reactive synthetic Ag (hCk-Ag) that allows studies of central B cell tolerance of kappa-bearing human B cells. We find two versions of tolerance in hu-mice: a central tolerance phenotype in which kappa-positive B cells are eliminated from the bone marrow and a second phenotype in which a population of kappa-low, CD19-low B cells are observed in the bone marrow and spleen. The phenotype observed segregates largely with cord blood donor, and is thus likely genetically determined. We are currently investigating the mechanisms of these tolerance phenotypes using intracellular staining for kappa, BrdU incorporation analysis, and molecular analysis of Rag expression and kappa deleting element in developing B cells. Hu-mice represent an ideal model to study the human immune system using the powerful genetic and cell biological methodologies developed in mice.

P2.07.13
Serial transfere of anergy status induced by TSST-1 into newly stimulated T cells

N. Negishi[1], *T. Sato*[2], *Y. Kametani*[2], *S. Hori*[3], *K. Okumura*[1,4], *S. Habu*[1];
[1]*Department of Immunology, Juntendo University School of Medicine, Tokyo, Japan,* [2]*Department of Immunology, Tokai University School of Medicine, Isehara, Japan,* [3]*RCAI, Riken, Yokohama, Japan,* [4]*Atopy (Allergy) Reserch Center, Juntendo University School of Medicine, Tokyo, Japan.*

The term “infectious tolerance” was referred to the suppression process in which anergy/unresponsiveness-induced status is transferred from one to another cell population. In this study, we induced anergy status in vivo by administration of superantigen/toxic shock syndrome toxin-1 (TSST-1) into OVA-TCR Tg mouse T cells, and analyzed how the anergy T cells conduct a suppressive potential in naïve T cells receiving TCR-mediated signaling. When the anergy T cells were co-cultured with naïve T cells in the presence of OVA, anergy status appeared in naïve T cells, which are distinguished from the 1st anergy cells by using (OVAxGFP) Tg mice. The 2ndry generated anergy cells could further lead the appearance of antigen specific unresponsiveness in newly stimulated naïve T cells by the co-culture with 3rd new naïve T cells. In the induced anergy T cells of three generations showing reduced IL-2, IL-10 expression, but not TGF-β or Foxp3, was highly detectable and accelerated during 24 hrs. Although APCs is known to produce IL-10, they don't seem to play a main role for transfer of anergy status into newly stimulated T cells because deletion of such APC didn't provide largely effect of production of IL-2 and IL-10. This assumption is compatible with another experimental result showing that naïve T cells cultured with OVA in the presence of IL-10 did not lead anegy T cells. These results suggest that TSST-1 driven anergy T cells, but not APCs, trigger the “infectious tolerance” in naïve T cells in an IL-10 less dependent manner.

P2.07.14
The role of GRAIL in anti-cancer immune responses

***R. Nurieva**, J. Wang, A. Sahoo, A. Alekseev;*
MD Anderson Cancer Center, Houston, TX, United States.

Severely suppressed immune system is a major risk factor in the tumor development. Strategies to improve immune cell survival and function are needed, and one potential approach is to manipulate the intrinsic properties of T lymphocytes by genetic ablation of tolerance/anergy associated genes. In recent years, the E3 ubiquitin ligases (Cbl-b, Itch and GRAIL) have been acknowledged as key molecules implicated in T cell tolerance. We as well as other groups have reported that $CD4^+$ and $CD8^+$ T cells activated in the absence of both CD28 and ICOS costimulation developed into tolerant T cells, associated with markedly upregulated expression of the E3 ubiquitin ligase GRAIL. Remarkably, genetic inactivation of GRAIL led to $CD4^+$ T cell hyper-responsiveness to TCR/CD3 signaling and their independency to costimulation. In addition, GRAIL deficiency abrogates the suppressive function of regulatory T cells, which are known to contribute to tumoral immune tolerance. There are growing evidences about the negative role of E3 ubiquitin ligases, Cbl-b and Itch, in a variety of cancers including solid tumors and hematopoietic malignancies. However, until now there is no knowledge on the role of GRAIL in tumor progression. Our data indicates that GRAIL controls proliferation and function of $CD8^+$ cytotoxic T lymphocytes. Moreover, ablation of GRAIL results in regression of lymphoma development. Thus, modulation of GRAIL activity might be an important approach to improve T-cell mediated anti-tumor responses.

P2.07.15
The soluble cytoplasmic tail of CD45 (ct-CD45) induces a non-canonical form of anergy in human T cells

***A. E. Puck**, M. Seyerl, S. Hopf, O. Majdic, G. Zlabinger, J. Leitner, P. Steinberger, J. Stöckl;*
Medical University of Vienna, Vienna, Austria.

The cytoplasmic tail of CD45 (ct-CD45) is proteolytically cleaved and released upon activation of human phagocytes. The soluble ct-CD45 was found to act on T cells as an inhibitory, cytokine-like factor that reduces T cell proliferation.
In this study, we aimed to elucidate the molecular mechanisms acting within T cells, upon ct-CD45 binding. We demonstrate that ct-CD45 induces a novel form of anergy in human peripheral blood T cells. Ct-CD45 inhibited the proliferation of purified T cells and their cytokine production. Co-stimulation failed to prevent this inhibitory signal. Moreover, we found that T cells activated via CD3/CD28 or CD3/CD63 in the presence of ct-CD45 failed to proliferate in response to restimulation which was reversible by exogenous IL-2 or IL-7. Recent studies have clearly demonstrated that such a hypo-proliferative or anergic state of T cells is an active process where “anergy factors” (e.g. EGR2, EGR3, CBL-b, DGK-α) are being induced to establish and maintain the unresponsive state. However, when we analyzed the gene expression profile of ct-CD45-induced anergic T cells we did not observe induction of any of these anergy factors. Characterizing the expression patterns of cell cycle regulatory factors, we found inhibition in the induction of cyclin D1 while other cyclins were unaltered.
In summary, ct-CD45 triggers an anergy program in T cells which is reversible by exogenous IL-2, acting independently of classical anergy factors. Inhibition of cyclin D1 suggests a cell cycle arrest in the early G1 phase, thus making it distinct from canonical T cell anergy.

P2.07.16
Characterization of the molecular regulatory pathways involved in MDSC-mediated tolerance

***S. Solito**[1], L. Pinton[1], V. Damuzzo[1], L. Perilli[1], G. Basso[2], P. Zanovello[1,3], V. Bronte[4], S. Mandruzzato[1,3];*
[1]Department of Surgery, Oncology and Gastroenterology, University of Padova, Padova, Italy, [2]Department of Woman and Child Health Onco hematology Laboratory, University of Padova, Padova, Italy, [3]Istituto Oncologico Veneto IOV-IRCCS, Padova, Italy, [4]Verona University Hospital and Department of Pathology, Immunology Section, University of Verona, Verona, Italy.

Myeloid-derived suppressor cells (MDSCs) represent a heterogeneous population of immature myeloid cells mediating immunosuppression in the tumor microenvironment. We recently demonstrated that GM-CSF and G-CSF allow a rapid generation of MDSCs from precursors present in human bone marrow (BM) aspirates, named BM-MDSCs. This cell population is heterogeneous but an immature subset resembling to promyelocytes and defined i-BM-MDSCs (immature BM-MDSCs), is responsible for the whole immune suppression mediated by BM-MDSCs; of note, i-BM-MDSCS are equivalent to MDSCs present in the blood of breast and colorectal cancer patients. When we compared miRNA expression of promyelocytes isolated from fresh BM cells with that of i-BM-MDSCs, we observed differentially expressed miRNAs involved in myeloid differentiation and proliferation, by suggesting a block in the differentiation of these immature cells, coupled to signalling pathways that we are presently investigating. We characterized the mechanisms by which MDSCs are able to interfere with T cell proliferation by culturing activated T cells with i-BM-MDSCs. After cell culture, the number of vital T cells is significantly reduced and part of the lymphocytes undergo apoptosis; moreover, the expression of some immunoregulatory receptors belonging to the B7 family is increased on i-BM-MDSCs only after contact with activated T cells. Additionally, we demonstrated that IL-10 is involved in B7-dependent MDSC-immunosuppression. Our results indicate that the interaction between activated T cells and MDSCs involves the activation of suppressive pathways mediated by inhibitory receptors and thus highlight molecules that could be potential targets of intervention for cancer therapy.

P2.07.17
PD-L1 expression induced by the 2009 pandemic influenza A (H1N1) virus impairs the human T cell response

***N. Valero-Pacheco**[1,2], L. Arriaga-Pizano[2], E. Ferat-Osorio[2], R. Pastelin-Palacios[3], M. Villasís-Keever[4], C. M. Alpuche-Aranda[5], L. E. Sánchez-Torres[1], A. Isibasi[2], L. C. Bonifaz[2], C. López-Macías[2];*
[1]National School of Biological Sciences, National Polytechnic Institute, Mexico City, Mexico, [2]Medical Research Unit on Immunochemistry (UIMIQ), Specialties Hospital, National Medical Centre “Siglo XXI,” Mexican Social Security Institute (IMSS), Mexico City, Mexico, [3]Facultad de Química, Universidad Nacional Autónoma de México, Mexico City, Mexico, [4]Unidad de Investigación en Epidemiología Clínica, Hospital de Pediatría, Centro Médico Nacional Siglo XXI. Instituto Mexicano del Seguro Social, Mexico City, Mexico, [5]Instituto Nacional de Salud Pública, Cuernavaca, Mexico.

PD-L1 expression plays a critical role in the impairment of T cell responses during chronic infections; nevertheless, the expression of PD-L1 on T cells during acute viral infections, particularly with the pandemic influenza virus (A(H1N1)pdm09), as well as the consequences of PD-L1 expression during infection, have not been explored. We found that A(H1N1)pdm09 induced PD-L1 expression on human dendritic cells (DCs) and T cells. PD-L1 expression impaired the T cell response against A(H1N1)pdm09 by slightly decreasing CD4+ T cell proliferation, promoting CD8+ T cell death and reducing cytokine production. Furthermore, we found increased PD-L1 expression on DCs and T cells from influenza-infected patients from the first and second pandemic waves in Mexico City. PD-L1 expression on CD8+ T cells correlated inversely with T cell proportions in patients infected with A(H1N1)pdm09 but not in those with influenza-like illness. Therefore, PD-L1 expression on DCs and T cells could be associated with an impaired T cell response during acute infection with A(H1N1)pdm09 virus.

P2.07.18

Induction of allogeneic immune tolerance by simultaneously blocking ICOS and OX40 costimulatory pathways

Y. Wang*;*
Key Lab for Critical Care Medicine of the Ministry of Health, Central laboratory of Tianjin First Center Hospital, Tianjin, China.

Aim: The aim of the present study was to investigate the effects of induced immune tolerance by simultaneously blocking ICOS/ICOSL and OX40/OX40L costimulatory pathways, as well as potential underlying mechanisms. **Methods:** A eukaryotic expression vector containing both of the CTLA4Ig and OX40Ig fusion protein genes, pEGFP-ICOSIg-OX40Ig, was constructed by homologous recombination. The induction of donor-specific hyporeactivity was evaluated through allogeneic mixed lymphocyte reaction (MLR) using the isolated Wistar rat splenocytes as stimulator cells and the Lewis rat splenocytes as responder cells incubated with ICOSIg, OX40Ig or ICOSIg and OX40Ig combined. ELISA and flow cytometry were also used to evaluate immune reactions. **Results:** Allogeneic MLR, lymphocyte proliferation was significantly inhibited in the three costimulatory blockade groups compared with that in control. Combined ICOSIg and OX40Ig fusion protein synergistically induced superior effect on inhibiting lymphocyte proliferation, and decreasing Th1/Th2-like cell cytokine production, compared with singular blockade of either ICOSIg or OX40Ig. The percentage of $CD4^+CD25^+$ regulatory T cells significantly increased when allogeneic lymphocyte was co-cultured with ICOSIg and OX40Ig combined. **Conclusion:** Combined ex vivo blocking ICOS/ICOSL and OX40/OX40L costimulatory pathways synergistically provided superior benefits on induction of immune tolerance.

P2.08.01
Functional relevance of NTAL adaptor cleavage

M. M. Arbulo-Echeverria, F. J. Garcia-Cozar, ***E. Aguado****;*
University of Cadiz, Cadiz, Spain.

Non-T-cell activation linker (NTAL) is a transmembrane adaptor protein involved in the proximal signaling associated to immune receptors expressed by B lymphocytes, NK cells, macrophages and mast cells. In B lymphocytes, engagement of the B cell antigen receptor (BCR) induces phosphorylation of its tyrosine residues, allowing the recruitment of several cytosolic mediators for downstream signaling pathways. Very recently, our group has demonstrated that the adaptor LAT, an adaptor protein structurally and evolutionarily related to NTAL and expressed by T cells, is proteolytically cleaved upon Fas engagement in a tyrosine phosphorylation dependent fashion. Here, we analyze NTAL adaptor proteolytic cleavage in mature B lymphocytes, monocytes and also in several cell lines. Upon Fas crosslinking NTAL is cleaved producing a N-terminal fragment of about 22 kDa, and this cleavage is abrogated in the presence of caspase 8/granzyme B inhibitor. Moreover, we identify the aspartic acid residue at which NTAL is cleaved, and, similar to LAT, this aspartic acid residue is located in proximity to a tyrosine residue. Consistently, phosphorylation induction of NTAL by pervanadate inhibits its Fas-mediated cleavage, suggesting that transmembrane adaptors cleavage constitute a general mechanism to negatively regulate intracellular signaling cascades associated to immune receptors.

P2.08.02
Analysis of TCR-Vβ repertoire in lung and blood lymphocytes of pulmonary sarcoidosis patients reveals presence of $CD4^+$ and $CD8^+$ T cell expansions

K. M. Ahlgren*, T. Ruckdeschel, A. Eklund, J. Wahlström, J. Grunewald;*
Karolinska Institutet, Stockholm, Sweden.

Sarcoidosis is a multisystem inflammatory disorder that can affect virtually any organ. The disease is characterized by granuloma formation and an accumulation of activated T cells in the affected organs. The etiology of sarcoidosis is not clear. Most evidence supports a genesis including environmental triggering by one or more still unknown antigens in the lungs, and an aberrant immune response in genetically susceptible individuals.
T cell receptor (TCR) Vβ-chain usage has been incompletely characterized in sarcoidosis patients. We surveyed the TCR Vβ usage in bronchoalveolar lavage (BAL) cells and peripheral blood from 15 HLA-typed Scandinavian sarcoidosis patients. In addition, PBMC from 9 healthy volunteers and BAL cells from three of them were examined. Using flow cytometry and 21 Vβ family-specific antibodies, we covered approximately 70 % of all Vβ chains.
In sarcoidosis patients, we identified 16 $CD4^+$T cell expansions in 271 analyses (5.9 %) in BAL cells and 9 $CD4^+$ T cell expansions in 276 analyses (3.3 %) in PBMC. The corresponding results in $CD8^+$ T lymphocytes were 21 expansions out of 240 analyses (8.7 %) of BAL cells and 12 expansions out of 263 analyses (4.6%) of PBMC. We found no difference in number of expansions between patients and controls in $CD4^+$ cells. However, expansions of T cells expressing Vβ5.1, Vβ7.1, Vβ18, Vβ21.3 and Vβ22 were found only in BAL from patients. This indicates qualitative rather than quantitative differences in Vβ-usage between patients and controls, and strengthens the hypothesis of specific antigen recognition in the lungs of sarcoidosis patients.

P2.08.03
The contribution of ligand affinity of the inhibitory coreceptor ILT2 to differential patterning of TCR at the immune synapse.

M. O. Aletrari*, K. Sabaratnam, R. Zhang, S. Dyball, S. Seyedmohammad, M. Purbhoo;*
Imperial College London, London, United Kingdom.

How activating and inhibitory signals integrate at the T cell immune synapse remains poorly understood. The inhibitory coreceptor Ig-like transcript 2 (ILT2) is expressed on T cells and binds MHC I (Kd=2-10 μM). ILT2 also binds the HCMV MHC homologue UL18 with 1000x higher affinity than MHC I. We have previously shown that binding of ILT2 to MHC I confined antigen-induced TCR accumulation to the periphery of the immune synapse and prevented TCR migration to the synapse centre, where ILT2 accumulated. This TCR exclusion is not observed when ILT2 is stimulated by UL18, where TCR and ILT2 cocluster.
We here show that this differential patterning of the immune synapse by viral and host ligands for ILT2 induces qualitatively different TCR signal transduction, but does not alter the dynamics of TCR recycling. Furthermore, we use model T cells expressing ILT2 variants with high-affinity for MHC I (Kd=40nM and 2.5nM) to investigate whether the differential pattering of TCR at the immune synapse results from the greater affinity of the UL18/ILT2 interaction compared to the MHC/ILT2 interaction. We observe that engagement of high-affinity ILT2 by MHC I induces peripheral localisation of the TCR. This suggests that the receptor-ligand affinity does not account for the observed differences in synaptic distribution of the TCR when ILT2 is engaged by MHC compared to UL18. Consequently, factors other than affinity are responsible for the ability of UL18 to differentially affect TCR patterning at the immune synapse and so enhance inhibitory signals which may aid viral immune evasion.

P2.08.04
Tollip-induced down-regulation of MARCH1

M. Bourgeois-Daigneault*[1], A. Pezeshki[1], T. Galbas[1], M. Houde[2], M. Baril[2], K. Früh[3], A. Amrani[4], S. Ishido[5], D. Lamarre[2], J. Thibodeau[1];*
[1]University of Montreal, Montreal, QC, Canada, [2]Institut de recherche en immunologie et en cancérologie, Montreal, QC, Canada, [3]Vaccine and Gene Therapy Institute,, Beaverton, OR, United States, [4]Université de Sherbrooke, Sherbrooke, QC, Canada, [5]Research Center for Allergy and Immunology, Yokohoma, Japan.

In addition to their classical antigen presenting functions, MHC class II molecules potentiate the TLR-triggered production of pro-inflammatory cytokines. Here, we have addressed the effect of Tollip and MARCH1 on the regulation of MHC II trafficking and TLR signaling. Our results show that MARCH1-deficient mice splenocytes are impaired in their capacity to produce pro-inflammatory cytokines in response to poly(I:C) and that TLR3 and MHC II molecules interact

in the endocytic pathway. Knocking down Tollip expression in human CIITA^{+} HeLa cells increased expression of HLA-DR but reduced the proportion of MHC II molecules associated with the CLIP peptide. Truncation of the HLA-DR cytoplasmic tails abrogated the effect of Tollip on MHC class II expression. While overexpression of Tollip did not affect HLA-DR levels, it antagonized the function of co-transfected MARCH1. We found that Tollip strongly reduced MARCH1 protein levels and that the two molecules appear to compete for binding to MHC II molecules. Altogether, our results demonstrate that Tollip regulates MHC class II trafficking and that MARCH1 may represent a new Tollip target.

P2.08.05
Intrinsic binding of V genes to autoantigens may contribute to BCR repertoire

*A. Q. Maranhão[1], B. W. Costa[1], P. M. M. Vieira[2], L. Guedes[1], M. E. T. Walter[1], T. Raiol[1], **M. M. Brigido**[1];*
[1]Universidade de Brasilia, Brasilia, Brazil, [2]Universidade de São Paulo, São Paulo, Brazil.

B-cell maturation occurs in several steps and it needs a constant stimulus for continuing its development. From the emergence of the pre-B-cell receptor, the signal transduction stimulates and supports B-cell development. Current viewpoints support that both a positive selection pressure for autoantigens and a tonic signaling constitutively stimulate B-cell maturation. In this work, we tested for the presence of a putative DNA binding site in a variable gene segment in its germline configuration, independent of VDJ recombination. After a survey in public antibody data bases, we chose a single mouse heavy variable gene segment highly represented in anti-nucleic acid antibodies and tested it for ssDNA binding in vitro. A phage display approach was used to search for an intrinsic binding to oligo deoxythimidine. The results revealed that binding to antigen can be biased by the use of specific DNA binding VH gene segment. The data shown here support the idea that some variable genes may have intrinsic reactivity towards endogenous autoantigens, and this property may contribute to the establishment of the immature B-cell repertoire.

P2.08.06
PAG (Cbp) as a positive reulator of mast cell signaling

***V. Bugajev**, L. Dráberová, M. Machyna, P. Dráber;*
Institute of Molecular Genetics, Academy of Sciences of the Czech Republic, Prague 4, Czech Republic.

Antigen-immunoglobulin E (IgE) complexes-mediated triggering of the high-affinity IgE receptor (FcepsilonRI) initiates activation of mast cells and basophiles. Early activation events include, among others, tyrosine phosphorylation of transmembrane adaptor proteins LAT (LAT1), NTAL (LAT2) and PAG (Cbp). Although the role of LAT and NTAL in mast cell signaling has been extensively documented, the role of PAG in mast cells remains elusive. To contribute to elucidating the role of PAG in antigen- or thapsigargin-mediated activation of mast cells, we compared activation events in mouse bone marrow-derived mast cells (BMMCs) with normal or reduced levels of PAG. To this aim we used lentiviruses as efficient vectors for transfer of four different shRNAs which lowered the expression levels of PAG by 70% to 55%. Although activation-induced tyrosine phosphorylation of whole cell lysate was not dramatically affected, PAG knockdowns strongly inhibited beta-glucuronidase release in both, antigen and thapsigargin activated cells. Calcium ions mobilization and extracellular uptake of radioactively labeled $^{45}Ca^{2+}$ was also reduced after antigen triggering. The combined data indicate that PAG is a positive regulator of mast cell signaling.

P2.08.07
The phosphatase JKAP inhibits T-cell receptor signaling and autoimmunity by inactivating Lck

***H. Chuang**[1], J. Li[1], J. Lan[2], D. Chen[2], C. Yang[1], J. W. Belmont[3], T. Tan[1,4];*
[1]Immunology Research Center, National Health Research Institutes, Zhunan Miaoli County, Taiwan, [2]Division of Allergy, Immunology, and Rheumatology, Taichung Veterans General Hospital, Taichung, Taiwan, [3]Department of Molecular & Human Genetics, Houston, TX, United States, [4]Department of Pathology & Immunology, Baylor College of Medicine, Houston, TX, United States.

JNK pathway-associated phosphatase (JKAP, also named DUSP22) is a JNK activator. JKAP also acts as a tyrosine phosphatase to dephosphorylate and inactivate focal adhesion kinase, leading to the suppression of cell motility. However, the physiological role of JKAP in T-cell receptor (TCR) signaling and immune regulation remains unknown. Here we report that JKAP directly interacts with, dephosphorylates and inactivates Lck at Y394, which in turn shuts off TCR signaling. JKAP-knockout T cells display enhanced cell proliferation and cytokine production upon anti-CD3 antibody stimulation. Lymphocyte development is normal in JKAP-knockout mice. JKAP-knockout mice show enhanced T-cell-mediated immune responses and are more susceptible to experimental autoimmune encephalomyelitis. Interestingly, aged JKAP-KO mice spontaneously develop inflammation and autoimmunity. Data from human patients with autoimmune diseases will be presented. Thus, our results indicate that JKAP is the major phosphatase that inactivates Lck in the TCR signaling turn-off stage, leading to suppression of T-cell immunity and autoimmunity. (Supported by NHRI-98A1-IMPP01-014)

P2.08.08
Downregulation of IRF3-IFNa/b pathway is crucial for the differentiation block induced by the leukemogenic fusion protein TEL/AML1

***A. de Laurentiis**[1], A. Myriam[2];*
[1]IEO, Milano, Italy, [2]IEO, milano, Italy.

With an incidence of 20-25%, TEL/AML1 fusion gene is the most common specific genetic rearrangement in acute lymphoblastic leukemia (ALL). ALL lead to an uncontrolled proliferation and spread out from their seat of undifferentiated B cells. Most of the genetic studies on these specific translocation provide the use of patient samples, thereby limited material and from people already presenting ALL. Also results from mouse models,the most failed in showing a phenotype since ALL require second and more changes. In this optic we first stabilized an hematopoietic cell-line (EML) expressing TEL-AML1 (EML-TA) in a stable way. This cell line is able to differentiate until B cells offering the opportunity for create a clear and complete panorama of genomics alterations along the hematopoietic steps and when expressing TEL-AML1 its differentiation is blocked as expected. In order to obtain a profile of total mRNA we run a complete gene profiling of EML at different steps of differentiation and compare it with the EML-TA cell line. From gene and subsequent protein analysis we identify IRF3-IFNα/β pathway as a crucial candidate altered by TEL-AML1. Infect by restoring its activity in EML-TA, cells were able to fully differentiate demonstrating it important role. Even more his disruption by siRNA was sufficient to block cell differentiation. We also identified IL7-mTOR as the activator pathway of IRF3-IFNα/β. This results are confirmed both in mouse (Lin-) and human (Reh cell line and CD34+ from PBMC) cells. This new inside the ALL differentiation block can offer new targets for ALL therapies.

P2.08.09
Higher sensitivity of restored human CD8 T-cells to virus- and tumor-derived antigens

J. Fischer[1]*, S. Stevanovic*[2]*, G. Grigoleit*[3]*, T. Hünig*[1]*;*
[1]*Institute for Virology and Immunobiology, Würzburg, Germany,*
[2]*Department of Immunology, Tübingen, Germany,*
[3]*Universitätsklinikum Würzburg, Würzburg, Germany.*

Research in human immunobiology is mainly based on working with peripheral blood mononuclear cells (PBMC). However, recent investigations have shown that circulating CD4 T-cells are less sensitive to several T-cell activating monoclonal antibodies and recall antigens as compared to tissue-resident cells. Interestingly, the impaired responsiveness of circulating T-cells could be restored by a short-term preculture step of PBMC at a high cell density (HDC PBMC, Römer P. et al. 2011).
Here we report that interferon-gamma ELISpot assays of HDC PBMC can be used as a sensitive in-vitro test for detection and characterization of antigen-specific CD8 T-cell responses in clinical and basic research. Recall responses to various virus- and tumor-derived antigens were significantly increased in sensitivity if CD8 T-cells were allowed to interact with monocytes during HD preculture of PBMC. Depletion of monocytes from PBMC before HDC completely abrogated the increased sensitivity of CD8 T-cells. Under defined long-term culture conditions, initial HD preculture even positively affected the responsiveness of expanded antigen-specific CD8 T-cells, whereas CD8 T-cells of unrelated specificity were unaffected.
Investigations on a molecular level showed significant differences in the RNA expression pattern of precultured CD8 T-cells compared to circulating CD8 T-cells. Changes in the gene expression of cell adhesion molecules, co-stimulatory molecules and metabolism might facilitate cell survival and frequent cell-cell interactions. This result supports the hypothesis that cell-cell interactions, especially between T-cells and matured monocytes, induce sub-threshold T-cell signals, which are responsible for an increase in sensitivity of T-cells towards antigens.

P2.08.10
Regulation of AP-1 activation in T cells by EGR-2

E. L. M. Ghaffari[1]*, T. Miao*[2]*, A. L. J. Symonds*[2]*, P. K. Bhullar*[1]*, S. Li*[1]*, P. Wang*[2]*;*
[1]*Brunel University, London, United Kingdom,* [2]*Barts and the London school of medicine and dentistry, London, United Kingdom.*

EGR-2 is a transcription factor that controls inflammatory responses and proliferation of T cells. Deficiency in Egr-2 and -3 in T cells results in impaired proliferation in response to antigen receptor stimulation. Electrophoretic Mobility Assay (EMSA) revealed that the impaired T cell receptor signalling is due to a defect in Activator Protein-1 (AP-1) activity. AP-1 is a heterodimeric protein composed ofAP-1 family members including c-Jun, JunB, c-Fos. Our data shows that EGR-2 directly bind with Batf, which prevents Batf's inhibitory function on AP-1 activation. In addition to the interaction with Batf, we found that EGR-2 can also bind with the AP-1 proteins c-Jun and JunB through the leucine zipper domain. Immunohistochemistry data revealed that EGR-2 and c-Jun are co-localised in the nucleus. Functional analysis using AP-1 luciferase report assay revealed that EGR-2 can enhance AP-1 activation. Our results demonstrate an intracellular regulatory mechanism mediated by Egr-2 in T cells for the control of antigen receptor mediated activation.

P2.08.11
VAV1 controls inflammation in Experimental Autoimmune Encephalomyelitis (EAE)

A. O. Guerreiro-Cacais*, M. N'Diaye, R. Berglund, A. D. Beyeen, M. Jagodic, T. Olsson;*
Department of Clinical Neuroscience, Neuroimmunology Unit, Karolinska Institutet, Stockholm, Sweden.

Vav1, a guanine nucleotide exchange factors for the Rho family of GTPases, plays an important role in T-cell and B-cell development, activation, tissue homing and effector functions. *Vav1* was found within a rat QTL that regulates the MS animal model EAE, and overlaps with several QTLs for immune-mediated diseases. Analysis of a human cohort showed association of certain haplotypes of the gene with MS. In this work we attempt to further characterize the function of Vav1 by using congenic rats that express different levels of Vav1 and are differentially susceptible to EAE.
In vitro stimulated naïve T cells of the EAE-protected strain (low Vav1) performed poorly in terms of activation, proliferation and cytokine secretion (especially IL-2) in response to TCR triggering. This defect was compensated by the addition of exogenous IL-2. Vav1 is also expressed by APCs, but only macrophages and dendritic cells showed any overt impairment in T cell stimulatory capacity, whereas the defect in B cells seemed restricted to TLR-mediated activation. Analysis of peripheral lymphoid tissue as well as CNS-infiltrating cells in autoantigen immunized animals showed only a minimal defect in all these parameters pointing to compensatory mechanisms in vivo. In fact the EAE-protected strain developed a Th17-skewed response, whereas the susceptible strain preferentially primed for Th1 cells. This Th17 skewing, together with a subsequent impairment in proliferation inside the CNS might account for a strong onset of disease, but decreased inflammatory parameters in later disease stages in the protected strain.

P2.08.12
Phage mini-antibodies and their use for detection of microbial cells by using electro-optical sensor

O. I. Guliy[1]*, I. Dykman*[1]*, S. Staroverov*[1]*, V. Bunin*[2]*, O. Ignatov*[1]*;*
[1]*Institute of Biochemistry & Physiology of Plants & Microorganisms RAS, Saratov, Russian Federation,* [2]*EloSystem GbR, Berlin, Germany.*

Nowadays, cell detection in molecular biology is performed with the help of genetic engineering technologies for cloning recognizing fragments (hypervariable immunoglobulin domains). These technologies are cheaper and can be competitive in selectivity with hybridoma technologies. One such method is antibody phage display. Obtaining the phage miniantibodies to Azospirillum brasilense Sp245 as example, and their use for detection of microbial cells by using electro-optical sensor. Measurements of cellular orientational spectra (OS) of the cells were measured with an ELUS EO analyzer at a wavelength of 670 nm.
The preparation of miniantibodies to Azospirillum brasilense Sp245 surface antigens was made by using a combinatorial phage library of sheep antibodies. The prepared phage antibodies were used for cell detection by dot assay, electro-optical analysis of cell suspensions, and transmission electron microscopy. The results demonstrate that when A. brasilense Sp245 interacted with anti-LPS and antiflagellin mini-Abs, the magnitude of the EO signal changed considerably. It has been also found that the detection of cell A. brasilense Sp245 using the mini-antibodies is possible even in the presence of other cultures.
The findings from this study can be used to develop a rapid test for the detection of bacterial cells and for the assessment of exposure of cell-surface antigenic determinants.
The work was supported by Ministry of Education and Science of Russian Federation, project no. 8852.

P2.08.13
Cdc42 controls cytokine secretion at the immune synapse

C. Hivroz[1]*, A. Bohineust*[1]*, K. Chemin*[2]*, S. Dogniaux*[1]*, S. Guegan*[3]*;*
[1]*INSERM U932, Institut Curie, Paris, France,* [2]*Center for Molecular Medicine (CMM), Stockholm, Sweden,* [3]*Hôpital Tenon, Service de Dermatologie-Allergologie, Paris, France.*

Remodeling of the T lymphocyte cytoskeleton at the immune synapse is characterized by polarization of the microtubule organizing center and of the polymerized actin of the T cell toward the antigen presenting cell, and "opening" of the actin meshwork in the central zone of the immune synapse. This cytoskeleton remodeling has been shown to plays a key role in TCR signaling, T cell activation and polarized delivery of cytotoxic granules. Since little is known on how newly synthesized cytokines, once produced, are routed within T cells and on the mechanisms involved in regulating their secretions, we

investigated the role of actin remodeling at the immune synapse in this process. To do so, we silenced the expression of the RhoGTPase Cdc42, a key regulator of cytoskeleton remodeling, in human primary CD4+ T lymphocytes and investigated how this silencing affected formation of the immune synapse and cytokine secretion. We showed that MTOC polarity at the IS, which does not depend on Cdc42, is not required for cytokine secretion by T lymphocytes, whereas microtubule polymerization is. In contrast, actin remodeling at the IS, which depends on Cdc42, controls - the formation of the polymerized actin-ring at the IS, - the dynamic concentration of IFN-γ containing vesicles inside this ring and - the secretion of these vesicles. These results reveal a previously unidentified role of Cdc42-dependent actin remodeling in cytokine exocytosis at the IS.

P2.08.14
OCILRP2 costimulates T cell activation by activating MAPK signaling pathway

Y. Hu;
Henan University school of Medicine, Kaifeng, Henan, China.

OCILRP2 is a typical Type-II transmembrane protein that is selectively expressed in the activated T lymphocyte, DC cell and B cells. It has been found to be a novel co-stimulator of T cell activation. However, the signaling pathways underlying OCILRP2 in the T cell activation are still not unclear. In this paper we found that shRNA silence OCILRP2 expression can inhibit the EL4 T cells' proliferation and IL2 production and reduce the MAPK3 and MAPK8 activation and Lck's tyrosine phosphorylation but not PI3K-AKT pathway. The antagonist OP2-antibody can partially impair the CD3/CD28-costimulated EL4 T cell activation, and inhibit the transcription factors NFAT, AP-1 and NF-kB activation. Furthermore, the immunoprecipitation results indicated that OCILRP2 could interact with DAP12 protein, an adaptor containing a intracellular ITAM motif that can transuduct the signal to the MAP kinase activation for T cell activation. Our data demonstrate that after binding to its ligands OCILRP2 and DAP12 forms heterodimer, which then activate the LCK-MAP kinases pathways and the transcription factors NFAT, AP-1 and NF-kB activation resulting in T cell activation.

P2.08.15
Generation of LYPLA1 knockout Jurkat T cells by transcription activator-like effector nuclease (TALEN) technology

*D. Biedenweg, U. Jehmlich, A. Alahmad, **M. Hundt**;
University of Greifswald, Greifswald, Germany.*

Jurkat T cells are a well-established model system to study TCR signaling. Several mutants have been generated, and the molecular bases for their TCR signaling defects have been identified. We wanted to use a gene-specific approach to generate LYPLA1 knockout Jurkat cells. LYPLA1 is a protein-palmitoyl thioesterase, and its pharmacological inhibition reduces IL-2 secretion after CD3/CD28 stimulation of Jurkat cells.
A TALEN target site within the first coding exon of the LYPLA1 gene was identified, and plasmids encoding for left and right TALENs were generated. Jurkat cells were co-electroporated with the TALEN plasmids and a plasmid coding for GFP to allow selection of transfected cells by fluorescence activated cell sorting.
The functionality of these TALENs in GFP positive Jurkat cells was first verified by enzyme mismatch cleavage. Thereafter, single GFP positive Jurkat cells were sorted, and clonally expanded. These clones were then screened by digestion with a restriction endonuclease that cuts within the wild type target site. Two out of 48 clones were identified as having DNA double-strand breaks repaired by error prone non-homologous end joining on both alleles. The genomic DNA of these clones was then verified to contain insertions and deletions in the targeted region of the first coding exon of LYPLA1 that induced frame shifts.
In conclusion, with the TALEN technology we generated gene-specifically altered Jurkat cells. Variation of the TALEN approach with homologous recombination to introduce a point mutation in the LYPLA1 gene and functional characterization of the LYPLA1 knockout clones are ongoing.

P2.08.16
B cells in patients with end-stage renal disease

***A. Jasiulewicz**, K. Lisowska, J. Witkowski;
Medical University of Gdańsk, Gdańsk, Poland.*

End-stage renal disease (ESRD) is the 5th stage of chronic renal disease which currently affects 873 million people in the world. One of the major problems, besides abnormalities associated with decreased glomerular filtration rate, is the higher prevalence of infections among hemodialyzed patients compared to healthy controls. Up to 36% of ESRD patients die of infection, which is the second main cause of death in this group. Earlier research focused mainly on T cells, leaving a gap in understanding B cells' biology in ESRD. The aim of this research was to evaluate: the expression of CD40, a key B cell surface antigen,, proliferation kinetics and immunoglobulin production. Peripheral blood mononuclear cells were isolated from full blood of ESRD patients and healthy volunteers. Cells were stained with CFSE and cultured in the presence of anti-CD3 as stimulator. Culture consisted of various erythropoietin (Epo) concentrations due to Epo intake by some patients. With the use of flow cytometry it was assessed that B cells of ESRD patients have significantly higher expression of CD40 ex vivo and IgG production, but are not able to maintain those levels after 5 days of cell culture as contrasted with healthy people. Non-Epo patients have higher percentage of apoptotic B cells than Epo patients and healthy people. High concentration of Epo in vitro helps patient's B cells to produce IgM. Research discovered definite influence of Epo on B cells and described certain differences between ESRD patients and healthy population.

P2.08.17
The human CD8β M-4 isoform dominant in effector memory CD8 T cells has distinct cytoplasmic motifs that confer unique properties

*M. Coman[1], D. Thakral[1], A. Bandyopadhyay[1], S. Martin[2], J. Riley[2], **P. B. Kavathas**[1];
[1]Yale University School of Medicine Department of Laboratory Medicine and Immunology, New Haven, CT, United States,
[2]University of Pennsylvania School of Medicine, Abramson Family Cancer Research Institute and Department of Pathology and Laboratory Medicine, Philadelphia, PA, United States.*

The CD8 co-receptor influences T cell recognition and responses to pathogen infected and tumor cells. During evolution the CD8B gene in the ancestor of humans and chimpanzees, acquired two additional exons. As a result, in humans, there are four CD8β splice variants (M1 to M4) that differ in their cytoplasmic tails. The M-1 isoform which is the equivalent of murine CD8β, is predominantly expressed in naïve T cells, whereas, the M-4 isoform is predominantly expressed in effector memory T cells. The characteristics of the M-4 isoform conferred by its unique 36 amino acid cytoplasmic tail are not known. In this study, we identified a dihydrophobic leucine-based receptor internalization motif in the cytoplasmic tail of M-4 that binds the clathrin adaptor protein AP-2 and regulates M-4 cell surface expression and downregulation. The M-4 cytoplasmic tail was able to associate with ubiquitinated targets in 293T cells and mutations in the amino acids NPW, a potential EH domain binding site, either enhanced or inhibited the interaction. In addition, the M-4 intracellular domain was itself mono-ubiquitinated in both 293T cells and a human T cell line. When peripheral blood human T cells expressed CD8αβ M-4, the frequency of MIP-1β secreting cells responding to antigen presenting cells was two-fold higher as compared to CD8αβ M-1 expressing T cells. Thus, the cytoplasmic tail of the CD8β M-4 isoform has unique characteristics, which likely contributed to its selective expression and function in human effector memory T cells. P2.08.18

A novel mechanism for the autonomous termination of pre-B cell receptor expression via induction of lysosomal-associated protein transmembrane 5

Y. Kawano[1], *R. Ouchida*[2], *J. Wang*[2], *S. Yoshikawa*[1], *D. Kitamura*[3], *H. Karasuyama*[1];
[1]*Department of Immune Regulation, Tokyo Medical and Dental University Graduate School, Tokyo, Japan,* [2]*Laboratory for Immune Diversity, RIKEN Research Center for Allergy and Immunology, Yokohama, Japan,* [3]*Division of Molecular Biology, Research Institute of Biological Sciences, Tokyo University of Science, Chiba, Japan.*

The expression of pre-B cell receptor (pre-BCR) is confined to the early stage of B cell development, and its dysregulation is associated with anomalies of B-lineage cells, including leukemogenesis. Previous studies suggested that the pre-BCR signal might trigger the autonomous termination of pre-BCR expression even before the silencing of the pre-BCR gene expression to prevent the sustained pre-BCR expression. However, the underlying mechanism remains ill defined. Here we demonstrate that the pre-BCR signal induces the expression of lysosomal-associated protein transmembrane 5 (LAPTM5) which leads to the prompt pre-BCR down-modulation. While the LAPTM5 induction had no significant impact on the internalization of cell surface pre-BCR, it elicited the translocation of a large pool of intracellular pre-BCR from the endoplasmic reticulum to the lysosomal compartment, concomitantly with the drastic reduction of intracellular pre-BCR proteins. This reduction was inhibited by lysosomal inhibitors, indicating the lysosomal degradation of pre-BCR. Notably, the LAPTM5 deficiency in pre-B cells led to the augmented expression of surface pre-BCR. Collectively, the pre-BCR induces the prompt down-modulation of its own expression through induction of LAPTM5 that promotes the lysosomal transport and degradation of the intracellular pre-BCR pool, and hence limits the supply of pre-BCR to the cell surface.

P2.08.19
Detection of antigen-stimulated cytokine-secretion in human T-cells at single cell levels on a live cell chip

H. Kishi[1], *A. Jin*[1,2], *H. Hamana*[1], *K. Tajiri*[1], *S. Hatakeyama*[1], *E. Kobayashi*[1], *T. Ozawa*[1], *T. Nagai*[1], *A. Muraguchi*[1];
[1]*Department of Immunology, University of Toyama, Toyama, Japan,* [2]*Department of Immunology, College of Basic Medical Science, Hrbin Medical University, Harbin, China.*

Previously we established “on chip single cell analysis method” called ISAAC (immune-spot array assay on a chip), which enabled us to detect secretion of antigen-specific antibody (Ab) from single Ab-producing cells and provided us a very efficient and rapid method to produce antigen-specific Ab. In this study, we report that we could apply the ISAAC to detect antigen-specific human T-cells. We used microwell array chips that have an array of 45,000 to 234,000 microwells whose shape and size are just fit to accommodate single lymphocytes. To evaluate the T-cell ISAAC system, we analyzed the EBV-specific $CD8^+$ T-cells derived from HLA-$A24^+$ latent healthy donors. To this end, we first selected volunteers whose $CD8^+$ T-cells expressed TCR that bound HLA-A*2402 restricted tetramer of the EB virus epitope mixture (EB/A24 tetramer). We purified $CD8^+$ human T-cells and applied the cells onto the chip whose surface was coated with IFN-γ-specific Ab and stimulated them with EB/A24 tetramer on the chip. Six hours after the stimulation, we detected secreted IFN-γ using fluorophore-conjugated IFN-γ-specific Ab on the chip. It was detected on the chip as doughnut-like spots. Without the stimulation, we did not detect any spots. The results show that T-cell ISAAC system enables us to detect antigen-specific human T-cells. Human T-cell ISAAC system might provide a very efficient and rapid method of antigen-specific T-cell detection in human primary T-cell populations and facilitate antigen-specific T-cell therapy in the future.

P2.08.20
Recombinant P. aeruginosa outer membrane proteins and immune response

A. V. Soldatenkova[1], *L. A. Geiderova*[1], *E. A. Akhmatov*[1], *N. A. Mikhailova*[1], *N. K. Akhmatova*[1], ***O. V. Lebedinskaya***[2];
[1]*I.I. Mechnikov Research Institute for Vaccines and Sera, RAMS, Moscow, Russian Federation,* [2]*Acad. E.A. Wagner Perm State Medical Academy, Perm, Russian Federation.*

There is an urgent need to develop new vaccines for prevention and immunotherapy of infections caused by *P. aeruginosa* since the agent has a high level of antimicrobial resistance, and the clinical course of disease is characterized by multiple organ damage. Induction of immune response under the influence of *P. aeruginosa* antigens is still poorly characterized.
To study the cytokine-mediated immune response in mice immunized with recombinant antigens of *P. aeruginosa*.
Recombinant *P. aeruginosa* outer membrane proteins OprL, OprF, hybrid protein OprF-I, which consists of of OprF and OprI sequences and recombinant toxoid (aTox) were produced. To obtain the expression of these proteins the BL21(DE3) and M15 *Escherichia coli* were used. Mice were injected intraperitoneally with 50 mg of *P. aeruginosa* antigenic preparations. Cytokine levels were determined in mice serum with test system FlowCytomixMouse Thl/Th2 10 plex.
We found that injection of antigenic preparations a wide spectrum of cytokines in mice was induced. The highest levels were observed in the ratio of IL-1 and IL-6 when oprF-I, oprL, aTox, oprF antigens were administered. OprFI actively stimulated the production of IL-2, and IL-5, IL-10, TNF-α and IFN-γ. OprF-I antigen contributed to the induction of IL-6, IL-17, TNF-a and IFNγ, while aTox – to the expression of IL-1, IL-2, IFN-γ. OprL antigen induced IL-17 and TNF-α to greatest extent, while IL-10 – to lesser extent.
The antigens of *P. aeruginosa* intraperitoneally administered to mice favored the formation of the immune response to induce both Th-1 and Th-2 pathways.

Functional heterogeneity has been considered as a principle mechanism of the adaptive immune response. Here we developed an imaging-based method for studying calcium signaling at the single-cell level as a function of time and stimulus. Jurkat T cells were exposed to stimulatory anti-CD3ε- or anti-CD59-coated surfaces and individual calcium time traces were analyzed via unsupervised clustering. This analysis revealed a heterogeneous calcium response of the cell population in a stimulus-dependent manner. Interestingly, an unresponsive subpopulation identified upon anti-CD59 stimulation coincided with a low CD3 surface expressing subpopulation observed in flow cytometry measurements. Further analysis of TCR/CD3 deficient or overexpressing cells showed that CD59-mediated signaling is strongly dependent on TCR/CD3 surface expression. However, in protein co-patterning and fluorescence recovery after photobleaching experiments no direct physical interaction was observed between CD59 and CD3 at the plasma membrane upon anti-CD59 stimulation. Nonetheless, siRNA-mediated protein knock-downs of downstream signaling molecules revealed that the Src family kinase Lck is essential for both signaling pathways. Moreover, physically linking Lck to CD3ζ completely abolished CD59-triggered calcium signaling, while signaling was still functional upon direct TCR/CD3 stimulation. Altogether, we demonstrate that Lck mediates signal transmission from CD59 to the TCR/CD3 pathway in Jurkat T

cells, and propose that CD59 may act via Lck to modulate T cell responses.

The initiation of B cell receptor signaling is sensitive to the stiffness properties of the substrate presenting the antigens

***W. Liu**, Z. Wan;*
Tsinghua University, Beijing, China.

B lymphocytes are activated upon antigen sensing by B cell receptors (BCRs). The substrate presenting the antigen can show different degrees of stiffness. It is not clear if B cells can respond to changes in substrate stiffness. Here we use high resolution, high speed live cell imaging techniques to capture the molecular events in B cell activation after the recognition of antigens tethered to polyacrylamide gel substrates with variable degrees of stiffness as quantified by Young's modulus (2.6-22.1 kPa). We show that the initiation of B cell activation is extremely sensitive to substrate stiffness. B cells exhibit much stronger activation responses when encountering antigens tethered to substrates with a high degree of stiffness as measured by the accumulation of BCR, pSyk and pTyr molecules into the B cell immunological synapse. Antigens tethered to stiff substrates induce the formation of more prominent BCR and pSyk microclusters with significantly enhanced colocalization as compared to antigens tethered to soft substrates. Moreover, the expression of the B cell activation marker CD69 is greatly enhanced in B cells encountering antigens on stiffer substrates. Through time lapse live cell imaging, we find that the different responses of B cells to substrate stiffness are only demonstrated 5 min after BCR and antigen recognition. Using a series of cytoskeleton inhibitors, we determine that the mechanosensing ability of B cells is dependent on microtubules, and only mildly linked to the actin cytoskeleton. These results suggest the importance of the mechanical properties mediated by substrate stiffness in B cell activation.

P2.08.23
C-type lectin related protein OCILRP2 enhances development and functional differentiation of mouse bone marrow-derived dendritic cells

***Y. Ma**;*
Henan University School of Medicine, Kaifeng, Henan China, China.

Osteoclast Inhibitory Lectin Related Protein 2 (OCILRP2) is a typical type II membrane protein, which selectively expresses in the immune tissues (e.g. dendritic cells (DC), B lymphocytes and activated T lymphocytes). Binding to its ligand NKRP1f, OCILRP2 can upregulate the T cell activation mediated by B7.1/CD28 co-stimulation. However, its roles in DC cells are still unclear. Here we found that a soluble OCILRP2-Ig protein, which works as an antagonist of OCILRP2, can significantly suppress the expression of CD80, CD86 and MHC-II molecules on the mouse bone marrow derived immature DC and LPS-induced mature DC. It also can inhibit DC cells' Antigen uptaking and allogeneic T lymphocytes stimulation and the production of inflammatory cytokines of IL-6, IL-12 and TNF-α but not IL-10 in vitro. Further study indicates that OCILRP2-Ig protein can block the OCILRP2-mediated NF-κB activation, which may result in the defective DC generation. Our studies reveal OCILRP2 plays an important role in the DC development and functional differentiation.

P2.08.24
Inhibition of PI3K/Akt pathway in antigen-stimulated B-lymphocytes and hybridoma cells induces their apoptotic death

***Y. Malyutina**, Y. Makarova, A. Kabakov;*
Medical Radiology Research Center, Obninsk, Russian Federation.

Interplay between signaling pathways in stimulated murine B-lymphocytes and Ig-secreting hybridomas was here studied. The in vivo immune response was induced in Balb/c mice by injection of serum-derived protein antigens such as bovine serum albumin or human apo-B100, or human fibronectin. Peripheral blood lymphocytes and splenocytes were isolated from the mice and subpopulations of the antigen-binding B-lymphocytes were then assorted using a FACS and the FITC-labeled antigens. Those subpopulations of B-cells stimulated by the labeled antigen binding to the cell surface immunoglobulin receptors were treated with certain inhibitors of cellular signaling. It was found that the stimulated murine B-lymphocytes become extremely sensitive to inhibitors of the PI3K/Akt pathway such as LY294002, wortmannin, Akti-X and 17AAG whose very low concentrations induced massive apoptosis in subpopulations of the treated B-cells which were pre-stimulated by the antigens. In contrast, the non-stimulated B-lymphocytes from the same cell fractions exhibited normal tolerance to low doses of those inhibitors (i.e. only slight levels of apoptosis). Analogous effects were observed with murine B-hybridoma cells stimulated by antigen binding. Importantly, when a constitutively activated (mutant) form of Akt was transiently overexpressed in the hybridoma cells, this significantly impaired their apoptotic death following the joint action of antigens and PI3K/Akt pathway inhibitors. We conclude that the Akt activation in B-cells stimulated by antigen-binding is necessary for their survival and subsequent propagation. Alternatively, blockade of the Akt activation may causally be realized for apoptotic elimination of autoreactive B-cells in the process of clonal selection in vivo.

P2.08.25
The actin and tetraspanin networks organize receptor nanoclusters to regulate B cell receptor-mediated signaling

***P. K. Mattila**[1], C. Feest[2], D. Depoil[2], B. Treanor[2], B. Montaner[2], K. L. Otipoby[3], R. Carter[4], L. B. Justement[5], A. Bruckbauer[2], F. D. Batista[2];*
[1]University of Turku, Turku, Finland, [2]London Research Institute, Cancer Research UK, London, United Kingdom, [3]Children's Hospital Boston and Immune Disease Institute, Boston, MA, United States, [4]National Institutes of Health, Bethesda, MD, United States, [5]University of Alabama at Birmingham, Birmingham, AL, United States.

The actin cytoskeleton is involved in numerous cellular events. Thus not surprisingly, increasing evidence also demonstrates the role for the cytoskeleton in various stages of lymphocyte activation. We recently observed that a mere transient alteration of the actin network leads to B cell activation. Here we show that the disruption of the cytoskeleton triggers signaling that not only requires the B cell receptor (BCR), but also the co-receptor CD19. In addition to the cytoskeleton, the co-operation of these two receptors is further coordinated by the CD81-tetraspanin web, which organizes CD19 in the plasma membrane. New insights into the initiation of the BCR signaling are supported by super-resolution microscopy, which demonstrates that endogenous IgM, IgD and CD19 exhibit distinct nano-scale organization within the plasma membrane of naïve B cells. These nanoclusters do not change in character during BCR signaling. Thus, we postulate that cytoskeleton reorganization releases pre-existing BCR nanoclusters, which can interact with CD19 held in place by the tetraspanin network. Our results not only suggest that receptor compartmentalization regulates B cell activation by surface-bound antigen, but also imply a potential role for CD19 in mediating ligand-independent BCR signaling necessary for B cell survival.

P2.08.26
CD22 ligand-binding and signalling domains reciprocally regulate B-cell Ca2+ signalling

***J. Müller**[1], I. Obermeier[1], M. Wöhner[1], C. Brandl[1], S. Mrotzek[1], P. Maity[2], M. Reth[2], L. Nitschke[1];*
[1]Chair of Genetics, Department Biology, University of Erlangen, Erlangen, Germany, [2]Faculty of Biology, University of Freiburg and Max-Planck Institute for Immunobiology and Epigenetics, Freiburg, Germany.

The transmembrane protein CD22 mediates the inhibition of calcium signal after BCR crosslinking. The extracellular domain of CD22 can bind to α2,6-linked sialic acids, while the cytoplasmic domain contains inhibitory motifs (ITIMs). In this study we wanted to analyse the

ligand-binding and signalling domain of CD22 independently and thereby determine their functional interplay.
We generated CD22-R130E knockin mice, in which CD22 is no longer able to bind sialic acids. The CD22-Y5,6F and CD22-Y2,5,6F mice with mutated CD22 ITIM-domains can´t recruit SHP-1 phosphatases to the CD22 cytoplasmic tail anymore.
In the bone marrow we found a reduction of recirculating B cells only in the CD22-ITIM knockin mice, but not in CD22-R130E knockin mice. In the spleen all mice had reduced marginal zone B cells. Only CD22-Y2,5,6F B cells showed also increased turnover in vivo and spontaneous cell death in vitro. Ca2+ measurements revealed a decreased flux after BCR stimulation in CD22-R130E B cells and higher flux in CD22-ITIM mutant B cells. The CD22-R130E mutation affected the CD22/BCR association, because less total, but more phosphorylated CD22 was co-precipitated with IgM.
These data indicate that the cis-ligand binding of CD22 is crucial for regulation of the B cell Ca2+ signalling. This control is mediated by ligand-dependent regulation of the association to the BCR. In contrast, the CD22-ITIM motifs are important for a direct inhibition of Ca2+ signalling. The loss of these inhibitory motifs changes the B cell turnover, the survival of the B cells and thereby affects the homeostasis of B cell populations.

Germline TSC1 mutations are permissive for T lymphocyte development and homeostasis in Tuberous Sclerosis individuals

K. Pilipow[1]*, V. Basso*[2]*, N. Migone*[3]*, A. Mondino*[4]*;*
[1]Lymphocyte Activation Unit San Raffaele Scientific Institute, Vita-Salute San Raffaele University and Fondazione Centro San Raffaele, Milan, Italy, [2]Lymphocyte Activation Unit, San Raffaele Scientific Institute, Milan, Italy, [3]Department of Genetics, Biology and Biochemistry, University of Turin, and S.C.D.U. Medical Genetics, A.O.U. San Giovanni Battista, Turin, Italy, [4]Lymphocyte Activation Unit San Raffaele Scientific Institute, Milan, Italy.

Antigen recognition on the surface of antigen presenting cells initiate a variety of intracellular signals critical for naïve T cells to commit to proliferate and differentiate. Others and we have shown the TSC/mTOR axis to be critical in coordinating cell quiescence, proliferation and fate determination. Blocking mTOR by Rapamycin, or genetic inactivation of components of the mTOR Complex (mTORC) or TSC1, unbalances mTORC1 and mTORC2 regulation, impacting on cell quiescence, proliferation and differentiation. In humans, germline mutations of TSC1 predispose to Tuberous Sclerosis Complex disease, an autosomal dominant disorder characterized by multifocal hamartomatosis. Whether such mutations impact on T cell functions in these individuals was unknown. To this aim we analyzed subset representation, phenotype and function of T cells from two independent families with characterized mutations of TSC1 in parallel to T cells from healthy volunteers and to mouse T cells with mono- or bilallelic deletion of Tsc1 (from T-lineage restricted Tsc1+/- and Tsc1-/- mice). We found that heterozygosis of Tsc1/TSC1 is sufficient for proper hamartin expression and both homeostatic and TCR-induced mTORC1 and mTORC2-dependent signaling in mice and human T cells. In contrast, loss of Tsc1/TSC1 following biallelic genetic inactivation and shRNA-induced down-regulation unbalanced mTORC-dependent FOXO1/3 regulation, leading to loss of mitochondrial potential and apoptotic cell death. Thus, while heterozygosis of Tsc1/TSC1 is sufficient for proper T lymphocyte development and homeostasis, its more severe loss is incompatible with both mouse and human T cell survival.

P2.08.28
Ligation of human Fc receptor like-2 (FCRL2) by specific monoclonal antibodies downregulates B cell receptor mediated signaling

M. Shabani[1]*, A. A. Bayat*[1]*, M. Jeddi-Tehrani*[1]*, H. Rabbani*[1]*, C. Ulivieri*[2]*, Z. Amirghofran*[3]*, C. T. Baldari*[2]*, F. Shokri*[4]*;*
[1]Avicenna Research Institute, Tehran, Iran, [2]Department of Evolutionary Biology, University of Siena, Siena, Italy, [3]Department of Immunology, Medical School, Shiraz University of Medical Sciences, Shiraz, Iran, [4]Department of Immunology, School of Public Health, Tehran University of Medical Sciences, Tehran, Iran.

Introduction: Regulation of the B cell antigen receptor (BCR) signaling is critical for balancing the B cell response and function. Human Fc receptor like-2 (FCRL2) could influence B cell signaling due to possession of both activating and inhibitory tyrosine-based immunoregulatory motifs. Since FCRL2 natural ligand has not been identified yet, we generated FCRL2-specific monoclonal antibodies (mAbs) and employed them to investigate influence of FCRL2 stimulation on BCR signaling in FCRL2 expressing B cell line. Methods: Anti-FCRL2 secreting hybridomas were produced using hybridoma technology and screened with the immunizing protein by ELISA and a stable CHO cell line expressing FCRL2 protein by FACS. Different concentrations of these mAbs and anti-IgM antibodies were used to stimulate FCRL2 expressing tumor cell line (CA46). Phosphorylation of some signaling molecules was analyzed by FACS and immunoblotting. Results: Two hybridoma clones producing mAbs specific for FCRL2 were selected (5A7-E7 and 3D8-G8). Both mAbs displayed no cross-reactivity with the other members of the FCRL family as tested by FACS and ELISA techniques. Engagement of FCRL2 by these mAbs resulted in significant inhibition of BCR signaling mediators such as calcium mobilization, phosphorylation of Erk, p38 and Jnk MAP kinases. A minor or no inhibition of the phosphorylation of whole protein tyrosine, Syk, Vav and Akt was observed in B cells treated with a cocktail of anti-FCRL2 and anti-BCR Abs. Conclusion: These findings indicate that FCRL2 ITIM motifs are functional and anti-FCRL2 mAbs may mimic the FCRL2 natural ligand by induction of inhibitory signals in B cells.

P2.08.29
Cell membrane permeable phosphopeptides of Gab1 inhibit signaling in B cells by interacting with SHP-2 phosphatase

E. Szarka[1]*, Á. Kertész*[1]*, J. Varga*[2]*, Á. S. Garai*[2]*, G. Gógl*[2]*, A. Reményi*[2]*, T. Janáky*[3]*, G. Váradi*[3]*, G. Tóth*[3]*, G. Sármay*[1]*;*
[1]Department of Immunology, Eötvös Loránd University, Budapest, Hungary, [2]Department of Biochemistry, Eötvös Loránd University, Budapest, Hungary, [3]Department of Medical Chemistry, University of Szeged, Szeged, Hungary.

The multisite docking protein Gab1 plays essential is role in growth factor, cytokine- and antigen receptor signaling. Gab1 has several tyrosine motifs that get phosphorylated upon cell activation and serves as a platform for SH2 domain molecules. One of the main binding partners of Gab1 is SHP-2 tyrosine phosphatase. The intimate interaction between phosphorylated Gab1 motifs and SHP-2 activates the phosphatase. SHP-2 by activating the Erk pathway may play a positive role in signaling, additionally, its role is crucial in many hematological malignancies and cancer.
Our purpose is to develop small molecule modulators based on the sequence of Gab1 to interfere with SHP-2 activity.
First we identified the proteins that bind to Gab1 N terminal phosphopeptide, GDKQVEY(p)LDLDLD from B cell lysate. This phosphopeptide of Gab1 binds PLCγ and SHP-2. We have analyzed the interaction between phosphopeptides and the SH2 domains of SHP-2 and found that the N terminal SH2 domain binds GDKQVEY(p)LDLDLD with one order of magnitude higher affinity as compared to the C terminal domain. In the contrary, the C terminal peptide of Gab1, DERVDY(p)VVVDQQK peptide binds only to the C terminal but not to N terminal SH2 domain.
Comparison of the phosphopeptide unbound and bound crystal structures of N terminal SH2 domain suggests that Tyr66 have a critical role in the allosteric activation of the phosphatase domain. Binding of GDKQVEY(p)LDLDLD to the N terminal SH2 domain enhances SHP-2 phosphatase activity in vitro, however, when administered as cell membrane permeable phosphopeptide into B cells, reduces Erk activity.

Perturbing human TCR signaling pathway through superantigen from Staphylococcus aureus: Multi objective optimization under FBA

***N. Tomar**, R. K. De;*
Indian Statistical Institute, Kolkata, India.

It is necessary to understand the dynamics of a cellular system to evaluate the capacity of an immune response at the time of infection. An integrated system was constructed that included Superantigen (SAg) expression regulatory and TCR signaling pathways of Homo sapiens to compare the pathogen (Staphylococcus aureus) perturbed and unperturbed system. A multi-objective optimization (MOO) formalism under Flux Balance Analysis (FBA) was developed, and analyzed in four ways: (1) Implemented on an unperturbed TCR signaling pathway of H. sapiens, with the objective to maximize the quantity of signal flow for inhibitory molecules (CBL and SHP1), and observed their signal flow values, which were later used as a base line for comparison. (2) The pathogen perturbed TCR signaling pathway (an integration of SAg expression regulatory pathway of S. aureus and TCR signaling pathway of H. sapiens), was studied with the objective of maximizing the quantity of signal flow for stimulatory molecules (ZAP70, LCK and FYN). (3) The same integrated pathway was studied on optimization of two conflicting objectives (minimization of SAg expression and maximization of the quantity of signal flow for TCR:CD3 complex and ZAP70). (4) Perturbation of the signal flow for some of the molecules (ZAP70, LCK, FYN) was performed, under pathogen perturbed and unperturbed conditions to check the effects of perturbation on CBL, SHP1 and Interleukins. Here, we figured out a relation between the TCR signaling inhibitory and stimulatory molecules - balance between these two keeps the system into resting/stimulating stage. Model predictions were validated through experimental evidences.

P2.08.31
Suppression of T cells proliferation by A novel generated monoclonal antibody, COS3A

***S. Wansook**, S. Pata, K. Mahasongkram, W. Kasinrerk, P. Khunkaewla;*
Suranaree University of Technology, Nakhonratchasima, Thailand.

Leukocytes surface molecules play crucial role in cell-cell interaction and communication. Some of them have been identified; still some of them are waiting to be identified. Present study, a novel generated monoclonal antibody (mAb) named COS3A was of interest. The COS3A recognizing molecule is expressed on surface of hematopoietic cells but not red blood cells. High expression of this molecule was induced upon T cell activation. Suppression of CD3-mediated T cell proliferation has been observed in the present of the mAb COS3A. This phenomenon was corresponding to inhibition of IL-2 and IL-4 production. Biochemical analysis revealed that the COS3A antigen has a molecular weight of about 30-70 kDa under non-reducing conditions. N-glycosidase F treatment reduced its size to 25 kDa. Similar results were endorsed by pretreatment the cells with tunicamycin, an inhibitor of N-glycosylation, before cell lysates preparation. In conclusion, COS3A molecule is a high N-glycosylated glycoprotein, which might play a critical role in regulation of T cell responses. Further biochemical identification and immunological function of this molecule are underway.

P2.09.01
New genetic variants of the *CCR5* gene in the Omani population

***A. A. Al-Jabri**, S. H. Al-Mahroqi;*
Sultan Qaboos University, Muscat, Oman.

Background: A number of polymorphisms were identified within the promoter and coding regions of the *CCR5* gene; some of which have been found to affect the CCR5 protein expression and function, consequently affecting HIV-1 binding to cells that normally express the CCR5 protein.
Aims: To identify all the polymorphic sites that exist within the *CCR5* gene as well as the *CCR2V64I* in Omani adult individuals.
Methods:We examined the distribution of the detected variants and compared them with other populations documented in the literature. Blood
samples were collected from 89 Omani adult individuals, and genomic DNA was amplified by polymerase chain reaction and sequenced to identify all the polymorphic sites that exist within a continuous region [of around 4.67 kb] of the *CCR5* gene and to detect the known V64I mutation in the *CCR2* gene.
Results and Conclusion: Out of 32 variable positions detected, four were new indels -2973A/-, -2894A/-, -2827TA/- and -2769T/-, all were located in the 5'UTR. Two new mutations were described for the first time, -2248G/A was detected in one subject in the Intron 1 region of the *CCR5*, whereas +658A/G was found in the coding region. These novel variations in the 5'UTR have shown to exhibit potential effects in the TF binding sites by *in silico* analysis that merit further investigation by experiments to validate our results. Moreover, we identified two novel haplotypes and eight known *CCR2-CCR5* haplotypes, those hapoltypes were found to be at different frequency pattern compared to that documented worldwide.

TNF-α gene promoter polymorphisms in Algerian patients with ankylosing spondylitis

***H. Amroun**[1], S. Salah[1], A. Toudert[1], F. Dehri[1], R. Allat[2], F. Mecabih[1], A. Alliouche-Kerboua[1], H. Djoudi[3], R. Tamouza[4], M. C. Abbadi[1];*
[1]Service d□Immunologie, Institut Pasteur d'Algérie, Alger, Algeria,
[2]Service de rhumatologie, Hôpital de Douéra, Douera, Algeria,
[3]Service de rhumatologie, Hôpital de Douéra, Alger, Algeria,
[4]Laboratoire d'immunologie et d'histocompatibilité, APHP, IUH, INSERM, Paris, France.

Tumor necrosis factor TNF-α is an important pro-inflammatory cytokine that has been implicated in the pathogenesis of ankylosing spondylitis (AS).To evaluate the role of TNF-α gene as susceptibility marker in Algerian AS patients, four single nucleotide polymorphisms (SNPs) (-238G/A, -308G/A, -857C/T and -1031 T/C) were analyzed in 341 patients with AS, and 357 healthy control subjects. The TNF-α SNPs were genotyped by Taqman technology; and lifecodes cytokines sso typing. The analysis of genotype frequency was performed with Phase data.
A statistically significant difference in the frequency of TNF -857 C/C (54.03% vs 77.94%; c2=43.67; P=3.9 x 10-11; OR=0.33) and TNF -857 C/T (42.99% vs 20.34%; c2= 40.65; P= 1.8 x 10-10; OR= 2.95) between patients and controls was found. Conversely, other SNPs (-238, -308, and -1031) did not show a significant allelic and genotypes frequency difference between patients and controls.
The haplotype analysis reveals six common haplotypes in our population (TCGG, TCAG, TCGA, TTGG, CCGG and CCGA). In comparison with healthy control subjects, the analysis of TTGG haplotype in the AS group showed a significantly correlation (p=1.3×10-8, OR = 2.28) as well as the TCGG haplotype in healthy control subjects (p=0.005, OR=0.74).In contrast, no significant difference for other TNF haplotypes was found. These results suggest that the -857 SNP plays a dominant role in susceptibility or resistance to AS in our population.

P2.09.03

Possible involvement of polymorphisms in OAS2, OAS3, and CD209 genes, associated with severe forms of tick-borne encephalitis, in predisposition to hepatitis C in Russian population

A. Barkhash[1], *G. Kochneva*[2], *E. Chub*[2], *S. Mikhaikova*[1], *A. Romaschenko*[1];
[1]*Institute of Cytology and Genetics, Russian Academy of Sciences, Siberian Branch, Novosibirsk, Russian Federation,* [2]*State Research Center of Virology and Biotechnology "Vector", Koltsovo, Novosibirsk Region, Russian Federation.*

Hepatitis C (HC) is a severe liver disease caused by single-stranded RNA virus of the Flaviviridae family. Previously, we reported an association of several single nucleotide polymorphisms (SNPs) in three innate immunity genes (OAS2, OAS3, and CD209) with human predisposition to severe forms of tick-borne encephalitis (caused by a virus from the same family) in Russian population (Barkhash et al., 2010, 2012). In this study, genotype and allele frequencies for five of these SNPs (OAS3 rs2285932 and rs2072136, OAS2 rs15895 and rs1732778, CD209 rs2287886) were analyzed in 75 HC patients and compared with previously studied population control (265 Novosibirsk citizens) (Barkhash et al., 2010, 2012). For all OAS gene SNPs, no significant differences between HC patients and the control group in genotype or allele frequencies were found. However, highly significant differences were found for the CD209 rs2287886 SNP: an increase in the frequency of A allele (46.6%) ($P = 0.001$), G/A genotype (60.3%) ($P = 0.001$), and a decrease in the frequency of G/G genotype (23.3%) ($P < 0.001$) were detected among HC patients as compared with the control group (31.5%, 39.0%, and 49.0%, respectively). Although an increase in A allele frequency is similar to data on predisposition to tick-borne encephalitis, the genotype distribution in patients and controls is different in case of HC and tick-borne encephalitis (Barkhash et al., 2012). Thus, we found that CD209 rs2287886 SNP is associated with predisposition to HC in Russian population. This work was supported by Russian Foundation for Basic Research (grant 11-04-01206a).

P2.09.04
Role of paired immunoglobulin-like receptor B (PirB) and T CD8 lymphocytes during axonal regeneration following peripheral axotomy

A. L. Bombeiro[1], *S. L. O. Nunes*[2], *B. M. Moreira*[2], *A. L. R. Oliveira*[1];
[1]*Biology Institute, State University of Campinas, Campinas, Brazil,*
[2]*Pontifícia Universidade Católica, Campinas, Brazil.*

Major histocompatibility complex class I (MHC-I) molecules, mostly known to present endogenous antigens to TCD8 cells, have been suggested to participate in the CNS synaptic plasticity process during development and after neuronal damage in the adult. Among the MHC-I ligands, PirB may be a key inhibitory molecule related to axonal refinement in response to reinervation of the target muscle. Here we evaluated the immunoreactivity against TCD8 cells, MHC-I, PirB and neurofilaments (axonal marker) following crushing of the sciatic nerve in WT, MHC-I-KO and RAG-KO mice two, four and eight weeks post injury (wpi). Additionally, the sciatic functional index (SFI) was obtained with an automated walking track test up to eight wpi. The SFI showed that all mice strains fully recovered motor function within four wpi, either in a progressive fashion, as observed in MHC-I-KO and RAG-KO mice, or presenting a subtle regression, as seen in WT mice (2-3wpi). Particularly at this stage TCD8 cells were in contact with axons, as revealed by confocal microscopy. MHC-I and PirB immunolabeling increased in WT concurrently with the axonal regeneration ($p<0.05$). In the absence of MHC-I, a higher amount of neurofilaments and PirB was found 2wpi ($p<0.05$), reaching normal levels thereafter. Also, in RAG-KO, MHC-I immunolabeling increased only at 2wpi ($p<0.01$), PirB decreased 4wpi ($p<0.01$) and neurofilament levels remained constant. Overall, the present results suggest that both TCD8 cells and PirB could be involved in the elimination of axonal sprouts during regeneration and following neuromuscular reconnection. Financial Support: FAPESP and CNPq.

P2.09.05
Possible roles of MICA and NKG2D and their interaction in the pathogenesis of autoimmune Addison's disease

E. Bratland[1], *A. Hellesen*[1,2], *K. Edvardsen*[1], *E. S. Husebye*[1,2];
[1]*Department of Clinical Science, University of Bergen, Bergen, Norway,* [2]*Department of Medicine, Haukeland University Hospital, Bergen, Norway.*

Autoimmune Addison's disease (AAD) is a classic organ-specific autoimmune disorder. Although the disease is characterized by antigen-specific antibody and T cell responses against the adrenal cortex, the exact mechanisms underlying tissue damage and immunopathology are largely unknown. Genetic risk for AAD has been associated with several loci in the HLA complex, including polymorphisms in the gene encoding the MHC class I polypeptide-related sequence A (MICA) protein. MICA is a stress-inducible antigen implicated in tumor surveillance and transplant rejection, but also in autoimmune disorders such as type 1 diabetes. The ligand for MICA, the NK cell activating receptor NKG2D is expressed on NK cells, γδ T cells and a subset of cytotoxic CD8+ T cells. There are thus numerous pathways involving MICA/NKG2D interactions that could play a significant part in the pathogenesis of AAD. The aim of the present study has been to investigate these pathways in the context of adrenal autoimmunity. Initially, we detected abundant expression of MICA on the adrenocortical carcinoma cell-line NCI-H295R (using immunofluorescence), but also on healthy adrenal tissue using immunohistochemistry. Furthermore, short-term IL-15 activated polyclonal T cell lines were able to kill NCI-H295R cells in a partly NKG2D dependent manner. Finally, antigen-specific T cell responses against defined peptides of 21-hydroxylase, the main antigen of AAD, were augmented in the presence of stimulating antibodies against NKG2D. We suggest that MICA/NKG2D interactions could contribute to adrenal autoimmunity in manners both dependent and independent of antigen-specific T cell recognition.

P2.09.06
Cross-presentation in renal transplant recipients

E. Breman, *P. P. van Miert, D. Roelen, F. H. Claas, C. van Kooten; LUMC, Leiden, Netherlands.*

Extracellular antigens are mostly presented in the context of MHC class II, whereas endogenous antigens are presented in class I. Both pathways can influence the recognition of alloantigens in the context of transplantation, and contribute to indirect and direct recognition respectively. However, exogenous antigens can also be cross-presented in the context of MHC class I. The contribution of cross-presentation to allorecognition in organ transplantation is currently not known.
Therefore, HLA-A2 tetramers were created with different HLA-A1/A3 derived peptides. Peptides were selected based on their binding capacity to HLA-A*0201 and their polymorphism when compared to the recipient HLA profile, and were calculated using HLA epitope prediction programs (SYFPEITHI, The Immune Epitope Database and Analysis Resource (IEDB), Bimas, IMGT/HLA Sequence Database, MAPPP, NetMHC). The HLA-A2 tetramers were labeled with PE and the five consistently highest scoring tetramer-peptide constructs were used to stain cross-reactive recipient CD8 T-cells in a renal transplantation cohort. Peripheral blood mononuclear cells (PBMC) from 20 renal transplant recipients (HLA-A2+) that received a HLA-A1/A3 mismatched kidney were stained. Stains were preformed on samples from before and 12-24 months after transplantation. Cross-reactive CD8 T-cells were found in one renal transplant recipient at 12 and 24months after transplantation. Further characterization of these cells indicated they were mainly present in the CCR7-/CD45RA+ effector memory population.
In conclusion, we have demonstrated that also cross-presented donor alloantigen may contribute to the recognition of transplanted organs. Current efforts are taking place to further isolate and clone the T-cells to asses their specificity and function.

P2.09.07
MHC Class I expression in hematopoietic and non-hematopoietic cells regulates NK cell licensing and viral control

***M. G. Brown**, H. Wei;*
University of Virginia, Charlottesville, VA, United States.

Inhibitory Ly49G2 receptor-expressing NK cells contribute are needed to control murine (M)CMV infection in MA/My and MHC class I Dk-expressing C57L mice. In bone marrow transplant (BMT) recipient mice, highly effective NK cell-mediated viral control requires Dk expression in both hematopoietic and non-hematopoietic cells. Because Dk is a licensing ligand for Ly49G2, we reasoned that Dk expression in discrete cell lineages modulates NK responsiveness and viral control. To address the question, we generated additional BMT mice and measured the effect of Dk expression on NK effector competency and virus control. As expected, G2+ NK cells in Dk-transgenic (Dk-Tg) mice reconstituted with Dk-Tg bone marrow were fully licensed and conferred MCMV resistance. Conversely, in BMT recipients with Dk expression restricted to only hematopoietic or non-hematopoietic cells, G2+ NK cells displayed reduced activation receptor stimulation and significantly less viral control. These data demonstrate that NK cell licensing is regulated by MHC class I expression in hematopoietic and non-hematopoietic cells and this corresponds to the extent of G2+ NK cell-mediated viral control. Whereas recent data has shown that licensing of adoptively transferred mature NK cells is sensitive to MHC I expression on non-hematopoietic recipient cells, ongoing adoptive transfer experiments with Dk-Tg and non-Tg mature NK cells further examines the relationship between NK cell licensing and their capacity for viral control.

P2.09.08
KIR-HLA interactions during pregnancy impact their population frequencies

***J. J. A. Calis**, C. Kesmir;*
Utrecht University, Utrecht, Netherlands.

The interaction between embryonic trophoblast cells and uterine Natural Killer (uNK) cells is known to stimulate blood vessel formation to supply nutrients to the placenta. If the embryonic cells express an allogenic HLA genotype that is more different from the mothers HLA genotype, the interaction with uNK cells can be stronger. To detect if an embryonic cell expresses allogenic HLA molecules, the uNK cell uses various Killer Immunoglobulin-like Receptors (KIRs). Different KIRs recognize different subsets of HLA molecules as ligands. In this study we tested whether the recognition of allogenicity during pregnancy influences the co-evolution of HLA and KIR genes. To this end, we first developed a simple model to calculate the chance of allogenic recognition as a function of the KIR ligand frequency in a population. This analysis revealed that the allogenic recognition would be optimal if a KIR molecule recognizes one-third of the HLA haplotypes. Second, for KIR2DL1, KIR2DL2/3, KIR3DL1 and KIR3DL2, the ligand frequency was examined in different populations. In agreement with our model, a ligand frequency of one-third was often observed. Moreover, for KIRs that are more frequent, KIR ligand frequencies were closer to the optimum (of one-third). In addition, we show that the frequencies of KIR2DL2 and KIR2DL3, that are located on the same locus, correlate with the optimality of their respective ligand frequencies. We conclude that the detection of allogenicity, which increases the chance of successful reproduction, has a profound impact on the co-evolution of HLA and KIR in the human population.

P2.09.09
HLA-B*46:01 associated with oncogenic HPV persistence

***H. Chen**[1], Y. Chen[2], M. Pan[1], C. Lin[3], S. You[1], C. Chen[1,4];*
[1]Academia Sinica, Taipei, Taiwan, [2]National Taiwan University Hospital, Taipei, Taiwan, [3]Taipei Medical University, Taipei, Taiwan, [4]National Taiwan University, Taipei, Taiwan.

Background: Human papillomavirus (HPV) is the major cause of cervical cancer. Persistence of oncogenic HPV is the pivotal step in the natural history of cervical carcinogenesis. We studied HLA class I with oncogenic HPV persistence.
Method: There were 11,923 women participated in this Community-Based Cervical neoplasia Screening Project (CBCSP), which provided two health examinations in 1991-1993 and 1993-1995. Deep-frozen cervical cells were used for HPV DNA amplification by polymerase chain reaction and genotyping by HPV Blot to identify 39 types of HPV. Genomic DNA from Buffy coat was extracted and identified HLA Class I polymorphism using the commercial kit, SeCore.
Result: There were 10,602 women with available Pap smear and cervical cells at enrollment. Among 909 women infected with oncogenic HPV, 580 women attended the follow-up visit, including 242 women persisted infection and 338 women cleared the virus. The allele frequency of HLA-B*46:01 was higher in persistence group than in clearance group (18.6% vs. 13.1%, p value = 0.009). Compare to 23.7% of women in clearance group harbored one or two allele of HLA-B*46:01, 34.7% of women in persistence group harbored it; the odds ratio was 1.7 (1.2-2.5, p value=0.004). A furtherconfirmation was made between women with cervical HSIL+ (almost oncogenic HPV persistent) and clearance group, a two-fold risk (1.3-3.3, p value=0.003) was obtained.
Conclusion: Our results suggested women harbored HLA-B*46:01 had impaired susceptibility to clear oncogenic HPV infection. The HLA pathway clues a possible mechanism for therapy development to clear HPV infection to replace life-long repeated Pap screening.

P2.09.10
Haplotypes of the HLA-G gene are associated TD1

*R. S. de Albuquerque[1], N. Lucena-Silva[2], C. L. Silva[1], E. Castelli[3], **E. Donadi**[1], C. Mendes-Junior[1];*
[1]University of São Paulo, Ribeirao Preto, Brazil, [2]Aggeu Magalhães Research Center, Recife, Brazil, [3]University of Goias, Ribeirao Preto, Brazil.

The TD1 (Type 1 Diabetes) is a multifactorial disease in which the autoimmune destruction of pancreatic cells. A recent study mapping the MHC region, performed on families with TD1 patients, identified the region of the HLA-G as an independent susceptibility gene for the disease A major function of HLA-G is the inhibition of Natural Killer cells and cytotoxic T cells. A relatively higher degree of variation is observed in the 5'URR and 3' UTR, wich may be in linkage disequilibrium. 29 SNPs have been identified in the HLA-G 5'URR , implicated in the regulation of HLA-G expression. 3'UTR region contains 3 polymorphisms related with several posttranscriptional regulatory elements. For the evaluation of the HLA-G 5'URR region variation and the 3'UTR fragments were amplified using PCR and sequenced, for 3'UTR 120 patients with TD1 and 120 controls, and the extended haplotypes 100 patients and 100 controls. The PHASE method and EM algorithm were used to infer haplotypes. Only the +3010 CC was significantly associated with protection, our group has identified the +3010C/G site as a putative target for microRNAs, suggesting a possible posttranscriptional control. We observed a significantly decreased frequency of the UTR-3 haplotype in patients. For extended haplotypes the HG 0104 haplotypes group, this haplotype is associated with the group , which have been considered as high-producing allele HLA-G. The results here presented indicate that the HLA-G gene may play a role in T1DM susceptibility, pathogenesis or both.

P2.09.11
Regulation of MHC class II expression in cancer cell lines involves the RNA binding protein EBP1

*L. Pisapia, A. Cortese, P. Barba, **G. Del Pozzo**;*
Instiitute of Genetics and Biophysics, CNR, Naples, Italy.

Many tumors including melanoma, glioblastoma, colorectal and breast carcinomas express MHC Class II molecules. The correlation between expression and clinical outcome is an open question and new findings could be reached through the study of CD4+ T cells MHCII tumor specific. Our interest is focused on MHCII post transcriptional regulation, and in M14 human melanoma cell line we demonstrated the existence of a mechanism that, coupling mRNAs

transcription and processing, guarantees the balanced synthesis of mRNAs and the regulated surface expression of the heterodimers. These events occur inside a ribonucleoprotein complex in which we identified EBP1, a characterized RNA binding protein, involved in the regulation of stability and translation of several transcripts, including MHCII.
EBP1, identified as ErbB3 binding protein, presents two isoforms in normal and cancer cells: p48 and p42. Literature data showed that EBP1 isoforms can act as oncogene or tumor suppressor and the different role could be related to the cell type and differentiation stages. In order to analyze the EBP1 function on MHCII expression, we knockdown or overexpress EBP1 isoforms in U87 glioblastoma, MCF7 breast cancer and murine melanoma B16. We determine MHCII expression and mRNA half-life by RT-qPCR and investigate on cancer phenotype by cell cycle analysis. Additionally we will study if EBP1 modulation influences the ability of B16-OVA cell line to present OVA antigens in ex vivo experiments.
In particular our aim is to verify whether EBP1 and other RNA binding proteins of complex regulating MHCII at post transcriptional level affect tumor antigens presentation.

P2.09.12
Major Histocompatibility Complex related LEI0258 allelic segregation in chicken

***A. Esmailnejad**, G. Nikbakht, F. Amini, N. Khazeni Oskoui;*
University of tehran, Tehran, Iran.

Background:The chicken Major Histocompatibility Complex (MHC) has a strong association to disease resistance/susceptibility, production and reproduction traits.Therefore, identifying its polymorphism in populations under selective breeding could be used for selection of disease resistant populations and development of effective vaccines.
Objectives:The aim of the present study was evaluating the MHC polymorphism in two populations of Khorasan indigenous chickens and commercial leghorn breed using microsatellite marker LEI0258 and investigating its segregation. Methods:335 specimens from Khorasan indigenous chickens and commercial Leghorn population (including parents (P) and offsprings (F1)) were analyzed.The MHC genotypes were determined using LEI0258 microsatellite.Allelic segregation analysis from parents to F1 and Hardy-Weinberg equilibrium were conducted using Chi-square test. Results:In Khorasan indigenous chickens 20 different alleles were identified for LEI0258 microsatellite.The allele 321 bp had the highest (22.88%) and the allele 182 bp had the lowest (0.16%) frequency respectively.In the commercial population (Leghorn breed) 3 alleles were found for this marker of which the allele 261 bp had the highest (50%) and alleles 487 bp had the lowest (6 %) frequency respectively.In segregation analysis and Hardy-Weinberg equilibrium of the Khorasan population, no significant differences were observed between parents and F1 progenies in terms of allelic frequencies.
Conclusion:These results indicate a higher genetic variation in indigenous chickens compared to commercial breed.There was not any preference for a particular allele in indigenous chickens and higher frequency of some alleles in F1 population, is due to the high frequency of the same alleles in parents population, their gametes make the population gene pool.

P2.09.13
Motifs of the naturally processed peptides presented by HLA-A*24:07

***M. Gustiananda**[1], D. Cox[2], C. McMurtrey[2], K. W. Jackson[2], D. Mojsilovic[2], W. Bardet[2], S. Cate[2], J. Yaciuk[2], S. Kaabinejadian[2], W. H. Hildebrand[2];*
[1]Eijkman Institute for Molecular Biology, Jakarta, Indonesia,
[2]Microbiology and Immunology, University of Oklahoma Health Sciences Center, Oklahoma City, OK, United States.

Class I HLA molecules mediate immune responses by presenting pathogen-derived peptides to CD8+ T-cells. HLA-A*24:07 is a predominant HLA allele of the Indonesian and South East Asian population. At the moment, there is only one T-cell epitope in the Immune Epitope Database reportedly restricted by A*24:07. HLA-A*24:02 is in the A24 supertype and, although HLA-A*24:07 is closely related to HLA-A*24:02, A*24:07 is not a member of the HLA-A*24 supertype. The two molecules share high homology except for amino acid residue 70, which is a histidine in A*24:02 and a glutamine in A*24:07. The side chain of residue 70 lies in the peptide-binding groove, positioned to impact primary and auxiliary peptide anchors. HLA disease association studies show that these two alleles behave differently in dengue infection as well as in type-1 diabetes. Using proteomic approaches, we systematically compared the peptides presented by A*24:07 and A*24:02. These two A24 were harvested from a matched cell line, immunoaffinity purified, and the A24 ligands were compared by Edman sequencing and tandem mass spectroscopy. Edman analysis indicated slight variations in binding pocket preferences and mass spectroscopy confirmed subtle but clear changes in peptide ligand presentation. This dataset of ligands can be used to improve A*24 predictive algorithms while the A*24:07 reagent can be developed as a tool for characterizing Indonesian and South East Asian immune responses.

P2.09.14
Superior detection of antigen specific CD4+ T-cells using pMHC-II tetramers with altered C-terminal peptide flanking residues

***C. J. Holland**, G. Dalton, D. K. Cole, A. Godkin;*
Cardiff University, Cardiff, United Kingdom.

Background: The importance of T-cells to human health is immense. T-cells are essential for immunity to pathogens and cancer, and they hold the key to vaccination. T-cells also cause a large number of autoimmune diseases and play an important role in organ transplant rejection. The devastating effects of low numbers of just one subset of T-cells, $CD4^+$ T-cells, are all too evident in HIV/AIDS. T-cell receptor (TCR) recognition of peptide epitopes presented by major histocompatibility complex class II (MHC-II) governs $CD4^+$ T-cell activation. The use of MHC-II multimers to identify antigen-specific populations has so far not replicated the success seen with MHC class I multimers. We have previously found modifying $CD4^+$ T-cell epitopes by the substitution of basic residues in the C-terminus enhances T-cell activation.
Aim: To explore the use of C-terminally modified epitopes to generate superior MHC-II tetramers.
Results: Substitution of Arginine into the C-terminus markedly increased the TCR binding affinity by up to two fold. Thermodynamic analysis and structural modelling suggests new electrostatic interactions between TCR and altered C-terminal peptide flank produced the observed TCR binding affinity increase. Furthermore, HLA-DR1 tetramers, with altered C-terminal flanks, could dramatically improve the staining of $HA_{306–318}$ specific $CD4^+$ T-cell clones and allow direct *ex vivo* staining of $HA_{306–318}$ specific $CD4^+$ T-cells from healthy, HLA-DR1 restricted, patients after vaccination.
Conclusion: C-terminally modified MHC-II epitopes can significantly improve TCR binding, offering a route to generate high affinity tetramers with no loss in antigen specificity, with possible attendant implications for vaccination strategies.

P2.09.15
Genetic variants of suppressor molecule BTLA in susceptibility to prostate cancer

***L. Karabon**[1,2], A. Szczepanska[1], K. Tupikowski[2], A. Partyka[1], A. Tomkiewicz[1], A. Wojciechowski[2], E. Pawlak[1], J. Dembowski[2], R. Zdrojowy[2], I. Frydecka[1];*
[1]Institute of Immunology & Experimental Therapy, Wroclaw, Poland,
[2]Medical University, Wroclaw, Poland.

Prostate cancer has become the most common cancers in men and is third men's cancer in terms of mortality in Poland. T cells play a key role in antitumor immunity; therefore expression of inhibitory molecules such as the B- and T-lymphocyte attenuator (BTLA) that inhibits lymphocyte activation could influence cancer susceptibility. An abnormal expression or dysfuncion may be caused by polymorphisms in gene encoding this molecule.
The aim of this study was to evaluate possible associations between *BTLAc.800G>A* (rs9288952), *BTLAc.590A>C* (rs76844316),

BTLAc.88+384C>T (rs1844089) and rs2705535C>T SNPs and susceptibility to prostate cancer.
Genotyping was done using allelic discrimination method with the TaqMan^{O}SNP Genotyping Assays in 162 prostate cancer's patients (pts)and in 260 healthy men originating from the same region in Poland.
The significant difference in distribution of genotypes was observed for rs1844089 SNP. The frequency of genotype [TT] was higher in patients than in healthy men as compare to carriers of C allele (CT+CC) genotypes, p=0,04). The distributions of alleles and genotypes for rs9288952, rs2705535 SNP were similar in patient's and control's groups. The *BTLAc.590A>C* site seems not to be polymorphic in the Polish population, since all typed individuals (100 pts and 100 controls) were AA homozygous.
The haplotype analysis showed that the haplotype rs9288952[G], rs1844089[T], rs2705535[G] was associated with about 2-fold increased risk of prostate cancer (6,3% vs 3,2%, chi^2= 4,6, p=0,03, OR= 2.116, 95%CI [1.053~4.251]).
Our data indicated possible role of polymorphisms in gene encoding suppressor molecule BTLA in susceptibility to prostate cancer.

P2.09.16
Association of HLA-G polymorphisms with gastric adenocarcinoma risk and clinical outcome

S. Khorrami[1], *R. Malekzadeh*[2], *H. Poustchi*[2], *R. Rahimi*[1], *A. Zavaran Hosseini*[1];
[1]*Tarbiat Modares university, Tehran, Iran,* [2]*Digestive Disease Research Center, Tehran, Iran.*

Background: Gastric cancer (GC) is the fourth most common gastrointestinal malignancy and the second leading cause of cancer death worldwide. Human leukocyte antigen-G (HLA-G) molecules are nonclassical HLA-class I molecules that play a crucial role in immuno-tolerance mechanisms. To study the involvement of the HLA-G gene polymorphisms in gastric cancer risk and severity, we investigated the HLA-G genotyping in Iranian Gastric adenocarcinoma patients.
Methods: This case-control study included 100 Gasteric cancer and 102 randomly selected healthy, unrelated Iranian individual's samples as a control.Of 100 cases, 21 (21%) were stage I/II and 79(79%) were stage III/IV. Genomic DNA was isolated from the whole blood using salting-out technique followed by PCR amplification of the exons 2 and 3 of HLA-G gene and performance of PCR-RFLP method. Also Concentrations of sHLA-G in serum were determined with the sHLA-G-specific enzyme linkedimmunosorbent assay (ELISA) kit.
Result:The obtained results indicated frequency of 9 alleles of HLA-G in Iranian individuals including G*01011 (4%), G*01012 (29.86%), G*01013 (10.8%), G*01015 (1.47%), G*01017 (1.96%), G*01018 (2.45%), G*01041 (29.4%), G*01043 (1.96%).The alleles G*01012 and G*01041 had the highest frequencies whereas the alleles G*01015, G*01017, and G*01043 were low frequent. As well data revealed that levels of sHLA-G in serum of GC patients were significantly higher than that in normal controls ($p < 0.0001$).
Conclusion: Our study reveals that HLA-G expression is more frequently observed in patients with advanced disease stage. Moreover, increased sHLA-G levels in plasma might be a useful preoperative biomarker for diagnosis.

P2.09.17
Frequencies of insertion/deletion polymorphism in HLA-G gene in non-small cell lung cancer patients and healthy controls in a Polish population sample

P. Kusnierczyk[1], *A. Wisniewski*[1], *R. Jankowska*[2], *A. Kowal*[2], *I. Porebska*[2];
[1]*Ludwik Hirszfeld Institute of Immunology and Experimental Therapy, Wroclaw, Poland,* [2]*Silesian Piasts University of Medicine, Wroclaw, Poland.*

Lung cancer is a major cause of cancer mortality worldwide. It is a most common neoplasm in males and second one in females in developed countries, including Poland. Non-small cell lung cancer (NSCLC) represents majority of cases. HLA-G is a non-classical MHC molecule expressed predominantly by the trophoblast, but its expression is observed also on some tumor cells, including NSCLC, where HLA-G+ patients survive shorter than HLA-G- ones. Although non-classical and not as polymorphic as classical HLA molecules, nevertheless its gene exhibits some degree of polymorphism, including 14 bp insertion or deletion (ins/del). HLA-G mRNA in del/del homozygotes is expressed on higher level than in individuals with insertion. The aim of this study was to determine the potential association of HLA-G ins/del polymorphism with a prevalence of NSCLC in our Polish population. Venous blood DNA samples from 324 NSCLC patients and 288 ethnically matched controls were typed by agarose gel electrophoresis of PCR products. No significant differences were found between patients and controls in distribution of genotypes: del/del, 35.5% in patients vs 33.3% in controls; ins/del, 50.0% in patients vs 51.1% in controls; ins/ins, 14.5% in patients vs 15.6% in controls. We conclude that other factors than ins/del polymorphism may be responsible for HLA-G expression on some NSCLC tumors.

P2.09.18
Association study among HLA, KIR, MICA, PARK2, and cytokine genes in patients with leprosy from Southern Brazil

P. S. Mazini[1], *D. S. A. Franceschi*[1], *C. C. C. Rudnick*[1], *P. G. Reis*[1], *M. T. Mira*[2], *A. M. Sell*[1], *V. M. Fava*[2], *J. E. L. Visentainer*[1];
[1]*Universidade Estadual de Maringá, Maringá, Brazil,* [2]*Pontífera Universidade Católica do Paraná, Curitiba, Brazil.*

Polymorphisms of HLA, KIR, MICA, PARK and cytokine genes were analysed in patients with leprosy and healthy volunteers from Brazil. HLA, KIR and MICA genes were genotyped by PCR-SSO. PARK2-2599 polymorphism was investigated by real time PCR. PCR-SSP was performed for: TNF-308/-238; IL2-330/+166; IL6-174; IFNG+874; TGFB1+869/+915; and IL10-592/-819/-1082. HLA-DRB1*16 was associated to per se leprosy (P=0.0059), tuberculoid and dimorph forms (P=0.016 and P=0.001, respectivelly), while the HLA-DRB1*16:02 was associated to lepromatous form (P=0.023). KIR2DS2 and KIR2DS3 frequencies were higher in tuberculoid leprosy when compared to lepromatous leprosy. Analysis of KIR-ligands reveled KIR2DL1-C2/C2 elevated in tuberculoid in comparison to all other leprosy subgroups and controls. A negative association between KIR2DL3-C1 and KIR2DL3-C1/C1 and the tuberculoid group was identified. Borderline patients exhibited a higher frequency of KIR3DL2-A3/11 than the controls and lepromatous patients, and a lower frequency of KIR2DL1-C2 than the controls and tuberculoid subgroup. MICA*027 allele was decreased (P= 0.01) in leprosy patients and MICA*010 (P = 0.05) and MICA*027 alleles (P = 0.01) in multibacillary leprosy patients compared to the control group. No significant difference of genotype frequencies among the groups for PARK2 gene was observed. For TNF-308, a higher frequency of GG genotype (P = 0.009), along with a decreased frequency of GA/AA genotypes was observed among leprosy patients as compared to the control group (P = 0.009). Analysis of IL10 genotypes revealed lower frequency of GCC/GCC haplotype in lepromatous leprosy patients (6.2%) in comparison to controls (15.4%). The study suggests the involvement of immune response genes in leprosy.

P2.09.19
Association of MICA gene with the development of chronic chagasic cardiopathy

P. G. Reis, C. M. Ayo, C. F. Oliveira, ***P. S. Mazini****, A. M. Sell, M. M. O. Dalalio, J. E. L. Visentainer;*
Universidade Estadual de Maringá, Maringá, Brazil.

Chagas' disease, caused by the protozoan Trypanosoma cruzi is an anthropozoonosis common in Latin America. Chronic chagasic cardiopathy (CCC) is the most serious clinical manifestation of disease; which has been found in approximately 30% of individuals infected. The aim of this study was to investigate the influence of MICA gene on the development of CCC in a population of southern Brazil. The study enrolled 171 serologically-diagnosed Chagas disease patients treated at the University Hospital of Londrina and the Chagas Disease Laboratory of the State University of Maringá. From 171 patients, it was possible to obtain the cardiological diagnosis of

only 129, and those who had an abnormal electrocardiogram were classified as patients with CCC (N=44) and those with normal electrocardiogram in patients without CCC (N=85). A control group was formed of 159 healthy individuals - spouses of patients or blood donors from the Regional Blood Bank in Maringá. Genotyping of MICA alleles was performed by PCR-SSOP. MICA*007 was more frequent in controls than in patients (0.3 vs. 2.8%, P=0.015, OR=0.10, 95% CI=0.002-0.74). In patients with CCC, MICA*008 was more frequent compared to patients without CCC (35.2 vs. 21.8%, P=0.029, OR=1.95, 95% CI = 1.10-3.46) and the controls (35.2 vs. 23.0%, P=0.028, OR=1.82, 95% CI=1.09-3.03). The haplotype MICA*008_HLA-B*08 showed a higher frequency in patients compared to controls (7.0 vs. 1.6%, P=0.028, OR=4.69, 95% CI=1.14-30.25). In conclusion, MICA*007 is linked to protection against Chagas disease, while HLA-B*008_MICA*08 is associated with susceptibility and MICA*008 has influence on the development of chronic chagasic cardiopathy.

P2.09.20
MIC and NKG2D genes polymorphism in Mexican population

M. E. Nieves-Ramirez[1], *E. Bravo-Flores*[2], *P. E. Alegre-Crespo*[2], *M. Tapia-Lugo*[2], *M. E. Perez-Rodriguez*[2];
[1]*National Autonomous University of Mexico, Mexico City, Mexico,*
[2]*Mexican Institute of Social Security, Mexico City, Mexico.*

Nowadays, the knowledge about polymorphism in genes involved in the immune response helps to identify the susceptibility or risk in the development of different human diseases. Therefore, the objective was to determine the distribution of MHC class I chain related genes (MIC) polymorphisms and Single Nucleotide Polymorphisms (SNP) rs1049174, rs2255336 and rs2617160 of KLRK1 (NKG2D) gene in the Mexican population by their interaction, MICA/MICB-NKG2D. The polymorphism of *MICA* and *MICB* genes and the SNPs of *NKG2D* were analyzed by Reference Strand Conformation Analysis (RSCA) and Sequence Specific Oligonucleotide Probes (SSOP)-Single Specific Primer (SSP) and allelic discrimination, respectively. We genotyped 336 samples of persons clinically healthy and MICA, MICB and NKG2D polymorphisms were identified by RSCA, SSOP-SSP and allelic discrimination, techniques, respectively. The most frequent allele were MICA *002:01 (33.28%), MICB *005:02 (63.09%), NKG2D rs1049174 *T (61.31%), NKG2D rs2255336 *C (61.31%) and NKG2D rs2617160 *G (93.30%). We also found that the most frequent combination of genotypes in the genes MICA/MICB was *002:01-*002:01/*005:02-*005:02 with 7.44%, while the combination of genotypes at SNPs NKG2D in positions rs1049174/rs2255336/rs2617160 was *A-*T/*C-*G/*G-*G with 45.53%. The data obtained provide other genetic markers involved in the immune innate response that can be considered for the study of susceptibility or protection in different diseases of public health and participation in transplants in Mexican individuals. FOFOI 2005/1/I/016, CONACYT 14019.

P2.09.21
Association between the HLA-G molecule and lymph node metastasis in papillary thyroid cancer

L. M. Nunes*;*
UTEP, El Paso, TX, United States.

Papillary thyroid carcinoma (PTC) is the most common type of thyroid cancer and can present as lymph node metastasis in 30 to 65% of cases when initially diagnosed. High frequency recurrence, distant metastasis and treatment resistance can be found in cases of PTC so early diagnosis and treatment are critical for improved prognosis and better survival rates. The characterization of new biomarkers has proved useful for the diagnosis and follow-up of these patients. HLA-G is a non-classical HLA class I molecule whose expression in cancer cells has been associated with tumor evasion of immune response. Therefore, the aim of this study was to investigate the HLA-G expression and its clinical significance in PTC. Paraffinembedded thyroid biopsies of 70 PTC patients (40 of whom had presented with metastasis) were evaluated. HLA-G-staining was observed in tumor cells in PTC, and the HLA-G expression was significantly associated with an increased occurrence of lymph node metastasis (p=0.0006) and capsular invasion (p=0.02) This preliminary data shows the HLA-G expression in thyroid carcinoma specimens for the first time and suggest that this expression could impair efficient anti-tumor immunity in PTC. This would indicate that HLA-G could have an independent prognostic value in PTC, principally for tumor recurrence.

P2.09.22
MHC class I chain related gene A polymorphism and gastroduodenal lesions in Mexican population infected by *Helicobacter pylori*

O. Partida-Rodriguez[1], *M. E. Nieves-Ramirez*[1], *L. Flores*[2], *E. Lazcano*[2], *J. Torres*[3], *M. E. Perez-Rodriguez*[3];
[1]*National Autonomous University of Mexico, Mexico City, Mexico,*
[2]*National Institute of Public Health, Cuernavaca Morelos, Mexico,*
[3]*Mexican Institute of Social Security, Mexico City, Mexico.*

MHC class I chain related gene A (*MICA*) is a highly polymorphic gene expressed in gastrointestinal epithelial cells. MICA activates NK and gamma delta T cells trough the binding of NKG2D receptor under cellular stress situations (infection or transformation). *Helicobacter pylori* (*H. pylori*) colonization of the gastric mucosa is a major cause for chronic gastritis and predisposition for peptic ulcer and gastric cancer. We analyze the associations between allelic and microsatellite polymorphism of *MICA*, and gastroduodenal lesions related to *H. pylori* infection in Mexican Mestizo patients.
We genotyped by RSCA technique 282 *H. pylori*-positive patient samples diagnosed by endoscopy and histology (non-atrophic gastritis=139, intestinal metaplasia=67, gastric cancer=34 and duodenal ulcer=42), and 96 *H. pylori* seropositive asymptomatic persons without gastric lesions. The allelic and microsatellital frequencies in the different groups of patients were statistically compared by chi-square and Fisher test (*pc*<0.05). We found in the asymptomatic group five microsatellites: A4 (5.8%), A5 (25.2%), A5.1 (10.7%), A6 (18.0%) and A9 (40.3%) and six *MICA* alleles: *001 (5.2%), *00201 (40.6%), *004 (17.2%), *00801 (10.9%), *010 (25.0%) and *011 (1.1%). In patients we observed a decrease of the 00201/00201 genotype frequency in duodenal ulcer (9.5%) when compared with non-atrophic gastritis (20.0%) and asymptomatics (23.0%), but it was not statistically significant. We did not find any association with gastric cancer. These results strongly suggest that the *MICA* polymorphism may not be associated with the gastroduodenal diseases provoked by *H. pylori* infection in Mexican population. (CONACyT 6957, FOFOI 2001/007 and 2002/110).

P2.09.23
***CTLA-4* and *CD28* gene polymorphisms in renal cancer in the Polish population**

A. M. Partyka[1], *K. Tupikowski*[2], *L. Karabon*[1], *A. Kolodziej*[2], *R. Zdrojowy*[2], *A. Tomkiewicz*[1], *I. Frydecka*[1];
[1]*Institute of Immunology and Experimental Therapy Polish Academy of Sciences, Wroclaw, Poland,* [2]*Medical University, Wroclaw, Poland.*

Renal cancer is one of the fastest growing cancers in Poland and number of cases has increased about 10% in the last decade. Since T cells play a key role in antitumor immunity, abnormal expression of co-stimulatory molecules CTLA-4, CD28 that regulate T-cell activity, could influence cancer susceptibility. An aberrant expression may be caused by polymorphisms in genes encoding those molecules.
The aim of this study was to evaluate the association between polymorphisms of *CTLA-4* and *CD28* genes and susceptibility to renal cancer in the Polish population.
Altogether 305 renal cancer patients and 380 healthy controls were genotyped by PCR-RFLP method for the following single nucleotide polymorphisms (SNP): *CTLA-4*g.319C>T (rs5742909), *CTLA-4*c.+49A>G (rs231775) and CT60A>G (rs3087243). Genotyping of the *CTLA-4* Jo31G>T (rs11571302), *CD28*c.17+3T>C (rs3116496) and *CD28*g.54779795G>A (rs3181098) SNPs was done using allelic discrimination methods with the TaqMan SNP Genotyping Assay.
We found a trend to a higher frequency of patients carrying the A allele in *CTLA-4*c.+49A>G polymorphism (AA + AG genotypes) compared to the GG homozygotes than in controls. Moreover CT60AA and Jo31TT genotypes we noticed rarely in renal cancer patients than in controls, compared to their heterozygotes

counterparts CT60GA and Jo31GT (p=0.04 and p=0.09, respectively). In addition we demonstrated a trend toward a lower frequency of AA homozygous in *CD28* rs3181098 polymorphism in patients compared to controls (p=0.09).
Our results indicates that polymorphisms in *CTLA-4* and *CD28* genes might be considered as potentially low-penetrating risk factor for renal cancer, but the results are required to be elucidated in further studies.

P2.09.24
Optimization of T-cell antigens for vaccine development

J. Pentier[1], *G. M. Dolton*[1], *J. Ekeruche*[1], *M. Clement*[1], *D. K. Cole*[1], *J. J. Miles*[1], *D. M. Lewinsohn*[2], *D. A. Price*[1], *L. Wooldridge*[1], *A. K. Sewell*[1];
[1]*Cardiff University, Cardiff, United Kingdom,* [2]*Oregon Health and Science University, Portland, OR, United States.*

A single T-cell can recognize upward to a million different peptides expressed at the surface of the Major Histocompatibility Complex (MHC) molecule. Unfortunately, T-cells may not always have the optimum specificity for their target antigens, thus preventing the clearance of infected or tumour cells. Therefore, improving the antigenicity and immunogenicity of T-cell epitopes is a major challenge for therapeutic vaccination. We have developed different technologies to modify peptide sequences in order to enhance their affinity for the T-cell receptor (TCR) such as combinatorial peptide libraries (CPLs).
We produced a T-cell clone (MEL5) restricted to the well characterized HLA-A*0201 and specific to a melanoma epitope. Combinatorial libraries were used to design peptides 1,000 fold more potent than the MEL 5 wild-type epitope. The priming of peripheral blood mononuclear cells from healthy donors with these agonists shows a high expansion of different clonotypic melanoma specific $CD8^+$ T-cells capable for the majority of donors to kill melanoma tumour cells. Using the same CPLs technology we have designed high affinity peptide for a *Mycobacterium tuberculosis* T-cell clone. Future work will allow us to determine if these agonists can be used for the development of potential mTB vaccines. These *in vitro* studies demonstrate the possibility to use these technologies to elicit high cytotoxic T-cell response against wild-type epitope using agonists in vaccination setting.

P2.09.25
The HLA-DRB1*01 allele confers genetic susceptibility to lepromatous leprosy in Mexicans

R. Ramos-Payan[1], *M. Escamilla-Tilch*[2,3], *N. M. Torres-Carrillo*[4], *M. Aguilar-Medina*[1], *M. I. Salazar*[2], *M. Fafutis-Morris*[5], *R. Arenas-Guzmán*[6], *S. Estrada-Parra*[2], *I. Estrada-García*[2], *J. Granados*[7];
[1]*Faculty of Biological and Chemical Sciences, Autonomous University of Sinaloa, Culiacan, Sinaloa, Mexico,* [2]*National School of Biological Sciences, National Polytechnic Institute, D.F., Mexico,* [3]*National Institute of Nutrition and Medical Science "Salvador Zubirán", D.f., Mexico,* [4]*National Institute of Geriatrics, Health Secretary, D.F., Mexico,* [5]*Jalisco´s Dermatological Institute "José Barbara Rubio", Guadalajara, Jalisco, Mexico,* [6]*General Hospital "Dr. Manuel Gea González", D.F., Mexico,* [7]*National Institute of Nutrition and Medical Science "Salvador Zubirán", D.F., Mexico.*

Background: Despite multidrug therapy had reduced the overall prevalence of leprosy in México, it remains endemic in some regions of the country. Some genetic basis for the immune susceptibility towards Mycobacterium leprae had been already established in different populations around the globe. Methods:
52 patients diagnosed with leprosy were classified according to the international criteria establish by Ridley and Jopling. 99 healthy individuals, unrelated to the patients and matched by ethnicity, were included as control group. Genomic DNA was purified according to Miller's method, and HLA-DRB1 locus was genotyped. Data was analyzed with Genosearch Typing software. Statistical analysis included $\chi 2$ test or Fisher's exact test and the odds ratio (OR). Significant p values ≤ 0.05) were corrected taking into account the number of alleles observed (pc).
Results: Here we report that HLA-DRB1*01 allele in a Mexican Mestizo population with leprosy is significantly more frequent (23.00%, pc < 0.001, OR = 5.60) than in healthy individuals (5.00%). The analysis of groups based on clinical classification confirmed the strong association of HLA-DRB1*01 (p<0.001, OR=4.6, n=41); and (p=0.03, OR=6.2, n=6), for lepromatous and dimorphic leprosy, respectively.
Conclusions: This is the first time the association of HLA-DRB1*01 with immune susceptibly to lepromatous leprosy is found on this population. The study of leprosy patients from known endemic regions may give more insights into the pathogenesis of the disease as well as its heterogeneous distribution in México.

P2.09.26
Victory model; Simulation of structures and functions of Antibody and MHC by innovative hands, forehand and arms modeling approaches

M. R. Ranjbar;
Tehran University, Tehran, Iran.

Introduction: Hand, forehand and arms (forelimb) molecular modeling for showing of Antibody and MHC structures and functions named "Victory model" in this article, that encompasses immunoanatomical models used to mimic the behaviour of biological molecules. "Victory model" name come from "Y"-shaped of antibody when we showing it by forelimb.
Method: The study consists of the three major phases: (a) conceptualization of the model based on the literature reviews in field of immunology, biochemistry, anatomy and computer science, (b) visualization the models by forelimb, and (c) refinement of the models and checking their quality of displaying concepts.
Results: About 72 different models obtained for showing different antibody structures and Isotypes (IgM, IgG and etc.), Ig variable and constant regions, disulfide bonds, Immunoglobulin diversity, Somatic hypermutation and affinity maturation, Activation of complement and interaction with other molecules and cells. Also, 25 forelimb models obtained for MHC class I and II structure and functions. In this study some hidden aspects of antibody interactions and functions, cause touchability of models with eyes, were defined that never have been understood.
Conclusion: The findings of the study presents a models for designing innovative training projects that enable teachers to better transfer concepts to student in immunology classes and students can simply exercise and have deep, accurate and touchable insight to structure and functions of antibody and MHC. Besides, it may raising discussions that forelimb may be takes some evolutions patterns and shaping forms from specific antigen recognizing proteins as both have responsibility in Control of Objects.

P2.09.27
HLA-DRB1*11 is associated with Papillon-Lefevre Syndrome in Mexican patients carrying a novel cathepsin C mutation.

J. G. Romero-Quintana[1], *M. Aguilar-Medina*[1], *L. O. Frías-Castro*[2], *J. E. Dueñas-Arias*[2], *E. Arámbula-Meraz*[1], *J. G. Romero-Navarro*[1], *R. Ramos-Payán*[1];
[1]*Faculty of Biological and Chemical Sciences, Autonomous University of Sinaloa, Culiacan, Sinaloa, Mexico,* [2]*Pediatric Hospital of Sinaloa, Culiacan, Sinaloa, Mexico.*

Background: Papillon-Lefèvre Syndrome (PLS) is characterized by aggressive periodontitis and palmoplantar hyperkeratosis. This autosomal recessive disorder, caused by mutations in cathepsin C (CTSC), has a worldwide prevalence of 1-4 cases per million in the general population. In México, the prevalence of this syndrome is unknown. The diagnosis of twenty patients in the state of Sinaloa highlights the need to characterize this syndrome in Mexicans.
Methods: HLA were typed in nine PLS patients and their relatives. Gene expression, enzymatic activity and mutational analysis of CTSC were assayed in these individuals. Frequencies of CTSC gene polymorphisms and HLA alleles were also determined in healthy individuals.
Results: HLA-DRB1*11 was found significantly more frequent (p = 0.0071) in patients than controls (33.33% vs. 7.32%), with an estimated relative risk of 6.33. Patients showed normal CTSC gene expression, but a deep reduction (up to 85%) in enzymatic activity in

comparison to unrelated healthy individuals. A novel loss-of-function mutation, c.203T>G (p.Leu68Arg), was found in all patients, and some carried the polymorphism c.458C > T (p.Thr153Ile). Allelic frequencies in patients, relatives and controls were 88.89%, 38.24% and 0.25% for G (c.203T>G); and 11.11%, 8.82% and 9.00% for T (c.458C>T).
Conclusions: This is the first report on the association of HLA-DRB1*11 with PLS. The novel loss-of-function mutation of CTSC gene (c.203 T > G) found in patients correlated with their diminished enzymatic activity. The study of additional PLS patients may give more insights into the etiology of the disease as well as its prevalence in México.

P2.09.28
Influence of TIM-1 haplotypes on CD4 counts in HIV seroprevalent North Indians

G. Sharma[1], *G. Kaur*[1], *A. Kimura*[2], *T. Nakajima*[2], *H. Ohtani*[2], *T. Naruse*[2], *S. K. Sharma*[3], *M. Vajpayee*[4], *N. K. Mehra*[1];
[1]*Department of Transplant Immunology & Immunogenetics, All India Institute of Medical Sciences, New Delhi, India,* [2]*Department of Molecular Pathogenesis, Tokyo Medical & Dental University, Tokyo, Japan,* [3]*Department of Medicine, All India Institute of Medical Sciences, New Delhi, India,* [4]*Department of Microbiology, All India Institute of Medical Sciences, New Delhi, India.*

Introduction: T cell immunoglobulin and mucin domain family member-1 (TIM-1) molecules are expressed on Th2 $CD4^+$ cells and regulate Th1/Th2 immune responses. The mucin domain (exon 4) of this molecule is characterized by high degree of variability. However, the distribution of TIM-1 haplotypes and their population specific influence on HIV/AIDS is largely unknown.
Material & Methods: Sequencing analysis of TIM-1 exon 4 was performed in 227 HIV +ve and 288 healthy individuals (North Indians). Haplotypes were compared among the groups by the chi square test. Continuous variables with the haplotypic background were compared by Wilcoxon rank-sum test.
Results: Seven TIM-1 haplotypes W-A, W-C, D1, D1*, D3-A, D3-C and D4 were observed. D3-A was observed predominantly (>0.465) followed by D3-C (0.219), D4 (0.214), W-A (0.057), D1 (0.021) and W-C (0.007) haplotypes. Differences among the healthy vs HIV +ve individuals were statistically insignificant, suggesting lack of influence on HIV susceptibility/resistance. Additionally, a novel D1 related haplotype D1* was observed (0.007). Further, significantly higher CD4 counts were observed in D3-A carrying HIV patients, however in subgroups of ART naïve and on ART patients, moderate influence was observed. These findings suggest a possible link of D3A with low levels of TIM-1 expression and hence lower Th2 promotion and enhanced Th1 responses. Incidentally, Th1 to Th2 shift is well associated with poor HIV prognosis.
Conclusion: We represent the first report on distribution of TIM-1 haplotypes in the North Indian population in context of HIV susceptibility/resistance and disease status.

P2.09.29
Association studies of functional *ICOS* gene polymorphisms with schizophrenia disease in the Polish population

A. M. Tomkiewicz[1], *L. Karabon*[1,2], *A. M. Partyka*[1], *D. Frydecka*[2], *A. Kiejna*[2], *A. Beszlej*[2], *I. Frydecka*[1];
[1]*Institute of Immunology and Experimental Therapy, Wroclaw, Poland,* [2]*Medical University, Wroclaw, Poland.*

Several reports indicate a possible role of the immune system dysregulation in the pathogenesis of schizophrenia. The inducible co-stimulatory molecule (ICOS) which is expressed on the T-cell surface after activation enhances all the basic T-cell responses proliferation, secretion of lymphokines, the up-regulation of molecules that mediate cell-cell interaction
The study was undertaken to evaluate the association between three *ICOS* polymorphisms (which were recently described as functional ones) and susceptibility to schizophrenia in a Polish population.
One hundred and fifty patients with schizophrenia and 170 healthy subjects were genotyped for the following polymorphisms: *ICOSc.1624C>T* (rs10932037), *ICOSc.602A>C* (rs10183087) and *ICOSc.2373G>C* (rs4675379) using allelic discrimination methods with the TaqMan® SNP Genotyping Assay.
We have noted that frequencies of alleles *ICOSc.1624C>T* [C], *ICOSc.602A>C* [A], and *ICOSc. 2373G>C* [G] were higher in patients of schizophrenia than in healthy controls, but differences did not reach statistical significance (0.930 vs. 0.898, p=0.16; 0.817 vs. 0.777, p=0.21 and 0.889 vs 0.852, p=0.19, respectively).
The result of the study although do not confirm the association of investigated polymorphisms with susceptibility to schizophrenia, while present weak trend to overpresence of wild-type alleles of *ICOS* gene and are warrant further investigation through extended studies.

P2.09.30
Change of C/A at the SNP −592 of human IL-10 gene increase serum IL-10 levels in patients with cervical lesions and cervical cancer

K. J. Torres Poveda[1], *M. Bahena Román*[1], *A. Lagunas Martínez*[1], *K. Delgado Romero*[2], *D. Cantú*[3], *A. García Carrancá*[3], *V. Madrid Marina*[1];
[1]*Instituto Nacional de Salud Pública, Cuernavaca, Mexico,* [2]*Health Services of State of Morelos, Cuernavaca, Mexico,* [3]*Unit of Biomedical Research in Cancer, Instituto Nacional de Cancerología, Mexico City, Mexico.*

An immunosuppressive state had been identified in women with human papillomavirus (HPV) persistent infection, characterized by high levels of interleukin (IL)-10 at cervix level. We have demonstrated that the -592 SNP in IL-10 gene promoter is associated with increased risk of cervical lesions (CL) and cervical cancer (CC). We analyzed whether exist significative differences of serum IL-10 protein between CL and CC cases and HPV negatives controls. Additionally, whether exchange in this SNP results in increased IL-10 gene promoter activity in HPV transformed cells.
Using a cross-sectional design, peripheral blood samples of CL patients (n=204), with CC (n=80) and without CL HPV positives (n=66) and HPV negatives (n=100) were used to evaluate seric concentrations of IL-10 by ELISA. Transient transfection assay was performed in C33 and HeLa cells with two luciferase constructs containing the IL-10 promoter (C allele or A allele). The serum IL-10 protein, were significantly higher in CL and CC cases (p<0.01), being higher in patients carrying the risk allele A. The mean levels of IL-10 increased in consecutive clinical stages of the CC. The C to A nucleotide exchange results in increased IL-10 gene promoter activity in C33 an HPV transformed cell line.
In conclusion, we demonstrated that the C to A nucleotide exchange in this SNP results in increased IL-10 gene promoter activity in HPV transformed cells, supporting its role as an activator element and that be associated with the expression regulation of IL-10 at systemic level, which was progressively higher in CL and CC cases.

P2.09.31
Comparison of the distribution of two promoter single nucleotide polymorphisms, -725C>G>T and -716T>G, in non-small cell lung cancer and healthy population sample

A. Wisniewski[1], *R. Jankowska*[2], *A. Kowal*[2], *I. Porebska*[2], *M. Wagner*[1], *P. Kusnierczyk*[1];
[1]*Ludwik Hirszfeld Institute of Immunology and Experimental Therapy, Wroclaw, Poland,* [2]*Silesian Piasts University of Medicine, Wroclaw, Poland.*

HLA-G, a human non-classical MHC molecule, is not expressed in pulmonary structural cells, but may appear in activated macrophages and dendritic cells infiltrating lung carcinomas, as well as in tumor cells themselves. Several polymorphisms, potentially affecting HLA-G gene expression, were described in its promoter region. We attempted to check whether these polymorphisms might be associated with susceptibility to non-small cell lung cancer (NSCLC). Here, we present our results on -725C>G>T and -716T>G single nucleotide polymorphisms (SNPs) distribution in 324 patients diagnosed with NSCLC and in 288 healthy control individuals, both groups of ethnical Poles inhabiting the Lower Silesia region. In -725 SNP, five different genotypes were found (CC, CG, CT, GG, and GT). Their frequencies in patients and controls did not differ (p=0.67).

Three genotypes were found in -716 SNP (TT, TG, and GG). Similarly to above mentioned SNP, also here no statistically significant differences were observed (p=0.16). We are planning to type for other polymorphisms in HLA-G genes in order to examine whether some of them, or haplotypes created by them, may influence the prevalence of NSCLC in our population.

P2.09.32
Associations of IFN-alpha genetic variation with the functional phenotype of T subsets

***J. Yu**, H. Chang, Y. Li, M. Wu, W. Chung, H. Chaung;*
National Pingtung University of Science and Technology, Pingtung, Taiwan.

Interferon-alpha (IFN- alpha) functions in viral defense and plays a key role between the innate and adaptive immune systems. This cytokine has numerous effects on the immune system including up-regulating the expressions of MHC molecules, cytokine and chemokines, inducing the maturation of dendritic cells, activating natural killer cells, and stimulating CD8+ T cell proliferation. Single nucleotide polymorphism (SNP) marker has been widely used for genetic investigations and thus can be an effective tool for determining the associations between genetic characteristics on immune system and disease susceptibility. In the present study, we characterized the IFN-alpha SNPs, T cell proliferation and phenotypic analysis of cell surface markers on porcine peripheral blood mononuclear cells (PBMC). Results showed that one SNP was found in -235 of the IFN-alpha promoter region. The PBMC with IFN-alpha -235 G/G genotype has significantly less CD4+- but higher CD8+-positive T cells than those with the -235 A/G and -235 A/A genotypes ($p<0.05$). The significantly increased cell proliferation of ConA-stimulated PBMC was found in those with the IFN-alpha -235 A/A genotype as compared with the -235 A/G and -235 G/G genotypes ($p<0.05$). Results indicated that IFN-alpha SNPs may be associated with the functional phenotypes and cell proliferation of T subsets.

P2.10 Autophagy and cell death in the immune system

P2.10.01
Elucidating the role of UVRAG in T cell biology

***S. Afzal**[1,2], H. Zhenyue[2], D. Brenner[2], T. Mak[1,2];*
[1]University of Toronto, Toronto, ON, Canada, [2]Campbell Family Institute for Breast Cancer Research, Toronto, ON, Canada.

Autophagy is a well-conserved intracellular degradation process that plays important roles in the regulation of cell survival and metabolism. Recently, there is an expanded role for autophagy in the adaptive immune system where it contributes to MHCII cross-presentation of endogenous antigens, and cell survival. Autophagosome formation has been observed in proliferating T cells and it is necessary for the regulation of T cell survival and proliferation. UVRAG, initially identified through its ability to partially complement UV sensitivity in xeroderma pigmentosum cells, has been shown to positively regulate the activity of the class III PI3 Kinase complex in autophagy. Using the conditional UVRAG deletion in T cells, we examined the role of UVRAG in T cell biology and autophagy. A thorough phenotypic analysis of these mice has shown a critical role for UVRAG in T cell development, homeostasis and function.

P2.10.02
Galectin-1 is a novel component of cytotoxic granules and contributes to in vivo CTL killing

***G. P. Amarante-Mendes**[1,2], T. C. Machado[1,2], N. J. Vieira[1,2], M. J. Dominguez[3], T. Zorn[1], M. Dias-Baruffi[4], M. M. Rodrigues[3], S. J. Martin[5];*
[1]Instituto de Ciências Biomédicas, Universidade de São Paulo, São Paulo, Brazil, [2]Instituto de Investigação em Imunologia, Instituto Nacional de Ciência e Tecnologia, São Paulo, Brazil, [3]Centro de Terapia Celular e Molecular and Departamento de Microbiologia, Imunologia e Parasitologia, Universidade Federal de São Paulo, São Paulo, Brazil, [4]Departamento de Análises Clínicas, Toxicologia e Bromatologia, Universidade de São Paulo, Ribeirão Preto, Brazil, [5]Smurfit Institute of Genetics, Trinity College Dublin, Dubliin, Ireland.

The mechanism of cytotoxicity mediated by Natural Killer (NK) cells and Cytotoxic T Lymphocytes (CTL) is involved in the control of cancer progression, virus mediated diseases and many other intracellular related pathologies. These cells are particularly adapted to promote contact mediated cell death due to their ability to produce a special type of organelles, namely secretory lysosomes, aka cytotoxic granules. By proteomic analysis, we identified dozens of putative novel cytotoxic granule proteins in NK and CTL granule preparations, as well as most of the already known granule constituents. Using confocal as well as electron microscopy we show that galectin-1, a protein previously described to have immunomodulatory activity, including regulation of apoptosis, is indeed present inside the cytotoxic granules. Moreover, using an adenoviral system to intramuscularly deliver antigens, we show that galectin-1 deficient mice display an increased frequency of specific CD8 T cells but an impaired in vivo CTL activity against antigen-specific targets. Taken together, our results show that galectin-1 is a novel component of the CTL granules and participate in in vivo cytotoxic T cell killing. Financial support: This research was partially supported by CNPq and FAPESP (Brazil) and NSF (Ireland).

P2.10.03
Autocrine and paracrine interferon-γ directly enhances CD8 T cell motility and contact-dependent cytotoxicity

***P. Bhat**[1,2], G. Leggatt[1], N. Waterhouse[3], I. Frazer[1];*
[1]The Universtity of Queensland Diamantina Institute, Buranda, Australia, [2]Princess Alexandra Hospital, Woolloongabba, Australia, [3]Mater Medical Research Institute, Buranda, Australia.

Many epithelial cancers, such as bowel and cervical cancer, are infiltrated by large numbers of activated CD8 T cells that are unable to effect tumour killing. We examine the basic mechanisms by which primary cytotoxic T cells kill primary epithelial cells presenting cognate antigen. We show that *in vivo*, IFN-gamma production by CD8 T cells is necessary for rejection of skin grafts expressing Ova. The ability of CD8 T cells to migrate to inflamed tissue was enhanced by paracrine IFN-gamma. We developed a novel quantitative and qualitative *in vitro* killing assay that enables assessment of cell-to-cell interactions and the mechanisms involved in cytotoxic killing, using live-cell microscopy of primary cells. Primary keratinocytes presenting Ova were co-cultured with antigen-specific CD8 T cells. CD8 T cells kill KC by caspase-3 dependent mechanisms following prolonged attachment times that were specific to target cell type. The kinetics of CD8 T cell migration, speed and travel distances, were closely related to their cytotoxic function. IFN-gamma, whether produced in autocrine fashion from antigen primed effector CD8 cells, or provided exogenously, enhanced CD8 T cell motility and cytotoxity. Significantly, inhibition of the autocrine activity of IFN-gamma on effector T cells for four hours resulted in dysfunctional cells that did not survive. We conclude that IFN-gamma is necessary locally to facilitate the effector functions of effector T cells even post-priming. The absolute need for local IFN-gamma to enable effector T cell cytotoxic function is critical in the development of immunotherapies for cancer and chronic viral infections.

P2.10.04
SLAMF-1 is a signaling receptor modulating autophagy in a subset of chronic lymphocytic leukemia patients with a good prognosis

C. Bologna[1], *R. Buonincontri*[2], *S. Serra*[1], *T. Vaisitti*[1], *V. Audrito*[1], *D. Brusa*[2], *S. Deaglio*[1];
[1]*Human Genetics Foundation (HuGeF) and Department of Medical Sciences, University of Turin, Turin, Italy,* [2]*Human Genetics Foundation (HuGeF), Turin, Italy.*

Human SLAMF-1 (signaling lymphocytic activation molecule) is expressed on hematopoietic cells where it acts as a co-activator through self-interactions. Moreover, it performs as a microbial sensor, regulating bacterial phagosome functions through an ubiquitous cellular autophagic machinery. We investigated the role of SLAMF-1 in B cells, exploiting chronic lymphocytic leukemia (CLL) as a model. CLL is characterized by the expansion of a monoclonal population of mature B lymphocytes, with a highly variable clinical course. In a cohort of 300 clinically and molecularly characterized CLL patients, the expression of SLAMF-1 correlates with a good prognosis. Functional experiments demonstrated that SLAMF-1 initiates a signaling pathway through a direct interaction with the adaptor molecule Eat-2 with the consequent activation of Vav-1, p38 and Jnk1/2. Furthermore, a prolonged engagement of SLAMF-1 led to the appearance of autophagic vesicles, as confirmed by biochemical analyses, confocal and transmission electron microscopy. The modulation of autophagy was mediated by reactive oxygen species and by the sequential phosphorylation of Jnk1/2 and Bcl-2: the final result is the activation of Bcl-2 and the release of Beclin-1, an essential member of the autophagic complex. The addition of ROS scavengers (SOD and catalase) and the Jnk1/2 inhibitor SP600125 led to a decrease in autophagy, validating the model. Taken together, these results suggest that SLAMF-1 could represent a novel marker for the subset of CLL patients with an indolent clinical course and highlight a hypothetical link between the activation of the autophagic process and a better clinical outcome in CLL, with potential translational implications.

P2.10.05
LPS induces intrinsic apoptosis of 6-sulfo LacNAc+ dendritic cells (slanDCs)

D. Camuesco, *F. Calzetti, M. Cassatella;*
Department of Pathology and Diagnostics, Division of General Pathology, University of Verona, Verona, Italy.

slanDCs are the most abundant myeloid DCs in human blood and are characterized by a high capacity to produce pro-inflammatory cytokines upon TLR-stimulation. While slanDCs, also known as a non-classical monocyte subset/CD16^{+}-DCs, are susceptible to spontaneous and oxidant-induced apoptosis, how they respond to LPS in terms of viability is unknown. Hence, our aim was to investigate the molecular mechanisms whereby LPS influences slanDC survival. slanDCs, isolated from buffy coats of healthy donors, were cultured in the presence or absence of death receptor agonists, H_2O_2 or LPS, in combination or not with apoptosis blockers or N-acetyl-cysteine. Cellular viability and caspase activities were determined by flow cytometry and luminescent assays, respectively. Reactive oxygen species (ROS) production was established by either the cytochrome C reduction assay or the nitroblue tetrazolium test. LPS accelerated spontaneous slanDC death independently from endogenous FasL-, TRAIL- and TNFα-involvement. These findings were in agreement with increases in caspase-9 and -3, but not caspase-8, activities. Furthermore, LPS-stimulated slanDCs produced ROS and were susceptible to oxidant-induced cell death upon incubation with H_2O_2, with the addition of N-acetyl-cysteine partially reducing the apoptotic cell percentage upon LPS-treatment. In conclusion, LPS negatively affects slanDC survival, suggesting the existence of self-regulatory mechanisms that limit slanDC activation. This effect is independent on death receptor-mediated extrinsic pathways. On the other hand, an oxidative process induced by LPS is involved in its pro-apoptotic effect on slanDCs.
Funded by the European Union Seventh Framework Program (FP7/2007-2013), grant agreement n° PIEF-GA-2010-275090

P2.10.06
Autophagy as a link between immunity and inflammation in idiopathic inflammatory myopathies

C. Cappelletti[1], *G. N. A. Vattemi*[2], *P. Tonin*[2], *F. Salerno*[1], *L. Maggi*[1], *L. Morandi*[1], *M. Mora*[1], *G. Tomelleri*[2], *R. Mantegazza*[1], *P. Bernasconi*[1];
[1]*Foundation Neurological Institute "C. Besta", Milan, Italy,* [2]*University of Verona, Verona, Italy.*

Idiopathic inflammatory myopathies (IIMs), a heterogeneous group of immune-mediated muscle disorders characterized by muscle inflammation and weakness, comprise inclusion body myositis (IBM), polymyositis (PM), juvenile dermatomyositis (JDM), and adult dermatomyositis (DM). An impairment in the autophagic pathway has been well documented in sporadic IBM, where it has been suggested to be responsible for the accumulation of multiple-protein aggregates, typical of the myopathy. The main candidates responsible for this impairment are suggested to be TLRs.
We evaluated the autophagic process also in PM and DM, in particular the interaction between autophagosome maturation and innate immune system.
LC3 and other autophagic molecules, together with TLR3, TLR4, HSP60 and HMGB1/2 were analysed in IIM and control muscles by qPCR, immunohistochemistry and immunoblot. Myoblasts and myotubes from PM, DM and control muscle biopsies were analyzed to evaluate changes in TLR and HMGB1/2 expression after induction or inhibition of autophagy.
Gene expression analysis showed a dysregulation of autophagy in all IIM subgroups. A tight correlation between autophagy and innate immunity in myopathic muscles compared to controls was highlighted by confocal microscopy; activation of stress response and the presence of bacterial infection were observed connected with an abnormal accumulation of autophagosomes in IIM myofibers.
These findings demonstrate the involvement of the autophagic process in the pathogenesis of all subtypes of IIMs; it is not clear if this mechanism represents a consequence or a cause of the induction of immune response and inflammation. Autophagic machinery components might represent a possible target for new therapeutic approaches for IIM.

P2.10.07
O-linked N-acetylglucosaminyl transferase (Ogt) promotes the survival of mature B cells

M. Chiang[1,2], *C. Wu*[1], *K. Lin*[1];
[1]*Genomics Research Center, Academia Sinica, Taipei, Taiwan,* [2]*Graduate Institute of Life Sciences, National Defense Medical Center, Taipei, Taiwan.*

O-linked β-N-acetylglucosamine (*O*-GlcNAc) modification (O-GlcNAcylation) is a process of adding GlcNAc to protein serine or threonine residues. This posttranslational modification is triggered by *O*-linked N-acetylglucosaminyl transferase (Ogt) and is involved in the regulation of many functions of proteins including protein stability, localization and transcriptional activities. *O*-GlcNAcylation plays important roles in many cell types and in many diseases such as diabetes, neuron degenerative diseases and cancer. In B cells, it was reported that accumulation of *O*-GlcNAcylation resulted from overexpression of Ogt led to enhanced B cell activation, but whether Ogt involves in the regulation of development, differentiation or survival of B cells was largely unknown. Thus, we created a mouse line in which *Ogt* was specifically deleted in B cells by crossing *Ogt*-floxed mouse to CD19-*cre* mouse. Deletion of *Ogt* in mice results in reduced B cell populations in bone marrow, spleens and lymph nodes. Further analysis of B cell subsets revealed that B cell development was normal but the numbers of mature B cells were decreased in *Ogt* deficient mice, which was linked with the enhanced apoptosis of mature B cells in *Ogt* deficient mice. These data suggest that Ogt may play a positive role in the survival of mature B cells. However, further studies are needed to elucidate the molecular mechanisms contributing this phenotype.

P2.10.08
Selective MHCII-mediated cell death as a potential mechanism for reversing inflammation in a chemically-induced mouse model of colitis

G. F. Dusio[1], *R. P. Tobin*[2], *L. Dao*[1], *S. Henderson*[1], *W. Cromer*[2], *H. Papacostantinou*[1], *M. K. Newell*[1,2];
[1]*Scott & White Memorial Hospital, Temple, TX, United States,* [2]*Texas A&M Health Science Center, Temple, TX, United States.*

Dysregulation of immune cell apoptosis is implicated in the pathogenesis of inflammatory bowel disease and selective depletion of pro-inflammatory, non-antigen specific B and T cells may be a rational therapeutic approach. We recently demonstrated that non-antigenspecific activation of resting B cells via Toll-like receptor (TLR) ligation leads to increased cell surface expression of MHC class II invariant chain peptide (CLIP) in the MHCII groove, thereby providing protection from T cell dependent MHCII-mediated cell death. Using a computational approach, we designed small peptides that reverse inflammatory symptoms in several animal models of chronic inflammation including TLR-induced preeclampsia and autoimmune myocarditis, by depleting CLIP+ immune cells. In the current study, we examined the in vitro effects of dextran sodium sulphate (DSS) or TNBS, classical chemical agents used in an animal model of colitis, on CLIP expression on murine B cells and gamma delta T cells isolated from spleen and Peyer's patches. Our results demonstrated that DSS/TNBS caused a significant expansion of B cell and gamma delta T cell populations. Moreover, flow cytometric analysis shows that in both live cell sub-populations there is increased expression of ectopic CLIP/MHCII complexes. Furthermore, our data demonstrate that peptide treatment of chemically-activated cells followed by treatment with anti-MHCII antibody resulted in increased MHC class II-mediated cell death.
These novel findings suggest increased CLIP expression on pro-inflammatory immune cells may contribute to DSS/TNBS-mediated colitis and predict an innovative therapeutic approach whereby peptide depletion of CLIP may reverse inflammation by selective cell death of pro-inflammatory MHCII cells.

P2.10.09
Low-density lipoprotein receptor-related protein-1 (LRP-1) mediates autophagy and apoptosis caused by Helicobacter pylori VacA

T. Hirayama[1], *K. Yahiro*[2], *M. Nakano*[1], *M. Noda*[2], *J. Moss*[3];
[1]*Nagasaki University, Nagasaki, Japan,* [2]*Chiba University, Chiba, Japan,* [3]*NHLBI, National Institutes of Health, Nagasaki, MD, United States.*

In *Helicobacter pylori* infection, vacuolating cytotoxin (VacA) induces mitochondrial damage leading to eventually apoptotic cell death. It has also been proposed that VacA-induced autophagy serves as a host mechanism to limit toxin-induced cellular damage. Apoptosis and autophagy are two dynamic and opposing processes that must be balanced to regulate cell death and survival. The VacA receptor(s) responsible for apoptotic cell death and autophagy has not been identified during intoxication.
Here we identify the low-density lipoprotein receptor-related protein-1 (LRP-1) as the VacA receptor for toxin-induced autophagy in the human gastric epithelial cell line AZ-521, and show that VacA internalization through binding to LRP1 specifically regulates the autophagic process including generation of LC3-II from LC3-I, which is involved in formation of autophagosomes and autolysosomes. Knockdown of LRP1 and Agt5 inhibited generation of LC3-II as well as cleavage of PARP, a marker of apoptosis, in response to VacA, whereas caspase inhibitor, Z-VAD-FMK, and necroptosis inhibitor, Necrostatin-1, did not inhibit VacA-induced autophagy, suggesting that VacA-induced autophagy via LRP1 binding precedes apoptosis. In addition, Both NPPB and DIDS inhibited VacA-induced LC3-II generation in AZ-521 cells suggesting that channel activity may be required for LRP1-dependent autophagy. Other VacA receptors such as RPTP[[Unsupported Character - Symbol Font ]], RPTP[[Unsupported Character - Symbol Font ]], and fibronectin did not affect VacA-induced autophagy or apoptosis. Therefore, we propose that a single cell surface receptor, LRP1, mediates VacA-induced autophagy as well as apoptosis in gastric epithelial cell line AZ-521 cells.

P2.10.10
Suppression of *Mcl-1* via RNA interference sensitizes human U937cells towards apoptosis induction

M. Jafarlou[1], *B. Baradaran*[2], *D. Shanehbandi*[3], *F. Othman*[1];
[1]*UPM, Serdang, Malaysia,* [2]*Immunology research center,, Tabriz, Iran,* [3]*Immunology research center, Tabriz, Iran.*

Human leukemia is one of the common hematological malignant diseases and a major leading cause of human death. The current primary treatment for leukemia is anticancer drug-based chemotherapy that uses one or more drugs to destroy cancer cells, often accompanied by the development of drug resistance and severe side effects. Therefore, it is imperative to develop other potential therapeutic agents for the treatment of this disease. Defects in apoptosis signaling contribute to this resistance. Myeloid cell leukemia-1 (Mcl-1) is an anti-apoptotic member of the Bcl-2 protein family which interferes with mitochondrial activation. Previous studies have shown that Mcl-1 is highly expressed in Human leukemia. In this study, we manipulated expression of the Mcl-1 protein in U937cells by RNA interference and analyzed its impact on apoptosis sensitivity of U937 cells *in vitro*.
RNA interference was performed by transfecting siRNA to specifically knock down Mcl-1 expression in U937 cells. Mcl-1 expression was measured by quantitative real-time PCR and Western blot. Induction of apoptosis after treatment with Mcl-1 siRNA was measured by MTT assay.
RNA interference efficiently downregulated Mcl-1 expression in U937 cells. Mcl-1 downregulation sensitized U937 cells to apoptosis. Sensitization was accompanied by profound activation of caspase-3. Mcl-1 knockdown significantly augmented apoptosis sensitivity of U937 cells.
Our data suggest that specific downregulation of Mcl-1 by RNA interference is a promising approach to sensitize U937 cells towards molecularly targeted therapies.

P2.10.11
Bcl-2 antagonist as an immunomodulatory drug for transplantation

A. M. Lew, *E. M. Carrington, I. B. Vikstrom, D. M. Tarlinton; Walter & Eliza Hall Institute, Parkville, Australia.*

The role of the Bcl-2 family members in cell death and survival appear to be ubiquitous, so that their iatrogenic perturbation might at first glance be expected to be non-specific. Nevertheless, the expression levels of pro- and anti-apoptotic molecules differ among tissues and indeed, as we have found among immune cells. We examined the effects of the drug ABT-737, a mimetic of the killer BH3 domain of the Bcl-2 family of proteins that induces apoptosis by antagonizing Bcl-2, Bcl-XL and Bcl-W (without any effect on A1 and Mcl-1) on the mouse immune system. Treatment with ABT-737 reduced the numbers of selected immunocyte sub-populations, most markedly in lymph nodes. It inhibited de novo immune responses but had little effect on pre-existing ones. ABT-737 was sufficiently immuno-modulatory to allow long-term survival of pancreatic allografts, reversing established diabetes in this model. Our findings provide an insight into the selective mechanisms of immune cell survival and how this selectivity enables a novel strategy for immune modulation.

P2.10.12
CD95 (Fas) and CD178 (Fasl) induce apoptosis in CD4+ and CD8+ cells from peripheral blood and spleen in dogs naturally infected by Leishmania spp

V. M. Lima, *B. B. Oliveira, L. M. Melo, J. Perosso, K. L. O. Silva; UNESP, Araçatuba, Brazil.*

Infected dogs are urban reservoirs of Leishmania chagasi, causative agent of visceral leishmaniasis, a public health problem in many countries including Brazil. The dogs have immune suppression and apoptosis of lymphocytes is involved in this process. To investigate apoptosis in CD4 + and CD8 + lymphocytes and the expression and function of major receptors involved in apoptosis, FAS (CD95) / FASL (CD178) and TRAIL (CD253) were evaluated by flow cytometry on

peripheral blood cells and spleen of 38 symptomatic dogs with moderate visceral leishmaniasis and 25 healthy dogs. Apoptosis of CD4 + cell and CD8 + cell from spleen and blood was greater in infected dogs than in healthy. In the CD4+ cell from blood and spleen of infected dogs was lower than observed in healthy dogs. In the CD8+ cell from infected dogs the expression of FAS increase whereas FASL decrease compared to healthy dogs. The apoptosis observed in CD4 + cells from blood and spleen decreased in the presence of blocking antibodies to FAS and FASL, the reduction of apoptosis in CD8 + cells by the presence of blocking antibodies was only observed in the spleen. Our data together show that apoptosis of CD4 + and CD8 + is a mechanism that is involved in the infectious process dogs Leishmania spp. with the participation of molecules FAS and FASL. Our results could help to improve the current understanding of the immune response in dogs infected with L. chagasi allowing future therapeutic interventions to reduce the depletion of lymphocytes.

P2.10.13
FASL −844 T/C polymorphism: A biomarker of good prognosis of breast cancer

W. Mahfoudh[1]*, N. Bouaouina*[2]*, L. Chouchane*[3]*;*
[1]Faculty of Medicine, Monastir, Tunisia, [2]Départment de Cancérologie Radiothérapie, CHU Farhat Hached, Sousse, Tunisia, [3]Department of Genetic Medicine, Weill Cornell Medical College, Doha, Qatar.

FAS/FASL system plays a crucial role in modulating apoptosis. The single nucleotide polymorphism of the FASL gene (FASL −844 T/C), is located within a putative binding motif of CAAT/enhancer-binding protein ß transcription factor. Higher basal expression of FASL is significantly associated with the FASL−844C allele. Transformed cells carrying the FASL-844CC genotype may create an immunoprivileged site by killing cytotoxic immune cells and thus escaping host immune-surveillance.
FASL −844 T/C polymorphism was examined in 438 patients with breast cancer using the polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) analysis.
FASL −844CC genotype was significantly associated with SBR 1-2 tumour grade (P = 0.007). In patients with diagnosis age ≤ 50 years, FASL −844CC genotype showed significant associations with T1-T2 clinical tumour size (P = 0.01) and SBR grade 1-2 (P = 0.02). A marginally significant association was also found with negative nodal status (P = 0.06).
Thus, it is possible that at younger ages, high expression of FASL in T lymphocytes carrying CC genotype may increase their ability to eliminate FAS-sensitive tumor cells. This aspect can probably contribute to the efficiency of the anti-tumor response of young patients and likely confers an advantage of a good prognosis.

P2.10.14
The effect of Z36 on Human T-cell Leukemia

T. Nakanishi*, Y. Song, J. Tsukada, T. Kanazawa, Y. Yoshida;*
University of Occupational and Enviromental Health, Japan, Kitakyushu, Japan.

Human T-cell Leukemia is aggressive and malignant blood disease. Above all, Adult T-cell Leukemia (ATL) has a very poor prognosis even with intensive chemotherapy, indicating the need for development for new drugs to treat the disease. Z36 which is BCL-XL inhibitor have been known induces autophagy. But the effect in Human T-cell Leukemia of Z36 is not reported.In this study, we demonstrate that the effect of Z36 on cell viability of Human T-cell Leukemia cell lines such as Hut 78, Hut 102, jurkat, MT-1, MT-2 and MT-4 in vitro. Z36 inhibited proliferation of all Human T-cell Leukemia cell lines with different sensitivity at 24 hr after the treatment. The effect of Z36 on Human T-cell Leukemia was restored by bafilomycin-A but not by 3-MA and choloroqine, which are known to be autophagy inhibitors. Western blot showed that Z36 induced LC3-II, which is known as a marker for autophagy. Proliferation of SiATG5-treated cells did not inhibit by Z36. These results suggest that Z36 induced autophagic cell death through ATG5 in human T-cell leukemia.

P2.10.15
An innovative method for assessing autophagy using the FlowSight imaging flow cytometer

H. R. Pugsley*, R. Kong, S. L. Friend, B. E. Hall, D. A. Basiji, P. Morrissey;*
Amnis part of EMD Millipore, Seattle, WA, United States.

Autophagy is a process in which normal cellular components that accumulate during growth and differentiation are degraded via the lysosome; it is a survival mechanism that reallocates nutrients from unnecessary processes to more vital processes in the cell. Basal levels of autophagy are usually low but can be up-regulated by numerous stimuli including starvation, physiological stress, pharmacological agents and infections. In addition, suppression of autophagy has been associated with cancer, neurodegenerative disorders, infectious diseases and inflammation. During autophagy, cytoplasmic LC3 is processed and recruited to the autophagosomal membranes; therefore, cells undergoing autophagy can be identified by visualizing LC3 puncta using immunofluorescence microscopy. While manual microscopy allows visual identification of autophagy on a per-cell basis, an objective and statistically rigorous assessment is difficult to obtain. To overcome these problems, we used the FlowSight imaging cytometry platform to collect imagery of large numbers of cells and assess autophagy in an objective, quantitative, and statistically robust manner. In this study, we demonstrate a method for determining image-based parameters for assessing the LC3 puncta in starved and non-starved U2OS RFP-LC3 human osteosarcoma reporter cells.

P2.10.16
Accumulation of autophagic adaptor protein, p62/sequestosome 1, in the brains of Alzheimer's disease

K. Tanji[1]*, T. Matsumiya*[1]*, A. Maruyama*[1]*, S. Odagiri*[1]*, F. Mori*[1]*, K. Itoh*[1]*, A. Kakita*[2]*, H. Takahashi*[2]*, K. Wakabayashi*[1]*;*
[1]Depts. of Neuropathol, Vascular Biology, Stress Response Science, Neuroanatomy, Hirosaki University Graduate School of Medicine, Hirosaki, Japan, [2]Dept. of Pathology, University of Niigata, Niigata, Japan.

p62/sequestosome 1 interacts with autophagy-related gene 8 family, which plays a critical role in the initial step of macroautophagy. p62 structurally contains an ubiquitin-associated domain at the carboxyl terminus, thereby binds with ubiquitinated and misfolded proteins. Based on these properties, p62 can selectively sequestrate substrates, and serve to degrade them. Also the increased level of p62 implies that autophagic flux is disrupted, because p62 is one of autophagic substrates. We investigated whether p62 expression level is altered in the brains with Alzheimer's disease (AD). Immunoblot analyses showed that p62 level is significantly increased in the brains with AD relative to controls. Further analyses showed that several stress-responsive genes are induced in AD brains. To explore the relationship between p62 and stress-responsive genes, we focused on the Keap1/Nrf2 system, which highly contributes to stress response. Immunoblotting revealed that total and p62-immunoprecipitated Keap1 levels are not altered between AD and controls. Interestingly, however, it was evident that the level of phosphorylated p62 at the serine residue 349 is significantly increased in AD brains. Considering this phosphorylated serine corresponds to the Keap1-binding region of p62, these findings suggest that the phosphorylation affects Keap1/Nrf2 system, leading to expression of stress responsive genes.

Interference of modified vaccinia virus Ankara with autophagy: implications for innate and adaptive immunity

K. A. Tappe[1]*, M. V. Stankov*[1]*, T. Frenz*[2]*, U. Kalinke*[2]*, G. M. N. Behrens*[1]*;*
[1]*Hannover Medical School, Hannover, Germany,* [2]*Institute for Experimental Infection Research, TWINCORE, Centre for Experimental and Clinical Infection Research, a joint venture between the Helmholtz-Centre for Infection Research (HZI), Braunschweig, and the Hannover Medical School, Hannover, Germany.*

Introduction: Modified vaccinia virus Ankara (MVA) represents a highly attenuated
strain of vaccinia virus that has been used as a vaccine delivery vector and recently suggested to be also effective as an adjuvant. MVA's high immunogenicity has been explained by its ability to target dendritic cells and its viral cytotoxicity leading to cross-presentation by bystander cells. Recently, immunogenicity of dying cells has been linked to the level of cellular autophagic activity. Therefore, we hypothesised that MVA infection interferes with target cell autophagic homeostasis leading to immunogenic cell death.
Methods: We analysed MVA effects on eukaryotic cell autophagy using HUH7 cells stably expressing LC3-GFP protein, fluorescence microscopy and flow cytometry. MVA effect on murine bone marrow-derived dendritic cells (BMDCs) was analysed using Cyto-ID® Autophagy Detection Kit and flow cytometry. Effects of MVA on cell viability and autophagy were correlated to viral effects on BMDCs capacity to induce T cell proliferation.
Results: MVA infection resulted in an enhanced autophagic flux in both HUH7 cells and BMDCs. Viral infection was accompanied by increased apoptosis. This combination of dying with autophagy appeared highly immunogenic and resulted in a substantial increase in CD8+ T cell proliferation. Importantly, raised CD8+ T cell proliferation was abgrogated upon autophagy inhibition.
Conclusion: Our data suggest that MVA's ability to induce cell death with autophagy in BMDCs contributes to a higher immunogenicity and provides a potential mechanism to explain MVA's potential effects as an adjuvant.

P2.10.18
Mechanisms of cytotoxic effects of different monoclonal antibody to tumor-associated ganglioside GD2

P. Vishnyakova*, I. Kholodenko, I. Molotkovskaya, R. Kholodenko; Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry of the Russian Academy of Sciences, Moscow, Russian Federation.*

Targets for cancer immunotherapy can be not just proteins, but also glycosphingolipids, e.g. gangliosides. GD2 is the most interesting tumor-associated ganglioside. GD2 expression on normal cells is restricted, but it abundantly expressed on the surface of neuroblastoma, glioma and several lymphomas. Recently was shown that GD2-mAb has direct cytotoxic effect on tumor cells. The role of GD2 in the mechanisms of the cytotoxic effects is unclear.
We have shown that GD2 on the surface of tumor cells can be not just target but also effector molecule. We found predominant role of GD2 in the reception and transduction of cytotoxic signal. To prove that GD2 is the single molecule for accepting of cell death signals the following experiments was made:
- investigation of cross-reactivity of different GD2-mAb to proteins and other gangliosides;
- analysis of ganglioside composition of GD2-positive tumor cells;
- comparison between cytotoxic effects and GD2 expression level on the surface of tumor cells. We used inhibitor of ganglioside biosynthesis PDMP and siRNA GM2/GD2 GM2/GD2 synthase to decrease GD2 expression level.
To determine whether GD2-mAb-induced cytotoxicity is apoptosis or necrosis we used different methodological approaches. In our work was investigated participations of lipid rafts, changes of cell volume, involvements of caspases, ATP, ROS, also was made analysis of mitochondria depolarization. The signal transduction of GD2-mAb-induced cytotoxity in tumor cell has both apoptosis and necrosis features. The results of our work open a new point of view to tumor-associated ganglioside GD2 as new receptor of cell death of tumor cells.

P2.10.19
Transcriptional control of FAS-ligand regulates the differential activation induced cell death of human Thelper cells

E. Volpe*, G. Ruocco, S. Santini, M. Cencioni, G. Borsellino, M. De Bardi, D. Barilà, L. Battistini;*
Fondazione Santa Lucia, Rome, Italy.

T cell immune response results from activation of naive CD4 T cells in functionally distinct Thelper (Th) subsets. The control of the homeostasis of the inflammatory Th cells, and in particular of the Th17 cells, is crucial to avoid autoimmune inflammation.
Limited information is available on the homeostatic signals that regulate survival and cell death of human Th cell subsets to control their expansion.
We analysed apoptosis induced by T cell receptor (TCR) stimulation of different Th subsets. We found that human Th17 clones are the most resistant to apoptosis compared to other Th subsets. Th1 clones are particularly sensitive to apoptosis and they express high levels of cleaved Caspase-8 and Caspase-3, which correlates with the cleavage of its substrate, poly(ADP-ribose) polymerase-1. We found that FAS receptor is expressed by all Th profiles. Interestingly, Th1 cells upon TCR stimulation specifically express FAS-ligand, whereas in Th17 cells this expression is impaired. Thus, we analysed the mechanisms involved in the differential expression of FAS-ligand in human Th1 and Th17 cells.
In summary, our results indicate that FAS-FAS-ligand interaction leads to Caspases' cleavage and cell death. In contrast, the lack of FAS-ligand induction in resistant Th17 cells impairs the Caspase 8 activation and the resulting cell death. We defined the mechanisms regulating FAS-ligand expression and their modulation may provide new targets to prevent persistent Th17-mediated inflammation in autoimmune disease.

P2.10.20
BCL3, induced by Tax and HTLV-1, inhibits NF-κB activation and promotes autophagy

H. Wang*, J. Wang, Z. Niu, C. Gao, J. Han, X. Zhu, X. Song;*
Research Center for Immunology,Xinxiang Medical University, Xinxiang, China.

The human T cell leukemia virus type 1 (HTLV-1) is a complex human retrovirus that causes an aggressive leukemia known as adult T cell leukemia (ATL).The HTLV-1-encoded oncoprotein Tax induces persistent activation of the nuclear factor-κB (NF-κB) pathway, which is perceived as the primary cause of ATL. BCL3, a member of the NF-κB inhibitor (IκB) family, is highly expressed in many HTLV-1-infected T cell lines and ATL cells. However, the role of BCL3 in Tax-induced NF-κB activation has not been fully elucidated. Here, we show that Tax induces BCL3 expression, which in turn negatively regulates the Tax-induced NF-κB activation. Interestingly, both BCL3 up-regulation and NF-κB inhibition promote the autophagy process in HTLV-1-infected cells. Consistent with this, over-expression of BCL3 also results in enhancement of rapamycin-, pifithrin-α- or starvation-induced autophagy in control cells. Together, these data demonstrate that BCL3 acts as a negative regulator of NF-κB activation and promotes autophagy in HTLV-1-infected cells

P2.10.21
A protective role of autophagy as an anti-oxidant system in human primary T cells: a potential therapeutic strategy for autoimmune diseases

R. Watanabe*, H. Fujii, T. Shirai, S. Saito, T. Ishii, H. Harigae;*
Tohoku University Graduate School of Medicine, Sendai, Miyagi, Japan.

Background: Autophagy is an intracellular degradation system that plays an important role in T cell survival. However, the precise mechanistic link between autophagy and cell death in human primary T cells is unclear because monitoring autophagy in small numbers of human primary cells remains controversial.
Methods: Human naïve and effector memory (EM) $CD4^+$ T cells were isolated from the peripheral blood samples of healthy donors and stimulated with anti-CD3/CD28-coated beads. Two days after

stimulation, GFP-LC3 fusion protein which can function as an autophagy sensor was overexpressed in human activated T cells using a retroviral vector system.
Results: We showed that autophagy was induced after T cell receptor stimulation. We also found that autophagy-defective naïve $CD4^+$ T cells were susceptible to apoptosis via the intrinsic apoptotic pathway, which resulted from the accumulation of reactive oxygen species (ROS) due to defective mitophagy. EMT cells had lower autophagic activity than naïve T cells, which contributed to their enhanced apoptotic cell death due to increased ROS. Moreover, a combination of an autophagy blocker and an inhibitor of the mitochondrial electron transport chain (mETC) synergistically increased intracellular ROS levels and enhanced apoptotic death of activated T cells.
Conclusions: These results suggest a protective role of autophagy as an anti-oxidant system in human activated T cells. A combination of an autophagy blocker and an inhibitor of the mETC could be a novel therapeutic strategy for autoimmune diseases.

P2.10.22
Restoration of ASC expression sensitizes colorectal cancer cells to genotoxic stress-induced caspase-independent cell death

S. Hong, I. Hwang, S. Park, ***J. Yu****;*
Department of Microbiology, Yonsei University College of Medicine, Seoul, Republic of Korea.

Apoptosis-associated speck-like protein containing a caspase recruitment domain (ASC), an essential component of the inflammasome complex, is frequently silenced by abberant methylation of its CpG islands in many tumor cells. However, the molecular function of ASC in cancer cells is not well characterized. Here, we investigated the effect of ASC expression in human colorectal cancer cell DLD-1, in which the *ASC* gene is epigenetically silenced by methylation. Restoration of ASC expression in DLD-1 cells by demethylating agent or by stable transfection potentiated cell death mediated by DNA damaging agent. Contrarily, ASC knockdown in HT-29 cells rendered cells less susceptible to etoposide toxicity. The increased susceptibility of ASC-expressing DLD-1 cells to genotoxic stress was independent of inflammasome or caspase activation, but partially dependent on mitochondrial ROS production and JNK activation. Taken together, our data suggest that ASC expression in cancer cells is an important factor in determining their susceptibility to chemotherapy.

P2.10.23
Lactobacillus rhamnosus GG modulates autophagy function in T cells and myeloid cells as mechanism for adjuvant effect in rotavirus vaccine induced effector T cell responses

L. Yuan*[1], K. Wen[2], E. Giri-Rachman[2], G. Li[2], J. Kocher[2], X. Yang[2], H. Wang[2], T. Bui[2], M. Weiss[2];*
[1]Virginia Tech, Virginia Tech, Blacksburg, VA, VA, United States,
[2]Virginia Polytechnic Institute and State University, Blacksburg, VA, United States.

Autophagy has direct effects in the regulation of adaptive immunity through limiting the duration of synapse formation between T cell and antigen presenting cell (APC) and magnitude of the ensuring T-cell activation. *Lactobacillus rhamnosus* GG (LGG) suppressed rotavirus-induced autophagy in ileal epithelium and significantly enhanced intestinal virus-specific effector T-cell response to a human rotavirus (HRV) vaccine in gnotobiotic (Gn) pigs, which led to our postulation that LGG promotes effector T-cell responses by down-regulating autophagy in T cells and APCs to stabilize immunologic synapse. To test this hypothesis, we studied the autophagy function in sort-purified ileal CD3+ T cells and SWC3+ myeloid cells (as APCs) from Gn pigs primed by rotavirus infection. Cells were stimulated *in vitro* with live LGG and/or purified HRV antigen with or without lysosomal inhibitor, bafilomycin A_1. In CD3+ T cells, LGG and HRV alone significantly reduced the expression of VPS34, Becline 1 and LC3-II, as well as LC3 turnover, and increased p62 accumulation compared to mock control. LGG+HRV significantly enhanced VPS34, Beclin 1, and Atg12 expression, whereas down-regulated LC3-II expression and LC3 turnover, and significantly increased p62 accumulation. In SWC3+ APCs, LGG+HRV significantly increased VPS34, Beclin 1 and Atg12 expression, whereas significantly reduced LC3-II expression and reduced LC3 turnover. In conclusion, LGG and HRV both down-regulate autophagy activity in T cells and APCs. LGG+HRV synergistically further reduced autophagy function. Reducing autophagy in T cells and APCs is potentially a novel mechanism for the adjuvant effect of LGG in enhancing effector T-cell responses to rotavirus vaccines.

P2.10.24
Rapid Dynamic Exchange of LC3 in Intracellular Protein Aggregates but not in Autophagosomes

L. Wang, ***Z. Zhang****;*
Britton Chance Center for Biomedical Photonics, Wuhan National Laboratory for Optoelectronics,Huazho, Wuhan, China.

The microtubule-associated protein light chain 3 (LC3) is a marker protein that is involved in the formation of autophagosomes and autolysosomes, which are usually characterized and monitored by fluorescence microscopy using fluorescent protein-tagged LC3 probes (FP-LC3). FP-LC3 and endogenous LC3 can also be incorporated into intracellular protein aggregates in an autophagy-independent manner. However, the dynamic process of LC3 associated with autophagosomes/autolysosomes or protein aggregates in living cells remains unclear. Here, the dynamic properties of the two types of FP-LC3-containing puncta were explored. The data reveal that the fluorescent signals of the FP-LC3 attached to phagophores or in mature autolysosomes do not recover after photobleaching, indicating that the dissociation of LC3 from the autophagosome membranes may be very slow or not constitutive. In contrast, the FP-LC3 in the protein aggregates exhibits fast kinetics of association and dissociation with the fluorescent puncta, indicating that a rapid exchange occurs between the aggregates and cytoplasmic pool. The later is mainly due to the transient interaction of LC3 and the ubiquitin-associated protein p62. Thus, we find the different dynamic properties of LC3 in two types of punctate structures using the quantitative imaging and analyzing approaches. Because of this finding, we provide a convenient and useful approach to distinguish autophagosomes from LC3-involed protein aggregates in living cells. Using this approach, we also find that the FP-LC3 puncta that localized adjacent to the phagophore marker Atg16L1 were protein aggregates, that exhibited different kinetics compared to the phagophores alone.

P2.12.01
Symmetry breaking in reconstituted actin cortices

E. Abu Shah*, K. Keren;*
Technion, Haifa, Israel.

The actin cytoskeleton plays a central role in many cellular processes. In particular, the dynamic actin cortex plays a pivotal role in cell division, in polarity, in motility and in the immune response. In all these contexts, the cortical actin network has to break symmetry to generate polar cytoskeletal dynamics. Despite extensive research, the mechanisms responsible for regulating cortical dynamics in vivo and inducing symmetry breaking are still unclear. We developed a reconstituted model system that self-organizes into dynamic actin cortices at the inner interface of water-in-oil emulsions. This artificial system undergoes spontaneous symmetry breaking, driven by myosin-induced cortical actin flows, which appear remarkably similar to the cortical flows involved in T-cell receptor organization in the immunological synapse. The contractile behaviour of the reconstituted cortices exhibits a sharp temperature-dependent transition, facilitating the use of temperature as an external parameter to control the onset of symmetry breaking. The reconstituted cortices further display occasional local detachment of the contractile actin network from the interface as seen in cellular blebs, and polar force generation, which can lead to deformation of the interface. Our in vitro model system recapitulates the rich dynamics seen in actin cortices in vivo, allowing us to reveal the basic requirements for actin cortex formation and symmetry breaking. Moreover, this synthetic system paves the way for further exploration of artificial cells towards the

realization of a minimal model system of the immunological synapse that can shed light on the mechanisms underlying the diverse cellular responses following T-cell activation.

P2.12.02
The study of nicotinic acetylcholine receptor α7 subunit expression in human lymphocytes using toxins and antibodies

***T. Dimitrieva**, E. Kryukova, D. Ryazantsev, E. Svirshchevskaya; Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry RAS, Moscow, Russian Federation, Moscow, Russian Federation.*

Nicotinic acetylcholine receptors (nAChRs) are transmembrane proteins assembled from α subunits (α1-α10) either alone or together with non-α subunits. Alpha 7 nAChR is neuronal subtype naturally expressed by hippocampus and DRG neurons however its expression is also shown for lymphoid cells. Non neuronal nAChR expression often is identified by anti-nAChRs antibodies which in some cases generate false positive results. For α7, antibody staining was found similar in wild-type and subunit specific knockout mice. The aim of the present study was to analyze α7 expression by human lymphocytes and various cell lines using antibody against α7 and a highly specific to α7 α-bungarotoxin (α-Bng). To control the specificity of α-Bng we generated HEK293 cells transiently expressing recombinant α7 in chimeric glycine receptor. Specificity of α-Bng binding to transfected cells was confirmed by cobratoxin competition at 100x excess. We demonstrated that anti-α7 antibodies bound both blood lymphocytes and various lymphoid and epithelial cell lines as was shown by flow cytometry and confocal microscopy. On the contrary α-Bng bound only transfected HEK293 cells and neurons from mouse ganglia but neither blood lymphocytes nor cell lines. These results do not correspond to earlier published data.

P2.12.03
Identification of signalling cascades during the inflammatory activation of phagocytes induced by S100A8 and S100A9

***S. Fassl**[1], J. Austermann[1], M. Riemenschneider[2], A. Witten[2], M. Stoll[2], J. Roth[1], T. Vogl[1];*
[1]Institue for Immunology, University Hospital Muenster, Muenster, Germany, [2]Leibniz-Institute for Arteriosclerosis Research, University of Muenster, Muenster, Germany.

This project focuses on the biological relevance of potential receptors for the inflammatory response in monocytes induced by the Damage Associated Molecular Pattern (DAMP) proteins S100A8 and S100A9. These phagocyte-derived molecules activate innate immune cells via toll-like-receptor 4 (TLR4). The receptor for advanced glycation end products (RAGE) has been suggested as alternative receptor.
Human monocytes were stimulated with S100A8 and S100A9 or LPS for 4 h. RNA was isolated and used for genome-wide gene expression arrays. Activated pathways were analyzed by using DAVID bioinformatics resources.
The gene expression arrays show differences in expression pattern of about 1000 genes for monocytes which are stimulated with LPS, S100A8 or S100A9 in comparison to non-stimulated cells. We found no prominent differences in up or down regulated genes between LPS and S100A8 or S100A9 stimulated cells. The majority of regulated genes are involved in TLR4 signalling and many are known targets of TLR4-dependent NF-kB-induced transactivation. This leads to the assumption that TLR4 is the main receptor involved in the activation of monocytes by S100A8 and S100A9, whereas RAGE seems to be not involved. However, a substantial number of genes induced by S100A8, S100A9 or LPS have not been described in the context of TLR4-signalling so far. Interestingly, stimulation of monocytes with S100A8 or S100A9 results in up-regulation of anti-apoptotic proteins on both mRNA and protein level. These findings were confirmed using functional apoptosis assays. Beside direct stimulatory effects S100A8 and S100A9 promote survival of a pro-inflammatory phenotype of monocytes.

P2.12.04
Type-1 serine/threonine phosphatases and PI3K signaling contribute for the TLR antagonist effect of Natterins

***M. Ferreira**, C. Lima, M. Lopes-Ferreira; Butantan Institute, São Paulo, Brazil.*

Studies carried out previously by our group have shown that the venom of *Thalassophryne nattereri* develops an inappropriate cellular inflammatory response characterized by a reduced number of leukocytes in the tissue injured. We identified in the venom a new proteases family named Natterins responsible to the inhibition of the leukocyte rolling in cremaster endothelial cells in a TLR2- or TLR4-MyD88-mediated signals dependent mechanism. Here, we investigated the involvement of phosphoinositide 3-kinase (PI3K) and type-1 protein serine/threonine phosphatase (PP1) in the Natterins antagonist effect. Using intravital microscopy we pretreated (i.p) Swiss mice for 30 minutes with MG132 (26S proteassome inhibitor at 10 μM); PP1 inhibitor (IPP-1 10 μM) or wortmannin (0.005 μM) a specific phosphatidylinositol 3-kinase inhibitor. Then, we investigated the number of leukocytes rolling in cremaster venules after topical application of 20 μL of LPS (0.02 μg/mL) in mice previously pretreated (6 h) with intraescrotal injection of Natterins (0.02 μg/mL). Control experiments were performed in saline- or Natterins-treated mice applied with 20 μL of saline or LPS. The number of rolling leukocyte in LPS-mice was higher compared with control-mice, but Natterins virtually abrogated the rolling of leukocytes in venules after topical application of LPS. Also, the early treatment with both IPP-1 or PI3K inhibitors blocked the inhibitory effect of Natterins in the rolling leukocytes induced by LPS, in contrast with MG132. These data provide a molecular level explanation for the antagonist function of Natterins that is dependent on serine/threonine phosphatase and PI3K signaling. S**upported by:** FAPESP and CNPq.

P2.12.05
T cell proliferation defect of DiGeorge syndrome patients is associated with impaired CrKL signaling

***M. Giacomelli**[1,2], R. Kumar[1,2], A. Prandini[1,2], A. Soresina[1], D. Moratto[1], S. Negri[1], O. Scomodon[1,2], A. Plebani[1], R. Badolato[1];*
[1]Institute of Molecular Medicine "Angelo Nocivelli", Pediatric Department, Brescia, Italy, [2]Scuola di Dottorato in Scienze della Riproduzione e dello Sviluppo, University of Trieste., Trieste, Italy.

DiGeorge Syndrome is a primary immunodeficiency that is caused by the heterozygous deletion of 22q11.2, characterized by conotruncal abnormalities, thymic hypoplasia, and bacterial or viral recurrent infections. The features of DiGeorge vary widely, even among patients of the same family, but the most common chromosomal deletion observed in DiGeorge patients comprises the *CRKL* gene which encodes for an adaptor protein involved in intracellular signaling.
We investigated T-cell functions in 4 patients with DiGeorge Syndrome and 22q11.2 deletion. In particular, we studied proliferation, apoptosis and CD25, CD69 expression on CD4, stimulated with IL-2 plus anti-CD3 and anti-CD28. In addition, we evaluated the CrKL expression and phosphorylation in patients and controls. PHA-activated T cells under IL-2 stimulation, we evaluated ERK1/2, STAT3 and STAT5 phosphorylation. In DiGeorge syndrome patients we observed a marked reduction of T cell proliferation as compared to control subjects and low level expression of both CrKL protein and phospho-CrKL. While, in control subjects, CrKL was strongly phosphorylated after stimulation with IL-2.
We show that CrKL is involved in IL-2 signaling, the main T cell proliferation factor. CrKL protein levels and its phosphorylation are markedly reduced in DiGeorge patients, suggesting that CrKL might play a role in the functional defects of T cells.

P2.12.06
CD38/CD203a/CD73 runs in human T lymphocytes a novel adenosinergic loop independent from CD39

A. L. Horenstein[1,2]*, A. Chillemi*[1]*, G. Zaccarello*[1]*, V. Quarona*[1]*, A. Zito*[1]*, F. Malavasi*[1,2]*;*
[1]Immunogenetics-University of Turin, Turin, Italy, [2]Centro di Ricerca in Medicina Sperimentale, Turin, Italy.

Tumor microenvironment is marked by increased levels of extracellular NAD+ as well as by selective up-regulation of the ectoenzymes involved in its metabolism. The final consequence is an increase of local concentrations of the nucleoside adenosine (ADO), a powerful pleiotropic molecule involved in the modulation of immunity and inflammation.
CD203a (pyrophosphatase, PC-1) and CD38 (NADase) are two members of a larger family of nucleotide-metabolizing ectoenzymes. Substrates of CD203a are ATP as well as NAD+ and ADPR produced by CD38. The final product is AMP which can be further metabolized by CD73 (5'-nucleotidase) to ADO.
The aim of our work was to demonstrate the presence of an adenosinergic axis connecting CD38, CD203a and CD73 in lymphocytes and likely in other cells of different lineage. This axis may lead to the production of extracellular ADO in a CD39 (diphosphohydrolase, NTPDase)-independent way. The working hypothesis was confirmed in a human Jurkat T cell line. The components of the pathway were induced to be surface expressed upon activation and the products of their enzymatic activities analyzed by HPLC assays. The results indicate that PMA-activated Jurkat T cells, expressing CD38/CD203a at high levels, metabolize extracellular NAD+ originating AMP. In turn, this is converted to ADO by Jurkat cells transfected with the CD73 gene. Our data suggests that the CD38/CD203a/CD73 signalling pathway may constitute a new adenosinergic axis which bypasses CD39 in the formation of AMP. This pathway may play significant roles in physiology (activation, differentiation) and in the regulating of immune response against tumors.

P2.12.07
Genetically engineered chimeric molecules targeting Influenza A viral antigen

I. I. Ivanova[1]*, N. Mihaylova*[1]*, N. Kerekov*[1]*, A. Erdei*[2]*, J. Prechl*[2]*, A. Tchorbanov*[1]*;*
[1]Institute of Microbiology, Bulgarian Academy of Sciences, Sofia, Bulgaria, [2]Immunology Research Group, Hungarian Academy of Sciences, Budapest, Hungary.

Objectives: The use of live and attenuated strains of viruses for vaccination comprises the risk of evoking epitopes possessing undesirable characteristics. DNA vaccination using naked DNA encoding viral antigens has the potential to induce both humoral and cellular immune responses as live attenuated viral vaccines do. We hypothesized that sequences encoding an epitope of virus hemagglutinin (IP) attached to sequences encoding a scFv antibody fragment against co-stimulatory cell surface receptors (CR1/2 on mouse B cells or FcγRI on human monocytes) would result in the in vivo expression of a chimeric viral peptide with increased immunogenicity.
Methods: Gene and protein engineering; DNA immunization; ELISA; Cytotoxic assay;
Results: The DNA constructs were engineered by linking of sequences encoding the scFv antibody fragment against the appropriate receptor and IP peptide representing a conserved epitope of influenza A virus hemagglutinin. We have inserted the DNA constructs into protein expression vector system and used them as naked DNA vaccine. Serum antibodies against the viral peptide were measured with ELISA. The cell-mediated immune response induced in the animals was evaluated using a cytotoxic assay.
An immunization with a DNA plasmid containing the described construct induced a strong anti-influenza cytotoxic response lasting for more than 6 months. After prime-boosting with protein chimeric molecule we obtained anti-influenza cytotoxic and antibody response.
Conclusion: Immunization of mice with pure DNA, encoding the antigen of interest attached to a scFv antibody fragment to positive receptors, followed by prime-boosting has been successfully used to induce protective immunity against a model pathogen.

Experimental and computational study of ROS and RNS in endothelial and leukocyte interactions

M. Kavdia*, J. Chen, S. Kar;*
Wayne State University, Detroit, MI, United States.

Endothelial oxidative stress increases leukocyte-endothelial cell interactions, which is accompanied by leukocyte activation and increased oxidative and nitrosative stress in the vasculature. Studies related to leukocyte-endothelial cell interactions have questioned whether leukocyte recruitment, adhesion and activation are sequential events. We developed parallel experimental and computational strategies to study the process of leukocyte-endothelial cell interactions in details. The experimental method involved determination of adhesion effect of THP-1 cells to HUVEC cells cultured under normal/high glucose conditions for 24 hours. The computational method involved a biotransport model for an isolated microvascular blood vessel segment to quantify the changes in the local NO, O2•- and peroxynitrite levels at different regions of the microvasculature during leukocyte-endothelial cell interactions. The key results include (i) A significant increase in adhesion of THP-1 cells to HUVEC cells was observed under high glucose conditions compared to normal glucose, (ii) High glucose treated HUVEC cells showed significant increase in reactive oxygen species (ROS) concentration and (iii) endothelial oxidative stress increased O2•- and peroxynitrite levels in the lumen by 4 fold. The results show that leukocyte adhesion and activation can be independent events. Supported by NIH R01 HL084337.

P2.12.09
Arhgap12 as a novel binding partner of GULP regulates Rac1 activity during Stablin-2-mediated cell corpse engulfment

S. Kim[1,2]*, D. Bae*[3]*, S. Kim*[3]*, H. Choi*[3]*, J. Pyo*[3]*, S. Park*[4]*, I. Kim*[3]*;*
[1]Department of Medicine, University of Ulsan, College of Medicine, Seoul, Republic of Korea, [2]Asan Institute for Life Sciences, Asan Medical Center, Seoul, Republic of Korea, [3]Department of Biochemistry and Cell Biology, Kyungpook National University, School of Medicine 101 Dongin-dong, Jung-gu, Daegu, Republic of Korea, [4]Department of Biochemistry, School of Medicine, Dongguk University, Kyungju, Republic of Korea.

Stabilin-2 is a phosphatidylserine receptor that mediates the clearance of apoptotic cells. An adaptor protein, GULP, directly interacts with stabilin-2 via its PTB domain and plays a key role in stabilin-2-mediated phagocytosis. However, mechanisms that control the stabilin-2-mediated cell corpse engulfment through actin rearrangement are largely unknown. Herein, we identified ArhGAP12 as a novel partner of GULP. ArhGAP12 interacted with the proline-rich motif of GULP via its Src homology 3 (SH3) domain and dissociated from GULP upon stimulation of stabilin-2. Knockdown of ArhGAP12 increased stabilin-2-mediated phagocytosis, while overexpressionof ArhGAP12 decreased phagocytosis. ArhGAP12 specifically controlled the activity of Rac1 but of not RhoA. Therefore, inhibition of Rac1 activity by ArhGAP12 led to the decrease of stabilin-2-mediated phagocytosis. Taken together, these results indicate that ArhGAP12 is a novel partner of GULP and plays an important role in stablin-2-mediated cell corpse engulfment by the regulation of rac1 activity.

P2.12.10
Acetylation modulates Interleukin-2 receptor signaling

T. Kuwabara*, M. Kondo;*
Toho University School of medicine, Ota-ku, Tokyo, Japan.

It is well known that interleukin-2 (IL-2) is a cytokine to modulate activation and proliferation of T cells. Furthermore, recent studies have revealed that an intact IL-2 receptor signaling pathway is crucial for regulatory T cell function and survival. IL-2 has an important role in immune responses. However, the precise molecular mechanisms underlying IL-2-mediated signaling in supportive or regulatory function of T cells has not been elucidated. Murine T cell line CTLL-2 was stimulated with IL-2, and examined the kinetics of intracellular signaling. As similar to the previous data, phosphorylation of janus

kinases 3 (jak3) and stat5 was detected. Furthermore, acetylated form of these molecules was also detected. To investigate IL-2-mediated acetylation of STAT5 in CTLL-2 cell, we examined the subcellular localization of lysine acetyltranferase (KAT) before and after IL-2 treatment. Activity of KAT was coprecipitated with IL-2 receptor beta chain and gamma chain. CBP was recovered from anti-IL-2R gamma chain immunoprecipitates in a ligand stimulation dependent manner. These findings prompted us to explore whether IL-2 could induce CBP nuclear export. In CTLL-2 cells, most of CBP was detected in nuclei. CBP started to increase its level in cytoplasm by receiving IL-2 treatment. These results suggest that acetylation plays a critical role from IL-2 receptor to its downstream Stat5 activation.

P2.12.11
Galphai2 and Galphai3 differentially regulate arrest and chemotaxis in neutrophils

Y. Kuwano[1,2]*, M. Adler*[3]*, H. Zhang*[2]*, A. Groisman*[3]*, K. Ley*[2]*;*
[1]*University of Tokyo, Tokyo, Japan,* [2]*La Jolla Institute for Allergy & Immunology, La Jolla, CA, United States,* [3]*University of California San Diego, La Jolla, CA, United States.*

Leukocyte recruitment to inflammation sites progresses in a multistep cascade. Chemokine stimulation is one of the most important stimuli and regulates multiple steps including arrest, transmigration and chemotaxis. The most important chemokine receptor in mouse neutrophils is CXCR2, which couples through Galphai2 and Galphai3 conforming heterotremeric G proteins. Neutrophils arrest in response to CXCR2 stimulation. This is defective in Galphai2 deficient neutrophils. Hear, we show that Galphai3 deficient neutrophils showed inhibited transmigration and normal arrest. We also tested Galphai2 or Galphai3 deficient neutrophils in a CXCL1 gradient generated by a microfluidic device. Galphai3, but not Galphai2, deficient neutrophils showed significantly reduced migration and directionality. This defect in Galphai3 deficient neutrophils were also confirmed in vivo. Galphai2, but not Galphai3, deficient neutrophils showed decreased Ca influx with CXCR2 stimulation. Conversely, Galphai3, but not Galphai2, deficient neutrophils exhibited reduced AKT phosphorylation with CXCR2 stimulation. We conclude that Galphai2 and Galphai3 differentially regulate signaling for arrest, transmigration and chemotaxis.

P2.12.12
RUNX transcription factors regulate the transcriptional activity of CD69

T. Laguna*, L. Notario, P. Lauzurica;*
Instituto de Salud Carlos III, Majadahonda, Spain.

CD69 receptor is considered a universally marker of leukocyte activation, however it is immediately expressed after lymphocyte activation and appears on other leukocyte surfaces at later times. It has been also related with the expression of the migration controller molecule S1P1, revealing also an expression dependent on the localization of the cells involved. This extremely fine-tune regulation requires several mechanisms to control CD69 expression. Through *in silico* studies, here we analyze the putative conserved transcription factor binding sites located within the previously described conserved non-coding sequences 1, 2, 3 & 4 (CNS1, CNS2, CNS3 & CNS4). These studies reveal the importance of CNS2 which binds the majority of transcription factors studied by prediction software and ChIP-seq data from ENCODE consortium. They also reflect the specificity of CNS2, CNS1 and promoter regulatory features for hematopoietic lineages. Also we show new evidences on the transcriptional regulation of CD69, defining a minimal core sequence of the *cis* acting element CNS2, responsible for the main enhancer activity of this region. This core region is controlled by different transcription factors, and among them RUNX binding site shows the most important contribution to transcriptional enhancement activity. In addition, silencing of RUNX1 in Jurkat cell line in basal state and under PKC stimulation showed a reduction in CD69 expression. This new data suggest a main role of RUNX1 in the transcriptional regulation of CD69, according to the previous studies that showed the reduction of CD69 expression in the thymocytes of CD4+ T cell-conditional KO mice.

P2.12.13
Identification of a novel immunoregulatory signaling pathway exploited by M. tuberculosis in dendritic cells

J. Laursen[1]*, E. Schoof*[2]*, J. N. Søndergaard*[1,3]*, R. Linding*[2]*, S. Brix*[1]*;*
[1]*Systems Biology of Immune Regulation, Center for Biological Sequence Analysis, DTU Systems Biology, Kgs. Lyngby, Denmark,* [2]*Cellular Signal Integration Group, Center for Biological Sequence Analysis, DTU Systems Biology, Kgs. Lyngby, Denmark,* [3]*Department of Tumor Immunology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.*

The causative agent of tuberculosis, M. tuberculosis, has infected over a third of the world's population and the persistence of latent infections poses a massive burden to health care systems and human well-being. The dendritic cell (DC) plays a crucial role in shaping the nature of the adaptive immune response after exposure to pathogens, and the interaction between M. tuberculosis and the dendritic cell is of profound importance for the course of infection. During their interaction, the DC is exposed to multiple M. tuberculosis-derived ligands recognized by a range of pattern recognition receptors, but the result is typically an immune response that is not very effective at clearing the bacteria from the host. The reason why the induced immune response is ineffective at clearing the bacteria is not fully understood, but clues may be given in the signaling pathways induced in DCs upon M. tuberculosis-exposure.
High resolution LC-MS/MS was used for a global analysis of the proteome and the phospho-proteome in human DCs upon stimulation with intact M. tuberculosis or purified lipopolysaccharide (LPS). Data were analyzed using MaxQuant and Python, and the algorithm NetworKIN was used for prediction of kinases responsible for the observed phosphorylation sites.
Multiple phosphorylation sites and protein kinases were identified that validate previously identified intracellular signaling structures induced in DCs by M. tuberculosis. Importantly, from the MS data analysis, FMS-related tyrosine kinase 3 (FLT3), that signals through JAK2 and STAT3, was identified as a novel protein kinase potentially activated in DCs by M. tuberculosis.

P2.12.14
The late endosomal transporter CD222 spatially regulates the distribution of proximal T cell signaling molecules

V. Leksa*, K. Pfisterer, F. Forster, W. Paster, V. Supper, P. Eckerstorfer, C. Donner, H. Stockinger;*
Molecular Immunology Unit, Institute for Hygiene and Applied Immunology, Center for Pathophysiology, Infectiology & Immunology, Medical University of Vienna, Vienna, Austria.

The complex regulation of T cell activation is not fully understood, but endosomal transport pathways are more and more recognized to play an important role in T cell signaling cascades. CD222, also known as the cation-independent mannose 6 phospate/insulin-like growth factor 2 receptor, is one of the central components of endosomal pathways - CD222 transports its cargo proteins both from the Golgi apparatus and from the cell surface to lysosomes. Further CD222 is thought to be involved in endosomal recycling pathways and protein transport from the Golgi to the plasma membrane. Upon T cell activation CD222 expression is subsequently upregulated on the cell surface, yet the biological relevance of this membrane accumulation remains elusive. Here, we aimed to investigate the impact of CD222 on T cell activation using lentiviral knock-down and zinc-finger nuclease knock-out approaches, mass spectrometry, co-immunoprecipitation and confocal laser scanning microscopy. We found that the silencing of CD222 in T cells resulted both in abrogated T cell effector functions, like cytokine secretion, and down-regulated calcium flux, whereas T cell proliferation remained unaffected. Via mass spectrometric analysis we identified several interaction partner candidates for CD222 known to be involved in T cell activation, which we confirmed by co-immunoprecipitation. Our data uncover a yet undescribed function of CD222 in T cell signaling and suggest a model for the mechanism of CD222-driven regulation of T cell activation.

This work is supported by the FWF - Austrian Science Fund (P22908).

P2.12.15

The activation and co-stimulatory functions of Fc receptor like 1 protein (FcRL1) in human B cells depend on phosphatidylinositol 3-kinase

C. Leu[1], *Y. Chen*[1], *T. Hsieh*[1], *G. R. A. A. Ehrhardt*[2], *M. D. Cooper*[3,4];
[1]*Institute of Microbiology & Immunology, National Yang-Ming University, Taipei City, Taiwan,* [2]*Department of Immunology, University of Toronto, Toronto, ON, Canada,* [3]*Department of Pathology and Laboratory Medicine, Emory University, Atlanta, GA, United States,* [4]*Emory Vaccine Center, Emory Center for AIDS Research, Emory University, Atlanta, GA, United States.*

Fc receptor like protein 1 (FcRL1) is expressed on the surface of all B cells starting from the pro-B stage. Our previous study has identified the activation and co-stimulatory activities of FcRL1 but the molecular mechanism by which FcRL1 activates B cells remains unknown. Here we report that cross-linking of FcRL1 induced its tyrosine phosphorylation, which recruited the association of Grb2 adaptor protein and phosphatidylinositol 3-kinase (PI3-K), and subsequently stimulated the activation of downstream ERK and Akt kinases. The tyrosine 369 (Y369) of FcRL1 was the major phosphorylation site after cross-linking and this residue was essential for the activation of Grb2/ERK and PI3-K/Akt pathways. The PI3-K-Akt pathway was required for FcRL1-mediated B cell proliferation. Interestingly, FcRL1 ligation induced modest tyrosine phosphorylation of CD19. Co-ligation of FcRL1 with surface IgM significantly increased the tyrosine phosphorylation of CD19 and the association of PI3-K to CD19. Altogether, our data suggests that the activation and co-stimulatory functions of FcRL1 are related to the PI3-K-Akt pathway.

P2.12.16

Sterile alpha motif (SAM) and individual H5 alpha helix mediates SLP-76 oligomer formation for microclusters and T-cell activation

H. Liu[1], *Y. Thaker*[2], *L. Stagg*[3], *H. Schneider*[2], *J. Ladbury*[4], *C. E. Rudd*[2];
[1]*Depatment of Biological Science, Xi'an Jiaotong-Liverpool University, SuZhou, China,* [2]*Department of Pathology, Cambridge University, Cambridge, United Kingdom,* [3]*MD Anderson Cancer Center, Houston, TX, United States,* [4]*MD Anderson Cancer center, Houston, TX, United States.*

Despite the importance of the immune adaptor SLP-76 in T cell immunity, it has been unclear whether SLP-76 directly selfassociates to form higher order oligomers for T-cell activation. In this study, we show that SLP-76 self-associates in response to TCR ligation as mediated by the N-terminal sterile alpha motif (SAM) domain. SLP-76 coprecipitatedalternately tagged SLP-76 in response to anti-CD3 ligation. Dynamic light scattering (DLS) and fluorescent microscale thermophoresis (MST) of the isolated SAM domain (residues 1-78) revealed evidence of dimers and tetramers. Consistently, deletion of the SAM region eliminated SLP-76 coprecipitation of itself, concurrent with a loss of microcluster formation, NFAT transcription and interleukin 2 production in Jurkat or primary T-cells. Further, different regions in the SAM domain independently contributed to self-association such that retention of the conserved single SAM H5 alpha helix sufficed to support SLP-76 binding to SLP-76 concurrent with smaller microclusters, but nevertheless, enhanced anti-CD3 driven NFAT transcription and IL-2 production. Our data identifies for the first time that anti-CD3 ligation induces SLP-76 oligomerization asmediated by the SAM domain.

P2.12.17

Functionally Relevant phoshorylatable Serine Clusters targeted by Casein Kinase 2 on the Cytoplasmic region of the human CD6 Lymphocyte Surface Receptor

L. Bonet[1], *M. Farnós*[1], *M. Martínez-Florensa*[2], *V. G. Martinez*[1], ***F. Lozano***[3];
[1]*Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain,* [2]*Immunovative Developments, Barcelona, Spain,* [3]*Hospital Clínic de Barcelona, Barcelona, Spain.*

CD6 is a transmembrane lymphocyte glycoprotein mainly expressed on T cells and a subset of mature B cells (B1a), where it physically associates with the antigen-specific receptor present on their surface. Accordingly, CD6 is typically involved in lymphocyte activation and differentiation through its interaction with CD166/ALCAM, an adhesion molecule from the Ig superfamily. More recently, it has also been implicated in sensing the presence of conserved bacterial cell wall components. Cross-linking of CD6 by either endogenous or exogenous ligands transduces intracellular signals of still incompletely understood nature through its long cytoplasmic tail, which lacks intrinsic catalytic activity but presents several consensus motifs suitable for phosphorylation and signal transduction. In the present work, mapping of constitutive and cell activation-induced serine phosphorylation sites has been achieved by deletion and/or point mutation analysis of the CD6 cytoplasmic tail. Two serine clusters (S480/482/484 and S560/562/565/567/568), which are embedded into Casein Kinase 2 (CK2) consensus motifs, are shown to be involved in the constitutive phosphorylation of CD6. Moreover, disruption of these serine clusters interferes with MAPK activation following CD6 binding to either specifc mAbs or previously reported endogenous (ALCAM/CD166) or exogenous (bacterial LPS) ligands. Interestingly, several alternatively spliced CD6 cytoplasmic isoforms devoid of the above mentioned serine clusters were isolated following lymphocyte activation. In conclusion, the data point to the regulation of CD6 function by intracytoplasmic CK2-phosporylation sites, which is either complementary or alternative to that of the extracellular ALCAM-binding site.

P2.12.18

Targeted mitochondrial antioxidant SkQ has anti-inflammatory properties in vitro and in vivo

A. Lukashev, *M. Skulachev;*
Institute of Mitoengineering, Moscow State University, Moscow, Russian Federation.

Reactive oxygen species (ROS) have versatile roles in inflammation as both signal mediators and effector molecules. Two distinct kinds of ROS are those produced in mitochondria as a byproduct of respiratory chain and on the plasma membrane of immune effector cells by NADPH oxidase. Distinguishing the relative impact of mitochondrial and cellular ROS is difficult because in inflammation the latter are produced in vast excess, and common antioxidants target ROS from any source. SkQ1 (plastoquinonyl-decyl-triphenylphosphonium bromide) is a representative of the family of mitochondria-targeted antioxidants. Triphenylphosphonium group combines positive charge and hydrophobic properties, providing highly specific accumulation of the quinone in the internal membrane of mitochondria. As a result, the concentration of SkQ1 in mitochondria is up to seven orders of magnitude higher. Stabilization of mitochondria results in multiple biological effects of SkQ1 that are observed in in vivo and in vitro in nanomolar range. Importantly, the window between antioxidant and prooxidant concentrations is about 1000-fold, providing high flexibility in experimental and potential clinical applications. This makes SkQ1 a promising tool to explore the role of ROS and the relative impact of endogenous (mitochondrial) and plasma membrane ROS in inflammation signaling pathways. Immunomodulating properties of SkQ1 have been shown in a number of in vivo models. It limits neutrophil infiltration and excessive inflammation in models of hepatitis (induced by D-Gal+LPS), bacterial pyelonephritis, autoimmune arthritis and wound healing. The molecular mechanisms of these effects are currently under investigation.

P2.12.19

SAP-mediated inhibition of Diacylglycerol kinase alpha regulates TCR-induced diacylglycerol signaling and restimulation induced cell death in XLP patients

*G. Baldanzi[1], E. Ruffo[1], **V. Malacarne**[1], K. E. Nichols[2], L. Patrussi[3], C. T. Baldari[3], A. Snow[4], A. Graziani[1];*
[1]Dep. Translational Medicine, University of Eastern Piedmont, Novara, Italy, [2]Div. of oncology, Children's Hospital of Philadelphia, Philadelphia, PA, United States, [3]Dep. of Evolutionary Biology, University of Siena, Siena, Italy, [4]Dep. of Pharmacology, Uniformed Services University of the Health Sciences, Bethesda, MD, United States.

X-linked lymphoproliferative disease (XLP) is a rare congenital immunodeficiency leading to a usually fatal lymphocytosis following EBV infection. It is characterized by loss of expression of SLAM-associated protein (SAP), which results in defective SLAM family receptors and TCR signaling. Recent evidences showed that SAP deficiency causes resistance to TCR re-stimulation induced cell death (RICD), a process that physiologically constrains T cell expansion during immune responses (Snow, JCI 2009).
We recently showed that, upon TCR stimulation, SAP mediates negative regulation of the enzymatic activity of Diacylglycerol kinase alpha (DGKα) (Baldanzi, J. Immunol. 2011). DGKα, phosphorylating diacylglcyerol to phosphatidic acid, is a well-known negative regulator of TCR signaling. In SAP-deficient Jurkat cells, inhibition of DGKα partially rescues defective TCR/CD28 signaling, including Ras and ERK-1/2 activation, PKCθ membrane recruitment, induction of NF-AT transcriptional activity and IL-2 production.
Here we show that both DGKα silencing and pharmacological inhibition restore diacylglycerol signaling in SAP deficient primary T cells, thereby enhancing T cell activation (ERK phosphorylation and cytokines production). Moreover, DGKα knockdown efficiently restores FASL and BIM expression, reestablishing TCR-induced apoptosis of SAP deficient cells. Intriguingly, DGKα silencing/inhibition fully restore RICD in SAP knockdown T cells, as well as in T cells from XLP patients. Thus, DGKα inhibition is sufficient to correct the defective TCR signaling and RICD in SAP defective cells ex-vivo, indicating a key role of the SAP-DGKα pathway in RICD control. These data also suggest that DGKα inhibition could be a novel pharmacological strategy for treatment of XLP and others lymphoproliferative diseases.

P2.12.20
Food contaminant mycotoxin Fumonisin B2 regulates the mTOR kinase signaling pathways in brain lymphocytes: implication for neurological disorders

***E. A. Martinova**;*
Russian Medical Academy of the post-diploma education, Moscow, Russian Federation.

Mycotoxin Fumonisin B2 (FB2, $C_{34}H_{59}NO_{14}$, *M*705) is produced by fungi *Fusarium moniliforme* and other species contaminated a corn world-wide. Previously we found that FB2 regulated the lymphocyte activation, proliferation, and apoptosis. Our late breaking data concerns the FB2 regulation of mTOR kinase signaling pathways in brain lymphocytes *in vivo*.
Methods: FB2 [0.01 - 1.0 μM] was injected intraperitoneally to FVB male mice 12 weeks old. Each 15 minutes to 2h and then each 1h to 6h three animals were killed by guillotine and brains were removed. One part of brain was frozen and stained with mTOR-related protein antibodies and for morphological examination. Other part was homogenized to obtain the isolated lymphocytes stained and analyzed by flow cytometry. Statistical analysis from three experiments was performed using ANOVA.
Results: FB2 regulates the key mTOR signaling proteins in brain lymphocytes: upstream inhibitors TSC1/TSC2 (hamartin and tuberin proteins), adapter protein 14-3-3, mTOR-associated proteins Raptor, Rheb, and HSP70, downstream effectors p70S6K1 and 4E-BP1 as well as some mTORC2-associated proteins. FB2 effects have been found to be irreversible concerning some proteins followed by the specific morphological changes in brain tissues. Brain B cells have been found to be activated under FB2 exposure and produced a large level of immunoglobulins. Activated CD8+ formed the clusters in cortex and white matter followed by neuronal cell death and oligodendrocyte apoptosis. Activated CD4+ T cells underwent an apoptosis.
Conclusion: food contaminant fumonisin B2 possesses the brain lesion due to the specific regulation of the mTOR signaling proteins.

P2.12.21
The influence of calpain-calpastatin system in human lymphocyte - assessment of lymphocyte signaling process of centenarians and elderly people

***A. Mikosik**[1], A. Jasiulewicz[1], J. Frackowiak[1], J. Foerster[2], D. Schetz[2], J. M. Witkowski[1];*
[1]Department of Pathophysiology, Medical University of Gdansk, Gdansk, Poland, [2]Department of Social and Clinical Gerontology, Medical University of Gdansk, Gdansk, Poland.

The calpain-calpastatin system (CCS) in the lymphocytes and many other cell types contains two neutral, cytoplasmic proteases (1- and 2-calpain) and their common endogenous inhibitor - calpastatin. Their property of cleaving only relatively few specific sites in the proteins and peptides, as well as their list of substrates, makes them potentially important regulators of the immune response. Thus it is feasible that the system may be involved (beneficially or otherwise) in the functioning of lymphocytes and its deregulation may impact on or participate in the process of immune system ageing; consequently, a hypothesis of different activity of the CCS in the immune cells of centenarians (as compared to younger healthy elderly) is valid and attractive.
Thus, the aim of current project is to establish the role of CCS system function for the effective immune response and of its malfunction as a potential participant in the mechanisms of the immune cells' ageing and cells signaling.
We assess the number status and activation of lymphocytes population and the amount and the activities of CCS in the various subpopulations of peripheral blood cells. We compare lymphocytes from Polish healthy centenarians and elderly. Our preliminary results suggest the differences in the expression of CCS members between the different lymphocyte populations (including the CD4+, CD8+, CD19+)and their activation in the age groups. Project funded by the Polish National Science Center grant DEC-2011/01/M/NZ3/02948 CALPACENT

P2.12.22
CD157-extracellular matrix proteins interactions enhance integrin-mediated signalling cascade in monocytes

***S. Morone**[1], A. Giacomino[1], R. Parrotta[1], N. Lo Buono[1], M. Cuccioloni[2], E. Ortolan[1], A. Funaro[1];*
[1]University of Torino, Torino, Italy, [2]University of Camerino, Camerino, Italy.

CD157 is a GPI-anchored ectoenzyme belonging to the NADase/ADP-ribosyl cyclase gene family involved in the control of human neutrophils and monocytes adhesion, migration and diapedesis. We demonstrated that CD157 physically interacts with β1 and β2 integrins in monocytes and its cross-linking by means of a monoclonal antibody (mimicking the natural ligand) recruits integrins to lipid rafts, promoting the transduction of optimal intracellular signals converging on the MAPK and PI3K pathways.
Here, we demonstrate that CD157 binds selected extracellular matrix proteins. Using solid phase binding assays and surface plasmon resonance analysis, we found that human recombinant CD157 binds to fibronectin, fibrinogen, laminin and collagen type I but not to vitronectin or to the polysaccharide components of extracellular matrix (such as heparin and hyaluronan). CD157 binding is concentration-dependent and is prevented by selected anti-CD157 monoclonal antibodies. Using recombinant fibronectin fragments, CD157 binding sites were mapped within the N-terminal and C-terminal heparin binding regions of fibronectin, which lack integrin-binding motifs.
Co-immunoprecipitation experiments using monocytic THP-1 cell line confirmed that: i) CD157 physically associates with fibronectin and ii) CD157 binding to fibronectin is required for promoting the association between CD157 and integrins.
We hypothesize that the simultaneous engagement of CD157 and integrins by distinct domains of fibronectin represents the physiological mechanism promoting the interaction between CD157

and integrins, leading to the optimal activation of the signalling cascade which controls crucial aspects of monocytes extravasation.

P2.12.23
IL-21 isoform is a membrane-bound ligand and activates directly interacted cells

***H. Nara**, M. Rahman, A. Araki, L. Jin, Y. Takeda, H. Asao;*
Department of Immunology, Yamagata University Faculty of Medcine, Yamagata City, Japan.

IL-21 is a pleiotropic cytokine that regulates the function of T cells, B cells, natural killer cells, and myeloid cells. We previously identified an IL-21 isoform, IL-21iso, in humans and mice, and found that IL-21iso was secreted in much smaller amounts than conventional IL-21. In this study, we determined that secreted IL-21iso also has less signaling activity than IL-21. However, the amounts of intracellular IL-21 or IL-21iso, and the level of STAT3 phosphorylation induced by the two IL-21 forms, were similar. IL-21-sensitive reporter cells co-cultured with cells producing IL-21iso showed STAT3 activation, apoptosis, and proliferation. However, when IL-21iso-producing cells were cultured in a transwell chamber, which prevented direct contact with the IL-21-sensitive cells, no IL-21iso-induced signaling was observed. Though IL-21iso is secreted in smaller amounts and has less potent signaling activity than IL-21, IL-21iso acts both on IL-21iso-bearing cells and other IL-21-sensitive cells through direct interactions probably without being secreted. Thus, IL-21iso's regulation of immune cells may be limited to the immediate proximity around the IL-21iso-producing cells, in regions such as immune organs or inflammation sites. Cytokine 61, 656-663, 2013.

P2.12.24
Differential TLR1/2 pro-inflammatory signaling during the first 9 months of life

***E. Nemes**[1], M. Shey[1,2], W. Whatney[1], C. Riou[3], T. Scriba[1], W. Hanekom[1];*
[1]South African TB Vaccine Initiative (SATVI) and School of Child and Adolescent Health, Institute of Infectious Disease and Molecular Medicine, University of Cape Town, Cape Town, South Africa, [2]Centre for the AIDS Program of Research in South Africa (CAPRISA), University of KwaZulu-Natal, Durban, South Africa, [3]Division of Immunology, Institute of Infectious Diseases and Molecular Medicine, University of Cape Town, Cape Town, South Africa.

Newborns are particularly susceptible to infections and generally respond poorly to vaccination. The underlying cause may be immaturity of innate immunity. Despite evidence that toll-like receptor (TLR) sensor function in newborns is well developed, we and others have shown lower mycobacteria-mediated production of pro-inflammatory cytokines in monocytes from newborns compared to older infants.
We investigated whether differential ligand activation of key pro-inflammatory signaling pathways downstream of TLR1/2, a major pathogen recognition receptor of mycobacteria, underlies age-related differences in innate cell responses.
We analysed cryopreserved mononuclear cells from cord (n=10) and peripheral blood collected from 10 week (n=7) and 36 week old (n=7) healthy infants. Degradation (D-) of NFκB-inhibitor IκB and phosphorylation (P-) of MAP kinases p38 and erk in monocytes stimulated with TLR1/2 ligand PAM3 was measured by flow cytometry.
Higher basal proportions of P-erk and D-IκB monocytes were observed in 10-week-old infants, compared with newborns. Upon stimulation infants of all ages showed increased IκB degradation and phosphorylation of p38 and erk. However, newborns displayed higher induction of P-erk and lower induction of D-IκB than older infants. Simultaneous activation of all three signal transduction molecules was observed predominantly in 10 and 36-week-old infants, while monocytes from newborns primarily exhibited activation of only one molecule at a time. In particular, induction of P-Erk, in the absence of P-p38 and D-IκB, was observed only in newborns.
Greater co-activation of pro-inflammatory signaling cascades, such as this TLR1/2 pathway, may underlie higher innate pro-inflammatory cytokine responses to mycobacteria in older infants, compared with newborns.

P2.12.25
Dasatinib leads to a reduced number of B cells in mice and promotes apoptosis of human CD19+ peripheral blood B cells

***M. P. Oksvold**[1], C. B. F. Thien[2], S. A. Dagger[2], L. Forfang[1], J. H. Myklebust[1], E. B. Smeland[1], W. Y. Langdon[2];*
[1]Dept. of Immunology, Inst. for Cancer Research, Oslo University Hospital, Oslo, Norway, [2]School of Pathology and Laboratory Medicine, University of Western Australia, Perth, Australia.

Dasatinib is a highly potent BCR-ABL and Src family kinase inhibitor which also inhibits a variety of other tyrosine kinases. It is currently approved for the treatment of imatinib-resistant chronic myeloid leukemia and Philadelphia chromosome-positive acute lymphoblastic leukemia, and there are ongoing clinical trials to evaluate its use in several other cancer types. Here we show that Dasatinib leads to a markedly reduced number of lymphocytes in mice treated for 2 and 4 weeks. The reduction in lymphocytes was due to a specific loss of $CD19^+$ B cells, since T cells numbers were not affected. A reduced level of $CD19^+$ B lineage cells was detected in bone marrow, blood and spleen. The effect on spleen was reflected by a clear reduction in organ size. In contrast, Dasatinib induced an increase in the number of myeloid cells. When human $CD19^+$ B cells were cultured with Dasatinib [128 nM], we observed a 7-fold increase in apoptotic cells after 5 days. In contrast, no similar effect on T cell viability was observed. However, Dasatinib induced a comparable broad inhibition of the early events of human B and T cell receptor signaling i.e. Src family kinases, Syk, PLCγ2, p70 S6 and ERK1/2 in B cells and CD3ζ, Src family kinases, ZAP70, PLCγ1, p70 S6 and ERK1/2 in T cells. Overall, this study reveals an important effect of Dasatinib with the specific loss of $CD19^+$ B cells, which may have an impact for patients on long-term Dasatinib treatment.

P2.12.26
Regulation of TCR trafficking and immune synapse assembly by Rab29

***A. Onnis**[1], S. Spanò[2], F. Finetti[1], L. Patrussi[1], J. E. Galan[2], C. T. Baldari[1];*
[1]University of Siena, Siena, Italy, [2]Yale University School of Medicine, New Haven, CT, United States.

Notwithstanding their central implication in vesicular trafficking, the function of several members of the Rab family of small GTPases remains elusive, as exemplified by Rab29/Rab7L1. Recently Rab29 has been shown to be selectively cleaved by GtgE, a type III secretion effector produced by broad-host Salmonella serovars. This finding provides not only insight into the biology of Salmonella but also a new tool to address the role of Rab29 in vesicular trafficking. Here we have addressed the potential implication of Rab29 in TCR trafficking. Rab29 was found to be associated with the endomembrane system, co-localizing with Rab8, which has been implicated in endosome recycling in polarized cells, as well as with the recycling Rabs, Rab4 and Rab11. Rab29 depletion by T cell transfection with a construct encoding GtgE resulted in impaired TCR recycling. Immune synapse (IS) assembly was also impaired in Rab29 depleted cells, as assessed by imaging protein tyrosine phosphorylation and TCR clustering at the IS. This defect resulted from the inability of the TCR to undergo polarized recycling to the IS. Collectively, these results provide the first evidence of a role for Rab29 in vesicular trafficking and identify a new player in TCR recycling and IS assembly.

A mutation in the moesin gene induces an alteration of T lymphocyte adhesion/migration process in a new combined immunodeficiency syndrome

F. Ouchani[1], *C. Lagresle*[1], *S. Luce*[1], *K. Jacobs*[2], *C. Picard*[1], *A. Fischer*[1], *G. De Saint Basile*[1], *N. Jabado*[2], *M. Cavazzana-Calvo*[1], *I. André-Schmutz*[1];
[1]*INSERM U768-Necker Hospital, Paris, France,* [2]*McGill University Health Center, Montreal, QC, Canada.*

In the present study, we report in four non related pediatric patients a new primary immunodeficiency associated with a missense mutation in the moesin gene. The disease is characterized by a profound T, B and NK lymphoid deficiency and neutropenia. Exome analysis of all patients revealed an identical 683C>T missens mutation in the exon 5 of moesin gene located in Xq11.1. The mutation introduces an amino acid change (p.R171W) in the highly conserved FERM domain. Moesin belongs to a group of proteins that link membrane proteins to actin and is implicated in various cellular functions such as survival, adhesion, migration and T-cell activation. Flow cytometric analysis of patients demonstrated a decreased expression of chemokine receptor CXCR4 and CCR7 on CD4+ and CD8+ T cells. In parallel, expression of adhesion molecule LFA1 and VLA-4 was increased on CD8+ T cells. Adhesion and migration assays performed on T lymphocytes of P1 indicated stronger adhesion capacities of CD8+ T cells on VCAM-1 and fibronectin and decreased migration capacities of CD4+ and CD8+ T cells in response to SDF-1 (CXCR4 ligand) or CCL21 (CCR7 ligand). An alteration of the ROCK/MLC pathway may explain these results. Altogether, our results indicate a role of moesin in the migration properties of lymphocytes in human.

P2.12.28
Characterization of THEMIS as a novel attenuator of TCR signalling

W. Paster[1], *A. Bruger*[1], *C. Brockmeyer*[2], *G. Fu*[3], *A. Kabat*[1], *C. Wuelfing*[4], *N. R. J. Gascoigne*[3], *O. Acuto*[1];
[1]*Sir William Dunn School of Pathology, Oxford, United Kingdom,* [2]*University of California, Berkley, CA, United States,* [3]*The Scripps Research Institute, La Jolla, CA, United States,* [4]*University of Bristol, Bristol, United Kingdom.*

Stimulation of the T cell antigen receptor (TCR) induces formation of phosphorylation-dependent signalling networks, ultimately leading to T cell proliferation and differentiation. Composition and dynamics of the TCR signalosome are still incompletely understood. Others and we have recently identified the T-cell-specific phosphoprotein Thymocyte-expressed molecule involved in selection (THEMIS), as a key player in the double positive thymocyte selection process. The exact role of THEMIS in signalling, especially in peripheral T cells, has remained poorly characterized and controversial. In the present study we show that THEMIS is a new member of the TCR-proximal signalosome. TCR ligation leads to rapid recruitment of THEMIS to the immunological synapse via the transmembrane adapter LAT, accompanied by Lck -and ZAP70-mediated Tyr-phosphorylation of conserved Tyr-residues at the C-terminus of THEMIS. LAT recruitment of THEMIS is dependent on the constitutively associated adapter molecule GRB2. We can further show that the THEMIS-GRB2 complex is indispensable for T cell development in vivo. In mature human T cells, shRNA-mediated knockdown of THEMIS expression leads to enhanced TCR-proximal phosphorylation events and an increase in expression of surface activation markers. Ultimately, in the absence of THEMIS, human peripheral T cells and model T cell lines are significantly more susceptible to activation-induced cell death due to deregulated signalling emanating from the TCR. Our data suggest that THEMIS contributes to a negative feedback that limits cell death during activation of peripheral T cells and have implications for the mechanism that sets the threshold between positive and negative selection during T cell development.

P2.12.29
Dendritic cell CD83 enhances calcium signaling in T lymphocytes by affecting calcium release from intracellular stores

M. P. Pinho, *I. K. Migliori, E. A. Flatow, J. A. M. Barbuto;*
Immunology Department, Biomedical Sciences Institute, University of São Paulo, São Paulo, Brazil.

CD83 is a marker of mature dendritic cells (mDCs) directly related to their limphostimulatory ability, but little is known about the mechanism of action of CD83. We aimed to show the influence of CD83, present in mDCs, upon the calcium signaling in T lymphocytes during the immunological synapse made between them. Monocytes were differentiated into mDCs by culture, for seven days, in the presence of GM-CSF, IL-4, and, in the last two days, TNF-α. In calcium signaling assays, purified T lymphocytes were incubated with the calcium indicator Fluo-4AM and analyzed in the presence of allogeneic mDCs. As expected, blockage of CD83 with a specific antibody reduced the proliferation of lymphocytes in the presence of allogeneic mDCs. CD83 antibodies reduced the calcium signaling amplitude observed in T lymphocytes by flow cytometry, fluorescent and confocal microscopy. The percentage of responding cells also reduced from 58.1% to 34.3% in the presence of antibody. Also, CD83 knockdown mDCs induced lower calcium signal amplitude in T lymphocytes, compared to scrambled siRNA-treated mDCs. In the absence of extracellular calcium, CD83 antibodies completely abrogated T cell signaling, which indicates that CD83 signaling might act upon calcium release from intracellular stores. These data suggest that the presence of CD83 in mDCs enhances T lymphocytes proliferation by inducing greater calcium release from intracellular stores in T lymphocytes. Supported by FAPESP #2009/54599-5 #2011/01082-5.

P2.12.30
Platelets and leukocytes reactivity in patients with ischemic stroke

I. Prylutska, *E. Barinov, O. Sulaieva, A. Kit;*
Donetsk National Medical University, Donetsk, Ukraine.

The most common cause of stroke is the sudden occlusion of a blood vessel by a thrombus or embolism, associated with platelet and leukocyte dysfunction. The last one determines the induction of pro-inflammatory cascade, cerebral injury progression and complications development.
The aim of this investigation was to estimate the cooperation between platelets and leukocytes in blood of patients with ischemic stroke depending on outcome.
Materials and Methods. The functional state of platelets and leukocytes was estimated in 40 patients with acute ischemic stroke. The 1st group includes 30 stroke survivors, the 2nd - 10 patients with lethal outcome. We assessed platelets aggregation induced by epinephrine (2,5 μM), ADP (5 μM), thrombin (1,5 NIH) and angiotensin II (1 μM). Platelet-leukocyte aggregates (PLA) in peripheral blood were analyzed morphologically.
Results. The total number of leukocytes and segmented neutrophils percentage rates in complete blood count were significantly higher in 2nd group of patients comparing with 1st group ($p=0,005$ and $p=0,026$ respectively). Pro-inflammatory activation of leukocytes was related with PLA formation and lysed leukocytes appearance, which number were significantly higher in 2nd group ($p<0,001$). Comparison of all agonists effects on blood cells activation shown the most prominent effect of thrombin, inducing formation of heterogeneous and homogeneous aggregates, which number was in two times higher in patients with lethal outcome comparing 1st group ($p=0,001$).
Conclusion. Ischemic stroke is associated with pro-inflammatory activation of platelets and leukocytes, accelerated by thrombin and reflected in PLA formation. These findings can be useful in ischemic stroke outcome prognosis.

P2.12.31
The chicken IFN- λ Receptor Complex

A. Rohringer[1,2]*, K. Goossens*[1,2]*, A. Ward*[2]*, A. Bean*[1]*;*
[1]CSIRO - AAHL, Geelong, Australia, [2]Deakin University, Geelong, Australia.

High Pathogenic Avian Influenza(HPAI) viruses, such as H7N9 and H5N1 HPAI, have an immense effect on poultry production and there is a need for new strategies to deal with these infections. Moreover, there is a clear need to understand the processes associated with the host response to virus to help to develop these new strategies. Host antiviral molecules and their receptors, like interferons(IFN), are key players in the antiviral immune response and mainly responsible for a successful resolution of an infection. With this in mind, we investigated IFN-λ and the IFN-λ specific component of the receptor complex, and their role in viral infections. We characterized the chicken IFN-λ receptor and showed that is has 60% and 59% amino acid sequence conservations to the human and mouse IFN- λ receptor, respectively. Analysis of the expression of IFN- λ receptor in chicken tissues showed its presence over a large range of tissues with the highest expression in the lung, spleen, intestine and cecal tonsils. Similarly, a number of chicken cell lines, such as the HD11 chicken macrophage-like cell line, tested positive for this receptor. To investigate the function of the IFN- λ receptor, RNAi mediated gene knock down was used to target the IFN- λ Receptor in HD11 cells. This silencing approach showed a greater than 50% knockdown of IFN- λR mRNA *in vitro*. These receptor gene silencing experiments will be used to assess the role of the IFN- λ receptor complex in the signaling response to viral infections.

P2.12.32
A novel tool to isolate and analyze lipid rafts

P. SchatzImaier*, J. Huppa, H. Stockinger;*
Medical University of Vienna, Vienna, Austria.

The experimental basis for the lipid raft concept are detergent-resistant membrane domains that contain high levels of cholesterol and sphingolipids and are enriched in glycosylphosphatidylinositol-anchored and palmitoylated proteins as well as a subset of transmembrane proteins, e.g. Lck and LAT in T cells. Various methods exist to isolate lipid rafts for biochemical analysis, with cell lysate fractionation via sucrose density gradient ultracentrifugation still being the gold standard for separation of raft markers. In general, these methods are laborious and time-consuming and need a large number of cells. Here we present a fast and easy method to harvest lipid raft proteins within minutes via passage of cells through a detergent gradient by low g centrifugation, requiring little starting material. Fine-tuning of gradient density and the usage of raft-conserving and -disrupting detergents enable not only the generation of a lipid raft fraction for conventional down-stream analysis as immunoblotting, but also the analysis of lipid raft composition on a single cell level via flow cytometry. Thus it is possible to easily monitor and quantify proteins integral to and associated with lipid raft domains at the cell surface, e.g. prior and post stimulation of the T cell receptor. In conclusion, we describe a method suitable for quick, easy, reproducible and sensitive analysis of lipid raft-associated molecules on a single cell level.

Regulation of soluble IL-15 complexes after irradiation, chemotherapy, and VSV infection

S. M. Anthony[1,2]*, M. E. Howard*[1]*, S. W. Stonier*[1,2]*, Z. Dai*[1]*, W. W. Overwijk*[1,3]*,* ***K. S. Schluns***[1,2]*;*
[1]UT MD Anderson Cancer Center, Houston, TX, United States, [2]Immunology Graduate Program, The University of Texas Graduate School of Biomedical Sciences, Houston, TX, United States, [3]Immunology Graduate Program, The University of Texas Graduate School of Biomedical Sciences,, Houston, TX, United States.

During the steady state, IL-15 is primarily located either intracellularly or on the cell surface, where it can stimulate lymphocyte development and homeostasis via transpresentation. Conversely, soluble (s) IL-15 complexes have been shown to be generated after irradiation or nonmyeloabablative chemotherapy; however, the mechanisms generating sIL-15 complexes are not clear. This lead us to investigate if sIL-15 complexes are generated in other types of lymphopenia or by other inflammatory events. We report here that while lymphopenia induced by sub-lethal irradiation increased serum sIL-15 complexes, lymphopenic RAG-/- mice do not express increased levels of serum sIL-15 complexes. Additionally, in contrast to other studies, nonmyeloabablative chemotherapy induced by cyclophosphamide (200mg/kg) did not increase sIL-15 complexes whereas antibody-mediated T cell depletion did increase sIL-15 complexes suggesting the manner of cell death dictates the mechanisms generating sIL-15 complexes. We next investigated the role of IFN-a in the induction of sIL-15 complexes and found that treating mice with IFN-a encoding plasmids(via hydrodynamic delivery), Poly I:C, or VSV potently induced serum sIL-15 complexes. Furthermore, similar to Poly I:C or VSV, irradiation increased serum IFN-a levels. Correlating to the lack of sIL-15 complexes, chemotherapy did not induce IFN-a. Type I IFN signaling was important as IFN-R-/- mice displayed impaired production of sIL-15 complexes in response to Poly I:C, VSV infection, or irradiation. Overall, these data provide evidence that IFN-a is an important upstream signal generating sIL-15 complexes.

P2.12.34
IL-10 receptor and endoplasmic reticulum stress impairs STAT3 activation in type 1 diabetes patients and their healthy first degree relatives

M. A. K. Sedhom[1]*, A. Cotterill*[2]*, K. Irvine*[3]*, R. Thomas*[1]*;*
[1]The University of Queensland Diamantina Institute, Woolloongabba, Brisbane, QLD, Australia, [2]Mater Children's Hospital, Brisbane, QLD, Australia, [3]Centre for Liver Disease Research, The University of Queensland School of Medicine, Wooloongabba, Queensland, Australia, Australia.

Autoimmune diseases including type 1 diabetes (T1D) result from disordered immune tolerance. We showed that an endoplasmic reticulum (ER) stress signature predicted poor outcome in recent-onset T1D patients, and is observed in a proportion of at-risk first degree relatives (FDR). To determine the relationship of ER stress to immune cell signalling, we compared monocyte and T cell STAT3 phosphorylation in response to IL-6 and IL-10 in 30 T1D, 35 FDR, 11 healthy controls, and 22 rheumatoid arthritis (RA) disease controls. Cytokine-stimulated signalling was detected in peripheral blood monocytes and T cells by flow cytometry. Expression of ER stress genes GRP78 and DDIT3 was quantified from PBMCs by RT-PCR. Induction of phospho (P)-STAT3 by IL-10 but not IL-6 was significantly reduced in T1D and FDR monocytes and T cells relative to healthy or RA controls. Basal levels of total STAT3 were comparable in all groups. This reduction in P-STAT3 response in T1D patients and FDR was associated with reduced IL-10-, but not IL-6-receptor expression by monocytes and T cells. IL-10 receptor expression and P-STAT3 induction in response to IL-6 and IL-10 were negatively associated with GRP78 and DDIT3 ER stress gene expression. IL-10 was shown to block ER stress in gut epithelium. Thus, our data implicate a disease-specific IL-10 receptor defect and its consequences on excess ER stress and disordered peripheral tolerance in T1D pathogenesis.

P2.12.35
Enhanced expression of adenosine-producing ectonucleotidases in activated and memory T cells

I. Shevchenko[1,2]*, A. V. Bazhin*[1]*, V. Umansky*[1,2]*;*
[1]Skin Cancer Unit, German Cancer Research Center (DKFZ), Heidelberg, Germany, [2]Department of Dermatology, Venereology and Allergology, University Medical Center Mannheim, Ruprecht-Karl University of Heidelberg, Mannheim, Germany.

Extracellular adenosine exerts its immunosuppressive effects through activation of cyclic AMP synthesis in target cells. Its accumulation is largely regulated by the activity of the cell-surface enzymes CD39 and CD73 converting pro-inflammatory ATP into immunosuppressive adenosine in a two-step process. It has recently been demonstrated that adenosine production strongly contributes to the immunosuppressive activity of regulatory T cells (Treg). To elucidate

the role of extracellular adenosine in T cell function, we investigated the expression of CD39 and CD73 in various T cell subpopulations in the *ret* transgenic model of melanoma and orthotopic model of pancreatic adenocarcinoma in mice. We confirmed that CD39 and CD73 are expressed at high levels on the vast majority of Treg. Furthermore, we detected both enzymes on $CD4^+FoxP3^-$ conventional T cells (Tcon). Notably, we found that the frequency of $CD39^+$ and $CD73^+$ cells among activated ($CD25^+$) Tcon is significantly higher than that within the $CD25^-FoxP3^-$ subset. Moreover, *in vitro* activation of both $CD4^+$ and $CD8^+$ T cells from healthy mice led to a significant upregulation of the CD39 expression. Studying memory $CD4^+$ and $CD8^+$ T cells *in vivo*, we found that both central and effector memory compartments are highly enriched in $CD39^+$ and $CD73^+$ cells, as compared to naïve T cells. Furthermore, after a short-term restimulation *in vitro*, the IFNγ-producing subpopulation contained a higher proportion of ectonucleotidase-expressing cells than the IFNγ-negative counterpart.
Taken together, our data suggest that CD39 and CD73 expressed on effector T cells might be involved in the regulation of T cell activation.

P2.12.36
Phenotypical analysis of transgenic mice expressing soluble human CD6 supports an immunomodulatory role for this protein

I. T. Simões[1], *V. G. Martinez*[1], *R. Fenutría*[1], *J. Alberola-Ila*[2], *F. Lozano*[1,3,4];
[1]*IDIBAPS (Institut d'Investigacions Biomèdicas August Pi i Sunyer), Barcelona, Spain,* [2]*Oklahoma Medical Research Foundation, Oklahoma, OK, United States,* [3]*Servei d'Immunologia, Hospital Clínic de Barcelona, Barcelona, Spain,* [4]*Departament de Biologia Cellular, Immunologia i Neurociències, Universitat de Barcelona, Barcelona, Spain.*

CD6, a SRCR-SF group B membrane receptor, is a membrane glycoprotein expressed in thymocytes, mature T cells, B1-a cells, NK cells, hematopoietic precursors, and some brain regions. This molecule is physically associated to the TCR, likely modulating its activation and differentiation signals. The ultimate function of CD6 has not yet been deciphered. Although initially considered as a co-stimulatory molecule, a recent report proposes that CD6 may act as a negative modulator, since CD6-negative lymphocytes were hyper-reactive to TCR-mediated stimulation. To date, no CD6 knock-out or knock-in mice have been developed, so the functional relevance of this protein remains unclear.
To gain insight into the function of CD6, we have developed transgenic C57Bl/6 mice expressing a circulating soluble form of human CD6 (shCD6). This shCD6 would supposedly work as a decoy receptor specifically blocking the ligand-receptor interactions mediated by membrane-bound CD6, thus resulting in a functional knocking-down of this protein. In these mice, shCD6 expression is under the transcriptional control of the lymphocyte-specific promoter from the lck tyrosine kinase, as well as of the Ig heavy chain enhancer, so that this molecule will be expressed both in T and B cells. The shCD6 is readily detected in the serum of these mice (at the ng/ml range) and preliminary phenotypical analysis shows significant changes in some specific lymphocyte subpopulations both in central and peripheral lymphoid organs. These support a relevant role of CD6-mediated interactions in lymphocyte development as well as in homeostasis of some peripheral lymphocyte subsets and the anti-tumoral response.

P2.12.37
Understanding signalling requirements of LTi cells in vivo and in vitro

J. Wagner, ***G. Turchinovich****, D. Finke;*
University of Basel, Dept. Biomedicine, Basel, Switzerland.

The diverse family of innate lymphoid cells (ILCs) is comprised of lymphocytes that, unlike T- and B cells, do not utilize antigen receptors generated via somatic recombination. These include cytotoxic NK cells, innate helper cells (also known as nuocytes or ILC2), lymphoid tissue inducer (LTi) cells, and closely related to them $NKp46^+$ IL-22-producing lymphocytes located in the lamina propria of the intestine, jointly referred to as ILC3. ILCs are currently in focus of a number of studies investigating their role in mucosal tissue homeostasis and the interaction of the immune system and gut microbiota. While considerable progress has been made in the understanding of physiological roles of LTi cells in controlling the organogenesis of lymphoid tissues and regulation of intestinal immunity, little is known about molecular mechanisms governing LT cells' (and other ILCs) responses to external stimuli, as well as the exact nature of stimuli themselves. Here, we demonstrate that canonical NFκB signalling can be readily activated in ILC3s by stimulation with IL-1β and TLR agonists, accompanied by activation of p38 and Jnk kinases. Additionally, we report preliminary evidence that canonical NFκB signalling is important for the development of *in vitro* differentiated ILC3 cells. We are currently investigating the role of NFκB and other signalling pathways in ILCs *in vivo*. These preliminary studies will contribute to better understanding of mechanisms of ILC function and development.

P2.12.38
Elucidation of IL-17 signaling pathways

E. Varfolomeev*, D. Vucic;*
Genentech Inc, South San Francisco, CA, United States.

Proteins that belong to the family of IL-17 ligands coordinate various aspects of inflammatory reactions to provide adequate responses to fungal and bacterial infections. However, their excessive signaling results in various immune-related pathologies such as rheumatoid arthritis, psoriasis, multiple sclerosis, asthma and others. At the same time, the molecular mechanisms of IL-17 signaling are not well understood. Stimulation of IL-17 receptors results in activation of several kinase pathways and stabilization of cytokines and chemokines mRNAs. IL-17 triggers the formation of receptor signaling complex containing several TRAF molecules that mediate activation of NF-kB and MAP kinase signaling pathways. Still, the role of individual TRAF molecules in IL-17 signal transduction pathway remains obscure. To reveal the functional significance of TRAFs for IL-17 receptor stimulation we have examined the composition of IL-17-induced protein signaling complexes in several cell lines. We also determined the functional outcome of individual and combined TRAF absence on IL-17 signaling. Understanding the significance of TRAF proteins for IL-17 signaling is important for the overall understanding of IL-17 biology and for the design of therapeutics that can be used in the treatment of human pathologies that are driven by IL-17 expression and activity.

P2.12.39
Biological evaluation of human PBMC and Th17 cells using MILLIPLEX® MAP cell signaling and cytokine panels

J. Hwang, T. Warmke, R. Keith, ***R. Wiese****;*
Merck Millipore, St Charles, MO, United States.

Peripheral Blood Mononuclear Cells (PBMC) are composed of all blood cells having a round nucleus. This includes lymphocytes, monocytes, and macrophages. The lymphocyte population is made up of T cells, B cells, and Natural Killer cells. Th17 cells are recently discovered T helper cells that play important roles in the establishment and maximization of the capabilities of the immune system. Th17 cells are derived from CD4+ lymphocytes which are prevalent in human PBMC samples. In this study, we used six Milliplex® Cell Signaling panels and the Human Th17 Circulating panel to compose a biochemical profile of PBMC before, during, and after a differentiation process. We also examined the effect of Fetal Bovine Serum treatment on undifferentiated and differentiated PBMC. Our differentiation process consisted of a 7-day treatment of four cytokines, IL-1β, IL-6, IL-23, and TGFβ, as demonstrated in *Zheng et al*. Our results from cell signaling panels demonstrated that several analytes showed increased constitutive expression and phosphorylation after differentiation and stimulation with Fetal Bovine Serum. Additionally, the human Th17 panel showed that cytokine treatments induced significantly increased secretion of many cytokines including Th17 cell specific cytokines from human PBMCs (e.g. IL-17F). In conclusion, the Th17 and cell signaling panels will be useful tools for Th17 cell-related cytokine and signaling profiling in PBMC and various biological samples.

P2.12.40
TRPV1 channel in CD4+ T cells regulates their activation and their inflammatory properties

S. P. Bertin[1], *Y. Aoki-Nonaka*[1], *P. de Jong*[1], *T. Han*[1], *T. Yu*[1], *R. Touma*[1], *S. Srikanth*[2], *Y. Gwack*[2], *A. Franco*[1], *E. Raz*[1];
[1]*UCSD, La Jolla, CA, United States,* [2]*UCLA, Los Angeles, CA, United States.*

TRPV1 is a calcium-permeable channel best studied in peripheral sensory neurons as a pain receptor. Here we demonstrate the functional expression of TRPV1 in CD4+ T cells and its physiological consequences. TRPV1 is activated by TCR ligation and acts as a non-store operated calcium channel. Moreover, TRPV1 is required for the proper transduction of the major TCR-mediated signaling events and is necessary for the subsequent T-cell cytokine production. Genetic and pharmacological inhibition of TRPV1 in human CD4+ T cells resulted in an impaired T cell activation profile similar to that observed in murine Trpv1-/- CD4+ T cells. In vivo, TRPV1 has an indispensible role in the acquisition of inflammatory properties by CD4+ T cells in two models of inflammatory bowel disease (IBD). These findings suggest that the inhibition of TRPV1 might be implemented to restrain pathogenic CD4+ T cell responses as it occurs in chronic inflammatory diseases such as IBD.

The role of ADAM10 in B cell biology

N. Chaimowitz*, R. Martin, L. Dean, D. Conrad;*
Virginia Commonwealth University, Richmond, VA, United States.

A disintegrin and metalloproteinase 10 (ADAM10) is a zinc dependent proteinase related to matrix metalloproteinases. ADAM10 has emerged as a key regulator of cellular processes by cleaving and shedding extracellular domains of multiple transmembrane receptors and ligands. In particular, ADAM10 has been identified as a key regulator of lymphocyte development. Here we report that ADAM10 is dispensable for early B cell development within the bone marrow. However, deletion of ADAM10 from all peripheral B cells or in post-switch cells leads to severe impairments in humoral responses. When ADAM10 was deleted from all peripheral B cells, a decrease in antigen specific IgG production was seen both with respect to serum levels and IgG ASCs, indicating that plasma cell (PC) differentiation is influenced. Cells producing high affinity antigen specific antibodies were particularly affected, consistent with defects in germinal center (GC) reactions. Moreover, changes in lymphoid architecture were also observed. Consistent with these findings, follicular dendritic cell (FDC)-reticula was undetectable following immunization. On the other hand, when ADAM10 was deleted in post-switch B cells, GC formation and lymphoid architecture were not impaired. Despite normal architecture, however, antibody production was still affected, likely due to abnormal gene expression in ADAM10-deficient PCs. Consistent with this hypothesis, PCs isolated from ADAM10Δ/ΔIgG1-cre+/- showed decreased expression of genes that facilitate plasma cell differentiation and function and increased expression of Bcl6, an inhibitor of PC differentiation. Our results thus demonstrate that B cell ADAM10 expression is necessary for optimal humoral responses.

P3.01.02
Roles of Polycomb group proteins in the maintenance of T cell fate

T. Ikawa[1], *H. Koseki*[1], *H. Kawamoto*[2];
[1]*Riken, RCAI, Yokohama, Japan,* [2]*Department of Immunology, Kyoto University, Kyoto, Japan.*

Cell fate is determined by the combination of lineage-specific gene regulatory programs and epigenetic regulation. We have previously shown that the transcription factor Bcl11b is essential for T cell lineage commitment (Ikawa et al. Science, 2010). However, the mechanisms that maintain the T cell fate after the commitment remain elusive. Here, we show that the Polycomb group (PcG) proteins play a key role in this process. PcG proteins are epigenetic gene silencers that are implicated in the maintenance of embryonic and adult stem cells. We have generated the conditional mutant mice of Ring1A/B (LckCre-Ring1A-/-Ring1Bfl/fl) to study the role of Ring1A/B in T cell development. The number of total thymocytes of Ring1A/B cKO mice was 10-20 times smaller than that of control mice. Most of the cells were blocked at early CD4-CD8- (double negative: DN) stage. The T cell development was only partially rescued by crossing Cdkn2a-/- mice, suggesting that the existence of other target genes of PcG proteins in the T cell differentiation. Interestingly, ectopic expression of B cell lineage-associated genes (CD19, Ebf1, Blnk, and Irf4) were found in DN cells from Cdkn2a, Ring1A/B TKO mice. The ChIP analysis showed that the Ring1B and histon H3K27 trimethylation is highly enriched in the regulatory regions of B lineage-associated genes in normal thymocytes. We are currently examining the lineage promiscuity of these DN cells in TKO mice for the role of PcG proteins in the maintenance of T cell fate after the T cell lineage commitment.

P3.01.03
The repression of myeloid genes by Bach family restricts common lymphoid progenitors fate to B cell lineage

A. Itoh-Nakadai[1,2], *R. Hikota*[1], *M. Matsui-Watanabe*[1], *M. Kobayashi*[1], *A. Muto*[1,2], *K. Igarashi*[1,2];
[1]*Department of Biochemistry Tohoku University graduate school of medicine, Miyagi, Japan,* [2]*CREST, Japan Science and Technology Agency, Sendai, Japan.*

Cell differentiation in multicellular organisms requires specification (the activation of a lineage-specific program) and commitment (the inhibition of alternative programs), in which the progressive gain and loss of lineage programs are orchestrated by the concerted action of transcription factors. B cell lineage specification and commitment are both dependent on the activity of early B cell factor-1 (EBF1). EBF1 directly promotes the expression of B cell specific genes, and establishes the transcriptional network for pro-B cell development. However, B-lineage commitment mechanism regulated by EBF1 is unclear. While the transcription factor Bach1 is ubiquitously expressed, Bach2 is specifically expressed in B-lineage cells. An analysis of compound Bach1/Bach2-deficiency (DD) suggests that these genes play critical function in the development of early B cells. We found that the expression of Bach2 preceded that of EBF1 in CLPs, and an overexpression of Bach2 in multipotent progenitors (MPPs) induced the differentiation of B220+ B cells and repressed the differentiation of CD11b myeloid in vitro. In DD mice, the numbers of CLPs and all stages of B cells significantly decreased. DD CLPs exhibited a lower frequency of B cell colony formation than WT cells, indicating a cell autonomous defect in the lineage choice. The expression of B cell specific genes decreased in DD CLPs, with concomitant manifestation of myeloid-association genes. We suggest that, in B cell development, specification is carried out by EBF1 and commitment is executed by Bach factors.

P3.01.04
FoxN1 is a Direct Transcriptional Regulator of Delta-like 4 in Thymic Stromal Cells

K. Kianizad[1], *H. Naik*[2], *D. K. Shah*[2], *M. Mohtashami*[2], *J. C. Zuniga-Pflucker*[1];
[1]*Sunnybrook Research Institute, University of Toronto, Toronto, ON, Canada,* [2]*Sunnybrook Research Institute, Toronto, ON, Canada.*

Notch signaling is a vital cue provided by thymic stromal cells (TSCs) to direct lymphocyte progenitors to become T-cells. This signaling is critical to enforce the T-cell fate to the progenitors emigrating from the bone marrow. The Notch ligand, Delta-like 4 (Dll4), is expressed by TSCs and is essential for Notch triggering within the thymus. Despite its importance, the molecular regulators of Dll4 expression remain unknown. We showed that Dll4 mRNA is lost in thymic stromal monolayer cultures (TSMCs). Our recent work demonstrates that this loss is quite rapid with only 2-10% of initial Dll4 mRNA levels remaining after 4h of culture. FoxN1 is an important transcription factor for successful TSC differentiation, and a candidate regulator of Dll4 expression. Not only was FoxN1 lost with similar kinetics in TSMCs, when ectopically expressed in the stromal cells, we noted an increase in Dll4 mRNA levels. Furthermore, there are 5 putative FoxN1 binding sites in the proximal promoter of Dll4, and the 3' UTR of Dll4 mRNA contains canonical AU-Rich elements (ARE), suggesting that ARE-mediated transcript degradation might affect Dll4 mRNA maintenance. Our recent results showed that activated p38, a kinase regulating ARE containing mRNA stability, is absent in TSMCs. We are now examining the role of the ARE pathway in Dll4 mRNA maintenance and the identity of the potential p38-dependent signals that control its function. By understanding Dll4 regulation, we will gain insight not only into the biology of the thymus but how structure affects function at the molecular level.

P3.01.05
Features of colony-forming cells-fibroblast precursors circulating in biological fluids

O. V. Lebedinskaya*;*
Acad. E.A. Wagner Perm State Medical Academy, Perm, Russian Federation.

Blood, transudation and exudate of serous sacs from different laboratory animals were examined to reveal clonogenic cells-fibroblast precursors therein (CFC-F). Guinea pig blood, peritoneal, pleural and pericardial fluids of rabbits, guinea pigs and rats, as well as rat peritoneal exudates demonstrated clonogenic cells that form fibroblast-like cell colonies in primary monolayer cultures. For the most part these belong to the population of inducible osteogenic cells-precursors. Inducible cells-precursors being detected in biological fluids according to their properties that are the degree of dependence on age and strains of animals, on the culture conditions - density of explanted cells, the presence of feeder (irradiated cells of allogenic or syngeneic bone marrow), gaseous medium composition, were found by morphology and diameter of their formed colonies, morphohistochemical peculiarities of their composing elements to be identical to stromal cells-precursors of bone marrow. Highest degree of correlation (over 0,8) was detected between clonogenic cells of bone marrow and peritoneal transudation, peritoneal transudation and exudate from rats with respect to dependence of CFC-F numbers and ECO-F values on animal age and density of explanted cells. Analysis of cell immunophenotype in monolayer cultures of cellular elements from murine peritoneal transudation demonstrates CD80+ cell predominance (63,4%), expression of MHCI (83,3%), some CD34+ cells and macrophages (20,0 and 21,8%, respectively). Guinea pig blood being taken from different sites of cardiovascular system demonstrates that highest level of CFC-F number is observed in blood outflowing from hematopoietic organs. Greatest proliferative activity possess clonogenic precursors being revealed in venous portions of circulatory system.

P3.01.06
Protein kinase CK2beta is an essential regulator of peripheral B cell development

F. Zaffino[1,2], *S. Manni*[1,2], *E. Mandato*[1,2], *L. Quotti Tubi*[1,2], *A. Brancalion*[1,2], *N. Compagno*[1], *B. Boldyreff*[3], *O. Filhol-Cochet*[4], *G. Semenzato*[1,2], *F. Piazza*[1,2];
[1]*Department of Medicine - University of Padova, Padova, Italy,* [2]*Venetian Institute of Molecular Medicine, Padova, Italy,* [3]*KinaseDetect ApS, Odense, Denmark,* [4]*INSERM, Grenoble, France.*

Serine-threonine kinase CK2 is involved in oncogenesis of B-cell derived tumors chronic lymphocytic leukemia and multiple myeloma. To gain insights into its role in B-lymphocytes, we generated CK2β conditional knockout mice in B-cells. Non B-cell lineages were normal in CD19-CRE CK2βflox/flox mice. In the bone marrow, CD19-CRE CK2βflox/flox mice displayed a reduction of B-cells and the B220high IgMhigh recirculating population was found dramatically reduced. B-cell progenitors were apparently not affected by CK2β loss. On the contrary, B220+ CD19+ B-cells in peripheral blood, lymph-nodes, spleen and peritoneal cavity were markedly reduced. However, splenic IgDlow IgMhigh B-cell subset was reduced whereas we observed an increase of the IgDhigh IgMlow population, indicating an imbalance between the frequency of follicular (FO) and marginal zone (MZ) B-cells. Detailed FO and MZ B-cell populations analysis showed that FO B-cells were reduced by approximately 35-40% (from 72% to 45%), whereas MZ B-cells were increased up to three folds (from 8.5% to 23%). Histological analysis of CD19-CRE CK2βflox/flox spleens revealed a reduction of the size of follicles, absence of spontaneous germinal centers and an expansion of the interfollicular-marginal zone areas. In vitro class switch recombination assays demonstrated a moderate impairment in IgG1 and IgG3 class switch. In vitro cell cycle analysis experiments suggested an impairment in G1-S and S-G2 transition of CD19-CRE CK2βflox/flox B cells. Results of in vivo experiments testing T-cell dependent and T-cell independent responses will be described.
Our results place CK2β as a novel regulator of B-lymphocyte development and survival.

P3.01.07
Poly(ADP-ribose)polymerase-1 (PARP-1) negatively controls regulatory T cell differentiation

F. Novelli[1], *E. Bennici*[1], *F. Laudisi*[1,2], *M. Sambucci*[1,3], ***C. Pioli***[1];
[1]*ENEA, Laboratory of Radiation Biology and Biomedicine, Rome, Italy,* [2]*Singapore Immunology Network (SIgN), Singapore, Singapore,* [3]*Cytokine Signaling Unit, Institute Pasteur, Paris, France.*

Poly(ADP-ribose)polymerase-1 (PARP-1) plays a relevant role in inflammatory/immune responses by affecting leukocytes activation and differentiation. Our previous findings showed that PARP-1KO mice display increased numbers of regulatory $CD4^+CD25^+/Foxp3^+$ T cells in thymus, spleen and lymph nodes compared with WT controls. We wondered whether PARP-1 affects differentiation, function and stability of Treg cells. Purified PARP-1KO naïve CD4 cells stimulated in the presence of TGFβ1 expressed Foxp3 mRNA at higher level and generated a higher number of $Foxp3^+$ inducible Treg cells (iTregs) than WT control cells. This finding was not due to a higher resistance to apoptosis induction but rather to a higher conversion rate to $Foxp3^+$ iTreg cells. PARP-1KO iTreg cells showed features (anergy, CTLA-4 expression) similar to WT cells. We also analyzed naturally occurring Treg cells and found that lack of PARP-1 did not affect Treg cell phenotype (CTLA-4, GITR) and functions. Indeed PARP-1KO Treg cells inhibited proliferation and cytokine production in freshly isolated $CD4^+CD25^-$, and in Th1- and Th2-polarized cells as efficiently as WT Treg cells. PARP-1KO Treg cells also controlled the graft versus host response in a MHC-mismatched model. We also wondered whether lack of PARP-1 could affect the stability of the Treg cell phenotype. Preliminary results showed that in the presence of inflammatory stimuli a higher percentage of PARP-1KO Treg cells maintained Foxp3 expression compared with WT Treg cells. In conclusion, our findings demonstrate that PARP-1 affects Treg cell differentiation contributing to the regulation of Foxp3 mRNA expression.

P3.01.08

The critical role of NADPH oxidase on inducible bronchus-associated lymphoid tissue formation in newborn mice

T. Shen[1], *Y. Lin*[1,2], *C. Shieh*[1,2];
[1]*Institute of Clinical Medicine, College of Medicine, National Cheng Kung University, Tainan, Taiwan,* [2]*Department of Pediatrics, National Cheng Kung University Hospital, Tainan, Taiwan.*

Inducible bronchus-associated lymphoid tissue (iBALT), an ectopic lymphoid tissue in respiratory epithelium, is associated with chronic lung diseases. Previous studies have shown that dendritic cells are crucial for iBALT formation. However, how leukocytes participate in the early iBALT formation remains unclear. Reactive oxygen species (ROS) produced by the activated oxidase (NOX2) of leukocytes have been known to be essential for immune defense, immunoregulation and leukocyte trafficking. In this study, we investigated the role of leukocyte-produced ROS on iBALT formation using a murine model. After repeated neonatal stimulation with lipopolysaccharide (LPS) through the airway, we found that there was well-organized iBALT formation, which was composed of T- and B-cell areas and high endothelial venules in young C57BL/6 mice. When comparing the iBALT induction of wild-type (WT) and neutrophil cytosolic factor 1 (p47phox component of NOX2) knockout ($Ncf1^{-/-}$) mice, we found that the number of well-organized iBALT formation decreased in $Ncf1^{-/-}$ mice. Although there were no significant differences in the number of $CD3^+$ T cell and $B220^+$ B cell in the lung, there were more iNOS-expressing cells within the iBALT increased nitrosylation in the lung tissue of WT mice. In addition, the airway hyperresponsiveness was higher in WT than that in $Ncf1^{-/-}$ mice after toluene diisocyanate stimulation. In conclusion, our study showed that leukocyte-produced ROS are critical for the formation of iBALT in LPS-stimulated newborn animals. The LPS-induced iBALT may exacerbate the airway hyperresponsiveness in chemical-induced asthma later in the development.

P3.01.09
Plasticity of antigen-specific Th17 and Regulatory T Cells in response to environmental cues

G. P. Tejón[1,2], *V. Manríquez*[1], *J. R. Mora*[2], *M. R. Bono*[1], *M. Rosemblatt*[1,3,4];
[1]*Departamento de Biología, Facultad de Ciencias, Universidad de Chile, Santiago, Chile,* [2]*Gastrointestinal Unit, Massachusetts General Hospital, Harvard Medical School, Boston, MA, United States,* [3]*Fundacion Ciencia & Vida, Santiago, Chile,* [4]*Facultad de Ciencias Biológicas, Universidad Andrés Bello, Santiago, Chile.*

Introduction. Th17 and regulatory T cells (Tregs) have been identified as independent T cell subsets bearing different effector functions. However accumulating evidence suggests that T cell phenotypes are more plastic than previously appreciated and that Treg convert to Th17 under appropriate conditions. In this study we analyzed the environment-induced reprogramming capacity of antigen-specific Th17 and Treg cells.
Materials and Methods. We adoptively transferred CD45.1 antigen-specific induced Tregs (iTreg) or Th17 cells generated in vitro into congenic (CD45.2) mice pre-treated in order to induce either inflammation or oral tolerance. Spleen, lymphoid organs and lamina propria were dissected at different time points and cells were analyzed to assess Foxp3 expression, IL-17 and IFN-γ production on the transferred cells.
Results. Our results indicate that under inflammatory conditions iTreg can be reprogrammed into Th17 or Th1 -like cells in vivo. On the other hand, adoptively transferred Th17 cells partially lost IL-17 production while upregulating Foxp3 expression after induction of oral tolerance, a result that is consistent with the conversion into Treg cells.
Discussion. Our data demonstrates a reciprocal plasticity in Treg and Th17 cell programs under condition of immune response and tolerance induction. A better understanding of the mechanisms controlling reprogramming in these cells should provide important tools for designing immunotherapeutic strategies to control autoimmunity and infections.

P3.02 Role of the stroma in innate and adaptive immunity

P3.02.01
Thymocyte selection regulates the homeostasis of IL-7-expressing thymic cortical epithelial cells in vivo

A. R. Ribeiro[1], *P. Rodrigues*[1], *C. Meireles*[1], *J. P. Di Santo*[2], ***N. L. Alves***[1];
[1]*Institute for Molecular and Cell Biology, Porto, Portugal,* [2]*Institut Pasteur, Paris, France.*

Thymic epithelial cells (TECs) help orchestrate thymopoiesis and TEC differentiation relies on bidirectional interactions with thymocytes. While the molecular mediators that stimulate medullary TEC (mTEC) maturation are partially elucidated, the signals that regulate cortical TEC (cTEC) homeostasis remain elusive. Using IL-7 reporter mice, in which YFP expression identifies TECs that co-express high levels of the essential thymopoietin IL-7 (Il7YFP+TECs), we show that Il7YFP+TECs reside within the CD205+Ly51+CD40lo cTEC lineage that co-expresses Dll4, Ccl25, Ctsl, Psmb11, Prss16, Ccrl1 and segregates from CD80+CD40himTECs expressing Tnfrsf11a, Ctss and Aire. Analysis of Ccrl1/IL-7 double reporter mice corroborates that Il7YFP+TECs define a cTEC subset. We find that the frequency of Il7YFP+TECs gradually declines as mTEC development unfolds. Using thymic organotypic cultures, we report that the thymocyte-induced reduction in Il7YFP+TECs dissociates from the RANK-mediated differentiation of CD80+mTECs, suggesting that Il7YFP+TECs are not direct mTEC precursors. Il7YFP+TECs are sustained in Rag2-/- mice, even following in vivo anti-CD3ε treatment that mimics the process of pre-TCR β-selection of thymocytes to the double-positive (DP) stage. Using Marilyn-Rag2-/- TCR transgenic, we find that positive selection into CD4 lineage moderately reduces the frequency of Il7YFP+TECs, while negative selection provokes a striking loss of Il7YFP+TECs. These results infer that the strength of MHC/peptide-TCR interactions between TECs and thymocytes during selection constitutes a novel rheostat that controls the maintenance of the IL-7-expressing cTECs.

P3.02.02
Host-derived osteopontin drives the metastatic spread of breast cancer tuning the immunesuppressive microenvironment of the lung niche

C. Chiodoni[1], *C. Tripodo*[2], *S. Sangaletti*[1], *I. Torselli*[1], *M. P. Colombo*[1];
[1]*Fondazione IRCCS Istituto Nazionale Tumori, Milan, Italy,* [2]*University of Palermo, Palermo, Italy.*

The matricellular protein osteopontin (OPN) has been involved in malignant transformation, tumor progression and metastasis. Nevertheless, while the pro-tumorigenic and pro-metastatic activity of tumor-derived OPN has been widely reported, the role of host-derived OPN has not been determined yet.
To solve such issue, we have injected into OPN-deficient mice 4T1 mammary tumor cells, spontaneously metastatizing to the lungs when injected into the mammary fat-pad, and found a significant reduction in lung metastases, despite similar primary tumor size. The growth of 4T1, as for the vast majority of tumors, is associated with the expansion of a heterogeneous immature myeloid population that contributes to its progression and metastatization. These cells, collectively referred as myeloid derived suppressor cells (MDSC), comprise a granulocytic (Gr-1high) and a monocytic (Gr-1int/low) subset, endowed with a higher immune suppressive capacity. Analysis of such population showed that the inhibition of lung metastases in OPN-deficient mice goes along with a skewing of MDSC polarization toward the Gr1high subset, whereas the Gr1int/low subset is more expanded in wild-type mice. Moreover, the latter subset, sorted from lungs of tumor-bearing OPN-deficient animals, is less suppressive in vitro toward CD8 T cells than its wild-type counterpart, and associated with a lower expression of arginase-1 and phospho-STAT3. Furthermore, we have also found in the lungs of OPN-deficient tumor bearing mice a reduction in another suppressive population, T regulatory FoxP3+ cells. All together, these data suggest that OPN is a regulator of the local immune response and a gatekeeper for metastatic colonization of the lung niche.

P3.02.03

In vivo evidence on mesenchymal stromal cells modulates the lymphomyeloid lineage commitment

S. Chou;
FU-JEN Catholic University, Department of Life Science, New Taipei City, Taiwan.

The development of hematopoietic stem/ progenitor cells (HSC/HPC) to immune lineage cells is regulated within the marrow microenvironment. Mesenchymal stromal cells (MSCs) is known to exhibit two key features that MSCs enhance the graft engraftment and hematopoietic reconstitution, but inhibit the host T cell activation to alloantigen challenged after allogeneic hematopoietic stem cell (HSC) transplantation. However, little is known about how MSCs affect immune cell lineage commitment. Here, we demonstrate that in vivo MSCs treatment could effect on both HSC differentiation and their microenvironment. MSCs obtained from bone marrow, amniotic fluid, and placenta were used in this study. In vitro, all types of MSCs expand HSCs, enhance multiple hematopoietic lineage development, and inhibit CD3 positive T cell functional activities. In a murine model of sub-lethal total body irradiation (TBI) showed that all MSCs reversed TBI-induced apoptotic program and decreased the loss of functional HPCs. In vivo MSCs increased LSK cell number and functional activity without inhibiting their differentiation. Detailed immunophenotyping demonstrated a MSCs-dependent increase in short-term HSCs/multipotent progenitors, as well as, MSCs elevated bone marrow HSCs to differentiate into myeloid progenitors (GMP) and pre-B lymphoid progenitors in the marrow. However, all types of MScs have significantly increased the differentiate outcome to B cells and NK cell lineage populations but inhibit the T cell lineage development and its functional activities in thymus, spleen, and blood. These data strongly suggested that the actions of MSCs on front-end and terminal of immune cells development may mediated by the different regulatory mechanisms.

P3.02.04
Thymic Nurse Cells from diabetic mice present phenotypic and functional alterations and express leptin receptor

C. Francelin[1], *R. Di Gangi*[1], *I. Geniseli*[1], *P. Nagib*[2], *J. Gameiro*[3], *T. Alves da Costa*[1], *R. Thomé*[1], *D. Villa-Verde*[4], *L. Verinaud*[1];
[1]*State University of Campinas, Campinas, Brazil,* [2]*Federal University of Goiânia, Goiânia, Brazil,* [3]*Federal University of Juiz de Fora, Juiz de Fora, Brazil,* [4]*Oswaldo Cruz Foundation, Rio de Janeiro, Brazil.*

Thymic nurse cells (TNCs) represent a particular model for thymic epithelial cells and thymocyte interactions since they are large epithelial cell that completely envelops about 2-
200 viable thymocytes, mostly CD4+CD8+ thymocytes. Since thymus is under an intense endocrine control, it is not surprising that leptin hormone plays an important role in maintaining the thymus structure and functionality. Previously, we have observed, during the hypoinsulinemia condition, that intrathymic leptin levels were decreased. Severe thymic alterations in both lymphoid and epithelial compartments were also seen. Here, we evaluated phenotypical and morphological alterations in TNCs from experimentally induced-diabetic mice. Phenotypic TNCs analysis, performed by optical and scanning electron microscopy, and by flow cytometry technique, revealed decreased numbers of TNCs isolated from diabetic mice and an increased proportion of small-sized TNCs, which contained few thymocytes. The observation of primary cultures of TNCs has also revealed an alteration in the pattern of thymocyte released by these cells and an increase of annexin positive TNCs isolated from diabetic mice. In addition, by immunohistochemistry, our results demonstrated that TNCs express leptin receptors and that leptin is produced by thymocytes released from the TNC interaction in control and diabetic mice. We conclude that TNCs from diabetic mice present morphological and functional alterations that may compromise both the development and the selection of the repertoire of T cells. Also, to our knowledge, this is the first time that the expression of leptin-receptor in TNCs is reported. This work was supported by FAPESP grants (#2010/19558-3 & #2010/06831-3).

P3.02.05
CD49b regulates the establishment and maintenance of T helper cell memory

A. Hanazawa[1,2], *K. Tokoyoda*[1,2];
[1]*German Rheumatism Research Center Berlin, Berlin, Germany,* [2]*Department of Immunology, Graduate School of Medicine, Chiba University, Chiba, Japan.*

We have demonstrated that professional memory CD4 T cells reside and rest in the bone marrow (BM) adhering to IL-7-expressing stromal niches. Their absence induces a defective generation of high-affinity long-lived plasma cells. However, the molecular mechanisms on their establishment and maintenance remain unclear. We here demonstrate the roles of CD49b, which is also called integrin alpha2 and is expressed on most memory CD4 T cells, in the establishment and maintenance of memory CD4 T cells in the BM. We first counted antigen-specific effector and memory CD4 T cells in immunized CD49b-deficient and wild-type mice. The number of CD49b-deficient memory CD4 T cells was significantly impaired compared to wild-type cells, while the number of effector cells in both mice was comparable. So, to clarify why CD49b-deficient memory CD4 T cells are not generated, we transferred CD49b-deficient effector CD4 T cells into naive mice and evaluated their migration ability into the BM. The loss of CD49b induced a defective migration of effector cells into the BM. Then, to examine a role of CD49b in the maintenance of memory CD4 T cells, we inhibited the integrin during memory phase with injection of Fab fragments of anti-CD49b neutralization antibodies. The inhibition of CD49b reduced the number of memory CD4 T cells in the BM. We suggest that CD49b regulates the establishment and maintenance of memory CD4 T cells controlling the immigration of memory cell precursors into the BM and also the persistence of memory CD4 T cells on their survival niches.

P3.02.06
Effects on vaccine memory after Doxorubicin treatment of healthy Rhesus Macaques

H. Ingelman-Sundberg[1], *S. Eksborg*[2], *K. Haanstra*[3], *M. Jonker*[3], *A. Nilsson*[1];
[1]*Karolinska Institutet, Stockholm, Sweden,* [2]*Karolinska University Hospital, Stockholm, Sweden,* [3]*Biomedical Primate Research Center, Rijswijk, Netherlands.*

It has previously been shown that children treated with chemotherapy for leukemia loose immunity they acquired from the childhood vaccination program. In this study, we aim to map the detailed events of the B-cell memory upon immunosuppressive treatment.
Healthy Rhesus Macaques, previously vaccinated against measles, were treated with 3 doses of either high-dose Doxorubicin (n=5) or NaCl solution (n=5), and the cellular and serological effects were evaluated. Interestingly, the peripheral lymphocyte and monocyte levels decreased only transiently after each dose of Doxorubicin, whereas the B-cell counts failed to recover in the treatment-free periods between the doses – in two animals also after cessation of treatment. This occurred in spite of high serum levels of the B-cell homeostasis protein BAFF, showing a pulsatile increase after every dose. The antibody titers remained stable throughout the treatment period, and 5 months after administration of the last dose. Probably, a direct effect on titers is seen only after more repeated dosing for a longer period. Ongoing research is now directed to quantify antigen-specific bone marrow plasma cells and memory B-cells from lymphoid organs, in order to further understand how chemotherapy interferes with vaccine memory. This may lead to a better understanding of how it can be protected during immunosuppressive treatment.

P3.02.07

Expression of IL-4 Receptor alpha on smooth muscle cells is not necessary for development of experimental allergic asthma

F. Kirstein[1], *W. G. C. Horsnell*[1], *A. L. Lopata*[2], *D. Kuperman*[3], *D. J. Erle*[4], *F. Brombacher*[1];
[1]*University of Cape Town, Cape Town, South Africa,* [2]*James Cook University, Townsville, Australia,* [3]*Northwestern University, Chicago, IL, United States,* [4]*University of California, San Francisco, CA, United States.*

Airflow in the lungs of patients with allergic asthma is impaired by excessive mucus production and airway smooth muscle contractions. Elevated levels of the cytokines IL-4 and IL-13 are associated with this pathology. In vitro studies have suggested that IL-4 receptor alpha signalling on smooth muscle cells is critical for airway inflammation and airway hyperresponsiveness.
In order to define the contribution of IL-4 and IL-13 to the onset of asthmatic pathology the role of their key receptor IL-4Ralpha in smooth muscle cells was examined in vivo.
By using transgenic SMC-MHCcreIL-4Ralpha-/lox mice deficient for IL-4Ralpha in smooth muscle cells, effects of impaired IL-4Ralpha signalling in these cells on the outcome of asthmatic disease were investigated. Allergic asthma was introduced in mice by repeated sensitisation with ovalbumin/alum followed by intranasal allergen challenge. Mice were investigated for the presence of airway hyperresponsiveness, airway inflammation, allergen specific antibody production, Th2 type cytokine responses and lung pathology.
Airway hyperresponsiveness, airway inflammation, mucus production, Th2 cytokine production and specific antibody responses were unaffected in SMC-MHCcreIL-4Ralpha-/lox mice when compared to control animals.
The impairment of IL-4Ralpha on smooth muscle cells had no effect on major aetiological markers of allergic asthma. These findings suggest that IL-4/IL-13 responsiveness in airway smooth muscle cells during the early phase of allergic asthma is not, as suggested, necessary for the outcome of the disease. Therefore, therapies targeting the IL-4Ralpha might have no direct effect on smooth muscle cells in an allergic asthma response. (J Allergy Clin Immunol 2010;126:347-54.)

Skin-resident fibroblasts create unique niches for regulating ATP-mediated mast cell activation

Y. Kurashima[1,2,3], *T. Amiya*[1,2,4], *K. Fujisawa*[1,2], *S. Sato*[1,2], *Y. Kogure*[1], *J. Kunisawa*[1,2,5], *H. Kiyono*[1,2,4];
[1]*Division of Mucosal Immunology, Department of Microbiology and Immunology, The Institute of Medical Science, The University of Tokyo, Tokyo, Japan,* [2]*Core Research for Evolutional Science and Technology (CREST), Japan Science and Technology Agency (JST), Tokyo, Japan,* [3]*Division of Infectious Genetics, Department of Microbiology and Immunology, The Institute of Medical Science, The University of Tokyo, Tokyo, Japan,* [4]*Department of Medical Genome Science, Graduate School of Frontier Science, The University of Tokyo, Chiba, Japan,* [5]*Laboratory of Vaccine Materials, National Institute of Biomedical Innovation, Ibaraki-shi, Osaka, Japan.*

Mast cells (MCs) play critical roles in both protective immunity against pathogenic microorganisms and the development of inflammatory responses. We previously reported that colonic MCs highly expressed one of the receptors for extracellular adenosine triphosphate (ATP), called P2X7, which was involved in the ATP-mediated excessive inflammatory symptom. Therefore, the suppression of P2X7-mediated MC-activation led to the inhibition of colitis. Here, we found that expression levels of P2X7 on MCs were different among tissues. Especially, the P2X7 expressions on skin MCs were significantly lower than that of MCs in other tissues. Along with this finding, only in the MCs from skin compartment, ATP-induced cytokine and chemokine productions were not observed. P2X7 expression was decreased when bone-marrow-derived MCs (BMMC) were adoptively transferred into the skin of MC-deficient $Kit^{W\text{-}sh/W\text{-}sh}$ mice, indicating that extrinsic inhibitory mechanisms exist specifically in the skin region. In agreement with this finding, co-culture of BMMCs with skin fibroblasts but not with stromal cells from other tissue resulted in the reduction of P2X7
expression in BMMCs. In addition, co-culture system using transwell plate indicated that cell-cell contact was not required for the inhibition of P2X7. Consequently, ATP-mediated cytokines and chemokine production were inhibited in skin co-cultured MCs. Our novel findings demonstrate skin-resident fibroblasts create unique niches for regulating homeostasis network by inhibition of P2X7 expression and function in MCs.

P3.02.09

PI3K p110δ controls stromal cell distribution and is expressed in gp38+ stromal cells in secondary lymphoid organs

T. M. Zotes[1], *S. Pérez-Yagüe*[1], ***R. Spada***[1], *C. O. Sorzano*[1], *K. Okkenhaug*[2], *B. Vanhaesebroeck*[3], *A. C. Carrera*[1], *D. F. Barber*[1];
[1]*Centro Nacional de Biotecnología (CSIC), Cantoblanco (Madrid), Spain,* [2]*Babraham Institute, Cambridge, United Kingdom,* [3]*Institute of Cancer (Queen Mary University of London), London, United Kingdom.*

Stromal cells create a network that physically supports lymphocyte displacement and anchorage of antigen-presenting cells and secrete chemokines involved in lymphocyte homing. Lack of PI3K p110δ subunit or catalytic activity in mice provokes structural anomalies in secondary lymphoid organs (SLO), which suggests a role for p110δ in their formation and maintenance. We tested whether lack of p110δ activity affects the immune response, not only through its role in lymphoid cells but also in stromal cells. We used p110δD910A/D910A mice, which express a catalytically inactive p110δ form, for bone marrow reconstitution assays. In lethally irradiated p110δWT/WT and p110δD910A/D910A mice reconstituted with total bone marrow from p110δWT/WT or p110δD910A/D910A donors, we studied total lymphoid cell number and the distribution of lymphoid cell subsets in homeostatic conditions and after antigen stimulation. We also analyzed the distribution and texture of SLO stromal cell populations in p110δWT/WT and p110δD910A/D910A mice and tested whether p110δ is expressed in those cells. Spleen structure in p110δWT/WT mice (organized) was similar to that of p110δWT/WT recipients reconstituted with p110δWT/WT or p110δD910A/D910A bone marrow, whereas that of p110δD910A/D910A mice (disorganized) was similar to that of p110δD910A/D910A mice reconstituted with p110δWT/WT or p110δD910A/D910A bone marrow. These findings suggest a role for p110δ in SLO stroma. p110δD910A/D910A SLO showed severe defects in T cell zone stromal cell distribution and impaired secretion of chemokines involved in T cell homing to SLO. Our data identify p110δ expression in gp38+ SLO stromal cell subsets and highlight the importance of these cells in immune response generation.

P3.02.10

Prostate cancer-associated stroma induces immunosuppressive monocytes

L. K. Spary, *J. Salimu, M. D. Mason, Z. Tabi;*
Institute of Cancer and Genetics, Cardiff University, Cardiff, United Kingdom.

The presence of monocytes within the tumour microenvironment of prostate cancer (PCa) patients is associated with poor prognosis. Increased numbers of $CD8^+$ T lymphocytes, however, correlate with a more favourable outcome. Although the immune modulatory effects of tumour cells have been studied widely, the role of PCa-associated stroma on the infiltration and the subsequent function of immune cells are largely unknown and are the subjects of this study. Isolating, culturing and characterising PCa-associated primary stromal cells from patients undergoing radical retropubic prostatectomy provided us with a unique and relevant cell type to carry out this study. We demonstrate that stromal cells produce monocyte chemotactic protein-1 (MCP-1) which triggers the migration of undifferentiated monocytes towards PCa-associated stroma. In the presence of tumour stroma, differentiation of monocytes into dendritic cells (DC) is uncharacteristic, consisting of high CD14 expression and elevated levels of immunosuppressive markers, such as programmed cell death ligand-1 (PD-L1) and CD200R, both able to induce T cell dysfunction. Raised levels of the immunosuppressive cytokine IL-10 are also present in monocytes cultured in the presence of PCa-associated stromal cells whilst levels of the stimulatory cytokine IL-12 are dramatically reduced. These monocytes are efficient phagocytes that are able to engulf antigens but their antigen-processing

mechanism is impaired as they are inefficient in cross-presenting these antigens to cytotoxic T cells. Our data provides strong evidence that PCa-associated stroma plays an important role in negatively regulating cellular immune responses in the tumour microenvironment, indicating the need for simultaneous targeting of tumour and stroma alike.

P3.02.11
Analysis of tumor microenvironment and immune responses against cancer stem cells and application to cancer immunotherapy

***T. Torigoe**, Y. Hirohashi, R. Morita, K. Yasuda, A. Takahashi, T. Kanaseki, N. Sato;*
Sapporo Medical University, Sapporo, Japan.

Cancer stem cells (CSCs), a small population of cancer cells with stem cell-like phenotype and tumor-initiating capacity, are important targets for cancer therapy because they are considered to be responsible for recurrence after chemotherapy. In order to clarify immunopathological properties of CSCs, CSCs with high capacity of tumor initiation were collected from various cancer cell lines by sorting a side population or ALDH1-positive cells. By comparative gene expression analysis of CSCs derived from human solid cancer cell lines, several CSC genes were identified, including SOX2, SMCP, DNAJB8 and OR7C1. These genes were expressed preferentially in CSCs, but barely detected in normal adult tissues except for testis. RNAi-mediated knockdown of the genes dramatically decreased the tumorigenic capacity, indicating that the genes could be associated with tumor-initiating capacity of CSCs. We could induce CSC-specific cytotoxic T-cells (CTLs) from peripheral blood lymphocytes of cancer patients after in vitro stimulation with CSC antigenic peptides. CSCs were susceptible to cytotoxicity of CTLs, while they were resistant to chemotherapeutic drugs. In addition, adoptive transfer of CSC-specific CTLs showed higher tumor suppressive capacity in vivo in a mouse transplantation model. On the other hand, some CSCs modulated tumor microenvironment through the interaction with stromal fibroblasts. Our findings highlighted novel CSC-specific antigens and important roles of stromal fibroblasts for the antigenicity and immune escape of CSCs.

P3.02.12
Aggregates of B cells and platelet MPs circulate in the human peripheral blood

***F. Yari**, M. Esmaeili, Z. Sharifi, M. Nikougoftar;*
Research center of Iranian Blood Transfusion Organization, Tehran, Iran.

Objective: Activated platelets shed microparticles (MPs) in vivo and definitely in vitro upon aging under storage. Like platelets, platelet MPs contribute to hemostatic and inflammatory responses. We sought to determine the interactions between platelet MPs and peripheral B lymphocytes in the healthy blood circulation to propose a possible role for platelet MPs in the regulation of B cell function.
Materials and Methods: Isolated B cells were studied for binding to platelet MPs using flow cytometry technique. Additionally, ELISA method was also used to demonstrate binding of MPs to B cells in the human blood. Moreover, new binding capabilities of B cells for MPs were studied by ELISA.
Results: B cells showed heterogenic populations in flow cytometry due to the formation of different sizes of aggregates between B cells and MPs. Using the ELISA method we also demonstrated the attachment of a percent of B lymphocytes to platelet MPs in the human blood. Moreover, addition of MPs in vitro increased ELISA absorbance.
Conclusion: Binding of platelet MPs to B cells apprears to take normally place in vivo and a percent of B cells circulate in the blood attached with platelet MPs.

P3.03 Thymic selection and T cell development

P3.03.01
Role of sonic hedgehog in T cell development

***A. Al-Shammary**;*
UCL, London, United Kingdom.

The Hedgehog (Hh) family of secreted intracellular signalling molecules plays a major role in many patterning processes and organogenesis during embryonic development and are involved in the homeostasis and renewal of adult tissues. The Hh family member, Sonic Hedgehog (Shh) has been previously found to influence T-cell development and transition at the double negative stage (DN). In this project we have utilized T-cell receptor transgenic mice models (TCR-transgenics) to investigate the role of Shh in T-cell development and repertoire selection. Our data from thymic organ cultures have shown that Shh influence T-cells selection and maturation during the later stages of T-cell development in their transition from double positive (DP) to single positive (SP) cell population.

P3.03.02
Analysing the role of E2F7 and E2F8 in peripheral T cells and during T cell development

***J. Beil**[1], R. Sapkota[1], A. Sledzinska[2], A. de Bruin[3], T. Buch[1];*
[1]Institute for Medical Microbiology, Immunology and Hygiene, TU München, Munich, Germany, [2]Institute of Experimental Immunology, University of Zürich, Zurich, Switzerland, [3]Department of Pathobiology, Faculty of Veterinary Medicine, Utrecht University, Utrecht, Netherlands.

Thymocytes undergo several important steps during their development towards mature T cells. Because of the random nature of the TCR rearrangement the positive selection checkpoint is necessary to ensure that the double positive (DP) cells can interact with the MHC molecule. Negative selection, which is important to eliminate self reactive thymocytes, is controlled by the avidity of the interaction between the TCR and the self antigen. We are analysing transcription factors expressed at the DP stage which may be involved in these processes. We identified E2F7 and E2F8 as potential candidates of our approach which belong to the E2F family that is known to be important for differentiation, apoptosis and function as transcriptional repressors important for the control of cell proliferation. Because the double deficiency is embryonic lethal we have crossed E2F7 fl/fl E2F8 fl/fl mice with Lck-cre and CD4-cre mice and analysed the phenotype of thymocytes and T cells. Astonishingly, we could show that the population sizes of CD4+ and CD8+ T cells, naïve T-cells, T regs and TCRγδ T cells are not altered compared to control mice. Furthermore, we investigated B cells, macrophages, dendritic cells, NK and NK T cells, again without finding any differences in conditional double knockouts compared to controls.

P3.03.03
CCL2 chemokine in central tolerance

***O. Cédile**[1], M. Løbner[1], H. Toft-Hansen[1], I. Frank[1], M. Irla[2], T. Owens[1];*
[1]Institute of Molecular Medicine, University of Southern Denmark, Odense, Denmark, [2]Centre Médical Universitaire (CMU), University of Geneva Medical School, Geneva, Switzerland.

The goal of the project is to study the role of CCL2 on dendritic cell (DC) recruitment and T cell tolerance in thymus.
CCL2 is a chemokine involved in the recruitment of immune cells during inflammation. DC can take up antigens in periphery and migrate into the thymus to mediate tolerance. Three DC subsets have been identified in mouse thymus and they all express CCR2, the main receptor for CCL2.
We separated thymocytes from stromal cells (mainly thymic epithelial cells (TEC) and DC) by percoll gradient centrifugation. We demonstrated by quantitative PCR that CCL2 was induced in stromal cells, mainly TEC (CD45-negative stromal cells), by interaction with autoreactive thymocytes. Analysis of thymic DC subsets in CCL2-deficient mice showed a decrease of the Sirpα+-subset.
To study the role of CCL2 in T cell tolerance, we took advantage of mice that overexpress CCL2 in thymus. Overexpression of CCL2 in

thymus of myelin oligodendrocyte glycoprotein (MOG)-specific TCR transgenic mice (2D2 mice) induced loss of CD4 from MOG-specific T cells in thymus and lymph node (LN). LN T cells from mice overexpressing CCL2 in thymus responded poorly to MOG and these mice were resistant to experimental autoimmune encephalomyelitis.
We conclude that CCL2 induced by interaction between autoreactive thymocytes and stromal cells is involved in regulation of T cell tolerance and we propose that DC recruitment plays a role.

P3.03.04
Does citrullination occur in medullary thymic epithelial cells?

***R. Engelmann**, A. Biemelt, A. Johl, B. Müller-Hilke;*
University of Rostock, Institute of Immunology, Rostock, Germany.

Introduction:
The presence of antibodies against citrullinated peptide antigens (ACPA) is a hallmark of rheumatoid arthritis. However, it is unclear how these autoantibodies develop. It has been proposed, that peripheral citrullination generates neoepitopes that are favored targets of autoreactive immune cells evading central tolerance induction. We investigated the expression of peptidyl arginine deiminases (PAD) in medullary thymic epithelial cells (mTEC).
Methods:
Thymic epithelial cells were isolated from 4-5 weeks old mice susceptible (DBA/1) or not susceptible (NMRI, C57BL/6) for collagen-induced arthritis (CIA). After TEC-enrichment by percoll density gradient centrifugation and magnetic depletion of CD45+ cells, immature mTEC (CD45-EpCAM+CD80lowLy-51-) and mature mTEC (CD45-EpCAM+CD80highLy-51-) were FACS-sorted. Cortical TEC were identified as CD45-EpCAM+CD80-Ly-51+. mRNA and protein were isolated from sorted mTEC populations for subsequent expression analysis.
Results:
Flow cytometry analysis revealed a significantly decreased number of mTEC in thymi of CIA-susceptible DBA/1 mice in comparison to NMRI and C57BL/6 mice, whereas the number of T cells and cTEC did not show any differences.
Subsequent quantitative PCR confirmed cell identity since mature mTEC showed significantly elevated expression of aire and the tissue restricted gene insulin2 compared to immature ones. Pad expression was higher in mature mTEC compared to immature mTEC and correlated well with the expression of aire. Furthermore, the expression of pad6 was significantly elevated in DBA/1 mature mTEC.
Conclusion:
Pad genes are readily expressed at RNA level in murine mTEC. However, it remains to be determined whether PAD protein and citrullination can also be found in mTEC. This is work in progress.

P3.03.05
Significant involvement of NF-κB-inducing Kinase in shaping mature T cell repertoire

***K. Eshima**, N. Shinohara, K. Iwabuchi;*
Kitasato University School of Medicine, Sagamihara, Kanagawa, Japan.

NF-κB-inducing kinase (NIK) is known to play a critical role for maintaining proper immune functions. This is exemplified in the spontaneous mutant mouse *alymphoplasia* (*aly*), which lacks functional NIK and has been demonstrated to be immune-compromised and also to be autoimmune-prone. In order to investigate the role of NIK in αβ T cell repertoire formation, we analyzed T cell development in *aly*/*aly* mice bearing a transgenic αβ TCR. The results showed that the maturation efficiency of idiotype^{high+} T cells in the TCR-Tg mouse was found to be lower in *aly*/*aly* mice as compared to that in *aly*/+ mice, implying that mature αβ T cell repertoire could be altered by the systemic lack of functional NIK. It was also noted that in one strain of negatively selecting background, the peripheral number of CD8^{low} idiotype^{high+} cells, which are thought to potentially represent γδ lineage of T cells, were markedly decreased in *aly*/*aly* mice. When the γδ T cells in *aly*/*aly* mice without TCR transgene were investigated, the proportion of γδ T cells in the periphery of *aly*/*aly* mice was found to be 1/2 to 1/5 of those in *aly*/+ mice. Analyses of bone marrow chimera mice suggested that NIK in host cells, rather than in donor cells, is important for maintaining normal number of peripheral γδ T cells. These results suggest that NIK may be involved in thymic positive selection of some αβ T cells and that NIK in non-hematopoietic cells is important for optimal development and/or maintenance of γδ T cells.

P3.03.06
Homeostatic properties and phenotypic maturation of murine CD4$^+$ pre-thymic emigrants in the thymus

***Q. Ge**, X. Xu, J. Dong;*
Peking University Health Science Center, Beijing, China.

After a tightly regulated developmental program in the thymus, “mature” single positive (SP) thymocytes leave the thymus and enter the periphery. These newly arrived recent thymic emigrants (RTEs) are phenotypically and functionally immature, and will complete a dynamic maturation in the peripheral lymphoid organs before being licensed to be resident naïve T cells. To study the early events occurring in the RTE maturation process, we identified the phenotype of CD4$^+$ pre-RTEs, a population of CD4$^+$ SP thymocytes that have acquired the thymus egress capability. Compared to peripheral naïve T cells, CD4$^+$ pre-RTEs displayed superior survival capability in lymphoreplete mice and faster proliferation under lymphopenic condition. The differences in Bcl2/Bim expression and/or heightened IL-7 signaling pathway may account for the pre-RTEs’ better responsiveness to homeostatic signals. Qa2, the expression of which indicates the phenotypic maturation of SPs and RTEs, was found to be upregulated in CD4$^+$ pre-RTEs in thymic perivascular space. Migratory dendritic cells surround this region contribute to Qa2 expression in pre-RTEs. The dendritic cell-driven Qa2 induction of CD4$^+$ pre-RTEs is independent of MHC class II and Aire molecules.

P3.03.07
Transcriptional modification induced in a human epithelial cell line by transfected AIRE

***C. Guitart**[1], F. Reyes[2], I. Alvarez[1], S. Boltaña*[2], D. Jaraquemada*[1];*
[1]Universitat Autònoma de Barcelona, Bellaterra, Barcelona, Spain,
[2]University of Stirling, Stirling, United Kingdom.

AIRE gene expression promotes the transcription of TRAs (tissue-restricted antigens) in thymus medullary epithelial cells. TRA expression is directly connected to the negative selection of T cells recognising peripheral antigens in thymus, presumably inducing the generation of peptides from TRAs to be presented by MHC on mTECs. The exact mechanism of AIRE action and the generation of TRA-derived peptides is unclear. To study TRA transcription, synthesis and processing we generated an AIRE+ cell by transfecting the human thyroid epithelial cell line HT93 with the AIRE gene. We performed bioinformatics analyses of microarray data on mRNA transcripts from transfected vs. untransfected HT93, focusing on the gene expression of significant transcripts and the genomic localization of AIRE-induced transcripts. The transcriptional analyses revealed that in response to AIRE, cells significantly triggered the regulation of 776 transcripts ($p<0.01$, t-test), including differentially up-regulated (283) and down-regulated (494) transcripts ($p<0.01$, t-test in whole transcriptomic analysis). Within up-regulated genes, we found 10 genes codifying potential TRAs. Other genes related to apoptosis, cell cycle and cytoskeleton were significantly upregulated. The analysis of the whole transcriptome by localisation of AIRE-regulated clusters showed that AIRE controls the up-regulation of several transcripts linked to canonical cellular process, . The identified transcripts suggest that AIRE regulates changes likely to strengthen the cell remodeling of the transcriptional program in the epithelial cell line and show the up-regulation of specific gene cassettes in all autosomal chromosomes. This pattern suggests that AIRE promotes a wide action on the chromatin transcriptional activation. *co-senior authors

P3.03.08
SOCS1 deficiency results in fatal inflammatory disease in the absence of thymic T cells

H. Honda[1], *T. Ohkawara*[1], *M. Fujimoto*[1], *S. Lee*[2], *T. Kishimoto*[2], *T. Naka*[1];
[1]*National Institute of Biomedical Innovation, Ibaraki, Osaka, Japan,* [2]*WPI-Immunology Frontier Research Center, Osaka University, Suita, Osaka, Japan.*

The suppressor of cytokine signaling (SOCS) family controls cytokine signaling and regulates the development of many inflammatory diseases. SOCS1 inhibits signaling of various cytokines, including IL-2, IL-7, IL-15 and IFN-γ. Previous studies revealed that SOCS1 knockout (KO) mice die within three weeks of age with a complex inflammatory disease, which is prevented by generating IFN-γ deficient or lymphocyte deficient SOCS1 KO mice. In addition, SOCS1 deficiency causes abnormal T cell activation and differentiation into IFN-γ-producing cells, suggesting that activated T cells play a key role in the disease.
To further investigate the T cell role in the disease, we crossed SOCS1 KO mice with nude mice to generate thymus-deficient SOCS1 KO mice (nude SOCS1 KO). Unexpectedly, nude SOCS1 KO mice showed growth retardation and early death similarly to SOCS1 KO mice. They also demonstrated IFN-γ signature like SOCS1 KO mice, as characterized by MHC class I up-regulation in bone marrow myeloid cells and STAT1 phosphorylation in liver. Interestingly, despite lacking thymus, T cells were expanded in nude SOCS1 KO mice and most of them were either CD4 or CD8 positive αβT cells. Furthermore, T helper cells differentiated toward Th1 rather than Th17 and Treg development was defective in these mice. These results suggest that T cells are the key cellular mediators of the disease due to SOCS1 deficiency even under athymic condition. Regulation of cytokine signaling by SOCS1 might be involved in thymus-independent T cell development and homeostasis.

P3.03.09
Regulation of CD8 T cell function by the small GTPase Arl4d

J. Kaczmarek*, L. Diehl;*
IMMEI, Bonn, Germany.

The liver is known to induce tolerance rather than immunity. Liver sinusoidal endothelial cells (LSEC) can induce a non-responsive state in naïve CD8 T cells after antigen-specific stimulation. Members of the ADP-ribosylation factor (ARF) family of guanine-nucleotide-binding (G) proteins, including the ARF-like (ARL) proteins, regulate membrane traffic and organelle structure by recruiting cargo-sorting coat proteins, modulating membrane lipid composition and interacting with regulators of other G proteins. Arl4D is localized to the plasma membrane and can recruit cytohesin-2/ARNO and modulate actin remodeling via regulating ARF6 activity.
We found Arl4d mRNA to be highly induced during CD8 T cell stimulation by LSEC. Using CD8 T cells from Alr4d-/- mice we found the lack of Alr4d to result in the overproduction of IL-2. As the amount of IL-2 produced by naïve CD8 T cells during antigen-specific interaction with LSEC is an important factor for the induction of non-responsive CD8 T cells, the action of Arl4d may be central to dampen IL-2 production and for subsequent abrogation of immediate effector function in naïve CD8 T cells by LSEC.

P3.03.10
Signal integration in thymocytes is crucial for thymic selection

S. Khailaie[1], *A. Toker*[2], *J. Hühn*[2], *M. Meyer-Hermann*[1,3];
[1]*Department of Systems Immunology, Helmholtz Center for Infection Research (HZI), Braunschweig, Germany,* [2]*Department of Experimental Immunology, Helmholtz Center for Infection Research (HZI), Braunschweig, Germany,* [3]*Bio Center for Life Science, Technische Universität Braunschweig, Braunschweig, Germany.*

Thymocytes are generated, selected and mature in the thymus to create a diverse, functional and self-tolerant T cell repertoire. Selection of thymocytes relies on the level of their T cell receptor (TCR) self-reactivity. Self-reactivity of thymocytes is quantified by repeated engagement of their TCRs with a diverse repertoire of self-peptides complexed with self-MHC molecule (spMHC) and may originate from either part of the complex. The role and relative importance of MHC versus self-peptides in the thymic selection is not resolved. The fact that the selected T cell repertoire is MHC-restricted, requires a good mechanistic explanation of how thymocytes are able to quantify their affinity to MHC. In order to analyze how thymocytes quantify their self-reactivity, extract their MHC affinity, and how they use this information for cell fate determination, we developed a signal integration model for thymic selection, mimicking the requirement of repeated TCR signaling for successful selection and cell maturation. In this model, a polyclonal repertoire of thymocytes sequentially interacts with diverse spMHCs and integrate the affinity-dependent TCR ligation signals. The strength and dynamics of the integrated signal is taken as a reference for cell fate determination. Quantification of the integrated signal and discrimination between its sustained and transient dynamics turns out as a successful basis for extracting affinity of thymocytes to MHC, detecting the existence of cognate self-peptide, and selecting a MHC-restricted self-tolerant T cell repertoire. Regulatory T-cell differentiation versus clonal deletion of autoreactive thymocytes is discussed with this model.

P3.03.11
Vascular Endothelial Growth Factor and Semaphorin 3A influence murine thymocyte migration in vitro

E. P. Kisseleva*, I. V. Lyamina;*
Institute for Experimental Medicine, St.Petersburg, Russian Federation.

Angiogenic Vascular Endothelial Growth Factor (VEGF) and axon guidance molecule Semaphorin 3A (Sema 3A) are known to be produced by thymic epithelial cells (Corbel C. et al., 2007; Lepelletier Y. et al., 2007) but their function in T-lymphocyte development is not known. Both factors have common receptor - Neuropilin 1 which is abundantly expressed on the surface of murine thymocytes. The aim of the study was to evaluate the role of VEGF and Sema 3A in murine thymocyte migration in vitro. With the help of transwell systems we found that Sema 3A at a concentration of 100 ng/ml possessed chemorepellent activity towards thymocytes while VEGF at the range of 1-100 ng/ml showed no effect. Incubation of thymocytes in the presence of anti-Neuropilin 1 antibodies abolished effect of Sema 3A. We further evaluated thymocyte adhesion to the monolayer of endothelial EA.hy 926 cells, preincubated with Sema 3A or VEGF during 4 hours. VEGF at a concentration of 50 ng/ml increased thymocyte adhesion 1,5 times while Sema 3A had no effect. As a positive control we used 10 ng/ml of TNF-α. Transendothelial thymocyte migration through the monolayer of endothelial cells preincubated with 50-100 ng/ml VEGF during 4 hours was increased 1,9 times as compared to the control cultures while preincubation with Sema 3A did not show any influence. These data suggest that both factors may act on transendothelial migration of thymocytes and their egress to periphery: Sema 3A - directly on thymocytes as chemorepellent while VEGF can modify endothelial cell.

P3.03.12
Shaping of epitope-specific CTL precursor populations by thymic selection

*J. Guan, W. Kan, S. J. Turner, **N. L. La Gruta**;*
University of Melbourne, Parkville, Australia.

Cytotoxic CD8+ T cells (CTL) play a significant role in the control and removal of virally infected cells and tumours by recognizing specific viral peptide fragments in complex with class I Major Histocompatibility Complexes (MHCI). Using a tetramer-based magnetic enrichment strategy to identify the extremely small number of epitope-specific CTL precursors (CTLps) from naïve mice, work from our group and others has demonstrated the importance of the naïve CTLp pool in determining CTL immune magnitudes after antigen challenge. The frequencies of naïve epitope-specific CTLps are highly reproducible between MHC-matched individuals for both mice and humans, suggesting that thymic selection plays a key role in their establishment. While the broad consequences of thymic selection are well established (i.e. self-MHC restriction and self-tolerance), the impact of selection events on the frequency and TCR usage within epitope-specific CTLp populations is unknown. Here, we investigate how the nature of the positively selecting MHCI ligand impacts on the emergent population of mature CD8+ T cells and their ability to respond to cognate pMHCI in the periphery. Furthermore, we address the extent to which naive CTLp populations are edited by negative selection, using mice lacking a key regulator of negative selection, the BH3-only protein, Bim. This work will address the fundamental question of whether the pre-immune repertoire is principally defined by TCR gene recombination or thymic selection events. Thus, it may have implications for manipulating CTL responses by defining how the characteristics of the preimmune CTL repertoire, and consequently antigen-driven CTL responses, are determined.

P3.03.13
CD8aa TCRab intraepithelial lymphocytes MHC restriction

*S. Mayans, D. Stepniak, S. Palida, A. Larange, H. Cheroutre, **F. Lambolez**;*
La Jolla Institute for Allergy and Immunology, La Jolla, CA, United States.

T lymphocytes develop in the thymus into two major lineages characterized by expression of ab and gd TCR. Each lineage can be further subdivided into distinct subsets that differ in TCR specificity, phenotype and function. CD8aa TCRab intraepithelial lymphocytes (T-IEL) located in the epithelium of the small intestine is phenotypically different from conventional T cells. CD8aa T-IEL have been studied for years however the question of their MHC restriction has not been elucidated. Therefore, we decided to clone TCR isolated from naturally arising CD8aa T-IEL and retrovirally express these TCRs in BM chimera. First, we cloned four TCRab that were expressed retrovirally in RagKO BM chimera. Analysis of the chimera showed that all TCR clones gave rise to T cells. The T cell that developed were CD4-CD8b- but CD8a+ and phenotypically identical to CD8aa T-IEL isolated from wild type mice. In addition, they were preferentially found in the gut. In order to define the MHC restriction of these particular TCRs, BM chimeras in various MHC-deficient backgrounds were generated. Subsequent analysis of the chimera for the presence of CD8aaTCRab IEL demonstrated that they are dependent either on Kb, Db MHC I, Qa2 or b2m-dependent MHC I aside from KbDb. In conclusion, our results indicate that CD8aa T-IEL develops from precursors expressing particular TCRs that allow their engagement in this unique T cell lineage. In addition, CD8aa T-IEL can harbor clones selected on different MHC molecules.

P3.03.14
The role of WW domain-containing oxidoreductase in lymphocyte development

***J. Lo**, L. Hsu;*
National Cheng Kung University Medical College, Tainan, Taiwan.

WW domain-containing oxidoreductase (WOX1) is a newly isolated tumor suppressor protein. Downregulation of WOX1 protein expression has been found in many types of human cancers. Previous studies have suggested that WOX1 is involved in many signaling pathways that regulate cell apoptosis. Ectopic WOX1 increases tumor necrosis factor, staurosporine, UV or p53-induced cell death. Conversely, functional suppression of WOX1 by dominant negative mutants or siRNA protects cells from apoptosis. Although many studies have revealed a role of WOX1 in regulating cancer cell apoptosis, whether WOX1 is involved in lymphocyte development is unknown. To explore the functional role of WOX1 in vivo, we have recently generated whole-body knockout murine models by targeting exon 1 or exons 2-4 of the gene. All WOX1-deficient mice died by three weeks of age. Reduced body weights and marked atrophy of the spleen and thymus were observed in WOX1-deficient mice. Significantly reduced cell numbers of splenocytes and thymocytes were determined in WOX1-deficient mice, as compared with the wild-type and heterozygous mice. By TUNEL assay, massive thymocyte apoptosis was found in WOX1-deficient mice. Moreover, we determined that WOX1-deficient mice exhibited a profound defect in B cell development. Together, using gene knockout mice, our study clearly demonstrates that WOX1 is a key regulator in lymphocyte development.

P3.03.15
The investigation of the expression of P2Y1 and P2Y2 nucleotide receptors on thymocytes using monoclonal antibodies

***M. Naciute**, R. Kvietkauskaite, N. Gerasimcik, J. Jursenaite, M. Mauricas, I. Girkontaite;*
State Research Institute Centre for Innovative Medicine Department of Immunology, Vilnius, Lithuania.

Extracellular nucleotides are an important mediator of cell-to-cell interactions in the nervous, vascular and immune system. Nucleotides are released by various cell types under physiological and stress conditions. Nucleotides act via wide range of P2X and P2Y nucleotide receptors. We investigated the expression of P2Y1 and P2Y2 receptors on various thymocyte populations using rat monoclonal antibodies. The rats were immunized with primary rat fibroblasts transfected with P2Y1 or P2Y2 nucleotide receptors. The specificity of monoclonal antibodies was tested by flow-cytometry and fluorescence microscopy. The obtained antibodies bind to very small population (1% or less) of all thymocytes. More antibody binding cells were detected on CD4-CD8- double negative and (CD4CD8)low thymocytes. Those thymocyte populations were analyzed according to the expression of CD44 and CD25 cell surface markers. The expression of P2Y1 and P2Y2 receptors were found mostly on CD44-CD25- cells. The majority (18-25%) of P2Y1 and P2Y2 receptor positive cells were from (CD4CD8)lowCD44-CD25- cells. Lower numbers of double negative CD4-CD8- CD44-CD25- thymocytes (3 - 6 %) were stained with antibodies to P2Y1 and P2Y2 receptors. Analyzing (CD4CD8)low thymocytes we found that the Y1-10 and Y2-2 antibodies bind to a small population of TCRβ+, Thy1.1int, CD3int, CD69+ and CD69-, DX5+ and DX5- thymocytes. The antibodies did not bind to TCRγ/δ-, CD3-, Thy1.1- thymocytes. ATP (but neither UTP nor dATP) at the concentration of 0.1mM induce apoptosis in thymocytes culturing them for 1 day. Y2-2 (but not Y1-10) antibodies protect from ATP induced apoptosis CD8+CD4-, DP, CD8-CD4+, (CD8CD4)low, but not DN thymocytes.

P3.03.16
Role of Miz-1 (Myc-Interacting Zinc-finger protein-1) as a regulator of p53 dependent pathways during pre TCR selection

M. Rashkovan[1,2]*, C. Kosan*[1]*, T. Möröy*[1,2,3]*;*
[1]IRCM, Montreal, QC, Canada, [2]McGill University, Montreal, QC, Canada, [3]Université de Montréal, Montreal, QC, Canada.

The Myc-Interacting Zinc-finger protein-1 (Miz-1) was first identified as a binding partner for the proto-oncogene c-Myc. While Miz-1 itself functions as a transcriptional transactivator, it enables c-Myc to act as a transcriptional repressor of genes regulating cell cycle progression, such as the cyclin dependent kinase inhibitors p21Waf1 or p15ink4b. Using mice engineered to express a non-functional form of Miz-1 (Miz-1ΔPOZ mice), we have accumulated evidence that Miz-1 exerts a role in DN3 pre-T cells at the so-called β-selection checkpoint. Our data suggest that cells undergoing V(D)J recombination (i.e. DN3s), require Miz-1 to restrain p53 activity, notably its ability to induce apoptosis through the upregulation of genes such as Bax, Noxa or Puma. This is supported by our finding that in the absence of a functional Miz-1, pre-TCR bearing cells are lost from the thymus by apoptosis, have high levels of Bax, Noxa and Puma and a reduced capacity to progress through the cell cycle, causing a very low thymic cellularity. Moreover, Miz-1ΔPOZ mice lacking p53 have a normal thymic cellularity and in particular, DN3 cells are present at almost normal frequencies and successfully transit through β-selection. These results are intriguing and suggest that activation of p53 has to be controlled when V(D)J recombination occurs and that Miz-1 can exert such a control on p53. We hypothesize therefore that Miz-1 is necessary to protect pre-T cells from premature apoptosis by restricting a p53-mediated DNA damage response that is initiated by double strand breaks that occur during V(D)J recombination.

P3.03.17
Thymic nurse cells play an important role in MHC restriction and express progenitor markers associated with epithelial maintenance

M. D. Samms*;*
The City College of New York, New York, NY, United States.

Thymic nurse cells (TNCs) were first characterized as lympho-epithelial complexes localized within the thymic cortex. Internalized immature thymocytes within specialized vacuoles were shown to undergo MHC restriction resulting in both positive as well as negative selection. In a recent report, we used the TNC-specific monoclonal antibody and also anti-cytokeratin antibodies K5 and K8 to show that a subset of TNCs bearing the phenotype $pH91^{+}K5^{+}K8^{+}$ to be strategically localized within the cortico-medullary junction of the murine thymus. Thymic epithelial cells exhibiting these markers ($K8^{+}K5^{+}$) have been suggested to play a role in the maintenance of thymic cortex and medulla. In this study, we examined the ontogenesis of the TNCs with the aid of pH91. Confocal microscopic analyses of embryonic thymic sections show the onset expression of the pH91-specific antigen to occur at E11.5 stage of development and persist throughout embryological development as well as postnatal mice. Analyses of $pH91^{+}$ cells show the concomitant expression of K5, K8, Foxn1 and P63. At E17.5 stage of development, we observe the formation of the multicellular, lympho-epithelial complexes that exhibit the $pH91^{+}K8^{+}K5^{+}Foxn1^{+}P63^{+}$ phenotype. Using FACs analysis, we show increases in MHC class II expression from E13.5 to E18.5 of thymus development. Taken together, these data show the TNC-specific antigen is expressed early in thymus development and TNCs may be important in the process of MHC restriction as well as maintenance of thymic epithelia.

P3.03.18
TCRβ but not the TCRδ enhancer exerts transcriptional control on the TCRα locus during development

R. M. Sapkota[1,2]*, A. Sledzinska*[1]*, C. Uthoff-Hachenberg*[3]*, B. Becher*[1]*, T. Buch*[1,4]*;*
[1]Institute of Experimental Immunology, University of Zurich, Zurich, Switzerland, [2]Institute for Medical Microbiology, Immunology, and Hygiene,Technische Universität München, Munich, Germany, [3]Institute for Genetics, University of Cologne, Cologne, Germany, [4]Institute for Medical Microbiology, Immunology, and Hygiene, Technische Universität München, Munich, Germany.

T lymphocytes develop in the thymus. Thymocytes at CD4-CD8- (DN) stage first recombine and express the T cell receptor beta chain (TCRβ). TCRβ pairs with the pre-T cell receptor alpha (pTα) and CD3 to form the pre-T cell receptor complex whose signalling induces progression to the CD4+CD8+ (DP) stage. At this DP stage, recombination of the TCRα locus and its expression normally take place. However, transgenic TCR mouse models are known to express TCRα prematurely at the DN stage. This suggests either that recombination is sufficient for expression and there is no further transcriptional control, or the transcriptional control in mice with insertion TCR transgenes is aberrant. To investigate these questions, we used a insertion mouse model with the transgenic TCRα exactly mimicking a physiological recombination event. We again found TCRα expression prematurely at the DN stage , and that the expression is highly enhanced by the presence of transgenic TCRβ. This suggests transcriptional control of the TCRα locus by TCRβ, and a possible mechanism could be via signalling through the pre-TCR. We used pTα deficient mice to test this possibility, and indeed found the TCRβ cannot enhance expression of TCRα in pTα knockout mice. This expression-enhancing effect of TCRβ was restored upon anti-CD3ε treatment which is expected to mimic pre-TCR signalling. Thus we show control of TCRα expression by TCRβ mediated through pre-TCR signalling. In addition, we show that in contrast to previous suggestions, TCRα expression does not depend on the presence of this element.

P3.03.19
Pharmacological inhibition of glycogen synthase kinase 3 regulates T cell development *in vitro*

J. Schroeder[1]*, L. Bell*[2]*, M. Janas*[3]*, M. Turner*[2]*;*
[1]Imperial College, London, United Kingdom, [2]Babraham Institute, Cambridge, United Kingdom, [3]GE Healthcare Life Sciences, Cardiff, United Kingdom.

The development of functional non-autoreactive T cells requires receptor-mediated transition through multiple checkpoints in the thymus. Double negative 3 (DN3) thymocytes are selected for the presence of a rearranged TCR beta chain in a process termed beta-selection which requires signalling via the preTCR and Notch1. Pre-selection DN3 are referred to as DN3a and express low levels of CD27 and CD98, while post-selection DN3 (which are TCR beta positive) express higher levels of CD27 and CD98. Additional signalling from Stromal-Derived Factor 1alpha (SDF1alpha)/CXCl12 ensures optimal proliferative expansion of DN3 thymocytes. Signal integration by these receptors converges on core pathways such as the Phosphatidyinositol-3-kinase (PI3K) pathway. Glycogen Synthase Kinase 3 (GSK3) is generally thought to be negatively regulated by the PI3K pathways.
We have shown that a GSK3-inhibiting drug, CHIR99021, promotes the proliferative expansion of DN3a cultured with recombinant Delta Like4 and SDF1alpha. Here we show that developmental progression of either DN3a or DN3b is promoted by CHIR99021. In the absence of preTCR- or Notch1-mediated signalling differentiation is rescued in a partial or entire manner respectively when CHIR99021 was present. Furthermore, inhibition of GSK3 using CHIR99021 appears to antagonize IL-7-mediated arrest of development at the DN stage. In addition to the effect on T cell development, CHIR99021 increased IL-7 dependent proliferation and caused enhanced cell recovery in these experiments. These experiments indicate a potentially important role for inactivation of GSK3 during the process of beta-selection.

P3.03.20

Role of conserved MHC residues for interaction with T cell antigen receptors

D. Silberman[1], *P. Marrack*[1,2], *J. W. Kappler*[1,2];
[1]*National Jewish Health/University of Colorado Denver, Denver, CO, United States,* [2]*HHMI, Denver, CO, United States.*

Most αβ T cell receptors (TCRs) survey the multitude of antigens via peptides presented in the context of major histocompatibilty complex (MHC) molecules displayed on the surface of antigen presenting cells. These TCRs make contact with conserved, solvent-exposed residues on α-helices of the MHC. Previously we have examined the effect of mutating these residues of MHCII IA^b on the response of a bulk T cell population. We have found that many of these mutations cause widespread interference of TCR recognition. To assure that this interference was caused by direct recognition of TCR elements, we examined the peptide repertoires of our most pronounced mutations by mass spectrometry and observed no gross differences. Furthermore, we are going to express these mutants as the only class II MHC in the thymus of a mouse and study their effect on thymic selection. We will either do this by generating a transgenic mouse or attempting to use zinc finger nuclease (ZFN) technology to make knock-in mice expressing these mutations. Using ZFNs designed for IA^b, we have generated many knockout mice. Once we have generated the mutant mouse, we will characterize the selected repertoire of T cells in the periphery. The evolutionary hypothesis suggesting TCRs and MHCs have coevolved would predict a reduction in the number of peripheral T cells, a reduction in the diversity of the repertoire, or a skewing of the V-gene usage.

P3.03.21
Generation of a conditional knock-out mouse for SATB1 to study its importance for CD4+ T cells

D. Sommer*, A. Peters, T. Wirtz, M. Mai, Y. Thabet, J. Degen, J. L. Schultze, M. Beyer;*
LIMES Institute, Bonn, Germany.

Special AT-rich-binding protein 1 (SATB1) is a nuclear protein, providing higher order chromatin organization and regulation of gene expression. SATB1 is highly important during T-cell development in the thymus and regulates about 2 % of thymocyte genes. Recently, we identified repression of SATB1 in regulatory T cells (Treg cells) as an important feature required to suppress Teffector-cell programs in Treg cells to maintain Treg-cell function.
To further address the functional impact of SATB1 in Teffector-cell programs, we recently generated a conditional SATB1 knock-out mouse to perform spatiotemporally controlled somatic removal of the SATB1 gene since the hitherto available complete knock-out mice lacked peripheral T cells and died from neurological defects after three weeks of age.
For the establishment of this conditional knock-out model we used an approach making use of a Cre-dependent genetic switch (FLEX switch), enabling the disruption of the SATB1 gene by deletion of the ATG-containing exon 2 with concomitant induction of a GFP reporter. Furthermore, gene targeting was performed by a novel approach, in which the recently developed transcription activator-like effector nucleases (TALEN) genome editing enzymes were co-injected with the linearized targeting vector into the nucleus of mouse pronuclear-stage embryos, thereby circumventing gene targeting in ES cell culture. This yielded a founder mouse with recombined 5' and 3' homology regions, which furthermore showed germline transmission of the targeted allele.
Breeding this mouse to different Cre-expressing mice will allow us to clarify the importance of SATB1 for the development and the function of effector T cells.

P3.03.22
Themis CABIT domains exert distinct functions in thymocyte positive selection

H. Suzuki*, T. Okada, T. Nitta, K. Kaji, H. Oda, M. S. Ppatrick;*
Natinal Center for Global Health and Medicine, Ichikawa-shi, Chiba, Japan.

Themis (Gasp) is a newly identified Grb2-binding protein highly expressed in immature thymocytes, that is essential for positive selection, but not for negative selection in the thymus. Despite possible involvement of Themis in TCR-mediated signal transduction, its function is still unknown and controversial. Themis contains a nuclear localization signal, a proline rich sequence, and two uncharacterized domains named CABIT (CABIT1, CABIT2). In the present study, we especially focused on the function of these newly identified CABIT domains.
We established a series of transgenic (Tg) mice expressing mutant Themis molecules including deletion of the highly conserved core region of CABIT1 and/or CABIT2 domains, called delta-Core1 and delta-Core2, respectively. All of the hCD2 promoter-driven mutant Tg mice were bred with Themis-deficient mice to evaluate the biochemical features of the molecules and the effect of each mutation on positive selection. Both Themis delta-Core1 and delta-Core2 mutation abolished association with Grb2 and tyrosine-phosphorylation upon TCR stimulation. Moreover, both Themis mutations resulted in defective positive selection. Interestingly, delta-Core2 Themis showed localization to the nucleus similar to wildtype, whereas delta-Core1 Themis revealed abrogated nuclear translocation. Furthermore, delta-Core1 Tg, but not delta-Core2 Tg, showed impaired T cell development even in the co-existence of wildtype Themis, indicating that Core1 deletion conferred dominant negative inhibition on T cell development.
Collectively, our current results indicate that CABIT1 and CABIT2 are both required for positive selection, and each of the CABIT domains exerts distinct functions during positive selection.

Background of Primary Immunodeficiencies in Patients with Severe Atopic Dermatitis

B. Torabi Sagvand[1], *A. Aghamohammadi*[1], *Z. Gholizadeh Moghaddam*[1], *B. Mirminachi*[2], *H. Abolhassani*[2], *Z. Hallaji*[3], *H. Mortazavi*[4], *H. Mortazavi*[4], *P. Mohammadinejad*[2];
[1]*Tehran University of Medical Sciences, Tehran, Iran,* [2]*Research Center for Immunodeficiencies, Pediatrics Center of Excellence, Children's Medical Center, Tehran University of Medical Sciences, Tehran, Iran,* [3]*2- Department of Dermatology, Razi Hospital, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran,*
[4]*Department of Dermatology, Razi Hospital, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran.*

Primary immunodeficiency diseases (PIDs) are a group of heterogeneous inherited disorders, characterized by recurrent infections, autoimmunity and malignancy. Some PIDs such as hyper IgE syndrome (HIES) and Wiskott-Aldrich syndrome (WAS) may be initially presented as atopic dermatisis (AD), especially in its severe form resulting in diagnostic delay and poor prognosis of patients. The aim of this study was to evaluate the frequency of PIDs among patients with severe AD and to determine factors that can help to raise suspicion toward these disorders. Seventy-five patients with a well-established diagnosis of severe AD were enrolled in this study. Initial immunological evaluations, including humoral and cellular investigation were performed in all individuals. Patients underwent further investigations in a case of suspicious to a probable PID.
Among all patients with severe AD, 5 (6.6%) were diagnosed with HIES and 1 (1.3%) with WAS. Family history of PIDs, family history of death in early infancy, positive history of recurrent infections such as skin and respiratory infections, otitis media and sinusitis were observed significantly higher in patients with a diagnosis of PID. The presence of an underlying PID could explain the poor prognosis and refraction to treatment of some patients with severe AD. Several clinical and laboratory findings can help the physicians to focus toward PIDs which are more serious. Delay in diagnosis of PID cases with skin manifestation of AD without proper management may results in lower quality of life and higher morbidity and mortality rates.

P3.03.24

A single cell approach to investigating the role of asymmetric cell division in fate determination of CD8+ T cells

M. Yassin[1], *R. Shimoni*[2], *K. Pham*[2], *J. Oliaro*[1], *M. Ludford-Menting*[1], *S. Russell*[1,2];
[1]*Peter MacCallum Cancer Centre, Melbourne, Australia,* [2]*Swinburne University of Technology, Melbourne, Australia.*

A hallmark of a successful immune response against infection is the ability to produce a population of effector cells that can fight the infection then be cleared, as well as the generation of long-lasting memory subsets to protect against future encounters. Although many models try to explain the mechanism by which immune cells are capable of differentiating into these lineages, the exact mechanism and history of fate commitment is still debatable. Our lab and others have recently shown the importance of asymmetric cell division in hematopoietic cell function and fate.
Here, we describe a single cell approach to understanding fate commitment of naive CD8 T cells in response to antigen presentation by dendritic cells. By using micro-wells and micromanipulation technologies, we have developed a high throughput time-lapse imaging platform that allows us to follow single cells through activation and subsequent divisions up to 9 rounds. In addition, we have designed a customized imaging analysis toolbox ('TACTICS') to generate lineage trees as cells progress through the division cycles. By correlating times and pattern of division with expression of differentiation markers , we have begun to investigate how behaviors and influences in the first divisions following antigen presentation can affect the propensity of a CD8T cell to adopt a memory or effector cell fate.

P3.03.25
Thymectomy in early childhood: decrease of naive CD4+ T cells and diminished immune response after vaccination

M. Zlamy[1], *C. Gögele*[1], *R. Würzner*[2], *R. Geiger*[3], *L. B. Zimmerhackl*[1], *M. Prelog*[4,1];
[1]*Department of Pediatrics I, Innsbruck, Austria,* [2]*Department for Hygiene, Mikrobiology and Social Medicine, Innsbruck, Austria,* [3]*Department of Pediatrics III, Innsbruck, Austria,* [4]*Department of Pediatrics I, Würzburg, Germany.*

Our study was aimed to evaluate the influence of thymectomy in early childhood on naive T cell populations, T cell receptor exicion circles (TRECs) and Ki67 expression in thymectomized patients (TP) compared to healthy age matched controls (HC). Further, our study was aimed to compare the immune response to a neo-antigen (tick born encephalitis virus vaccination, TBEV) in TP and HC. Flow cytometry data were used to compare naive T cell (CD4+ CD45RA+CD62L+) and memory T cell(CD28+CD45RO+) counts of 101 TP and 81 HD. 44 TP and 56 HC were vaccinated against TBEV following the Austrian immunization schedule using FSME Immune junior (Baxter, Vienna, Austria). TBEV specific IgG values and IgG specific avidities were measured 4 weeks after the second and third vaccination and two years after the third vaccination using a commercially available ELISA. TP showed significantly lower values according to naive T cells ($p<0.001$) and lower TRECs ($p<0.001$) compared to HC. TREC counts showed a significant correlation with ongoing time after thymectomy ($p<0.001$). TP showed a higher percentage of Ki67+ naive T cells compared to HC ($p<0.01$). Four weeks after the second TBEV vaccination significantly lower TBEV specific IgG values were detected in TP when compared to HC ($p<0.05$). TP showed alterations in the peripheral T cell subpopulations similar to findings in elderly people after physiological thymic involution. TP showed a diminished immune response but a normal memory function of the immune system.

P3.04.01
Construction and functional activity of fibronectin scaffold containing different chains of hypervariable complementarity determining regions of mouse antibody against human IgG4

G. V. Brovman[1], *L. E. Petrovskaya*[1], *T. A. Yagudin*[2], *E. V. Svirshchevskaya*[1];
[1]*Shemyakin and Ovchinnikov Institute of Bioorganic Chemistry RAS, Moscow, Russian Federation,* [2]*Institute of Biochemistry RAS, Moscow, Russian Federation.*

Antigen binding affinity of antibody is determined by 6 chains of hypervariable complementarity determining regions (CRDs). It is not known how many chains mediate specific binding of full antibody. The aim of this work was to construct fibronectin (FN) scaffold of mouse antibody against human IgG4 with different sets of chains. CDRs were cloned from mouse monoclonal antibody 5C7 into 3FN10 scaffold in E.coli system. We constructed variants with one light (L) and one heavy (H) chains; two L chains L1-L3 and two H chains H2-H3; as well as four chains L1-L3-H2-H3; the latter was done by bicistron cloning. Fab fragment was cloned in Saccharomyces cerevisiae yeast system. Single chains constructs did not bind IgG4; two chain constructs recognized IgG4 with low affinity; L1-L3-H2-H3 construct demonstrated the affinity compared with Fab fragments and only slightly less than 5C7 antibody. Thus we demonstrated that four CDRs chains in 3FN10 scaffold can mimic the full-length antibody binding.

P3.04.02
Bi-polarized function of the 3' regulatory region at the immunoglobulin heavy chain locus

F. Braikia, D. Haddad, A. Khamlichi, ***C. Conte****;*
CNRS UMR5089-IPBS / University of Toulouse, Toulouse, France.

Expression of complex loci in mammals is developmentally regulated or induced by specific stimuli. Regulation of gene expression is often effected by distant regulatory elements and involves a complex interplay between enhancers, silencers, insulators, locus control regions (LCRs) and target promoters.
An LCR, named the 3' regulatory region (3'RR), is located downstream of the immunoglobulin heavy chain (IgH) locus, and is composed of 4 enhancers that act in synergy to effect a long-range activation of various inducible germ-line (GL) promoters. Enhancer RNAs (eRNAs) have been described at the 3'RR but their function is unknown. Additionally, whether the target promoters compete for the 3'RR activity is presently unknown. It is also unclear whether the 3'RR effect is exclusively targeted towards upstream promoters or whether it is bi-directional.
In an attempt to tackle these topics in vivo, we generated a knock-in mouse line in which the Iα GL promoter was duplicated downstream of the 3'RR, and performed chromatin studies as well as transcription analyses on a single-cell basis.
We will present our most recent data on the effect of this mutation on GL transcription derived from the various GL promoters, on the competition between GL promoters, and on eRNAs' expression.

P3.04.03
Specification of the Vκ gene repertoire at the mouse Igκ gene locus

Y. Xiang, S. Park, ***W. T. Garrard****;*
UT Southwestern Medical Center, Dallas, TX, United States.

The processes of Ig gene monoallelic activation and silencing, as well as locus contraction and looping, are essential for regulating V(D)J-recombination and creating a diverse antibody repertoire. However, the mechansisms for these events currently are poorly understood. We have previously identified six DNase I hypersensitive sites (HS1-

6) within the mouse Igκ gene V-J intervening region and have shown in pre-B cells that HS1-2 specifies locus contraction and looping, and HS3-6 specifies recombination silencing. These sequences have been termed Cer and Sis, respectively. Targeted deletion of either Cer or Sis leads to the preferential usage of Jκ-proximal Vκ genes. Interestingly, each element possesses a pair of functional CTCF binding sites, although Vκ gene germline transcription is only modestly upregulated upon deletion of either element. Here we address the question of whether Cer and Sis may be functionally redundant and act independently as insulator boundaries by preventing the downstream enhancers from activating proximal Vκ gene germline transcription. Targeted deletion of HS1-6 strikingly led to 96% of the Vκ gene usage from the Jκ-proximal 12 Vκ genes, resulted in >20-fold increases in their germline transcription, and led to increased non-lineage-specific Igκ gene rearrangements in T cells. Thus, our studies demonstrate that DNase I hypersensitive sites within the Jκ-Cκ region are essential for generating locus contraction and looping, and for creating a diverse tissue-specific antibody repertoire by preventing inappropriate proximal Vκ gene germline transcription.

P3.04.04
Reassessing HLA-DRB3, DRB4 and DRB5 expression in different cell types

E. A. Gonzalez-Navarro[1], *R. Faner*[2], *E. Rigol-Monzó*[1], *X. Coll*[1], *E. Garcia*[3,1], *N. De Moner*[3,1], *L. Carretero*[3,1], *D. Archila*[1], *M. Juan*[1,3];
[1]*HOSPITAL CLINIC, Barcelona, Spain,* [2]*Fundació Investigació Sanitària Illes Balears (FISIB), CIBER Enfermedades Respiratorias, Mallorca (CIBERES)., Mallorca, Spain,* [3]*Fundació Clínic-IDIBAPS, Barcelona, Barcelona, Spain.*

The immune response depends on the CD4+ T cell antigen presentation by HLA class II molecules, remaining the DR- region the most studied and variable. While all individual always present DRB1 loci, the presence or absence of DRB3, DRB4 or DRB5 loci is variable in different individuals, defining DR high variability. The continuous presence of DRB1 defines our knowledge about DRB1 (peptide binding capacity, regulation of their expression ,...) as equivalent to DR molecule, extrapolating DRB1 functions to DRB3/B4 / B5 loci.
The present study try to evaluate whether the regulation of the DRB3/4/5 expression is analogous to DRB1, assessing the quantification of DRB3/4/5 expression in relation with the corresponding DRB1 level of each haplotype in several class-II-expressing cells; we have studied both cell-surface expression (flow-cytometry levels) and mRNA transcription (RT-PCR levels). In parallel, a bioinformatic assessment of 5'-region of different DRB3/4/5 loci and alleles was developed to evaluate this region by high throughput sequencing.
Our results define differences in the relative proportions of each locus according the different cell populations and DR haplotypes; it is consistent with the observation that there are minor differences in the promoter 5'-region of DRB3, DRB4 and DRB5, someway defining differential transcriptional mechanisms. It seems logical to suggest that these differences could require reassessment of our knowledge in the DRB3/4/5 functional role, and consequently they could re-define a differentiable peptide repertoire for each DRB3/4/5 loci.

P3.04.05
Intrinsic bias and public rearrangements in the human immunoglobulin VLambda light chain repertoire

K. Hoi*, G. Ippolito, G. Georgiou;*
The University of Texas at Austin, Austin, TX, United States.

With the rapid advancement of next-generation sequencing technologies (NGS), study of the immunoglobulin B-cell receptor (BCR) repertoire has become increasingly feasible. Herein, we conducted a deep repertoire study of the BCR lambda light chain (IGL) using Roche 454 NGS to generate ~180k IGL variable gene transcript sequences derived from B cells collected from two healthy human individuals' peripheral blood mononuclear cells and three NOD-*scid-IL2R*$_{\gamma}^{null}$ mice engrafted with human hematopoietic stem cells. In addition, we have included ~500k IGL sequences provided by Rinat-Pfizer derived from two pairs of monozygotic twins. We found that IGL preferential gene segment utilization is common and, surprisingly, public CDR-L3s are shared at a minimal frequency of ~20% across the multiple samples. This included the presence of identical full-length IGLs. Additionally, comparative analysis between public and private CDR-L3 groups highlighted notable differences such as reduction of N/P nucleotide addition within the public group. Overall the data suggest positive selection of BCR IGL chains independent of the IGH chain. In general, BCR repertoire studies present the challenge of managing and analyzing daunting quantities of raw sequence data, so we have begun development of a cloud-based solution (APPSOMA) to provide a universally accessible server for data storage, management, and computational tools to streamline the repertoire analysis process. This service will be made available to the public. As such, the results from our IGL repertoire study will be derived from the cloud-based pipeline to showcase its benefits and convenience to the repertoire community.

P3.04.06
Defects in VDJ recombination and thymocyte development induced by T cell-specific deletion of protein phosphatase 4/PP4

E. Hsing, F. Liao, W. Hsou, Y. Lin, Y. Jhou, ***C. Huang****;*
National Health Research Institutes, Zhunan, Miaoli County, Taiwan.

Thymocyte development is regulated at many dimensions such as gene rearrangement, receptor generation and repertoire selection, of which all are essential for establishing a protective immune system for the host. Protein phosphatase 4 (PP4) is a ubiquitous serine/threonine phosphatase that has been shown to regulate MAP kinase signaling and irradiation-induced DNA repair. Recently we generated mice with T cell specific-ablation of PP4, and observed defects in their thymocyte development. Mixed bone marrow chimera experiment showed that PP4 deficiency induced partial blocks at multiple developmental stages. Further characterizations revealed reduced IL-7 responses and increased apoptosis in PP4-deficient thymocytes. More interestingly, in these thymocytes we also found accumulation of VDJ recombination intermediates via linker-mediated PCR, implicating defects in gene rearrangement; results from an inducible in vitro VDJ recombination assay corroborated this conclusion. The introduction of TCR transgenes rescued PP4-deficient thymocyte numbers to WT levels, suggesting defective TCR generation as the major contributor to the impaired thymocyte development in PP4-deficient mice. Finally, enhanced H2AX phosphorylation and foci formation in PP4-deficient thymocytes suggested altered NHEJ responses as the mechanism of PP4-mediated regulations. Our results thus provide clear evidences that PP4 is an essential component of VDJ recombination and thymocyte development, and further raise the possibility of therapeutic modulation of immune repertoires with PP4-inhibiting compounds.

P3.04.07
XLF is required for the generation of junctional diversity by TdT

H. IJspeert*, I. Jerchel, R. Leite, N. S. Verkaik, J. J. M. van Dongen, D. C. van Gent, M. van der Burg;*
Erasmus MC, Rotterdam, Netherlands.

V(D)J recombination takes place during lymphocyte development in order to generate a large repertoire of T and B cell receptors. This process starts with the introduction of DNA double strands breaks by the recombination activating genes (RAG1/RAG2). Subsequently, the breaks are processed by factors of the non-homologous end-joining (NHEJ) pathway and non-templated (N) nucleotides are introduced by terminal deoxynucleotidyl transferase (TdT) to generate junction diversity. Finally, these breaks are repaired. Mutations in the NHEJ factor XLF (Cernunnos) result in an immunodeficiency syndrome characterized by sensitivity for ionizing radiation, microcephaly, and developmental delay. We showed that compared to deficiencies in the NHEJ factors Artemis and DNA-PKcs, XLF deficiency has a more pronounced effect on DNA repair given the extreme radiosensitivity,

whereas the effect on V(D)J recombination was milder. Moreover, we found that XLF deficient patients have a reduced CDR3 length of the immunoglobulin heavy chain and T-cell receptor gamma rearrangements caused by a significant reduction in the number of N-nulceotides. This may imply that XLF is essential for the generation of junction diversity by TdT. We showed that XLF is not necessary for the recruitment of TdT to DNA ends, indicating that XLF might be required for proper positioning of TdT within the repair complex. In conclusion, XLF has a prominent role in DNA repair and during V(D)J recombination XLF is involved in the generation of junctional diversity by TdT.

P3.04.08
High throughput sequencing data reveals the shape of the immunoglobulin repertoire

***K. J. L. Jackson**, A. M. Collins;*
University of New South Wales, Sydney, Australia.

VDJ recombination generates such unfathomable diversity among lymphocyte receptors that it has been said that any immunoglobulin heavy chain (IGH) rearrangement is likely to be generated just once in a human lifetime. Deep sequencing now allows us to test this prediction.
Unique features of the IGH gene locus means that HTS data from a single individual can be used to generate empirically-derived distributions of probabilities associated with each part of the rearrangement process. This has allowed us to create large, simulated repertoires of IGH sequences, defining the 'shape' and composition of an individual's IGH repertoire. Simulation results have been cross-validated with observed repertoires from other genotype-matched individuals.
VDJ recombination is not an unconstrained generator of incomprehensible diversity, but rather has evolved to shape the IGH repertoire towards a relatively small pool of high frequency IGHs. Remarkably, around 5% of the possible VDJ rearrangements are carried by 95% of naïve B cells, and these are shared with other individuals of similar genotype. A long 'tail' of low frequency, extremely diverse IGHs are unique to an individual. The highest frequency IGHs are each carried by about a million naïve lymphocytes, while each IGH in the tail is carried by a unique lymphocyte. The core of the B-cell repertoire is genetically hard-wired, and this may ensure that each individual possesses a repertoire of functionally important IGH at high copy number. This 'shape' of the repertoire has important implications for the ontogeny of the immune response, and for the kinetics of immune reactivity.

P3.04.09
Identifying factors responsible for maintenance of immunoglobulin class switch recombination

***M. X. Le**[1], S. Ramachandran[1], R. M. Nepal[1], A. Chopra[1], T. Ketela[1,2], J. Moffat[1,2], A. Martin[1];*
[1]University of Toronto, Toronto, ON, Canada, [2]Donnelly Centre for Cellular and Biomolecular Research, Toronto, ON, Canada.

Class switch recombination (CSR) in B-cells occurs in response to antigenic stimulation and is responsible for the production of additional antibody isotypes present in an immune response. The mechanism behind this genetic rearrangement requires mutations introduced by the enzyme activation induced cytidine deaminase (AID) and careful interplay of several DNA repair processes in a manner which remains poorly understood.
Our laboratory recently completed a genome-wide shRNA screen in pursuit of uncharacterized factors involved in CSR. We applied a lentiviral shRNA library based knock-down approach with the CSR-inducible murine B-cell line, CH12F3-2. From this screen we identified an extensive list of candidate factors required for maintenance of CSR, which we have validated on an individual basis. We have carried out further studies on a select group of these putative CSR factors based on bioinformatics analysis and literature review.
One of the genes of exceptional interest identified from the screen encodes an evolutionarily conserved protein with putative functions in DNA damage repair, DNA replication, and transcription. Our studies confirm an additional role for maintenance of CSR in B-cells. We demonstrate that the gene of interest exhibits its function following AID mutagenesis and formation of DNA double-stranded breaks, consistent with published reports suggesting a DNA repair function for this protein. We also reveal that a reduced level of this protein leads to cell cycle arrest and a delayed response to genotoxic stress. Our results reveal a novel link between DNA repair and successful CSR.

P3.04.10
Detection Of Interferon Alpha Receptor 2 in Interferon Resistant HCV Patients

***S. R. Marazi**, A. Rashid, Q. Bashir;*
Army Medical College, National University of Sciences & Technology,(NUST), Rawalpindi, Pakistan.

Hepatitis C virus (HCV) infects more than 3 percent of world's population and 10 percent of Pakistan's population. The virus multiplies in the host with novel methods, defending itself from host immune response, leading ultimately to liver cirrhosis and hepatocellular carcinoma (HCC). The approved therapy for the disease is interferon alpha (INF-α) in combination with ribavirin. The disease is incurable/ resistant due to multiple viral and cellular factors. A strong functional host system can minimize the viral count to zero.
In my study, the detection of IFNAR-2 was examined in patients who were resistant to IFN therapy (administered once or twice). Their liver biopsy specimens were then used to investigate the detection of IFNAR2.The significance of this work was based on the fact that IFN has a thousand fold greater affinity to IFNAR-2 as compared to IFNAR-1, making it a key factor in the initiation of IFN signalling pathway. However IFNAR-2 mRNA was detected in 90% of the patients in this study, while all the responders were positive for IFNAR-2. The results of my study also showed that there was no significant difference in the presence of IFNAR-2 in HCV patients responding or showing resistance to IFN therapy. Accordingly, after sequencing the complete coding region of IFNAR-2, DNA sequence revealed a novel transition at nucleotide positions converting amino acid proline into arginine resulting in resistance to IFN therapy in HCV patients

P3.04.11
In vivo analysis of Aicda gene regulation: critical balance between upstream enhancer and intronic repressor for the appropriate expression

*L. Huong[1,2], M. Kobayashi[1], M. Nakata[1], G. Shioi[3], H. Miyachi[1], T. Honjo[1], **H. Nagaoka**[4];*
[1]Kyoto University, Kyoto, Japan, [2]Thai Nguyen University of Medicine and Pharmacy, Thai Nguyen, Viet Nam, [3]RIKEN Center for Developmental Biology, Kobe, Japan, [4]Gifu University, Gifu, Japan.

The Aicda gene, encoding activation-induced cytidine deaminase (AID) is strongly transcribed in activated B cells to diversify immunoglobulin genes, yet low-level expressions upon physiological/pathological stimuli in various cells have been reported. Mutagenic nature of AID has shown to be involved in tumor development. Here, by using a transgenic strategy with bacterial artificial chromosomes (BAC), we examined the in vivo function of Aicda regulatory elements which cluster in two regions, namely approximately 8-kb upstream of the transcription start site (region 4) and the first intron (region 2). Deletion of either of regions completely abolished the expression of Aicda-BAC-reporters, indicating critical roles of these elements. Furthermore, we found that the selective deletion of two C/EBP binding sites in region 4 inactivates its enhancer activity in spite of the presence of the intact NF-κB-, STAT6- and Smad-binding-sites. On the other hand, the selective deletion of E2F- and c-Myb-binding-sites in region 2 increased the frequency of the cells with active Aicda promoter in germinal center B cells, indicating that E2F and c-Myb function as silencer in vivo. Interestingly, the silencer deletion did not cause the ectopic activation of Aicda promoter, indicating that specific stimulation of the enhancer is required for Aicda activation. In summary, the precise regulation of the Aicda promoter appears to dependent on a coordinated balance of activities between the enhancer and silencer elements.

P3.04.12
T-cell receptor (TCR) profiling by next-generation sequencing

***T. Oron**, L. Marchand, Q. Li, C. Polychronakos;*
Research Institute of the McGill University Health Center, McGill University, Montreal, QC, Canada.

Background
T-lymphocytes have the capacity to recognize antigens from millions of pathogens with a remarkable degree of specificity, due to the molecular diversity of the T cell receptor (TCR) repertoire. Because of this diversity, the TCR, arguably the most important molecule in both host defense and autoimmunity has been impossible to study in-depth with conventional sequencing. Next-generation sequencing, by defining individual molecules, now allows the delineation of this repertoire in unprecedented depth.
Objective
To evaluate the accuracy of our innovative TCR profiling protocol.
Experimental Approach
RNA from T cells clones with one defined TCR rearrangement was mixed at different concentrations with samples of normal human CD4+ T cells. A 5'-RACE protocol that we have developed was used for the unbiased amplification of all TCRs, despite the large diversity of their 5' ends. Amplicons were multiplexed and sequenced at a depth of 1,000,000x on the Illumina MiSeq. V, J and D segment choice were assigned by a paired-ends modification of the IMGT algorithm. Copy count of TCR clones was used to calculate the frequency of each clone in every mix.
Results
In our preliminary studies the assay was able to accurately detect the specific clones as well as their concentrations in each mix. It was found to be sensitive, reliable and repeatable.
Conclusions
Accurate profiling of the TCR repertoire using 5' race and next generation sequencing is a promising unbiased and precise method.

P3.04.13
AID expression in pancreas promotes an inflammatory response

***A. Pérez-García**[1], P. Pérez-Durán[1], F. X Real[2], A. Ramiro[1];*
[1]Centro Nacional de Investigaciones Cardiológicas (CNIC), Madrid, Spain, [2]National Cancer Research Center (CNIO), Madrid, Spain.

Activation-induced deaminase (AID) is essential for the reactions of antibody secondary diversification in germinal centers, namely somatic hypermutation (SHM) and class switch recombination (CSR), which take place in B cells that have been activated by antigen. However, AID activity is not completely restricted to immunoglobulin genes and can trigger both the accumulation of mutations in numerous loci and the generation of lymphomagenic chromosome translocations. This potentially oncogenic activity of AID may not be limited to the B cell lineage, as it has been shown that AID expression can be induced in epithelial cells through the activation of the NF-κB pathway. Importantly, NF-κB-dependent inflammation is an important player in many neoplasias, including pancreatic adenocarcinoma (PDAC). To analyze the role of AID in the development of PDAC we have generated a conditional mouse model for AID overexpression in pancreas ($ROSA26^{AIDki/+}p48Cre^{ki/+}$). AID activity was confirmed by the detection of mutations by next generation sequencing. Intriguingly, $ROSA26^{AIDki/+}p48Cre^{ki/+}$ mice did not seem to develop PDAC. However, analysis of aged $ROSA26^{AIDki/+}p48Cre^{ki/+}$ mice revealed an inflammatory response in the pancreas. This inflammation was characterized by the appearance of CD3 and Pax5 positive foci and increased levels of TNFα and IL1ra. We propose that AID activity in epithelial pancreatic cells could promote relatively widespread lesions on the DNA leading to the activation of the DNA damage response, which in turn would promote the expression of NKG2D ligands, the recruitment of cells expressing NKG2D receptors and the removal of damaged cells, thereby blocking PDAC development.

P3.04.14
Holy cow - reshaping bovine antibody diversity with disulfide-bonded ultralong CDR H3s

***V. Smider**[1,2], F. Wang[1], D. Eckiert[1], I. Wilson[1], P. Schultz[1], M. Criscitiello[3], Y. Zhang[1], I. Ahmad[1], A. Torkamani[1], W. Mwangi[3];*
[1]The Scripps Research Institute, La Jolla, CA, United States, [2]Fabrus Inc, La Jolla, CA, United States, [3]Texas A & M University, College Station, TX, United States.

Cows have limited genome encoded combinatorial diversity potential, yet mount a robust antibody response. Cows have few V-regions but exceptionally long CDR H3 loops, however the mechanism for creating diversity is not understood. Crystal structures of two cow antibodies reveal that these CDR H3s form a very unusual architecture composed of a b-strand "stalk" that supports a structurally diverse, disulfide-bonded, "knob" domain. Deep sequencing revealed that ultralong CDR H3s contain a remarkable complexity of cysteines, suggesting that these disulfide-bonded mini-domains may arise during repertoire development. Sequence analysis indicates that diversity arises from somatic hypermutation of an ultralong DH with a severe codon bias towards mutation to cysteine. These unusual antibodies can be elicited to recognize defined antigens through the knob domain. Thus, the bovine immune system produces an antibody repertoire composed of CDR H3s of unprecedented length that fold into a diversity of mini-domains generated through combinations of somatically generated disulfides.

P3.04.15
T cell receptor repertoire plasticity in peripheral CD8 T cells

***P. G. Thomas**, G. Wang, J. L. McClaren, M. Y. Morris, P. C. Doherty, P. Dash;*
St. Jude Children's Research Hospital, Memphis, TN, United States.

Using a technique for the paired amplification of TCRα and β chains from single cells, we have discovered a surprising plasticity in the peripheral TCR repertoire, particularly under conditions of inflammation. This plasticity includes multiple instances of TCR revision, where changes are made in the TCR coding sequence by de novo rearrangement. Here we describe the induction of this process in murine CD8+ T cells derived from influenza-infected lungs and human T cells derived from CMV-infected individuals ex vivo or stimulated in single-cell cultures in vitro. Taking advantage of the co-expression of productive and non-productive *Tcra* alleles, we demonstrated secondary rearrangement in the TCRβ locus ex vivo, while the in vitro cultures demonstrated a remarkably high rate of revision following strong stimulation. Not surprisingly, revision was found to be RAG-dependent. Utilizing a model of peripheral deletion of RAG2, we showed that mice deficient in revision showed delayed onset and severity of disease in an experimental autoimmune encephalomyelitis (EAE) model, but also produced a less functional T cell response following infectious challenge. Thus, peripheral TCR revision appears to be a robust process that contributes to optimal T cell functionality during infection but may also contribute to the development of autoimmunity.

P3.05 Antigen processing and presentation

P3.05.01
Hypoxia directly enhances dendritic cell antigen presentation

***S. Aiello**, F. Rocchetta, N. Azzollini, P. Cassis, S. Solini, M. Mister, G. Remuzzi, M. Noris;*
Mario Negri Institute for Pharmacological Research, Ranica, Italy.

Danger molecules from ischemic tissues activate innate immunity by increasing dendritic cell (DC) immunogenicity.
To evaluate whether hypoxia directly impacts on DC antigen presentation capacity, we used mouse B6-OVA-DCs, expressing chicken OVA peptides in the context of class I and II MHC, and OVA-specific TCR-transgenic B6 syngeneic CD8 (OTI) and CD4 (OTII) T cells.
Bone-marrow derived OVA-DCs were pre-exposed for 4hr to 1% (hypoxia) or 20% O_2 (normoxia) and then used as stimulators of OTI

or OTII T cells for 2 days. Higher numbers of IFNγ-producing CD8 and CD4 T cell clones emerged ($p<0.05$) in response to hypoxic than to normoxic OVA-DCs (OTI 162±26, OTII 72±20 vs: OTI 115±23, OTII 36±15 spots/50000 cells, n=4). A larger increase of IFNγ-producing clones was found in response to hypoxic OVA-DCs exposed to conditioned medium (cm) from hypoxic OVA-B6 renal tubuli vs normoxic OVA-DC exposed to cm from normoxic tubuli ($p<0.01$).
Similarly, non-transgenic B6-DCs pre-incubated with OVA protein (plus hypoxic tubular cm) during hypoxia, induced higher numbers of IFNγ-producing T cell clones than normoxic B6 DCs (pre-incubated with OVA plus normoxic tubular cm): OTI 60±15, OTII 50±10 vs OTI 31±8, OTII 23±6 spots, n=3, $p<0.05$. This indicates that hypoxia augmented the capacity of DCs to present and cross-present antigens to CD4 and CD8 T cells, respectively.
Altogether these results suggest that hypoxia increases antigen presentation by DCs both by direct action on DCs and through release of soluble factors from injured tissues. Such events eventually translate into an augmented adaptive T cells immune response.

P3.05.02
Synthetic immunoactive fragments of Survivin: selection and application for monomer and dimer detection

E. V. Akhidova[1], *M. V. Kalintseva*[1], *T. D. Volkova*[1], *I. Y. Yakupov*[1], *D. O. Koroev*[1], *L. E. Zavalishina*[2], *O. M. Volpina*[1];
[1]*Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry, Russian Academy of Sciences, Moscow, Russian Federation,* [2]*Moscow Gertsen Oncology Research Institute, Moscow, Russian Federation.*

We have selected 15 immunoactive fragments of Survivin and synthesized them. Survivin is overexpressed in tumor tissues and exists in monomeric and dimeric forms. It was shown that the monomer participates in mitosis regulation while the dimer's function is not clear yet. Survivin monomer and dimer detection in normal and tumor cells is necessary for functional studies of survivin state and for tumor differential diagnostics. We proposed that the immunoactive fragments of survivin will be able to induce specific antibodies for selective detection of monomer and dimer. All the selected peptides included B- epitopes of survivin and several of them included predicted T-helper epitopes. Prediction of T-helper epitopes was based on the algorithm where the motif consists of nine amino acid residues with a hydrophobic residue in the 1-st position and positively charged residue at the 9-th position. All the synthetic fragments with T-helper epitopes were able to induce antibody response in experimental animals in a free nonconjugated with a protein carrier form. Peptides without T-helper epitopes were immunoactive only as KLH-conjugates. Monospecific antibodies to different regions of survivin were obtained from rabbit antipeptide sera using an affinity chromatography on sorbents with immobilized peptides. Using western blot of cell lysates from different types of tumor we selected antibodies which were able to differentiate monomeric and dimeric forms of survivin. These antibodies may be used for cancer diagnostics and functional studies of survivin state.
Supported by RFBR grants 12-04-31590,13-04-00654.

P3.05.03
The impact of sub-cellular localization, dose, and expression pattern of tumour antigen on cross-presentation efficiency

C. Anyaegbu, *S. Fisher, R. A. Lake, B. W. S. Robinson;*
University of Western Australia, Perth, Australia.

Effective cross-presentation mediated anti-tumor immunity requires the identification of suitable target-antigens. Yet, much remains unclear about the significance of tumor-antigen properties such as sub-cellular localization, dose, and expression pattern, in efficient cross-presentation induction. The subcellular localization of an antigen within a tumour cell, may affect how efficiently it is cross-presented in different physiological contexts.
In this study, we compared tumor specific T-cell responses elicited by mouse B16-F10 melanoma tumours expressing a model antigen (CL4 epitope of haemagglutinin), in cytoplasmic, secretory, or nuclear sub-cellular compartments within the tumor-cell. All three tumor cell-lines similarly expressed ~7 fg of antigen per cell.
Our results show that cross-presentation is remarkably sensitive to antigen-dose. Cross-presentation induced proliferation of CL4-TCR transgenic $CD8^+$ T-cells was evident at as little as 0.35 ng, near maximal from 0.70 – 2.45 ng without change, and maximal at 3.5 ng of inoculated antigen-bearing cells. At 0.35 ng of antigen-bearing cells, we found that nuclear localized antigen was less efficiently cross-presented compared to its cytoplasmic and secreted counterparts. Furthermore, gemcitabine (an apoptosis inducing chemotherapy) augmented cross-presentation efficiency when antigen was cytoplasmic and nuclear localized, but intriguingly diminished when antigen was secreted.
Put together, our data suggests that the dose and localization of an antigen within a tumor can influence the robustness of the anti-tumor T-cell response. In addition, gemcitabine can augment cross-presentation by presumably unmasking previously unavailable nuclear antigens via apoptosis. These findings imply that the sub-cellular localisation of an antigen should be taken into account when designing immunotherapy and chemotherapy strategies.

P3.05.04
High resolution mass spectrometry reveals unanticipated depth and diversity of HLA peptidomes

M. Bassani-Sternberg, *M. Mann;*
Max Planck Institute of Biochemistry, Martinsried, Germany.

The HLA peptidome reflects the state of health of each cell to the immune system, and is thought to communicate the changes in the cellular proteome under pathological conditions such as virus infection or tumorigenic transformation. In this study we used a linear quadrupole - Orbitrap mass spectrometer and together with the MaxQuant bioinformatics platforms to acquire the largest HLA peptidome to be identified so far in any single system. The HLA peptidomes purified from the B-cell acute lymphoblastic leukemia isogenic lines SupB15WT and SupB15RT where the latter is resistant to imatinib treatment, revealed multi-level complexity. This complexity was validated in other primary and cancer cell lines. A subset of the cellular proteins representing fundamental tissue specific characteristics are selectively presented in all cell types analyzed, and in addition proliferation, transcription and translation are presented in cancer cells. Interestingly, individual proteins yield many different peptides with epitopes that fit the cellular HLA allele's consensus binding motifs contrary to the 'one epitope per protein' hypothesis. SupB15WT cells were treated with imatinib, and the changes in their HLA repertoires were quantified with label-free or SILAC methods. Interestingly, the expression levels of their proteins of origin did not predict expression levels of their HLA peptides indicating that the cellular mechanisms responsible for the processing of the HLA peptides play a key role in diversifying the repertoire of HLA peptidomes.

P3.05.05
Tumor associated MUC1 carried by microvesicles is cross-processed by Dendritic cells generating immunogenic MUC1 glycoepitopes and is cross-presented to CD8+T cells

F. Battisti[1], *H. Rahimi*[1], *F. Belleudi*[2], *C. Napoletano*[1], *I. Zizzari*[1], *M. Antonilli*[3], *V. Visconti*[1], *F. Bellati*[3], *M. Nuti*[1], *A. Rughetti*[1];
[1]*Department of Experimental Medicine, Sapienza, Rome, Italy,* [2]*Department of Clinical and Molecular Medicine, Sapienza, Rome, Italy,* [3]*Department of Obstetrics and Gynaecology, Sapienza, Rome, Italy.*

The induction of an efficacious anti-tumor immune response (IR) requires the cross-processing and presentation of tumor antigen by Dendritic Cells (DCs). Block of endocytated tumor associated antigen (TAA) in the early compartments of the intracellular processing machinery shifts the IR towards a Th2 balance. MUC1 is one of the most relevant tumor associated glycoprotein expressed by epithelial cells and its immunogenicity is altered by the glycosylation profile. Moreover soluble MUC1 antigen has shown to be blocked in endolysosomal compartment of DCs thus inducing mostly a Th2 response. Objective of this study was to investigate whether glycosylation pattern and MUC1 bound to microvesicles could influence the antigen processing by DCs. MUC1 as soluble molecule, independently by the glycosylation profile, appears to be blocked in the pre-endosomal compartment. Receptor-mediated endocytosis pushes further the processing in the HLAII compartment. Cross-

processing of MUC1 in HLAI compartment is observed only when MUC1 is carried by microvesicles (MUC1-MVs). Moreover only DCs stimulated with MUC1-MVs are able to induce IFN-γ production by MUC1 specific CD8+T cells. The distinct processing of the MUC1 membrane bound is accompanied by deglycosylation processes thus generating Tn-MUC1 immunogenic glycoepitopes. These results show that MUC1 undergoes to alternative processing pathways depending by its form of release thus modifying MUC1 immunogenicity. Moreover these experimental evidence can be important to design efficacious glycoantigen formulations for DC-based cancer vaccines.

P3.05.06
Differential antigen-dependency of CD4+ and CD8+ T cells

A. C. Behrendt[1]*, H. Rabenstein*[1]*, J. Ellwart*[2]*, M. Horsch*[2]*, J. Beckers*[1]*, R. Obst*[1]*;*
[1]Ludwig-Maximillian-University, Munich, Germany, [2]Helmholtz Center, Munich, Germany.

The presence of cognate antigen is the key requirement for the differentiation and expansion of T cells. Nevertheless, the impact of stimulus duration has only rarely been compared between CD4+ and CD8+ T cells side by side. We followed proliferation of both subsets upon transient or persistent TCR stimulation and found CD4+, but not CD8+ T cells to be more dependent on prolonged antigen presentation for extensive proliferation. The impaired ability of CD4+ T cells to expand in the absence of antigen was not caused by coinhibitory signals or a lack of inflammatory cytokines. The antigen dependency of CD4+ T cells was not affected by Th1/Th2 polarization or memory differentiation and thus is likely to be a lineage intrinsic feature. The prolonged proliferation of CD8+ T cells after ceasing the TCR stimulus resulted in complete effector differentiation and was independent of self-peptide/MHC I complexes. Transcriptome analyses revealed gene expression of CD4+ T cells to be more dependent on persistent TCR stimulation than of CD8+ T cells. These data reflected the biology of MHC molecules, as we could demonstrate that MHC class II, but not class I molecules were stabilized on activated dendritic cells in vivo.

P3.05.07
Immunoproteasome induction and MHC class I molecules presentation in motor neurons of a familial Amyotrophic Lateral Ssclerosis mouse model

G. Nardo, R. Iennaco, M. Trolese, ***C. Bendotti****;*
IRCCS-Istituto Mario Negri, Milano, Italy.

Amyotrophic Lateral Sclerosis (ALS) is a fatal neurodegenerative disease, characterized by selective death of motor neurons. Growing evidence suggest that the immune system play a role in the pathogenesis and progression of ALS. We recently found in SOD1G93A mice, the most reliable animal model of ALS, a progressive upregulation of the immunoproteasome subunit, LMP7, starting before symptoms until the advanced stage of disease.
Immunoproteasome recognizes and degrades polyubiquitinated protein substrates to generate small protein fragments that can be used by major histocompatibility complex (MHC) class I molecules for the display of antigens to the adaptive immune system. Therefore, we aimed to examine the expression of MHCI and the associated β2 microglobulin (β2m), together with LMP7 in the spinal cord and peripheral nerves of SOD1G93A mice at differenst stages of the disease using immunohostochemical analysis and confocal microscopy.
We report that motor neurons and surrounding glial cells in SOD1G93A mice at early stages of the disease, exhibit a remarkable induction of LMP7, MHC-I and β2 microglobulin. In particular a remarkable overexpression of all these proteins was found in the motor axons and neuromuscular junction of SOD1G03A mice during the disease course.
These data suggests that the activation of the adaptive immune system molecules both at central and peripheral level take part in the pathogenesis and/or progression of ALS. Studies are ongoing to investigate the beneficial or detrimental effect of this immune response.

P3.05.08
In vitro study of Thyroglobulin peptides associated to HLA-DR3 under thyroid antigen presentation conditions

T. Ciudad[1]*, A. Kim*[2]*, J. Alonso*[1]*, E. A. James*[3]*, W. W. Kwok*[3]*, S. Sadegh-Nasseri*[2]*, D. Jaraquemada*[1]*;*
[1]IBB, Universidad Autónoma de Barcelona, Cerdanyola del Valles, Spain, [2]Johns Hopkins University, Baltimore, MD, United States, [3]Benaroya Research Institute at Virginia Mason, Seattle, WA, United States.

Thyroglobulin (Tg) peptides are presented in vivo by HLA-DR molecules in human autoimmune Graves' disease and at least one of these (Tg2098) has been shown to induce autoimmune thyroiditis in HLA-DR3 transgenic mice. Here, we have indentified immunodominant epitopes from Tg that are bound and presented to HLA-DR3, using an new in vitro cell-free system that recreates the MHC class II antigen processing compartment.
We used soluble HLA-DR3, HLA-DM and thyroglobulin to mimick different processing conditions, i.e. (i) dendritic cell processing (Cathepsin B, H and S at pH5) and (ii) predigestion of Tg as in the thyroid colloid (cathepsins B, L and S at pH 7) before antigen uptake. Peptide/HLA-DR3 complexes were immunoprecipitated with the anti-DR monoclonal antibody L243. Bound peptides were eluted with trifluoroacetic acid 0.1% and filtered through a 10-kDa molecular weight cut-off Microcon filter. Samples were analyzed by MALDI and peptides were sequenced using a LTQ Orbitrap. MS/MS fragmentation spectra were searched using SEQUEST against a combined Human UniProt target/decoy database.
Predigestion of Tg significatively increased the number of sequenced peptides, especially those predicted to be high affinity binders, as well as the number of peptides in each nested set. Moreover, 3 peptides previously described in literature were sequenced using this in vitro system. The immunodominant peptide (Tg2098) only appeared when Tg was predigested. Data suggests that degradation in peripheral tissue may condition antigen presentation, allowing the generation of a greater diversity of peptides than those generated by the digestion of full antigens.

Epitopes of 21-hydroxylase targeted by autoreactive T cells in patients with autoimmune Addison's disease are also targeted by T cells in mice immunized with 21-hydroxylase protein

K. Edvardsen[1]*, E. Bratland*[1]*, A. Hellesen*[1,2]*, E. S. Husebye*[1,2]*;*
[1]Department of Clinical Science, University of Bergen, Bergen, Norway, [2]Department of Medicine, Haukeland University Hospital, Bergen, Norway.

Autoimmune Addison's disease, or primary adrenocortical insufficiency, is a prototypic organ-specific autoimmune disorder, caused by immune-mediated destruction of the adrenal cortex and subsequent lack of steroid hormones. The disease is characterized by antigen-specific immune responses against certain enzymes vital for steroid hormone biosynthesis, most specifically 21-hydoxylase (21OH), which is exclusively expressed in the adrenal cortex. Both serum autoantibodies and peripheral blood T cell responses against 21OH can readily be demonstrated in patients with Addison's disease. Although patient T cell responses against 21OH epitopes display a broad pattern (partly reflecting HLA differences), dominant peptide epitopes have also been described, such as a B*0801 restricted epitope towards the C-terminal end of the protein. In the present study we have compared *ex vivo* T cell responses against 21OH peptides in Addison's disease patients and in mice immunized with full-length human 21OH protein. Interestingly, the dominating epitopes in patients are also targeted by T cells in immunized mice, in both the CD4+ and CD8+ compartments. This trend was also noted across several mouse strains carrying different MHC haplotypes. We therefore conclude that these epitopes probably are naturally processed and presented from the full-length 21OH protein.

P3.05.10
Sub-optimal antigen presentation of CD8+ T cell epitopes by dendritic cells infected with Trypanosoma cruzi

J. Ersching[1,2]*, K. R. Bortoluci*[3,2]*, M. M. Rodrigues*[3,2]*;*
[1]Universidade de São Paulo, São Paulo, Brazil, [2]Centro de Terapia Celular e Molecular, Sao Paulo, Brazil, [3]Universidade Federal de São Paulo, São Paulo, Brazil.

Introduction: The $CD8^+$ T cell mediated immune response observed after infection with the protozoan parasite *Trypanosoma cruzi* is sub-optimal characterized by a low T cell fitness. A possible explanation for the sub-optimal immune response could be related to a defective antigen presentation by dendritic cells (DC). Here, we tested the hypothesis that antigen presentation of $CD8^+$ T cell epitopes by *T. cruzi*-infected DC is sub-optimal.
Results: Murine bone marrow derived cultured DC were infected *in vitro* and used to stimulate IFN-γ secretion by effector $CD8^+$ T cells collected from infected mice. By sorting, we observed that once exposed to *T. cruzi*, both DC infected or not stimulated specific T cells. The activation of T cells was dependent on TAP, ribosomes, proteasomes and *trans*-Golgi network, indicating that epitopes are processed and presented through the canonical cytosolic pathway. Nonetheless, infected DC stimulated significantly less specific $CD8^+$ T cells when compared to DC pulsed with peptide or infected with a recombinant human adenovirus type 5 expressing a *T. cruzi* $CD8^+$ T cell epitope. The difference cannot be attributed to the amount of antigen produced upon infection as it did not change when we used different doses of parasites or adenoviruses. Also, we were unable to find differences on the DC activation markers (CD40, CD80, CD86 and MHC-II).
Conclusion: We concluded that DC infected *in vitro* with *T. cruzi* are sub-optimal to present parasite derived $CD8^+$ T cells epitopes, a fact that may explain the sub-optimal activation of these cells we described.

P3.05.11
Bone marrow endothelial cells of patients with multiple myeloma: antigen presenting functions and T cell regulation

A. Ferrucci*, P. Leone, R. Ria, V. Racanelli, A. Vacca;*
Department of Internal Medicine and Clinical Oncology, University of Bari Medical School, Bari, Italy.

Immunity against cancer is hampered by local mechanisms promoting tumor evasion from T cell surveillance or tumor-specific T cell tolerance in the tumor microenvironment. We have analyzed the antigen presenting capacities of endothelial cells from bone marrow of patients with multiple myeloma (MM), an inexorably lethal plasma cell malignancy. We have found that bone marrow endothelial cells basally express both class I and class II MHC molecules as well as the costimulatory molecules CD80 and CD86. The expression level of these molecules is slightly lower than that of professional antigen presenting cells, such as dendritic cells, from the same patients. Bone marrow endothelial cells also express the components of the MHC class I antigen processing machinery which include the constitutive proteasome subunits δ (β1), MB1 (β5) and ζ (β2); the interferon-γ (INF-γ)-inducible proteasome (immunoproteasome) subunits LMP2 (β1i), LMP7 (β5i) and LMP10 (β2i); the peptide transporters TAP1 and TAP2 and the endoplasmic reticulum chaperones calnexin, calreticulin, ERp57 and tapasin. When bone marrow endothelial cells are cultured, CD80 and CD86 expression decreases, class II MHC molecule largely disappears and class I MHC molecule does not significantly change. Both class II MHC and costimulatory molecule expression are restored by bone marrow endothelial cell exposure to IFN-γ and IL-6. Cultured bone marrow endothelial cells can activate purified allogeneic and autologous CD4 and CD8 T cells.

P3.05.12
Inhibition of ERAP1 function promotes human NK cell immune responses against tumors: an innovative strategy of anticancer immunotherapy

L. Cifaldi[1], P. Romania[1], D. Pende[2], F. Locatelli[1], ***D. Fruci***[1]*;*
[1]Ospedale Pediatrico Bambino Gesù, Rome, Italy, [2]Istituto Nazionale per la Ricerca sul Cancro, Genoa, Italy.

Endoplasmic reticulum aminopeptidase 1 (ERAP1) plays a key role in regulating the immune system function by trimming peptides for MHC class I antigen presentation. We have recently demonstrated that inhibition of ERAP1 in a murine T cell lymphoma results in tumor rejection in syngeneic mice by triggering innate and adaptive anti-tumor immune responses. Tumor rejection is mainly due to an immediate NK cell response and depends on the MHC class I-peptide repertoire presented by ERAP1-silenced cells.
Since the engagement of several human NK cell inhibitory receptors is strictly dependent on the composition of MHC class I-bound peptides, it is plausible that all individuals expressing these receptors could be sensitive to ERAP1 inhibition. To identify HLA class I-KIR combinations that are relevant to ERAP1 inhibition, several human cell lines, i.e. the C1R transfectants and tumor cell lines, were pharmacologically and genetically inhibited for ERAP1 function and tested for NK cell recognition. Herein, we show that suppression of peptide trimming affects the engagement of specific KIRs by enhancing NK cell killing. These results suggest a potential role for human ERAP1 in regulating NK cell immunity and establish rules to identify individuals who could benefit from ERAP1 inhibition for NK cell-mediated immunotherapeutic protocol.

P3.05.13
Human mesenchymal stromal cells derived from cervical neoplasisas down-regulate the expression of HLA class I molecules on cervical cancer cells

R. García-Rocha[1]*, J. J. Montesinos*[1]*, M. L. Mora-García*[2]*, M. C. Moreno-Lafont*[3]*, M. E. Castro-Manreza*[1]*, B. Weiss-Steider*[2]*, A. Monroy-García*[1]*;*
[1]Instituto Mexicano del Seguro Social, México, Mexico, [2]Universidad Nacional Autónoma de México, México, Mexico, [3]Instituto Politécnico Nacional, México, Mexico.

Mesenchymal stromal cells (MSCs), have the ability to home to tumors and participate in tumor stroma formation and support the growth of neoplastic cells; however, little is known about the way MSCs favor the immune evasion of tumor cells. Since the expression of HLA class I molecules (HLA-I) on tumor cells is necessary for their immune recognition, in this work we analyse whether MSCs influence the expression of HLA-I on cervical cancer cells (CeCa). For this purpose, tumor cells derived from CaSki cell line (HPV16+) were co-cultured for 96 h with MSCs derived from bone marrow- (BM-), normal cérvix- (NC-) and CeCa at ratio 1:1. In these experiments tumor cells cells were separated from MSCs by transwell chamber. After co-culture, CeCa cells were analyzed for HLA-I expression by flow cytometry and real time PCR. We observed that, HLA-I expression on CaSki cells diminished by 21.44%, 9.7% and 35.45% in the presence of BM- NC- and CeCa-MSCs respectively. Interestingly, the HLA-I downregulation on CeCa cells was strongly associated with a diminished expression of mRNA of the HLA class I heavy chain, mainly when CeCa cells were co-cultuted with CeCa-MSCs. In addition, conditioned media derived from CeCa/CeCa-MSCs cocultures were able to induce a strong HLA-I downregulation on CeCa cells. These results suggest that tumor-infiltrated MSCs may influence the immune evasion of tumor cells through the secretion of soluble factors that induce HLA-I downregulation. P3.05.14
Effect of MBA on therapeutic protein immunogenicity

T. Gefen[1,2], *J. Vaya*[1,3], *S. Khatib*[1,3], *D. Heller*[2,3], *E. Aizenstein*[1,3], *J. Pitcovski*[1,3];
[1]*MIGAL Galilee Research Institute, Kiryat Shmona, Israel,* [2]*Department of Animal Sciences, Robert H. Smith Faculty of Agriculture, Food and Environment, Hebrew University, Rehovot, Israel,* [3]*Tel Hai College, Upper Galilee, Israel.*

Antibodies play a central role in prophylaxis and prevention of infectious agents. The advantages of passive immunization with animal antibodies are: rapid adjustment to new forms of pathogens, ability to provide a multi epitope mixture of antibodies, relatively low cost of research and development, simple and inexpensive production due to the very efficient yield of antibodies in large animals' serum or chickens' egg yolk. However, passive vaccination with animal antibodies comprises a major disadvantage: repeated injections from the same cross-species source can evoke a strong immune response in the treated individual against the antibodies themselves. Although conjugation of polyethylene glycol (PEG) to the antibodies can potentially reduce their immunogenicity, the reduction is inconsistent and may significantly harm antibody activity. In previous work we have shown that conjugation of mannosamine-biotin adduct (MBA) molecules to antibodies efficiently decreases their immunogenicity and does not impair antibody activity.
Since the MBA molecule masks the antibodies better than currently used molecules, and to improve the MBA molecule or design additional masking molecules, we are currently investigating the immunological mechanism by which MBA decreases the immune response. The research focused on mechanisms involved in modified protein degradation and presentation by antigen-presenting cells. This could provide a better understanding of immune response regulation/silencing of foreign antigens. In addition, masking antibodies may pave the way to a novel, inexpensive and accessible approach for the prevention and treatment of infectious diseases.

P3.05.15
Identification of gliadin peptides restricted by the HLA Class I B8 encoded by B*0801 allele in linkage with the celiac disease-associated DR3-DQ2 haplotype

S. Picascia[1], *J. Sidney*[2], *A. Camarca*[1], *G. Mazzarella*[1], *A. Sada*[1], *G. Iaquinto*[3], *S. Auricchio*[4], *A. Sette*[2], *R. Troncone*[4], ***C. Gianfrani***[1];
[1]*Institute of Food Sciences-CNR, Avellino, Italy,* [2]*La Jolla Institute for Allergy and Immunology, San Diego, CA, United States,* [3]*Gastroenterology Unit, Moscati Hospital, Avellino, Italy,* [4]*Department of Pediatrics and E.L.F.I.D, University Federico II of Naples, Naples, Italy.*

Initial studies associated the HLA Class-I A*01 and B*08 alleles with genetic susceptibility to celiac disease (CD), although further analysis showed a primary association with alleles encoding for HLA DQ2 molecules. Thus, because of the strong linkage disequilibrium of A*01 and B*08 with the DR3-DQ2 haplotype, a potential role of A1 and B8 molecules in CD pathogenesis should be revaluated. We screened 2 alpha-, 2 omega-, and 2 gamma-gliadin proteins using bioinformatic algorithms available from the IEDB (www.iedb.org) for the presence of peptides predicted to bind A*0101 and B*0801. The top 1% scoring 9- and 10-mer peptides were synthesized and tested in MHC-peptide binding assays using purified A*0101 and B*0801 molecules. 23/97 peptides with binding motifs to A*0101 or B*0801 bound purified molecules with high affinity (IC50<500nM). Of these, 20/23 (87%) bound B*0801, whilst 3/23 (13%) bound A*0101. Peptides were assayed singularly by γ-IFN-ELISPOT in fresh PBMCs from 24 celiac patients on gluten free diet, grouped according to the presence or absence of A1 or B8 alleles. Several HLA B8-binding gliadin peptides induced strong IFN-γ responses in at least two HLA B8positive patients. Immunogenicity of selected peptides was further assessed on short-term CTL obtained from PBMC of responsive celiac patients. In conclusion, gliadin contains peptides that activate HLA B8-restricted CD8 T cells, suggesting that HLA Class I alleles may contribute to the increased susceptibility to CD of subjects carrying the HLA-DR3-DQ2 haplotype. Our data support a role of adaptive CD8 T cells in CD pathogenesis.

P3.05.16
Identification of inducible lymphoid structures in the skin: a key site to elicit contact hypersensitivity responses

Y. Natsuaki[1,2], *G. Egawa*[1], *S. Nakamizo*[1], *S. Hanakawa*[1], *T. Hashimoto*[2], *Y. Miyachi*[1], ***K. Kabashima***[1];
[1]*Department of Dermatology, Kyoto University Graduate School of Medicine, Kyoto, Japan,* [2]*Department of Dermatology, Kurume University School of Medicine, Fukuoka, Japan.*

Epicutaneous sensitization is established in the draining lymph nodes where dendritic cells (DCs) and T cells colocalize, however it remains unclear how the elicitation of cutaneous immune responses are efficiently induced in the skin.
To address this issue, we used murine contact hypersensitivity (CHS) as a delayed-type hypersensitivity model, which consists of the sensitization and elicitation phases. Initially, using CD11c-DTR (diphtheria toxin receptor) and Langerin-DTR knockin mice, we identified dermal DCs (dDCs), but not Langerhans cells, as a responsible DC subset for elicitation of CHS. This finding suggests that the dermis is the primary site for elicitation. Next, we visualized the dynamics of dDCs and memory T cells in the elicitation phase of CHS using two-photon microscopy, and found that dDCs accumulated in perivascular areas and interacted with skin-infiltrating memory T cells for several hours. This immunological synapse-like interaction was essential for memory T cells proliferation in situ in an antigen and integrin LFA-1 dependent manners. Intriguingly, dDC accumulation was abrogated by depletion of macrophages by means of LysM-DTR chimeric mice. Taken together, we have demonstrated for the first time that lymphoid structures are induced at the post capillary venules in the elicitation phase of CHS, and that this complex consists of perivascular macrophages, dDCs and memory T cells which interact via stable conjugated formation to induce efficient cutaneous acquired immune responses.

P3.05.17
Novel antigenic MHC class I peptides are generated and presented in the absence of tapasin

T. Kanaseki[1], *K. Camfield*[2], *N. Shastri*[2], *N. Sato*[1];
[1]*Sapporo Medical University, Sapporo, Japan,* [2]*University of California, Berkeley, Berkeley, CA, United States.*

Circulating CD8+ T cells recognize target cells by surveying the peptide MHC class I complex (pMHC I) on the surface, however the mechanisms of peptide processing yet remain to be clarified. Here we show that processing inside the endoplasmic reticulum (ER) profoundly affects the pMHC I repertoire formation and consequent T cell responses. In the absence of tapasin, a key component of the peptide loading complex (PLC), the repertoire is quantitatively and qualitatively altered, and the cells present a set of novel antigenic peptides that are never observed in wild type. Both induced antibody responses specific to tapasin-deficient cells and instability on the surface suggest the unique structure of novel antigenic pMHCIs. Indeed, a large-scale peptide sequencing by mass spectrometry reveals that the repertoire contains many unique peptides, which lose conventional anchor motives for MHC I binding. Our findings provide the molecular mechanism by which peptides are processed by PLC, and imply that such anchor-less peptides elicit CD8+ T cell responses to the cells with antigen processing defects.

P3.05.18
On the role of heparan sulfates in antigen cross-presentation

D. Knittel*, A. Savatier, J. Boulain, M. Léonetti;*
CEA, Gif-sur-Yvette, France.

We have previously shown that heparan sulfates (HS) can play a role in MHC class II restricted presentation of antigens (Ag) endowed with the ability to bind these sulfated polysaccharides. Furthermore, we showed that when such Ag are included in immune complexes, their MHC class II restricted presentation is increased up to 700 fold, demonstrating that HS can also contribute to receptor-mediated Ag class II restricted presentation (Léonetti and al., 2010). Here, we aimed to determine if HS also play a role in receptor-mediated Ag cross-presentation.

To investigate this aspect, we constructed three fusion proteins, which can bind immunoglobulins through their ZZ moiety and thus can target surface immunoglobulins. Two of them, called ZZOvaTat22-57 and ZZOvaDTR-BD can also bind HS while the third, called ZZOva, is devoid of this property. Cell binding experiments show that ZZOvaTat22-57 and ZZOvaDTR-BD can bind the Jaws II dendritic cell line, whereas ZZOva does not. Furthermore, in vitro studies show that ZZOvaTat22-57 and ZZOvaDTR-BD are 27 times more efficiently cross-presented than ZZOva. Then, to investigate whether HS can also influence cross-presentation mediated via other receptors, we complexed the three proteins with different anti-CD antibodies. We observed a synergistic effect when the Ag is targeted to the MHC class II molecule and has the capacity to bind HS.
Our results show that HS may positively influence different pathways of receptor-mediated Ag cross presentation. These findings might pave the way to a new generation of vaccine with improve T-cell stimulating properties.

P3.05.19
Porcine leukocyte antigen-derived peptides that are presented by human MHC molecules

***C. Lee**, C. Park, K. Kim, S. Im;*
Chungbuk National University, College of Pharmacy, Cheongju, Republic of Korea.

T cell-mediated xenorejection responses are reported to be mediated primarily by $CD4^+$ T cells, and the activation of xenospecific $CD4^+$ T cells occurs mostly from indirect recognition of xenoantigens. In indirect xenorecognition, human T cells are activated by porcine leukocyte antigen (SLA)-derived peptides that are processed and presented in the context of human MHC molecules on host antigen presenting cells. In an effort to design strategies to mitigate human CD4+ T cell-mediated xenorejection, we firstly identified HLA DR4-restricted immunogenic peptides derived from SLA. The peptide exhibiting the most potent binding capacity to HLA-DRB1*0401 *in vitro* was LRSWTAADTAAQISK. However, the peptide eliciting the most potent $CD4^+$ Th1 response in HLA-DRB1*0401-transgenic mouse was LRSWTAADTAAQISK, which differs only one amino acid at position 14. We also identified three SLA-derived HLA-A2-restricted peptides, and the peptide-specific CTL-inducing activities of the peptides were compared in HLA-A*0201-transgenic mice. Our findings have implications not only for the identification of an immunogenic indirect epitope derived from SLA molecules, but also for the development of epitope-specific immunoregulation strategies.

P3.05.20
A new a high throughput method to assess quantitative and qualitative differences in the antibody response

***A. Mariani**, F. Buricchi, G. Volpini, S. Budroni, A. Di Domenico, F. Castellino, G. Del Giudice, D. Medini, O. Finco;*
Novartis Vaccines, Siena, Italy.

The ideal vaccine is able to confer long-term protection, therefore not only it must induce high antibody titers, but these antibodies must be functional, that means able to bind the pathogen with high affinity and to neutralize it. Monitoring and understanding how vaccination or infection can modulate the antibody affinity maturation to bring to a most efficient response to a pathogen still remains a hard task. The quantitative evaluation of the antibody response after infection/vaccination is easily performed by conventional ELISA assays but can require high volume samples not always available. The methodologies currently used to evaluate antibody affinity (e.g Surface Plasmon Resonance; Quartz Crystal Microbalance; Solution Equilibrium Titration) are time consuming, no high-throughput, often not suitable for the analysis and characterization of very high affinity antibodies and polyclonal antibodies. In the present study we explore the possibility to evaluate affinity of monoclonal antibodies to specific antigens by analyzing the antigen-antibody reaction profiles obtained by Gyrolab® system, a technology that allows to perform miniaturized immunoassays in a high throughput manner. We describe the experimental protocol that would allow to determine in a high-throughput manner the affinity/avidity of antibodies specific for antigens of different nature (proteins, carbohydrates, glycoconjugates) or antigen portions (peptides, domains, fusions).

P3.05.21
Cooperative effects of ankylosing spondylitis-associated ERAP1 polymorphisms in the generation and destruction of HLA-B27 ligands

***A. Martin-Esteban**, C. Gomez-Molina, A. Sanz-Bravo, J. Lopez de Castro;*
CBMSO, Madrid, Spain.

The endoplasmic reticulum aminopeptidase 1 (ERAP1) is responsible for trimming antigenic peptide precursors before loading onto MHC class I molecules. Single nucleotide polymorphisms in ERAP1 have been associated with ankylosing spondylitis (AS), a disease strongly dependent on HLA-B27. It has been hypothesized that altered processing of the HLA-B27 peptidome by polymorphism in this enzyme contributes to this disease. Since natural ERAP1 variants are complex allotypes carrying multiple AS-associated polymorphisms, the contribution of individual changes and their possible interacting effects remain ill-defined. Thus, we analyzed the influence of two AS associated changes, K528R and D575N, in all possible combinations in the generation and destruction of HLA-B27 ligands from peptide precursors in vitro by mass spectrometry. Hydrolytic activity of the four variants towards a fluorogenic substrate showed that the relative effect of changes at one position was dependent on the nature of the residue at the other position, demonstrating their co-operative effect on ERAP1 activity. The four variants showed significant differences in their trimming of synthetic peptide precursors, and on the destruction of the HLA-B27 ligands generated from them. These differences were both variant and peptide-dependent. Surprisingly, since both generation and destruction of the natural epitopes were similarly affected by ERAP1 polymorphism, variants differing in activity often yielded comparable amounts of a given natural ligand. This suggests that alterations in the epitope generation/destruction balance by ERAP1 polymorphism might be limited to a subset of the HLA-B27 peptidome and the pathogenetic role of ERAP1 in AS is through their functional interaction with HLA-B27

P3.05.22
Citrullination of myelin antigens increases binding to Multiple Sclerosis associated MHC class II molecules and enhances T cell responses

***P. C. Merky**[1], M. Khademi[1], N. Abdelmagid[1], E. A. James[2], S. Haag[1], T. Olsson[1];*
[1]Karolinska Institute, Stockholm, Sweden, [2]Benaroya Research Institute, Seattle, WA, United States.

Our study aims at characterizing the adaptive immune response towards citrullinated myelin proteins in multiple sclerosis (MS). Specific T cell responses towards modified peptides were assessed for a role in disease progression. MS might appear from breakdown of immunological self-tolerance, induced by recognition of self-proteins that have undergone uncontrolled posttranslational modifications (PTM). Citrullination is a catalyzed process, whereby arginine is deiminated to citrulline. In MS, disease severity seems to follow the citrullination degree of myelin basic protein (MBP), T cell responses to citrullinated MBP are detected in MS patients, and citrullination of MBP elicits stronger Th1 responses in vitro. Given the high level of citrullinated MBP protein in MS brain tissue, a response to de novo formed citrullinated MBP-peptides could promote disease.
Stimulating PBMCs with a set of immunodominant citrullinated and non-citrullinated MBP- and MOG-peptide pairs revealed that 4 peptide pairs significantly modulated cytokine responses in MS patients compared to healthy controls. HLA-blocking during stimulation and peptide-binding studies on MHC class II molecules showed that these peptides were preferentially binding to MS associated DR molecules, with a stronger binding affinity to MHC for the citrullinated peptide versions.
Using such modified myelin peptides as antigens, we are able to study MHC class II peptide interactions and T-cell immunity, and we are provided with leads to study fine specificity and regulation of T-

and B-cell responses in different stages of disease development in humans.

P3.05.23
Thromboxane A2 controls primary T cell - DC interactions in vivo

F. Moalli[1], *P. Halbherr*[1], *M. Pieczyk*[1], *S. Narumiya*[2], *J. Stein*[1];
[1]*University of Bern, Theodor Kocher Institut, Bern, Switzerland,*
[2]*Department of Pharmacology, Kyoto University, Kyoto, Japan.*

Thromboxane A2 (TXA2) is a prostanoid formed by thromboxane synthase. Macrophages and activated dendritic cells (DCs) produce TXA2, while the TXA2 receptor TP is expressed by naïve T lymphocytes. In vitro assays have shown that high doses of pharmacological TP agonists induce chemokinetic motility of T cells and thereby decrease non-cognate T cell-DC interactions. Its in vivo function in lymphoid tissue during the control of dynamic T cell-DC interactions with varying peptide-MHC density and affinity has remained elusive. Control and TP-deficient TCR transgenic CD4+ T cells were adoptively transferred into recipient mice prepared for intravital twophoton microscopy (2PM) scanning. We observed that, when activated DCs were presenting cognate peptide, the migration speed of peptide-specific CD4+ T cells was markedly reduced in the absence of TP expression as compared to wild type cells as a function of the antigenic dose. Thus, in presence of low pMHC density on DCs, the decrease of TP-deficient CD4+ T cell speed was more pronounced than at high pMHC densities. This reduction in T cell motility correlated with prolonged interactions times between TP-deficient CD4+ T cells and DCs and increased activation parameters. In contrast, TXA2 secretion by activated DCs without cognate pMHC did not affect T cell motility parameters irrespective of TP expression, indicating that TXA2 acts locally at the T cell-DC immunological synapse. In sum, our data identify TXA2-induced TP signaling as a negative regulator of T cell-DC interactions under conditions of low pMHC abundance, which may contribute to prevent excessive immune reactions and autoimmunity.

P3.05.24
Independent transport of MHC class II and H2-DM to processing compartments and convergence with molecules of distinct trafficking pathways

J. Cortés[1], *G. Pérez-Montesinos*[2], *C. Sánchez*[1], *L. C. Bonifaz*[2], ***J. Moreno***[3];
[1]*Autonomous University of the State of Morelos, Cuernavaca, Mexico,* [2]*Centro Médico Siglo XXI, IMSS, Mexico City, Mexico,* [3]*National Institute of Public Health, Cuernavaca, Mexico.*

$CD4^+$ T cells recognize peptides bound to MHC class II molecules (MHCII). Antigenic peptides presented by MHCII predominantly derive from exogenous proteins and are acquired in an endosomal/lysosomal compartment termed *MIIC*. For efficient peptide binding to MHCII, the lumen of *MIICs* also contain DM, a non-classical MHCII, which upon physical contact with an MHCII, relaxes its structure and releases the invariant chain-derived CLIP. For efficient MHCII-DM interaction certain APCs, such as B cells additionally express another non-classical MHCII, known as DO, which retains DM, preventing its binding to MHCII until the lysosomal pH reaches an optimal low. However, as the majority of dendritic cells (DC) fail to express DO, another mechanism must exist to keep DM from binding MHCII in DC. We examined this issue in mouse bone marrow-derived DCs differentiated for five days with GM-CSF, plus 24h in the presence of LPS. At time 0 (no LPS) most MHCII were intracellularly distributed in small Rab7+ and some Rab7+/Rab5+ vesicles, which upon addition of LPS progressively converged into large, pericentriolar Rab7+/Rab5+/Rab9+/Lamp2+ compartments, to eventually be transported to the periphery, associated only to Rab11 with or without the invariant chain. On the other hand, in early stages, DM was in small Rab5-/Rab7+ vesicles, which eventually converged with MHCII+/Rab7+/Rab5+/Rab9+/Lamp2+ compartments to remain there when MHCII had already departed for the cell surface. These results indicate that in some DC, DM and MHCII are kept physically appart until they arrive in the processing compartments.

P3.05.25
Ultrastructure of human autologous macrophage lymphocyte rosettes in Chagas disease

I. T. C. Novak, *A. D. Orquera;*
National University of Cordoba, Faculty of Medicine, Institute of Cell Biology, Cordoba, Argentina.

The processing and antigen presentation are involved in human macrophage lymphocyte rosette (MLR) and in this phenomenon of multiple immune synapse (IS) the autologous antigens of senescent neutrophils are presented by endocitic way like phagocytosis of cells undergoing apoptosis naturally in the body. In Chagas disease cardiomyopathy *T. cruzi* is the etiologic agent but also autoimmune phenomena have been described and observed an increment in occurrence of this phenomenon and CD4 PAS-positive lymphocytes producing IFN gamma are involved. Material and methods: healthy human blood samples, anticoagulated with heparin (n = 10) and chagasic samples (n=6) (Blood Bank, UNC) Autologous cultures in TC199 medium (SIGMA, St. Louis, MO). Samples: 48, 72, 96 and 120 h. MLR technique. PAS technique. Samples of MLRs underwent electron microscopy. Results: MLRs of chagasic patients involved more lymphocytes. Significant differences were observed between PAS positive lymphocytes from MLRs ($p < 0.01$). In Chagas cultures were observed plasma cells and neutrophils up to 48 h. Ultrastructure: redistribution of mitochondria in lymphocytes of MLRs, to the IS area. We observed multivesicular, multilamellar and tubular structures in spatial organization of MIIC along time culture in macrophages. In lymphocytes were observed differences in arrangement of chromatin between healthy individuals and Chagas patients as in previous works. Is noted that in cytoplasm were observed double-membrane vesicles to a greater extent in Chagas patients, we postulate costimulator B7 molecules carriers and we are preparing further studies to immunostaining. In all cases observed exosomes, IS and MLR phenomenon greater degree in chagasic patients cultures.

P3.05.26
The non-classical class II genes of the chicken, DMA and DMB, are similar to those of mammals, but a second DMB gene (DMB1) is differentially expressed with unusual regulatory and structural features

A. Parker[1], *K. Staines*[2], *C. Butter*[2], *J. Kaufman*[1,3];
[1]*University of Cambridge, Department of Pathology, Cambridge, United Kingdom,* [2]*Institute for Animal Health, Compton, United Kingdom,* [3]*University of Cambridge, Department of Veterinary Medicine, Cambridge, United Kingdom.*

Although smaller, simpler and rearranged, the chicken major histocompatibility complex (MHC) contains most of the core antigen presentation genes found in the mammalian MHC. Strong associations of chicken MHC haplotypes with resistance to pathogens and response to vaccines are attributed to single dominantly-expressed MHC class I (BF) and class II (BL) molecules. The single dominant class I is the result of co-evolution with the closely-linked antigen processing genes TAP and tapasin, but the situation for class II is less clear. To facilitate investigation of whether single dominant class II expression could result from similar co-evolution with associated antigen presentation molecules, we characterised the chicken class II DM region. We show that chickens have three DM genes in their MHC, a single alpha chain gene DMA, and, unusually, two beta chain genes DMB1 and DMB2, of which DMB2 is dominantly-expressed. The chicken DM genes encode proteins with high structural and sequence homology to those described in mammals. However, the two beta chains differ substantially at the amino acid level and several features of DMB1 suggest an unusual function. We find DMB1 and DMB2 differentially expressed in tissues at the RNA and protein level, with DMB1 strongly expressed in intestinal epithelial cells, suggestive of a role in gut immunity. In pursuing the functional properties of the DMs and their interaction with the classical class II molecules, we aim to enhance our understanding of chicken MHC associations with immune responses and, more generally, illuminate mechanisms underlying class II evolution.

P3.05.27
Role of the external loops in the formation of antigenic structure of OmpF porin from *Yersinia pseudotuberculosis*

***O. Y. Portnyagina**, O. D. Novikova, O. V. Sidorova, V. A. Khomenko; G.B. Elyakov Pacific Institute of Bioorganic Chemistry, Vladivostok, Russian Federation.*

Porins are the components of Gram-negative bacteria outer membrane (OM) playing a crucial role at the pathogen - host interrelations. Porins are the factors of microbial pathogenicity, participating in the forming of protective immunity at the same time. We have investigated the antigenic structure of the recombinant porin from OM of *Yersinia pseudotuberculosis*, the causative agents of pseudotuberculosis, using polyclonal antibodies against the full -sized OmpF porin (RP) and against the mutant porins with deletions of the some external loops of the protein (del1, del4, del6, del8). As result of refolding conducted by dialysis and ion-exchange chromatography, the recombinant proteins were obtained as trimers and were used for immunization. It is interesting to note the more immunogenicity of del4 and del6 porins for mice, compared with RP. Perhaps, the absence of the loop sites corresponding to L4 and L6 makes some of T-epitopes more "accessible" to form a ternary complex of antigen / T-receptor / MHC receptor. On the contrary, deletion of the loop L1 led to 50% loss of antigenic epitopes involved in the formation of the humoral immune response against the OmpF porin. Lack of loops L6 and L8 was found to have no effect on the structure of B-epitopes formation for both RP and the mutants, as soon as efficiency of antibody - antigens binding was similar. At the same time, deletions of the loops L1 and L4 caused the loss of 10% and 20% of antigenic epitopes, respectively.

P3.05.28
The wild-type hemochromatosis protein HFE inhibits MHC I antigen presentation

***A. Reuben**, M. Phénix, M. M. Santos, R. Lapointe; CRCHUM - Université de Montréal, Montréal, QC, Canada.*

MHC class I (MHC I) antigen presentation is an ubiquitous process by which cells present endogenous proteins to $CD8^+$ T lymphocytes during immune surveillance and response. Hereditary hemochromatosis protein, HFE, is involved in cellular iron uptake but, while structurally homologous to MHC I, is unable to bind peptides. However, increasing evidence points to a role for HFE in the immune system. In this study, we investigated the impact of HFE on MHC I antigen presentation. Using transient HFE transfection assays in a model of antigen presenting cells (293-A2/APC), we show that wild-type HFE, but not C282Y-mutated HFE, inhibits the secretion of macrophage inflammatory protein 1-beta (MIP-1β) from $CD8^+$ T lymphocyte clones generated to specifically-recognize selected antigens. Wild-type HFE expression also resulted in major decreases in $CD8^+$ T lymphocyte activation as measured by 4-1BB expression. We further demonstrate that inhibition of antigen recognition was maintained regardless of MHC I surface levels, β2-microglobulin competition, HFE ability to interact with transferrin receptor, antigen origin, or epitope affinity. We identified the α1-2 domains of HFE_{WT} as being responsible for inhibiting antigen recognition. However, recognition of externally peptide-pulsed 293-A2/APC remained uninhibited in presence of wild-type HFE, indicating that HFE may affect T cell recognition by interfering with intracellular antigen processing. Overall, our data point to a new physiological role for wild-type HFE in the MHC I antigen presentation pathway, which could modulate antigen immunogenicity and the cellular immune response.

P3.05.29
Carbon monoxide decreases endosome-lysosome fusion and inhibits soluble antigen presentation by dendritic cells to T cells

*V. Tardif[1], **S. A. Riquelme**[2], S. Remy[1], L. J. Carreño[2], T. Simon[1], C. A. Riedel[3], P. Blancou[1], S. Bueno[2], I. Anegon[1], A. M. Kalergis[2,1,4]; [1]INSERM, UMR 1064, Nantes, F44093 France; CHU Nantes, ITUN, Nantes, F44093 France; Université de Nantes, Faculté de Médecine, Nantes, F44093 France, Nantes, France, [2]Millenium Institute of Immunology and Immunotherapy, Facultad de Ciencias Biológicas. Pontificia Universidad Católica de Chile, Santiago, Chile, [3]Millenium Institute of Immunology and Immunotherapy, Facultad de Ciencias Biológicas, Universidad Andrés Bello, Santiago, Chile, [4]Departamento de Reumatología, Facultad de Medicina. Pontificia Universidad Católica de Chile, Santiago, Chile.*

Heme oxygenase-1 (HO-1) inhibits immune responses and inflammatory reactions via the catabolism of heme into carbon monoxide (CO), Fe^{2+} and biliverdin. We have previously shown that either induction or treatment with exogenous CO inhibits LPS-induced maturation in human dendritic cells (DCs). Here, we have evaluated the capacity of CO, to regulate antigen presentation on MHC-I and MHC-II molecules by murine DCs. We observed that CO treatment significantly inhibited the capacity of DCs to present soluble antigens to T cells on class I and class II MHC molecules. Inhibition was restricted to soluble OVA protein, as no inhibition was observed for antigenic OVA-derived peptides or bead-bound OVA protein. Further, CO failed to inhibit MHC-I presentation when DCs expressed OVA as an endogenous antigen, suggesting that inhibition was probably due to impairment of processing of internalized soluble antigens. Inhibition of antigen presentation was not due to reduced antigen uptake by DCs, as both endocytosis and phagocytosis remained functional after CO treatment. On the contrary, CO significantly reduced the efficiency of fusion between late endosomes and lysosomes and not by phagosomes and lysosomes. These data suggest that CO can inhibit the DC ability to present exogenous soluble antigens to both $CD8^+$ and $CD4^+$ T cells by blocking antigen processing at the level of late endosome-lysosome fusion.

P3.05.30
Brucella spp. lumazine synthase (BLS) vaccine carrier as a model to study antigen processing and persistance

***A. H. Rossi**, V. A. Alzogaray, F. A. Goldbaum, P. M. Berguer; Immunology and Molecular Microbiology Laboratory - Leloir Institute Foundation, Buenos Aires, Argentina.*

BLS is a highly immunogenic stable decamer, successfully used as a carrier for several proteins. BLS immunization activates murine dendritic cells (DC) and recruits DC, B cells, CD8+ and CD4+ cells at the draining lymph nodes (LN) via TLR4. BLS induces the cross-presentation of associated peptides and a TLR4-dependent specific cytotoxicity. Here, we show which cells BLS is associated with after immunization and its intracellular localization in vitro. Mice were immunized in the hind footpad with BLS-Fluorophore. At 4hs BLS was found in 30±4% of DC and in 10±2% of B lymphocytes at popliteal LN, and in 14±3% of the DC at the inguinal LN. At 120h BLS was still found within DC. In TLR4-deficient mice similar results were observed until 4hs; at longer times BLS was not observed. These results show that BLS resides for longer periods in DC and suggest that DC carry BLS to the inguinal LN. Subcellular cocalization of BLS was studied by confocal microscopy. Peritoneal macrophages (Mo) and BMDC were incubated with BLS-Fluorophore. Only minor colocalization was observed with classical antigen presentation markers. BLS colocalized with TLR4 at the cell membrane at 5min and with cytoplasmic TLR4 at 6h. BLS was observed at least until 6hs in BALB/c BMDC or Mo; in TLR4-deficient mice it was found only for 1h. These results suggest that BLS binds to TLR4 at the plasma membrane and subsequently enters to the cytoplasm. BLS would escape the endocytic pathway of antigen processing. BLS persistence is dependent on TLR4 signaling.

P3.05.31
Stable antigen is most effective for eliciting CD8+ T cell responses after DNA vaccination and infection with recombinant vaccinia virus in vivo

C. Schliehe[1], *A. Bitzer*[2], *M. van den Broek*[3], *M. Groettrup*[2,4];
[1]*Research Center for Molecular Medicine (CeMM) of the Austrian Academy of Sciences, Vienna, Austria,* [2]*University of Konstanz, Department of Biology, Immunology Division, Konstanz, Germany,* [3]*University Hospital Zurich, Oncology, Zürich, Switzerland,* [4]*Biotechnology Institute Thurgau, Kreuzlingen, Switzerland.*

The induction of strong CD8+ T-cell responses against infectious diseases and cancer has remained a major challenge. Depending on the source of antigen and the infectious agent, priming of CD8+ T cells requires direct and/or cross-presentation of antigenic peptides on major histocompatibility complex (MHC) class I molecules by professional antigen-presenting cells (APCs). However, both pathways show distinct preferences concerning antigen stability. Whereas direct presentation was shown to efficiently present peptides derived from rapidly degraded proteins, cross-presentation is dependent on long-lived antigen species. Here, we analyzed the impact of antigen stability on DNA vaccination and recombinant vaccinia virus (VV) infection using altered versions of the same antigen. The long-lived nucleoprotein (NP) of lymphocytic choriomeningitis virus (LCMV) can be targeted for degradation by N-terminal fusion to ubiquitin or, as we show here, to the ubiquitin-like modifier FAT10. Direct presentation by cells either transfected with NP-encoding plasmids or infected with recombinant VV in vitro was enhanced in the presence of short-lived antigens. In vivo, however, the highest induction of NP-specific CD8+ T-cell responses was achieved in the presence of long-lived NP. Our experiments provide evidence that targeting antigens for proteasomal degradation does not improve the immunogenicity of DNA vaccines and recombinant VVs. Rather, it is the long-lived antigen that is superior for the efficient activation of MHC class I-restricted immune responses in vivo. Hence, our results suggest a dominant role for antigen cross-priming in DNA vaccination and recombinant VV infection.

P3.05.32
The Mer Receptor Tyrosine Kinase promotes B-cell antigen processing through the IgD B-cell Receptor

W. Shao[1], *Y. Zhen*[1], *F. Finkelman*[2,3], *P. Cohen*[1];
[1]*Section of Rheumatology, Department of Medicine, Temple University, Philadelphia, PA, United States,* [2]*Department of Medicine, Cincinnati Veterans Affairs Medical Center, Cincinnati, OH, United States,* [3]*Division of Immunology, University of Cincinnati College of Medicine, Cincinnati, OH, United States.*

The Mer receptor tyrosine kinase facilitates macrophage and DC apoptotic-cell clearance and regulates immune tolerance. Mer may also be important in B-cell activation, as B cells in Mer-KO mice fail to develop autoantibodies when allo-activated by T cells. In vivo cross-linking of membrane IgD is a well-studied model of T-dependent B-cell activation. BCR cross-linking leads to antigen presentation to T cells, which then get activated and provide cognate help to a new set of B cells, resulting in a large IgG response. To test the role of Mer in the immune response to B-cell membrane IgD cross-linking, Mer-KO mice were given goat anti-mouse IgD intraperitoneally. Mer-KO mice had significantly lower IgE and IgG anti-goat IgG responses compared to B6 WT controls. In vivo cytokine capture assay (IVCCA) studies revealed decreased IL-4 but increased IFN-γ levels in Mer-KO mice. FACS and BrdU incorporation studies revealed comparable initial B-cell activation and proliferation between Mer-KO mice and WT controls, but subsequent T-cell proliferation and activation was arrested in Mer-KO mice. The antigen processing ability of B cells was estimated by using monoclonal anti-IgD antibody labeled with pHrodo-SE, a pH-sensitive fluorogen with increased fluorescence in acidic environments, i.e. lysosomes during antigen processing. Mer-KO B cells showed more than two-fold decreased antigen processing compared to WT B cells subjected to the same treatment. Taken together, Mer expression is required for optimal B-cell antigen processing. The mechanism may involve protein transport and microtubule rearrangement.

P3.05.33
Genetic Regulation of the Bovine Immune System and Implications for Health

K. Thompson-Crispi[1], *R. Ventura*[1,2], *F. Schenkel*[1], *F. Miglior*[3,4], *B. Mallard*[1];
[1]*University of Guelph, Guelph, ON, Canada,* [2]*Beef Improvement Opportunities, Guelph, ON, Canada,* [3]*Guelph Food Research Center, Agriculture and Agri-Food Canada, Guelph, ON, Canada,* [4]*Canadian Dairy Network, Guelph, ON, Canada.*

Diseases that affect dairy cattle contribute to economic loss with adverse implications for human and animal health and food safety. The inclusion of immune response (IR) traits in breeding objectives shows promise for improving inherent animal health. Dairy cows classified as High Immune Responders in herds across Canada and one large herd in the US have been found to have improved response to vaccination, increased milk and colostrum quality and a decreased occurrence of disease. The objective of this research was to perform a genome-wide association study to determine genetic profiles associated with enhanced antibody-mediated IR (AMIR). A total of 680 Holstein cows from 58 herds across Canada were immunized with a type 2 test antigen to measure serum antibody. High (n=81) and Low (n=82) AMIR cows were genotyped using the Illumina Bovine SNP50. A total of 198 SNP were significantly associated with AMIR. Of these, the majority (83%) were on chromosome 23, which contains the bovine Major Histocompatability Complex (MHC). Candidate genes within 250,000 base pairs of the significant SNPs included genes in the MHC, complement system and cytokines, including interleukin-17. Based on these genes, various biological pathways associated with AMIR were identified, including the antigen processing and presentation pathway, important in host defense. The significant genetic variation associated with AMIR in this study suggests that including AMIR in genomic selection could help decrease the incidence of disease in the dairy industry thereby minimizing the use of antibiotics, improving animal health, milk quality and food safety.

P3.05.34
The influence of MHCII haplotypes on T cell priming and disease development in a chronic model of rheumatoid arthritis

J. Tuncel[1], *S. Haag*[1], *D. E. Mason*[2], *S. Thordardottir*[1], *A. C. Y. Yau*[1], *E. C. Peters*[2], *R. Holmdahl*[1];
[1]*Karolinska Institutet, Stockholm, Sweden,* [2]*Genomic Institute of the Novartis Research Foundation, San Diego, CA, United States.*

The genetic component in rheumatoid arthritis is explained largely by MHCII genes. However, the priming of autoreactive T cells occurs prior to the clinical onset and is therefore poorly characterized. Pristane-induced arthritis (PIA) in the rat is a T cell driven chronic arthritis model, which is free from exogenous antigens and therefore ideal to study the effect of MHC-genes in an autoimmune context. We recently established a panel of five recombinant strains, which differ only in a 0.2 Mb region in the MHCII locus. Here we performed a comparative analysis of the development of PIA in these strains and show that this interval affects onset, progression and severity of early arthritis while it does not regulate chronicity. PIA was RT1-B (HLA-DQ) associated in all strain as indicated by the expression of MHCII and the reduction of acute and chronic PIA by blocking of RT1-B but not RT1-D (HLA-DR). The ligandome of both MHCII molecules was analyzed and multiple peptides from ubiquitous RA-related auto-antigens identified. The presence of haplotype-specific invariant chain-derived peptides on RT1-B correlated with disease protection, suggesting that an unedited MHCII peptide repertoire increases PIA susceptibility. Arthritis protection was further associated with an immature T cell phenotype, a more vigorous T cell proliferation and a Th17 bias. Moreover, neutralization of IFN-g, but not IL-17, before onset ameliorated disease in all strains. In contrast, the arthritis progression was strictly dependent on IL-17 but not IFN-g and neutralization of IL-17 was accompanied by a substantial reduction of neutrophils.

P3.05.35
Stem-cell transplantation restores CD8 T-cell immunity and corrects MHC class I deficiency

A. P. Williams[1], *Y. Gao*[1], *R. Carter*[1], *A. Cazaly*[1], *S. I. Khakoo*[1], *A. Mant*[1], *A. J. Cant*[2], *S. Gadola*[1], *P. D. Arkwright*[3], *T. J. Elliott*[1];
[1]*University of Southampton, Southampton, United Kingdom,* [2]*University of Newcastle, Newcastle, United Kingdom,* [3]*University of Manchester, Manchester, United Kingdom.*

Major Histocompatibility Complex class I (MHC class I) deficiency is a primary immunodeficiency disorder that is associated with aberrant CD8 T cell and natural killer cell (NK) development and function. Clinical presentations consist of recurrent bacterial infections, chronic inflammation and necrotizing, granulomatous skin lesions.
We analyzed a patient who was initially transplanted for an unknown immunodeficiency disorder associated with CD8 lymphopenia to evaluate if a distinctive MHC class I disorder was present.
Extended MHC class I investigations and NK evaluations were undertaken to determine the nature of the primary defect and its consequence upon immune reconstitution.
A marked reduction in MHC C and E alleles was noted in the individual with preservation of MHC class I expression in MHC A and B alleles. Novel flow cytometry for intracellular transporter associated with antigen processing (TAP) proteins demonstrated an absence of TAP1 and TAP2 consistent with MHC class I deficiency. Following a matched unrelated stem cell transplant there was clinical improvement associated with restoration of TAP 1 and TAP 2 expression in the hematopoietic lineage and CD8 T cell reconstitution. Pre transplant NK cells displayed a defect in recognition of MHC class I negative targets and a distinctive over expression of NKG2A and killer immunoglobulin like receptors (KIR). These defects partitioned post transplant with maintenance of hyporesponsiveness to MHC class I negative targets but correction of NKG2A and KIR expression.
Stem cell transplantation was successfully undertaken for MHC class I deficiency, correcting CD8 deficiency and some aspects of NK cell development.

P3.05.36
Systematic analysis of the antigen processing machinery in HPV-positive cell lines

J. Winter*, A. Steinbach, K. M. Grabowska, A. K. Grabowska, A. B. Riemer;*
German Cancer Research Center (DKFZ), Heidelberg, Germany.

Clearance of human papillomavirus (HPV)-induced lesions is mediated by a cellular immune response, consisting of both cytotoxic T lymphocyte (CTL) and T helper (Th) cell responses. However, HPV has evolved multiple immune evasion strategies, among which modulation of expression of antigen processing machinery (APM) components directly interferes with T cell recognition of HPV-transformed cells.
Thus, we here aim to systematically analyze the expression of all APM components in a comprehensive collection of HPV-positive cells, including cervical and head and neck squamous carcinoma cell lines, as well as in three HPV-negative controls. Gene expression levels are determined by a quantitative real-time PCR screening, and protein levels by immunoblotting. To address the immunoproteasome and a feasible induction of APM component expression levels, all cells are analyzed with and without interferon (IFN)-gamma treatment.
We observed altered expression levels for some APM components in several HPV-positive cell lines compared to primary keratinocytes. However, transcriptional and translational downregulation of some components was reversed in an IFN-gamma-positive milieu.
Taken together, this study will provide a systematic appraisal of HPV-mediated APM changes, and if these could possibly be counteracted by IFN-gamma in the tumor microenvironment.

P3.06.01
The effect of a high intensity interval exercise on the proliferative response of lymphocytes

R. Tossige-Gomes, ***K. Costa****, S. M. Magalhães, V. O. Ottone, F. C. Magalhães, F. T. Amorim, E. Rocha-Vieira;*
Federal University of Jequitinhonha and Mucuri Valleys, Diamantina, Brazil.

The exercise provides a challenge for the whole body homeostasis, and the immune system displays substantial disturbances in response to a single exercise session. In recent years, high intensity interval exercise (HIIE) has stained out as a modality of training. This study evaluated effect of a HIIE session on lymphocyte proliferative response in young sedentary men (n=6, 24.7 ± 3.5 yrs, BMI 21.5 ± 2.3 kg/m2 and VO2 max 34.2 ± 4.1 mLO2.kg-1.min-1). Volunteers performed a HIIE session, in a cycle ergometer, which consisted of 9 series of 1 min at 100% of peak power, with 75 seconds of active recovery, at 30W, between series. Venous blood was collected before, immediately after and 30 minutes after HIIE. Peripheral blood mononuclear cells of individuals were stained with Carboxyfluorescein Succinimidyl Ester (10mM) and stimulated with the Staphylococcus aureus enterotoxin B superantigen (SEB) (100 ng/mL) or PHA (0.001 mg/mL), for 5 days at 37°, 5% CO2. Cell proliferation analysis was performed using flow cytometry. Data was analyzed using One-way Anova, considering a=0.05. The proliferative response of lymphocytes to SEB stimulation was reduced immediately and 30 minutes after HIIE (P = 0.01), compared to rest values, although there was no effect of HIIE on the lymphocyte proliferative response to PHA stimulation (P = 0.25). HIIE reduced the super antigen-stimulated lymphocyte proliferation, what may affect the adaptive arm of the immune response. Mechanisms potentially involved on the modulation of lymphocyte proliferation response by HIIE, like cell activation and cytokine secretion, is under investigation.

P3.06.02
Regulatory T cells control Th1 priming by inhibiting the CD70/CD27 pathway

M. Dhainaut*, C. Coquerelle, S. Uzureau, V. Acolty, J. Denoeud, G. Oldenhove, E. Pays, M. Moser;*
Université Libre de Bruxelles (ULB), Gosselies, Belgium.

Although naturally occurring Tregs are essential to prevent auto-immune disorders, the molecular basis of their suppressive function is still ill defined. Based on several observations showing that Tregs selectively control the development of Th1-type responses, we sought to determine the effect of suppression on the Th1-prone interleukin-12 and CD70 costimulatory molecule.
Our data show both in vivo and in vitro that Tregs inhibited the CD27/CD70 pathway, while sparing IL-12 production. Treg depletion in vivo resulted in increased CD70 expression on dendritic cells (DCs) and enhanced IFNγ production that was prevented by injection of neutralizing mAb to CD70. In vitro, Tregs inhibited CD70 expression on activated splenic DCs in a CD27-dependent manner. Surprisingly, CD70 downregulation correlated with intercellular transfer of intact CD27 from Tregs to DCs. Indeed, when cultured with retrovirally transduced T cells expressing a (intracellular) GFP- and (extracellular) HA- tagged CD27, DCs acquired both GFP and HA. The analysis of the CD27 and CD70 localisation by confocal microscopy using retrovirally transduced BMDCs (mCherry-CD70) and T cells (CD27-GFP) revealed the formation of tunneling nanotubes that spanned from DCs to T cells and supported vesicular traffic of CD27 to DCs in a CD70-dependent process. Whether both molecules are internalized and degraded in DCs remains to be determined.
Our data thus suggest a novel mechanism, in addition to CTLA-4 inhibition of CD80/CD86 costimulation, by which CD27+ Tregs might tune DC function by regulating the surface expression of CD70.

P3.06.03
XCR1 promotes the activation of CD8+ T lymphocytes by optimizing their interaction with CD8a+ dendritic cells.

***S. Ghilas**, K. Crozat, M. Dalod;*
CIML, Marseille, France.

The main function of dendritic cells in the immune system is the detection of pathogens and the initiation of adaptive immune responses. Resident CD8α+ dendritic cells are highly efficient for cytotoxic T lymphocytes priming. Indeed, they are major producers of interleukin-12, a cytokine particularly important in the activation of CD8+ T lymphocytes. They are also able to load protein derived from exogenously antigens onto MHC class I molecules; a mechanism called cross-presentation. Moreover, this DC subset expresses specifically the chemokine receptor XCR1. With migrating CD103+ DC, CD8α+ DC are the unique murine cell types that express XCR1. The ligand of XCR1 is the XCL1 chemokine which is highly secreted by activated CD8+ T lymphocytes. CD8+ T cells activation was previously shown to be impaired in XCR1-deficient mice, but the underlying mechanism is unknown. Our results show that XCR1 is not involved in CD8α+ DC maturation but rather stabilizes their contacts with CD8+ T cells. Hence, XCR1 on CD8α+ DC promote the activation of CD8+ T cells by optimizing their interactions with CD8α+ DC. These results open new perspectives on the understanding of the role of XCR1 in the initiation of efficient CD8+ T cell responses by CD8α+ DC. This work received funding from Aix-Marseille Université (scholarship from the University President to S.G.), Association pour la Recherche sur le Cancer (ARC, funding to K.C. and M.D.) and the European Research Council under the European Community's Seventh Framework Programme (FP7/2007-2013 Grant Agreement no. 281225 to M.D.).

P3.06.04
The Inducible Costimulator (ICOS) facilitates interleukin-4 synthesis through phosphoinositide 3-kinase signaling

***M. Gigoux**[1,2], A. Lovato[1,2], J. Leung[1,2], J. Leconte[1,3], N. Sonenberg[4], W. Suh[1,2,3];*
[1]Institut de Recherches Cliniques de Montréal, Montréal, QC, Canada, [2]Department of Microbiology and Immunology, Faculty of Medicine, McGill University, Montréal, QC, Canada, [3]Department of Microbiology and Immunology, Université de Montréal, Montréal, QC, Canada, [4]Department of Biochemistry, McGill University, Montréal, QC, Canada.

The Inducible Costimulator (ICOS) is a member of the CD28 family of costimulatory receptor that is highly expressed in follicular helper T cells (Tfh), a subset of CD4 T cells that migrate to the B cell zone and facilitate germinal center reaction. Although ICOS is known to play a critical role in shaping the Tfh population during immune reactions its role in the effector function of Tfh cells has been unclear. Here we demonstrate that ICOS assists TCR-mediated signal transduction by potentiating PI3K-Akt-mTOR signaling cascade that leads to hyperphosphorylation of the key translational regulators, p70S6K and 4E-BP1. Consistently, ICOS costimulation promotes the formation of polysomes on IL-4 mRNA in a PI3K-signaling dependent manner. Here we provide evidence that IL-4 production is diminished during T-B co-culture when ICOS-PI3K signaling axis is disrupted in T cells. Thus, ICOS-PI3K signaling facilitates translation of IL-4 mRNA and this may augment IL-4 production during T-B interaction in germinal centers.

P3.06.05
Discovery of a novel immune checkpoint regulator of the B7 family that negatively modulates T cell activation

***I. Hecht**[1], J. R. Podojil[2], K. McNamee[3], I. Vaknin[1], A. Oren[1], A. Toporik[1], G. Cojocaru[1], G. Rotman[1], R. Williams[3], S. D. Miller[2];*
[1]Compugen, Tel Aviv, Israel, [2]Dept. of Microbiology-Immunology, Feinberg School of Medicine, Northwestern University, Chicago, IL, United States, [3]Kennedy Institute of Rheumatology, University of Oxford, London, United Kingdom.

Using Compugen's discovery platform, CGEN15001T was recently identified as a novel member of the B7/CD28 protein family. Ectopic membrane expression of CGEN15001T in HEK293 cells resulted in inhibition of T cell activation. To further investigate CGEN15001T function, a fusion protein designated CGEN-15001 was produced, consisting of the extracellular domain of CGEN-15001T fused to IgG Fc. CGEN-15001 inhibited activation of murine and human naïve or effector T cells, reduced Th1/Th17 responses while promoting Th2 responses and secretion of anti-inflammatory cytokines, and enhanced iTregs differentiation. In vivo, CGEN-15001 demonstrated therapeutic effects in murine models of multiple sclerosis (RR-EAE) and rheumatoid arthritis (CIA). In the CIA model, administration of CGEN-15001 to mice with existing disease resulted in reduction of clinical score, joint swelling and histological score. Increase in the collagen-specific IgG1/IgG2a ratio was observed in the serum of CGEN-15001 treated mice, in line with the Th1/Th17 to Th2 shift observed in vitro and in the RR-EAE model. Furthermore, short term treatment of RR-EAE from onset of disease remission resulted in long lasting remission and inhibition of epitope spreading, suggesting induction of immune tolerance.
CGEN15001T is expressed in various cancers, including hematological, carcinomas, sarcomas and melanoma, in both tumor cells and subtypes of tumor infiltrating immune cells.
The immunomodulatory activity of CGEN-15001T and its expression in tumors support its role as immune checkpoint. The therapeutic efficacy in murine models of rheumatoid arthritis and multiple sclerosis support the therapeutic potential of CGEN-15001 for treatment of autoimmune diseases, by restoring and maintaining immune balance.

P3.06.06
Nucleic acid-mediated T cell activation through a novel sensing mechanism induces Th2 responses

***T. Imanishi**[1], S. Akira[2], T. Saito[1];*
[1]RIKEN Research Center for Allergy and Immunology, Yokohama, Japan, [2]Laboratory of Host Defense, WPI Immunology Frontier Research Center, Osaka University, Suita, Japan.

Recent studies including ours have shown that Toll-like receptors (TLRs) are functionally expressed not only on innate immune cells, but also on T cells, and some TLR ligands exhibit costimulatory functions of T cells upon TCR stimulation. However, we found that costimulation by TLR3 ligand poly(I:C) or TLR9 ligand CpG-DNA was independent of TLRs, whereas TLR2 ligands-mediated costimulation was dependent on TLRs. Surprisingly, the costimulation function by DNA was independent of CpG motif. Furthermore, we found that genomic DNA complexed with antimicrobial peptides, but not genomic DNA alone were internalized into naïve T cells and induced costimulatory responses. We demonstrate that this nucleic acid-mediated costimulation does not require all known nucleic acid sensors such as RIG-I-like receptors (RLRs) and STING-dependent cytosolic DNA sensors, ASC inflammasome. This response was mediated by enhancing the activation of NFAT and NF-κB. We also found that nucleic acid-mediated costimulation resulted in promoting IL-4 expression and suppressing IFN-γ expression directly on T cells in the absence of the involvement of any innate cells. Collectively, these results suggest an unexpected role for nucleic acid-mediated costimulation that promotes Th2 responses through a unique mechanism different from those in innate immune system.

P3.06.07
Semaphorin 4A regulates activation of CD8+ T cells

D. Ito[1,2]*, S. Nojima*[1,3]*, A. Kumanogoh*[1,2]*;*
[1]*Department of Immunopathology, WPI Immunology, Frontier Research Center, Osaka University, Suita city, Japan,* [2]*Department of Respiratory medicine, Allergy and Rheumatic disease, Graduate School of Medicine, Osaka University, Suita city, Japan,* [3]*Department of Pathology, Osaka University Graduate School of Medicine, Suita city, Japan.*

Semaphorins are soluble and membrane-bound proteins originally identified as axon guidance factors which are involved in the development of the neuronal system. However, accumulating evidence indicates that several semaphorins, so-called 'immune semaphorins' are crucially involved in various phased of immune responses, that is, from the initiation to the effector phases of immune responses. Among immune emaphorins, Semaphorin 4A (Sema4A) has been shown to be expressed in dendritic cells, regulating helper T-cells. Indeed, Sema4A-dificient mice display dis-regulation of helper T-cells, resulting in developed atopic dermatitis and airway hypersensitivity. However, the involvement of Sema4A in CD8+ T-cells has not been determined. Here, we found predominant expression of Sema4A in CD8+ T-cells. In addition, Sema4A-deficient CD8+ T cells were hypo-responsive to TCR stimulation by anti-CD3, in which production of cytokines, such as IFN-g, TNF-a, and IL-2 was significantly impaired. Moreover, the induction of the T-box transcription factors, Eomesodermin (Eomes) and T-bet, which are required for effector and memory CTL differentiation of CD8+ T-cells, was also decreased. Collectively, our findings indicate an important role of Sema4A in activation and differentiation of CD8+ T-cells.

P3.06.08
CD28 costimulates the CD4+ T cell tolerogenic response to exogenous antigen in vivo

A. Jaekel[1]*, E. Mettke*[1]*,* ***N. Reeg***[1]*, Y. Yang*[1]*, A. Hutloff*[1,2]*, H. Mages*[1]*, S. Gurka*[1]*, R. Kroczek*[1]*;*
[1]*Robert Koch-Institute, Berlin, Germany,* [2]*German Rheumatism Research Centre Berlin (DRFZ), Berlin, Germany.*

The survival of the host critically depends on the appropriate immune response to harmless exogenous antigens versus dangerous pathogens. The reaction of CD4+ T cells under inflammatory conditions has been analyzed in detail in the past. In contrast, the tolerogenic CD4+ T cell response is much less characterized and has often been regarded as an incomplete form of the inflammatory reaction.
Using an adoptive transfer system we compared the tolerogenic and inflammatory responses of antigen-reactive CD4+ T cells in vivo using phenotypic, functional, and gene expression analyses. The results show that the T cell program which is elicited by pure antigen contains numerous elements of the inflammatory reaction (e.g. IL-2), but is overall a tolerance-specific program including surface molecules (e.g. RANKL, CD160, 4 1BB) and chemokines (e.g. CCL1), which do not participate in the inflammatory reaction.
Secretion of IL-2 in response to pure antigen raised the question about an involvement of CD28 in the tolerogenic response. Although CD28 strongly modulated only a limited number of genes, it had a critical influence on IL-2 secretion, cell division, and expansion of CD4+ T cells in the tolerogenic reaction, mirroring its rather selective but decisive influence in the inflammatory T cell response. Thus, CD28 not only acts as a potent T cell costimulator under inflammatory conditions, but also has a major role in the tolerance reaction. Our data extend the current paradigm of CD28 costimulation beyond its known key role in the inflammatory T cell response and the homeostasis of regulatory T cells.

P3.06.09
TIM-3 does not act as a receptor for galectin-9

J. Leitner[1]*, K. Grabmeier-Pfistershammer*[2]*, A. Rieger*[2]*, W. F. Pickl*[3]*, G. Zlabinger*[3]*, P. Steinberger*[1]*;*
[1]*Division of Immune Receptors and T cell activation, Institute of Immunology, Center for Pathophysiology, Infectiology and Immunology, Medical University of Vienna, Vienna, Austria,* [2]*Division of Immunology, Allergy and Infectious Diseases, Department of Dermatology, Medical University of Vienna, Vienna, Austria,* [3]*Institute of Immunology, Center for Pathophysiology, Infectiology and Immunology, Medical University of Vienna, Vienna, Austria.*

T cell immunoglobulin and mucin protein 3 (TIM-3) was originally identified as a marker for murine T helper type 1 cells. TIM-3 was found to negatively regulate murine T cell responses. Galectin-9 was described as a binding partner that mediates T cell inhibitory effects of TIM-3. Moreover, it was reported that like PD-1 the classical exhaustion marker, TIM-3 is up-regulated in exhausted murine and human T cells and TIM-3 blockade was described to restore the function of these T cells.
Here, we show that the activation of human T cells is not affected by the presence of galectin-9 or antibodies to TIM-3. Extensive studies on the interaction of galectin-9 with human and murine TIM-3 did not yield evidence for specific binding between these molecules. Moreover, profound differences were observed when analysing the expression of TIM-3 and PD-1 on T cells of HIV-1 infected individuals: TIM-3 was expressed on fewer cells and also at much lower levels. Furthermore, whereas PD-1 was preferentially expressed on CD45RA-CD8 T cells, the majority of TIM-3-expressing CD8 T cells were CD45RA+. Importantly, we found that TIM-3 antibodies were ineffective in increasing anti-HIV-1 T cell responses in vitro, whereas PD-L antibodies potently reverted the dysfunctional state of exhausted CD8 T cells.
Our results are not in support of an interaction between TIM-3 and galectin-9 and yield no evidence for a functional role of TIM-3 in human T cell activation. Moreover, our data indicate that PD-1, but not TIM-3 is a promising target to ameliorate T cell exhaustion.

P3.06.10
Endothelial-lymphocyte interaction causes proliferation and transient Foxp3 enrichment of CD4+ T lymphocytes

W. Lim*, E. Healy, T. M. Millar;*
University of Southampton, Southampton, United Kingdom.

Peripheral tolerance is regulated in part by suppressor cells of the $Foxp3^+$ regulatory T cell (Tregs) phenotype, failure of which leads to immune disorders. The vascular endothelium forms the barrier between the blood and tissue but actively recruits and activates immune cells. Previously murine $CD4^+$ T lymphocytes were shown to be activated via interaction with endothelial cells (ECs) causing Treg induction. Using human ECs and $CD4^+$ T lymphocytes we now show endothelium dependent $CD4^+$ proliferation and transient $CD25^+$ $Foxp3^+$ expression.
$CD4^+$ T lymphocytes were co-cultured with naïve or TNF or IFNg activated human ECs, in the presence of phytohaemagglutinin (PHA) or anti-CD3/28 antibodies. After 72 or 120 hours, lymphocyte proliferation was assessed by CFSE dilution and Treg induction was determined using CD25, CD127 and Foxp3 expression using flow cytometry.
$CD4^+$ cells only proliferated in the presence of EC or when combined with EC - PHA or EC - CD3/28. This proliferation was not enhanced when the EC were activated with TNF or IFNg. At 72h, 80-90 % of the proliferated cells expressed $Foxp3^+$. By 120h this dropped to 20-30 % despite further proliferation. $Foxp3^+$ expression was not changed following activation of the EC with TNF or IFNg.
ECs act as accessory cells for $CD4^+$ proliferation, enriching the population of $Foxp3^+$ cells. The transient expression of $Foxp3^+$ however may show further regulation by EC on T cell phenotype. This potential induction of Tregs points to the EC-T cell interaction as a novel target for Treg control in inflammation.

P3.06.11
Setting an intrinsic brake on T cell division number: Roles for TCR affinity and IL-2 concentration

J. M. Marchingo[1,2], *S. Heinzel*[1,2], *C. J. Wellard*[1,2], *M. R. Dowling*[1,2], *P. D. Hodgkin*[1,2];
[1]*The Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia,* [2]*The University of Melbourne, Melbourne, Australia.*

Kinetic mechanisms mediate the selective expansion of high-affinity T-cells during an immune response. Such processes include changes in time to first division but not times through subsequent divisions, which are typically constant. The proportion of cells that survive through each division also alters with stimulation affinity and is thought to be a dominant form of affinity-based regulation. Here we investigate an additional mechanism where the number of divisions that a T-cell undergoes following stimulation is 'programmed' and, as a consequence, higher affinity cells progress further and come to dominate the response.
We first quantified the effect of TCR-Ag affinity on T-cell division progression and survival by tracking proliferation of wild-type or Bim-deficient OT-I T-cells stimulated with a range of different affinity OVA peptides. We found high-affinity T-cells underwent greater expansion even when survival was enforced by Bim deficiency. This difference in expansion between affinities was traced to differences in the maximum number of divisions the T-cells were able to undergo before reverting to the quiescent state. We examined other T-cell stimuli and identified IL-2 as a potent modulator of the T-cell division limit, contributing towards selective expansion. By progressively subculturing cells *in vitro*, and applying mathematical modeling we determined a typical dose response between IL-2 concentration and the average division number that ranged from ~2 to over 12 divisions.
Although we cannot exclude a role for survival in mediating selective expansion, these results show that the programmed division capacity of T-cells plays an important survival-independent role in regulating selective expansion.

P3.06.12
Role of metalloprotease ADAM17 in regulating ICOSL-mediated humoral immune response

J. Marczyńska[1], *A. Ozga*[1], *A. Włodarczyk*[1], *D. Michalczyk*[1], *M. Banaś*[1], *M. Kwitniewski*[1], *A. Hutloff*[2], *J. Scheller*[3], *S. Rose-John*[3], *J. Cichy*[1];
[1]*Jagiellonian University, Kraków, Poland,* [2]*German Rheumatism Research Centre Berlin, Berlin, Germany,* [3]*Christian-Albrechts-Universität zu Kiel, Kiel, Germany.*

Immune cells regulate cell surface receptor expression during their maturation/activation. Although many of these receptors are regulated largely at the level of expression, protease mediated ectodomain shedding represents an alternative means of refashioning the surface of immune cells. Shedding is largely attributed to a family of ADAM metalloproteases, including ADAM17 also known as TACE (TNF-α converting enzyme). Although ADAM17 is well known to contribute to innate immune response by releasing diverse membrane proteins, such as cytokines (TNF-α), cytokine receptors (TNF-R1, TNF-R2, IL-6R) and adhesion molecules (L-selectin), much less is known whether/how this metalloprotease regulates adaptive immunity. To determine if ADAM17 contributes to regulating adaptive immune responses we took advantage of ADAM17 hypomorphic (ex/ex) mice, in which ADAM17 gene and protein expression is reduced by 90-95% as compared to WT littermates. Here we show that B cells express more activated ADAM17 compared to T cells and that ADAM17 deficiency results in spleen and lymph node enlargement, as well as increased levels of Ag-specific class-switched immunoglobulin production following immunization with ovalbumin. Moreover, we demonstrate that impaired down-regulation of surface levels of co-stimulatory molecule ICOSL in ADAM17 ex/ex mice might contribute to the development of exaggerated Ab responses. Therefore, our data suggest a functional link between ADAM17 and ICOSL in controlling adaptive immune responses.

P3.06.13
IL-35 is induced in human T cells upon co-stimulation via CD43 and PD-1

M. Modak[1], *M. Seyerl*[1], *R. Aigner*[1], *O. Majdic*[1], *D. Olive*[2], *G. Zlabinger*[1], *J. Stöckl*[1];
[1]*Institute of Immunology, Vienna, Austria,* [2]*Inserm U1068, Centre de Recherche en Cancerologie de Marseille, Marseille, France.*

Regulatory T cells (Treg) are not only crucial for the maintenance of immunological self-tolerance but are key mediators of infectious tolerance. IL-35, a member of IL-12 family is an inhibitory cytokine associated with Treg. Recently, we have shown that human rhinovirus (HRV) induces IL-35 producing Treg via up-regulation of B7-H1 (CD274) and sialoadhesin (CD169) on rhinovirus treated DCs (R-DC) as one of the immune evasion mechanisms. Thus, a combined set of co-stimulatory signals for T cells seems to be critical to induce IL-35. To further elucidate the underlying mechanism, the T cells isolated from human peripheral blood, were stimulated with a panel of plate-bound monoclonal antibodies (mAbs) against putative accessory T cell surface receptors. The IL-35 induction was analyzed by qPCR, intracellular staining and by sandwich ELISA. Among the various combination tested, co-engagement of CD3 and CD43 along with agonist anti-PD-1 mAb was identified to most potently induce IL-35, compared to the other prominent T cell activation pathways. However, upon stimulation via CD3+CD43+PD-1 the T cell signature cytokine profile (IL-2, IL-4, IL-10, IL-17, IL-22, IFNγ) remained unaltered compared to the other T cell activation pathways.
Though the primary effect of IL-35 is suppression of T cell proliferation, our data suggests that mechanism of suppression by such IL-35+Treg is rather dependent on the presence of antigen presenting cells (APC). Thus, our findings identify a novel pathway to induce immune-inhibitory T cells.

P3.06.14
High throughput generation of antibody secreting B-cell clones from peripheral blood of rabbits

S. Offner[1], *F. Ros*[1], *I. Thorey*[1], *G. Tiefenthaler*[1], *K. Kaluza*[1], *V. Lifke*[1], *J. A. A. Fischer*[1], *S. Klostermann*[1], *J. Endl*[1], *E. Kopetzki*[1], *A. Pashine*[2], *B. Kaluza*[1], *J. Platzer*[1], *S. Seeber*[1];
[1]*Roche Diagnostics GmbH, Penzberg, Germany,* [2]*Hoffmann-La Roche, Penzberg, Germany.*

We have developed a robust high throughput B-cell cultivation method using peripheral rabbit B cells. This rapid procedure generates a diverse set of antibodies using blood of immunized rabbits. The entire workflow includes (i) the identification and isolation of single B cells from rabbit blood expressing IgG antibodies, (ii) an elaborate short term B-cell cultivation to produce sufficient monoclonal antigen specific IgG for comprehensive phenotype screens, (iii) the isolation of VH and VL coding regions via PCR from B-cell clones producing antigen specific and functional antibodies followed by the sequence determination, and (v) the recombinant expression and purification of IgG antibodies. Rabbits immunized with the human IL1RL1 antigen (also known as ST2, DER4, FIT-1, IL33R, ST2L, ST2V, T1) were used for the proof-of-concept study. The IL33-IL1RL1 ligand-receptor system plays an important role in autoinflammatory diseases such as asthma, ulcerative colitis or arthritis. The fully integrated and to a large degree automated platform yielded clonal and very diverse IL1RL1-specific antibodies. Due to the high IgG productivity of the cultivated B-cell clones the IL1RL1-inhibiting IgGs from individual animals could be identified already during primary screening, thus substantially lowering the workload for the subsequent B-cell PCR workflow. In summary, this powerful B-cell cultivation method has proven to be an efficient and robust tool for the rapid generation of antigen specific and functional monoclonal rabbit antibodies without sacrificing the immunized animal.

P3.06.15
Co-stimulatory effects of PD-1 in sublingual mucosa-mediated CD4$^+$ T cell responses

T. Ohno[1], *C. Zhang*[1], *H. Yagita*[2], *M. Azuma*[1];
[1]*Tokyo Medical and Dental University, Tokyo, Japan,* [2]*Juntendo University School of Medicine, Tokyo, Japan.*

Objective. PD-1 is a co-inhibitory receptor on T cells that binds two ligands, B7-H1 and B7-DC. The B7-H1:PD-1 pathway is involved in peripheral tolerance, especially at the local inflammatory responses. At the same time, co-stimulatory effects of either B7-H1 or B7-DC have been reported. The sublingual mucosa has been used as a route for sublingual immunotherapy and sublingual vaccination, which induce opposite immune responses. The mechanisms by which sublingual mucosa-mediated immune responses are controlled are unclear. In this study, we investigated the involvement of PD-1 in sublingual mucosa-mediated antigen-specific CD4$^+$ T cell responses.
Methods. Cell tracking dye-labeled DO11.10 T cells were transferred into RAG2KO or SCID mice, OVA was applied onto sublingual mucosa with or without a mucosal adjuvant, cholera toxin (CT), and then CD4$^+$ T cell responses were measured.
Results. Sublingual OVA-painting induced antigen-specific CD4$^+$ T cell proliferation of regional lymph nodes. CT did not clearly affect the ratios of dividing cells, but enhanced the ratios of IFN-γ-producing cells. PD-1 blockade using anti-PD-1 mAb or the use of PD-1-deficient DO11.10 T cells markedly inhibited the T cell proliferation and these were especially obvious in the presence of CT. PD-1 was comparably induced with the increasing of cell division. Induction of B7-H1 on sublingual mucosal dendritic cells (DCs) at the OVA-painted sites was markedly inhibited and MHC class II expression was reversely enhanced.
Conclusions. Our results suggest a novel co-stimulatory function of PD-1 in sublingual mucosa-mediated CD4$^+$ T cell responses.

P3.06.16
Combining molecular adjuvant or a sub-immunizing dose of inactivated Foot and Mouth Disease Virus (FMDV) with plasmids encoding P12A3C or VP1 protein enhances DNA vaccine potency

E. Pereyra[1], *V. Gnazzo*[1], *I. Soria*[1], *C. Langellotti*[1], *C. Bellusci*[1], *A. D´Antuono*[2], *M. Nora*[2], *V. Quattrocchi*[1], *P. Zamorano*[1], *C. Mongini*[3];
[1]*INTA, Buenos Aires, Argentina,* [2]*CEVAN, Buenos Aires, Argentina,* [3]*CEFYBO, Buenos Aires, Argentina.*

In this study we evaluated the ability to induce protective immune responses using formulations including plasmids encoding the secreted form of VP1 protein (pVP1s) or the polyprotein P12A3C (pP1)of FMDV in combination or not with pCD40L and pIL15 or a sub-immunizing dose of inactivated FMDV (iFMDV).
BALB/c mice were inoculated id with pP1 or pVP1s vaccines in combination or not with a chemical adjuvant and one sub-immunizing dose of iFMDV. Negative controls were inoculated with empty plasmids, or adjuvant. No difference in antibody titers was found among the pP1 groups. On day 7 after the last immunization, vaccinated mice were challenged with $10^{4.5}$ TCID50 of FMDV. 75% and 50 % of animals were protected when received pP12A3C and pIL15 or pCD40L and the chemical adjuvant without a sub-immunizing dose of iFMDV), respectively. Animals vaccinated with pVP1s alone or with adjuvant with a single sub-immunizing dose of iFMDV enhanced dramatically the antibodies titers and were protected against the viral challenge, while negative controls were infected. Our results demonstrated that pP1vaccines were effective at priming and suggest that IL15 and CD40L can contribute to immune-enhancement and protection against FMDV challenge. Besides, an inoculation with pVP1 or pP1 and a sub-immunizing dose of iFMDV leads to complete protection and consequently may represent a useful strategy for improving the potency and efficacy of FMDV-DNA vaccines.

P3.06.17
The impact of CD27 signaling on Wnt-mediated T cell expansion

C. Ruckstuhl[1], *C. Schürch*[1,2], *C. Riether*[1], *A. Ochsenbein*[1,3];
[1]*Tumor Immunology, Department of clinical research, University of Bern, Bern, Switzerland,* [2]*Institute of Pathology, University of Bern, Bern, Switzerland,* [3]*Department of Medical Oncology, Inselspital, Bern University Hospital and University of Bern, Bern, Switzerland.*

The costimulatory molecule CD27 and its unique ligand CD70 are considerably involved in adaptive immunity. CD27 belongs to the tumor necrosis factor receptor (TNFR) family and is expressed on human and murine T, B and NK cells and hematopoietic stem cells. CD70 expression is restricted to activated lymphocytes and mature dendritic cells upon immune activation. Triggering of CD27 on T cells promotes T cell survival, expansion and differentiation. Whereas CD27-mediated T cell survival mechanisms have been studied for some time now, the way by which CD27 stimulation increases T cell proliferation is less well understood. We recently demonstrated that the CD70-CD27 interaction stimulates leukemia stem cell proliferation by increasing Wnt signaling via TNFR-associated factor 2 (TRAF2) and NCK-interacting protein kinase (TNIK).
We now hypothesized that CD27 may have an impact on T cell expansion via the Wnt pathway as well. To investigate a possible link between CD27 and Wnt signaling in T cells, we activated human CD8+ T cells in the presence or absence of inhibitory anti-CD27 monoclonal antibody. Proliferation, TNIK and b-catenin localization, Wnt-specific transcription factor activity and Wnt target gene mRNA levels were analyzed.
Blocking CD27 signaling attenuated nuclear localization of TNIK and b-catenin, resulting in reduced activation of the Wnt pathway. We propose that CD27 signaling promotes T cell proliferation by activating the Wnt pathway via TRAF2 and TNIK. Therefore, targeting the CD27-TRAF2-TNIK-b-catenin signaling axis may offer an attractive strategy to modulate CD8+ T cell responses in infections and autoimmunity.

P3.06.18
Constitutively active STAT3 acts as a tolerogenic factor in human CD4+ T-cells

K. G. Schmetterer[1,2,3], *A. Neunkirchner*[2,3], *D. Wojta-Stremayr*[2,3], *J. Leitner*[2], *P. Steinberger*[2], *W. F. Pickl*[2,3];
[1]*Department of Laboratory Medicine, Vienna, Austria,* [2]*Institute of Immunology, Vienna, Austria,* [3]*Christian Doppler Laboratory for Immunomodulation, Vienna, Austria.*

Purpose/Objective:
The signal transducer and activator of transcription 3 (STAT3) is a key integrator of signals provided by a multitude of cytokines and factors. Yet, the role of STAT3 in human CD4+ T-cells is not well established. Current research indicates Th17-inducing but also tolerogenic roles. We assessed the effects of STAT3 activation in human T-cells.
Materials and Methods:
A constitutively active mutant of STAT3 (STAT3C) was generated and cloned into an IRES-GFP harboring retroviral vector. Upon transduction into peripheral blood CD4+ T-cells phenotype, cytokine secretion, proliferation and suppressive potential in response to qualitatively different stimuli was analyzed.
Results:
STAT3C+ T-cells showed clear-cut transgene expression and phenotypically displayed an effector T-cell phenotype in regard to the characteristic regulatory T-cell markers CD25, CD39, CD127 and CTLA-4. Following anti-CD3 stimulation in concert with costimulatory signals via either CD80-CD28 or CD58-CD2, STAT3C+ T-cells were hyporesponsive and secreted a distinct cytokine profile. This included a significant reduction of IL-2, IL-13, IFN-γ and TNF-α secretion and a four-fold increase in IL-10 production. In co-cultures with CD4+ responder T-cells, STAT3C+ T-cells showed significant suppressive capacity following CD58 co-stimulation or moderate anti-CD28 co-stimulation, while supra-physiological levels of anti-CD28 costimulation abrogated this suppressive capacity. Suppression was contact-dependent but independent of IL-10 and TGF-β.
Conclusions:
Our data provide a clear-cut relation between activation of STAT3 and the acquisition of an anti-inflammatory cytokine profile and suppressive function. Consequently, the main function of STAT3 in

human CD4+ T-cells seems to be the regulation of tolerogenic processes.

P3.06.19
Adapters TRIM and LAX regulate transport and surface expression of CTLA-4 via Rab8 vesicles

H. Schneider[1], *M. C. Banton*[1], *K. L. Inder*[2], *E. Valk*[3], *C. E. Rudd*[1];
[1]*University of Cambridge, Cambridge, United Kingdom,* [2]*University of Queensland, Brisbane, Australia,* [3]*Leibniz Institute for Age Reserach, Fritz-Lipmann-Institute, Jena, Germany.*

CTLA-4 potently inhibits T-cell activation, and yet primarily resides in intracellular compartments such as the *trans*-Golgi network (TGN). Little is known regarding the mechanism(s) by which the co-receptor is shuttled to the cell surface. We previously showed that the type I transmembrane adapter T-cell receptor interacting molecule (TRIM) facilitates the formation of CTLA-4 containing vesicles for transport to the cell surface. In this study, we demonstrate that the related transmembrane adapter LAX (linker for activation of X cells) binds and coordinates with TRIM and Rab8 the transport of CTLA-4 from the TGN to the cell surface. LAX co-localized with TRIM and CTLA-4 in Rab8 positive vesicles and bound to the small GTPase Rab8 via its N terminal region. Both adapters promoted the reorientation of the microtubule-organizing center (MTOC) to the site of TCR engagement for polarized CTLA-4 release, while disruption of LAX/Rab8 binding or down-regulation of Rab8 substantially reduced CTLA-4 surface expression. These findings suggest that the multimeric complex CTLA-4/TRIM/LAX, with LAX binding to Rab8, cooperates to mediate the transport of CTLA-4 to the cell surface resulting in inhibition of T-cell responses. In addition to uncovering a new coordinator of CTLA-4 surface expression on T-cells, our results suggest a novel function for type 1 transmembrane proteins in the intracellular transport of receptors to the cell surface.
This work was supported by the Wellcome Trust and BBSRC.

P3.06.20
Signaling through Flt3 on activated splenic B-cells drives plasma cell differentiation

M. N. D. Svensson*, K. Månsson, K. M. E. Andersson, M. Bemark, M. Brisslert, M. Bokarewa;*
University of Gothenburg, Gothenburg, Sweden.

The tyrosine kinase receptor Flt3R plays an important role in early B-cell development. Mice lacking either the Flt3R or its ligand (FL) have reduced numbers of pre-B-cells in the bone marrow (BM) but normal mature B-cell numbers in the periphery and normal levels of serum Igs. Although Flt3R is down-regulated on pre-B-cells, this receptor reappears on activated B-cells in the spleen where its function is still unknown. In the present study we investigate how Flt3 signaling on activated B-cell affects terminal differentiation and antibody production.
Mice deficient for FL (FLKO) and their wild type (WT) counterparts were immunized against a T-cell dependent antigen (mBSA). FLKO mice were found to have an increased frequency of splenic Flt3+ B-cells, a population showing increased expression of MHCII, CD80, CD86 and CD40 when compared to Flt3- B-cells. Interestingly, the frequency of plasma cells was significantly increased in both spleen and BM of FLKO mice compared to WT, which was associated with an increased serum level of IgM and increased expression of the plasma cell associated genes IRF4, Blimp1 and XBP1. Although, serum levels IgG antibodies were not altered after immunization, FLKO mice failed to produce high-affinity IgG1 antibodies against mBSA.
We show that Flt3 expression on splenic B-cells define an activated B-cell population. Increased Flt3+ B-cells in FLKO mice are accompanied by a higher frequency of plasma cells and increased IgM production, but FLKO mice fail to produce high affinity IgG1 antibodies.
We propose that functional Flt3 signaling is essential for plasma cell differentiation.

P3.06.21
PD-1 blockage reverses immune dysfunction and hepatitis B viral persistence in a mouse animal model

H. Tzeng[1], *P. Chen*[2], *P. Hsu*[1];
[1]*Graduate Institute of Immunology, National Taiwan University College of Medicine, Taipei, Taiwan,* [2]*Department of Microbiology, National Taiwan University College of Medicine, Taipei, Taiwan.*

Persistent hepatitis B viral (HBV) infection results in chronic hepatitis, liver cirrhosis, and hepatocellular carcinoma (HCC). Recent studies in animal models of viral infection indicate that the interaction between the inhibitory receptor, programmed death (PD)-1, on lymphocytes and its ligand (PD-L1) play a critical role in T-cell exhaustion by inducing T-cell inactivation. High PD-1 expression levels by peripheral T-lymphocytes and the possibility of improving T-cell function by blocking PD-1-mediated signaling confirm the importance of this inhibitory pathway in inducing T-cell exhaustion. We studied T-cell exhaustion and the effects of PD-1 and PD-L1 blockade on intrahepatic infiltrating T-cells in our recently developed mouse model of HBV persistence. In this mouse animal model, we demonstrated that there were increased intrahepatic PD-1-expressing CD8+ T-cells and increased CD4+ FoxP3+ T cells in mice with HBV persistence, but PD-1 upregulation was resolved in mice which had cleared HBV. The Intrahepatic CD8+ T-cells expressed higher levels of PD-1 and lower levels of CD127 in mice with HBV persistence. Blockade of PD-1/PD-L1 interactions increased HBcAg-specific interferon (IFN)-γ production in intrahepatic T lymphocytes. Furthermore, blocking the interaction of PD-1 with PD-L1 by an anti-PD-1 monoclonal antibody (mAb) reversed the exhausted phenotype in intrahepatic T lymphocytes and viral persistence to clearance of HBV *in vivo*. Our results indicated that PD-1 blockage reverses immune dysfunction and viral persistence of HBV infection in a mouse animal model, suggesting that the anti-PD-1 mAb might be a good therapeutic candidate for chronic HBV infection.

P3.06.22
Convergent and divergent effects of costimulatory molecules in conventional and regulatory CD4+ T cells

E. Wakamatsu[1], *R. Abe*[1], *D. Mathis*[2], *C. Benoist*[2];
[1]*Tokyo University of Science, Noda, Japan,* [2]*Harvard Medica School, Boston, MA, United States.*

Costimulatory molecules of the CD28 family on T lymphocytes integrate cues from innate immune system sensors and modulate activation responses in conventional CD4(+) T cells (Tconv) and their FoxP3(+) regulatory counterparts (Treg). To better understand how costimulatory and coinhibitory signals might be integrated, we profiled the changes in gene expression elicited in the hours and days after engagement of Treg and Tconv by anti-CD3 and either anti-CD28, -CTLA4, -ICOS, -PD1, -BTLA, or -CD80. In Tconv, a shared "main response" was induced by CD28, ICOS, and, surprisingly, BTLA and CD80, with very limited CD28-specific (primarily Il2) or ICOS-specific elements (including Th1 and Th2 but not the follicular T signature). CTLA4 and PD1 had a very subtle impact in this system, similarly inhibiting the response to anti-CD3. Treg responded to the same costimulatory hierarchy and to the same extent as Tconv, but inducing different clusters of genes. In this reductionist system, costimulatory or coinhibitory engagement mainly elicits generic responses, suggesting that the variability of their effects in vivo result from temporal or anatomical differences in their engagement, rather than from inherently different wiring.

P3.06.23
The immunomodulatory potency of interleukin 2 applied as 'natural adjuvant' bound to virus-like nanoparticles is critically influenced by its membrane-anchor characteristics

D. Wojta-Stremayr[1,2]*, A. Neunkirchner*[1,2]*, K. G. Schmetterer*[2]*, W. F. Pickl*[1,2]*;*
[1]*Christian Doppler Laboratory for Immunmodulation, Vienna, Austria,* [2]*Institute of Immunology, Medical University of Vienna, Vienna, Austria.*

Decoration of virus-like nanoparticles (VNP) with functionally active, immunomodulatory molecules enhances particle immunogenicity and promotes selective immune recognition of the antigens they bear. In this study we investigated the influence of membrane characteristics of artificially membrane-bound cytokines. One (1Ig), two (2Ig) or four (4Ig) immunoglobulin(Ig)-like domains of CD16b were inserted between the model cytokine Interleukin 2 (IL-2) and the minimal GPI-anchor acceptor sequence of CD16b (GPI). We compared targeting of IL-2 fused to different membrane-anchors to lipid rafts of producer cells and VNP and tested the influence of the membrane-anchor on the biological activity and co-stimulatory potency in antigen-specific and non-specific assays. We identified a membrane-anchor - 2IgGPI - conferring an up to tenfold increase of targeting of IL-2 onto VNP, when compared to the minimal GPI-anchor acceptor sequence. When co-expressed on VNP with H-2D^{b} presenting the lymphocytic choriomeningitis virus glycoprotein peptide 33-41 (LCMV-GP$_{33-41}$), as antigen-specific signal 1, IL-2::2IgGPI was superior to IL-2::GPI to co-stimulate proliferation and accumulation of primary LCMV-GP-specific P14 TCR transgenic T-cells *in vitro.* Correspondingly, IL-2::2IgGPI induced increased numbers of terminally differentiated CD25^{high}CD127^{neg}KLRG1^{pos} effector cells with potent effector functions (IFNγ production and cytotoxic activity) when compared to IL-2::GPI. In contrast, co-stimulation with IL-2::GPI rather favored formation of CD25^{lo}CD127^{+}KLRG1^{-} memory precursor cells. Corresponding loss-of-function variants of IL-2 induced consistently less pronounced T-cell proliferation and differentiation. Artificially membrane-anchored cytokines decorating VNP used as convenient immunization platform might represent a novel interesting tool to shape immune responses.

Differential expression of CD21 in different species

M. Šinkora*, J. Šinkorová;*
Institute of Microbiology of the Academy of Sciences of the Czech Republic, v.v.i., Nový Hrádek, Czech Republic, Nový Hrádek, Czech Republic.

All mature B cells in humans and mice are CD21 positive until B cells become plasma cells. This expression profile closely matches the role of CD21 in enhancing of BCR signaling, involution of CD21 in B cell responses and antigen presentation, and the promotion of B cell survival. However, studies in sheep show two populations of mature B cells that differ in expression of CD21. These CD21^{-} and CD21^{+} mature B cell populations were shown to have distinct recirculation characteristics, and phenotype or tissue distributions. Some reports in pigs also indicate that porcine mature B cells could express CD21 differentially. For these reasons we have analyzed expression profile of three mAbs IAH-CC51, BB6-11C9.6 and B-Ly4 that are routinely used to detect porcine CD21 on the surface of B lymphocytes. Cross-reactive studies show that CD21 is always present on the surface of all mature B cells but can be expressed in at least two differential forms. We used IAH CC51 mAb that recognize those forms together with anti-CD2 to define four subpopulations of B cells. Ontogenetic and in vitro culture studies, analysis of cell size, expression of CD11b and class-switched phenotype together with measurement of proliferation and cell death, revealed that these subsets represent functionally distinct populations of B cells. Phenotypic and functional features collectively suggest that distinct subsets of mature B cells can express differential forms of CD21, which can be significant for their function. This work was supported by Czech Science Foundation grant P502/10/0038.

Diving could encounter the immune system of divers due to long term stressors and disasters. This study was designed to understand comprehensive effect of diving on the cellular and humoral components of immune system in a number of persons with long-term exposures. The cross-sectional study was developed on 25-male-expert divers. The immunologic parameters were compared in these individuals with 25 sex-age-matched healthy controls. Serum levels of IgA ($p<0.001$) and IgM ($p=0.003$) were significantly decreased in divers compared to the controls; while the levels of IgG and IgE ($p<0.001$) were significantly increased. Absolute count of B cells was significantly lower in the divers group, compared to the controls ($p<0.001$). Specific-antibody-responses of divers was also defective ($p<0.01$). An increased activity of classic pathway of complement components was detected in the divers ($p<0.001$). Absolute count of natural killer cells in the divers was also significantly higher than the controls ($p<0.001$). Humoral, cellular and complement components of the immune system could be involved during long-term diving.

Class Switch Recombination Process in Common Variable Immunodeficiency

A. Aghamohammadi*, H. Abolhassani, S. Moazzeni, A. Salek Farrokhi, P. Mohammadinejad, B. Mirminachi;*
Research Center for Immunodeficiencies, Pediatrics Center of Excellence, Children's Medical Center, Tehran University of Medical Sciences, Tehran, Iran.

Common variable immunodeficiency (CVID) is a heterogeneous group of disorders characterized by hypogammaglobulinemia and recurrent bacterial infections. Impaired antibody production in these patients is due to defect in differentiation of naïve B cell into plasma cells. Class switch recombination (CSR) which plays a critical role in the production of different Immunoglobulin classes may be defective in a group of CVID patients. The aim of this study was to investigate the CSR process of CVID patient's B lymphocytes, by evaluating the expression of IgE mRNA and protein in an IgE inductive medium. Peripheral blood mononuclear cells (PBMCs) from twenty nine CVID patients and 21 healthy controls were isolated and cultured in the presence of rhIL-4 and CD40L. IgE mRNA and IgE protein were measured by RT-PCR and ELISA techniques, respectively. Normal production of IgE mRNA was recorded in 23 out of 29 patients (79.31%) as well as all controls; while the remaining 6 patients (20.69%) were unable to express IgE mRNA indicating a defect in CSR. PBMCs of 16 out of 29 patients (55.2%) could not produce normal values of IgE comparing with controls after stimulation by IL-4 and CD40L. IgE production is impaired in most of the CVID patients. Defects in post CSR (IgE mRNA transcription) processes such as protein production and secretion can be the causative mechanism of CVID in patients with normal mRNA and impaired protein productions. Determination of these defects can help to clarify the various underlying mechanisms in etiology of CVID.

P3.07.05
Allelically included B cells with two specificities are eliminated in the periphery

L. Baudewijn[1], *S. Gjoerup Saekmose*[2], *C. Dellgren*[1], *T. Barington*[1];
[1]*Odense University Hospital, Department of Clinical Immunology, Odense, Denmark,* [2]*Næstved Sygehus, Næstved, Denmark.*

The basis for monospecificity of B cells is allelic exclusion of immunoglobulin (Ig) heavy (H) and light (L) chain genes during early differentiation. Allelic exclusion at the IgH locus requires expression of the pre-B cell receptor containing the *mu* chain and an in-frame ("productive") VDJ rearrangement from one of the two IgH alleles inhibiting further IgH gene recombination.
We investigated to which extent mature human B cells carrying a frame-shift mutation in exon 1 of the *mu* gene (*mu*CH1) express productive VDJ-CH1 transcripts originating from the mutant allele. According to the feedback inhibition model of allelic exclusion, 12 % of these B cells may carry two productive VDJ rearrangements -one that has been expressed as VDJ-Ig*mu*CH1 but failed to assemble into a surface-expressed B cell receptor due to the mutation and one that has been expressed in a membrane bound *mu* chain and saved the B cell from elimination. It is possible that after antigen stimulation, class switch recombination might occur on both functionally rearranged alleles leading to generation of plasma cells and memory B cells with dual specificity thereby breaking allelic exclusion. We amplified, cloned and sequenced VDJ-CH1 transcripts from mature B cells from a heterozygous human carrying a frame-shift *mu*CH1mutation. We analyzed 950 unique clones of which 90% contained a productive VDJ rearrangement. Less than 1 % of the functionally rearranged transcripts originated from the mutant allele. These data suggest counter-selection of "double producers" when they expand in the peripheral immune system.

High-throughput mutant mouse characterisation is a powerful tool to identify novel immune phenotypes

E. L. Cambridge, *A. O. Speak, S. Clare, T. Sanger Mouse Genetics Project, R. Ramirez-Solis, D. J. Adams, G. Dougan, J. K. White; WellcomeTrust Sanger Institute, Cambridge, United Kingdom.*

As part of the Sanger Mouse Genetics Project (MGP) we have generated over 900 knockout mouse lines. Following expansion, dedicated groups of mice are phenotyped through an extensive and standardised battery of tests assessing development, physiology and metabolism, and yielding data on >280 parameters for every line with a biobank resource also available. The status of the immune system in naïve mice is tested by flow cytometric profiling of peripheral blood leukocytes (PBL). Complementing this, the response to infection is probed by challenging with two bacterial systems; a mucosal response to Citrobacter rodentium, and a systemic response to Salmonella Typhimurium. To date 564 alleles have been phenotyped in the naïve state, 495 of which have completed the infection challenges. Immune testing is an expanding area of the MGP with increased analysis in the naïve state to include the addition of spleen, lymph node and bone marrow flow cytometric profiling, cytotoxic T cell function, autoimmune diagnostics and epidermal immune cell composition have been added to the pipeline. New challenges will be added to probe a wider range of responses and will now include DSS, Influenza and Trichurius. This rich source of information is openly available on the Sanger Mouse Portal (http://www.sanger.ac.uk/mouseportal/).

Functional analysis of synaptobrevin family members in secretion of antibodies by human plasma cells

L. Gómez-Jaramillo, L. Delgado-Pérez, F. Mora-López, R. Romero-García, G. Jiménez-Gómez, A. García-Poley, J. A. Brieva, ***A. Campos-Caro****;*
Hospital Universitario Puerta del Mar, Cádiz, Spain.

Plasma cells (PC) are B-lymphocytes terminally differentiated with the purpose of manufacturing and secreting immunoglubulins (Ig). VAMPs (Vesicle Associated Membrane Proteins) or v-SNAREs are a subfamily of SNARE (Soluble N-ethylmaleimide-sensitive factor Attachment protein REceptor). SNARE complex required for exocytosis are made up of three proteins, one from each SNARE subfamily (VAMPs, Syntaxins (STX) and SNAP25). The aim of this study is characterize the presence of several VAMPs proteins in human PC and examines their functional roles on Ig secretion process.
Expression of VAMP proteins PC was examined by Western-blot, immunofluorescence and immunoprecipitation assays (IP) were carried out in the human U266 cell line in order to identify which VAMPs can interact with other SNAREs that could participate in the SNARE complex for Ig secretion in antibody secreting cells. Experiments of loss of function were performed using specific iRNAs.
Western-blotting assays revealed that VAMP-2,-3,-4,-5,-7 and VAMP-8 but no VAMP-1 were expressed. The majority of v-SNAREs were localized in cytoplasmic vesicular structures with no overlapping staining patterns with any subcellular structures marked with LAMP1, EEA1, Giantin, Cadherin or Calnexin. IP assays demonstrated an interaction of VAMP7 with STX4 and SNAP23 and interactions between VAMP2 and VAMP3 with both STX3 and STX4. Functional results from iRNA assays shown a statistically reduction of antibody secretion with iRNA specific for VAMP2. We identified several possible SNARE complexes including SNAP23/STX3/VAMP2, SNAP23/STX3/VAMP3, SNAP23/STX4/VAMP2, SNAP-23/STX4/VAMP3 and SNAP23/STX4/VAMP7. However, previous and present iRNA functional assays only imply as SNARE complexes candidates to the ones containing VAMP2 and/or STX4.

P3.07.08
B cell responses toward bacterial pathogens in human tonsils

***E. Faenzi**, F. Buricchi, E. Viciani, G. Santoro, F. Bagnoli, M. Barocchi, F. Castellino, G. Del Giudice, A. Manetti, O. Finco;*
Novartis Vaccines, Siena, Italy.

The first contact between microorganisms and the human host takes place in the upper respiratory tract and oro-pharyngeal mucosa. Current data on B cell responses in nasopharyngeal-associated mucosa are limited because, more frequently, the immune memory response to a pathogen or a vaccine is analyzed in peripheral blood. Therefore, understanding the mechanisms underlying the effector and memory B cell responses at the site of host-pathogen interaction is of great interest in the vaccine field.
Aim of the present study was to evaluate effector and memory B cells from palatine tonsils of children and adult patients that underwent surgery.
We measured IgG+ and IgA+ plasmacells (PC) and memory B cells (MBC) specific for antigens known to be immunogenic from *S.aureus*, *S.pneumoniae* and *S. pyogenes*. Frequencies of PC and MBC were calculated as percentages of total IgG/IgA positive B cells in the tonsils. Microbiologic culture data from tonsil swabs were also available for each analyzed sample.
We demonstrate that the antigen recognition profile of MBC and PC is different in children versus adults for most of the tested antigens. In addition, we show a relationship between the pathogens isolated from the tonsils and the pattern of the antigen specific B cell response. We provide also evidence that antigens of the biofilm phase of *S.aureus* can be seen by the immune system, leading to the development of biofilm-specific MBC and PC. These data provide new insights in the profiling of the B cell response at the site of interaction between host and pathogen.

P3.07.09
Ectonuclotidase activity in class switch recombination of murine B cells

***C. E. Faliti**[1], R. Rigoni[1], M. Proietti[1], E. Traggiai[2], F. Grassi[1];*
[1]Institute for Research in Biomedicine IRB, Bellinzona, Switzerland,
[2]Novartis, Basel, Switzerland.

Class switch recombination (CSR) is an irreversible somatic recombination mechanism by which B cells switch their surface immunoglobulin class expression from IgM and IgD to other isotype with distinct effector function. This diversification is essential for a protective adaptive humoral immune response. B cell receptor (BCR) activation together with exogenous signals, including tumor necrosis factor (TNF) family members, Toll-like receptors (TLRs) ligands or cytokines trigger CSR. Here we show that extracellular adenosine critically contributes to CSR in murine mature B cells. Murine naïve B cells release ATP upon coordinate B cell receptor (BCR) and Toll Like Receptors (TLRs) stimulation. The released ATP is hydrolysed to adenosine by plasma membrane ectonucleoside triphosphate diphosphohydrolase 1 (ENTPD1) CD39 and ecto-5'-nucleotidase (5'-NT) CD73. Remarkably germinal center and isotype switched B cells displayed higher expression of CD73. Moreover, CD39 and CD73 deficient B cells showed in vitro a significant impairment in their capacity to differentiate to class switch plasma cells upon BCR and TLR engagement, underlying the role of adenosine in the B cells isotype switching process. Ig CSR-deficiencies in human can be dependent from an intrinsic B cell defect, however most of them are still molecularly undefined and diagnosed as common variable immunodeficiency (CVID). Notably, CVID patients with impaired class switched antibody responses are selectively deficient in CD73 expression in B cells, suggesting that CD73 dependent adenosine generation contributes to the pathogenesis of this disease.

P3.07.10
Primary Antibody Deficient Patients and ENT Complication

***A. Ghajar**, A. Aghamohammadi, A. Kouhi, M. Tavakol, M. Afarideh, H. Abolhassani;*
Research Center for Immunodeficiencies, Pediatrics Center of Excellence, Children's Medical Center, Tehran University of Medical Sciences, Tehran, Iran.

The main clinical presentation of patients with primary antibody deficiency (PAD) incorporates upper respiratory tract infections comprising otitis media, sinusitis and pneumonia. This study was designed to investigate clinical and paraclinical hearing loss associated complications in important types of PAD comprehensively. Among all diagnosed patients with PAD, a cross sectional study was conducted on 55 PAD patients with diagnosis of selective IgA deficiency (SIgAD), common variable immunodeficiency (CVID), X-linked or autosomal recessive agammaglobulinemia and hyper IgM syndromes (HIgM). All patients were undergone of physical examination, tuning fork tests, pure tone audiometry, speech audiometry and auditory brain stem response. Otologic complications were detected in 54.5% of PAD patients. Conductive hearing loss was the main otologic complication amongst PID patients (73.3%) followed by SNHL which was present in 8 cases. Otitis media with effusion (21.8%), chronic otitis media (16.3%), tympanic perforation (10.9%), tympanosclerosis (5.4%) and auditory neuropathy (3.6%) were other complications in PAD patients. CVID and XLA patients with prophylactic usage of antibiotic had lower rate of ENT complications (p=0.04) and Otitis media with effusion (p=0.027) respectively. Given the high prevalence of hearing loss in PAD patients, a systematic otological investigation is recommended as an integral part of the management and follow-up of these patients.

P3.07.11
IL-4 promotes B cell maturation in synergy with BAFF and confers resistance to cell death in negative selection checkpoints

***A. Granato**, B. Baptista, M. Bellio, A. Nóbrega, E. Hayashi;*
UFRJ, Rio de Janeiro, Brazil.

IL-4 plays an essential role in the activation of B cells. Constitutive expression of IL-4 results in mature B cell compartment hyperplasia and is associated with antibody mediated autoimmunity, suggesting failure of tolerance safeguard mechanisms. Here, we analyzed the effect of IL-4 on in vitro B cell maturation, from immature to transitional stages, and its influence on BCR-mediated negative selection. Starting either from purified IgMneg B cell precursors, or sorted bone marrow immature (B220lo IgMlo CD23neg) and transitional (B220int IgMhigh CD23neg) B cells from C57BL/6 mice, we compared the maturation effects of IL-4 and BAFF. We found that IL-4 stimulated the generation of CD23+ T2-like B cells from CD23neg transitional B cells, and this effect was comparable to BAFF. Remarkably, IL-4 showed unique protective effect against anti-IgM apoptotic signals on transitional B cell checkpoint, not observed with BAFF. Moreover, IL-4 and BAFF strongly synergized to promote B cell maturation, and again IL-4 rendered this process refractory to BCR-mediated cell death. IL-4 leads to the reduction of pro-apoptotic Bim protein levels, which are induced by BCR crosslinking. Diminished levels of intracellular Bim protein correlates with protection to BCR induced cell death. Evidences support the notion that down-modulation of Bim by IL-4 occurred in a post-transcriptional manner. Together, these results contribute to the understanding of IL4 role in B lymphocyte physiology, unveiling a previously undescribed activity of this cytokine on the maturation of B cells, which could have important implications on the breaking of B cell central tolerance in autoimmunity.

P3.07.12
The hierarchical process of differentiation of long-lived antibody-secreting cells is dependent on integrated signals derived from antigen and IL-17A

L. Z. Grund[1,2]*, M. Lopes-Ferreira*[1,2]*, C. Lima*[1,2]*;*
[1]Immunoregulation Unit, Special Laboratory of Applied Toxinology (CEPID/FAPESP), Butantan Institute, São Paulo, Brazil, [2]Department of Immunology, ICB - University of São Paulo, São Paulo, Brazil.

Two B cell populations are responsible for humoral immune memory: memory B cells (Bmem) and the long-lived antibody-secreting cells (ASC). In this study, we proposed to confirm whether Bmem contribute to ASC differentiation. Using cellular suspensions of peritoneal cavity, spleen and bone-marrow from mice with chronic humoral response against *Thalassophryne nattereri* venom (48 d), we purified CD19-positive Bmem that were cultivated in an *in vitro* system in the presence of venom, or cytokines as IL-17A, IL-21, IL-23, and IL-33. We demonstrated the existence of a hierarchic process of differentiation in which Bmem differentiated in CD138-positive ASC with intracellular IgG and able to secretion. IL-17A or IL-21/IL-23/IL-33 improves the ability of venom to induce intracellular IgG of peritoneal derived-ASC. Only cognate stimulation with venom is sufficient to down-regulate the expression of CD45R/B220. BAFFR is up-regulated in splenic or bone marrow derived-ASC stimulated by venom, CpG or cytokines. Only splenic derived-ASC up-regulate Bcl-2 expression after CpG or the combination of IL-21/IL-23/IL-33. Finally, the activation of ASC for IgG1 secretion is triggered by venom proteins in peritoneal cavity and by the inflammatory milieu in medullar niche. These results show the importance of the integration of signals downstream of BCR and cytokine receptors in modulating ASC differentiation, focusing in the microenvironment niche of their generation. **Support by:** Fapesp and CNPq.

P3.07.13
Granzyme B-secreting B cells: suicidal or lethal?

M. Hagn*, D. Brasacchio, A. Brennan, J. Lopez, K. Thia, V. Sutton, J. A. Trapani;*
Cancer Immunology Program, Peter MacCallum Cancer Centre, Melbourne, Australia.

Serpin B9 (formerly PI-9) is a potent inhibitor of the human serine protease Granzyme B (GrB). GrB mediates target cell apoptosis when released by cytotoxic T lymphocytes or natural killer cells. These cells express high levels of intracellular Serpin B9 to protect themselves from misdirected GrB. Classically, PI-9 expression in accessory cells, such as B cells, was thought to protect them from accidental exposure to locally secreted GrB. By contrast, we recently reported that human B cells are able to secrete active GrB, and therefore Serpin B9 expression in B cells might serve a broader purpose than described to date. Here, we show that human B cells constitutively express Serpin B9, whereas GrB mRNA and protein are induced de novo by interleukin-21 (IL-21) and B cell receptor (BCR) cross-linking. Interestingly, the viability of cells remained high, suggesting the constitutive levels of Serpin B9 were able to protect B cells despite high expression of GrB. Using confocal microscopy, we show that GrB localises to the B-cell secretory pathway, through co-localisation with calreticulin, GM130 and EEA1; markers of the endoplasmic reticulum, Golgi and early endosomal compartments, respectively. Furthermore, IL-21/anti-BCR induces a unique transcriptional profile, different to naïve B cells or plasma cells, indicated by a distinct impact on the IRF4-Blimp1-Bcl6 axis. Our studies strongly suggest an important role for GrB secretion by B cells, pointing to a role in B cell homeostasis, either autoregulatory in the context of activation-induced cell death (AICD), or cytotoxic in our classical understanding of target cell death.

P3.07.14
Participation of arginine methyltransferase 1 in B cell development and differentiation

K. Hata*, N. Yanase, E. Takada, J. Mizuguchi;*
Tokyo Medical University, Tokyo, Japan.

Development and proliferation of B lineage cells are tightly controled by intracellular signaling network. Activity of these signaling components is modulated by post-translational protein modifications, including phosphorylation, acetylation, and methylation. Protein arginine methylation catalyzed by protein arginine methyltransferases (PRMTs) plays a crucial role in transcription and signal transduction. To examine the role of PRMT1, a major enzyme in mammalian cells, in B cells, we established B cell-specific PRMT1-deficient mice through Cre-lox approach. Development of B cells, but not T cells, was impaired in B cell-specific PRMT1-deficient mice. Concentrations of immunoglobulin including IgM and IgG1 in sera were also diminished in the PRMT1-deficient mice compared with control. NP-specific IgM and IgG3 responses were also decreased in the PRMT1-deficient mice following immunization with type II T-independent antigen NP-Ficoll in vivo. Moreover, generation of IgG3-positive cells induced by polyclonal B cell activator lipopolysaccharide (LPS) together with IL-4 and CD40-ligand (CD40-L) was reduced in the PRMT1-deficient B cells compared with WT cells. However, IgG3 concentration of the culture supernatant from the LPS-stimulated B cells was comparable between PRMT1-deficient and WT cells, suggesting that PRMT1 regulates IgG3 secretion from IgG3 plasma cells. Finally, arginine methylation of p19 and p21 were increased following stimulation with LPS/IL-4/CD40-L in WT B cells, whereas p19 methylation was missing in PRMT1-deficient B cells, suggesting that p19 is a possible target of PRMT1 responsible for B cell activation and differentiation. Together, arginine methylation catalyzed by PRMT1 plays a crucial role in B cell development and differentiation.

P3.07.15
Distinct processing of the pre-B cell receptor and the B cell receptor

J. Haimovich, S. Cohen, M. Toren, ***N. Hollander****;*
Tel Aviv University, Tel Aviv, Israel.

It is well established that pre-BCR signaling governs proliferation and differentiation of pre-B cells. It has been suggested that signaling by the µ heavy chains of the pre-BCR induces survival and differentiation of pre-B cells, while the surrogate light chains are essential for proliferation and clonal expansion. However, the mechanism by which pre-BCR µ chains initiate differentiation signals is not clear, as physiological ligands have not been identified. We have demonstrated that while oligosaccharide moieties of µ heavy chains in the BCR are of the complex type as expected, those of the pre-BCR on the surface of pre-B cells contain oligosaccharide moieties of the high-mannose type only. This is unique, because high-mannose glycans are generally restricted to the endoplasmic reticulum in mammalian cells. It is therefore hypothesized that mannose-specific lectin-like molecules may function as the non-antigen ligand that triggers the pre-BCR.
We further examined the processing of the unusually glycosylated µ heavy chains in pre-B cells. We demonstrated that the pre-BCR reaches the cell surface by a non-conventional brefeldin A-sensitive monensin-insensitive transport pathway. Although pre-BCR complexes consist of µ heavy chains with high-mannose oligosaccharide moieties, they are stably expressed in the plasma membrane and demonstrate turnover rates similar to those of the BCR. Thus, rapid internalization cannot account for their low surface expression. Rather, we demonstrated that the low pre-BCR abundance in the plasma membrane results, at least in part, from insufficient production of surrogate light chains, which appears to be a limiting factor in pre-BCR expression.

P3.07.16
A functional BCR in human IgA and IgM plasma cells

*D. Pinto, E. Montani, F. Sallusto, A. Lanzavecchia, **D. Jarrossay**; IRB, Bellinzona, Switzerland.*

Plasma cells are terminally differentiated cells of the B cell lineage that secrete antibodies at high rate. Serum IgG antibodies and consequently IgG PCs can persist for a lifetime, although displacement by newly generated PCs and susceptibility to FcgammaRIIB-mediated apoptosis increase their turnover. In contrast, the IgA PCs present in the lamina propria show a high turnover rate. These findings suggest different mechanisms of regulation of IgG and IgA PCs.
BCR expression is required for memory B cells survival, but is thought to be lost on mature plasma cells due to a secretory switch in the Ig mRNA. Here, we report that human IgA and IgM unlike IgG plasma cells express a membrane functional BCR associated with the Igα/Igβ heterodimer. Importantly, this is shown for in vitro derived as well as ex vivo plasma cells isolated from bone marrow and gut lamina propria. BCR crosslinking on IgA and IgM plasma cells led to Ca2+ mobilization, ERK1/2 and AKT phosphorylation and impacted survival of IgA plasma cells. These findings demonstrate a fundamental difference between human IgG, IgM or IgA plasma cells and suggest that the IgA plasma cell repertoire may be modulated by specific antigens with implications for the regulation of the mucosal immune system.

P3.07.17
The surrogate light chain selects Mu heavy chain based on its DH CDR-H3 sequence

***M. A. Khass**, L. Watkins, Y. Zhuang, E. Capriotti, P. D. Burrows, H. W. Schroeder Jr.;*
University of Alabama at Birmingham (UAB), Birmingham, AL, United States.

Formation of the Pre B cell receptor (Pre BCR) is a key step in B cell development. The Pre BCR is formed by the binding of the surrogate light chain proteins (SLC) to the Mu heavy chain (Mu HC). We sought to test the hypothesis that the sequence of the DH heavy chain complementarity determining region 3 (CDR-H3) differentially affects the interaction between SLC and Mu HC. We used Bromodeoxyuridine (BrdU) incorporation and analysis of apoptosis to assess B cell turnover, cell cycle progression and cell loss as functions of CDR-H3 content mainly at the Pre B cell stage. We also, measured the degree of formation of Pre BCR based on binding of SLC to Mu HC with different CDR-H3 contents. B lineages enriched for hydrophobic CDR-H3 had difficulty forming Pre BCR, increased cell loss and inefficient cell cycle progression at the transition from early to the late pre-B cell. On contrary, mice limited to use of a single, normal DH with tyrosine enriched CDR-H3 followed the wild-type pattern of B cell development. Our findings suggest that immunoglobulin heavy chains with hydrophobic CDR-H3s have poor binding to SLC, resulting in decreased cycling activity and increased apoptosis at the Pre B cell stage. These findings may explain how humans minimize the use of hydrophobic CDR-H3s in their developing B cells since humans lack Dμ protein formation. Moreover, explain decreased prevalence of neutralizing antibodies with CDR-H3s enriched for charged and hydrophobic amino acid contents in HIV, influenza and other infections.

P3.07.18
Therapeutic effects of anti-APRIL blocking antibody on murine IgA nephropathy

***Y. Kim**[1,2], Y. Suzuki[2], H. Bertrand[3], H. Suzuki[2], M. Maikuma[2], M. Muto[2], S. Izui[4], S. Hirose[5], Y. Tomino[2];*
[1]Division of Nephrology, Department of Internal Medicine, Kyung Hee University College of Medicine, Seoul, Republic of Korea, [2]Division of Nephrology, Department of Internal Medicine, Juntendo University School of Medicine, Tokyo, Japan, [3]Division of Hematology, University Hospital of Geneva, Geneva, Switzerland, [4], Division of Hematology, University Hospital of Geneva, Geneva, Tokyo, Japan, [5], Department of Pathology, Juntendo University, School of Medicine, Tokyo, Japan.

Background:A proliferation inducing ligand(APRIL) is member of tumor necrosis factor and blocking selective antibody-mediated APRIL blockade delays disease development in lupus mouse model by preventing proteinuria, kidney lesions, and mortality. TACI/BCMA axis is critical for IgA production and the patients with IgAN show serum elevation of APRIL. However, APRIL antagonism alone has never been tested until now in IgAN. So we are purposed to reveal its effect on murine IgAN.
Methods:We treated female IgAN prone mice(grouped ddY mice), which was recently established by our group(J Am Soc Nephrol 23; 1364, 2012), with 100mg i.p. of anti-APRIL blocking monoclonal antibody(Apophe) or control mouse IgG(cIg) twice a week during 6weeks starting at 7weeks of age, and checked serum levels of IgA, albuminuria. Pathological changes and immunoflorescence findings of(IgA, IgG, IgM and C3) and also cellular effects in bone marrow, spleen and peripheral blood were also evaluated.
Results: Until 4weeks, Apophe treatment showed reduced albuminuria with decrease of serum levels of IgA. Serum levels of IgG in Apophe group after 4weeks was lower than those of cIg group. Glomerular IgA deposition, but not IgG and IgM, at 6weeks in Apophe group was significantly decreased than that in cIg(4.12±0.17 vs 4.48±0.16, p=0.001).Flow cytometric analyses revealed that Apophe treatment induced significant attenuation of Gr(-)/FcrRIV(+) monocytes in peripheral blood.
Conclusion:Anti-APRIL treatment ameliorates murine IgAN with decrease of serum levels of nephritogenic IgA and its glomerular depositions. Present findings suggest that APRIL pathway may be importantly involved in the pathogenesis of IgAN and thus a therapeutic target.

P3.07.19
SLAM-dependent and independent mechanism of IgE induction

***A. Kitoh**[1], N. Kusuba[1], Y. Miyachi[1], S. Sakaguchi[2], Y. Yanagi[3], K. Kabashima[1];*
[1]Department of Dermatology, Kyoto University Graduate School of Medicine, Kyoto, Japan, [2]Laboratory of Experimental Immunology, WPI Immunology Frontier Research Center, Osaka University, Suita, Japan, [3]Department of Virology, Faculty of Medicine, Kyushu University, Fukuoka, Japan.

Accumulating evidence suggests that IgE production induced by epicutaneous sensitization with protein antigen are associated with the development of allergic diseases such as allergic asthma and food allergy as well as the pathogenesis of atopic dermatitis. However, the precise mechanism of IgE induction by epicutaneous antigen exposure remains to be elucidated.The costimulatory molecule SLAM (Signaling Lymphocytic Activation Molecule, also known as CD150) is a glycoprotein expressed on activated lymphocytes and antigen-presenting cells. It has been reported that SLAM signal regulates IL-4 production by Th2 cells and follicular helper T cells, suggesting the possible role of SLAM in Th2 response and IgE induction. In fact, previous report showed that SLAM-deficient mice were less susceptible to the development of hyper-IgE and allergen-induced airway hypersensitivity after intraperitoneal sensitization.Here we investigated the role of SLAM in IgE induction by epicutaneous sensitization. Unexpectedly, SLAM-deficient mice showed increased levels of antigen-specific IgE after epicutaneous immunization with ovalbumin (OVA) as wild-type mice, while the elevation of antigen-specific IgE after intraperitoneal OVA immunization was significantly attenuated in SLAM-deficient mice. These results indicate that, in contrast to intraperitoneal immunization, epicutaneous immunization with protein antigen

induces antigen-specific IgE production in a SLAM-independent manner. We further revealed the precise mechanisms of SLAM-dependent and -independent IgE induction, which may provide a fundamental finding for specifically suppressing IgE production by epicutaneous antigen exposure.

P3.07.20
Differences between IgG4+ and IgG1+ B cells provide insight into regulation of the IgG4 response

L. C. Lighaam[1]*, E. Vermeulen*[1]*, E. L. Culver*[2]*, K. J. Meijlink*[1]*, T. H. den Bleker*[1]*, P. Ooijevaar-de Heer*[1]*, E. Barnes*[2]*, R. C. Aalberse*[1]*, S. M. van Ham*[1]*, T. Rispens*[1]*;*
[1]Sanquin Blood Supply, Amsterdam, Netherlands, [2]Translational Gastroenterology Unit, John Radcliffe University Hospitals NHS Trust and Nuffield Department of Medicine, Oxford University, Oxford, United Kingdom.

IgG4 antibodies are a peculiar subclass of human immunoglobulins that display limited capacity to trigger effector mechanisms. Partly, this can be explained by the fact that IgG4 can exchange half-molecules, rendering bi-specific, monovalent antibodies. In allergy, IgG4 antibodies compete with IgE and decrease allergic symptoms. Because of these properties, IgG4 belongs to the humoral arm of immune tolerance. How this tolerogenic humoral immune response is regulated is unknown, as information on IgG4+ B cells is lacking. We isolated IgG4+ B cells and show that there are phenotypical differences between IgG4+ B cells and IgG1+ B cells. These differences may provide insights why the IgG4+ response is differentially regulated from the IgG1 immune response and whether there is crosstalk between the regulatory networks that control humoral and cellular immune tolerance. IgG4+ B cells express higher levels of the low affinity FcεR while expression of inhibitory FcγRIIb was not altered compared to IgG1 cells. Expression of complement receptors is reduced on IgG4+ B cells, possibly making them less sensitive to regulation via complement. Although IgG4+ B cells are part of the humoral tolerogenic repertoire, we show that IgG4+ B cells are not classical Bregs, since they are not CD24hiCD38hi and more importantly, do not produce IL-10. Taken together, these findings indicate IgG4+ B cells are differentially regulated than IgG1 B cells. The specific expression pattern of regulatory receptors on the IgG4+ B cells may provide insight in the pathways that control the tolerogenic humoral immune response.

P3.07.21
The role of the histone demethylase Jmjd3 in B-cell lymphopoiesis

R. Mahshid[1]*, T. Burgold*[2]*, B. Khoramian*[2,3]*, M. Caganova*[2]*, F. Mainoldi*[1]*, M. Reth*[4]*, G. Natoli*[2]*, G. Testa*[2]*, S. Casola*[1]*;*
[1]IFOM, Milano, Italy, [2]European Institute of Oncology, Milano, Italy, [3]University of Florida College of Medicine, Gainesville, FL, United States, [4]Max Planck Institute for Immunobiology, Freiburg, Germany.

Jmjd3 (Kdm6B) is a Histone H3 lysine-27 demethylase involved in transcriptional regulation and lineage determination. Jmjd3 plays an important role in macrophage differentiation and activation 1-3. It is expressed also in other hematopoietic lineages including B-lymphocytes. Jmjd3 transcripts were detected throughout B cell development reaching the highest levels in B cell progenitors. The function of Jmjd3 in B cell development remains unknown. To study the role of Jmjd3 at defined stages of B cell lymphopoiesis, we generated Jmjd3 conditional knock-out mice (Jmjd3fl). Jmjd3fl mice were crossed to the Mb1-cre strain to inactivate the demethylase starting from pro-B cells. Preliminary flow cytometry analyses of cell suspensions from lymphoid organs of Jmjd3 conditional mutant mice revealed fewer bone marrow B cells and a reduction in the fraction of CD5+ B-1a peritoneal cavity B cells. Instead, differentiation of follicular and marginal zone B cells was largely unaffacted by Jmjd3 inactivation. These data indicate that Jmjd3 regulates early B-cell development and the establishment of a normal pool of CD5+ B-1 B cells. Experiments are underway to identify the molecular targets regulated by Jmjd3 in these B-cell subsets

P3.07.22
Protease-activated receptor (PAR)1 and PAR2 have opposing effects on B-lymphocyte function during different stages of maturation

K. J. McKelvey*, Y. Chan, C. J. Jackson, M. Xue;*
Sutton Arthritis Research Laboratory, Kolling Institute of Medical Research, University of Sydney at Royal North Shore Hospital, St Leonards, Australia.

Protease-activated receptors (PARs) play an important role in immune responses, although their role in B-lymphocytes is unknown. In this study we demonstrate, for the first time, that PAR1 and PAR2 are expressed by human B-cell lines (Ramos, Raji and Epstein Barr Virus-transformed lymphoblastoid cell line 1 [EBV-LCL1] cells) representing different stages of B-lymphocyte maturation. Using PAR agonists (Ag), antagonists (At) and confirmed by murine wild-type (WT), PAR1 and PAR2 knock-out (KO) splenic B-lymphocytes, we reveal that PAR1 At, but not PAR2 At, potently inhibited proliferation in all stages of B-cell maturation, while markedly increasing cytokine secretion of interleukin (IL)-1b, IL-10 and tumour necrosis factor (TNF)-a. PAR1 At had differential effects on IL-6 secretion; increased IL-6 in Ramos and Raji cells, but complete inhibition in EBV-LCL1 cells. In Ramos and EBV-LCL1 cells PAR1 At increased and PAR2 At decreased immunoglobulin (Ig)M. IgG secretion was similarly regulated in EBV-LCL1 cells. Investigation into the PAR signalling pathways revealed that in Ramos cells, PAR2 signalling was via nuclear factor (NF)-kB in Ramos cells, while in Raji and EBV-LCL1 cells PAR1 and PAR2 signalling required extracellular signal-regulated kinase (ERK) activation. This was confirmed by IL-6 secretion following NF-kB and ERK inhibition. In conclusion, we report that PAR1 and PAR2 have largely opposing effects on B-lymphocyte function during different stages of maturation.

P3.07.23
Ataxia Telangiectasia Patients Presented by Class Switch Recombination Defect: Elevated Serum Levels of IgM

B. Mirminachi[1]*, A. Aghamohammadi*[1]*, H. Abolhassani*[1]*, S. Ghosh*[2]*, A. Borkhardt*[2]*;*
[1]Research Center for Immunodeficiencies, Pediatrics Center of Excellence, Children's Medical Center, Tehran University of Medical Sciences, Tehran, Iran, [2]Inserm U768, Rene´ Descartes-Paris 5 University and Unit of Pediatric Immunology-Hematology, Necker-Enfants Malades Hospital, Assistance Publique Ho´pitaux de Paris, Paris, France.

Ataxia telangiectasia (AT) is a rare primary immunodeficiency disorder with various clinical manifestations. Increased serum levels of IgM and recurrent infections can be the presenting feature in a few cases of AT patients and may be initially misdiagnosed as hyper-IgM (HIgM) syndrome.
This study was designed to investigate class switch recombination (CSR) as a critical mechanism in B lymphocytes' maturation to produce different isotypes of antibody in response to antigen stimulation in AT cases with HIgM presentation. Quantitative IgE production after stimulation by IL-4 and CD40L was considered as an indicator for CSR function. We also compared their results with sex and age matched controls of AT patients with normal values of IgM.
We report four AT patients who presented episodes of recurrent infections during infancy and high serum levels of IgM. Laboratory evaluation in these cases revealed defective CSR while none of 3 controls had a defect in the CSR process.
The characterized defect in AT is a mutation in the ataxia telangiectasia mutated (ATM) gene. This gene may result in CSR defects due to impaired DNA break repair. A special association of AT and HIgM may indicate a new subgroup of AT patients according to their clinical phenotype and CSR condition.

P3.07.24
B cell development undergoes profound changes during pregnancy

***D. O. Muzzio**, A. C. Zenclussen, F. Jensen;*
Otto-von-Guericke University Magdeburg, Magdeburg, Germany.

Mammalian pregnancy represents a challenge to the rules of immunology. The maternal immune system has to tolerate the semi-allogeneic fetus while protecting mother and fetus against infections. The participation of B cells in this important issue is poorly understood. Here, we aimed to analyze B cell development during early and mid-pregnancy in mice. Mature IgM^+IgD^+ (B220 gated) B cells were significantly augmented in the bone marrow of pregnant females (P) as compared to non-pregnant mice (NP). Similarly, IgM^+IgD^+ mature as well as $CD19^+CD138^+$ plasma and $CD19^+CD27^+$ memory B cells percentages were significantly higher in P mice as compared to NP mice. Alongside to a splenomegaly observed in P mice, B cell compartment was strongly affected by pregnancy in the spleen. P mice showed significantly lower percentages of $CD23^{hi}CD21^-$ (B220 gated) follicular B cells while significantly higher percentages of $CD23^-CD21^{lo}CD1d^{hi}$ (B220 gated) marginal zone and IgM^+IgD^+ mature B cells compared to NP controls. In peritoneal cavity, the percentages of $CD19^+CD23^+$(B2) and $CD19^+CD23^-CD5^-CD11b^+$ (B-1b) B cells were significantly higher while $CD19^+CD23^-CD5^+CD11b^+$ (B-1a) levels were strongly reduced in P mice as compared to NP mice. Mature B cells ($B220^+CD21^+$) were significantly elevated in paraaortic lymph nodes lymph that drain the uterus in P mice as compared to NP mice.
Our data demonstrate profound changes in B cell populations in both, bone marrow and periphery that suggests important regulations of B cell development during gestation.

P3.07.25
Influence of Wnt5a treatment on B-1 cells viability in vitro

***L. Osugui**, M. C. T. Novo, M. F. L. Laurindo, A. F. Popi;*
Unifesp, Sao Paulo, Brazil.

Hematopoietic Stem Cells (HSC) are pluripotent cells, which are self-renewing and able to give rise to all lineages of the blood. Recently, studies demonstrated the presence of signal transduction by Wnt pathway in lymphocyte development and HSC self-renewal. The expression of lymphoid and myeloid markers by B-1 cells, likewise in HSC, involves complex signaling pathways. Previous data from our group have showed that B-1 cells express components of Wnt/beta-catenin pathway, including Wnt ligants and receptors. In order to understand the implications of Wnt pathway in B-1 cells *in vitro*, the viability of B-1 cells co-cultivated with OP9 cells and treated with two distinct Wnt recombinants (Wnt3a or Wnt5a) were analyzed, after 72 hours. Our results suggest that B-1 cells treated with Wnt5a recombinant present a reduced number of viable cells. As is known, some cytokines are essential to maintain B-1 cells alive *in vitro,* such as IL-6 and IL-10. We evaluated the presence of some cytokines by CBA Th1/Th2/Th17 kit in our model. We have detected an increase in the IL-6 levels at non-treated and Wnt3a treated groups. Besides the Wnt5a treatment augments IL-10 levels, we observed a reduction of IL-6 levels. These data indicate that B-1 cells are responsive to Wnt5a, and implicates in changes of cytokine levels. The participation of a non-canonical Wnt/Ca^{2+} pathway in this modulation is being studied.

P3.07.26
Effects of Ouabain on B and T lymphocytes at mice

*R. P. S. Barbosa[1], T. A. G. Vianna[1], J. M. C. Silva[1], K. M. Costa[2], F. B. Do Canto[2], V. R. Cabral[1], R. Fucs[1], **L. S. Paiva**[1];*
[1]UFF, Niterói/RJ, Brazil, [2]UFRJ, Rio de Janeiro, Brazil.

Ouabain (OUA) is a steroid produced by the adrenal and found at mammalian plasma. Ouabain can regulate immune functions, for example, the inhibition of proliferation induced by mitogens. It has been suggested that OUA is released together with other glucocorticoids during stress situations. Here, we evaluated whether the release of Ouabain can regulate lymphocytes subpopulations. Balb/C or C57BL/6 mice were injected intraperitoneally with 0.56mg/Kg OUA for 3 days. B and T cells were analyzed by flow cytometry, 24 hours after the last injection. Our results show that in bone marrow and spleen there was a decrease in mature B cells. In the spleen was observed a reduction notably in follicular B cells and no effect in regulatory B or B1 cells was observed. The B1 peritoneal cells were not affected by Ouabain. In the spleen, OUA induced apoptosis of B cells *in vitro,* but not *in viv*o. Ouabain also partially inhibited the proliferation *in vitro* of splenic B cells in response to LPS. Furthermore, Ouabain raised the B lymphocytes migration to lymph nodes. At the thymus, OUA had no effect on T cell subpopulations, but the number of TCD4+Foxp3+ in the spleen was reduced significantly. In the case of T cells, OUA did not induce an increase on apoptosis or inhibition of proliferation in response to α-CD3. We did not observe an increase in the migration of T cells to the lymph nodes. Ouabain seems to use different mechanisms for the regulation of B and T cells subpopulations.

P3.07.27
Combination effect of LPS and MDP on antibody production by mouse B cells

*S. Lee[1], Y. Yoo[1], J. Lee[1], P. Kim[2], G. Seo[2], **S. Park**[1];*
[1]Department of Microbiology, College of Medicine, Konyang University, Daejeon, Republic of Korea, [2]Department of Molecular Bioscience, College of Biomedical Science, Kangwon National University, Chuncheon, Republic of Korea.

Toll-like receptors (TLRs) and Nod-like receptors (NLRs) are pattern recognition receptors (PRRs) that recognize specific conserved bacterial structures. Several studies have reported that B cells express both TLRs and NLRs, and the receptors signaling contribute to B cell activation. However, the roles of the receptors in antibody production by B cells are not fully understood. In this study, we investigated the effect of Nod2 agonist MDP in combination with TLR4 agonist LPS on B cell proliferation, viability, and antibody production *in vitro* culture of purified mouse spleen resting B cells. MDP cooperated with LPS to induce B cell proliferation and viability. Furthermore, MDP and LPS synergistically increased only both IgG2b production and germline (GL) γ2b transcripts (GLTγ2b) expression. In the experiment with Nod2- and TLR4-deficient mice, we found that the cooperative effect of MDP and LPS is dependent on the receptors, Nod2 and TLR4. On the other hand, LPS/MDP-induced B cell proliferation was mediated by JNK and RIP2/p38 pathway, but these pathways did not affect GLTγ2b expression. Taken together, our present study suggests that cross-talk between Nod2 and TLR4 signaling enhances B cell proliferation via RIP2/p38 and JNK pathways and specifically increases IgG2b production through increasing GLTγ2b expression. Thus, MDP in combination with LPS directly enhances B cell activation and selectively reinforces IgG2b production independent of T cells and B cell receptor (BCR) stimulation, and thereby MDP can be developed as an effective B cell adjuvant.

P3.07.28
Immunization of Common Variable Immunodeficiency (CVID) patients with Influenza induces increase in switched memory B cells and plasmablasts

***M. Pedreschi**[1], A. K. B. Oliveira[2], M. T. Barros[2], A. Cohon[2], J. Kalil[3], C. M. Kokron[1];*
[1]Laboratory of Clinical Immunology and Allergy, Sao Paulo, Brazil, [2]Division of Clinical Immunology and Allergy, Sao Paulo, Brazil, [3]Institute of Investigation in Immunology III, Sao Paulo, Brazil.

CVID is a primary antibody deficiency characterized by hypogammaglobulinemia, increased susceptibility to infections and impaired antibody response to specific antigens. Several immunological defects were described in this heterogeneous group of patients. Patients present defects in B lymphocytes maturation, resulting on alterations in differentiation, frequency and function of its subtypes. Immunization is an important measure to reduce infections however, in CVID patients response is controversial and experience, limited. Thus, our objectives were to evaluate the behavior of B cell subtypes and specific antibody production before and after

vaccination with influenza vaccine (H1N1 and H2N3) and the effect of vaccination on the number of infections. CVID patients were selected from PID outpatient clinic of Hospital das Clínicas, São Paulo. Blood samples were collected before and one month after vaccination. PBMCs were separated and stimulated with PWM, *Influenza* viral lysate and hemagglutinin peptide for 6 days. B cell subtypes (naïve, marginal zone, switched memory B cell and plasmablast) frequency and activation were evaluated by flow cytometry. Influenza specific antibodies were measured by ELISA and H1N1 specific antibodies by hemagglutination inhibition. Our results show reduction in the frequency of respiratory infections in the 12 month period after vaccination although no protective antibody levels were produced. Moreover, we observed a significant increase in the number of switched memory B cells and plasmablasts in CVID patients one month after immunization. These results reinforce the benefits of vaccination of CVID patients and bring some insights into the mechanisms by which this clinical improvement may occur.

P3.07.29
CD38 ligation promotes proliferation and ERK phosphorylation of bone marrow B-cell precursors in mice

H. Romero-Ramirez[1,2], *M. Morales-Guadarrama*[1], *R. Pelayo-Camacho*[3], *R. Lopez-Santiago*[4], *L. Santos-Argumedo*[1];
[1]*Department of Molecular Biomedicine, Center for Research and Advanced Studies (CINVESTAV)., Mexico, Mexico,* [2]*Department of Immunology, National School of Biological Sciences, IPN., Mexico City, Mexico,* [3]*Oncology Hospital, National Medical Center "SXXI" IMSS. Mexico City, Mexico, Mexico,* [4]*Department of Immunology, National School of Biological Sciences, IPN, Mexico, Mexico.*

CD38 is a 45 KD transmembrane protein, expressed by immature and mature lymphocytes. Expression and function of CD38 throughout the B-cell differentiation pathway have been poorly studied in mice. Here we report CD38 expression from the earliest stages of B cell development. Pre-pro-B, pro-B, pre-B and immature B cells from murine bone marrow were all positive for CD38, but immature B cells showed the highest expression. Pro-B stage contains two distinct cell populations on the basis of CD38 expression that may correspond to developmental stages.
No differences were found between WT and CD38-/- mice in the B-cell lineage frequencies and absolute numbers within bone marrow, indicating that CD38 is dispensable during B-cell ontogeny, probably because its function may be being replaced by the homologous molecule CD157 which is also expressed from early states of maturation in the bone marrow. Interestingly, highly purified immature B cells proliferated upon CD38 ligation, and no apparent apoptosis was recorded under these conditions. Moreover, ERK was phosphorylated after CD38 crosslinking. In conclusion, the expression of CD38 is tightly regulated during the ontogeny of murine B-cells lineage and functional CD38 may play a role throughout the early development process of B cells as its engagement induces proliferation. This work was fully supported by Conacyt-México 153733.

P3.07.30
Patients with X-linked Agammaglobulinemia Survival Rate : Mortality and Morbidity

A. Aghamohammadi[1], *H. Abolhassani*[2], *F. Sefatgol*[3], *F. Shahriari*[3], *S. Sefatgol*[3], ***M. Sefatgol***[2];
[1]*Tehran University of Medical Sciences, Tehran, Iran,* [2]*Research Center for Immunodeficiencies, Pediatrics Center of Excellence, Children's Medical Center, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran,* [3]*Research Center for Immunodeficiencies, Pediatrics Center of Excellence, Children's Medical Center, Tehran University of Medical Sciences, Tehran, Iran., Tehran, Iran.*

Background: X-linked agammaglobulinemia(XLA) is a genetic disorder characterized by a defect in the generation of mature B cells, lack of antibodies production, and susceptibility to recurrent bacterial infections. Understanding of the risk factors responsible for morbidity and mortality in these patients can help in a better management of this disorder. However, there is a lack of specific studies in the literature regarding the morbidity and mortality of XLA patients. Objective: This study is designed to evaluate morbidities and mortality and survival rates in Iranian patients with XLA diagnosis during the past 20 years.Methods: We have registered the clinical data of the XLA patients and followed them up till 2010. At the time of diagnosis, a four-page questionnaire including complete medical information was filled for all patients. Follow-up information was gathered either by reviewing the patients' hospital records or regular visiting the patients. Results: Among 41 patients, 11 patients(26.8%) have died during follow up period. The most common first manifestation was pneumonia. All of the complications before the initiation of treatment such as pneumonia, otitis media and diarrhea, were reduced after immunoglobulin replacement except sinusitis and conjunctivitis. There were significant association between some immunologic and clinical characteristics such as lymphocyte subsets, consanguinity marriage and mortality.Conclusion:Despite recent advances in the treatment of XLA, these patients still suffer from severe complications. Associations between poor prognosis and clinical and some immunologic characteristics of the patients may help physicians to select poor prognoses patients at higher risk of mortality to develop prevention strategies for them.

P3.07.31
Retinoic acid acts as a selective human IgA switch factor

G. Seo[1], *S. Park*[2], *J. Kim*[1], *Y. Jang*[1], *J. Lee*[1], *H. Han*[1], *S. Kang*[1], *S. Kim*[1], *B. Jin*[1], *S. An*[1], *J. Choe*[1], *P. Kim*[1];
[1]*Kangwon National University, Chuncheon, Republic of Korea,* [2]*Konyang University, Daejeon, Republic of Korea.*

Retinoic acid (RA) is known to have several activities which lead to potent mucosal IgA response. Nevertheless, its exact role in human IgA synthesis was not delineated yet. We asked if RA can specifically induce IgA isotype switching in human B cells. We found that RA increased IgA production and the expression of germ-line IgA1 and IgA2 transcripts (GLTα1 and GLTα2), and that this was paralleled by the increase of frequency of IgA-secreting B cell clones as assessed by limiting dilution assay. Under the same conditions, RA did not increase IgM and IgG production. Am80, an agonist of RA receptor (RAR) increased IgA production. In addition, the RA activity was abrogated by LE540, an antagonist of RAR, suggesting that RAR pathway is involved in RA-induced IgA production. Taken together, these results indicate that RA has activity as an IgA switch factor through RAR in human.

P3.07.32
Adaptor protein Swiprosin2/EFhd1 during early B cell development

M. Stein[1], *S. Dütting*[1], *S. Brachs*[1], *W. Schuh*[1], *A. Turqueti-Neves*[2], *D. Vöhringer*[2], *H. Jäck*[1], *D. Mielenz*[1];
[1]*Nikolaus-Fiebiger-Centre, Division of Molecular Immunology, Erlangen, Germany,* [2]*University hospital Erlangen, Department of Infection Biology, Erlangen, Germany.*

The pre-B cell receptor (pre-BCR) regulates proliferation and differentiation of pre-B cells by changing their transcriptome. One of the genes that become down-regulated by the pre-BCR is *efhd1*. Swiprosin2/EFhd1 and Swiprosin1/EFhd2 are two conserved proteins with 65% sequence homology, functional protein-interaction sites and two calcium-binding EF-hand domains. We have shown that in contrast to EFhd1, EFhd2 is expressed throughout all B cell stages and is involved in pro-apoptotic B cell receptor (BCR) signalling and in the germinal center reaction. EFhd1 has been implicated in carcinogenesis and cell proliferation. Its function in B lymphocytes, however, remains elusive.
Ectopic expression of EFhd1 in pro-B cells *in vitro* by retroviral transfection leads to slower decrease in surface c-kit expression, indicating slower differentiation into pre-B cells. Transgenic mice (*efhd1tg*) expressing EFhd1 constitutively under the VH promoter and Eμ enhancer reveal a trend to reduced B cells after the pre-B cell check point in the bone marrow (BM). In mixed BM chimeras, wild type B lymphocytes have a significant advantage over *efhd1tg* in the BM. Down regulation of EFhd1 by the pre-BCR therefore aids efficient subsequent B cell development. To analyse the role of EFhd1 during early B cell development, in addition to the *efhd1tg* model, a

conditional *efhd1*$^{-/-}$ mouse is being established. Future aims include phenotypic characterization of *efhd1*$^{-/-}$ mice, focusing on development, survival and homing of B lymphocytes. Functional redundancy of the homologous proteins EFhd1 and EFhd2 will be analysed by crossing *efhd2*$^{-/-}$ mice with *efhd1tg* mice and, later, *efhd1*$^{-/-}$.

P3.07.33
Serine/threonine phosphatase PP4 is required for pro-B cell development by promoting Ig VDJ recombination

Y. Su[1]*, T. Tan*[1,2]*;*
[1]*Immunology Research Center, National Health Research Institutes, Zhunan, Miaoli County, Taiwan,* [2]*Department of Pathology & Immunology, Baylor College of Medicine, Houston, TX, United States.*

PP4 phosphatase regulates a number of crucial cellular physiologies. However, the role of PP4 in B cells has never been reported. Through the analysis of B cell-specific *pp4* knockout mice, we identify the essential role of PP4 in B-cell development. Deficiency of PP4 in B lineage cells leads to a strong reduction of pre-B cells in numbers, an absence of immature B cells and a complete loss of mature B cells. In PP4-deficient pro-B cells, Ig DJ_H recombination is impaired. In the meanwhile, Ig μ H chain expression is strongly reduced. Consistent with these findings, the residual PP4-deficienct pre-B cells show a cell cycle arrest at G1 phase. In addition, an increased apoptosis and an excessive DNA damage are detected in these mutant cells. We showed that the enforced expression of transgenic Ig in PP4-deficient mice drives B-cell development and overcomes IgM^+ B cells. Our study reveals a novel function of PP4 in pro-B cell development by promoting V_HDJ_H recombination.

P3.07.34
Y-Chromosome-linked B- and NK-cell deficiency in mice

S. Sun[1]*, A. Asao*[1]*, T. Takahashi*[2]*, T. So*[1]*, M. Kondo*[3]*, N. Ishii*[1]*;*
[1]*Tohoku University Graduate School of Medicine, Sendai, Japan,* [2]*Central Institute for Experimental Animals, Kawasaki, Japan,* [3]*Toho University School of Medicine, Tokyo, Japan.*

There are no primary immunodeficiency diseases linked to the Y chromosome, because the Y chromosome does not contain any vital genes. We have established a novel mouse strain in which all males lack B and NK cells and have Peyer's-patch defects. By 10 weeks of age, 100% of the males had evident immunodeficiencies. Mating these immunodeficient males with wild-type females on two different genetic backgrounds for several generations demonstrated that the immunodeficiency is linked to the Y chromosome and is inherited in a Mendelian fashion. Although multicolor fluorescence in situ hybridization (FISH) analysis showed that the Y chromosome in the mutant male mice was 1/3 shorter than that in wild-type males, exome sequencing did not identify any significant gene mutations. The precise molecular mechanisms are still unknown. Bone marrow chimeric analyses demonstrated that an intrinsic abnormality in bone marrow hematopoietic cells causes the B- and NK-cell defects. Interestingly, fetal liver cells transplanted from the mutant male mice reconstituted B and NK cells in lymphocyte-deficient *Il2rg-/-* recipient mice, while adult bone marrow transplants did not. Transducing the EBF gene, a master transcription factor for B cell development, into mutant hematopoietic progenitor cells (HPCs) rescued B-cell but not NK-cell development both *in vitro* and *in vivo*. These Y-chromosome-linked immunodeficient mice, which have preferential B- and NK-cell defects, may be a useful model of lymphocyte development.

P3.07.35
ACKR3 (CXCR7) expression on late germinal center B cells

M. Thelen*;*
Institute for Research in Biomedicine, Bellinzona, Switzerland.

Atypical chemokine receptors (ACKRs) differ from typical receptors by their inability to trigger G-protein mediated signal transduction, such as chemotaxis, but instead sequester chemokine ligands for lysosomal degradation or transcystosis. The scavenger receptor ACKR3 (formerly CXCR7) binds with high affinity CXCL12 and somewhat lower affinity CXCL11. ACKR3 is expressed on non-hematopoietic cells and neoplasms, as well as on leukocytes. Here we investigated the function of ACKR3 at late stages of B cell maturation, when B cells differentiate into antibody-secreting plasmablasts before they become long-lived plasma cells. By using specific mAb we characterized two populations of $ACKR3^+$ cells in tonsillar mononuclear cells (TMCs), one being presumably memory B cells or early plasmablasts ($FSC^{low}CD19^+CD38^{mid}$) and the other being plasmablasts or early plasma cells ($FSC^{high}CD19^+CD38^+$). Further analysis of receptor expression on TMCs showed that ACKR3 is expressed on $CD19^+CD27^+$ memory B cells, on $CD19^+CD38^+CD138^-$ and intracellular immunoglobulin high ($icIg^{high}$) plasmablasts, but not on $CD19^+CD138^+icIg^{high}$ plasma cells. The transient expression pattern on B cells, suggests a potential contribution of ACKR3 in the process of final B cell maturation. By using an *in vitro* differentiation system, we found an marked inverse correlation of ACKR3 and CXCR5 cell surface levels, whereas expression of CXCR4 remained almost constant during maturation. Moreover transwell migration assays revealed that inhibition of ACKR3 markedly increases CXCR4-mediated chemotaxis towards CXCL12, especially at late stages of B cell maturation. The findings unveil an important role of ACKR3 in regulating the migration of plasmablasts at late stages of B cell maturation.

P3.07.36
Inhibition of germinal center formation and humoral immune responses by EB virus protein LMP1

C. Tsai*, T. Yasui, T. Minamitani, K. Morita, S. Sakakibara, H. Kikutani;*
Department of Molecular Immunology, Research Institute for Microbial Disease, WPI Immunology Frontier Research Center, Osaka University, Osaka, Japan.

Germinal center (GC) is critical for the generation of high-affinity B cells. It has been reported that Epstein-Barr virus (EBV) preferentially infects GC B cells where EBV-encoded Latent membrane proteins (LMPs) such as LMP1 and LMP2a are expressed, suggesting that LMPs may modify B cell differentiation. However, it has not been well characterized how LMPs affect GC B cell differentiation. Here, we generated the knock-in mice expressing LMP1 in an activation-induced cytidine deaminase (AID) promoter-dependent manner ($LMP1^{Aid}$). Flow cytometric analysis showed the enlarged cell size and the increased expression of surface markers including CD95, CD69, CD80, MHC class II, and PD-L1 in $LMP1^+$ B cells when compared with $LMP1^-$ B cells. No typical GC was formed in spleens, lymph nodes and peyer's patches of immunized $LMP1^{Aid}$ mice although $CD38^{medium}GL7^+Bcl\text{-}6^-$ abnormal B cells and Tfh cells were generated. Antigen-specific antibody responses were severely impaired in immunized $LMP1^{Aid}$ mice. In addition, $LMP1^{Aid}$-derived B cells could suppress GC formation and antigen-specific antibodies production by wild type B cells in immunized bone-marrow chimera mice. When *in vitro* stimulated with IL-4, IL-5, and LPS, IgG1 and IgM production were markedly impaired in B cells from $LMP1^{Aid}$ mice, whereas IL-6 and IL-10 production were significantly enhanced. In conclusion, LMP1 expression in GC-committed B cells resulted in the impairment of typical GC formation and the inhibition of antibody production, suggesting that LMP1-expressing B cells might act as regulatory B cells to suppress humoral immune responses. We will discuss how EBV evades immune responses by using LMP1.

P3.07.37
B cell progenitors and precursors change their microenvironment in fetal liver during early development

M. Tsuneto[1], *K. Tokoyoda*[2], *E. Kajikhina*[1], *A. Hauser*[2], *T. Hara*[3], *S. Tani-ichi*[3], *K. Ikuta*[3], *F. Melchers*[1];
[1]*Max Planck Institute for Infectionbiology, Berlin, Germany,* [2]*German Rheumatism Research Center (DRFZ), Berlin, Germany,* [3]*Kyoto university, Kyoto, Japan.*

The microenvironments, in which B-lymphocytes develop in fetal liver, are largely still unknown. Among the non-hematopoietic cells we have identified and FACS-separated two subpopulations, $CD45^-TER119^-VCAM\text{-}1^+$ cells that are either $CD105^{high}LYVE\text{-}1^{high}$ or $CD105^{low}ALCAM^{high}$. Immunohistochemical analyses find three of four $c\text{-}Kit^+IL\text{-}7R\alpha^+B220^{low}CD19^-SLC^-$ B-progenitors in contact with vascular endothelial-type $LYVE\text{-}1^{high}$ cells on embryonic day 13.5. One day later $c\text{-}Kit^+IL\text{-}7R\alpha^+$ cells develop to $CD19^{-\ and\ +}$, SLC-expressing, DHJH-rearranged pre/pro and pro/preB-I cells. Less than 10% are still in contact with $LYVE\text{-}1^{high}$ cells, but half of them are now in contact with mesenchymally-derived $ALCAM^{high}$ liver cells. All of these $ALCAM^{high}$ cells, but not the $LYVE\text{-}1^{high}$ cells produce IL-7 and CXCL12, while both produce CXCL10. Progenitors and pro/preB-I cells are chemo-attracted *in vitro* towards CXCL10 and 12, suggesting that lymphoid progenitors with Ig gene loci in germline configuration enter the developing fetal liver at E13.5 from vascular endothelium, attracted by CXCL10, and then migrate within a day to an $ALCAM^{high}$ liver cell-microenvironment, differentiating to DHJH-rearranging, surrogate light chain-expressing pre/proB and pro/preB-I cells, attracted by CXCL10 and 12. Between E15.5 and E16.5 preB-I cells expand 10 fold in continued contact with $ALCAM^{high}$ cells, and begin VH- to DHJH-rearrangements in further differentiated $c\text{-}Kit^-IL\text{-}7R\alpha^-$ preBII cells.

P3.07.38
B cell-intrinsic role of DOCK2 in T cell-dependent humoral immunity

M. Ushijima[1,2], *A. Nishikimi*[1,2,3], *Y. Fukui*[1,2,3];
[1]*Division of Immunogenetics,Medical Institute of Bioregulation, Kyushu University, fukuoka, Japan,* [2]*Japan Science and Technology agency, CREST, Tokyo, Japan,* [3]*Research Center for Advanced Immunology, Kyushu University, Fukuoka, Japan.*

The small GTPase Rac has been implicated in various cellular functions by acting downstream of multiple receptors including B cell receptor (BCR). However, its role in humoral immunity and the upstream regulator are poorly understood. DOCK2 is an atypical Rac activator predominantly expressed in hematopoietic cells. We found that DOCK2 is essential for BCR-mediated Rac activation and critically regulates immunological synapse formation. To examine B cell-intrinsic role of DOCK2 in humoral immunity, we used the knock-in mice expressing antigen-specific BCR in a class-switchable manner. When the knock-in mouse-derived B cells were transferred into wild-type mice with the cognate antigen, germinal center (GC) formation and class switch recombination occurred normally in the absence of DOCK2. However, while IgG+ wild-type B cells rapidly expanded and differentiated to syndecan-1+ plasma cells, these processes are severely impaired in DOCK2-deficient B cells, suggesting that DOCK2 regulates post GC B cell differentiation through immunological synapse formation. On the other hand, we also found that initial generation of extrafollicular plasma cells is impaired in the absence of DOCK2. DOCK2-deficient B cells exhibited a defect in EBI2-mediated Rac activation and failed to move properly to extrafollicular sites. These results thus indicate that DOCK2-Rac axis controls plasma cell differentiation, at least, by two distinct mechanisms during humoral immune responses.

P3.07.39
Impact of genetic deficiencies in the TLR signaling pathways on human IgM+IgD+CD27+ B cells

S. Weller[1], *S. Storck*[1], *L. Israel*[2], *S. Zhang*[2], *A. Puel*[2], *J. L. Casanova*[2], *C. Picard*[3], *J. C. Weill*[1], *C. A. Reynaud*[1];
[1]*INSERM U783, Paris, France,* [2]*INSERM U980, Paris, France,* [3]*Center for the Study of Primary Immunodeficiencies and Pediatric Hematology-Immunology Unit, AP-HP, Necker Hospital, Paris, France.*

We studied peripheral B-cell subsets in patients deficient for key factors of the TLR signaling pathways. All TLRs, except TLR3 that signals through the TRIF adaptor, require MyD88 and IRAK-4 to mediate their function. TLR4 and the TLR2 heterodimers (with TLR1, TLR6 and possibly TLR10) require in addition the adaptor TIRAP, whereas UNC-93B is needed for the proper localization of intracellular TLR3, TLR7, TLR8 and TLR9. We found that IgM+IgD+CD27+, but not switched B-cells, were strongly reduced in MyD88-, IRAK-4- and TIRAP-deficient patients. In contrast, the numbers of IgM+IgD+CD27+ B-cells were normal in the absence of TLR3, TRIF and UNC-93B, suggesting that UNC-93B-dependent TLRs, and notably TLR9, are dispensable for the presence of this subset in blood. Hence, we propose a role for TIRAP-dependent TLRs, (TLR1, 2, 6 and 10) in the development and/or maintenance of IgM+IgD+CD27+ B-cells (Weller et al. Blood. 2012; 120(25): 4992-5001). Interestingly, TLR10 whose expression is restricted to B and plasmacytoid dendritic cells was expressed at higher level in IgM+IgD+CD27+ compared to switched B-cells in healthy individuals. An exome sequencing strategy allowed us to identify patients with mutations in TLRs. We focused on 3 missense mutations in TLR10 predicted to possibly damage its structure and function. While 2 variants showed normal cell-surface expression when transfected into HEK293T cells, the third one remained intracytoplasmic. We will test on IgM+IgD+CD27+ B-cells in vivo the impact of this mutation as well as other mutations in TLR1,2 and 6 described by Ben-Ali et al. as deleterious (Hum Mutat. 2011;32(6):643-52).

P3.07.40
Follicular dendritic cells induce a new class of myeloid cells with unique B cell stimulating activities: specific dependence on IL-34/CSF-1R signaling pathway

F. Yamane, *K. Matsui, H. Tanimoto, E. Iwasaki, M. Asakura, H. Tokumitsu, Y. Nishikawa, N. Kanayama, M. Magari, H. Ohmori; Graduate School of Natural Science and Technology, Okayama University, Okayama, Japan.*

We have been analyzing roles for follicular dendritic cells (FDCs) in controlling germinal center (GC) reaction using a mouse FDC line, FL-Y, which was established in our laboratory, and has been shown to be useful as a model of native FDCs. When we cultured FL-Y cells with Lin-, c-kit+ spleen cells for 7-9 days, we observed expansion of a new class of CD11b+ myeloid cells (Gr-1-, CD11c-, F4/80+, CXCR4+, CCR2+, CX3CR1-), which was named FDMCs (FDC-induced myeloid cells). FDMCs had unique B cell-stimulating activities. Division of anti-CD40-stimulated B cells was markedly enhanced when they were co-cultured with FDMCs, and the FDMC-activated B cells acquired GC B cell-associated markers efficiently, suggesting a role for FDCMs in GC reaction. FL-Y cells produced CSF-1 and IL-34, both of which has been showed to induce macrophages development by signaling through a common receptor, CSF-1R. We examined the involvement of these cytokines in FDMC generation using neutralizing Abs. Interestingly, FDMC generation was clearly blocked by an anti-CSF-1R Ab, but neutralization of CSF-1 had no inhibitory effects. On the other hand, an anti-IL-34 Ab strongly suppressed FDMC generation. Similar IL-34-specific dependence was confirmed by the gene 'Knockdown' (KD) in FL-Y cells using shRNA, thus demonstrating that FDMC induction is specifically dependent on the IL-34/CSF-1R pathway. To our knowledge, this is the first report describing a CSF-1R-mediated signaling pathway that exclusively respond to IL-34. Further investigations are underway to elucidate molecular mechanisms underlying the specific action of IL-34.

P3.07.41

The Non-Canonical function of UNG in AID induced Antibody Gene Diversification

***A. S. Yousif**, N. A. Begum, T. Honjo;*
Department of Immunology and Genomic Medicine, Graduate School of Medicine-Kyoto University, Yoshida Sakyo-ku, Kyoto 606-8501, Japan, Kyoto, Japan.

Activation-induced cytidine deaminase (AID) is essential to antibody memory formation, which requires immunoglobulin (Ig) locus specific genomic alterations, such as class switch recombination (CSR) and somatic hyper mutation (SHM). It has been proposed that CSR and SHM are initiated by AID induced DNA cleavage that requires AID mediated dU formation in DNA and its removal by UNG. In contrast to AID deficiency, where both the processes were completely abolished, CSR and SHM were differentially affected in UNG deficiency, suggesting a novel function of UNG. Here we show that the *bona fide* uracil repair enzyme UNG acts non-canonically to regulate DNA end-joining and erroneous repair required for CSR and SHM, respectively. One of our intriguing observations is that UNG acts as a potent suppressor of AID induced SHM. In addition, a catalytic mutant of UNG was found to be as proficient as wild type UNG restoring the mutation load and base bias. It appears that UNG associated faithful base excision repair complex competes with the error prone polymerase complex like Rev1 involved in SHM. Further analysis of switch recombination junctions revealed that UNG promotes the alternative-nonhomologous end-joining (a-NHEJ) repair pathway. We provide evidence that the CSR defect attributed to the deregulated recruitment of critical DNA repair factors and improper S-S synapse formation. Therefore, UNG distinctly regulates CSR and SHM, which are dissociable and independent of its catalytic activity, and thus providing compelling evidence on its non-catalytic function in AID induced genomic instability.

P3.08.01
Chemokine receptor (CKR) expression on memory CD4+ Th2 cells in mice during an allergen-mediated exacerbation of allergic asthma

***B. Bosnjak**, M. M. Epstein;*
Medical University of Vienna, Vienna, Austria.

Chemokine-CKR interactions play an important role in allergic asthma. In asthmatics and experimental mice, CCR3, CCR4 and CCR8 are considered major players. However, data from mice lacking these receptors are inconclusive and the mechanisms underlying chemokine-CKR-mediated migration in allergic asthma remain unclear. We sought to characterize CKRs on CD3+CD4+CD62L-CD44+ memory Th2 cells in lungs of mice during allergen-induced disease exacerbation. We administered intranasal allergen to mice recovered from allergic asthma and compared CKR cell surface expression 3 and 7 days after allergen rechallenge on memory CD4+ T cells from the lungs and spleens of bicistronic IL-4 reporter-4get mice. We found no change in expression of any of the 13 CKRs on spleen IL-4+ or IL-4- CD4+ T memory cells. In contrast, allergen rechallenge increased the expression of CCR4, CCR5, CCR6, CCR7, CCR8, CCR9, CXCR3, CXCR4 and CXCR6 on IL-4+ and IL-4- memory CD4+ T cells in lung, but did not influence the expression of CCR3, CXCR2, CXCR5, and CXCR7. These data demonstrate differences in CKR expression on memory cells in spleen and lung and support the notion that there are organ-specific memory cell subpopulations. In addition, the increased expression of numerous CKRs on CD4+ T cells in lung during disease exacerbation suggests that either there are several memory cell subsets bearing distinct CKRs or that lung memory cells express high numbers of CKRs. Both possibilities would explain a lack of phenotype in CKR deficient animals and indicate that targeting CKRs to treat allergic asthma might be difficult.

P3.08.02
The role of CD244 in regulating *M. tuberculosis* antigen-specific $CD4^+$ T cell function

***X. Cheng**, B. Yang, J. Jiang, X. Wang;*
Institute of Tuberculosis, Beijing, China.

CD244 (2B4) is a member of the signaling lymphocyte activation molecule (SLAM) family of immune cell receptors and it plays an important role in modulating NK cell and $CD8^+$ T cell immunity. The role of CD244/2B4 on human $CD4^+$ T cell function in active tuberculosis (TB) patients has not been reported so far. In this study, we investigated the expression and function of CD244/2B4 on $CD4^+$ T cells from active TB patients and latent infection individuals. Active TB patients had significantly elevated CD244/2B4 expression on *M. tuberculosis* antigen-specific $CD4^+$ T cells as compared with latent infection individuals, and the expression of CD244/2B4 was associated with disease persistence in active TB patients. Compared with CD244/2B4-dull and -middle $CD4^+$ T cells, CD244/2B4-bright $CD4^+$ T cell subset had significantly reduced expression of IFN-γ, suggesting that CD244/2B4 expression may modulates IFN-γ production in *M. tuberculosis* antigen-responsive $CD4^+$ T cells. Activation of CD244/2B4 signaling by cross-linking led to significantly decreased production of IFN-γ. Blockage of CD244/2B4 signaling pathway of T cells from patients with active TB resulted in significantly increased production of IFN-γ, compared with isotype antibody control. In conclusion, CD244/2B4 signaling pathway has an inhibitory role on *M. tuberculosis* antigen-specific $CD4^+$ T cell function.

P3.08.03
Dose-dependent differential effects of thrombin in allergic bronchial asthma

***C. D'Alessandro-Gabazza**, Y. Matsushima, A. L. Chelakkot Govindalayathil, Z. Roeen, T. Takagi, T. Yazuma, T. Kobayashi, M. Toda, E. C. Gabazza;*
Mie University, Tsu, Japan.

Apart from its role in the coagulation system, thrombin plays an important role in the inflammatory response through its protease-activated receptor (PAR)-1, but its role in the immune response is unclear. This study evaluated the modulatory role in allergic bronchial asthma. Bronchial asthma was induced in mice by sensitization and challenge with ovalbumin. Mice with low but sustained coagulation activation had reduced allergic inflammation and allergic asthma was inhibited by low doses but worsened by high doses of thrombin. Allergic asthma was worsened by antithrombin, argatroban, hirudin and anti-thrombomodulin antibody. Mice with an increased concentration of an inhibitor of both thrombin and activated protein C had worsened disease. Heterozygous PAR-1 mice had less allergic inflammation but PAR-1 agonist worsened it. Allergic bronchial inflammation was worsened in mice that received adoptive transfer of PAR-1 agonist-treated Th2 cells compared to controls. Low concentrations of thrombin suppressed but high-dose of it enhanced maturation and secretion of cytokines in dendritic cells. The effects of thrombin on allergic asthma are dose-dependent with detrimental effects at high-dose being mediated by PAR-1 while low doses were protective via thrombomodulin. These data demonstrate that thrombin modulates the outcome in allergic bronchial asthma.

P3.08.04
Serine protease inhibitor characteristics of human T helper 2 cells

***S. M. Edelman**[1], T. Äijö[2], I. Koho[1], H. Kallionpää[1], S. Tuomela[1], R. Lahesmaa[1];*
[1]Turku Centre for Biotechnology, Turku, Finland, [2]Aalto University School of Science, Espoo, Finland.

Atopic diseases are characterized by IgE mediated immune responses towards allergens and high expression levels of T helper 2 (Th2) type cytokines. Many of the atopic allergens possess serine protease activity. A serine protease inhibitor SPINK5 gene is reported to play a suppressive role in atopic skin diseases. Interestingly, differentiating human Th2 cells have also shown elevated expression

levels of a serine protease inhibitor kunitz-type 2 (SPINT2). However, an in-depth understanding how protease inhibitors potentially modulate allergic reactions in atopic diseases is missing.
This study aims at characterizing the expression and secretion of SPINT2 from differentiating and fully polarized human Th2 cells and identifying the specific gene expression patterns of SPINT2 displaying Th2 cells.
We used naïve CD4+ T cells isolated from umbilical cord blood and activated them to induce differentiation of Th0, Th1 and Th2 cells. The kinetics of SPINT2 expression was detected at RNA and protein levels by qRT-PCR and flow cytometry. We examined the subset specific gene expression profiles with Affymetrix arrays from RNA extracted from Th2 cells sorted based on their SPINT2 surface expression.
Th2 cells expressed and secreted significantly more SPINT2 throughout the differentiation process compared to other Th subsets. With the genome wide gene expression analysis we found 97 differentially expressed genes in SPINT2 positive Th2 cells, including genes linked to NK cell associated cytotoxic pathways and chemokine genes related to asthma and migration of Th2 cells. The results are expected to gain new important information on serine protease inhibitor exploitation of Th2 cells.

P3.08.05
New column-free procedure for the enrichment of human Th1(CD4+CXCR3+) cells from peripheral blood

***M. Fairhurst**, J. Yu, S. de Jong, T. Thomas;*
STEMCELL Technologies, Vancouver, BC, Canada.

Upon appropriate activation naïve T helper (Th) precursor cells proliferate and become polarized toward various cell subtypes distinguishable by their effector function and chemokine expression. Th1 cells regulate cellular immunity via the autocrine growth factor IL-2 plus IFN-γ and TNF-β, activating macrophages, cytotoxic T, NK and B cells in the effort to eliminate intracellular pathogens. Although no single specific marker is used to identify Th1 cells, they preferentially express the chemokine receptors CXCR3 and CCR5 and can be further characterized by intracellular staining for IFN-γ. We have developed a 2-step EasySep™ immunomagnetic column-free method for the enrichment of Th1(CD4+CXCR3+) cells from fresh peripheral blood nucleated cells. First, non-CD4 T cells are targeted for depletion using dextran-coated magnetic particles and a cocktail of antibody complexes. Labeled cells are separated using an EasySep™ magnet, and pre-enriched CD4 T cells are poured off. CXCR3+ cells are then positively selected from the pre-enriched CD4 T cell fraction. The procedure can be automated using RoboSep™. With an initial frequency of 10 ± 3% CD4+CXCR3+ cells, purities of 90 ± 4% (n=12) can be obtained. When stimulated, a high proportion of these cells produce IFN-γ (68 ± 12%) compared with total CD4 T cells and pre-enriched CD4 T cells. Less than 1% of the isolated cells produce cytokines associated with Th2 or Th17 cell subtypes (IL-4 or IL-17 respectively). Enrichment of unstimulated human Th1(CD4+CXCR3+) cells enables the investigation of chronic inflammation responses and mechanisms of regulation in human models of disease.

P3.08.06
Identification and characterization of the secreted form of TMEM98 that promotes Th1 cell differentiation both *in vitro* and *in vivo*

***W. Fu**, Y. Zhang, Y. Cheng, P. Wang, T. Li, W. Pan, D. Ma, W. Han;*
Department of Immunology, School of Basic Medical Sciences, Peking University Health Science Center&, Beijing, China.

Cytokines are secreted proteins that mediate the communication among immune cells. They play critical roles in the differentiation and effector function of $CD4^+$ T cells. More importantly, cytokines have made effective targets for drug development for a variety of diseases. Therefore, identifying novel potential cytokines will be of great value. We have established an immunogenetic platform to identify secreted proteins with modulatory effects on immune cells. In this study, we demonstrate that TMEM98 is a type II transmembrane protein that is secreted by a non-classical pathway. GEO profile analysis indicated that TMEM98 might be involved in anti-viral and anti-tumor immunity. We found that mouse $CD4^+$ T cells upregulated TMEM98 upon stimulation, especially on activated Th1 cells. When placed under Th1-skewing conditions, recombinant TMEM98 could increase both the percentage of IFN-γ^+ cells and IFN-γ secretion into culture medium. Moreover, T-bet expression, the key Th1 transcription factor, was also upregulated. These findings were confirmed *in vivo,* as recombinant TMEM98 administration significantly increased antigen-specific IFN-γ production and serum antigen-specific IgG2a in the mBSA-induced delayed-type hypersensitivity (DTH) model. Overall, these observations emphasize an essential role of TMEM98, a novel secreted protein, in promoting Th1 cell differentiation, thereby adding to the understanding of Th1 cell development.

P3.08.07
NFκB attenuates IL-5 production and upregulates T-box transcription factors in Th2-like T cells

***M. Hashiguchi**, A. Kobayashi, Y. Kashiwakura, H. Kojima, Y. Kanno, T. Kobata;*
Department of Immunology, Dokkyo Medical University School of Medicine, Tochigi, Japan.

IL-5 plays important roles in eosinophil differentiation, expansion, and recruitment. The regulation of IL-5 seems critical for the treatment of eosinophil-mediated allergic reactions. However, the precise mechanisms for IL-5 regulation remain unknown. In this study, we investigated how IL-5 production is regulated. The transduction of GATA-3 into a murine T cell hybridoma as well as OT-II $CD4^+$ T cells resulted in acquiring the ability to produce IL-5 in response to an antigenic stimulus. This production was dependent on the cAMP-PKA pathway, but not on p38 activation. Neither transduction of MEK nor NFATc1 altered IL-5 production. On the other hand, transduction of NIK largely impaired IL-5 production. RelA and RelB similarly impaired IL-5 production. The transduction of GATA-3 decreased the expression of *Tbx21* and *Eomes*, but the additional transduction of RelA abrogated the decreased expression of GATA-3-induced *Tbx21* and *Eomes* in T cell hybridoma, and upregulated IFN-γ production from GATA-3-transduced OT-II $CD4^+$ T cells. These results suggested that strong enhancement of the NFκB pathway downregulates IL-5 production and upregulates T-box protein expression to shift an immune response from Th2 to inflammatory Th1.

P3.08.08
T-lymphocytes effectors/memory cells detection by intracellular cytokines staining in children of different age and adults

***J. G. Lagereva**[1,2], J. B. Beykin[1,2];*
[1]Clinical and Diagnostic Centre, Ekaterinburg, Russian Federation,
[2]Institute of immunology and physiology of the Ural branch of Russian Academy of Sciences, Ekaterinburg, Russian Federation.

The method of intracellular marker cytokines staining was applied in order to quantify normal levels of Th1, Tc1, Th2, Tc2, Th17, Tnc17 subpopulations in children of different age and in adults. The studied group consisted of 150 children and adolescents aged 7 months - 18 years and 45 adults of 25-45 years of age. It has been found that Th1 and Tc1-lymphocytes absolute and relative levels significantly lower in infants of 7-12 months of age than in adults. Simultaneously the Th2 lymphocytes count was similar in 7-12 months old infants and adults, whilst Tc2-lymphocytes absolute count was higher in 7-12 months old infants than in all other age groups. Th17, Tnc17 lymphocytes absolute counts were higher in 7-12 months old infants than in adults. Thus, Th2(Tc2)/Th17(Tnc17) immune response polarization was found in 7-12 months old infants which possibly helps Th2-mediated allergic disorders manifestation in atopy predisposed infants. Th1(Tc1) and Th2(Tc2) lymphocytes absolute counts were not different significantly in children older than 12 months old and in adults. Th2-lymphocytes levels decreasing and IL17A-positive cells levels increasing trends were identified in 15-18 years old adolescent group. This phenomenon can mediate the induction of autoimmune disorders predisposition at this age. Th1/Th2 counts proportion and Tc1/Tc2 counts proportion were 18.7 and 56.8, respectively in adults of 25-45 years of age. Correlations analysis

identified the strongest correlation between Th1/Tc1 subpopulations and memory cells. Relative increase in Th1 и Tc1 lymphocytes portion linked to T-memory cells pool formation reflects immune system maturation within the infants aging.

P3.08.09
Generation of mutants forms of mite allergen Der p 5 with reduce IgE binding

S. Lahiani[1], *S. Khemili*[2], *A. Bouaziz*[1], *I. Bitam*[3], *D. Gilis*[2], *M. E. Dumez*[1], *M. Galleni*[1];
[1]*Centre for Protein Engineering University of Liege, Liège, Belgium,* [2]*Unité de Bioinformatiquegénomiqueetstructurale, UniversitéLibre de Bruxelles, Belgium,* [3]*Université M'HAMED BOUGARA, Boumerdès, Algeria.*

Group 5 dust mite allergens Der p 5, Der f 5 and Blot 5 are part of a most important allergen group, and cause allergic disease. Based on the structure of Blot 5, linear and conformational epitopes of this allergen have been identified. Our aim is to characterized B-cell conformational epitopes of the Der p 5 allergen from *Dermatophagoides pteronyssinus* by using the web-server SEPPA and experimental validation of these results.
Two antigenic determinants: N57-K70 and R91-I100; the major surface-exposed charged residues in this region have been selected for site-directed mutagenesis. Single and multiple mutations in alanine have been introduced by PCR. Mutants have been produced in *Pichia pastoris,* purified and their stability and IgE binding capacity have been compared.
The data obtained show that the different mutants are stable at 37°C. Compared to rDer p 5, the mutants rDer p 5 E61A, rDer p 5 K65A, rDer p 5 K70A and rDer p 5 Q94AR95A display a very weak IgE reactivity, as measured by sandwich ELISA. These results will contribute to the determination of B cell epitopes to develop hypoallergenic variants of Der p 5 suitable for use in allergen-specific systemic immunotherapy or desensibilisation.

P3.08.10
The role of neuronal adhesion molecule AMIGO2 in T cell function and inflammatory diseases

Z. Li*, J. Kuja-Panula, H. Rauvala, L. Tian;*
Neuroscience Center, University of Helsinki, Helsinki, Finland.

Introduction: The nervous and immune systems communicate with each other constantly and delicately to maintain own homeostasis. So far, many molecules have been identified to be expressed and utilized by both systems.
Objectives: To elucidate the roles that neuronal adhesion molecules play in the neuroimmune crosstalk, in order to provide a novel and global understanding of interaction between these two systems. AMIGO2, induced by HMGB1 in rat hippocampal neurons, is expressed mostly by endothelial, neuronal and immune cells and inhibits apoptosis and promotes neuronal survival, while little is known about its regulatory role on immune system, especially T cell function.
Methods: To study these, we generated a conventional AMIGO2 knockout mouse line. To investigate its role in T cell development, we immunophenotyped the splenocytes and thymocytes from KO mice by flow cytometry and found that T cells are slightly increased. T cell activation and proliferation assays show that KO T cells are significantly more activated and proliferative in response to CD3 ligation or ConA stimulation and survive better under mild stimulation in vitro. Interestingly, using acute EAE model, we found that KO mice have delayed onset of disease development. Currently, we are studying its role in regulating T cell differentiation and characterizing the molecular mechanisms underlying various immune regulatory functions, which may help us interpret the in vitro and in vivo results.
Conclusions: Absence of Amigo2 leads to enhanced T cell survival, activation, and proliferation in vitro, and increased amount of T cells and more resistance to EAE disease development.

P3.08.11
IL-27 regulates Th1 lymphocytes and induces Th17-dependent protection against experimental Trypanosoma cruzi infection

T. Medina*, G. K. Silva, D. Fonseca, R. Sesti, M. C. Silva, J. S. Silva;*
Sao Paulo University, Ribeirao Preto, Brazil.

IL-27 is a heterodimeric cytokine known to induce IL-10-producing Tr1 cells and to regulate Th1, Th2 and Th17 subsets, depending on the underlying disease. Because the infection caused by *Trypanosoma cruzi* normally induces heart inflammation mirrored by an outstanding migration of Th1 cells, we analyzed the regulatory role of IL-27 in this disease. After infecting WT, IL-17R$^{-/-}$, IL-23$^{-/-}$ and IL-6$^{-/-}$ mice, we verified an impressive cardiac inflammation and damage in the absence of Th17-related molecules (IL-17R$^{-/-}$, IL-23$^{-/-}$ and IL-6$^{-/-}$ mice), leading them to the premature death when compared to the control group. This cardiac inflammation was reflected by a Th1 deviation in the absence of Th17-related molecules, since that we found reduced IL-27 mRNA expression in the heart tissue in the absence of Th17-related molecules. The decreased IL-27 expression was associated with increased IL-2 levels in the heart tissue, which inhibited both Th17 and regulatory T cells. This milieu enriched by IL-2 promoted CXCL9 and CXCL10 chemokines in the heart tissue, thus inducing a deleterious Th1 migration to this organ, characterized by a local increased expression of IL-12, T-bet, iNOS, IFN-γ and TNF. To confirm the regulatory role of IL-27 in the Chagas Disease, we detected increased serum IL-27 levels in patients with free or mild cardiomyopathy when compared to patients with moderate or severe cardiomyopathy. Here, we showed that IL-27 was able to control a deleterious Th1 response in the heart tissue, thus preventing the striking myocarditis induced after *T. cruzi* infection.

P3.08.12
IL-4 receptor alpha signalling on dendritic cells is required for optimal Th2 responses in house dust mite induced allergic airway disease and schistosomiasis

N. E. Nieuwenhuizen[1,2,3], *H. H. Ndlovu*[2,3], *F. Kirstein*[2,3], *R. Hurdayal*[2,3], *F. Brombacher*[2,3];
[1]*Max Planck Institut, Berlin, Germany,* [2]*Institute of Infectious Diseases and Molecular Medicine, Cape Town, South Africa,* [3]*International Centre for Genetic Engineering and Biotechnology, Cape Town, South Africa.*

Th2 responses are responsible for the symptoms of allergic airway disease, but are required for protection against helminth infections such as schistosomiasis. While IL-4 is the main inducer of Th2 responses, the precise mechanisms leading to Th2 differentiation are unclear.The aim of this study was to determine the role of IL-4Ralpha signalling on DCs in the induction of Th2 type immune responses.CD11c^{cre}IL-4Ralpha]$^{-/lox}$ mice, lacking IL-4Ralpha expression on DCs and alveolar macrophages, were generated by gene targeting and site-specific recombination using the cre/*lox*P system under control of the CD11c locus, and tested in mouse models of house dustmite (HDM) -induced allergic airway disease and schistosomiasis. CD11c^{cre}IL-4Ralpha $^{-/lox}$ mice sensitized and challenged with HDM extract had reduced eosinophils in the bronchiolar lavage fluid and decreased airway hyperreactivity compared to littermate controls. This was associated with significantly reduced numbers of Th2 cytokine secreting CD4^{+} T cells and decreased levels of IL-33 in lung homogenates. In *Schistosoma mansoni* infection, both Th1 and Th2 responses were reduced in CD11c^{cre}IL-4Ralpha$^{-/lox}$ mice, which had noticeably smaller lymph nodes containing lower numbers of cells than littermate controls, indicating suboptimal activation of immune responses in the absence of IL-4Ralpha signaling on DCs. CD11c^{cre}IL-4Ralpha $^{-/lox}$ mice had increased morbidity and mortality, associated with smaller granulomas in the intestine and liver, raised TNF levels in the serum and a shift towards classical activation of macrophages.In conclusion, IL-4Ralpha signaling on dendritic cells promotes the development of Th2 responses against house dust mite allergens and the helminth *Schistosoma mansoni*.

P3.08.13
Differential mechanisms of contact hypersensitivity development to dinitrochlorobenzene (DNCB) in rats

***A. Popov Aleksandrov**, I. Mirkov, J. Djokic, M. Ninkov, D. Miljkovic, D. Kataranovski, M. Kataranovski;*
Institute for biological research "Sinisa Stankovic", Belgrade, Serbia.

Contact hypersensitivity (CHS) is a T cell-mediated skin inflammatory reaction to haptens. As there are implications that genetic background might influence reaction, in this study CHS to dinitrochlorobenzene in Dark Agouti (DA) and Albino Oxford (AO) rats, which develop different type (Th1/Th2) of immune response to various stimuli, was investigated. More intense ear swelling response (ear thickness, cell infiltration, inflammatory mediator content in conditioned medium of ear skin explants) was observed in DA as compared to AO rats and was associated with higher proliferative activity (*ex vivo, in vitro* hapten- and IL-2-stimulated) and effector cytokine (IFN-γ, IL-17) production/mRNA expression in draining lymph nodes (DLN) during challenge phase. Concerning Th2 cytokines during challenge phase, unchanged IL-10 was noted in both strains, but increased IL-4 production only in AO rats. While relative number of $CD8^+$ cells in DLN was increased in both strains, number of $CD8^+CD11b^+$ was increased only in DA rats. Relative number of $CD4^+$ cells was decreased in DA (unchanged in AO rats), however number of $CD4^+CD25^+Foxp3^+$ was unchanged in both strains. During sensitization phase, DLN activity (*ex vivo* and IL-2-stimulated proliferation, IFN-γ and IL-17 production/mRNA expression) was increased in both strains, but lower in AO rats. IL-10 and IL-4 production were unchanged during this phase. Reduced lymphoproliferative activity and IFN-γ and IL-17 production, together with increased IL-4 production during challenge phase, could be underlying mechanisms of lower intensity of CHS expression in AO rats.

P3.08.14
A novel strategy for integrating gene expression profiles derived from multiple publicly available datasets highlights novel hub genes and pathways in mouse models of allergic asthma

***M. Riba**[1], J. M. Garcia-Manteiga[1], B. Bosnjak[2], M. M. Epstein[2], E. Stupka[1];*
[1]Center for Translational Genomics and Bioinformatics, San Raffaele Scientific Institute, Milan, Italy, [2]Medical University of Vienna, Department of Dermatology, DIAID, Experimental Allergy, Vienna, Austria.

There are 30 studies of gene expression profiling of lungs from mice with allergic asthma, which shed new light on the molecular mechanisms of disease, but the experimental designs between them differ. Nevertheless, relevant genes and pathways underlying disease pathogenesis may emerge from the integration of these datasets. From 12 publically available datasets, we selected 6 for meta-analysis on the basis of the microarray platform and *in vivo* experimental protocol. Our strategy was to combine a top down pathway-centered and a bottom up gene-centered analyses. The first approach consisted of selecting asthma-specific pathways from a combination of 'enriched biological terms' in each individual study. Secondly, we combined differentially expressed genes from individual datasets to create a gene list. From 22,690 genes and 131 samples, we obtained a core-network of more than 300 interconnected genes unraveling known (STAT1, JAK2) and unknown hubs (PU.1, CDK1). Additionally, we successfully selected known and unknown disease-related pathways, such as T-cell activation during an immune response, B-cell mediated immunity, phagocytosis and complement activation. The power of this strategy is the possibility to uncover key molecules underlying disease pathogenesis utilizing datasets derived from disparate experiments.

P3.08.15
Expression of cytokines and transcription factors in CD4+ T cell in myasthenia gravis

*V. Yilmaz, P. Oflazer, F. Aysal, Y. G. Parman, F. Deymeer, **G. Saruhan-Direskeneli**;*
Istanbul Medical Faculty, Istanbul, Turkey.

When activated, CD4+ T cells differentiate and secrete cytokines to modulate other cells, influencing the pathogenesis of autoimmune diseases. Helper T cell subsets [Th1, Th2 and Th17, T follicular helper (Tfh)] as well as regulatory T cells (Treg) effect disease pathogenesis in many autoimmune diseases. In this study, Th cell subtypes are evaluated and compared with another autoimmune disease, namely rheumatoid arthritis (RA).
CD4+ T cell population from 63 generalized myasthenia gravis (MG) without thymoma (26 anti-AChR+, 18 anti-MuSK+ and 19 double-negative-MG), 12 RA patients and 20 healthy donors (CON) were included. TBET, GATA3, RORG, BCL6, CD40L and IFNG, IL10, IL17A, IL21 mRNA levels were determined semi-quantitatively by PCR with specific primer sets using Sybr Green. Quantification of target gene levels were performed by comparing 2 -αα CT values with GAPDH.
Expression of TBET, GATA3, RORG as well as CD40L was lower in MG than CON ($p= 0.018$, $p= 0.033$, $p= 0.026$ and $p<0.001$). The expression levels of IL10, IFNG, IL17A, IL21, BCL6 in CD4+ T cells were similar in the MG as well as in the subgroups with or without treatment. TBET and CD40L were also down regulated in CD4+ T cells of MG patients without treatment ($p= 0.01$). Similarly TBET, GATA3, RORG and CD40L expressions in RA were also decreased compared to CON (all $p< 0.001$).
Th1 downregulation and the lower levels of the B cell costimulation by CD4+T cells is implicated in the peripheral blood of MG patients.
This study is supported by TUBITAK

P3.08.16
MiRNA expression and function in CD4 T cells from asthmatic airways

***L. J. Simpson**[1], G. Seumois[2], P. Vijayanand[2], P. Woodruff[1], M. Ansel[1];*
[1]University of California, San Francisco, San Francisco, CA, United States, [2]La Jolla Institute for Allergy and Immunology, La Jolla, CA, United States.

Atopic asthmatics are prone to developing T-helper type 2 (Th2) responses, and Th2 cells are central in the inflammatory response in the lung due to production of the pro-inflammatory cytokines interleukin-13 (IL-13), IL-5, and IL-4. Additionally, production of the cytokines IL-17A, IL-17F, and IL-22 by Th17 cells may be involved in airway smooth muscle remodeling and airway hyper-responsiveness in asthma. MicroRNAs (miRNAs) regulate gene expression programs by reducing the stability and translation of target mRNAs, and they are particularly important in cell identity decisions within the hematopoietic lineage. In order to understand the role of miRNAs in CD4 T cells in asthma, we determined the expression of a panel of miRNAs in CD4 T cells sorted from bronchoalveolar lavage fluid from asthmatic and healthy subjects, and found differential expression of a small number of miRNAs. Further functional analyses in both human and mouse CD4 T cells indicate that these miRNAs play a role in regulating the differentiation of naïve CD4 T cells into Th2 or Th17 effector cells, and may contribute to the pathogenic properties of T-helper cells in the airways of asthmatics.

P3.08.17
Differences in the polarization of the inflammatory response of patients with chronic obstructive pulmonary disease (COPD) secondary to smoking and to biomass smoke exposure

***H. Solleiro-Villavicencio**, M. I. Vargas-Rojas, A. Ramírez- Venegas, R. H. Sansores-Martínez, M. Velázquez-Uncal, O. Pérez-Bautista, R. Quintana, R. Falfán-Valencia, I. Pupko-Sissa;*
Instituto de Enfermedades Respiratorias, Mexico City, Mexico.

Introduction. Smoking and exposure to biomass smoke cause the release of pro-inflammatory mediators, as well as the activation of T helper (Th) cells. This inflammatory response can lead to the development of COPD; however, there are different clinical features between patients with COPD secondary to smoking (sCOPD) and to exposure to biomass smoke (bsCOPD), and these may be due to the kind of predominant Th response.
Aim. Quantify the $TCD4^+$ cells subpopulations and the cytokines in peripheral blood of patients with sCOPD, bsCOPD and healthy controls (HC).
Methods. 41 patients were recruited, 24 sCOPD and 17 bsCOPD; we included 25 HC. Through flow cytometry the proportion of $TCD4^+$ cells subpopulations was defined. The serum cytokines were quantified through Luminex system. The differences between groups were evaluated with a Kruskal-Wallis test, and a post-hoc analysis was performed through a U of Mann Whitney test.
Results. A prevalence of Th17 cells was observed in the sCOPD group (10.3 ± 3.4%), when compared with bsCOPD (3.5 ± 0.9%) and HC (0.9 ± 0.4%) $p<0.001$. Th2 cells were predominant in the bsCOPD patients (4.4 ± 1.3 %), in comparison with sCOPD (2.5 ± 0.8 %), and HC (1.1 ± 0.4 %). IL-4 and IL-10 are in a higher concentration in bsCOPD versus sCOPD.
Conclusions. Our data show a polarization of Th17 cells in sCOPD, and of Th2 cells in bsCOPD. There are differences in the wsCOPD and the sCOPD cytokine profiles, which may explain some of the clinical features observed in the COPD phenotypes.

P3.08.18
Transgenic Expression of Survivin Compensates the OX40-Deficiency in Driving Th2 Development and Allergic Inflammation

***J. Song**, D. Lei, R. Haque;*
Penn State University College of Medicine, Hershey, PA, United States.

Two major types of signals are required for optimal T cell activation, with one derived from the T cell receptor (TCR) and the other from a number of costimulatory receptors. Emerging evidence has suggested that the protein survivin, a member of the inhibitor of apoptosis (IAP) family (also called baculoviral inhibitor of apoptosis repeat-containing 5 or BIRC5), may be an important intermediate contributing to the development of efficient T cell responses. However, the importance of survivin to T cell-driven inflammatory responses has not been demonstrated. Here, we show that survivin transgenic mice exhibit increased antigen-driven Th2 lung inflammation, and that constitutive expression of survivin reverses defective lung inflammation in the absence of OX40 costimulation. We found that while OX40-deficient mice are compromised in generating Th2 cells, airway eosinophilia, and IgE responses, survivin transgenic/OX40-deficient mice generate normal Th2 responses and exhibit strong lung inflammation. These results suggest that OX40 costimulation crucially engage survivin during antigen-mediated Th2 responses, and promote the notion that survivin could be a vital intracellular molecule of costimulation that regulates allergic responses or lung inflammation.

P3.08.19
Resistin, Tumor Necrosis Factor-α and Insulin Resistance in Normal Pregnancy

***A. Sotoodeh Jahromi**[1], F. Mehdizadeh[2];*
[1]Jahrom University of Medical Sciences, Jahrom, Iran, [2]Student Research Committee, Jahrom University of Medical Sciences, Jahrom, Iran.

Intoduction: Pregnancy is associated with glucose metabolism disorders and insulin resistance (IR). Insulin resistance may facilitate supply of appropriate nutrients particulary of glucose t! o fetus for fetal growth and metabolism. The mechanism responsible for insulin resistance has not been clearly stated. Objective: The purpose of this study was to evaluate the role of resistin and Tumor Necrosis Factor-α (TNF-α) in insulin resistance during pregnancy. Approach: Serum resistin and TNF-α concentrations were measured by ELISA in 86 healthy pregnant women (26, 23 and 37 of them in the 1st, 2nd and 3rd trimesters, respectively) and in 21 healthy non pregnant women in a cross sectional study. Results: Resistin concentration was significantly higher in the third trimester (9.5±3.3 ng mL1) as compared with non pregnant women (7±3.3 ng mL1). Serum TNF-α levels were also significantly increase in pregnant women (2.6±1.9 pg mL1) as compared with maternal healthy controls (0.8 ±0.7 pg mL1). There were significant correlations between gestational age and BMI ($r=0.28$, $p=0.01$), resistin ($r=0.36$, $p=0.002$) and TNF-α($r = -0.44$, $p<0.0001$). There was not a significant correlation between gestational age and Insulin Resistance (IR). We also did not found correlation between IR and resistin as well as between IR and TNF-α in pregnant women.Conclusion: TNF-α and resistin do not appear to contribute greatly to pregnancy-induced insulin resistance in healthy pregnancy.

P3.08.20
Identifying the T helper cell population involved in class-switching to IgE

***S. Subramaniam**[1,2], J. He[1], L. Jones[1], M. Curotto de Lafaille[1];*
[1]Singapore Immunology Network, Singapore, Singapore, [2]Nanyang Technological University, Singapore, Singapore.

IgE antibodies are key players in allergic diseases and can be generated by direct switching of IgM/IgD cells, or by sequential switching of IgG1 cells to IgE. The characteristics of the IgG1 cells involved in the switching to IgE and the nature of IL-4 producing T cells involved in direct and sequential switching are not known. The goal of this work is to identify the T cell populations that help naïve and IgG1 cells to switch to IgE.
When comparing the memory/activated population of cells in the lymphoid organs of immunized TBmc 4get mice, we found at least 2 types of IL-4 producing cells identified based on PD1 expression, in agreement with published work. Real-time PCR analysis of the GFP^+PD1^+ cells in the lymphoid organs showed expression of IL-4, IL-21, CXCR5 and Bcl6, confirming its Tfh nature. Conversely, the GFP^+PD1^- population lacked Tfh markers, representing a Th2-like population. Using this system, we found that the Th2-like cells were the best helpers to induce naïve B cells to class-switch to IgE both in an in-vitro and an in vivo model.
We are also investigating the specific characteristics of IL-4 Tfh populations found in systemic and mucosal lymph nodes, to correlate with their differential ability to promote immunoglobulin class switching to IgE.
Supported by SIgN-A*STAR core funding to M.A.C.L.

P3.08.21
Retrogenic expression of human TCR in HLA-DR4 transgenic NOG mice

***T. Takahashi**, I. Katano, R. Ito, M. Ito;*
Central Institute for Experimental Animals, Kawasaki, Japan.

Humanized mouse is a key technology for translating basic researches to clinical applications.
We have generated HLA-DR4 expressing NOG mice (DR4 NOG). In this meeting, we are going to report retrogenic expression of human

TCR genes from cow-milk allergy patients. We isolated 2 independent TCR genes from HLA-DR0405-restricted $CD4^+$ T cell clones (HA5.7 and YA4) specific for a bovine lactoglobulin (BLG) peptide. Using retroviral or lenti vectors, we introduced the TCR genes into HSC and transferred into DR4 I-$A^{-/-}$ NOG mice. The expression of the TCR was monitored by FACS using anti-TRBV antibody and bi-cistronic GFP. In 3 months after HSC-transplantation, $CD4^+$ T cells appeared in the peripheral blood and gradually expanded. When those mice were analyzed at 5 months post HSC-transfer, in the thymus, the skewing of GFP positive thymocytes to $CD4^+CD8^-$ SP cells were detected. In the periphery, both HA5.7- and YA4-derived $GFP^+TRBV^+CD4^+$ T cells were identified. Stimulation of the spleen cells with the BLG peptide in vitro induced significant proliferation of $GFP^+TRBV^+CD4^+$ T cells. These T cells also produced IFN-g in response to the peptide stimulation. When using HLA-matched HSC, anti-BLG IgG was also detected in the sera of the mice.
Collectively, our results suggest that human TCR genes can be expressed in humanized mice in a functional manner. This system may help recapitulating human food allergy. We are now generating GM-CSF/IL-3 transgenic DR4 I-$A^{-/-}$ NOG mice, in which human myeloid cells including mast cells can develop.

P3.08.22
The effect of toll-like receptor 4 on the development of acquired immunity against Salmonella infection

P. Tourlomousis[1], *P. Mastroeni*[1], *K. A. Fitzgerald*[2], *D. J. Maskell*[1], *C. E. Bryant*[1];
[1]*University of Cambridge, Department of Veterinary Medicine, Cambridge, United Kingdom,* [2]*University of Massachusetts Medical School, Department of Medicine, Worcester, MA, United States.*

Interaction of TLR4 with the lipopolysaccharide of *Salmonella enterica* serovar Typhimurium (*ST*m) rapidly activates innate immunity to control microbial growth *in vivo*. Effective clearance of the bacteria requires engagement of acquired, antigen-specific immunity. It is unclear whether TLR4 is essential for the development of classical T_H1 immunity against *ST*m. To address this question, *Tlr4*$^{-/-}$ and congenic wild-type mice were challenged with attenuated *ST*m. *Tlr4*$^{-/-}$ mice had significantly higher microbial burden confirming the crucial role TLR4 plays in restricting bacterial growth early in infection. Bacterial clearance, however, which is primarily driven by CD4-dependent T_H1 immunity, was unimpaired in *Tlr4*$^{-/-}$ mice. To investigate this further, we first characterised the ability of *Tlr4*$^{-/-}$ and wild-type bone marrow-derived dendritic cells (BMDCs) to polarise wild-type naïve $CD4^+$ T cells in response to *ST*m *in vitro*. We found that *Tlr4*$^{-/-}$ BMDCs were impaired in polarising wild-type naïve T cells as opposed to their wild-type counterparts. We then assessed the quality of immunological memory by stimulating $CD4^+$ T cells obtained from the spleens of immunised mice with *ST*m cell extract. IFN- and Il-2 production by *Tlr4*$^{-/-}$ $CD4^+$ T cells was substantially reduced compared to that produced by wild-type cells. *Tlr4*$^{-/-}$ mice immunised with live *ST*m were as protected as wild-type when exposed to what would be a lethal infection in unvaccinated animals. Our *in vitro* work clearly suggests that TLR4 is indispensable for the development of robust T_H1 responses against *ST*m. *In vivo*, however, compensatory mechanisms exist that drive pathogen clearance and generation of protective immunity.

P3.08.23
Formation of the utero-(pre) placental blood flow in pregnant women with threatened abortion in early pregnancy due to impaired immune-hormonal homeostasis

I. I. Voronova*, T. N. Demina;*
Department of Obstetrics, Gynecology and Perinatology FIPOI Donetsk National Medical University, Donetsk, Ukraine.

Results. In pregnant women with threatened abortion in the first trimester, due to the low level of progesterone, compared with rates of women with physiological pregnancy, was shown increased production of cytokines Th I and indicators of vascular resistance (resistance index (RI) and pulse index (PI)) in the spiral arteries which were shown by increasing concentration of α-TNF (14,65 pg/ml(14.03-16,2) and 7.2 pg/ml(6.3-7,5), respectively, p< 0,01), γ-IFN (9,34pg/ml (8.16-12,1) and 3.95 pg/ml(3.55-4.35), respectively, p<0,01) and IL-2 (9.74 pg/ml(7.3-12,77) and 5.1 pg/ml(4,3-5,9), respectively, p<0,01) with a parallel decrease in the concentration of IL-4 (0.68 pg/ml(0.58-0,84) and 1.49 pg/ml(1.38-1,64), respectively, p<0,01) and IL-10 (4.96 pg/ml(4.2-5.94) and 9.2 pg/ml(8.59-9,6), respectively, p<0,01), as well as increased RI (0,67(0,65-0.69) and 0.55(0,49-0,62), respectively, p<0,01) and PI (1,35(1,32-1,38) and 0.84(0,78-0,91), respectively, p<0,01) in the spiral arteries. At the same time, was revealed correlation between γ-IFN and RI (ρ=0,43; p<0,01) and PI (ρ=0,58; p<0,01) of spiral arteries, between α-TNF and RI (ρ=0,39; p<0,01) and PI (ρ=0,52; p<0,01) of spiral arteries and between the level of IL-4 and RI (ρ=-0,42; p<0,01) and PI (ρ =-0,59; p<0,01) of spiral arteries.
Conclusions. In pregnant women with threatened abortion in the first trimester, due to the low level of progesterone, a systemic shift was revealed in the balance of regulatory cytokines towards Th1 and their correlation to the vascular resistance in the spiral arteries, which attests to a disturbance in the formation of the utero-(pre-) placental blood flow and can be primary predictor of placental insufficiency.

P3.08.24
Myofibroblast Apoptosis, Removal from the Lungs and Attenuation of Fibrosis by FasL+ Immune Cells

S. B. Wallach-Dayan*, L. Elkayam, R. Golan-Gerstl, R. Breuer;*
Lung Cellular and Molecular Biology Laboratory, Institute of Pulmonary Medicine, Hadassah–Hebrew University Medical Center, Jerusalem, Israel.

Immune surveillance can be exerted upon self cells, usually after being transformed, senescent or infected; however, we previously found, in the bleomycin (BLM) experimental-model of idiopathic-pulmonary-fibrosis, that fibrotic-lung myofibroblasts resist Fas-induced apoptosis and escape immune surveillance. Yet, mechanisms for physiological scar removal from sites of injury remain obscure. Here we show that upon resolution of fibrosis, myofibroblasts are susceptible to CD4+T cell-induced apoptosis and to T cell-dependent immune surveillance in allogeneic-BALB/c, but not in immune-deficient congeneic-SCID mice. Impaired immune surveillance, as detected, in SCID mice, or in humans under immunosuppressive therapy, results in the development or worsening of lung fibrosis, thus showing that immune surveillance is important for limiting aberrant fibroblast accumulation and development of fibrosis in vivo. FasL-negative mouse primary-T cells, and primary-T cells or human Jurkat T cell-line, in which we interfered with FasL/Fas interaction, failed to induce myofibroblast apoptosis. Accordingly, following IT-BLM, when compared to FasL-deficient mice with wild-type (wt) immune cells (wt/gld), FasL-deficient (gld/gld) mice, accumulate myofibroblasts in their lungs and develop fibrosis. Our study indicates that, functional FasL+ immune cells and CD4+ T cells, may control abnormal in vivo myofibroblast accumulation by inducing myofibroblast cell death and that immune surveillance represents an important extrinsic component of myofibroblasts apoptosis and a fibrosis barrier. Factors interfering with immune cell-myofibroblast interaction via Fas/FasL may abrogate immune surveillance. Annulling these factors may pave a new direction to control human lung fibrosis.

P3.08.25
Impact of immunosuppressive drugs on killing capacity and cytokine production of BKV-specific T cells

B. J. D. Weist*;*
Berlin Brandenburg Centrum für Regenerative Therapien - Charité Universitätsmedizin Berlin, Berlin, Germany.

Immunosuppression (IS) of kidney allograft recipients is currently the indispensable method to avoid graft rejection. Nevertheless, suppression of the cellular immunity is an important risk factor for the reactivation of Polyomavirus BK (BKV) and the development of BKV-associated nephropathy (BKVAN). However, the impact of diverse immunosuppressive drugs on the multifunctionality and cytolytic capacity of BKV-specific T-cells remained unclear.
BKV-specific T-cell lines were generated from BKV-seropositive healthy donors and cultured under treatment of Prednisone,

Mycophenolate Mofetil (MMF), Rapamycin, Cyclosporin A (CsA) and Tacrolimus, respectively. Subsequently, phenotype, proliferation, cytokine production and killing capacity of the obtained BKV-specific T-cells were assessed by flow cytometry.
As expected, IS had a negative effect on T-cell proliferation, headed by MMF. The downregulation of IFNg production by calcineurin inhibitors (as previously described) and by prednisone was observed, whereas Tacrolimus revealed the highest suppressive potential. Furthermore, calcineurin inhibitors and Prednisone, but not Rapamycin and MMF, deteriorate the multifunctionality of BKV-specific T-cells. Surprisingly, even the CsA, Tacrolimus and Prednisone treated T-cells revealed their virus-specific cytolytic abilities.In case of BKV-reactivation the reduction or break of CsA, Tacrolimus and/ or Prednisone treatment might be required to restore the beneficial multifunctionality of naturally occurring BKV-specific T-cells. However, in a future setting of a possible BKV-specific adoptive T-cell transfer, such a change of the IS drug regimen seems to be non-essential, as the virus specific cytolytic capacity itself is less affected. These findings need to be considered in context of an adoptive T-cell-therapy as well as for vaccine development to ensure therapeutic feasibility.

P3.08.26
Bromodomain-Containing-Protein 4 (BRD4) Regulates RNA Polymerase II Serine 2 Phosphorylation in Human CD4+ T Cells

J. Yeong[1], *W. Zhang*[1], *P. Celine*[1], *C. Sum*[1], *N. Thiessen*[2], *S. Jones*[2], *S. Pettersson*[3], *S. Knapp*[4], *H. Yang*[1], *K. Chin*[1];
[1]*Singapore Immunology Network, Singapore, Singapore,* [2]*Bioinformatics Laboratory, Vancouver, BC, Canada,* [3]*Department of Microbiology, Cell and Tumor Biology, Karolinska Institutet, Stockholm, Sweden,* [4]*University of Oxford, Structural Genomics Consortium, Oxford, United Kingdom.*

Transcriptional elongation by RNA polymerase II (Pol II) is regulated by positive transcription elongation factor b (P-TEFb) in association with Bromodomain-containing protein 4 (BRD4). We used genome-wide chromatin immunoprecipitation sequencing in primary human CD4+ T cells to reveal that BRD4 co-localizes with Ser2-phosphorylated Pol II (Pol II Ser2) at both enhancers and promoters of active genes. Disruption of bromodomain:histone acetylation interactions by JQ1, a small-molecule bromodomain inhibitor, resulted in decreased BRD4 binding, reduced Pol II Ser2, and reduced expression of lineage-specific genes in primary human CD4+ T cells. A large number of JQ1-disrupted BRD4 binding regions exhibited di-acetylated H4 (lysine-5 and -8) and H3K27 acetylation (H3K27ac), which correlated with the presence of histone acetyltransferases and deacetylases. Genes associated with BRD4/H3K27ac co-occupancy exhibited significantly higher activity than those associated with H3K27ac or BRD4 binding alone. Comparison of BRD4 binding in T cells and in human embryonic stem cells revealed that enhancer BRD4 binding sites were predominantly lineage-specific. Our findings suggest that BRD4-driven Pol II phosphorylation at serine 2 plays an important role in regulating lineage-specific gene transcription in human CD4+ T cells.

P3.08.27
Effect of extremely low frequency electromagnetic field (ELF-EMF) on some cytokines production of rats

A. Zamani[1,2], *I. Salehi*[3], *K. Ghazikhanlou Sani*[4];
[1]*Department of immunology, School of medicine, Hamadan University of Medical Sciences, Hamadan, Iran,* [2]*Research Center for Molecular Medicine, Hamadan University of Medical Sciences, Hamadan, Iran,* [3]*Department of Physiology, School of Paramedical Sciences, Hamadan University of Medical Sciences, Hamadan, Iran,* [4]*Department of Radiology, School of Paramedical Sciences, Hamadan University of Medical Sciences, Hamadan, Iran.*

A link between exposure to extremely low frequency electromagnetic field (ELF-EMF) and some cancers has been suggested. This can be due to ELF-EMF effects on the immune system, where $CD4^+$ T cells play an important role. Naïve $CD4^+$ T cells differentiate into effector T_H1, T_H2 and T_H17 subsets according to the presence of different cytokines. T_H1 cells are critically important in protecting us against tumors. Therefore, the present study was designed to test the hypothesis that ELF-EMF can modulate cytokines like IFN-γ, IL-4, IL-6 and IL-12 that regulate the $T_H1/T_H2/T_H17$ balance. 40 adult male Wistar rats were randomly assigned to ELF-EMF-exposed and sham-exposed control groups. The ELF-EMF-exposed group was exposed to a flux density of 100 μT, frequency 50 HZ, 2h/day/7 days a week for 3 months. The sham-exposed control group was placed in identical chambers without ELF-EMF. Results show that serum IL-12 levels are decreased from 418±47pg/ml in sham-exposed controls to 300±23pg/ml ($p<0.05$) in ELF-EMF-exposed rats. PHA-activated IL-6 production in spleen cultures (1356±92 pg/ml) and total blood cultures (418±40 pg/ml) of ELF-EMF-exposed rats was higher ($p<0.001$) compared with controls (905±74 pg/ml), (182±26 pg/ml), respectively. However, the serum levels of IFN-γ, IL-4 and IL-6 and levels of IFN-γ, IL-4 and IL-12 in whole spleen cultures and total blood cultures of the two groups were not significantly different. In conclusion, ELF-EMF may change the $T_H1/T_H2/T_H17$ balance towards down-regulation of T_H1 (decrease of IL-12) type response and upregulation of T_H17 (increase of IL-6) type response.

New light of the il23/th17 in pemphigus foliaceus

O. Abida[1], *S. Krichen-Makni*[1], *D. Bouzid*[1], *A. Masmoudi*[2], *M. Abdelmoula*[1], *M. Ben Ayed*[1], *T. Sellami-Boudawara*[1], *H. Turki*[3], *H. Masmoudi*[1];
[1]*Habib Bourguiba University Hospital, Sfax, Tunisia,* [2]*Hedi Cheker University Hospital, Sfax, Tunisia,* [3]*Hedi Cheker University Hospital, Sfax, Tunisia.*

The pemphigus foliaceus (PF) is considered as a Th2 disease, with a partial shift to Th1 during the remission phase. This classical Th1/Th2 paradigm previously defining PF could be challenged with the recent discovery of Th17 T cells. The IL-23/IL-17 axis plays an important role in many autoimmune skin diseases. The aim of our research was to investigate the expression of IL-23, IL-17 and TNF-α on PF patients and healthy individuals skin biopsies.
Biopsies obtained from 17 PF patients and 17 healthy controls were assessed by immunohistochemical analysis using specific polyclonal antibodies (anti-IL17, anti-IL23 and anti-TNF α). Immunohistochemical staining for IL-17 positive T cells showed the presence of these cells only in PF specimens, but these cells do not appear to be abundant in PF skin (5% of lymphocyte in PF skin). Interestingly, a significant correlation between IL17 expression and antibody titers was observed ($r=0.878$; $p=0.021$). Keratinocytes and dendritic cells in lesional PF skin expressed higher levels of IL-23 compared with normal skin (0.794±0.356 and 24.7% in patients versus 0.588±0.264 and 14.1% in healthy controls, respectively). Specific staining for TNF-α in cryostat sections confirmed the higher expression of this cytokine by monocytes and fibroblastes in PF versus controls skin ($p=0.023$ and $p<0.0001$, respectively). Furthermore, the TNF-α, IL17 and IL23 expression appeared to be significantly correlated in PF skin compared with normal skin, as well.
Taken together, these results suggest that the IL-23/Th-17 axis may play a central role in the pathogenesis of the PF.

P3.10.02
Differential mucosal expression of Th17 related genes between inflamed and non-inflamed colon of patients with Crohn's disease

A. Abidi[1], *N. Lidiraa*[1], *M. Fekih*[2], *N. Ben Mustapha*[2], *K. Hamdi*[1], *B. Neili*[1], *A. Gati*[1], *A. Filali*[2], *A. Ben Ammar-Elgaaied*[1], *R. Marrakchi*[1];
[1]*Faculty of Sciences of Tunis, Tunis, Tunisia,* [2]*La Rabta hospital, Tunis, Tunisia.*

A causal role is attributed to inflammation in several diseases through cellular mediators and cytokines. These molecules are involved in inflammatory bowel diseases including Crohn's disease (CD) and have both tissue-protective and inflammatory effects in the gut.
The main objective of this study is to evaluate the implication of Th17 cells in colonic inflammation in CD. Th17 are considered

developmentally distinct from Th1 and Th2 cells and characterized as preferential producers of interleukin 17A. Th17 lymphocytes are significant and sometimes even decisive in the establishment of a protective immune response during bacterial and fungal infections The expression level of the Th17 related cytokines: IL22, IL17A and the IL23 receptor where compared between inflamed and non inflamed colonic tissues from the same patients.
A total 20 macro-dissected intestinal tissue samples from CD patients were obtained during colonoscopy. The mRNA expression level of each gene was determined by RT-PCR. Evaluation of mRNA expression levels in colonic and control samples from 20 patients revealed that IL17A, IL22 and IL23R were expressed at higher levels in inflamed biopsies.
The increased expression of these genes was predominantly observed in inflammatory samples from CD patients and associated with more intense inflammation. Our findings suggest the implication of Th17 cells in the pathogenesis of CD. This study demonstrates that tissue inflammation in CD patients is clearly associated with increased expression levels of Th17 related cytokines.

P3.10.03
The role of β2 adrenergic receptor signaling during the reciprocal differentiation of Th17 and Foxp3+ Treg cells

***L. P. Araujo**, M. G. Guereschi, M. C. Takenaka, V. M. Nascimento, J. T. Maricato, A. S. Basso;*
UNIFESP, São Paulo, Brazil.

The nervous system can interact with the immune system via the sympathetic nervous system. $CD4^+$ T cells express adrenergic receptors, mainly the β_2 adrenergic receptor (β_2AR). β_2AR signaling in $CD4^+$ T cells seems to impair Th1 differentiation. The aim of this study was to investigate the impact of β_2AR signaling in the reciprocal differentiation of Th17 and $Foxp3^+$ Treg cells. Sorted naïve $CD4^+$T cells ($CD4^+CD62L^+Foxp3^-$) from $Foxp3^{gfp}$ KI mice were cultured with plate bound anti-CD3, IL-6, TGF-β, IL-23, IL-1β, TNF-α, anti-IL-4 and anti-IFN-γ for 3 or 5 days. A specific β_2AR antagonist was administered in the culture. The expression of IL-17A was determined by intracellular cytokine staining and ELISA. We observed that in control cultures about 12-16% of the naïve $CD4^+$ T cells differentiated into IL-17-producing cells. The treatment with the specific β_2AR antagonist did not change the percentage of IL-17-producing $CD4^+$ T cells as compared with control. However, the expression of IL-17 was significantly reduced in cells after β_2AR antagonist treatment. Confirming this result, we also found lower IL-17 levels in the supernatants from cultures treated with the β_2AR antagonist as compared to those observed in control cultures. Following β_2AR blockade, the lower IL-17 production by anti-CD3 activated $CD4^+$ T cells cultured under Th17-skewing conditions was associated with higher frequency of $CD4^+$ T cells expressing Foxp3 (3 day). Our data suggest that the endogenous production of catecholamines can impact the differentiation of Treg cells and the production of IL-17 by CD4+ T cells via β_2 adrenergic receptor signaling.

P3.10.04
Regulation of cytokine gene expression in human T helper cells: role of IL-2 and pSTAT5 in the activation-dependent down-regulation of IL-17 production

***D. Aschenbrenner**, F. Mele, A. Lanzavecchia, F. Sallusto;*
Institute for Research in Biomedicine, Bellinzona, Switzerland.

TH17 cells represent a distinct lineage of CD4+ T helper cells characterized by the production of IL-17A, IL-17F, and IL-22 that are involved in autoimmunity as well as in host defence .In humans,TH17 differentiation is induced by IL-6, IL-1β, IL-23 and TGF-β and requires the activation of transcription factors such as RORγt and STAT3.
Here we show that, following activation, TH17 memory cells transiently down-regulate IL-17 production while, in some cases, up-regulating IL-10 production in a reciprocal manner. Regarding the activation-dependent reciprocal switch from IL-17 to IL-10 production, we demonstrate that IL-17 producing cells can be recovered from activated CD4+ CCR6+ memory T cells which produce IL-10 and that were isolated from peripheral blood or synovial fluid of patients suffering from Juvenile Idiopathic Arthritis (JIA). We further demonstrate that the down-regulation of IL-17 in TH17 cells is accompanied by the down-regulation of RORγt. Based on published on our findings we propose a mechanism of activation-dependent down-regulation of IL-17 that involves the competition of IL-2-induced pSTAT5 with pSTAT3 for binding to the IL-17 locus, thereby reducing IL-17 transcription. Interestingly we further found that also TH2 cells down-regulate their signature cytokine IL-4 upon activation, while the expression of the master transcriptional regulator GATA3 is maintained and IL-2 does not seem to play a role in the process of down-regulation. Inhibition of IL-17 production in activated TH17 cells represents a new regulatory function of IL-2 besides its role in inhibiting TH17 differentiation, and in the development, survival and function of regulatory T cells.

P3.10.05
Identification of a novel subset of human circulating memory CD4(+) T cells that produce both IL-17A and IL-4.

***M. Capone**, L. Cosmi, L. Maggi, V. Santarlasci, V. Querci, F. Liotta, P. Parronchi, E. Maggi, S. Romagnani, F. Annunziato;*
University of Florence, Florence, Italy.

BACKGROUND: IL-17A has been suggested to play a pathogenic role in bronchial asthma and other allergic disorders. OBJECTIVE: Study of the relationship between human IL-17A-producing CD4+ T cells (TH17) and IL-4-producing CD4+ Tcells (TH2). METHODS: T-cell clones generated from the CCR6+CD161+ fraction of human circulating CD4+ T cells, which contains virtually all TH17 cells, as well as circulating CD4+ T cells from both healthy subjects and patients with asthma, were assessed by flow cytometry for their cytokine production profile. RESULTS: A small proportion of CCR6+CD161+CD4+ T-cell clones showed the ability to produce both IL-17A and IL-4 (TH17/TH2). TH17/TH2 clones also produced IL-5, IL-8, IL-9, IL-13, IL-21, and IL-22 and displayed the ability to induce the in vitro secretion of IgE. A very few
TH17/TH2 cells were found among circulating CD4+ T cells from normal subjects, but their proportions were significantly increased in the circulation of patients with chronic asthma. TH17/TH2 cells could not be derived from naive umbilical cord blood CD4+ T cells under any experimental condition. However, when circulating memory CCR6+CD161+CD4+ T cells were cloned under appropriate polarizing conditions, TH17/TH2 clones originated in the presence of IL-4, suggesting that an IL-4-rich microenvironment may induce the shifting of memory TH17 cells into TH17/TH2 cells. CONCLUSION: Because of its peculiar functional properties and the increased numbers in the circulation of patients with bronchial asthma, this previously unknown population of TH17/TH2 cells may play some role in the pathogenesis of this disease.

P3.10.06
Generation of effector T cells from costimulation from immune complexes and complement

***A. Chauhan**, T. Moore;*
Saint Louis University, Saint Louis, MO, United States.

CD4+ T helper (TH) cells are the major driver of host immunity. Costimulation from CD28 is essential for the generation of the CD4+ T effector population. Lack of CD28 costimulatiory signal results in an anergic population. We earlier reported changes associated with T cell activation from signals derived from immune complexes (ICs) and C5b-9, a byproduct of complement activation. Now we report that the signal from the ICs and C5b-9 successfully substitutes for the CD28 requirement in generation of IL-17A+ and IL-22+ populations. Further activated CD4+ T cells engage ICs via FcγRIIIA and produce high levels of IFN-γ. T-bet was not required for this IFN-γ production. IFN-γ contributes to tissue damage and regulates the function of TH17 and Treg cells by inducing T-bet. Elevated levels of ICs are present in infections, cancers, and their defective clearance lead to the development of autoimmunity. In such scenarios, IFN-γ produced from IC stimulation could influence the expression of key regulators of peripheral tolerance such as PD1 and ICOS. Thus, we demonstrate the first non-membrane associated costimulator and new IFN-γ producing population that is FcγRIIIA+. These results are vital for

understanding the disease pathology and for the development of safe biological therapies. In many patients biologics upon infusion forms ICs.

P3.10.07
Role of Notch receptor signaling in CD4+ T helper 1 and T helper 17 cell differentiation

M. Coutaz[1], *F. Auderset*[1], *S. Schuster*[1], *F. Radtke*[2], *F. Tacchini-Cottier*[1];
[1]*Department of Biochemistry, WHO Immunology Research and Training Center, University of Lausanne, Epalinges, Switzerland,* [2]*School of Life Sciences, Swiss Institute for Experimental Cancer Research, EPFL, Lausanne, Switzerland.*

CD4+ T helper cells (TH) are involved in host defense to pathogens and in the maintenance of immune homeostasis. Upon antigen-specific recognition, naive CD4+ T cells differentiate into several functionally distinct subsets of CD4+ TH cells characterized by the secretion of a specific pattern of effector cytokines. A relationship between TH1 and TH17 cells has been reported, illustrated by counter-regulation and also by the plasticity of TH17 cells that can differentiate into TH1 cells. However, the mechanisms involved in this control are not defined. Among the different factors contributing to the differentiation of CD4+ TH cells, Notch receptor signaling has been reported to influence either the differentiation and/or the function of CD4+ TH cells. To investigate the contribution of Notch signaling in the control of TH1 and TH17 cell functions, mice carrying a T cell-specific deletion of both Notch1 and Notch2 (N1N2ΔCD4Cre) were infected with the protozoan parasite Leishmania major. Despite their resistant C57BL/6 genetic background, N1N2ΔCD4Cre mice were unable to control lesion development and parasite growth, due to impaired secretion of IFN-γ by TH1 cells. Moreover, upon restimulation with L. major, the absence of Notch receptors also prevented the secretion of TH17 cytokines by dLN cells. These results demonstrate a new crucial role for Notch signaling in the differentiation of functional TH1 and TH17 cells during the course of this infection. Furthermore, they suggest that the modulation of Notch signaling in immune responses involving both TH1 and TH17 immunity could impact on disease development.

P3.10.08
Defective Th17 development in human neonatal T cells involves reduced RORC2 mRNA content

S. De Roock*, A. Stoppelenburg, R. Scholman, S. Hoeks, J. Meerding, B. Prakken, M. Boes;*
Laboratory for Translational Immunology, Wilhelmina Childrens Hospital, UMC Utrecht, Utrecht, Netherlands.

The neonatal immune system shows an impaired response upon activation compared to adults. This phenomenon may involve $FOXP3^+$ regulatory T cells (Treg) and Th17 cells.
In order to investigate this, we compared $CD4^+CD25^-CD45RO^-$ naive T cells from human cord blood (CB) with cells from adult peripheral blood (APB). Cells were activated *in vitro* by anti-CD3 in the presence of viable antigen presenting cells (APC). The induction of regulatory T cells and Th17 cells was analysed by flow cytometry. Cytokine production was measured by multiplex immunoassays and RORC and IL-17 mRNA content by PCR.
Activation of CB cells resulted in a significantly higher percentage of functional Treg than in APB. No Th17 cells were observed in CB, whereas in APB cultures IL-17, IL-21 and IL-22 were produced in significant quantities. As inflammatory cytokines produced by APC have a major role in directing T cells towards a Th17 phenotype, we tested IL-1β and IL-6 concentration in cell culture supernatants. High amounts of these cytokines were found in APB, but not in CB cultures. Addition of recombinant cytokines IL-1β, IL-6 or IL-23 could not imprint a Th17 phenotype in CB cells, but merely reduced the amount of induced Treg. Measurement of RORC2 mRNA - coding for RORγT protein, the Th17 defining transcription factor - showed a significantly lower content in CB compared to APB after activation.
These data show that factors upstream of RORC transcription can prevent Th17 development and can have implications for understanding Th17 and Treg development and neonatal immune maturation.

P3.10.09
Phagocytosis of different source of infected apoptotic cells: does a trigger to Th17 or Th1 differentiation?

N. N. Dejani[1], *F. F. Verdan*[1], *V. E. Nino*[2], *F. N. Dias*[2], *A. C. G. Salina*[2], *A. I. Medeiros*[2];
[1]*USP, Ribeirao Preto, Brazil,* [2]*Unesp, Araraquara, Brazil.*

Phagocytosis of infected apoptotic cells (ACs) with *Escherichia coli* by dendritic cells (DCs) promotes the production of anti-inflammatory cytokines such as TGF-β but also pro-inflammatory cytokines as IL-6 and IL-23 and these cytokines microenvironments induce the Th17 differentiation. The *aim* of our study is to understand whether distinct sources of PAMPs could trigger the same immunostimulatory effect. Therefore, we co-cultured DC with apoptotic cells infected with Gram-negative and Gram-positive bacteria to evaluate the cytokine profiles produced in response to efferocytosis by dendritic cells. As a source of infected apoptotic cells, C57BL/6J mice were intraperitoneally injected with 1 mL thioglicollate plus live *E. coli* or live *Streptococcus pneumoniae,* and 13 h later the cells were collected from peritoneal cavity lavage. Then, these infected apoptotic neutrophils were irradiated with UV (350mJ) to induce apoptosis. BMDC were co-cultured at 1:3 ratio with both infected apoptotic neutrophils during 18h and supernatant was collected for the *measurement* of IL-1α, IL-1β, IL-6 and TGF-β by ELISA. Our results showed that distinct cargo of infected apoptotic cells induced a differential cytokine profile, such as IL-1α (AC+*E.coli*, 255±51 and AC+*S.pneumoniae*, 986.7±59.8 pg/ml) and IL-1β (AC+*E.coli,* 803±17 and AC+*S.pneumoniae,* 1439 ±170.4 pg/ml), TGF-β (AC+*E.coli,* 705±31 and AC+*S.pneumoniae,* 509±81) and IL-6 (AC+*E.coli,* 26740±1109 and AC+*S.pneumoniae*, 2625±363.5 pg/ml). Our results show that DCs are able to discriminate differentially the cargo from infected apoptotic cells and the next step is to further understand how it impacts the adaptive response.

P3.10.10
Cytokine regulation of immunopathology in *Echinococcus multilocularis*

X. Ma[1], *L. Luo*[2], ***J. B. Ding***[3], *Y. Zhu*[2], *N. Pang*[2], *H. Wen*[2];
[1]*1st Affiliated Hospital of Xinjiang Medical University, Urumqi,Xinjiang, China,* [2]*First affiliated hospital of Xinjiang Medical University, Urumqi,Xinjiang, China,* [3]*Department Immunolgy, Xinjiang Medical University, Urumqi,Xinjiang, China.*

Alveolar echinococcosis (AE) is a rare but potentially fatal disease. It is caused by infection with the larval (metacestode) stages of Echinococcus multilocularis (Em). A Th1 / Th2 imbalances is the most important immunologyical change in the course of a parasitic infection. Th17 cells have been identified as a new subset of T helper cells and several cytokines are involved in regulating their activation and differentiation. Th17 cells and IL-17 play an important role in the parasitic diseases. During the course of E.m infection course, our results showed a trend of constantly increasing levels of IL-17 was observed. IL-17 levels were elevated significantly ($P < 0.05$, respectively) at 6 and 10 month post-infection. TGF-β1 concentration was also elevated significantly at 6 and 10 months. Levels of IL-6 reached a maximum at 2 days post-infection , then dropped at 1 month, followed by a steady rise until 2 months. Levels of IFN-γ increased after Em infection, reaching a peak at 3 months, and decreased thereafter. IL-4 levels remained low until 2 months, and increased after 3 months. TGF-β was highly expressed in the late infection, and showed a similar phase variation to IL-17, which indicates that TGF-β1 may have a important role in promoting Th17 cell differentiation. With the growth of hydatid cysts, this process, and not a serious inflammation reaction infiltration formed the fibre layer and separated the hydatid cyst from the host tissue. This protective mechanism can effectively evade the host immune response.

P3.10.11
Pharmacological modulation of epigenetic regulation of Treg and Th17 differentiation in vitro

M. Fritz[1], *C. Doñas*[1], *V. Manriquez*[2], *G. Tejon*[2], *M. Bono*[2], *A. Loyola*[1], *M. Rosemblatt*[1,2,3];
[1]*Fundacion Ciencia & Vida, Santiago, Chile,* [2]*Facultad de Ciencias, Universidad de Chile, Santiago, Chile,* [3]*Facultad de Ciencias Biologicas, Universidad Andres Bello, Santiago, Chile.*

Depending upon signals from innate immune cells induced by pathogenic agents, naïve $CD4^+$ T cells differentiate into several effector fates including T helper 1 (Th1), Th2, and Th17. Also, instead of becoming effector cells, $CD4^+$ T cells can become regulatory cells that help in suppressing immune responses. These effector and regulatory $CD4^+$ T cell lineages protect the body from infection but, in some cases, contribute to autoimmunity and inappropriate inflammation. Although transcription factors are critical in regulating cellular differentiation, epigenetic factors also play important roles in T cell differentiation. Posttranslational modifications of histones, such as acetylation and methylation, are implicated in regulating gene expression by controlling chromatin structure and DNA accessibility.
We aimed to pharmacologically modulate the differentiation of Th17 and Treg cells *in vitro*, by altering the acetylation and methylation status of histone H3.
We show that the methyltransferase inhibitor Methylthioadenosin (MTA) decreases the differentiation of naïve $CD4^+$ T cells towards Th17 cells *in vitro* in nearly 50%, while increasing global H3K27me3 levels, without affecting the differentiation towards Tregs.
In the other hand, the histone deacetylase inhibitor Trichostatin A (TSA) increases the differentiation of naïve $CD4^+$ T cells towards Tregs nearly 10%, with a concomitant increase in global H3ac levels. Moreover, Tregs generated in the presence of TSA showed increased suppressive function, probably by mechanisms involving CD39 and CD73.
Our work suggests that epigenetic drugs could be used to modulate the differentiation and function of Th17 and Tregs. [Financed by Fondecyt 1100448 (MR),1100557 (MRB), 1120170 (AL)]

P3.10.12
Independent molecular control of IL-17 and IL-22 in the human Th17 response

M. Cardone[1], *L. Provezza*[2], *E. Zoratti*[2], *O. Poffe*[2], *A. Dzutsev*[1], *E. Wang*[3], *G. Batoni*[4], *G. Carra*[2], *G. Trinchieri*[1], ***F. Gerosa***[2];
[1]*Center for Cancer Research, National Cancer Institute, Frederick, MD, United States,* [2]*Dipartimento di Patologia e Diagnostica, Universita' di Verona, Verona, Italy,* [3]*Department of Transfusion Medicine, National Institutes of Health, Bethesda, MD, United States,* [4]*Dipartimento di Ricerca Traslazionale e Nuove Tecnologie, Pisa, Italy.*

IL-17 and IL-22 are cytokines considered distinctive of Th17 cells and associately produced by such cells. To approach the problem of the relationship in the expression of IL-17 and of IL-22 we analyzed the production of these cytokines, as well as of IFN-γ, in memory Th cells specific for Candida albicans, commonly regarded as a classic exemple of Th17 cells, or for M. tuberculosis, a pathogen which requires production of IFN-γ for resolution of infection. Moreover, naïve $CD4^+$ T cells were cultured in the presence of Th17-promoting mixture of IL-1β, IL-6 and IL-23 or supernatant from DCs stimulated with zymosan (SNDCzym), or perturbating these microenvironments using various combinations of IL-1β, IL-6 and IL-23, or with SNDCzym in which various combinations of IL-1β, IL-6, IL-12 and IL-23 have been neutralized using specific antibodies or IL-1RA.
Ex vivo, M. tuberculosis-specific memory Th cells express IFN-γ, while IL-17 and IL-22 cells are virtually absent; candida-specific memory Th cells expressed consistent percentages IL-17, IL-22 or IFN-γ, with a significant correlation between expression of IL-17 and IL-22 in different donors, suggesting a dependent expression of IL-17 and of IL-22 in these memory cells.
However, in naive Th cells, perturbation of the Th17-promoting microenvironments identified (a) an independent production of IL-17 and of IL-22, depending on the combination of the cytokines IL-6, IL-23 and IL-1, which played pivotal and sometimes opposing roles in the regulation of IL-17, IL-22 and IFN-γ expression, (b) correlation profiles between Th effector cytokines and Th – associated genes, including transcriptional regulators.

P3.10.13
Transfection of human naïve $CD4^+$ T-cells with mir-326 and study of their differentiation to Th-17 cell

M. Ghayedi, *P. Rahimzadeh, S. Morteza Gholi, H. Namdari, F. Noorbakhsh, E. Salehi;*
Tehran University of Medical Science, Tehran, Iran.

Th17 cells are known to play a critical role in adaptive immune responses to several important extracellular pathogens. T helper 17 (Th17) cells have important roles in autoimmune diseases, inflammatory immune responses and cancers.Therefore, it is essential to understand the mechanisms that regulate Th17 differentiation. The development of T cells is also controlled by complex protein signalling networks that are subject to regulation by miRNAs. Here, we report invitro differentiation of naïve CD4+ Tcells to Th17 cells in the presence of miR-326. Naïve $CD4^+$ T cells were isolated from normal blood samples and cultured in X-VIVO 20 serum-free medium. Purified cells were treated with combinations of polarizing cytokines (TGF-β, IL-1β,IL-23 and IL-21) and miR-326 followed by analysis of the expression of characteristic genes and their relevant cytokines by real-time quantitative RT-PCR and flowcytometry method, respectively. Our studied showed that cells transfected with miR-326 could produce more Il-17 compared to cells differentiated in Th17-polarizing conditions, as determined by protein and mRNA levels detected by flow cytometry and Real Time PCR. IFN-γ was also slightly increased in T cells transfected with miR-326 compared to cells stimulated by cytokines. Our data show a critical role for miR-326 in Th17 differentiation and cytokines related to this subset.

P3.10.14
Activation of TGF-β-induced non-Smad signaling pathways during Th17 differentiation

S. Haupeltshofer[1], *M. Hasan*[2], *B. Neumann*[2], *K. Angstwurm*[2], *R. Gold*[1], *I. Kleiter*[1];
[1]*Neurology department, Bochum, Germany,* [2]*Neurology department, Regensburg, Germany.*

T helper (TH)17 cells, a proinflammatory subset of effector T cells, are involved in the pathogenesis of autoimmune diseases such as multiple sclerosis. Although the cytokine TGF-β has been shown to positively regulate the development of murine interleukin (IL)-17 producing CD4+ T cells, the canonical Smad-dependent intracellular signaling pathway seems to be dispensable for TH17 differentiation. By using a protein antibody array we characterized the phosphorylation status of signaling proteins downstream of the TGF-β receptor during differentiation of naïve murine CD4+CD62L+ T cells to the TH17 phenotype. To identify Smad-independent signaling pathways we compared the protein phosphorylation between wild type T cells and T cells with overexpression of the Smad pathway inhibitor Smad7. We found that proteins of the PI3K/AKT/mTOR pathway are activated at specific phosphorylation sites during TH17 differentiation, independently of Smad signaling. Pharmacological inhibition of these pathways caused decreased IL-17 production by differentiated TH17 cells in vitro. Our data show that Smad-independent intracellular signaling pathways contribute to TGF-β-induced TH17 differentiation, and expand our understanding of inflammatory pathways relevant for multiple sclerosis.

P3.10.15
The aryl hydrocarbon receptor: differential contribution to Th17 and Tc17 development

M. D. Hayes, *V. Ovcinnikovs, I. Kimber, R. J. Dearman;*
The University of Manchester, Manchester, United Kingdom.

The aryl hydrocarbon receptor (AhR) has been shown to play an important role in the polarization of T helper (Th) cell subsets; specifically it is required for optimal Th17 cell activation. Th17 cells

provide immunity against extracellular pathogens and are implicated in autoimmune and allergic diseases. An analogous subset of T cytotoxic (Tc) cells, designated Tc17, has also been identified but their dependence upon the AhR is relatively unknown. In the current investigations the role of the AhR in cytokine production by Th17 and Tc17 cells has been compared. Tc (CD8+) and Th (CD4+) cells were isolated by negative selection from the peripheral lymph nodes of naive mice and polarized with plate-bound anti-CD3 and anti-CD28 antibodies and appropriate cytokine cocktails (Th1/Tc1: interleukin [IL]-12; Th17/Tc17: IL-6, transforming growth factor-β and IL-1β). Cell differentiation was assessed as a function of mRNA and protein expression for interferon-γ and key IL-17 cytokines. Both Tc17 and Th17 cells displayed a type 17 profile demonstrated by relatively low interferon-γ and high IL-17 and IL-22 production. Using a selective AhR antagonist (CH-223191), Th17 and Tc17 cell activity was reduced significantly. In contrast, addition of the natural AhR agonist 6-formylindolo[3,2-b]carbazole (FICZ) markedly enhanced cytokine expression for Th17 cells only. These data demonstrate that the optimal development of Th17 cells is much more dependent upon AhR activation than is the development of Tc17 cells, thus endogenous AhR ligands play a much greater role in driving Th17 cell responses in vitro.

P3.10.16
T cell-dependent IgA induction by plastic Th17 cells

[1]*MRC National Institute for Medical Research, London, United Kingdom,* [2]*WPI iFReC, Osaka University, Osaka, Japan,* [3]*Department of Lymphocyte Physiology, IGC, Oeiras, Portugal,* [4]*III. Medizinische Klinik, Universitätsklinikum, Hamburg-Eppendorf, Germany.*

Th17 cells are an essential T helper subset for the mucosal host defense against extracellular pathogens. Effector functions of Th17 have been studied in terms of neutrophil migration and the induction of anti-microbial peptides in epithelial cells. However, a Th17-mediated humoral immune response remains largely unknown. We investigated whether Th17 cells are responsible for antigen-specific immunoglobulin (Ig) A response at mucosal sites. IgA secreted in the lumen is important for the neutralization of toxins and response to pathogens, but also critically involved in shaping the diversity of the commensal microbiota. Intestinal Peyer's patches are essential lymphoid organs for the generation of T cell-dependent IgA production for gut homeostasis. Using IL-17 fate reporter mice we show that endogenous Th17 cells in lymphoid organs of naïve mice home preferentially to the intestine and are maintained independently of IL-23. In Peyer's patches such Th17 cells acquire a T follicular helper (Tfh) phenotype with high levels of Bcl-6, IL-21, CXCR5 and PD-1 following the downregulation of IL-17 and Rorgt and induce the development of IgA-producing germinal center B cells. Bone marrow (BM) chimera mice deficient in Th17 cells (Rorc-/- BM to Tcra-/-) fail to generate antigen specific IgA responses following a single challenge with cholera toxin, providing evidence that Th17 cells are the crucial subset required for high affinity T cell-dependent IgA production.

P3.10.17
A novel assay format for ELISA measurement of antigen-specific human IL-21 production by peripheral mononuclear cells

J. Y. Huang*, C. Ehrnfelt, T. Bengtsson, S. Paulie, N. Ahlborg;*
Mabtech AB, Stockholm, Sweden.

Interleukin (IL)-21 regulates the activation and development of NK, B and T cells. Dysfunctional regulation of IL-21 has been implicated in several conditions, in particular autoimmune diseases. *In vitro* studies of IL-21 are thus of high relevance and functional methods for the quantitation of IL-21-levels as well as IL-21-producing cells are vital. The aim herein was to develop ELISA and ELISpot assays for *in vitro* analysis of IL-21-levels and IL-21-producing cells, respectively.
Monoclonal antibodies (mAb) to hIL-21 were made. Several mAbs identified, neutralized the biological effect of IL-21 as measured by inhibition of IL-21-induced IgG production in human PBMC.
By ELISpot, high numbers of IL-21-producing cells were found after stimulation (Phytohaemagglutinin; PHA) of human PBMC, weaker but positive responses were also observed after antigen-specific stimulation with *Candida albicans* extract or Tetanus toxoid. In contrast, demonstration of IL-21-levels in cell culture supernatants by ELISA was only feasible after PHA stimulation. Hypothesizing is that the lack of detection of antigen-induced IL-21 in cell supernatants was due to cellular receptor consumption of IL-21 during cell culture. PBMC were stimulated with antigen in the presence of the neutralizing anti-IL-21-detection mAb. Following this procedure, it was possible to measure IL-21 by ELISA also after antigenic stimulation.
Addition of a neutralizing antibody to the cell culture enables detection of antigen specific human IL-21-produced by human PBMC and may generally facilitate the analysis of IL-21 in *in vitro* cultures. This strategy may be applicable also to the ELISA analysis of other cytokines/factors that are difficult to detect.

P3.10.18
Ecto-nucleoside triphosphate diphosphohydrolase 7 controls Th17 cell responses through regulation of luminal ATP in the small intestine

H. Kayama*, T. Kusu, K. Takeda;*
Graduate School of Medicine, Osaka University, Suita, Japan.

Extracellular ATP is released from live cells in controlled conditions, as well as dying cells in inflammatory conditions, and, thereby, regulates T cell responses, including Th17 cell induction. The level of extracellular ATP is closely regulated by ATP hydrolyzing enzymes, such as ecto-nucleoside triphosphate diphosphohydrolases (ENTPDases). ENTPDase1/CD39, which is expressed in immune cells, was shown to regulate immune responses by downregulating the ATP level. In this study, we analyzed the immunomodulatory function of ENTPDase7, which is preferentially expressed in epithelial cells in the small intestine. The targeted deletion of Entpd7 encoding ENTPDase7 in mice resulted in increased ATP levels in the small intestinal lumen. The number of Th17 cells was selectively increased in the small intestinal lamina propria in Entpd7(-/-) mice. Th17 cells were decreased by oral administration of antibiotics or the ATP antagonist in Entpd7(-/-) mice, indicating that commensal microbiota-dependent ATP release mediates the enhanced Th17 cell development in the small intestinal lamina propria of Entpd7(-/-) mice. In accordance with the increased number of small intestinal Th17 cells, Entpd7(-/-) mice were resistant to oral infection with Citrobacter rodentium. Entpd7(-/-) mice suffered from severe experimental autoimmune encephalomyelitis, which was associated with increased numbers of CD4(+) T cells producing both IL-17 and IFN-γ. Taken together, these findings demonstrate that ENTPDase7 controls the luminal ATP level and, thereby, regulates Th17 cell development in the small intestine.

P3.10.19
Human Th17 cells: a unique cell type in health and disease

K. Ko[1]*, M. S. Powell*[1]*, E. Orlowski*[1]*, S. Prickett*[2]*, D. Krumbiegel*[3]*, P. Hogarth*[1]*;*
[1]*Burnet Institute, Melbourne, Australia,* [2]*Monash University, Melbourne, Australia,* [3]*SA Pathology, Adelaide, Australia.*

Human Th17 cells, an effector memory $CD4^+$ T helper cell subset, are important for releasing pro-inflammatory cytokines in bacterial immunity. In disease, Th17 cells have been detected in the active sites of inflammation such as in the synovial fluid of arthritic joints.
To study the rare population of Th17 cells we have developed a method for the isolation, expansion and long term culture of human Th17 cells (cells that exclusively produce IL-17A upon activation), to compare its unique characteristics to Th1 cells (produces IFN, and not IL-17A) and Th17 polyfunctional cells (cells capable of co-producing high levels of IL-17A and IFN). Th17 cells and Th17 polyfunctional cells selected for by the surface markers CCR6 and CCR4, while the Th1 cells lack both. The cells are cultured without polarising cytokines and are stably committed to being characteristically a Th17, Th1 or Th17 polyfunctional cell in the long term *in vitro* culture, even upon additional restimulations with antigen presenting cells to further expand cell number. Typically up to $1x10^7$ cells is expanded from the initial seeding of 2 cells per well.

Comparative analysis of gene expression between the three cell subsets has allowed for the identification of markers unique upregulated in Th17 cells from healthy peripheral blood, and also comparative differences with cells sourced from an active site of inflammation.
This characterisation of Th17 cells will enable a better understanding of the potential pathogenic nature of this rare cell type, enabling specific targeting in both basic research and clinical therapeutics for disease.

P3.10.20
Therapeutic effect of RORγt-DNA-binding domain in TH17-mediated Autoimmune diseases

***S. Lee**, T. Park, S. Park, J. Cho, N. Kim;*
Yonsei university, Seoul, Republic of Korea.

Interleukin (IL)-17 secreting T helper cell, T_H17 plays a crucial role in causing autoimmune diseases such as experimental autoimmune encephalomyelitis (EAE) which is an animal model of multiple sclerosis (MS). Although previous studies reported the molecular and cellular mechanisms by which EAE is induced, a therapeutic drug that cures the disease by modulating T_H17 differentiation and its function has not been developed yet. Transforming growth factor (TGF)-beta1/IL-6 and IL-21 induced T_H17 differentiation required expression of a transcription factor, retinoic acid receptor-related orphan receptor gamma t (RORγt). Here, we demonstrate that a cell permeable form of DNA-binding domain (DBD) of RORγt (tRORγt-TMD) competitively inhibits the functions of endogenous RORγt while its ligand-binding domain (RORγt-LBD) does not achieve such effects. In the presence of HH-RγD, $CD4^+CD25^-CD62L^{high}$ naïve T cells couldn't differentiate into T_H17 but it was shown that such treatment did not entail any inhibitory effects against T_H1 or T_H2 differentiation, which suggests T_H17-specific functionality of HH-RγD. EAE treated with HH-RγD significantly reduced clinical severity/incidence of EAE and showed a dramatic reduction in the number of inflammatory cell infiltration into the central nervous system (CNS). In summary, we demonstrate that a HH-RγD can selectively control T_H17 differentiation *in vivo* and *in vitro*, and can be a novel therapeutic reagent to treat many inflammatory diseases associated with T_H17.

P3.10.21
Distinctive features of classic and nonclassic (Th17 derived) human Th1 cells

***A. Mazzoni**, L. Maggi, V. Santarlasci, M. Capone, M. Rossi, V. Querci, F. Liotta, E. Maggi, L. Cosmi, F. Annunziato;*
University of Florence, Florence, Italy.

T helper17 (Th17) lymphocytes represent a third arm of the CD4(+) T-cell effector responses, in addition to Th1 and Th2 cells. Th17 cells have been found to exhibit high plasticity because they rapidly shift into the Th1 phenotype in inflammatory sites. In humans, Th1 cells derived from Th17 cells express CD161, whereas classic Th1 cells do not; these Th17-derived Th1 cells have been termed nonclassic Th1 cells. In this study, we examined similarities and differences between classic and nonclassic human Th1 cells by assessing a panel of T-cell clones, as well as CD161(+) or CD161(-) CD4(+) T cells derived ex vivo from the circulation of healthy subjects or the synovial fluid of patients with juvenile idiopathic arthritis. The results show that nonclassic Th1 cells can be identified based on CD161 expression, as well as the consistent expression of retinoic acid orphan receptor C, IL-17 receptor E, CCR6, and IL-4-induced gene 1, which are all virtually absent in classic Th1 cells. The possibility to distinguish these two-cell subsets by using such a panel of markers may allow the opportunity to better establish the respective pathogenic roles of classic and nonclassic (Th17 derived) Th1 cells in different chronic inflammatory disorders.

P3.10.22
Discovery of potent and selective retinoid related orphan receptor gamma (ROR-Gamma) inverse agonists for the treatment of Th17 mediated diseases

***K. Nellore**, M. Bejugam, A. Ramanathan, S. Mukherjee, A. Lakshminarasimhan, S. S. Dodheri, N. Rao, R. Damarla, S. Samajdar, H. Subramanya;*
Aurigene Discovery Technologies Ltd., Bangalore, India.

Background: Th17 cells play a key pro-inflammatory role in a variety of autoimmune diseases. The nuclear hormone receptor RORγ controls the differentiation of Th17 cells and expression of IL-17. Methods: Novel RORγ inverse agonists were designed using structure and knowledge based methods. Compounds were screened in a RORγ radio-ligand binding assay using ^3H 25-Hydroxycholesterol, as well as in a cell based reporter assay to demonstrate inverse agonism. Selected compounds were screened against RORα to evaluate selectivity. Crystal structure of RORγ in complex with known inverse agonists as well as novel compounds, were solved. Th17 differentiation assay was developed using primary mouse CD4+ve T-cells to determine functional effect of the compounds. Pharmacokinetic profile in mice was determined for selected compounds. Results: Novel hits from multiple structural classes have been identified, with IC_{50} in the range of 5 - 500 nM in binding assay. Compounds from the lead series demonstrated good activity (< 1 μM) in reporter assay. Co-crystal structure of novel compounds clearly showed the mode of binding. Several compounds demonstrated > 10 fold selectivity against RORα in a reporter assay. Compounds from multiple series have shown significant inhibition of IL-17 release from differentiated Th17 cells. Lead compounds have shown good pharmacokinetic properties in mice. Conclusions: We have identified novel and structurally diverse small molecule inverse agonists of RORγ. Selectivity against RORα and cell based activity has been demonstrated for compounds from multiple series. Relevant efficacy models have been established and profiling of lead compounds in these models in on-going.

P3.10.23
Unravelling the transcriptional circuit regulating IL-10 production in human Th17 cells

***S. Notarbartolo**[1], D. Aschenbrenner[1], A. Lanzavecchia[1,2], F. Sallusto[1];*
[1]Institute for Research in Biomedicine, Bellinzona, Switzerland, [2]ETH, Zurich, Switzerland.

IL-17 producing $CD4^+$ cells (Th17) are a subset of effector T helper cells known to play an important role in host defence against fungi and extracellular bacteria, but also involved in tissue inflammation and autoimmune diseases, such as multiple sclerosis, inflammatory bowel disease, and rheumatoid arthritis. The function of Th17 cells depends critically on the range of cytokines produced and on the balance between pro- and anti-inflammatory cytokines. Autoreactive Th17 cells producing IFN-γ and GM-CSF are pathogenic in a mouse model of EAE, while Th17 cells producing IL-10 are not. We have recently shown that *C. albicans*-specific human Th17 cells produce IL-17 and IFN-γ, while *S. aureus*-specific human Th17 cells produce IL-17 and, after restimulation, IL-10. While the ontology of the two different Th17 subsets has been clarified, it still remains elusive what is the transcriptional circuit that regulates the expression of the immunoregolatory molecule IL-10. Using a combination of transcriptional profiling and epigenetic approach, we identified the transcription factor c-MAF as a candidate for the regulation of IL-10 production in human Th17 cells, thus potentially representing a discriminant factor between pathogenic and non pathogenic Th17 cells.

P3.10.24
Differential regulation of T cell responses and disease severity by mycoplasma and its superantigen in autoimmune diabetic mice

***M. M. Nourian**, H. Mu;*
University of Utah School of Medicine, Salt Lake City, UT, United States.

Infection has been extensively documented as a serious problem causing high mortality and morbidity in diabetic populations. Due to the complex nature of immunological mechanisms, little is known regarding how an infection affects the outcomes of diabetes. Our laboratory has previously established a mouse model of septic shock by infecting mice with the Mycoplasma arthriditis. M. arthritidis produces a potent superantigen (SAg) MAM, which has been shown to be at least partially responsible for the lethal toxicity induced in certain susceptible mouse strains. In the present study, we have investigated how diabetic immune cells respond to the M. arthritidis and MAM SAg. By using two well-defined animal models of diabetes, STZ and NOD mice, we found that STZ mice infected with M. arthritidis developed severe lethal toxicity and the immune cells predominantly produced pro-inflammatory cytokines TNFα, IL-6, IL-1β, chemokines CCR2/4 and Tbx21, a Th1-related transcription factor; while MAM-activated T cells from NOD mice display a mixture of Th1 and Th17 profiles which are associated with the elevated levels of ICOS molecule and a unique transcription factor LSF (tfcp2). Since ERK, a signaling protein of MAPK family, is reported to be responsible for the phosphorylation of LSF in T cell activation, we propose a novel ERK-LSF-ICOS signaling cascade is required for the Th1/Th17 development in NOD mice in response to MAM. Our findings further suggest that the inhibition of these molecules might be potentially therapeutic in the alleviation of mortality and morbidity in diabetic individuals with severe infections.

P3.10.25
Th17 and IL17 expression in Autoimmune Polyendocrine Syndrome Type 1 and Addison disease: what's the difference?

A. Parolo[1]*, R. Scarpa*[1]*, C. Agostini*[1]*, C. Betterle*[2]*;*
[1]Allergology and Clinical Immunology, Department of Medicine, University of Padova, Padova, Italy, [2]Division of Endocrinology, Department of Medicine, University of Padova, Padova, Italy.

Introduction: Autoimmune Polyendocrine Syndrome Type 1 (APS-1) is an autosomal recessive disorder caused by mutations in AIRE; patients are often affected by chronic mucocutaneous candidiasis (CMC). There are increasing evidences that T cell subpopulation Th17 is involved in protection against *Candida* species infections. Addison disease (AD) is the most common cause of autoimmune primary adrenal cortex insufficiency.
Aim: Evaluate Th17 cells in APS-1 patients with CMC and in AD.
Materials and methods: We studied 8 APS-1 patients with CMC and 14 patients affected by AD (not APS-1). As controls we considered 20 healthy volunteers. Flow cytometry analysis using monoclonal antibodies against CD3, CD4, CD8, CD5, CD19, CD56, CD16, CD57 was performed; Th17 population was studied using monoclonal antibodies against IL23R and IL17. We determined the RORγt expression, a transcriptional factor involved in Th17 differentiation, with real time PCR .
Results: In APS-1 patients we found an increased level of IL23R and increased expression of RORγt; IL17 was normal. In patients with AD we observed an increase of IL23R and IL17; RORγt was normally expressed. In healthy group IL23R, IL17 and RORγt were normal.
Discussion: Our findings reveal an interesting difference between APS-1 suffering from CMC and the AD patients: while Th17 count was increased in both groups, IL17 was increased only in patients with AD; furthermore in APS-1 patients there was a higher expression of RORγt. This suggests a function impairment of IL17 in ASP-1, probably due to autoantibodies against IL17 recently described in these patients.

P3.10.26
The kinase PKCα selectively upregulates interleukin-17A during Th17 cell immune responses

M. Meisel[1]*, N. Hermann-Kleiter*[1]*, R. Hinterleitner*[1]*, T. Gruber*[1]*, K. Wachowicz*[1]*, **C. Pfeifhofer-Obermair***[1]*, F. Fresser*[1]*, M. Leitges*[2]*, C. Soldani*[3]*, A. Viola*[3]*;*
[1]Medical University, Innsbruck, Austria, [2]The Biotechnology Center of Oslo, Oslo, Norway, [3]Instituto Clinico Humanitas, Milan, Italy.

Transforming growth-factor β (TGFβ) has been implicated in T helper 17 (Th17) cell biology and in triggering the expression of interleukin-17A (IL-17A), which is a key Th17 cell cytokine. Deregulated Transforming growth-factor β receptor (TGFβR) signaling has been implicated in Th17-cell-mediated autoimmune pathogenesis. Nevertheless, the full molecular mechanisms involved in the activation of the TGFβR pathway in driving IL-17A expression remain unknown. Here, we identified protein kinase C α (PKCα) as a signaling intermediate specific to the Th17 cell subset in the activation of TGFβRI. We have shown that PKCα physically interacts and functionally cooperates with TGFβRI to promote robust SMAD2-3 activation. Furthermore, PKCα-deficient (Prkca(-/-)) cells demonstrated a defect in SMAD-dependent IL-2 suppression, as well as decreased STAT3 DNA binding within the Il17a promoter. Consistently, Prkca(-/-) cells failed to mount appropriate IL-17A, but not IL-17F, responses in vitro and were resistant to induction of Th17-cell-dependent experimental autoimmune encephalomyelitis in vivo.

P3.10.27
IL-17 is predominantly expressed by neutrophils, but Th17 cells are associated with survival in cervical cancer

S. Punt*, E. Kritikou, G. Fleuren, E. S. Jordanova, A. Gorter;*
Leiden University Medical Center, Leiden, Netherlands.

Cervical cancer is the fourth leading cause of death by cancer in women worldwide. The role of IL-17 in cancer, produced both by Th17 and innate immune cells, has remained unresolved. We studied the phenotype of IL-17 expressing cells in 26 cervical, head and neck, ovarian, endometrial, prostate, breast, lung and colon carcinoma specimens using immunohistochemical double and immunofluorescent triple stainings. In cervical cancer, the majority of IL-17 positive cells were present in the tumor stroma, 66% neutrophils (CD15 positive), 23% mast cells (tryptase positive), 8% innate lymphoid cells (CD127 positive) and 3% Th17 cells (CD3 positive). 82% of the neutrophil population expressed IL-17, compared to 1% of the $CD3^+$ T cells. Neutrophils were the large majority (21-69%) of the IL-17 positive cell population in the six other cancer types, compared to a minority (maximum of 6%) of Th17 cells. Also in these other cancer types, the majority of neutrophils expressed IL-17 (43-92%), compared to a maximum of 1% of T cells. The effect of the IL-17 expressing cells on clinico-pathological parameters was studied in 160 cervical cancer specimens. Although there was no effect of the number of IL-17 positive cells, neutrophils or mast cells on survival (based on the median number of cells), Th17 cells were positively correlated with improved survival (p=0.02). A high number of IL-17 positive cells and neutrophils were correlated to less vaso-invasion (p=0.003). In conclusion, although IL-17 was predominantly expressed by neutrophils, a high number of Th17 cells correlated with improved survival.

P3.10.28
Characterisation of a population of human CCR6 TH1 cells expressing RORC

*S. M. Restorick, L. Durrant, M. Voice, P. Moss, **S. J. Curnow**;*
University of Birmingham, Birmingham, United Kingdom.

CD4+ T helper (TH) subsets can be defined by the cytokines they produce and their transcription factor expression. The paradigm of Tbet and IFNγ denoting TH1 cells and RORC and IL-17 signifying a TH17 cell is well established. Initially these subsets were thought to have a stable phenotype however there are small subsets of cells that co-express cytokines normally attributed to separate lineages (i.e. IFNγ+IL-17+). TH1/TH17 cells can be induced in vitro through IL-12

stimulation of TH17 cells. There is evidence that the TH1/TH17 cells can switch off IL-17 and become a TH1 cell.
We have shown that human peripheral blood CD4+ TH1/TH17 cells express lower levels of IFNγ per cell than single IFNγ secretors (MFI Median=143.7 compared with median=72.4 [p=0.034]), though a similar level of IL-17 than single IL-17 secretors (MFI Median=59.23 compared to median=73.61 [p=0.32]). TH1/TH17 cells co-express Tbet and RORC both at protein and mRNA level and all express the chemokine receptor CCR6. Non classical TH1 cells have been classified in the literature as CD161+ IFNγ+. We are characterising a population of non-classical TH1 cells that express CCR6. We have established CCR6+ non-classical TH1 cells co-express RORC and Tbet and have other signatures of TH17 cells such as IL-23R expression but secret neither IL-17a nor IL-17f. We are investigating the effect of IL-23 on non-classical TH1 cells. We also wish to discover if there are transcriptional reasons why no IL-17 is detectable if RORC is expressed.

P3.10.29
Rarity of human T helper 17 cells is due to retinoic acid orphan receptor-dependent mechanisms that limit their expansion

V. Santarlasci[1], *L. Maggi*[1], *M. Capone*[1], *V. Querci*[1], *D. Cavalieri*[2], *F. Liotta*[1], *R. De Palma*[3], *E. Maggi*[1], *L. Cosmi*[1], *F. Annunziato*[1];
[1]*University of Florence,DENOTHE Center, Florence, Italy,*
[2]*Department of Pharmacology "M. Aiazzi Mancini"University of Florence, Florence, Italy,* [3]*Department of General Pathology Second University of Naples, Italy, Naples, Italy.*

The reason why CD4(+) T helper 17 (Th17) cells, despite their well-known pathogenic role in chronic inflammatory disorders, are very rare in the inflammatory sites remains unclear. We demonstrate that human Th17 cells exhibit low ability to proliferate and to produce the T cell growth factor interleukin-2 (IL-2), in response to combined CD3 and CD28 stimulation. This was due to the upregulated expression of IL-4-induced gene 1 (IL4I1) mRNA, a secreted L-phenylalanine oxidase, which associated with a decrease in CD3ζ chain expression and consequent abnormalities in the molecular pathway that allows IL-2 production and cell proliferation. High IL4I1 mRNA expression was detectable in Th17 cell precursors and was strictly dependent on Th17 cell master gene, the retinoid acid related orphan receptor (RORC). Th17 cells also exhibited RORC-dependent CD28 hyperexpression and the ability to produce IL-17A after CD28 stimulation without CD3 triggering. Our findings suggest that the rarity of human Th17 cells in inflamed tissues results from RORC-dependent mechanisms limiting their expansion.

P3.10.30
Disequilibrium of Tregs and TH17 cells in the pathogenesis of autoimmune skin disorder: Pemphigus vulgaris

A. Sharma*, A. Raju, V. Anand, S. Khandpur;*
All India Institute of Medical Sciences, New Delhi, India.

Background: Pemphigus vulgaris(PV) is an auto-immune blistering disease forming auto-antibodies against desmoglein 3 (Dsg3). Treg and TH17 cells play important role in autoimmune diseases. Reason of paucity of Treg cells in PV lesions and Involvement of homing receptor and its ligand needs to be explored. We aim to assess the frequency of Treg and TH17 cells, circulatory and quantitative expression of their cytokines, transcription factors, chemokine receptor-ligands in PV.
Methodology: 25 active PV patients (confirmed by clinical, histological and anti-Dsg3 levels), 15 controls (non-inflammatory lypoma patients) were included. Serum TGF-β, IL-17, CCL20 and CCL22 levels were analysed by ELISA. Molecular expression of Foxp3, CCR4, CCL22 and RORγt, CCR6, CCL20 was performed by Real time PCR. Frequency of Treg and TH17 cells was assessed by flow cytometry.
Results: Frequency of TH17 cells was significantly higher than Treg cells ($p<0.02$, $p<0.008$) in circulation of PV patients vs controls. For Tregs, levels of TGF-β were significantly elevated whereas CCL22 lowered in patients. Foxp3 expression was higher in tissues whereas relative expression of CCR4 was significantly lower in both blood and tissue ($p<0.05$) of patients. For TH17, significantly elevated level of IL-17 was found in patients. Relative expression of RORγt, CCR6 and CCL20 was significantly high in both blood and tissue of patients ($p<0.001$) as compared to controls.
Conclusion: Augmented expression of RORγt, CCR6, CCL20, Foxp3, CCL22 and lower expression of CCR4 in tissue signifies chemokine receptor-ligand imbalance of Treg cells that might affect the suppressive ability of iTregs over TH17 in the pathogenesis of PV.

P3.10.31
Characterization of the immune mechanisms involved in periodontal disease in obese rats.

D. R. Stach-Machado*;*
UNICAMP, Campinas, Brazil.

Periodontal disease (PD) is a chronic inflammatory disease that affects the tissues that support the teeth and is the most prevalent bone disorder in humans. The etiological agent is the dental plaque however the host immune response determinates the susceptibility and progression of PD. Obese individuals have a higher susceptibility to periodontal disease and this is more severe, therefore this study aimed to evaluate the immune mechanisms involved in the development and progression of induced periodontal disease in obese rats. The obesity experimentally mimicked by high fat diet (HFD) is characterized by inducing impaired glucose tolerance and hyperinsulinemia. These animals showed a higher protein and gene expression level of pro-inflammatory cytokines, such as IL-17, IL-6 and IFN-γ indicating a polarization toward Th1 and Th17 immune profile. These pro-inflammatory cytokines profile stimulate the induction of matrix metalloproteinases (MMP) expression and inhibition of their regulators as TIMPs, and overexpression of RANKL (receptor activator of nuclear factor kappa B ligand) and inhibition of osteoprotegerin (OPG), which imbalances is responsible for the degradation of the extracellular matrix and bone resorption in PD. Our results allowed to correlate the HFD induced metabolic changes resulted in exacerbation of inflammatory response in gingival tissue with PD.

P3.10.32
The histamine H_4 receptor mediates inflammation in models of arthritis via inhibition of Th17

R. L. Thurmond*, J. M. Cowden, F. Yu, M. Zhang, P. Ling, S. Nguyen, M. Farahani, J. Zhu, J. P. Riley, P. J. Dunford;*
Janssen Research and Development, San Diego, CA, United States.

The histamine H_4 receptor (H_4R) has been shown to drive inflammatory responses in models of asthma, colitis and dermatitis and in these models it appears to impact both innate and adaptive immune responses. Many of these models involve Th2 mechanisms and the effect of the H_4R was postulated to be driven by inhibition of these T cell responses. The effect on T cells prompted the question as to whether the H_4R could modulate responses of other T cell subtypes and, therefore, have a role in autoimmune disease. In this study both H_4R-deficient mice and a specific H_4R antagonist were utilized to investigate the involvement of the H_4R in mouse arthritis models. Both H_4R-deficient mice and mice treated with the H_4R antagonist exhibited reduced arthritis disease severity in both collagen antibody-induced arthritis (AIA) and collagen-induced arthritis (CIA) models. This was evident from the reduction in disease score and in joint histology. In the CIA model treatment with the H_4R antagonist reduced the number of Th17+ cells in the lymph node and the total production of IL-17. Th17 cell development in vivo was reduced in H_4R-deficient mice or in mice treated with an H_4R antagonist. Finally, in both mouse and human blood treatment with an H_4R antagonist reduced the production of IL-17 when cells were stimulated in vitro. These results implicate the H_4R in disease progression in arthritis and in the production of IL-17 from Th17 cells; thus supporting future clinical exploration of H_4R antagonists for the treatment of rheumatoid arthritis.

P3.10.33
IL-2 interferes with CD4+ T cell homing by reducing the expression of the α4 integrin

***J. Triebus**, D. Engelbert, A. Hamann;*
German Rheumatism Research Center, 10117 Berlin, Germany.

To provide optimal host defense against pathogens naive CD4+ T cells differentiate into different T helper cell subsets after they have encountered their cognate antigen. This process is accompanied by a massive IL-2 production, which in turn modulates the expression of cytokine receptors to help specify and maintain differentiated states. More specifically, IL-2 induces Th1 polarization by enhancing expression of T-bet and IL-12Rβ2 subunit. Similarly to Th1, IL-2 stimulates Th2 differentiation by inducing IL-4Rα and keeping the Il4 gene locus accessible. Moreover, IL-2 was shown to be crucial for the reciprocal balance between Th17 cells and FOXP3+ regulatory T cells (Tregs). Whereas in the absence of IL-2 the numbers Treg cells decline, the numbers of Th17 cells increase. As shown previously, IL-2 seems to be not only crucial for the T cell fate but also for their homing capacities as IL-2 suppresses CCR6, which is important for Th17 cells gut-homing (Wang et al., Mucosal Immunol., 2009).We could observe a similar mechanism for the integrin alpha 4 chain (ITGA4) of the specific gut-homing molecule α4β7 integrin complex. Addition of IL-2 to Th17 cells led to a dose-dependent decrease of the itga4 expression. Inhibition of IL-2 induced STAT5 resulted in an increase of itgα4 both on RNA and protein levels. Understanding the molecular mechanisms underlying itga4 modulation by IL-2 and subsequent function in gut migration would contribute to the knowledge of T cell driven inflammatory diseases of the gut like Crohn's disease and could help to improve clinical therapies.

P3.10.34
Infected apoptotic adherent or non-adherent cells instruct DCs to trigger Th17 differentiation

***F. F. Verdan**[1], N. Dejani[1], V. E. Niño[2], F. N. Dias[2], A. C. G. Salina[2], A. I. Medeiros[3,4];*

The phagocytosis of infected apoptotic cells (AC) by dendritic cells (DC) promotes the production of anti-inflammatory cytokines such as TGF-β but also pro-inflammatory cytokines as IL-6 and IL-23, resulting in the differentiation of Th17 cells. We have asked ourselves whether the quality of infected cell could differentially impact the DC instruction toward Th17 using infected adherent or non-adherent cells. C57BL/6J mice were intraperitoneally injected with 1 mL thioglicollate plus 106 live E. coli and 13 h later the cells were collected from peritoneal cavity lavage. Apoptotic cells were generated by UV irradiation (350mJ) and confirmed by Annexin-V/PI detection. BMDC were co-cultured at 1:3 ratio with adherent or non-adherent infected apoptotic cells for 18 h and supernatant was collected for differentiation assay and detection of Th-17 related cytokines, IL-6 and TGF-β, by ELISA. For the phagocytosis assay the infected apoptotic cells were labeled with CFSE. Our results showed that DC were able to phagocyte both adherent and non-adherent cells in a similar way and instruct Th17 differentiation as well. Interestingly, non-adherent cells were capable to induce a 3-fold higher production of IL-6 together with a small amount of TGF- β, while adherent cells were less capable to produce IL-6 and better at promoting TGF-β production. Our result shows the ability of DCs to be instructed from diverse infected cells and further promotes differentiation of Th17 cells. The result suggests that apoptosis of infected cells are a standard instruction for DC to trigger Th17 response.

P3.10.35
Protein Kinase C θ regulates Th1/Th17 plasticity

***K. Wachowicz**, N. Kleiter, N. Thuille, G. Baier;*
Medical University Innsbruck, Innsbruck, Austria.

Mature CD4+ cells can polarize into functionally distinct T helper subsets (Th1/Th2/Th17/iTreg). This differentiation is often regulated by opposing molecular pathways, but still some plasticity between the subsets exists. This phenomenon is especially remarkable in case of Th1 versus Th17 lineage development, although underlying mechanisms are not fully understood. Protein Kinase C θ (PKCθ) is a well established player in proximal T cell receptor signaling, but less is known about its contribution to differentiation and function of particular Th subsets.
We investigated the role of PKCθ in Th17 differentiating cells. According to our observations, in vitro differentiated PKCθ-defficient CD4+ cells express normal levels of Th17 marker genes (IL-17, RORγt), but at the same time produce more factors typical for the Th1 subset (IFNγ, T-bet). Increased expression of IFNγ and T-bet in PKCθ-deficient cells was specific for Th17-promoting conditions and this phenomenon could not be attributed to TGF-β resistance. In concert with increased IFNγ production, also phosphorylation of STAT1 was enhanced and sustained in PKCθ-defficient cells. This phenotypical plasticity switch was confirmed also in vivo, in the mouse model disease EAE (Experimental Autoimmune Encephalomyelitis).
Our observation suggests that PKCθ is involved in modulation of molecular pathways underlying Th1 and Th17 lineages differentiation and their plasticity. Defining mechanisms of such contribution will not only clarify the flexibility of T cell polarization, but may also shed light on the pathogenesis of autoimmunity and cancer.

P3.10.36
Myeloid-derived suppressive cells promote Th17 cell differentiation and IL-17 production

***X. Wang**, H. Yi, C. Guo, X. Yu;*
Virginia Commonwealth University, Richmond, VA, United States.

Myeloid-derived suppressive cells (MDSCs) have been implicated in the pathogenesis of several diseases, including cancer and autoimmune disorders. We found that CD11b+Gr-1+ MDSCs from tumor- or experimental autoimmune encephalomyelitis (EAE)-bearing mice promote the differentiation of naïve CD4+ T cell precursors into Th17 cells in a highly efficient manner. The presence of MDSCs also results in elevation of IL-17A production and upregulation of the orphan nuclear receptor RORA and RORC in T cells. IL-1beta-derived from MDSCs is identified as a major mediator of the enhanced Th17 differentiation, which involves the IL-1 receptor on CD4+ T cells. Depletion of MDSCs leads to significantly reduced Th17 response and decreased clinical scores of EAE as well as myelin injury. Our data reveal a new feature of MDSC action in the shaping of inflammatory Th17 cell responses and provide additional insights into the pleiotropic functions of this myeloid cell population. These new findings support the concept of targeting MDSCs for potentially effective intervention of Th17 cell/IL-17-mediated immunopathology in cancer and autoimmune diseases (e.g., multiple sclerosis).

P3.10.37
Runx1-deficiency in CD4+ T Cells Causes Fatal Autoimmune Inflammatory Lung Disease due to Spontaneous Hyperactivation of Cells

***W. F. Wong**;*
University of Malaya, Kuala Lumpur, Malaysia.

The Runx1 transcription factor is abundantly expressed in naïve T cells but rapidly down-regulated in activated T cells, suggesting that it plays an important role in a naïve stage. In the present study, we showed that mice harboring Runx1-deleted CD4+ T cells developed a fatal autoimmune lung disease. CD4+ T cells from these mice were spontaneously activated and preferentially homed to the lung. At early age, lung peribronchiovascular regions of the mice were infiltrated with CD4+ lymphocytes, while at later stage, interstitial regions were massively occupied with immune cells and alveolar spaces were filled with granular exudates that resembled pulmonary alveolar proteinosis in humans. Mice suffered from respiratory failure as well as systemic inflammatory responses which caused early dead at around 7-8 months old. Runx1-deleted CD4+ T cells in the mice expressed various cytokines including IL-17 and IL-21 which promoted neutrophils and monocytes activation and triggered formation of IgG+ plasma B cells, respectively. Among these, the deregulation of IL-21

transcription was likely to be associated with Runx-binding sites located in an IL-21 intron. Our data indicate that Runx1 plays an essential role in repressing the transcription of cytokine genes in naïve CD4+ T cells and thereby maintains cell quiescence.

P3.10.38
The effects of traditional Chinese medicine type on Th17 cells in chronic hepatitis C patients received antivirval therapy

***S. Wu**, Z. Xiaolian;*
Wuhan University, Wuhan, China.

Objective: To observe the change of Th17 cells and IL-17 expression in patients with chronic hepatitis C virus infection before and after treatment with peginterferon alfa-2α plus ribavirin with or without traditional Chinese medicine type “prescription of harmonizing and tonifying liver and spleen”.
Methods: The study consisted of 80 subjects, including 24 patients treated with peginterferon alfa-2α plus ribavirin, 26 patients treated with peginterferon alfa-2α plus ribavirin and traditional Chinese medicine type, and 30 healthy controls. The frequency of circulating Th17 cells were analysed by flow cytometry. The peripheral serum IL-17 levels and HCV RNA were measured by ELISA and Real-Time PCR.
Redults: The frequency of Th17 cells was increased in patients with chronic hepatitis C compared with healthy controls. The elevated prevalence of Th17 cells is positivedly associated with ALT and HCV RNA. In addition, after 12 weeks’ treatment, Thl7 cells were significantly decreased in patients treated with peginterferon alfa-2α plus ribavirin and traditional Chinese medicine type than patients treated with peginterferon alfa-2α plus ribavirin.
Conclusion: Thl7 cells are correlated with the severity of liver inflammation and decreased after treatment with peginterferon alfa-2α plus ribavirin and traditional Chinese medicine type. Traditional Chinese medicine type can improve immune function in CHC patients treated with peginterferon alfa-2α plus ribavirin.

P3.10.39
Distinct Th17 inductions contribute to the gender bias in CVB3-induced myocarditis

***S. Xiong**[1,2], Z. Li[1], Y. Yue[1], W. Xu[1];*
[1]Institutes of Biology and Medical Sciences, Soochow University, Suzhou, Jiangsu Province, China, [2]Institute for Immunobiology, Fudan University, Shanghai, China.

Viral myocarditis is often caused by coxsackievirus B3 (CVB3) infection and occurs more frequently in male. So far the mechanisms for this sex difference are not fully elucidated. Th17 cells are required for the development of CVB3-induced myocarditis, but their impact on the gender bias in viral myocarditis is still unknown. Here, the frequencies of splenic Th17 cells in CVB3-infected male and female mice were compared, and the impact of sex hormones on Th17 cell differentiation was also evaluated. We found that in infected male mice, Th17 cell frequency was remarkably increased and significantly higher than that in female mice. When neutralizing IL-17 by monoclonal antibody, the male prevalence of myocarditis was obviously abolished, further confirming the effect of Th17 cells on gender bias in viral myocarditis. It was also found that estradiol significantly inhibited the Th17 differentiation post CVB3 infection both in vitro and in vivo. However, testosterone showed no such effects. In this study, we reported that Th17 cells were predominantly induced in CVB3-infected males than females as the inhibitory effect of estrogen on Th17 differentiation, and played an important role in the sex differences in the sensitivity to CVB3-induced myocarditis. This study may help us understand the role of Th17 cells in viral myocarditis and facilitate the development of corresponding therapeutic strategies.

P3.10.40
The predominant Th17 phenotype in gastric cancers may be associated with HLX expression decrease blocking Th1 cell specific T-box transcription factor

*Z. Su, T. Wang, P. Zhang, X. Ji, **H. Xu**;*
Department of Immunology & Laboratory Immunology, Jiangsu University, Zhenjiang, China.

Th0 cells differentiate into Th1 or Th2 depending on multiple transcription factors acting on specific time points to regulate gene expression. Th17 cells, a subset of IL-17 producing T cells distinct from Th1 or Th2 cells has been described as key players in inflammation and autoimmune diseases as well as cancer development. In this study, we investigated the expression level of IL-17, IFN-γ, RORγt, *HLX* and *T-bet* and Th17-related cytokines in gastric cancer tissues and assessed the possible mechanism and their clinicopathological parameters. Serum, peripheral blood mononuclear cells (PBMC), tumor and adjacent normal tissues were obtained from 60 patients with gastric cancer. IL-17, IL-21, IL-23, IFN-γ, RORγt, *HLX* and *T-bet* mRNA expression levels were quantified by real-time RT-qPCR; Serum IL-17, IL-21, IL-23, and IFN-γ were detected by ELISA; Th17 infiltration was examined by immunofluorescence. Expression of IL-17, IL-21, IL-23 and RORγt mRNA was found to be significantly up-regulated in PBMC compared with healthy people; whereas, expression of IFN-γ, *HLX* and *T-bet* was obviously down-regulated. Serum IL-17, IL-21, IL-23 were increased, IFN-γ was decreased. And Th17 cells infiltrated the cancer tissue. All the data indicated that Th17 was a predominant phenotype in gastric cancers; the data also indicated that the Th1 response was inhibited. From the above data we speculated that the predominant Th17 response in gastric cancers may be associated with HLX expression decrease blocking Th1 cell specific T-box transcription factor

P3.10.41
A probiotic strain of Lactobacillus L casei stimulates gene expression in PBMC in obese people

*M. Zarrati, **E. Salehi**, F. Shidfar, K. Bidad, F. Najafi, Z. Gheflati, M. Meydani, M. Hosein Zadeh, V. Mofid;*
Tehran University of Medical Science, Tehran, Iran.

Objective: We tried to determine whether dietary supplementation with yogurt, enriched by some strains of probiotics with or without weight reduction diet, could be effective on gene expression of PBMCs from obese subjects.
Design: This randomized doubled-blind controlled clinical trial was performed recruiting 75 healthy persons with BMI=25-40. Participates consumed 200 g/day yogurt containing Lactobacillus acidophilus La5, Bifidobacterium BB12 and lactobacillus casei DN001 108 CFU/gr. Subjects were randomly assigned to three groups: Those who consumed conventional yogurt under low calorie diet (LCD) (n=25), subjects who got probiotic yogurt with LCD (n=25) and those who consumed probiotic yogurt without any LCD (n=25) for 8 wk. Fasting blood samples were taken at baseline and after a 8 wk intervention to measure changes of gene expression for FOXP3, T-bet, GATA3, TNF-α, IFN-γ ,TGF-β and ROR-γt in PBMCs.
Results: Expression of ROR-γt was reduced (p=0.007) while FOXP3 expression enhanced ($p<0.001$) significantly in all three groups after intervention. Changes in expression of TNFα, TGFβ, and GATA3 were not significant between groups after intervention (p=0.39, p=0.43 and p=0.16, respectively). Expression of T-bet was significantly decreased in probiotics groups ($p<0.001$). Expression of IFNγ was decreased significantly in all three groups after intervention.
Conclusions: Weight reduction diet and probiotic yogurt had synergistic effects on gene expression in subgroups of T lymphocytes in overweight and obese persons, and the combination of a weight reduction regimen and consumption of probiotic yogurt appears to be more effective at improving immune vigor and reducing inflammatory mediators than consumption of probiotics alone.

P3.10.42
Antagonistic regulation of human Th17 and GM-CSF-producing T helper cells

*R. Noster[1], R. Riedel[2], M. Mashreghi[2], A. Radbruch[3], **C. E. Zielinski**[4]; [1]Charité Universtätsmedizin Berlin, Charité-Universitätsmedizin Berlin, Germany, [2]DRFZ, Deutsches Rheuma-Forschungszentrum Berlin, Germany, [3]DRFZ, Deutsches Rheuma-Forschungszentrum, Germany, [4]Charité Universtätsmedizin Berlin, Berlin, Germany.*

The pathogenicity of Th17 cells in mouse models of autoimmunity has recently been associated with their production of granulocyte-macrophage-colony-stimulating factor (GM-CSF). Here, we have analyzed the expression of GM-CSF by human T helper cells. The induction of GM-CSF expression by human T helper cells is constrained by the IL-23/STAT3/ROR-γt/Th17 cell axis but promoted by the Th1 axis. While STAT3 blocks GM-CSF induction, STAT5 promotes it. Ex vivo, most GM-CSF+ T helper cells co-express IFN-γ and T-bet. A distinct subset of GM-CSF+ T cells does not express Th1, Th2 and Th17 signature cytokines or master transcription factors, and thus constitutes an independent T helper cell lineage, the Th-GMCSF subset. Our findings suggest a role for GM-CSF+ T cells in the inflamed brain of multiple sclerosis patients as well as in the healthy skin.

P3.11.01
CD2 expression determines two lineages of γδ T cells in swine

***M. inkora**, K. těpánová;*
Institute of Microbiology of the Academy of Sciences of the Czech Republic, v.v.i., Nový Hrádek, Czech Republic.

Swine together with ruminants and birds belongs to the group of γδ-high species in which γδ T cells are regularly present in the blood and secondary lymphoid organs and may account for >70% of all T cells. This is in sharp contrast with γδ-low species such as rodents and humans in which γδ T cells are rare in circulation and are preferentially limited to epithelia. In this respect, γδ-low species almost lack circulating $CD2^{-}$ γδ T cells that are numerous in γδ-high species. Analysis of porcine γδ T cells shows that $CD2^{+}$ and $CD2^{-}$ γδ T cells differ in many aspects. These two subsets have differential distribution in the blood and secondary lymphoid organs, differential expression of TCR, differential capacity to modulate TCR expression, differential susceptibility for proliferation, differential capacity to modulate CD8 expression and differential expression of other auxiliary molecules and TCRγ chains. CD2— γδ T cells are also absent in immature thymocytes. However, repertoire of TCRδ is polyclonal in both subsets indicating there is the same extent of diversification and equal capability of immune responses. The tissue distribution of $CD2^{+}$ and $CD2^{-}$ γδ T cells is also independent of bacterial colonization and it is already established in the thymus. Results collectively indicate that $CD2^{+}$ and $CD2^{-}$ γδ T cell subsets represent two independent lineages and that $CD2^{-}$ γδ T cells is a specific lineage that is missing in the blood of humans and mice. This work was supported by Czech Science Foundation grant P502/12/0110.

P3.11.02
IL-17-producing gamma-delta T cells are crucial for the development of autoimmune arthritis in IL-1 receptor antagonist-deficient mice

***A. Akitsu**[1,2,3], H. Ishigame[2], S. Kakuta[2], S. Saijo[2], Y. Iwakura[1,2,3]; [1]Research Institute for Biomedical Sciences, Tokyo University of Science, Chiba, Japan, [2]The Institute of Medical Science, University of Tokyo, Tokyo, Japan, [3]Core Research for Evolutional Science and Technology (CREST), Japan Science and Technology Agency, Tokyo, Japan.*

A high proportion of IL-17 producing-gamma-delta T (γδ17) cells was detected in joints of Il1rn-/- mice, a model of rheumatoid arthritis, whose development depends on IL-17 and T cells. However, their pathogenic roles are not well understood. To clarify the roles of γδ T cells and CD4+ T cells in the development of arthritis, γδ T cells or CD4+ T cells were depleted in Il1rn-/- mice using antibodies. The development of disease was suppressed in both cases, suggesting both γδ T cells and CD4+ T cells were involved in the pathogenesis. Adaptive transfer experiment showed that the combination of CD4+ T cells and γδ17 cells were required for the development of arthritis in scid/scid mice, while γδ17 cells alone could induce in the Il1rn-/- background because Il1rn-/-nu/nu mice still developed arthritis. Furthermore, we generated mice with γδ17 cells, but without Th17 cells, by adoptively transferring Il17-/-Il1rn-/--CD4+ T cells into nu/nu mice in which γδ17 cells are present. We found that these mice still developed arthritis and that only γδ T cells produced IL-17, indicating that extrathymic γδ17 cells are also important for the development of arthritis in the absence of Th17 cells. These observations suggest that joint-specific CD4+ T cells or IL-1 production directs tissue specificity and γδ17 cells play effector functions in the development of arthritis.

P3.11.03
Changes in Granzyme B expression in gamma delta T-cell in (HTLV-1)-associated myelopathy/tropical spastic paraparesis patients

***R. C. Albuquerque**[1], O. Espindola[2], M. A. Lima[3], A. C. C. Leite[3], M. J. Andrada-Serpa[2], J. Echevarria-Lima[1]; [1]Lab. de Imunologia Básica e Aplicada, Depto. de Imunologia - Instituto de Microbiologia Paulo de Góes-Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil, [2]Lab. de Pesquisa em Patogenia Viral, Rio de Janeiro, Brazil, [3]Lab. de Pesquisa Clínica em Neuroinfecções - Instituto de Pesquisa Clínica Evandro Chagas, Fundação Oswaldo Cruz, RJ - Brazil, Rio de Janeiro, Brazil.*

Human T-cell lymphotropic virus type 1 (HTLV-1) is an etiologic agent of adult T-cell leukemia and HTLV-1-associated myelopathy/tropical spastic paraparesis (HAM/TSP). HAM/TSP is a chronic inflammatory disease characterized by the loss of motor movement in response to spinal marrow cells destruction by T lymphocytes. HTLV-1 preferentially infects T CD4+ lymphocytes. The efficient immune response seems to be important to control viral replication and associates disease development. γδ T cells are increasingly recognized as having important functional roles in a range of diseases, such as infection, autoimmunity and cancer. Thus far, the relationship between HTLV-1 infection and γδ T lymphocytes during HAM/TSP disease is poorly understood. In this study, we compared the phenotype of these cells of health donors and HTLV-1 carriers. The total γδ T cell population was not significantly altered in HTLV-1 infected donors. Similar results were observed in T γδ cells subtypes, analyzing Vδ2, Vγ9 and CD27 expression. In HAM/TSP patients, the percentage of granzyme B expression in γδ T cells was significantly lower than in asymptomatic patients and non-infected donors. These results suggest that the reduction of granzyme B expression impairs γδ cytotoxic activity related to proviral load control and HAM/TSP progression.

P3.11.04
Involvement of γδ-T cells in the pathogenesis of autoimmune skin disorder: Pemphigus vulgaris

***V. Anand**[1], A. Raju[1], D. Das[1], S. Khandpur[2], V. Sharma[2], A. Sharma[1]; [1]Department of Biochemistry, All India Institute of Medical Sciences (Aiims), New Delhi, India, [2]Department of Dermatology & Venereology, All India Institute of Medical Sciences (Aiims),, New Delhi, India.*

BACKGROUND: Pemphigus vulgaris (PV) is an autoimmune, intraepithelial, blistering disease affecting the skin and mucous membranes, mediated by circulating autoantibodies. In most of the autoimmune skin disorders auto reactive T cells are critical for the induction and regulation of antibody production. γδ-T cells are primarily located in epithelial surfaces and participates in many autoimmune diseases. In this maiden attempt we elucidated the involvement of γδ-T cells in pathogenesis of PV by phenotypic characterization and their cytokine polarization in PV patients.
METHODOLOGY: 30 cases of active PV confirmed by histopathology (H & E) & anti-Desmoglein 3 levels and 30 healthy individuals as

controls were included. Serum levels of IFN-γ as TH1 marker and IL-4 as TH2 marker were estimated by high sensitivity ELISA test. Phenotypic determination of γδ-T cells and their intracellular cytokine polarization was quantified by Flow cytometry (FACs).
RESULT: Circulatory level of IL-4 was found to be significantly higher ($p<0.001$) whereas IFN-γ was low ($p<0.01$) in patients than controls. FACs result showed higher percentage of γδ-T cells expressing IL-4 (6.8%) than IFN-γ (2.7%) in PV patients as compared to controls The FACs results were in concordance with our circulatory cytokine levels.
CONCLUSION: FACs result explained increased population of IL-4 expressing γδ-T cells in PV patients and found to be TH2 polarized. The involvement and induction of γδ T cells in Pemphigus Vulgaris immune dysregulation reinforces the need of detailed analysis by observing cytotoxicity of γδ T cells. This approach might be beneficial in designing targeted therapy in future.

P3.11.05
Exploiting NKG2D and lymphoid stress surveillance response in seronegative spondyloarthritis

***E. Binda**, A. Manzo, B. Vitolo, S. Bugatti, C. Montecucco;*
Dipartimento di Medicina Interna e Terapia Medica, Sezione di Reumatologia e Tossicologia Clinica, Università' di Pavia, Pavia, Italy.

A number of biomarkers are currently being investigated in patients with seronegative spondyloarthitis (SpA) since they may be used to predict exacerbation and monitor the clinical response to an intervention.
Natural killer group 2, member D (NKG2D) is an activating receptor present on the surface of natural killer (NK), CD8 T cells, γδ T cells and under certain conditions CD4 T cells. NKG2D receptor binds to a family of ligands that are distant relatives of major histocompatibility complex class I molecules.
Environmental stress such as genotoxic/oxidative stress, heat shock and viral infections stimulate NKG2D ligands expression. Recent studies have demonstrated that NKG2D ligands are induced on proliferating rheumatoid arthritis (RA) synoviocytes and may thus contribute to progression of rheumatic disease.
Here we investigate the expression of NKG2D ligands in synovial tissue from SpA patients and we compare it with samples from RA patients and healthy controls. We monitor NKG2D regulation also in in-vitro cultured SpA and RA synoviocytes in response to physiological stimuli such as oxidative stress, heat-shock and mechanic stretch.
Downregulation of NKG2D receptor on peripheral blood mononuclear cells (PBMC) represents a physiological regulatory mechanism of NK and gd T cells in response to activation and it is mediated by the production of pro-inflammatory proteins.
Hence the production of key cytokines by circulating NKG2D+ cells may indicate the impaired response of the immune system to stress in rheumatic disease.
We believe that understanding the contribution of NKG2D pathway in rheumatic pathologies may provide rational for emerging targeted therapies.

P3.11.06
T Cell Dysregulation in Chronic Fatigue Syndrome/Myalgic Encephalomyelitis

***E. W. Brenu**[1,2], S. L. Hardcastle[1,2], T. K. Huth[1,2], L. Cosgrave[2], D. R. Staines[3,2], S. M. Marshall-Gradisnik[1,2];*
[1]School of Medical Sciences, Griffith University, Gold Coast, Australia, [2]The National Centre for Neuroimmunology and Emerging Diseases, Griffith Health Institute, Griffith University, Gold Coast, Australia, [3]Queensland Health, Gold Coast Public Health Unit, Robina,, Gold Coast, Australia.

Gamma delta (γδ) T lymphocytes comprise about 1-10% of peripheral lymphocytes. Although, functionally distinct from the more diverse αβ T cells, γδ T cells have important roles in pathogenesis and inflammation. γδ T cells secrete cytokines and chemokines essential for regulating adaptive immunity. In diseases such as Chronic Fatigue Syndrome/Myalgic Encephalomyelitis (CFS/ME) decreased activity of cytotoxic T cells and elevations in FOXP3 secreting T cells have been reported. Dysregulation in T cell function may be an important component of the CFS/ME immune profile. Hence, the objective of this study was to determine the role of γδ T cells in CFS/ME patients. 20 CFS/ME patients (age=51.8±1.74 years) and 30 non-fatigued controls (age= 53.19±1.35years) were recruited for the study. Inclusion into the CFS/ME group was based on the Centre for Disease Prevention and Control (CDC 1994) criteria definition for CFS/ME. 10mL of whole blood was collected from all participants. The whole blood samples were stained with a cocktail of monoclonal antibodies containing CD4, CD62L, CD27, CD45RA, CD3, CD11a, CD94, V delta-1 and V delta-2. Following which samples were analysed on the flow cytometer. The statistical analysis used to determine differences in the data was ANOVA with significant set at P=0.05. Compared to non-fatigue controls, modifications in cell number were observed in the CFS/ME patients. The results demonstrate that CFS/ME may be characterised by discrepancies in other subsets of T cells.

P3.11.07
***In vivo* IFN-alpha/ribavirin treatment modulates Vγ9Vδ2 T-cell function during chronic HCV infection**

***E. Cimini**[1], C. Bonnafous[2], H. Sicard[2], C. Vlassi[1], G. D□Offizi[1], M. Capobianchi[1], F. Martini[1], C. Agrati[1];*
[1]National Institute for Infectious Diseases, Rome, Italy, [2]Innate-Pharma, Marseille, France.

In chronic HCV infection, treatment failure and defective host immune response highly demand improved therapy strategies. Vγ9Vδ2 T-cells represent a good target for HCV immunotherapy, since phosphoantigen (PhAg)-activated Vγ9Vδ2 T-lymphocytes are able to inhibit subgenomic HCV replication by IFN-γ release. A profound impairment of IFN-γ production by Vγ9Vδ2 T-cells during chronic HCV infection was previously shown. Interestingly, *in vitro* IFN-α partially restored Vγ9Vδ2 T-cells responsiveness to PhAg, by stabilizing IFN-γ-mRNA.
In order to verify how *in vivo* IFN-α/RBV treatment could affect Vγ9Vδ2 T-cells phenotype and responsiveness to PhAg in HCV-infected patients, 10 subjects underwent a longitudinal study before and after treatment. IFN-α/RBV therapy did not significantly modify Vγ9Vδ2 T-cell numbers and differentiation profile. Interestingly, Vγ9Vδ2 T-cell responsiveness remained unmodified until 3 weeks of therapy, but dropped after one month, suggesting that repeated *in vivo* IFN-α administration in the absence of TCR-mediated signals results in Vγ9Vδ2 T-cell anergy.
The present work defines the window of possible application of combined strategies targeting Vγ9Vδ2 T-cells during chronic HCV infection; specifically, the first 3 weeks from the beginning of treatment may represent the optimal time to target Vγ9Vδ2 T-cells *in vivo*, since their function in terms of IFN-γ production is preserved.

P3.11.08
γδ T cells are required for the development of autoimmune anti myeloperoxidase glomerulonephritis

***P. Gan**, J. D. Ooi, S. A. Summers, D. Odobasic, A. R. Kitching, S. R. Holdsworth;*
Monash University, Melbourne, Australia.

The relationship between γδ and αβ T cells in the generation of autoimmunity is not well defined. This study explores the role of γδ T cells in the pathogenesis of autoimmune anti-myeloperoxidase (MPO) anti-neutrophil cytoplasmic antibody (ANCA) associated glomerulonephritis (GN) by comparing the development of autoimmunity to MPO and resulting GN among WT and TCRδ-/- mice. Autoimmunity was induced by MPO immunization in Freunds Adjuvant (CFA) and GN triggered using a subnephritogenic dose of antiglomerular basement membrane antibody. Deficiency in γδ T cells resulted in significant attenuation of functional (proteinuria; 3.2±0.3 vs 2.3±0.2mg/24hr, $p<0.05$) and histological (abnormal glomeruli; 34.4±2.9 vs 20.0±3.1%) renal injury and glomerular leukocytic infiltration (macrophage; 5.3±0.7 vs 1.3±0.7cells/glomerular cross section [c/gcs], neutrophils; 1.4±0.2 vs 0.3±0.06c/gcs and CD4 T cell; 1.4±0.3 vs 0.3±0.06c/gcs), $p<0.05$. Attenuated renal injury observed in TCRδ-/- mice correlated with decrease in systemic anti-MPO autoimmunity with decreased MPO specific CD4 T cell responses

assessed by; dermal MPO induced DTH (swelling 0.24±0.04 vs 0.02±0.01Δmm) and decreased frequency of IFNγ producing CD4 T cells (Elispot 82.2±19.0 vs 20.1±7.1cells), all $p<0.05$. However humoral immunity was unaffected (similar ANCA titres between groups; 0.3±0.03 vs 0.3±0.05OD_{450nm}, p=0.7). Analysis of dendritic cells (DC) in lymph nodes draining immunisation sites showed significantly reduced DCs ($6.3x10^4$±$7.4x10^3$ vs $4.2x10$±$4.1x10^3$ cells/draining LN) with increased percentage of DC apoptosis (1.6±0.3 vs 3.4±0.6%), $p<0.05$. Thus γδ T cells affect pathogenic anti MPO autoimmunity by optimising the development of CD4 T effector adaptive autoimmune responses.

P3.11.09
Differentiation of human peripheral blood Vδ1 T cells expressing Natural Cytotoxicity Receptors: implications for immunotherapies and the understanding of γδ T cell function

K. Hudspeth[1,2], *D. V. Correia*[3,4], *M. Fogli*[5], *M. Gomes da Silva*[6], *J. Mikulak*[1], *A. Roberto*[1], *S. Della Bella*[1], *B. Silva-Santos*[7], *D. Mavilio*[1];
[1]*Istituto di Ricovero e Cura a Carattere Scientifico (IRCCS), Istituto Clinico Humanitas, Rozzano, Italy,* [2]*Universita' degli Studi di Milano, Milano, Italy,* [3]*Univesidade de Lisboa, Lisbon, Portugal,* [4]*Instituto de Medicina Molecular, Lisbon, Portugal,* [5]*Section of Microbiology, Department of Experimental and Applied Medicine, Brescia, Italy,* [6]*Instituto Portugues de Oncologia de Lisboa, Francisco Gentil, Lisbon, Portugal,* [7]*Instituto de Medicina Molecular, Faculdade de Medicina, Univesidade de Lisboa, Lisbon, Portugal.*

Natural Cytotoxicity Receptors (NCRs) were originally identified as specific natural killer cell activating receptors that, upon binding to their endogenous ligands, trigger the killing of tumor cell targets. Here we describe a population of Vδ1+ T cells from human peripheral blood that can differentiate in vitro to express the NCRs NKp30, NKp44 and NKp46. We show that the expression of NKp30 endows Vδ1+ T cells with the ability to lyse, in vitro, both hematologic tumor cell lines as well as chronic lymphocytic leukemia cells isolated from patients. Moreover, we found that these cells are also able to produce CC chemokines upon the triggering of NKp30, which suppresses HIV-1 viral replication in CD4+ T cells in vitro. This evidence not only further discloses the key role of NK cell receptors in certain γδ T cell functions, but also suggests that Vδ1+ T cells specifically harbor a powerful therapeutic potential through the induction of NCRs, whose function can be manipulated for the treatment of various diseases.

P3.11.10
Mycobacterium tuberculosis antigen specific changes of CDR3 length distribution of Vδ2 chain of human γδ T lymphocytes

B. LI[1,2], *F. Ma*[1,2], *Y. Ding*[1,2], *Z. Wang*[3], *S. Guo*[1,2], *D. Xu*[1,2], *Y. Chen*[2], *J. Tang*[1,2];
[1]*Department of Immunology, Bengbu Medical College, Bengbu, China,* [2]*Anhui Key Laboratory of Infection and Immunity, Bengbu, China,* [3]*The infectious Disease Hospital of Bengbu, Bengbu, China.*

The human γδ T cells can be activated by both non-peptide and peptide antigens from Mycobacterium tuberculosis (Mtb). Recent studies show that phosphate antigen activated γδ T cells fail to, but Mtb activated γδ T cells potentially inhibit intracellular Mtb growth. Mtb heat resistant antigen (Mtb-HAg), a peptide antigen, has been shown to preferentially stimulate Vγ9Vδ2 T cells. However, the characteristic of diversity of TCR Vδ2 region of Mtb-HAg stimulated Vγ9Vδ2 T cells has not been investigated. In this study, by using size spectratyping of length of CDR3 fragment of Vδ2 gene, the length of the most dominant peak of CDR3 fragments of Vδ2 gene in Mtb-HAg activated γδ T cells was significantly larger than that of γδ T cells from fresh PBMC. In addition, the frequency of the most dominant peak of Vδ2-CDR3 fragments of γδ T cells in patients with pulmonary TB (0.28±0.06) was significantly higher than that in health donor subjects (0.20±0.03) ($p<0.05$). The RT-PCR products of dominant peaks of Vδ2-CDR3 fragments of PBMC from four TB patients were cloned and sequenced. All cloned Vδ2 CDR3 regions contained conserved "CACD" and "KLIFGKG" at the N- and the C-terminus, respectively, but there were distinct different inner sequences of most dominant peak of the Vδ2-CDR3 regions among these TB patients. In conclusion, Mtb antigen or infection biased distribution of Vδ2-CDR3 fragment of Vγ9Vδ2+ T cells indicates that Mtb infection induces the oligoclonal expansion of human γδ T cells.

P3.11.11
Respiratory syncytial virus infection influences FasL-mediated apoptosis of γδ T cells in a murine model of allergen sensitization

B. Liu*, S. Zeng, J. Liu, F. Qi;*
China Medical University, Shenyang, China.

We have reported previously that adoptive transfer of γδ T cells increased the number of inflammatory cells as well as the percentage of eosinophils in the lungs of allergic mice, suggesting that γδ T cells may play a proinflammatory role in OVA-induced allergic responses. RSV infection before sensitization to OVA decreased the number of Th2-type γδ T cells. However, the underlying mechanisms remain unknown. In this study, by using BALB/c mice that were inoculated intranasally with live RSV before or after sensitization to OVA, we found that adoptive transfer of γδ T cells from OVA-sensitized and challenged mice enhanced not only the number of inflammatory cells but also the production of Th2 cytokines in the lungs and allergy-related antibodies in the serum, further confirming that γδ T cells act as pro-inflammatory cells or a promoter for the development of allergic asthma. RSV infection before sensitization to OVA decreased the number of total γδ T cells as well as activated γδ T cells by augmenting apoptotic death of the γδ T cells. Furthermore, prior RSV infection increased the absolute number of FasL-expressing γδ T cells in the lungs of allergic mice. Blocking FasL with monoclonal antibody diminished the percentage of apoptotic death of the pulmonary γδ T cells. These results suggest that RSV infection protects against the subsequent development of OVA-induced allergic responses by enhancing apoptotic death of pulmonary γδ T cells via FasL-dependent pathway.

P3.11.12
Sensing cellular stress by γδ TCR

R. Marlin[1], *H. Kaminski*[1], *S. Netzer*[1], *V. Pitard*[1], *C. Harly*[1], *E. Scotet*[2,3], *J. Moreau*[1,4], *J. Dechanet-Merville*[1];
[1]*UMR CNRS 5164, Bordeaux, France,* [2]*INSERM UMR892, Nantes, France,* [3]*CNRS UMR6299, Nantes, France,* [4]*Immunology and Immunogenetic laboratory, Bordeaux Hospital, Bordeaux, France.*

Human non-Vδ2 γδ T cells constitute a first line of defence in epithelium and organs by recognizing modified cells as virus infected or transformed cells. This reactivity suggests recognition of stress-associated self-antigens by non-Vδ2 TCRs. In order to identify these uncharacterized antigens, we set up a strategy comprising mice immunization with tumor cells targeted by non-Vδ2 TCRs and selection of mAbs able to specifically abrogate the reactivity of γδ TCR transductants against these targets.
In this study, we focused on a Vγ8Vδ3 TCR, which conferred to transductant a restricted reactivity against U373MG glioblastoma cell line. A blocking mAb (FMS-01) was generated against U373MG that specifically abrogated recognition by both Vγ8Vδ3 transductant and T cell clone, suggesting that FMS-01 mAb targets the antigenic ligand of Vγ8Vδ3 TCR. Surprisingly, we showed that modification of U373MG culture conditions as high level cell confluence, thermic choc, hypoxic stress or CMV infection, increased the reactivity of Vγ8Vδ3 transductant and T cell clone. These stress conditions were able to induce Vγ8Vδ3 transductant activation against other glioblastoma cell lines (U343MG and U251MG). This recognition of stressed cells was TCR dependent and blocked by FMS-01 mAb. Moreover, stress increased expression of FMS-01 targeted antigen that directly correlated with Vγ8Vδ3 transductant activation. Identification of FMS-01 targeted antigen is in process.
In conclusion, our results show that stress conditions can induce the expression of γδ TCR antigens. Because these antigens are critical for γδ T cell recognition, their identification could lead to new immunotherapeutical treatments in cancer such as glioma.

P3.11.13
Human Vγ9Vδ2 T cells can selectively promote TH1 or TH2 responses via interactions with dendritic cells or B cells in vitro

***A. Petrasca**, D. G. Doherty;*
Trinity College Dublin, Dublin, Ireland.

The Vγ9Vδ2 subset of human γδ T cells can induce maturation of dendritic cells (DC) into antigen-presenting cells (APC) and B cells into antibody-secreting plasma cells. Since B cells are capable of presenting antigens to T cells, we investigated if Vγ9Vδ2 T cells can influence antigen presentation by these cells. Vγ9Vδ2 T cells, B cells and monocytes were isolated from human blood. Vγ9Vδ2 T cells were expanded by phosphoantigen stimulation and monocytes were induced to differentiate into immature DC. Vγ9Vδ2 T cells were co-cultured with equal numbers of DC or B cells. Expression of APC markers, production of cytokines and antibodies, and stimulation of T cells by the DC or B cells was then measured using flow cytometry and ELISA. Vγ9Vδ2 T cells induced expression of CD86 and HLA-DR and the secretion of IL-6, IL-12, TNF-α and IFN-γ by DC. They augmented the ability of DC to stimulate proliferation and IFN-γ production by antigen-specific and alloreactive T cells. In contrast, Vγ9Vδ2 T cells induced CD86 expression, but downregulated HLA-DR expression, by B cells and they promoted the release of IL-4 and IgG, IgA and IgM by B cells. B cells matured with Vγ9Vδ2 T cells stimulated proliferation but not cytokine secretion by conventional T cells. These data suggest that Vγ9Vδ2 T cells can induce maturation of DC and B cells into APCs, but while they prime DC to stimulate TH1 responses, they prime B cells to stimulate TH2 responses.

P3.11.14
Understanding the crosstalk between γδ T cells and osteoclasts in patients with breast cancer

***S. P. Phalke**[1], V. Parmar[2], R. Badwe[2], S. Chiplunkar[1];*
[1]ACTREC-TMC, Navi Mumbai, India, [2]TMH, Mumbai, India.

Bone metastasis is a common cause of morbidity in breast cancer patients. Aminobisphosphonates are widely used in treatment of bone metastasis and skeletal disorders. Aminobisphosphonates increase endogenous pool of isopentenyl pyrophosphate (IPP) of mevalonate pathway in tumor cells, which acts as potent antigen for γδ T cells. γδ T cells are unique subsets of T-lymphocytes that are activated by aminobisphosphonates and phosphoantigens (bromohydrin pyrophosphate, IPP). The present study aims at understanding the crosstalk between γδ T cells and osteoclasts in patients with breast cancer metastasis. Multicolor flow cytometry showed higher expression of RANKL on γδ T cells of breast cancer patients. Stimulation with aminobisphosphonate (zoledronate) increased RANKL expression on γδ T cells. Osteoclasts generated from $CD14^+$ monocytes of breast cancer patients and healthy individuals in the presence of zoledronate activated γδ T cells showed reduced osteoclastogenesis as analysed by 23c6 mAb (CD51/61) and DAPI staining. Osteoclasts generated in the presence of cell free supernatants of activated γδ T cells showed reduced resorption area (pits) on Osteoclast Activity Assay Substrate. Cytokine analysis of activated γδ T cells showed presence of IFN-γ, antiosteoclastogenic cytokine. Zoledronate activated γδ T cells have high propensity to migrate to bone and inhibit osteoclastogenesis. Aminobisphosphonate activated γδ T cell based immunotherapy would be a promising approach to treat bone metastasis in breast cancer.

P3.11.15
Toll-like receptor 2 ligand enhances effector function but not antigen presentation properties of gamma-delta T cells

***D. Poo**[1], W. Wang[1], M. Teo[1], H. Toh[1,2];*
[1]National Cancer Centre Singapore, Singapore, Singapore, [2]DUKE-NUS Graduate Medical School, Singapore, Singapore.

Background: Activated gamma-delta T cells possess potent cytotoxicity against broad range of cancer cells. They are also involved in the activation of dendritic cells through their expression of cytokines. Gamma-delta T cells also acquire antigen presenting cell properties upon activation. These properties make gamma-delta T cells an attractive platform for cancer immunotherapy. Toll-like receptors (TLR) 2 and 3 are expressed by gamma-delta T cells. We aim to explore if TLR2 and TLR3 ligands could enhance the functions of activated gamma-delta T cells and thus enhancing their usefulness for immunotherapy.
Methods: Peripheral blood gamma-delta T cells of healthy donors were activated by zoledronate (Zometa, Novartis, USA). Activated cells were expanded by culturing in the presence of IL-2 (100ng/ml), IL-15 (10ng/ml), and either TLR2 ligand Pam3CSK4 (100ng/ml) or TLR3 ligand Poly(I:C) (100ng/ml) for up to 14 days. The cells were assayed for antigen presenting cell markers (such as CD86, HLA-DP,DQ,DR and CCR7) and cytokine expression (IFN-gamma and TNF-alpha) by flow cytometry.
Results: Upon activation, gamma-delta T cells rapidly upregulated granzyme, as well as CD86 and HLA-DP,DQ,DR expression that peaked at days 7-10. Neither the addition of Pam3CSK4 nor Poly(I:C) resulted in any enhancement in these expression. However, Pam3CSK4 stimulated enhancement in CCR7 and IFN-gamma expression.
Conclusion: TLR2 and TLR3 ligands (Pam3CSK4 and Poly(I:C) respectively) did not enhance the expression of antigen presenting cell markers on gamma-delta T cells. However, Pam3CSK4 was found to upregulate IFN-gamma and CCR7 expression, implying its potential in enhancing cytotoxicity and lymph node-homing properties of gamma-delta T cells.

P3.11.16
Phenotypic characterisation of Human Vγ9Vδ2 T-cells

***P. L. Ryan**[1], L. A. Bergmeier[1], D. J. Pennington[2];*
[1]Institute of Dentistry, Barts and The London School of Medicine and Dentistry, Queen Mary University of London, London, United Kingdom, [2]Centre for Immunology and Infectious Disease, Blizard Institute, Barts and The London Medical School, Queen Mary University of London, London, United Kingdom.

Human Vγ9Vδ2 T-cells are commonly divided into subtypes using CD27 and CD45RA surface expression, reflecting their cytokine production, proliferative and plastic potential; [27^+RA^+] Naïve-T_N, [27^+RA^-] Central Memory-T_{CM}, [27^-RA^-] Effector Memory; T_{EM}, and a [27^-RA^+] T_{EM} subset expressing CD45RA-T_{EMRA}. However, the use of these markers fails to adequately describe Vγ9Vδ2 T-cell biology.
Objective: To characterise the different Vγ9Vδ2 T-cell phenotypes using different cell surface markers.
Methods: Peripheral blood mononuclear cells (PBMCs) were isolated by density gradient separation from the peripheral blood of 20 healthy subjects and stained for cell surface receptors: CD3, Vδ2, CD27, CD45RA, CD28, CD11a, CD16 and CD56. Flow cytometry was used to determine extracellular marker expression on Vγ9Vδ2 T-cells.
Results: Our results highlight the heterogeneous nature of Vγ9Vδ2 T-cell subsets defined using CD27 and CD45RA. Notably, T_N cells include both a $CD11a^{hi}$ and $CD11a^{lo}$ subset, while T_{CM} cells can be sub-divided, often equally, into $CD28^+$ and $CD28^-$ populations. We have also identified a mutually exclusive relationship between the expression of CD28 and CD16 on T_{CM}, T_{EM} and T_{EMRA} cells. As CD28 and CD16 have important functional roles in T-cell activation, we are presently investigating the functional abilities of the populations described.
Conclusion: We have identified considerable surface heterogeneity in T_N, T_{CM}, T_{EM} and T_{EMRA} Vγ9Vδ2 T-cell subsets suggesting a comparable degree of functional heterogeneity. A better understanding of Vγ9Vδ2 T-cell phenotypes should provide improved insight for the study of these cells in associated diseases such as; Crohn's disease, Behçet's disease and Bisphosphonate-related osteonecrosis of the jaw (BRONJ).

P3.11.17
Human peripheral Vδ1+ γδ T cells can develop into αβ T cells

*H. Ziegler[1], J. Haarer[1], M. Sterk[1], H. Rammensee[2], R. Handgretinger[1], **K. Schilbach**[1];*
[1]Childrens Hospital University Tübingen, Tübingen, Germany, [2]Dept. of Immunology, Interfaculty Institute for Cell Biology University of Tübingen, Tübingen, Germany.

The T cell compartment can be divided in two large classes: αβ and γδ T cells. It is believed that they develop in the thymus from a common progenitor and that the choice between αβ and γδ T cell fate is the first lineage decision made by progenitors after they commit to the T-cell lineage. However, here we show that peripheral Vδ1+ γδ T cells in an inflammatory environment can transdifferentiate into αβ T cells. Upon their extrathymic route of differentiation, that resembles well-characterized molecular program of thymic αβ lineage development, Vδ1+ T cells upregulate CD4+ coreceptor, develop Vδ1+ CD4+CD8+ double positive cells, show heterodimeric CD8αβ, transcribe RAG, preTα and express a particular Vβchain on their surface. Simultaneously inflammation confers controlled initiation of rearrangement in the TCRα locus. Transdifferentiation of Vδ1+ T cells at the clonal and bulk-culture level into functional CD4+ or CD8+ αβ T cells via a Vδ1+/αβ+TCR double positive stage suggests that, upon inflammatory stimuli, Vδ1+ T-cell conversion participates in the induction of adaptive immune responses. Identifying an innate T cell as an αβ T-cell progenitor and showing the developmental steps linking the progenitor to adaptive, thymus-independant αβ T-cell responses as inflammatory conditions is of utmost relevance and will deeply impact evaluation of immune responses in infection, malignancy and autoimmune processes.

P3.11.18
The regulatory role of TCR Vδ1$^+$ NKT cells in systemic sclerosis patients with interstitial pneumonia

***S. Seiji**, D. Goto, M. Horikoshi, I. Matsumoto, T. Sumida;*
University of Tsukuba, Ibaraki, Japan.

Purpose. Interstitial pneumonia (IP) is a serious complication in systemic sclerosis (SSc). However, the exact mechanism of IP remains elusive. The purpose of this study is to clarify the role of TCR Vδ1$^+$ NKT cells in SSc patients with IP.
Methods. The proportion of TCR Vδ1$^+$ NKT cells in PBMCs from healthy controls (HC, n=22) and SSc patients (n=35) was analyzed by flow cytometry. In SSc patients with IP, the correlation between proportion of TCR Vδ1$^+$ NKT cells in PBMCs and serum KL-6 levels was analyzed. Cytokine (IFN-γ, TNF-α, IL-4, IL-17) and chemokine (CCL2, CCL3, CCL4, CCL5) secretion assay using TCR Vδ1$^+$ NKT cells from HC and SSc patients was performed.
The effect of culture supernatant of TCR Vδ1$^+$ NKT cells on fibroblast proliferation was evaluated.
Results. The proportion of TCR Vδ1$^+$ NKT cells was significantly higher in IP-negatives (mean±SEM, 1.03±0.32%) than IP-positive patients (0.28±0.07%, $p<0.05$) and HC (0.23±0.09%, $p<0.05$). In IP-positive SSc patients, the proportion of TCR Vδ1$^+$ NKT cells correlated negatively with serum KL-6 values (r=-0.464, $p<0.05$).
Upregulation of CCL3 and downregulation of IFN-γ production were noted in TCR Vδ1$^+$ NKT cells of IP-positive SSc patients upon TCR stimulation compared with HC. Fibroblast proliferation was promoted with medium supplemented with culture supernatant derived from IP-positive SSc patients, whereas that from HC was not.
Conclusions. TCR Vδ1$^+$ NKT cells might play a regulatory role in the pathogenesis of IP in SSc patients.

P3.11.19
γδ T cells react against the murine cytomegalovirus

***S. Sell**[1], M. Dietz[2], A. Schneider[1], M. Mach[2], T. Winkler[1];*
[1]Department of Genetics, Institute for Biology, University of Erlangen-Nuremberg, Erlangen, Germany, [2]Institute for Clinical and Molecular Virology, University Hospital Erlangen, Erlangen, Germany.

The cytomegalovirus (CMV) is a large beta herpesvirus and various layers of the innate and adaptive immune system provide control in CMV-infected individuals. In this study we focused on the protection mediated by γδ T cells against this virus.
Using the murine model we studied protective capacities of γδ T cells after infection with the murine cytomegalovirus (MCMV). We furthermore started to characterize γδ T cells reacting and expanding after CMV infection.
Adoptive transfer of γδ T cells purified from spleens and lymph nodes of infected donor mice protected immunocompromised hosts (Rag-/- mice) from the lethal course of disease and virus titers were markedly decreased 14 days after infection in several organs.
To examine, whether there is a role for γδ T cells during MCMV infection in immune competent mice as well, we infected wildtype C57BL/6 and TCRδ-/- mice and compared viral titers on days 3 and 5 after infection. TCRδ-/- mice showed significant higher viral titers in several organs. This indicates that γδ T cells also play a role in immune competent mice during the early stage of infection.
We further characterized the γδ T cells reacting and expanding after CMV infection regarding their expression of certain surface molecules using flow cytometry. The percentage of CD44 expressing γδ T cells increased after infection, what points to an activated state of these cells. In addition we observed a long-lasting increase in NKG2D expressing cells after infection, which is concomitant with down modulation of CD27.

P3.11.20
TCR requirements for γδ T cell development

***N. Sumaria**[1], D. J. Pang[1], J. F. Neves[1,2], K. V. Stoenchev[1], B. Silva-Santos[3,4], D. J. Pennington[1];*
[1]Blizard Institute, Barts and The London School of Medicine, Queen Mary University of London, Whitechapel, United Kingdom, [2]Programa Doutoral de Biologia Experimental e Biomedicina, Centro de Neurociências e Biologia Celular, Universidade de Coimbra,, Coimbra, Portugal, [3]Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal, [4]Instituto Gulbenkian de Ciência, Oeiras, Portugal.

Gamma delta (γδ) T cells play important roles in immune responses against pathogens and tumours which seem to strongly correlate with the secretion of cytokines such as IFNγ and IL-17A. Recent evidence suggests that γδ cells are predominantly pre-committed to certain effector fates during thymic development; T cell receptor (TCR)-agonists favouring the development of IFNγ-producing γδ cells (that are variously identified by CD27, CD122 and NK1.1), whereas the absence of ligand interactions was suggested to generate IL-17A-producing γδ cells (identified as CD27(-), but expressing CCR6). The aim of this study was to determine the role of the TCR and TCR signalling in the development of γδ T cell subsets and in the adoption of effector fates in the thymus.
Our results demonstrate that at least 4 distinct subsets of γδ T cells can be identified in both the periphery and the thymus of C57BL/6 mice. These subsets display distinct cytokine-secreting and proliferative potential as well as variable TCR usage. Our data in vitro demonstrate a γδ developmental sequence where CD27(-) IL-17A-secreting γδ T cells are generated from CD27(+) precursors. In addition, we find that TCR signalling induced by cross-linking with an activating antibody or in a ligand-independent manner does not favour the development of CD27(-) IL-17A-secreting γδ T cells. Whilst our results suggest that effector fate of γδ subsets is not likely to correlate with ligand-dependent versus ligand-independent signalling it remains to address whether it correlates with quantitative and/or qualitative differences in TCR signalling between the different subsets.

P3.11.21

CD30L/CD30 signaling plays a critical role in maintenance and activation of IL-17A-producing γδ T cells in mucosa-associated tissues in mice

X. Sun[1]*, E. R. Podack*[2]*, Y. Yoshikai*[3]*, C. Lu*[1]*;*
[1]*Institute of Immunology, China Medical University, Shenyang, China,* [2]*Department of Microbiology and Immunology, University of Miami,, Miami, FL, United States,* [3]*Division of Host Defense, Medical Institute of Bioregulation, Kyushu University, Fukuoka, Japan.*

CD30 ligand (CD30L, CD153), a member of the TNF superfamily, and its receptor CD30 are important for differentiation and activation of $CD4^+$ Th17 cells. In the present report, we demonstrate that the IL-17A-producing γδ T cells normally developed in the fetal thymus, whereas $Vγ1^-Vγ4^-$ γδ T cells expressed Vγ6/Vδ1 gene transcript selectively decreased in mucosa-associated tissues in naïve CD30KO or CD30LKO mice. Moreover, CD30 and CD30L were expressed preferentially by $Vγ1^-Vγ4^-$ γδ T cells in naïve mice. The bacteria clearance was attenuated by the impaired response of the IL-17A-producing γδ T cells and decreased infiltration of neutrophils in CD30KO or CD30LKO mice*. In vivo* administration of agonistic anti-CD30 mAb restored the ability of protection against *L. monocytogenes* by enhancing $Vγ1^-Vγ4^-$ γδ T cells producing IL-17A not only in WT but also CD30LKO mice. Taken together, it appears that CD30L/CD30 signaling plays an important role in the maintenance and activation of IL-17A-producing γδ T cells presumably bearing Vγ6 in the mucosa-associated tissues of mice.

P3.11.22
Developing a protocol for large scale generation of antigen-pulsed gamma-delta T cells for cancer immunotherapy

W. Wang*, K. Poo, M. Teo, H. Toh;*
National Cancer Centre Singapore, Singapore, Singapore.

Background: Gamma-delta T cells are members of the innate immune system that display potent cytotoxicity against broad range of cancer cells. Activated gamma-delta T cells also acquire antigen presenting cell functions. We therefore aim to explore and develop a protocol for adopting antigen-pulsed gamma-delta T cells as dual function cytotoxic cell-plus-vaccine platform for cancer immunotherapy.
Methods: Gamma-delta T cells in the peripheral blood mononuclear cells (PBMC) of healthy donors were activated by zoledronate and expanded by culturing in the presence of IL-2 (100ng/ml) and IL-15 (10ng/ml), followed by magnetic isolation and pulsed with Epstein-Barr virus latent membrane protein 2 (LMP2)-derived peptide library. Cytotoxicity of the cells was assessed by DELFIA BATDA fluorometric assay against human cancer cell line targets. Antigen presenting cell markers (CD86, HLA-DP,DQ,DR and CCR7) and intracellular cytokine expression (granzyme B, IFN-gamma and TNF-alpha) were assayed by flow cytometry.
Results: Upon activation, gamma-delta T cells rapidly upregulated granzyme B and IFN-gamma expression, as well as CD86 and HLA-DP,DQ,DR expression that peaked at days 7-10. At day 14, between 30-60 fold expansion of peripheral blood gamma-delta T cells was achieved. Cytotoxicity assays showed that these cells retain potent non-HLA-restricted killing of human cancer cell lines. Co-culturing of LMP2 peptide-pulsed gamma-delta T cells with autologous PBMCs for 14 days resulted in up to seven-fold expansion of LMP2 epitope-specific CD8 T cells.
Conclusion: Gamma-delta T cells generated by this protocol achieved good expansion and possessed potent cytotoxicity and antigen presentation functions. The protocol will be validated on NPC patient PBMCs.

P3.11.23
The role of phosphoantigen-expanded human γδ-T cells in the control of Epstein-Barr virus infection

Z. Xiang*, J. Zheng, Y. Liu, G. Qin, Y. Liu, J. Guan, K. Lam, Y. Lau, W. Tu;*
Department of Paediatrics and Adolescent Medcicine, HKU, Hong Kong, Hong Kong.

Background. Epstein-Barr virus (EBV) is a ubiquitous infectious agent which infecting more than 90% of the world's population. And it is well known to be linked to several specific human malignancies. Also, in immunocompromised patients, EBV causes lymphoid proliferation that results in the appearance of lymphomas. The limitations of current therapies for treating EBV-associated disorders have led to the development of alternative strategies to enhance host immunity against EBV. The antiviral activities of γδ-T cells against other varied viruses have been demonstrated. However, little is known about their antiviral activities against EBV infection in human.
Methods. Human Vγ9Vδ2-T cells were expanded by phosphoantigen aminobisphosphonate pamidronate (PAM), and then co-cultured with EBV-transformed human autogolous B cells (EBV-LCLs). The antiviral mechanisms of Vγ9Vδ2-T cells against EBV in vitro were determined.
Results. PAM selectively activated and expanded human Vγ9Vδ2-T cells, and up-regulated the expression of TRAIL, NKG2D and perforin in Vγ9Vδ2-T cells. The PAM-expanded human Vγ9Vδ2-T cells can efficiently recognize and kill the autologous EBV-LCLs and significantly inhibited viral replication in vitro. The cytotoxicity of Vγ9Vδ2-T cells against EBV-LCLs was dependent on NKG2D, TRAIL activation and was mediated by Fas-Fas ligand and perforin-granzyme B pathways. The killing of EBV-LCLs by Vγ9Vδ2-T cells was also dependent on cell-cell contact and required the activation of EBV-transformed cells.
Conclusion. PAM-activated Vγ9Vδ2-T cells can effectively kill autologous EBV-infected B cells in vitro, suggesting a novel approach by using phosphoantigens to activate human Vγ9Vδ2-T cells against EBV infection.

P3.11.24
Assessment of immune dysfunction in IgA-nephropathy patients

M. Yurkevich*, H. Ivanchik, S. Bagatka, K. Komissarov, V. Pilotovich, M. Zafranskay;*
Belarusion Medical Academy of Post-Graduate Education, Minsk, Belarus.

Although IgA nephropathy (IgAN), which features IgA deposition in kidney mesangium, is considered a benign condition, a high proportion of patients progress to renal failure.
Methods: The immune profile was assessed in 36 patients with biopsy-proven primary IgAN and 30 healthy donors (HD). Flow cytometry measurement of lymphocytes phenotype, T cells proliferation in response to phytohemagglutinin (PHA), γδ T cells response to isopentenyl pyrophosphate (IPP) and ELISA for serum IgA determination were used. The stimulation index (SIγδ) was determined as a ratio between the amount of T cells in medium and IPP-stimulated T cells.
Results: IgAN patients demonstrated significantly decreased number of circulating CD19+ B cells predetermined by reduced CD19+5- B2 lymphocytes. In addition, CD19+ B-cells in IgAN patients had elevated membrane-bound IgA1 expression (20,1(9,8÷40,8)% vs 9,9(5,9÷14,1)% in HD, $p<0,05$).
Serum IgA was significantly higher in IgAN than in HD, with 37% of patients having IgA level upper the normal 95th percentile.
T cells with αβ T-cell receptor (TCR) were in the normal range and there wasn`t difference in T cells response to 2,5mg/ml PHA between patients and HD. However decrease of circulating CD3+ T lymphocytes expressed Vδ2 TCR was established (1,9(1,2÷2,9)% in IgAN vs 3,2(1,6÷5,8)% in HD, $p<0,05$) and their significant expansion in response to 5mM IPP was observed. SIγδ for patients was 11,1(7,4÷70,0) in comparison to 5,4(3,1÷8,4) for donors.
Conclusion: Immune profile of IgAN patients, including both B cells arm of immune system and γδ T lymphocytes function, contribute to filling gaps in our knowledge about IgAN development.

P3.12 Follicular helper T cells

MyD88 activated Monocyte-derived CD11b+ dendritic cells enhance Follicular Helper T cell differentiation

***S. Chakarov**, N. Fazilleau;*
Centre de Physiopathologie de Toulouse Purpan, Toulouse, France.

Adjuvant combinations could result in synergistic enhancement of the immune response. In this context, how Toll-like Receptor (TLR) agonists contribute to antigen-specific T cell-dependent B cell responses was assessed in vivo. We found that when vaccine adjuvant was combined to MyD88-dependent but not to Trif-dependent TLR agonists, differentiation of antigen-specific T Follicular helper cells (Tfh), which regulate high-affinity B cells, was increased without changing the overall magnitude of the antigen-specific T cell response. This phenomenon correlated with an enhancement of germinal center reaction, antigen-specific plasma cells and circulating antibodies. Increase of Tfh differentiation was driven in vivo by enhanced production of IL-6 by antigen-presenting monocyte-derived CD11b+ dendritic cells. In contrast, nor B cells or plasmacytoid dendritic cells that also secreted IL-6 in response to TLR agonist were involved as shown in vivo in their absence. Thus, some TLR agonists imprint the specialized program of Tfh function needed to promote high-affinity B cell protection in vivo specifically through T cell differentiation by enhancing IL-6-production by monocyte-derived CD11b+ dendritic cells.

P3.12.02
Regulation and B-cell help mediated by distinct subsets of IL-10-producing T-cells

***F. Facciotti**[1], B. Haeringer[2], N. Gagliani[3], M. Paroni[1], P. Gruarin[1], L. Pignataro[4], R. Flavell[3], S. Abrignani[1], J. Geginat[1];*
[1]INGM, Milan, Italy, [2]DRFZ- German Rheumatology Research Institute, Berlin, Germany, [3]Yale School of Medicine, New Haven, CT, United States, [4]Fondazione IRCCS Cá Granda, Ospedale Policlinico di Milano, Milan, Italy.

IL-10 is a B-cell growth factor produced by CD4+ helper T-cells, but also mediates suppression of T-cell responses by regulatory T-cells. We have recently identified two subsets of IL-10 producing CD4+ CCR6+ memory T cells and IL-7R- effector T cells with suppressive capacities in human blood (Haringer et al., JEM 2009, Rivino et al. JEM 2010).
Here, we identified a phenotype that distinguishes IL-10-producing regulatory T-cells and IL-10-producing helper cells in humans and mice. We directly compared memory and effector T cells for the regulation of IL-10 production, and analysed their phenotypes and B-help functions in peripheral blood and in secondary lymphoid organs.
IL-10-producing regulatory T-cells co-expressed CCR5 and PD-1, but were negative for CCR6 and IL-7R. Purified CCR5+CCR6-IL-7R-CD4+ T-cells did not display B helper functions because they failed to up-regulate CD40L. Moreover, they actively suppressed T-cell proliferation and T-cell dependent IgG production. Conversely, IL-10-producing CCR6+IL-7R+CD4+ T-cells helped B-cell antibody production in an IL-10-dependent manner. CCR6+CD4+ T-cells secreted IL-10 in B-cell follicles but were distinct from conventional follicular helper T-cells, which were CCR6- and helped independently of IL-10.
Experiments in mice confirmed findings with human cell populations. CCR6+IL10+cells provided antigen specific B cell help, while IL10-producing CCR5+PD1+ cells exerted suppressive functions.
In conclusion, two distinct IL-10-producing T cell subsets are present in human and mice blood and lymphoid organs, which can be distinguished by chemokine receptor expression. We propose that these two subsets have opposing functions in humoral immune responses.

P3.12.03
Role of Notch signal in the generation of follicular helper T cells (TFH) and memory T cell

***Y. Harada**[1], K. Tokoyoda[2], K. Miyauchi[3], Y. Harada[1], A. Hanazawa[2], S. Ohno[4], Y. Yanagi[4], T. Takemori[5], M. Kubo[1,3];*
[1]Division of Molecular Pathology, RIBS, Tokyo University of Science, Noda, Japan, [2]German Rheumatism Research Centre, Berlin, Germany, [3]Laboratory for Signal Network, RCAI, RIKEN Yokohama Institute, Yokohama, Japan, [4]Kyushu University, Fukuoka, Japan, [5]Immunological Memory, RCAI, RIKEN Yokohama Institute, Yokohama, Japan.

Follicular helper T cells (TFH) are specialized T cell subset localizing in germinal centers (GCs), and their secreting cytokines, IL-4 and IL-21 facilitate B cell help in the antibody responses. Conserved noncoding sequence 2 (CNS2) have been characterized as an intrinsic enhancer element specific for the IL-4 expression in TFH cells. However, it still remains unclear how CNS2 is specifically activated on TFH cells, and whether TFH cells can be memory cells. Here we demonstrated that deficiency of Rbpj, a downstream transcription factor of Notch signaling completely abrogated the CNS2 mediated IL-4 expression in TFH cells, indicating that Notch signaling determine an identity of TFH cells. Antigen priming promoted the plasticity of CNS2 active TFH cells to differentiate into TH2 and TH17 cells. Furthermore, CNS2 active TFH cells reduced the expression of CXCR5 and re-localized in T cell area as IgG1 and IgE regulating memory cells that rapidly form and re-entered into the GCs after antigen priming. In contrast, the transfer of the TFH cells derived from Rbpj deficient mice diminished memory formation. These findings indicate that Notch signaling is intrinsic to control the IL-4 expression in TFH cells and to maintain the memory T cells.

P3.12.04
Role of BCL6 and PD-1 in CD4 memory T cell development

***K. Hollister**, H. Wu, A. Dent;*
Indiana University School of Medicine, Indianapolis, IN, United States.

Follicular T helper (TFH) cells have been shown to play an indispensable role within the germinal center (GC). To study the effects of TFH cell loss, our lab has developed a mouse line wherein BCL6, the master transcription factor behind TFH cell differentiation, is conditionally deleted in specific cell subsets ($BCL6^{fl/fl}$). When mated to Cre-CD4 mice, loss of BCL6 specifically in CD4 T cells resulted in a complete absence of GCs. Data from control mice confirmed the correlation between BCL6 and PD-1 expression, with the highest levels of both found in TFH cells. Further analysis showed the few $CD4^{+}$ $CXCR5^{+}$ $ICOS^{+}$ $PD\text{-}1^{hi}$ cells found in $BCL6^{fl/fl}Cre^{CD4}$ mice have higher rates of apoptosis than those in control mice. Because previous studies have shown that Bcl6 regulates T cell memory, we investigated whether there were any effects on CD4 T cell memory development and found $BCL6^{fl/fl}Cre^{CD4}$ mice have an altered memory cell phenotype, with higher levels of central memory cells and fewer effector memory cells than control mice. Furthermore, memory cells in these mice show significantly lower rates of apoptosis as well as surface expression of PD-1. Taken together, this data suggests a complex regulatory network involving BCL6 and PD-1 expression, which effects not only TFH cell differentiation, but the development of CD4 T cells into effector versus central memory cells as well.

P3.12.05
B cell antigen presentation induces Tfh-differentiation from Th2 cells in vitro

***S. Horiuchi**, H. Takebuchi, S. Konishi, K. Haniuda, T. Moutai, S. Takatsuka, D. Kitamura;*
Research Institute for Biomedical Science Tokyo University of Science, Noda-City, Chiba, Japan.

During T-dependent immune responses, after antigen presentation from B cells to CD4 T cells, B cells proliferate extensively to form germinal center (GC), and CD4 T cells differentiate into distinct effector helper T cell subsets, such as Th1, Th2, and follicular helper

T (Tfh) cells. To clarify the mechanisms of the differentiation of B cells and CD4 T cells, we analyzed B cells and T cells co-cultured in the culture system we have recently established, in which B cells are cultured on feeder cells expressing CD40 ligand and BAFF. By using this culture system, we show that, when cultured with naïve B cells in the presence of antigens under the Th2 conditions (i.e. with IL-2 and IL-4), in-vitro-derived Th2 cells differentiate into cells with Tfh-like phenotype (CXCR5+ PD-1+ ICOS+ and IL-21 producing). Surprisingly, these Th2-derived Tfh-like cells retained the function of producing IL-4 and expressed GATA3 mRNA. On the other hand, B cells cultured with Th2 cells, in the presence of antigens, differentiate into cells with pre-memory like phenotype (B220+ CD38+ FAS+ GL7+) and plasma cells (Blimp1+ CD138+). Thus, we demonstrate efficient in vitro differentiation of Th2 cells into Tfh-like cells that also retain the nature of Th2 cells, which are reminiscent to a recently proposed Tfh subset. We also show that antigen-presenting B cells are necessary for the differentiation of Tfh-like cells.

P3.12.06
ICOS is critical for maintenance of the T follicular helper phenotype

*R. K. Franke[1,2], J. P. Weber[1,2], F. Fuhrmann[1,2], M. Al Baz[1,2], D. Vu Van[1,2], H. W. Mages[2], R. A. Kroczek[2], **A. Hutloff**[1,2];*
[1]German Rheumatism Research Centre Berlin (DRFZ), Berlin, Germany, [2]Robert Koch Institute, Berlin, Germany.

The development of T follicular helper (TFH) cells can be divided into different phases: the early expression of the master transcription factor Bcl-6 in the T cell zone, the upregulation of CXCR5 and migration towards the B cell zone, and late phases where fully matured TFH cells interact with germinal center (GC) B cells. The costimulatory molecules CD28 and ICOS both have been shown to be important for TFH cells.
Using an *in vivo* T/B cooperation system with antigen-specific T and B cells, we dissected the requirement for CD28 and ICOS in different phases of TFH development. Whereas CD28 was already critical for very early steps, ICOS knock-out T cells normally upregulated Bcl-6 and migrated towards the B cell zone. However, these functions reversed in late phases. Blocking of CD28 with CTLA-4-Ig did not have any effect on already differentiated TFH cells. In contrast, blockade of the ICOS pathway resulted in a complete loss of the TFH phenotype within 48 hours. The reversion of the TFH phenotype started within hours by downregulation of molecules important for the localization of TFH cells, leading to redistribution to the T cell zone. This further resulted in breakdown of the GC response and loss of GC B cells within the next 4 days. We could show that continuous ICOS costimulation is required for a unique transcriptional program which stabilizes the TFH phenotype. These findings are important in the context of treatment for autoimmune diseases where TFH cells play a critical role for pathology.

P3.12.07
A positive feedback loop between splenic long-lived plasma cells and follicular helper T cells

***E. Jang**, W. Chp, J. Youn;*
Laboratory of Autoimmunology, Department of Anatomy & Cell Biology, College of Medicine, Hanyang University, Seoul, Republic of Korea.

Long-lived plasma cells (LL-PCs) are crucial for persisting chronic inflammatory disorders, but how they impinge on the pathogenesis remains unclear. We found that Foxp3+ regulatory T cell-depleted autoimmune mice, referred to as K/BxNsf, exhibited an abnormal accumulation of autoantigen-specific LL-PCs in their spleens but not in the bone marrow. K/BxNsf LL-PCs were less susceptible to the cytotoxic action of cyclophosphamide and escaped from immune complex-mediated apoptosis by downregulating FcγRIIb. They expressed lower levels of costimulatory molecules and the intracellular machinery for antigen presentation than conventional short-lived plasma cells (SL-PCs), which was associated with their reduced capacity of CD4+ T cell priming. Most importantly, antigen-pulsed LL-PCs drove CD4+ T cells to induce follicular helper T cell-specific factors such as BCL-6 and IL-21, while SL-PCs failed to do. Thus, our results suggest that, unlike SL-PCs, LL-PCs abnormally accumulated in the spleen of autoimmune mice form a positive feedback loop with follicular helper T cells, thereby favoring the persistence of humoral autoimmunity. [Supported by a grant from KRF 20110015826 and 201200000000945].

P3.12.08
Roles of follicular helper T (TFH) cells in antibody based protective immunity in influenza virus vaccination

***M. Kubo**[1,2], K. Miyauchi[1], A. Sugimoto-Ishige[3], T. Kaji[3], Y. Takahashi[4], T. Takemori[3];*
[1]Laboratory for Signal Network, RCAI, RIKEN Yokohama Institute, Yokohama, Japan, [2]Division of Molecular Pathology, RIBS, Tokyo University of Science, Noda, Japan, [3]Immunological Memory, RCAI, RIKEN Yokohama Institute, Yokohama, Japan, [4]Department of Immunology, National Institute of Infectious Diseases, Tokyo, Japan.

The elevation of antibody's affinity for virus neutralization is achieved by class-switch and somatic mutation of B cells in germinal center (GC). GC formation is highly dependent on unique helper T cell subset, follicular helper T (TFH) cells. The transcriptional repressor Bcl6 is a master regulator of TFH cells and GC formation, and its deletion results in the loss of TFH cells. To address the role of TFH cells in the influenza A virus (IAV) infection, we evaluated the protective responses for IAV in the T cell and B cell specific Bcl6 deficient mice (Bcl6f/f CD4-cre and Bcl6f/f mb1-cre). During the IAV infection and vaccination process, Bcl6 deficiency severely diminished the IAV specific IgG1 production in the consequence of loss of TFH cell and GC formation. However, the Bcl6 deficient mice exhibited normal IgG2b and IgG2c productions, which is a dominant antibody specific for virus HA antigen. Furthermore, in normal IAV vaccinated mice, the IgG2c producing B cells resided in both inner and outer GC area, while the IgG1 producing B cells were preferentially resided in inner area of GC. Serum from the vaccinated Bcl6 deficient mice had a protective immunity as efficient as normal mice, suggesting that IgG1 and IgG2b&c responses may be controlled independently by distinct helper T cell subset, and the IgG2b&c antibody responses and the protective immunity against IAV are independent on the TFH cells and GC formation.

P3.12.09
Costimulation through GITR increases follicular helper T cell formation and leads to control of a chronic viral infection.

*M. F. Pascutti[1], C. Brandao[1], R. W. van Olffen[2], T. Poplonski[1], R. A. W. van Lier[1], **M. A. Nolte**[1];*
[1]Sanquin, Amsterdam, Netherlands, [2]AMC, Amsterdam, Netherlands.

The glucocorticoid-induced TNF receptor family-related protein (GITR) is an important costimulatory receptor on T cells. We have previously shown that enhanced costimulation through GITR increases the formation of both effector and regulatory $CD4^+$ T cells. Here we explored whether it could also affect humoral immunity and T cell help to B cells. Although development of mature B cells was not affected in GITRL transgenic (tg) mice, we found that the number of follicular helper T cells ($CXCR5^+$ $PD1^+$ $CD4^+$ T cells, Tfh) was significantly increased, including the absolute number of Tfh-B cell conjugates, as revealed by ImageStream analysis. Tfh from GITRL tg mice had normal expression levels of ICOS, SLAM and CD44 and slightly lower levels of CD62L and CCR7 compared to wild-type (WT) littermates. Interestingly, Tfh from GITRL tg mice produced more IFN-γ and IL-10, which was accompanied by a biased antibody repertoire (decreased IgG3 and increased IgA, IgG2a and IgG2b). Since Tfh have been implicated in the late control of viral replication, we infected WT and GITRL tg mice with LCMV Clone 13. Surprisingly, at day 30 after infection, we could not detect viral genome in spleen and liver from GITRL tg mice, while WT mice were still infected. Also, PD-1 expression was strongly decreased on virus-specific $CD8^+$ T cells, which correlated with faster viral clearance. All in all, these results indicate that GITR-mediated costimulation enhances the control of chronic viral infections, by boosting and modulating Tfh cell responses.

P3.12.10

The implications of skin epidermal and dermal antigen-presenting cells in T follicular helper cell polarization

C. Nuttens[1], *L. Chonco*[1], *O. Bonduelle*[1], *S. Munier*[2], *B. Verrier*[2], *B. Combadiere*[1];
[1]*INSERM/UPMC U945, Paris, France,* [2]*IBCP, Lyon, France.*

T follicular helper cells (TFH), a lineage of CD4+ T cells, play a pivotal role in isotypic switch of immunoglobulin (Ig) after interaction with professional antigen-presenting cells. The cutaneous vaccination route has been shown to be more effective at inducing both cellular and mucosal immune responses. Mouse pre-clinical studies have demonstrated a good level of efficacy of intradermally-injected poly-lactic-acid nanoparticles (PLA-NPs), coated with the HIV-derived protein p24, in initiating a favorable immune response. The skin contains numerous dendritic cells (e.g. epidermal Langerhans cells (LCs) and dermal CD207+ dendritic cells (CD207+ dDCs)), specialized in the capture and presentation of antigens. As TFH are highly implicated in IgA class switching, we thus questioned the role of LCs and dermal DC in the induction of TFH for shaping IgA production.
Our results in mice model highlight two different transport pathway of ID-injected p24-NPs to the aDLN: i) rapid and passive migration to the subcapsular sinus and ii) transport by skin DCs and inflammatory cells. While free p24-NPs are taken up by LN-resident DCs, cell-bearing NPs are located in T and B cell zones. We noted the high efficacy of ID-injected p24-NPs to induce TFH polarization and the expansion of IgA-secreting B cells in aDLNs. Interestingly, deficiency in LCs affects both responses. In contrast free draining NPs were not able to induce neither TFH nor IgA responses.
Our work highlights the importance of skin DCs in eliciting a strong antibody response and contributes to our knowledge of the complex cellular mechanisms orchestrating intradermal vaccination.

P3.12.11
Regulation of follicular helper T cells in Peyer's patches by endoluminal ATP

A. Romagnani*;*
IRB, Bellinzona, Switzerland.

Follicular helper T (T_{FH}) cells have emerged as the specialized supplier of B cell help during T cell dependent humoral response. T_{FH} home B cell follicles trough the expression of CXCR5 and express high level of several costimulatory molecules including ICOS, PD1 and CD40L. Precursor of T_{FH} cells in Peyer's patches (PPs) are regulatory T cells (T_{regs}) that lose FoxP3 expression. The development of T_{FH} necessitates the B-T cells interaction and the expression of the transcription factor B cell lymphoma 6 (Bcl6). The purinergic P2X7 receptor is a non-selective cationic channel activated by extracellular ATP. Prolonged P2X7 stimulation or high concentration of ATP provokes opening of a pore permeable to molecules up to 900 Da and cell death. *P2rx7* is a T_{regs} signature gene and is upregulated upon T_{regs} conversion to T_{FH} cells in PPs, rendering this T cell subset particularly sensitive to apoptosis induction by extracellular ATP.
p2rx7 deficiency led to significant increase in T_{FH} cells in PPs with increased ICOS that in turn boosted CXCR5 expression. PPs from *p2rx7*$^{-/-}$ mice showed significant expansion of GC B cells in PPs and increase in fecal IgA. Increased T_{FH} differentiation in PPs is a T cell intrinsic property of *p2rx7*$^{-/-}$ T cells since *p2rx7*$^{-/-}$ T_{regs} reconstituted PPs in *cd3*$^{-/-}$ reconstituted mice more robustly than wild-type cells. Oral administration of ATP led to a strong decrease in T_{FH} cells thereby showing that endoluminal ATP can control through P2X7 T_{FH} cells abundance and adaptive mucosal immunity in the gut.

P3.12.12
TLR9 signaling acts on multiple elements of the germinal center to enhance antibody responses

D. Rookhuizen*, A. L. DeFranco;*
University of California, San Francisco, San Francisco, CA, United States.

Recent studies have demonstrated important roles of nucleic acid sensing toll-like receptors (TLRs) in promoting protective antibody responses against several viruses. To dissect how recognition of viral nucleic acids by TLRs enhances germinal center (GC) responses, mice selectively deleted for MyD88 in B cells or dendritic cells (DCs) were immunized with antigen bound to a TLR9 ligand. TLR9 signaling in DCs boosted GC magnitude by expanding follicular helper T cells (TFH) and as a consequence, antigen-specific GC B cells, whereas in B cells it improved GC quality through affinity maturation, class switch to IgG2a, and enhanced B cell memory. Qualitative changes resulting from B cell-intrinsic and -extrinsic effects, as well as quantitative effects emerging from DCs, were associated with changes in the relative numbers of TFH and FoxP3+ follicular regulatory CD4+T cells (TFR) and in modulation of their expression of the costimulatory receptors ICOS and PD-1. These data indicate a widespread role for TLR/MyD88 signaling in DCs and B cells in the enhancement of antibody responses through coordinated regulation of multiple elements of the GC response.

P3.12.13
Antibody production and T forlicular helper response in mice immunized with modified HIV-1 envelope gp120

H. Yu, D. Tian, J. Wang, X. Wang, C. Guo, Y. Li, ***M. Zhuang****, H. Ling;*
Harbin Medical University, Harbin, China.

5%-25% of HIV-1 infected individuals produce broad neutralizing antibodies (bNAb). A HIV-1 vaccine (RV144) has shown a protection partially associated with epitopes within envelope V2 regions. It is well accepted that both NAbs and non-NAbs are important for protection against HIV infection. However, the mechanisms for antibody production in HIV-1 vaccination are still less known. In the present study, to develop HIV-1 envelope immunogens and explore T follicular helper function in Ab production, we modified the envelope derived from a HIV-1 primary R5 strain, immunized mice using DNA prime-protein boost strategies. Antibody production, T cell development as well as B cell differentiation by the vaccination have been examined (This work was supported by a Grant of Natural Science Foundation of China 81271824).

P3.13 Regulatory T cells: basic aspects

P3.13.01
Increased $CD8^+$ regulatory T cells in breast cancer

F. Riazi-Rad[1], *Z. Saraf*[2], *R. Omranipour*[3], *M. Alimohammadian*[1], ***S. Ajdary***[1];
[1]*Pasteur institute of Iran, Tehran, Iran,* [2]*Tarbiat Modares University, Tehran, Iran,* [3]*Cancer Institute of Tehran University Of Medical Sciences, Tehran, Iran.*

Cancer progression and metastasis has been correlated with the presence of immunosuppressive factors. Regulatory T cells (Tregs) are partially responsible for attenuating antitumor immune responses in patients with cancer. Tregs are a heterogeneous population of cells composed of subsets with different phenotypes and functions. Most of these cells constitutively express Forkhead box protein P3 (Foxp3), a transcription factor critical for Tregs cell development and function. $CD4^+$ Tregs have been extensively studied in many different types of cancer, however less is known about $CD8^+$ Tregs. In the present study, we evaluated the frequency of $CD8^+$ Tregs in 20 patients with breast cancer. Blood samples, lymph nodes and tumor tissues were evaluated for the proportion of $CD8^+$ $CD25^+$, $CD8^+$ $Foxp3^+$, and $CD8^+$ $CD25^+$ $Foxp3^+$ T cells as a percentage of the total $CD8^+$ cells, by flow cytometric analysis with triple-color staining.
The results showed the mean (+SE) ratio of CD4/CD8 in blood, lymph node and breast tissue were 1.73 (+0.7), 3.73 (+0.45) and 0.51

(+0.09), respectively. The percentage of $CD8^+$ $CD25^+$ T cells (28.3+7.2), $CD8^+$ $Foxp3^+$ (30+7.4), $CD8^+$ $CD25^+$ $Foxp3^+$ (25.7+7.1) cells in tumor tissue were significantly (P<0.01) higher than those of PBMCs. Moreover, the percentage of $CD8^+$ $Foxp3^+$ in tumor was significantly higher than that of lymph node (P<0.01).
An enrichment of CD4 T cells in lymph node and CD8 T cells in tumor tissue is evident. In addition, it seems that $CD8^+$ Tregs are accumulated at tumor sites compared with peripheral tissues and may participate in forming a suppressing environment.

Regulatory T cells during tumor development in the APCmin/+ mouse model of colon cancer

***P. Akeus**, V. Langenes, A. von Mentzer, S. Raghavan, M. Quiding-Järbrink;*
Dept. of Microbiology and Immunology, Gothenburg University, Gothenburg, Sweden.

Regulatory T cells (Treg) are important to prevent autoimmunity, microbial driven inflammation and allergy. In colorectal cancer, Treg infiltration is associated with a better patient outcome, in contrast to most other tumours. To evaluate the function of Treg in colorectal cancer, we have used $APC^{min/+}$mice that spontaneously develop tumours in the intestine due to a mutation in the *APC* tumor suppressor gene.
Co-culture experiments with $CD4^+CD25^+$Treg and $CD4^+CD25^-$ responder T-cells was performed to examine the function of Treg. Splenic Treg from $APC^{min/+}$mice suppressed the proliferation of conventional wild-type T cells in a dose-dependent manner to the same extent as wild-type Treg. This suppression was independent of age and tumor burden. Cytokines was examined in the supernatants of suppression assay and revealed an increased production of IL-17 and a decreased production of IFN-γ compared to responder cells cultured alone. The frequencies of Treg, $CD4^+$ and $CD8^+$ were determined by flow cytometry and immunoflorescence and revealed an accumulation of Treg and a decrease of conventional T-cells in the tumors. To further evaluate if Treg actively inhibit lymphocyte migration into tumors, $APC^{min/+}$mice were crossed with DEREG mice, in which Treg can be selectively depleted through injections with diphteria toxin. Treg depletion resulted in an increased infiltration of conventional T cells into intestinal tumors.
In conclusion, our results show that $APC^{min/+}$mice have functionally active Treg and that Treg depletion leads to an increased infiltration of T cells into the tumors, suggesting that Treg have important effects on local T cell recruitment to tumors.

P3.13.03
Asymptomatic *Leishmania major*-infected individuals exhibit lower frequency of regulatory T cells compared to the healed individuals

***M. Alimohammadian**, F. Bahrami, H. Darabi, F. Riazi-Rad, V. Khaze, S. Ajdary;*
Pasteur Institute of Iran, Tehran 13169-43551, Iran.

Recent studies have suggested critical roles for regulatory T cells (T_{reg}) in leishmaniases. Here using human subjects, we investigated the role of these cells in individuals healed from *Leishmania major* infection (symptomatic), compared to healthy subjects with positive leishmanin skin test (asymptomatic). Volunteers from an endemic area of *L. major* in Iran (Damghan) were screened with leishmanin skin test. Peripheral blood samples from both symptomatic (16) and asymptomatic (18) groups along with two control groups from healthy residents of either the endemic (15) or a non-endemic area (10) were collected. The percentage of T_{reg} ($CD4^+CD25^+Foxp3^+$) was determined by monoclonal antibodies using flow cytometry. Moreover, the responder T ($CD4^+CD25^-$) and T_{reg}-enriched ($CD4^+CD25^+$) cells were isolated (n=4) by magnetic cell sorting and the suppressive capacities of the latter were interpreted by in vitro proliferation assays. The results revealed that the asymptomatic group had significantly lower percentage of T_{reg} (0.43 ± 0.07%), compared to the symptomatic cases (0.83 ± 0.17 %; p<0.05). The co-culture of the isolated responder ($CD4^+CD25^-$) and T_{reg}-enriched ($CD4^+CD25^+$) cells in 1:1 ratio caused significantly lower percentage of proliferation in the healed and the asymptomatic groups (57 % ± 0.06 and 61% ± 0.14, respectively; p<0.05), compared to the controls. These data suggest that despite the similar suppressive activity of T_{reg} in both groups, the lower frequency of the T_{reg} in the asymptomatic persons may prolong the Th1 responses, leading to persistence of a very limited number of the parasite in the inoculation sites and prevention of lesion formation.

P3.13.04
Analysis of the Treg cell proteome by differential quantitative mass spectrometry

***M. Barra**[1], D. Richards[1], J. Hansson[2], M. Delacher[1], J. Krijgsveld[2], M. Feuerer[1];*
[1]DKFZ, Heidelberg, Germany, [2]EMBL, Heidelberg, Germany.

Regulatory T cells (Treg cells) are involved in the regulation of immune responses to pathogens and tumors as well as in the regulation of the immune homeostasis. While gene expression profiles of Treg cells have been generated to identify targets, only limited data are available on the protein level. We now performed differential quantitative mass spectrometry of the Treg cell proteome.
Murine Treg cells and conventional CD4+ T cells (Tconv cells) were FACS purified. The isolated proteins from both populations were differentially labeled with stable isotopes. Differential quantitative mass spectrometry was performed to measure relative protein abundance. The experiment was replicated 4 times and identified targets were confirmed by flow cytometry as far as antibodies were available.
We were able to identify a total of 5225 proteins, while 3756 were present in all 4 replicates, among those 164 were significantly differentially expressed in Treg cells compared to Tconv cells. The generated mass spectrometry data correlated with the gene expression data for many candidates. Classic regulatory T cells markers like Foxp3, GARP, IL2rβ, GITR and Nrp1 were highly expressed on Treg cells compared to Tconv cells on both RNA and the protein level. In addition, the proteome data set was enriched for differences that affected the Treg population as a whole unlike the mRNA data. The comparison of RNA and protein data allowed us to identify interesting targets that were differentially regulated between the RNA and protein. We are currently working to characterize identified targets in Treg cell development and function.

P3.13.05
Association between SNP rs 2234711 and tuberculosis

***B. Beiranvand**[1], S. abediankenari[2], M. Rezaei[3], E. beiranvand[4];*
[1]Jundishapur University of Medical Sciences, Ahvaz, Iran, [2]Immunogenetics Research Center, Faculty of Medicine, Mazandaran University of Medical Sciences, Sari, Iran, [3]Faculty of Medicine, Mazandaran University of Medical Sciences, Sari, Iran, [4]Pasteur Institute of Iran,Tehran, Member of Research Committee, Mazandaran University of Medical Sciences. Sari, Tehran, Iran.

Introduction: The FOXP3 gene encodes a transcription factor thought to be essential for the development and function of regulatory T cells(Treg), which are play a key role in balancing immune responses to maintain peripheral tolerance against antigens .The Studies have found an association between common polymorphisms in FOXP3 and some of infection diseases. However, data about FOXP3 gene in TB is limited. The aim of present study was to analyze the association between FOXP3 gene polymorphism and susceptibility to TB in the North of IRAN.
Methods: In a case-control study, 183 TB patients and 183 controls were recruited according to age and gender. We investigated one FOXP3 promoter single nucleotide polymorphism (SNP), -3279 A>C (rs3761548) by using PCR sequence-specific primer (PCR-SSP) technique.
Results: We found no evidence for increased risk associated with the FOXP3 and rs3761548 (-3279 AC) genotype (P > 0.05).
Conclusion: In this study, we showed that there were no differences between TB patients compared to controls. It is concluded that understanding the relationship between TB and Foxp3 gene needs additional experiments in different populations.

P3.13.06
Prolactin Effect in Cd4+Cd25hicd127low/- Regulatory T Cell Function in Human

F. Blanco-Favela[1,2]*, V. Legorreta-Haquet*[1]*, K. Chávez-Rueda*[1]*, E. Montoya-Diaz*[1]*, L. Chavez-Sanchez*[1]*, L. Arriaga-Pizano*[1]*, E. Zenteno-Galindo*[2]*;*
[1]IMSS, México City, Mexico, [2]UNAM, Mexico City, Mexico.

Among its many functions, prolactin participates in the immune response favoring the activation, differentiation and proliferation of T cells. However, the mechanisms through which prolactin participates in the regulation of regulatory T cells (T_{reg}) are still unknown. Our goal was to determine whether prolactin plays a role in T regulatory cell function.
We determined the expression of prolactin and its receptor in regulatory T cells and effector T cells (T_{eff}) from 15 healthy individuals. Furthermore, we evaluated the functional activity of regulatory T cells by examining proliferation and cytokine secretion in cells activated with anti-CD3/CD28 in the presence or absence of prolactin. We report that regulatory T cells constitutively express prolactin receptor, whereas T effectors cells require stimulation with anti-CD3/CD28 to induce prolactin receptor expression. On the other hand, expression of prolactin is constitutive in both populations. In cell cultures, we found that the addition of prolactin inhibited the suppressor effect mediated by regulatory T cells, reducing suppression in the T_{reg}:T_{eff} culture from 37.4 to 13 % when compared to prolactin is added to co-cultures of T_{reg}:T_{eff} ($p < 0.05$). While, cultures favored a Th1 cytokine profile, with increased production of TNF and IFN. We report for the first time that prolactin receptor expression is constitutive in regulatory T cells, unlike T effectors cells, which require stimulation to induce prolactin receptor expression. Prolactin inhibits regulatory T cell function, apparently through the induced secretion of Th1 cytokines.

Surface protein glycosylation status profoundly influences T-cell functional characteristics. We aimed to compare surface glycosylation profiles of regulatory (T-reg) and conventional (T-conv) $CD4^+$ mouse T-cells that may underlie specialised functions. $CD4^+$ T-cells were isolated from C57BL/6-FoxP3-EGFP mice in which GFP expression is exclusive to T-reg. Surface glycosylation and proliferation was then evaluated by multi-colour flow cytometric analysis using a panel of 17 biotinylated lectins (carbohydrate binding proteins), labelling with the cell proliferation dye eFluor670® and gating on T-regs (GFP^+) and T-conv (GFP^-) at rest and following activation.
Freshly-isolated splenic T-regs demonstrated significantly higher surface binding of 5/17 lectins (GSL-I, DSL, PHA-E, PHA-L and SNA-I) compared to T-conv. These differences were maintained following 5-day culture without an activation stimulus or following weak activation stimulus (0.1 - 1.0 ug/ml Concanavalin A). However, in strongly stimulated cultures (anti-CD3/anti-CD28 antibodies), the lectin-binding profiles of T-conv changed to resemble those of T-regs.
