PL1.01
Mitochondrial transport by microtubule acetylation is essential to NLRP3-inflammasome activation

***S. Akira**, T. Misawa, T. Saitoh;*
WPI Immunology Frontier Research Center, Osaka University, Suita Osaka, Japan.

Detection of pathogen components and subsequent induction of innate immune responses, such as the production of inflammatory cytokines and type I interferon (IFN), is mediated by pattern-recognition receptor (PRR) that include Toll-like receptor (TLR), RIG-I-like receptors (RLR), C-type lectin receptor, NOD-like receptor and intracellular sensor for DNA (AIM2, DAI, IFI16 and DDX41). In addition to infectious insults, endogenous damage-associated molecular pattern molecules (DAMPs) also activate these receptors, resulting in sterile inflammation. In response to Nigericin, monosodium urate, or silica particles, NLRP3 forms the inflammasome with its adaptor protein ASC and mediates innate immune responses. Chemical compound screening revealed that tubulin polymerization inhibitors including colchicine specifically suppress NLRP3-inflammasome activation. NLRP3-inflammasome inducers cause aberrant mitochondrial homeostasis to reduce the NAD^+ level, which in turn inactivates the NAD^+-dependent α-tubulin deacetylase Sirtuin 2 (SIRT2), resulting in accumulation of acetylated α-tubulin. Accumulated acetylated α-tubulin mediates ASC-NLRP3 contact to promote NLRP3-inflammasome activation. These findings indicate that, in addition to direct activation of NLRP3, the creation of optimal sites for signal transduction by microtubules is required for entire activation of the NLRP3-inflammasome.

PL.3.01
On Immunity in, Biomarkers for, and Vaccines against Tuberculosis

***S. H. E. Kaufmann**;*
Max Planck Institute for Infection Biology, Berlin, Germany.

Tuberculosis (TB) is a health threat of global dimension. TB is also a highly interesting target for immunologic research since it reflects the outcome of a longstanding co-evolutionary process between the pathogen and the human host. Worldwide 2 billion individuals are infected with *Mycobacterium tuberculosis*, of whom 90% remain latently infected under control of a balanced immune response. In 10% of infected individuals TB emerges due to dysbalanced immunity. T lymphocytes are central regulators of protection and pathology and mononuclear phagocytes serve both as effectors against and as habitat for the pathogen. Interactions focus on granulomas which as solid granulomas contain the pathogen, and as necrotic/caseous granulomas promote disease and dissemination. (I) Immune mechanisms which control inflammation in TB will be discussed including sensing of pathogen patterns and the role of regulatory cytokines, chemokines and micro-RNA. (II) The current vaccine BCG prevents disseminated childhood TB but fails to protect against pulmonary TB. We have genetically modified BCG to improve its protective efficacy. This vaccine is currently undergoing chemical testing with promising results. (III) Global gene expression profiling has provided deep insights into the host response in TB. Biosignatures have been defined which distinguish latent infection without disease from active disease. Such biomarkers not only provide the basis for novel intervention measures but also shed light on mechanisms underlying protection/pathology. Reciprocity between basic and translational research will provide new avenues in TB research.

PL.4.01
Interactions between the cellular and the humoral arm of innate immunity

***A. Mantovani**;*
Istituto Clinico Humanitas, University of Milano, Rozzano, Italy.

Innate immunity consists of a cellular and a humoral arm. The role of negative regulators, including TIR8 (a member of the IL-1 receptor family) and D6 (a decoy and scavenger chemokine receptor) will be discussed. We have used the long pentraxin PTX3 as a paradigm for the humoral arm of innate immunity and its interplay with cells. PTX3 is a multifunctional soluble pattern recognition receptor characterized by a C-terminal domain highly homologous to C-reactive protein and serum amyloid P component, associated to a N-terminal domain unrelated to other known proteins. PTX3 is produced upon stimulation with proinflammatory cytokines and Toll-like receptor engagement by different cell types, including endothelial cells, monocytes/macrophages, dendritic cells, fibroblasts and epithelial cells. The molecule binds with high affinity complement component, microbial moieties, growth factors and apoptotic cells. PTX3 plays non-redundant functions including innate immunity against selected microorganisms to regulation of inflammation. In addition PTX3 has a regulatory function. PTX3 serves as a paradigm for the interplay between the cellular and the humoral arm of innate immunity.

PL.6.01
Dissecting the antibody response to pathogens and self antigens

***A. Lanzavecchia**[1,2];*
[1]Institute for Research in Biomedicine, Bellinzona, Switzerland, [2]Institute of Microbiology, ETH Zurich, Zurich, Switzerland.

Memory B lymphocytes and long lived plasma cells represent a repository of the antigenic experience of an individual. By analyzing the specificity and function of these cells we can gain insights into the human immune response to pathogens and vaccines, identify correlates of protection, and isolate neutralizing antibodies and protective T cells. To interrogate human memory B cell and plasma cell repertoires we developed two culture-based high-throughput methods that are used to isolate, with high efficiency, human monoclonal antibodies of distinctive specificities. Unusually potent neutralizing antibodies against human cytomegalovirus were isolated from infected donors and used to identify the viral ligands and to design an experimental vaccine. We also isolated antibodies of exceptional breadth, such as a pan-influenza A neutralizing antibody and an antibody that neutralizes both respiratory syncytial virus and metapneumovirus. By targeting conserved structures, these broadly neutralizing antibodies are less prone to select escape mutants and are therefore promising candidates for prophylaxis and therapy of infections as well as tools for the design of improved subunit vaccines. We also isolated and characterized autoantibodies from patients with pemphigus, pulmonary alveolar proteinosis and other autoimmune diseases. By reverting the antibodies to the germline we investigate the role of somatic mutations in the generation of broadly neutralizing antibodies and autoantibodies.

PL.8.01
The Inflammasome in Health and Disease

***R. A. Flavell**[1,2];*
[1]Howard Hughes Medical Institute, Yale University School of Medicine, New Haven, CT, United States, [2]Department of Immunobiology, Yale University School of Medicine, New Haven, CT, United States.

Dysregulation of the immune system and host-microbiota interaction has been associated with the development of metabolic diseases such as obesity and diabetes. Recent studies in our lab have

elucidated the important function of inflammasomes as steady-state sensors and regulators of the gut microbiota. Mice with disrupted inflammasome pathway have been shown to develop a colitogenic microbial community, which resulted in exacerbation of chemical-induced colitis and diet-induced steatohepatitis. As increasing evidence has demonstrated the profound effect of intestinal microbiome on host metabolism, the goal of this study was to examine the role of inflammasome-regulated microbiota in the pathogenesis of obesity and associated metabolic disorders. Notably, we found that mice lacking the inflammasome adaptor ASC developed increased adiposity and impaired glucose tolerance on regular chow. When fed with a high fat diet (HFD), mice lacking ASC, NLRP6, caspase-1 or IL-18 all manifested exacerbated obesity, adiposity and insulin resistance. 16S-rRNA based metagenomic analysis demonstrated an altered fecal microbial composition in HFD-fed ASC KO mice. Cross-fostering to WT mothers and antibiotic treatment diminished the aberrant microbiota in ASC KO mice and abrogated their metabolic phenotype. Together, these data suggest that the inflammasomes play a critical role in regulating energy metabolism via modulation of the gut microbiome.

PL.9.01
Cancer Immunoediting: From basic mechanisms to novel immunotherapies

***R. D. Schreiber**;*
Washington University, St Louis, MO, United States.

Cancer Immunoediting is the process by which the immune system controls and shapes cancer. We originally envisaged and subsequently showed that, in its most complex form, cancer immunoediting occurs in three phases: Elimination (i.e., cancer immunosurveillance—the host-protective phase of the process); Equilibrium (i.e., immune mediated tumor dormancy—the phase in which tumor cells that survive elimination are subjected to immunologic growth control and undergo editing); and Escape (i.e., the phase where immunologically sculpted or immunoselected tumors with either reduced immunogenicity or enhanced immunosuppressive capacity emerge to become clinically apparent, progressively growing tumors). Strong experimental data supporting each phase of the process have been obtained using mouse models of cancer and compelling clinical data have revealed that a similar process also occurs in humans. Our efforts now focus on elucidating the molecular and cellular mechanisms that underlie each phase of cancer immunoediting and in identifying the critical checkpoints that regulate progression from one phase of the process to the next. This focus led to development of a novel method of cancer exome sequencing and its use in defining mutational tumor antigens as key targets for adaptive immunity in nascent developing unedited cancers. Furthermore, we showed that immunoselection is a major immunoediting mechanism. We are now applying this approach to identifying mutational antigens in clinically apparent, edited tumors that can be used as targets for different forms of cancer immunotherapy including checkpoint blockade therapy. Our long-term goal is to develop rapid, safe, specific and effective personalized cancer immunotherapies.

Perspectives in immunology

PS1.01
On Understanding Immunity or what Immunology is all about

***R. Zinkernagel**;*
University of Zurich, Zurich, Switzerland.

1) Definition of specificity; by phenolic haptens or by protective antigenic sites against infections? 2) Importance of antigen as the (major, only?) regulator of immunity. 3) Protective immunity by vaccines against the classical acute childhood infections (e.g. measles), against chronic persistent infections (e.g. TB, leprosy, HIV or malaria)? 4) How is there no reactivity against extralymphatic intact organs and self-antigens, except when these are brought into secondary lymphatic organs in sufficient amounts and for sufficient time periods? 5) Are there important effector T cell class differences induced by phagocytosed antigens? And is crosspresentation > 10^6 fold less efficient than direct presentation? 6) Affinity maturation of antibodies against poorly or noncytolytic infections is slow, and against infectious agents that cause cell death too slow, and therefore irrelevant 'for memory'. 7) So called immunological memory is an experimental artefact. It is the pre-existent level of protective (neutralizing) antibodies (or the number of pre-activated T cells) that determine protection. Re-stimulation of so called memory B- or T cells takes 2 - 5 days and therefore is generally too slow for efficient protection.
The discussed parameters and limitations of the immune system, and of its function, show that we cannot do better immunologically than co-evolution if we use the same tools as evolution has been using. But we certainly can do better if we use new tools not used by evolution such as antibiotics, antivirals or pharmacologically active small molecules.

PS.2.01
Primary T cell immunodeficiency and immunopathology

***A. Fischer**;*
INSERM U768 & Unité d'Immunologie Hématologie Pédiatrique, Hôpital Necker-Enfants Malades, Université Paris Descartes; Imagine Institute, Paris, France.

Modern tools in genomics have made easier the identification of monogenic inherited diseases that include a number of T cell immunodeficiencies. Their study continues to provide a flurry of informations on T cell biology and mechanisms underlying immunopathological findings frequently observed in T cell ID such as inflammation and auto immunity. Therefore, T cell PIDs may serve as models to capture pathophysiology of more common immunopathological disorders. Examples will be presented and discussed.

PS.3.01
Beyond anti-TNF Therapy for Rheumatoid Arthritis: Can we get close to a cure?

***M. Feldmann**, R. Williams, F. Brennan, P. Taylor, C. Monaco;*
Kennedy Institute of Rheumatology, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, London, United Kingdom.

The treatment of rheumatoid arthritis has progressed in recent years, with the incorporation of low dose methotrexate and 'biologicals' into routine treatment of disease. Of the biologicals, the TNF inhibitors, both monoclonal antibody and monoclonal antibody-like TNF receptor Ig fusion protein have been the most successful. While treatment is beneficial in the majority of patients, the exact percentage depending on the stage of disease, this therapy does not yield a cure; but approximately a 50% benefit. Our challenge is thus to learn how to get closer to a cure. We and others have been working on a number of approaches. Our approaches include analysing the cytokine abnormalities in non-responder patients, analysing the inhibitory pathways which are not functioning effectively in RA patients, and selectively interfering with the source of the antigen, the citrullination pathway. In case these approaches fail to develop the necessary solutions, we are also working on an empirical approach, using CyToF (mass spectrometry linked to flow cytometry) to evaluate which signalling pathways are upregulated in active disease patients compared to inactive RA, or non-responders compared to responders.

PS.4.01
T cell receptors, their specificity and role in selection

P. Marrack[1,2], *J. White*[2], *E. Kushnir*[2], *D. Becker*[2], *H. Krovi*[3], *J. Scott Browne*[4], *R. Bedel*[2], *L. Gapin*[2], *J. Kappler*[2], *J. Kappler*[2];
[1]*CO, United States,* [2]*National Jewish Health, Denver, CO, United States,* [3]*University of Colorado, Denver, Denver, CO, United States,* [4]*La Jolla Institute of Allergy and Immunology, La Jolla, CA, United States.*

More than thirty years ago others discovered the phenomenon of positive selection in the thymus. During this event, thymocytes are selected to mature only if their receptors react with low affinity with the MHC + peptide combinations on thymus cortical epithelial cells. One consequence of positive selection is the fact that mature T cells are much more likely to react with any given foreign peptide bound to an allele of MHC that they encountered in the thymus (self restriction) than with peptides bound to foreign MHC. In the studies to be presented here we examined the structural basis for the bias for self restriction. Our results show that the phenomenon is governed by the variable regions and also by the CDR3, somatically created, regions of the T cell receptors on T cells.
The latter finding is unexpected because T cell receptor CDR3 regions are usually thought to react with the peptide bound to MHC, rather than the MHC itself. If the peptide is the basis for the MHC allele specificity of positive selection it is a mystery how the self peptides that drive positive selection can reproducibly resemble, in their amino acids that contact the T cell receptor, foreign peptides. The mysteryand its possible resolutions will be discussed.

PS.5.01
Macrophage Receptors and Immune Activation

S. Gordon*;*
University of Oxford, Oxford, United Kingdom.

Monocyte/macrophages represent a family of specialised phagocytes present in lympho-haemopoietic and other tissues.I shall present an account of their origin, distribution and activation, emphasising tissue macrophage microheterogeneity in situ and plasticity. Recent microarray and proteomic analysis has established gene expression signatures which underlie their known properties, and point to novel functions. This will be illustrated by studies in human and mouse, with special reference to alternative activation of macrophages by Th2 cytokines. The talk will emphasise the role of non-opsonic plasma membrane receptors implicated in innate and adaptive immunity.
The Th2 cytokines IL-4, IL-13 and their receptors initiate a distinct alternative activation phenotype in macrophages. We have identified biomarkers such as transglutaminase 2 as conserved indicators of alternative activation in human as well as mouse macrophages in vitro. The expression of such markers has been validated in human and mouse asthma models and suggests heterogeneity in monocyte as well as tissue macrophage populations.

PS.7.01
IL-6: New era comes for the treatment of inflammatory autoimmune diseases

T. Kishimoto*;*
Immunology Frontier Research Center, Osaka University, Suita City, Japan.

IL-6 was originally identified as a T cell-derived cytokine, which induces antibody production in B cells. A series of subsequent studies have revealed that IL-6 has a pleiotropic activity in various tissues and cells and its deregulated expression is responsible for several chronic inflammations and hemopoietic malignancies. Humanized antibody against 80kd IL-6R (Tocilizumab) has shown significant therapeutic effect in RA, JIA, Castleman's diseases, several other autoimmune inflammatory diseases, such as progressive sclerosis, reactive arthritis, polymyalgia rheumatica, adult still's desease and uveoretinitis. Cytokine storm induced by hyperactivation of T cells has been shown to be controlled by Tocilizumab. Recently, TH17 is shown to be responsible for the pathogenesis of autoimmune diseases and IL-6 together with TGF-β are essential for the induction of TH17. We identified a new transcription factor required for Th-17 cell induction, which is induced by IL-6 and TGF-β. This molecule, aryl hydrocarbon receptor (Ahr) interacts with Stat1 and Stat5 and abrogates their negative activity in the induction of Th-17 cell differentiation. Experimental arthritis is completely abrogated in T cell-specific Ahr-deficient mice. Therapeutic effect of Tocilizumab indicates that overproduction of IL-6 is responsible for the pathogenesis of autoimmune diseases. We identified a novel molecule, Arid5a, which specifically stabilizes mRNA of IL-6, sustains its overproduction and plays an important role in the promotion of inflammatory processes and autoimmune diseases.

PS.8.01
Evolution of Adaptive Immunity

M. D. Cooper*;*
Emory University School of Medicine, Atlanta, GA, United States.

An alternative adaptive immune system has been defined in the surviving jawless vertebrates, lampreys and hagfish. Surprisingly, in this ancient immune system, leucine-rich-repeat gene segments are used instead of immunoglobulin V(D)J gene segments to generate very large repertoires of antigen receptors, called variable lymphocyte receptors (VLR), for T-like and B-like lymphocytes. Functional interactions between these lamprey lymphocyte populations are implied by their reciprocal expression of interleukins (IL-8 and IL-17) and their cognate receptors. Immunological memory is suggested in lampreys by their heightened secondary VLR antibody responses and increased antibody affinity. The unique structural characteristics and specificities of the lamprey VLR antibodies indicate their potential value as diagnostic reagents for infections and malignancies in humans. The similarities between the alternative adaptive immune systems in jawless and jawed vertebrates suggest they evolved as parallel solutions that balance the advantages and disadvantages of a highly diverse repertoire of lymphocyte antigen receptors.
Supported by NIH grants R01AI072435 and R01GM100151

Lunchtime lectures

LL.1.01
Immunological tolerance: mechanisms and therapeutic applications

A. K. Abbas*;*
University of California San Francisco, San Francisco, CA, United States.

The immune system exists in a balance between the generation of effector and memory lymphocytes to protect against pathogens and the generation of Foxp3+ regulatory T cells (Tregs) to prevent or limit inflammatory reactions. Failure of control mechanisms is the fundamental cause of many inflammatory disorders. We have exploited transgenic mouse models to examine T cell responses to systemic and tissue-restricted self antigens and how these responses are controlled. Exposure of naive CD4 T cells to systemic or tissue antigens under various conditions leads to the development of pathogenic effector cells, and inflammatory disease. The disease resolves spontaneously, associated with the generation and activation of Tregs. Tregs that encounter tissue antigen acquire increased suppressive activity, and a fraction of these Tregs persists as a memory population that continues to control subsequent inflammatory reactions in the tissue. Thus, Tregs go through a sequence of development in the thymus, activation in the periphery to perform their function, and survival as memory cells, which is fundamentally similar to the life history of all lymphocyte populations. The generation and maintenance of pathogenic effector T cells vs protective Tregs are determined by: i) the duration of antigen exposure, with persistent antigen reducing effectors and preserving Tregs, and ii) cytokines, especially IL-2, which, at low concentrations, preferentially expands and maintains Tregs.
Elucidating the stimuli that generate and maintain functional Tregs in tissues will likely be valuable for manipulating immune responses in inflammatory diseases and for optimal vaccination and cancer immunotherapy.

LL.3.01
T Cell Memory and Exhaustion

***R. Ahmed**;*
Emory Vaccine Center and Department of Microbiology and Immunology, Emory University School of Medicine, Atlanta, GA, United States.

Acute viral infections result in the generation of a long-lived and self-renewing pool of highly functional memory CD8 T cells. These memory CD8T cells play an important role in faster control of infection upon re-exposure to the same pathogen. In contrast, chronic antigen stimulation during persistent viral infections or during cancer can lead to functional exhaustion of CD8 T cells. A characteristic feature of these exhausted CD8 T cells is sustained expression of inhibitory receptors such as PD-1. It is now well established that PD-1 plays a major role in T cell exhaustion and that blockade of the PD-1 inhibitory pathway can restore function in exhausted T cells. The role of PD-1 in T cell exhaustion was first described in mice during chronic LCMV infection and these observations have been extended to other chronic infections in mice, non-human primates and humans. Most recently, PD-1 directed immunotherapy has shown promising results in a phase I clinical trial in cancer patients. In this talk I will describe a new role for PD-1 in regulating T cell differentiation and also discuss strategies for enhancing PD-1 directed immunotherapy.

LL.4.01
Calcineurin/NFAT control of innate immunity

T. Zelante[1], J. Fric[2], A. Wong[2], T. Ping[2], E. Newell[2], ***P. Ricciardi Castagnoli**[3,1];*
[1]SIgN/ A-STAR, Singapore, Singapore, [2]SIgN/A-STAR, Singapore, Singapore, [3]Singapore.

Dendritic cells (DC) are well known as initiators and regulators of immunity. Microbe's uptake, antigen processing/presentation and cytokine production are well known DC functions. In contrast, the network of signaling pathways leading to regulation of transcription and gene reprogramming still need to be determined to better understand fine-tuning of DC functions.
In this regard, the finding that Calcineurin/NFAT signaling pathway is activated in DC upon fungal and microbial encounter raise the question about the role of NFAT-regulated genes in DC biology. Interleukin2 (IL2) is one of the genes that we found to be regulated by Calcineurin/NFAT signaling in DC.
Herein, we describe recent insights in understanding the production of IL2 against microbial particulates. In particular, 1,3-β glucan triggers IL2 production and interestingly, the concentration, the size as well as the solubility of these microbial particulates determine different dose-responses. The different levels of IL2 are found to be dependent on Dectin-1 and Syk/PLCγ2 signaling which leads to the activation of the calcineurin/NFAT signaling pathway. While there is compelling evidence that transcriptional regulation of IL-2 in DC is tightly controlled, the mechanisms and the biological relevance in vivo are not yet fully understood. Therefore, targeted deletion of the IL2 gene in DC has been achieved by the generation of conditional IL2 flox-flox x CD11c-cre mice. Notably, the associated phenotype, as revealed by the CyTOF technology, clearly indicates a regulatory mechanism of DC-produced IL2 in vivo.

LL.5.01
Memory

***J. Weill**;*
Inserm U783 Université Paris Descartes, Paris, France.

Most vaccines are antibody mediated but one does not have a clear picture on the heterogeneity among memory B cells and plasma cells generated by these vaccines and on how each subset will behave during a recall response. Recent studies in mice have underlined the role of the nature of the antigen in the generation of persistent germinal centers and how the latter may influence the response of the different memory B cell subsets: return to germinal centers to further mutate their Ig receptors, thus increasing the affinity and the diversity of the response and/or giving rise to antibody secreting plasma cells. Moreover most studies are done in mice but there are clear differences between the murine and human B cell compartment, notably concerning the controversial nature of the IgM "memory" sub-population. Finally some auto-immune diseases are clear examples of long-lasting B cell responses thus offering a panel of all the possibilities of the system.

LL.10.01
Non-canonical inflammasome activation targets caspase-11

***V. Dixit**;*
Genentech, Inc., South San Francisco, CA, United States.

Caspase-1 activation by inflammasome scaffolds comprised of intracellular nucleotide-binding oligomerization domain (NOD)-like receptors (NLR) and the adaptor ASC is believed essential for production of the pro-inflammatory cytokines interleukin (IL)-ß and IL-18 during the innate immune response. We found that C57BL/6 gene-targeted mice that caspase-11 (also known as caspase-4) is critical for caspase-1 activation and IL-1ß production in macrophages infected with *Escherichia coli, Citrobacter rodentium*, or *Vibrio cholerae*. Mouse strain 129 exhibited similar defects in IL-1ß production and harboured a mutation in the *Casp11* locus that attenuated caspase-11 expression. This finding is important because published targeting of the *Casp1* gene was done using 129 ES cells. *Casp1* and *Casp11* are too close in the genome to be segregated by recombination so the published *Casp1*$^{-/-}$ mice lack both caspase-11 and caspase-1. Interestingly, *Casp11*$^{-/-}$ macrophages secreted IL-1ß normally in response to ATP and monosodium urate, suggesting that caspase-11 is engaged by a non-canonical inflammasome. *Casp1*$^{-/-}$ *Casp11*$^{129mt/129mt}$ macrophages expressing caspase-11 from a C57BL/6 BAC transgene failed to secrete IL-1β regardless of stimulus, confirming an essential role for caspase-1 in IL-1ß production. Caspase-11 rather than caspase-1, however, was required for non-canonical inflammasome-triggered macrophage cell death, indicating that caspase-11 orchestrates both caspase-1-dependent and -independent outputs. Finally, loss of caspase-11 rather than caspase-1 protected mice from a lethal dose of lipopolysaccharide (LPS). These data highlight a unique proinflammatory role for caspase-11 in the innate immune response to clinically significant disease states.

LL.11.01
Molecular mechanism for antibody memory generation

***T. Honjo**;*
Kyoto University Graduate School of Medicine, Kyoto, Japan.

Recent studies have revealed that the mechanisms for generating immune and genetic diversity share several critical features. Meiotic recombination, V(D)J recombination, CSR and SHM all require H3K4 trimethyl histone modification on the chromatin of the target DNA. Screening of histone chaperones revealed the FACT complex, Spt5 and Spt6 are involved in epigenetic marking of AID targets. Genetic instability related to dinucleotide or triplet repeats depends on DNA cleavage at the aberrant DNA structure by topoisomerase 1 (Top1). We also showed that Top1 initiates DNA cleavage in both SHM and CSR. These similarities suggest that AID hijacked the basic mechanism for genome instability when AID evolved in jawless fish. We showed that AID reduces Top1 protein by translation suppression. AID augments the frequency of mutations approximately 1,000 folds by reducing the Top1 protein, enhancing the formation of aberrant (non-B) DNA structure in Ig as well as other loci. Although AID has the risk of introducing genome instability, evolution selected AID probably because of the advantage conferred on the host of being protected against pathogens by the enormous immunoglobulin diversification. We studied the mechanism for reduction of the Top1 protein by AID and found that the miRNA-Ago2 complex binds the 3' UTR of Top1 mRNA by AID activation. The results support the hypothesis that AID edits miRNA to down-modulate Top1 mRNA translation. Furthermore, we found UNG suppresses SHM by its scaffold function for correct repair. Another non-canonical function of UNG is involved in synapse formation of cleaved ends during CSR.

LL.12.01
Three Horsemen of the Anti-Apocalypse

T. W. Mak[1,2];
[1]*ON, Canada,* [2]*Campbell Family Institute, Toronto, ON, Canada.*

Immune response activation is necessary for anti-pathogen defense but can result in inflammation and/or life-threatening septic shock due mainly to TNFα production. An emerging concept is that several novel parameters cooperate to balance pathogen control against host damage. One such parameter is tissue-specific regulation of TNFα secretion by iRhom2. Another parameter is the pre-priming by commensal bacteria of innate immune responses, a process controlled in part by the newly identified IgM Fc receptor TOSO. Finally, regulation of TNFα production to prevent inflammatory damage is also mediated by the vagus nerve circuit, which involves the synaptic transmitter acetylcholine expressed by leukocytes. Thus, a future approach to both steering towards a desired immune response and mitigating inflammation and septic shock may be to manipulate iRhom2 activation, vagal nerve feedback circuitry and/or microbiotal influence where they impinge on the immune system. We will describe four intertwining projects whose results support this new thinking.

LL.14.01
Toward an integrative biology of T cells and dendritic cells

B. Malissen;
Centre d'Immunologie de Marseille Luminy, INSERM, CNRS, Aix-Marseille Université, Marseille, France.

T cells probe the surface of dendritic cells (DCs) in search of cues reflecting the antigenic and inflammatory status of the body tissues. It remains a daunting task to understand how T cell activation is regulated through the summation of a multitude of positive and negative inputs and how their integration contributes to the unfolding of appropriate T cell responses. One of our major objectives is to understand how mutations that reduce TCR signaling output paradoxically lead to severe immune pathologies in both the mouse and human species. More specifically, we would like to elucidate the mechanisms through which during physiological, antigen-driven T cell responses some signaling "hub" used by the TCR leads first to activation of intracellular signaling pathways and then exerts with a temporal delay a feedback inhibition that leads to rapid attenuation of the whole TCR signaling pathway. In the absence of such negative feedback, T cell responses evolves into chronic pro-inflammatory T cell responses that perpetuate themselves in a TCR-independent manner and induce the production of massive amounts of autoantibodies. After giving an overview of the major actors of T cell activation, we will present some recent genetic and proteomic approaches that we have developed to tackle the complexity of T cell activation under physiological conditions and at the systemic levels.
Key words: T cells, dendritic cells, functional genomics

LL.15.01
Immune tolerance mediated by T regulatory type 1 cells

M. G. Roncarolo[1,2,3];
[1]*San Raffaele Scientific Institute, Milan, Italy,* [2]*San Raffaele Telethon Institute for Gene Therapy, Milan, Italy,* [3]*Vita-Salute San Raffaele University, Milan, Italy.*

T regulatory type 1 (Tr1) cells are a population of Tregs induced in the periphery by IL-10. Tr1 cells control immune responses through IL-10 and TGF-β, and Granzyme B-mediated killing of myeloid APC.
Tr1 cells are identified by their unique cytokine profile (IL-10+IL-4-IL-17-). Tr1 cells express transiently FOXP3 upon activation; but FOXP3 expression never reaches the high levels characteristic of FOXP3+ Tregs. By gene expression profile of human Tr1 cell clones we identified two surface markers (CD49b and LAG-3) that are stably and selectively co-expressed on murine and human Tr1 cells. The co-expression of CD49b and LAG-3 allows tracking Tr1 cells in peripheral blood of patients who developed tolerance after allogeneic hematopoietic stem cells transplantation (allo-HSCT).
Proof-of-principle clinical trials in allo-HSCT demonstrated the safety of cell therapy with Tr1 cells polarized in vitro with DC-10. A phase I/II trial using this polarized Tr1 cells is planned in patients after kidney transplantation.
Results obtained in patients treated with in vitro generated Tr1 cells demonstrated the feasibility of this approach. However, the polarized Tr1 population includes contaminating non-Tr1 cells, which may represent a drawback for Tr1 clinical applications. The co-expression of CD49b and LAG-3 enables the isolation of highly suppressive Tr1 cells from in vitro polarized Tr1 cultures.
In conclusion, Tr1 cells are inducible Tregs that play a key role in maintaining immunological homeostasis. The identification of CD49b and LAG-3 as Tr1-specific biomarkers will facilitate the study of Tr1 cells in vivo and the use of Tr1 cells for forthcoming therapeutic interventions.

LL.16.01
The emerging diversity of immunological memory

A. Radbruch[1], *A. Hauser*[2], *H. Chang*[1], *K. Tokoyodoa*[1];
[1]*Deutsches Rheuma-Forschungszentrum Berlin, a Leibniz Institute, Berlin, Germany,* [2]*Charite, Humboldt University, and Deutsches Rheuma-Forschungszentrum Berlin, a Leibniz Institute, Berlin, Germany.*

Memory plasma cells, memory B and memory T cells provide protective immunity and reactive memory to recurrent pathogens. Recent results challenge the current paradigm that all memory cells are circulating throughout the body in quest of antigen, and are maintained by homeostatic proliferation. This may be true for memory B and T cells of the peripheral blood, which decay in numbers over time, and thus provide a kind of systemic shortterm memory for´recently encountered pathogens. We have recently shown that the bone marrow, which is not drained by the lymphatic vessels, is home of professional T memory lymphocytes providing systemic longterm memory. These cells rest in terms of pro-liferation and gene expression, and express distinct markers of differentiation, e.g. CD69 and Ly6C, discriminating them from cells of the periphery. They are individually maintained in survival niches organized by mesenchymal stroma cells, which express interleukin-7. Some time ago, we had demonstrated a similar principle of organisation for memory plasma cells. Their precursors, plasmablasts of secondary immune reactions immigrate into the bone marrow, guided by CXCL12, and then dock onto CXCL12 expressing mesenchymal stroma cells, which organize their survival as resting memory plasma cells. To this end, they recruit accessory cells like eosinophilic granulocytes. Survival of the memory cells is conditional on being in the niche. A third type of memory, local memory, is provided by memory cells located in distinct tissues, like skin and lung. These cells provide efficient local immunosurveillance at the site of entry of a recurrent pathogen.

LL.17.01
Life and Death Decisions: Annexin AI expressed on apoptotic cells downregulates the immune response

P. H. Krammer, *B. Linke, V. Jahndel, H. Weyd;*
German Cancer Research Center (DKFZ), Heidelberg, Germany.

Removal of excess cells by apoptosis maintains tissue homeostasis. To preclude the development of autoimmunity, dying cells are rapidly cleared by neighbouring phagocytes, such as dendritic cells (DC). The uptake of apoptotic cells usually does not lead to an autoimmune response, even though many self-antigens are presented by professional antigen presenting cells. We reasoned that apoptotic cells might play an active part in preventing autoimmunity by modulating DC activity, possibly leading to the development of "tolerogenic" DC. To define signals on the surface of apoptotic cells involved in this process, we raised monoclonal antibodies against apoptotic cells and screened for their ability to differentiate between live and apoptotic cells. Using this approach, the lipid binding protein annexin A1 (Anx 1) was identified on the surface of early apoptotic cells. Recombinant Anx 1and Anx1-transfected insect cells confirmed a role for this protein in suppression of pro-inflammatory cytokine secretion, upregulation of costimulatory surface molecules and T cell stimulatory capacity of DC. In mice, exposure of Anx 1 on apoptotic

cells leads to non-activation of antigen-specific T cells. Our results indicate that Anx 1 acts as an endogenous anti-inflammatory signal on apoptotic cells, suppressing the immune response against self antigens. Thus, Anx 1 may contribute to the induction of peripheral tolerance.

LL.18.01
Tyrosine kinases and phosphatases in inflammation and autoimmunity

*C. L. Abram[1], B. G. Neel[2], **C. A. Lowell**[1];*
[1]University of California, San Francisco, San Francisco, CA, United States, [2]University of Toronoto, Tornoto, ON, Canada.

The balance between activating signals, initiated by tyrosine kinases, and inhibitory signals, mediated by tyrosine phosphatases, is critical for determining the overall outcome of the immune response. Shp1 is one of the major tyrosine phosphatases responsible for inhibitory signaling in innate immune cells. Mice carrying mutations in *Ptpn6*, the gene encoding Shp1, are referred to as *motheaten* mice. These animals develop a complex autoimmune/inflammatory disease that results in early mortality. Shp-1 regulates multiple cell signaling pathways in different hematopoietic cell types; however, the cellular and molecular mechanisms of autoimmunity and inflammation in *motheaten* mouse strain remains unclear. Using floxed *Ptpn6* mice, we dissected the contribution of innate immune cells to the *motheaten* phenotype. *Ptpn6* deletion in neutrophils, achieved using MRP8-cre (*s100a8-cre*) resulted in cutaneous inflammation but not autoimmunity. By contrast, dendritic cell deletion, achieved using CD11c-cre (*Itgax-cre*) caused severe autoimmunity without inflammation. Genetic and biochemical analysis showed that loss of Shp1 in neutrophils resulted in Src-family and Syk kinase hyperactivation, which in turn lead to dysregulated integrin-mediated neutrophil activation. By contrast, in dendritic cells, lack of Shp1 primarily affected MyD88 dependent pathways, leading to exaggerated TLR and IL-1β signaling responses that drove autoimmunity. Deletion of the inhibitory Lyn kinase, which is upstream of Shp1, in dendritic cells, produced a similar TLR hyperresponsiveness, leading to autoimmunity, probably as a consequence of exaggerated responses to commensal flora. Our results demonstrate how distinct Lyn/Shp1-regulated pathways in different cells contribute to complex disease phenotypes.

LL.20.01
Toxoplasma recognition by TLR11/TLR12 heterodimmers: a tale of mice (cats) and men

***R. Gazzinelli**[1,2];*
[1]Oswaldo Cruz Foundation, Belo Horizonte, Brazil, [2]Universidade of Massachusetts Medical School, Worcester, MA, United States.

Mouse is the natural intermediate host for the protozoan Toxoplasma gondii. Given all the tools available to study mouse immunology, experimental murine toxoplasmosis became very attractive to study the immunological mechanisms of host resistance to protozoan infections. Intriguingly, recent studies reveal that mice developed two host specific (absent in men and most vertebrates) TLRs, i.e., TLR11 and TLR12 that work as heterodimers for detecting T. gondii. While these are the primary TLRs involved in rodent resistance to this parasite, in the absence of such TLRs, the nucleic acid sensing TLRs (NAS-TLRs) participate in detecting and mediating host resistance to acute infection with T. gondii.The absence of functional genes encoding TLR11 and TLR12 in human genome, lead us to investigate the importance of the NAS-TLRs, as alternative receptors for detecting T. gondii in men. Here, we will discuss the importance of TLRs on innate immunity of toxoplasmosis, giving emphasis to the evolutionary aspects of these findings, both on parasite life cycle and human disease.

LL.21.01
The defensin and HMGN1 alarmins have potent adjuvant effects

*F. Wei, D. Yang, P. Tewary, O. M. Z. Howard, **J. J. Oppenheim**;*
National Cancer Institute, Frederick, MD, United States.

High-mobility group nucleosome-binding protein 1 (HMGN1) is a potent alarmin that induces antigen-specific Th1 immune response by interacting with TLR4. Inoculation of EG7, a mouse thymoma transfected to overexpress OVA, into Hmgn1-/- and littermate-matched Hmgn1+/+ mice revealed that the tumor grew much faster in Hmgn1-/- than in Hmgn1+/+ mice. EG7-bearing Hmgn1-/- mice had fewer splenic OVA-specific CD8 cells, suggesting that endogenous HMGN1 contributed to the development of antitumor responses. To determine whether exogenous HMGN1 could also enhance antitumor defense, we inoculated EG7-N1, an HMGN1-expressing EG7 tumor cell line, or parental EG7 into C57BL/6 mice. EG7-N1 tumor grew slower than EG7 tumors in the mice, while both cell lines proliferated equally in vitro, suggesting that the murine immune system was more resistant to HMGN1 expressing tumors.We next constructed a series of eukaryotic expressing plasmids encoding the genes of HMGN1, gp100 (a murine melanoma-associated antigens), or HMGN1-gp100 fusion gene, and used these plasmids as DNA vaccines. C57BL/6 mice vaccinated by gene gun with various plasmids were subcutaneously implanted with B16F1 melanoma (2×104/mouse).Mice vaccinated with HMGN1-gp100 plasmid inhibited tumor growth, whereas control mice developed tumors. T cells from mice immunized with HMGN1-gp100 plasmid generated interferon-gamma and gp100-specific cytotoxic activity. Overall, the data illustrate that HMGN1 contributes to the generation of antitumor immunity and suggest that the alarmin HMGN1 may be used as an effective tumor vaccine adjuvant.

LL.26.01
Chemokine antagonism: an in vivo mechanism for regulating inflammation during viral infection and tumorigenesis

***M. Albert**, R. Barreira da Silva, A. Casrouge;*
Institut Pasteur & Inserm U818, Paris, France.

We recently demonstrated the first in vivo evidence of dipeptidylpeptidase 4 (DPP4) mediated chemokine antagonism in human disease pathogenesis. DPP4 (also known as CD26) is a member of the family of X-prolyl dipeptidylpeptidases (DPPs), and is capable of enzymatically removing the N-terminal two amino acids of proteins. Specifically, we detected N-terminal truncation of the chemokine interferon-induced protein 10 (IP-10 or CXCL10) in chronic hepatitis C virus (HCV) patients, which correlated with higher DPP4 plasma activity, reduced trafficking of CXCR3-expressing lymphocytes and poor response to treatment. DPP4 truncation of IP-10 generates a dominant negative form of the chemokine, which binds its receptor, CXCR3, but does not induce signaling. As a result, we suggested that DPP4 perturbs lymphocyte trafficking in the context of HCV pathogenesis, thus accounting for DPP4 activity being a correlate of treatment failure. Our basic and translational research program is currently focused on the regulation of DPP4 and its ability to perturb lymphocyte trafficking in an in vivo setting, with potential impact on therapeutic vaccination or enhancement of naturally occurring immune responses. Additionally, we aim to establish new tools and unique insight into DPP4 regulation that may help integrate its role in different pathologic contexts and biological processes.

LL.28.01
Genetic determinants of B cell lymphoma transformation and immune escape

***R. Dalla Favera**;*
Columbia University, New York, NY, United States.

Diffuse Large B cell Lymphoma (DLBCL) represents the most common form of B cell derived non-Hodgkin Lymphoma (B-NHL), accounting for ~30% of the de-novo diagnoses and also arising as a frequent clinical evolution of Follicular Lymphoma (FL), the second most common type of B-NHL. The molecular pathogenesis of DLBCL is associated with a number of genetic lesions that appear in part to

distinctly segregate with individual phenotypic subtypes of this malignancy, which appear to derive from germinal center B cell-like (GCB-DLBCL) or from post-GC B cells resembling in vitro activated B cells (ABC-DLBCL), suggesting that these two disease groups utilize distinct oncogenic pathways. However, the lesions that have been identified so far likely may represent only a fraction of those necessary for malignant transformation. Thus, the identification and functional characterization of the entire set of structural alterations present in the DLBCL genome is required for a complete understanding of its pathogenesis and for the development of rationally targeted therapeutic approaches. Toward this end, we have integrated whole-exome sequencing analysis and copy number variation analysis for a comprehensive definition of the DLBCL coding genome. The results have identified a novel set of recurrent genetic lesions, which, in turn, identify novel altered pathways In DLBCL, including those involving chromatin remodeling, germinal-center development and immune escape.

LL.34.01
A dance of death: HIV-1 and immunodominant T cells

A. McMichael[1,2]*, S. Campion*[2]*, L. Dorrell*[2]*, T. Hanke*[2]*, N. Goonetilleke*[2]*;*
[1]*United Kingdom,* [2]*Weatherall Institute of Molecular Medicine, Oxford, United Kingdom.*

CD8+ T cell responses to viruses focus on small numbers of epitopes. Across a population immunoprevalent responses are determined by MHC type some of which become immunodominant. The immunodominance hierarchies reflect epitope quantity on infected cells and prevalence of HIV specific T cells in the naïve repertoire.
In acute HIV-1 infection, initial immunodominance hierarchies are influenced by sequence variability in the single infecting virus. The first T cells then rapidly select escape mutations, which quickly impair T cell control. New responses and escapes follow, shifting the patterns of immunodominance. The rate escape is determined by T cell response relative magnitude countered by fitness cost of each escape mutation. Escape slows as T cell response breadth increases, but all epitopes escape eventually and the virus persists, as ability to make new CD8 T cell responses is impaired.
CD4+ T cell responses to HIV-1 are less narrow and examination of the pre-immune CD4+ T cell repertoire shows that a considerable contribution to primary T cell response from cross reactive memory T cells as well as classical naïve T cells. Furthermore, epitopes are often presented by several different HLA class II allotypes. Thus rules for class II MHC epitope and CD4+T cell selection differ. The recent vaccine induction (Hansen et al Science 340, 940, 2013) of anti-SIV CD8+ T cells that respond to epitopes presented by class II MHC, with no clear immunodominance hierarchy, has major implications for future control of HIV-1 by vaccines.

SS.5.02
Human genetics of infectious diseases

J. Casanova*;*
The Rockefeller University, New York, NY, United States.

The hypothesis that inborn errors of immunity underlie infectious diseases is gaining experimental support. However, the apparent modes of inheritance of predisposition or resistance differ considerably between diseases and between studies. A coherent genetic architecture of infectious diseases is lacking. We suggest here that life-threatening infectious diseases in childhood, occurring in the course of primary infection, result mostly from individually rare but collectively diverse single-gene variations of variable clinical penetrance, whereas the genetic component of predisposition to secondary or reactivation infections in adults is more complex. This model is consistent with (i) the high incidence of most infectious diseases in early childhood, followed by a steady decline, (ii) theoretical modeling of the impact of monogenic or polygenic predisposition on the incidence distribution of infectious diseases before reproductive age, (iii) available molecular evidence from both monogenic and complex genetics of infectious diseases in children and adults, (iv) current knowledge of immunity to primary and secondary or latent infections, (v) the state of the art in the clinical genetics of non-infectious pediatric and adult diseases, and (vi) evolutionary data for the genes underlying single-gene and complex disease risk. With the recent advent of new-generation deep resequencing, this model of single-gene variations underlying severe pediatric infectious diseases is experimentally testable.

SS.7 Innovative flow cytometry to decipher immune cell function (with the contribution of BD Bioscience)

SS.7.01
Innovative tools to incorporate low density antigens in multicolor panels

J. Rohrer*;*
BD Biosciences, San Jose, CA, United States.

Careful antibody panel design is a mandatory step for successful polychromatic flow cytometry. Factors to consider include instrument performance, level of antigen expression, fluorochrome brightness, and spillover. Until recently the limited availability of bright fluorochromes created a challenge when designing panels aimed at identifying several low expressed antigens simultaneously. The development of BD Horizon Brilliant polymer dyes opens a new era in flow cytometry due to their considerable brightness compared to conventional dyes, allowing for easier design and implementation of 10-12 color panels. Moreover, because of the brightness of these fluors, the resolution of dim markers can be greatly improved, allowing the development of high-sensitivity immunophenotyping. Finally, the availability of multiple dyes for different laser lines allows to build 4-5 color panels with minimal set-up requirements reducing the spillover concerns to their minimum.
In this tutorial we will present recommendations for multicolor panel design when incorporating these new reagents,as well as recommendations on instrument configuration and setup. Examples of surface and intracellular applicationsthat benefit from the use of these dyes will also be presented.

SS.7.02
Regulatory B cells maintain regulatory T cells whilst inhibiting Th17 and Th1 differentiation

C. Mauri*, E. Rosser, N. A. Carter, F. Flores-Borja;*
University College London, Division of Medicine, Centre for Rheumatology Research, The Rayne Institute, London, United Kingdom.

In the last few years, significant progress in understanding the biology of B cells and their function in health and disease has been attained. It is now well establish that in addition to produce antibody, B cells present antigens and produce a variety of cytokines. Amongst the different B cell subsets, those producing IL-10 have been ascribed with regulatory function. We have shown that regulatory B cells (Breg) restrain inflammation by controlling the expansion of TH1 and TH17 whilst contributing to the maintenance of regulatory T cells. Translation of our results to human has demonstrated the importance of Bregs in controlling inflammatory responses in patients with rheumatological disorders. In this presentation I will discuss the phenotype and function of Bregs in the context of healthy individuals and the impact that altered cellular function within the Breg

compartment has in patients with systemic lupus erythematous and rheumatoid arthritis. Of late there has been an exponential growth in the literature on regulatory B cells in the areas of infectious disease, autoimmunity and cancer. This reflects the interest in the therapeutic potential of this regulatory subset.

SS.8 Infectious agents and autoimmunity - Part II (with the contribution of Italian Ministry of Health and Italian Multiple Sclerosis Foundation)

SS.8.01
***Porphyromonas gingivalis* and autoimmunity in rheumatoid arthritis**

***P. Venables**;*
Kennedy Institute, Oxford University, Oxford, United Kingdom.

Pathogenic autoantibodies in autoimmune disease are often disease-specific and antigen-specific. They tend to belong to "families" of biologically related proteins. In rheumatoid arthritis (RA), the family is that of citrullinated proteins. Although more than 20 potential citrullinated autoantigens have been described in RA, only four, citrullinated fibrinogen, vimentin, collagen and α-enolase, have be thoroughly characterised, epitope-mapped and animal models established.
Citrullinated α-enolase was discovered by my group over 8 years ago and having shown that it was a true autoantigen in approximately 50% of RA patients, we then went on to map its immunodominant epitope(s) to a peptide designated citrullinated enolase peptide-1 (CEP-1). Anti-CEP-1 is linked to the subset of RA in which smoking and shared epitope are major interacting gene/environment risk factors. Antibodies to the CEP-1 peptide have also been linked to *Porphyromonas gingivalis* infection, based on sequence homologies and cross reactivity between *P. gingivalis* enolase and the human antigen. More recently, we have shown that immunising DR4 transgenic mice with *P. gingivalis* enolase induces an erosive arthritis and autoantibodies to mammalian enolase. *P. gingivalis* produces a unique bacterial deiminase (termed PPAD) which can citrullinate bacterial antigens and human enolase. All of these developments show that defining an autoantibody to a specific antigen in RA supports the gene/environment/autoimmunity paradigm and provides indications of the upstream events in pathogenesis.

SS.8.02
Virus-host interactions in multiple sclerosis

***J. Lünemann**;*
University of Zurich, Zurich, Switzerland.

Genetic and environmental factors jointly determine the susceptibility to develop Multiple Sclerosis (MS). Collaborative efforts during the past years achieved substantial progress in defining the genetic architecture, underlying susceptibility to MS. Similar to other autoimmune diseases, HLA-DR and HLA-DQ alleles within the HLA class II region on chromosome 6p21 are the highest-risk-conferring genes. Less-robust susceptibility effects have been identified for MHC class I alleles and for non-MHC regions. The role of environmental risk factors and their interaction with genetic susceptibility alleles are much less well defined, despite the fact that infections have long been associated with MS development. Current data suggest that infectious triggers are most likely ubiquitous, i.e., highly prevalent in the general population, and that they require a permissive genetic trait which predisposes for MS development. Improving our understanding of the environmental factors involved in MS might lead to new and more effective approaches to prevent this disease.

SS.8.03
Epstein-Barr virus and lymphoid neogenesis in autoimmunity

***F. Aloisi**, B. Serafini, B. Rosicarelli, C. Veroni, R. Magliozzi;*
Istituto Superiore di Sanità, Rome, Italy.

In recent years Epstein-Barr virus (EBV) has gained increasing credibility as the main culprit of some major B-cell related autoimmune diseases, like systemic lupus erythematosus (SLE), rheumatoid arthritis (RA) and multiple sclerosis (MS). Evidence supporting a pathogenic role for EBV in these autoimmune diseases comes from epidemiological, serological, virological and histopathological studies. The presence of a higher viral load in the peripheral blood of SLE and RA patients and in the chronically inflamed target tissues in MS and RA, as well as quantitative and qualitative differences in the immune response toward EBV in SLE, RA and MS suggest poor control of viral infection. However, it is still unclear whether EBV dysregulation has a role in autoimmune disease development or acts as an activator of the underlying disease process. EBV offers numerous mechanisms to perturb the immune system, including immortalization of autoreactive B cells, molecular mimicry and stimulation of inappropriate immunopathological responses. In this presentation I shall summarize evidence linking EBV infection to formation of ectopic lymphoid tissue, a common feature of several organ-specific autoimmune diseases, and shall discuss the possibility that establishment of extra-lymphatic foci of EBV persistence and reactivation plays a role in inducing and sustaining B- and T-cell responses leading progressively to tissue destruction.

SS.11 Moving translational immunology forward through public-private partnership (with the contribution of IMI – Innovative Medicine Initiative)

SS.11.03
Translating inflammatory understanding towards patient benefit: Lessons from anti-TNF therapy

***M. Feldmann**, R. Maini;*
Kennedy Institute of Rheumatology, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, London, United Kingdom.

Monclonal antibodies, first generated by Kohler and Milstein in the 70's were recognized as a wonderful invention. But there were significant hurdles in translating their potential into effective therapy and the monoclonal antibody era of therapeutics did not occur until 2000's. Hurdles which had to be overcome were the potential immunogenicity of monoclonal antibodies in patients, and the production of antibodies in sufficiently large quantities, Kgs to tons for treating humans. Reducing immunogenicity was achieved by molecular biological techniques, first 'chimerization', replacing the murine antibody backbone by human IgG, but leaving the mouse antigen combining site, to 'humanized' or fully human antibodies. Greg Winter contributed much in this latter field of generating human monoclonals.
Our contribution was to define a good target for antibody therapy, the cytokine TNF in rheumatoid arthritis, which if blocked yields sufficient clinical benefit to have become drugs of choice used in millions of patients. In 2011 this family of drugs became the best-selling class of pharmaceuticals, with sales of $25 billion. How we discovered this target and overcame the hurdles to getting this treatment adopted will be discussed.

Tumor-induced myeloid-cell mediated immune suppression: Its all the RAGE

***S. Ostrand-Rosenberg**;*
University of Maryland Baltimore County, Baltimore, MD, United States.

Immunotherapies that activate innate and/or adaptive immunity have significant potential for the treatment and prevention of metastatic cancer. However, immunotherapies are frequently ineffective because cancer patients contain immune suppressive myeloid cells. “Myeloid-derived suppressor cells” (MDSC) and Tumor-Associated Macrophages (TAMs) are the dominant myeloid populations present in virtually all patients with solid tumors. Collectively, MDSC and TAMs facilitate tumor progression by suppressing T and NK cell activation, polarizing immunity towards a tumor-promoting type 2 phenotype, perturbing the trafficking of naïve T cells, promoting tumor vascularization, promoting tumor cell invasion and metastasis, and protecting tumor cells from chemotherapy. Multiple studies have confirmed that optimal immunotherapy requires the neutralization of MDSC and TAMs. Both MDSC and TAMs are driven by chronic inflammation which also enhances their synergism. Chronic inflammation is a complex phenomenon and there are many pro-inflammatory mediators. Many of these mediators are regulated by the pro-inflammatory alarmins High Mobility Group Box protein 1 (HMGB1) and S100A8/A9 which activate cells through the Receptor for Advanced Glycation Endproducts (RAGE) and Toll-like receptors (TLRs). HMGB1 is a major driver of MDSC accumulation and potency and mediates its effects by (i) increasing MDSC ability to suppress T cell activation; (ii) increasing the synergism between MDSC and macrophages by increasing MDSC production of IL-10 in MDSC-macrophage cross-talk; (iii) increasing the differentiation of MDSC from hematopoietic progenitor cells; and (iv) driving the ability of MDSC to prevent T cell trafficking by cleaving the T cell homing receptor L-selectin (CD62L).

S.1.05
Regulation of inflammation and mucosal innate immunity by HVEM, a TNF super family receptor

***M. Kronenberg**, J. Shui, D. Takahashi, A. Larange, G. Kim, S. Zahner, H. Cheroutre;*
La Jolla Institute for Allergy & Immunology, La Jolla, CA, United States.

The herpes virus entry mediator (HVEM) is a TNF super family receptor that binds multiple ligands, including TNF and Ig super family members. We have explored the role of HVEM in epithelial cells, a radiation resistant cell type critical for preventing chronic inflammation and enhancing host defense. During *Citrobacter rodentium* infection by oral gavage, *Hvem*$^{-/-}$ mice had impaired colonic epithelial responses, resulting in higher bacterial burdens, inflammation and increased mortality. HVEM stimulation induced epithelial responses by a novel signaling pathway, NIK-dependent Stat3 activation, resulting in the expression of genes important for mucosal immunity. HVEM signaling also induced IL-22R1 expression, which boosted IL-22 signaling, leading to further enhanced Stat3 activation in the epithelium. While HVEM or IL-22R signaling alone induced Stat3 activation in epithelial cells *in vitro*, during infection *in vivo*, both Stat3-activating pathways were required. Likewise, in *Streptococcus pneumoniae* infection, HVEM was required not only for survival and bacterial clearance, but also for Stat3 activation and induction of innate epithelial responses in the lung. In the *C. rodentium* model, HVEM controlled bacterial clearance by interacting with the Ig family molecule, CD160, which is prominently expressed by innate-like intraepithelial lymphocytes, while a different Ig family member, BTLA, is important in the lung. Our findings establish HVEM as a crucial regulator of innate defense at mucosal surfaces, including the gut and the lung, by acting as a signaling receptor enhancing epithelial Stat3 activation and inducing epithelial IL-22R1 expression.

S.2 Therapy of autoimmune and autoinflammatory diseases

S.2.04
Treg therapy in autoimmunity and transplantation: preclinical and clinical experiences

***J. A. Bluestone**[1,2], S. Bailey-Bucktrout[2], M. DuPage[2], S. Gitelman[2], K. Herold[3], L. Masiello[2], A. Putnam[2], Q. Tang[2], E. Trotta[2], M. Yadav[2];*
[1]CA, United States, [2]UCSF, San Francisco, CA, United States, [3]Yale, New Haven, CT, United States.

Type I diabetic patients suffer from the lack of immune homeostasis and unregulated autoimmune destruction of islet β cells. The lack of regulation has been attributed, in part, to the loss of a highly specialized regulatory T cell. Accumulating evidence suggests that defective regulation is due to the instability and loss of Tregs in the inflamed pancreatic islets. Treg instability and loss results from reduced IL-2 sensitivity and IL-2 signaling via STAT5 as instability is reversed, and immune regulation restored, with IL-2 therapy. However, IL-2 therapy can also activate effector T cells and NK cell subsets as well as induce the expansion of unwanted cells such as eosinophils. Thus, the use of IL-2 immunotherapeutically will benefit from the generation of selective IL-2 muteins that can specifically target Tregs. This presentation will focus on several aspects of Treg and IL-2 biology including their function and stability in mouse and human autoimmune settings. The application of various immunotherapies in controlling Tregs in autoimmune lesions as well as clinical approaches to selectively enhance Treg function will be presented. This work is supported by NIH and JDRF.

S.3 Microbial triggers for inflammation

S.3.02
Commensal microbe-dependent induction of effector T cells in the lamina propria

***D. R. Littman**;*
Skirball Institute, NYU School of Medicine, New York, NY, United States.

The vertebrate intestinal tract is colonized by hundreds of species of bacteria that outnumber the total cells in the host, yet must be compartmentalized and tolerated to prevent invasive growth and harmful inflammatory responses. Signaling initiated by commensal bacteria contributes to compartmentalization, preventing mononuclear phagocyte-mediated transport of the non-invasive bacteria to sites where adaptive immune responses can be induced, e.g. the mesenteric lymph nodes. Nevertheless, T cell responses against non-invasive commensals can occur, as exemplified by responses elicited by the segmented filamentous bacteria (SFB). SFB adhere to the epithelium in the terminal ileum of mice and induce differentiation of Th17 cells that contribute to autoimmune disease in susceptible mice. We found that intestinal Th17 cells from SFB-colonized mice have T cell antigen receptors (TCRs) largely specific for SFB proteins, suggesting that SFB antigen presentation occurs within a niche specialized for Th17 cell differentiation. Based on the mouse studies and evidence for Th17 cell involvement in rheumatoid arthritis (RA), we compared the fecal microbiomes of RA patients and healthy individuals, and found an over-representation of bacterial strains most closely related to *Prevotella copri* in newly-diagnosed untreated patients. The implications of how individual constituents of the microbiota contribute to the effector/memory T cell repertoire and to organ-specific autoimmune disease will be discussed.

S.3.03
Regulation of Pathogen Colonization by Virulence Factors and the Microbiota

***G. Nunez**;*
University of Michigan, Ann Arbor, MI, United States.

The mechanisms that allow pathogens to colonize the intestine and the indigenous microbiota to inhibit pathogen colonization remain

unclear. We found that that germ-free animals are unable to eradicate *Citrobacter rodentium*, a model for human infections with attaching/effacing (A/E) bacteria. These bacteria are food- and waterborne non-invasive pathogens which attach to and colonize the intestinal tract by inducing characteristic A/E lesions on the intestinal epithelium, leading to transient enteritis or colitis in humans. The genome of A/E pathogens including Enterohemorragic *Escherichia coli* (EHEC), enteropathogenic *E. coli* (EPEC) and *C. rodentium* harbor the locus of enterocyte effacement (LEE) that is critical for bacterial colonization and the ability to cause pathology. We found that early in infection, LEE virulence genes were expressed and required for pathogen growth in conventionally raised but not germ-free mice. LEE virulence gene expression was downregulated during the late phase of infection, which led to relocation of the pathogen to the intestinal lumen where it was out-competed by commensals. The ability of commensals to out-compete *C. rodentium* was determined, at least in part, by the capacity of the pathogen and commensals to grow on structurally similar carbohydrates. Moreover, dietary carbohydrates can influence the ability of members of the gut microbiota to out-compete the pathogen in the intestine. Our studies indicate the members of the microbiota use metabolic pathways to out-compete pathogens. Furthermore, intestinal pathogens have developed strategies to avoid competition with commensals based on the expression of virulence factors during the early phase of the infection.

S.3.04
Mechanisms and consequences of NFAT signaling pathway activation in innate immune cells in LPS-induced inflammatory conditions

F. Granucci[1,2];
[1]*University of Milano-Bicocca, Milano, Italy,* [2]*University of Milano-Bicocca, Department of Bitechnology and Biosciences, Milan, Italy.*

Innate immunity is the most ancient form of response to pathogens and it relies on evolutionary conserved signaling pathways, i.e. those involving the NF-kB pathway. Nevertheless, increasing evidence suggests that factors that have appeared more recently in evolution, such as the Nuclear Factor of Activated T cell transcription factor family (NFATc), also contribute to innate immune response regulation in vertebrates. We have observed that exposure to inflammatory stimuli, such as LPS, induces the activation of NFATc factors in innate immune cells, including conventional dendritic cells (DCs), with a mechanism TLR4-independent involving instead CD14. Therefore, from the one hand, the plasma membrane localized CD14 is required for the microbe-induced endocytosis of TLR4. This CD14-dependent endocytosis pathway is upregulated during DC maturation and is required for the efficient stimulation of antigen specific T lymphocytes. The CD14-dependent TLR4 endocytosis relies on the Syk-Plcγ2 pathway. On the other hand, CD14 promotes the activation of the NFAT pathway in DCs. In turn, NFATs contribute to the regulation of IL-2 and PGE2 production, antigen transport to the lymph nodes and DC life cycle. These three NFAT-controlled phenomena and the consequences of their activation will be discussed.

S.4 Leukocyte signaling

S.4.01
T cell metabolism and differentiation

D. Cantrell;
University of Dundee, College of Life Sciences, Dundee, United Kingdom.

T lymphocytes use networks of serine/threonine kinases to interpret information from antigens, cytokines and nutrients to make appropriate responses that control T cell function. Two important nutrient controlled serine/threonine kinases for peripheral T differentiation are the mammalian target of rapamycin complex 1 (mTORC1) and the adenosine monophosphate (AMP)-activated protein kinase (AMPK). mTORC1 functions to control effector T cell differentiation whereas AMPK monitors energy stress to negatively regulate mTORC1 activity and to control the effector/memory transition of immune activated T cells. High-resolution mass spectrometry analysis of the T cell proteomes reveals that mTORC1 controls T cell differentiation by regulating the expression of key transcription factors that control the expression of effector molecules and the effector T cell migratory program. How is mTORC1 activity controlled during immune responses? A key insight is that antigen and cytokine receptors regulate mTORC1 by controlling the cellular uptake of glucose and the large neutral amino acid (LNAA) leucine. The intracellular supply of glucose and amino acids to T cells is thus regulated by pathogen exposure and the T cell antigen receptor (TCR). In the context of leucine uptake, a single System L transporter, slc7a5, mediates LNAA uptake in activated T cells. Strikingly, Slc7a5 null T cells cannot metabolically reprogram in response to antigen and fail to differentiate to effector cells. These findings reveal fundamental mechanisms linking pathogen control of nutrient uptake in T cells to serine/threonine kinase mediated signaling pathways that control T cell function.

S.4.03
Control of T cell signaling by membrane binding of TCR-CD3 ITAMs

K. Wucherpfennig[1,2], *E. Gagnon*[2], *D. Schubert*[2];
[1]*MA, United States,* [2]*Harvard Medical School, Boston, MA, United States.*

The CD3 epsilon and zeta cytoplasmic domains of the T cell receptor bind to the inner leaflet of the plasma membrane (PM), and a NMR structure showed that both tyrosines of the CD3 epsilon ITAM partition into the bilayer. Electrostatic interactions between acidic phospholipids and clusters of basic CD3 epsilon residues were previously shown to be essential for CD3 epsilon and zeta membrane binding. Phosphatidylserine is the most abundant negatively charged lipid on the inner leaflet of the PM and makes a major contribution to membrane binding by the CD3 epsilon cytoplasmic domain. We have found that TCR triggering by peptide-MHC complexes induces dissociation of the CD3 epsilon cytoplasmic domain from the plasma membrane. Release of the CD3 epsilon cytoplasmic domain from the membrane is accompanied by a substantial focal reduction in negative charge and available phosphatidylserine in TCR microclusters. These changes in the lipid composition of TCR microclusters even occur when TCR signaling is blocked with a Src kinase inhibitor. Local changes in the lipid composition of TCR microclusters thus render the CD3 epsilon cytoplasmic domain accessible during early stages of T cell activation. We propose that membrane binding sequesters tyrosine residues of an ITAM in the hydrophobic phase of the lipid bilayer and that receptor triggering induces release of an ITAM from the membrane through localized changes in the lipid microenvironment of TCR microclusters.

S.4.04
Tyrosine kinases in leukocyte activation and migration

A. Mocsai;
Semmelweis University, Budapest, Hungary.

Myeloid leukocytes such as neutrophils or macrophages are critical components of innate immunity but their improper activation may also lead to tissue damage during autoimmune inflammation. We have previously shown that certain neutrophil responses require Src-family kinases, Syk and PLCγ2. Therefore, we tested the role of tyrosine phosphorylation pathways in in vivo inflammatory reactions. Src-family kinases, Syk and PLCγ2 were all found to be required for autoantibody-induced inflammatory reactions such as the K/BxN serum-transfer arthritis in experimental mice. Given the role of tyrosine kinases in β_2 integrin-mediated leukocyte activation, we hypothesized that Src-family kinases, Syk and PLCγ2 are also required for β_2 integrin-mediated leukocyte migration. Surprisingly, neutrophil migration in a conventional Transwell assay did not require Src-family kinases, Syk or PLCγ2 even though it was strongly reduced by the genetic deficiency of the β_2 integrin-chain CD18. In addition, the Src-family kinase inhibitor dasatinib did not affect in vitro neutrophil migration. In vivo competitive migration assays (in which wild type and knockout cells are allowed to migrate to the site of inflammation within the same animal) also revealed that Src-family kinases, Syk and PLCγ2 were not required for neutrophil or monocyte migration in sterile peritonitis or autoantibody-induced arthritis

models. On the other hand, tyrosine kinases were required for cytokine production by neutrophils and macrophages. Taken together, Src-family kinases, Syk and PLCγ2 are required for neutrophil activation and cytokine production but do not play any direct role in CD18-mediated migration of myeloid cells to the site of inflammation.

Colony stimulating factors and macrophage lineage phenotypes

***J. A. Hamilton**;*
University of Melbourne Department of Medicine, Royal Melbourne Hospital, Parkville, Victoria, Australia.

Macrophage-CSF (M-CSF or CSF-1) and granulocyte macrophage-CSF (GM-CSF) were originally defined as hemopoietic growth factors. Subsequent evidence indicates that they can also affect the function of mature myeloid cells, for example, macrophages/dendritic cells. There is heightened recent interest in their biology partly because clinical trials which target their action are underway in inflammation/autoimmunity.
The comparative effects of M-CSF and GM-CSF on murine and human monocyte/macrophage populations in vitro will be presented indicating marked differences and even opposite and competing responses. The relationships between the phenotypes of such CSF-1-treated populations to so-called M1 and M2 polarization states will be discussed. In vivo data arising out of their depletion/blockade, either in the steady state or during inflammation, indicate that M-CSF and GM-CSF both probably control macrophage lineage function and/or survival relatively late in lineage development, perhaps helping to explain the efficacy following their targeting. Unanswered questions will be raised and some future strategies recommended.

S.5.03
Fate mapping the origins of fetal and adult myeloid cells

***H. R. Rodewald**, K. Busch, A. Forsthuber, K. Klapproth;*
German Cancer Research Center, Heidelberg, Germany.

It has remained a challenge to measure in vivo the developmental flow from hematopoietic stem cells (HSC) to myeloid and lymphoid lineages. Therefore, information on key quantitative numbers that characterize the generation and maintenance of the immune lineages is scarce, including answers to the questions how many HSC are active at any time, and how many HSC or their progeny give rise to a particular cell type. We have devised a fate mapping strategy to induce a genetic and inheritable mark in long-term HSC in the bone marrow. In this system, we traced the hematopoietic output from HSC, and measured the developmental flow along hematopoietic branches. Frequencies of myeloid output from HSC are about ten-fold higher compared to lymphoid cells. Moreover, myeloid output is constant while lymphoid cell production appears sporadic during normal adult hematopoiesis. Bone marrow transplantation experiments into non-myeloablated recipients revealed a fast and complete conversion of monocytes from host to donor type. In contrast, the group of recently recognized tissue-resident myeloid cells, which include microglia in the brain, Kupffer cells in the liver, or Langerhans cells in the skin are not, or only incompletely replenished from adult bone marrow HSC. Using a lymphoid marker for fate mapping, we surprisingly traced the origin of many tissue-resident myeloid cells to a developmental window in the fetal liver. A lymphoid mark on fetal derived tissue-resident but not monocyte-derived macrophages suggests closer myeloid-lymphoid relationships in fetal development versus adult maintenance of the immune lineages.

S.5.04
Uncovering the regulation of gene expression in human neutrophils

***M. A. Cassatella**;*
University of Verona, Verona, Italy.

Historically, polymorphonuclear neutrophils have been considered as innate immune cells with an anti-infectious and pro-inflammatory functions, due to their ability to phagocytose and to produce powerful antimicrobial peptides, proteolytic enzymes and reactive oxygen intermediates. Recently, however, unsuspected biological features of neutrophils have been uncovered. Indeed, it has been shown that neutrophils also display a high degree of plasticity as well as contribute to the control of innate and adaptive immune responses. For instance, various experimental models have validated in vitro data proving that, after migration to an infection site, neutrophils are stimulated to synthesize and secrete many proinflammatory cytokines and chemokines. In such regard, it is well known that member of TLRs represent a class of receptors able to trigger neutrophil-derived cytokines and chemokines. However, our knowledge on the TLR-dependent signaling components and molecular mechanisms that, in neutrophils, regulate cytokine gene expression is still incomplete. Similarly, very little is known on the molecular bases underlying the differential capacity to express cytokines by neutrophils and autologous monocytes in response to the same TLR agonist. Data demonstrating that changes in chromatin organization and posttranslational modifications differentially control the transcriptional outputs also in human neutrophils will be presented.

S.5.05
Host vs. microbe in the human neutrophil phagosome

*Y. Y. Pang[1], J. Schwartz[1], J. M. Boyd[2], A. R. Horswill[3], **W. M. Nauseef**[1];*
[1]Inflammation Program and Department of Internal Medicine, Roy J. and Lucille A. Carver College of Medicine, University of Iowa, Iowa City, IA, United States, [2]Department of Biochemistry and Microbiology, Rutgers University, New Brunswick, NJ, United States, [3]Department of Microbiology, Roy J. and Lucille A. Carver College of Medicine, University of Iowa, Iowa City, IA, United States.

In their capacity as the predominant circulating effector cell in human innate immune defense against infection, polymorphonuclear neutrophils (PMN) exert the majority of their antimicrobial action in phagosomes. Antimicrobial agents delivered from granules and reactive oxygen species generated *de novo* by the NADPH oxidase can reach high concentrations, including that of the potent antimicrobial agent HOCl generated by myeloperoxidase-mediated oxidation of chloride. Despite the toxic environment in PMN phagosomes, 10-20% of ingested *Staphylococcus aureus* (SA) survives and eventually escapes. To test the hypothesis that ingested SA repair host-induced damage as a strategy for survival in PMN, we examined the role methionine sulfoxide reductases (msr), enzymes that repair oxidized methionine residues, in the fate of ingested SA. A deletion mutant lacking two isoforms of msr (msrA1 and msrB) was more susceptible to killing by reagent H_2O_2 or HOCl and by PMN. In addition, transcription of *msrA1B* increased briskly after ingestion by normal PMN. Unexpectedly, *msrA1B* upregulation was even greater in SA ingested by PMN in which NADPH oxidase activity was blocked by diphenyleneiodonium or genetically absent (CGD PMN). Isolated PMN granules without exogenous oxidants stimulated increased expression of *msrA1B*, and screening of a library of two-component deletion mutants of SA suggested that vancomycin-responsive VraSR regulated *msr* expression, thereby providing a novel link between oxidative protein repair and cell wall homeostasis in SA. Identification of those transcriptional responses of ingested microbes that promote their survival in PMN will provide better insight into pathogenesis of infection and inspire novel strategies for antimicrobial therapy.

Mechanotransduction processes involved in T cell development and cognate recognition

*Y. Choi[1,2], J. S. Duke-Cohan[1,2], W. Chen[3], B. Liu[3], J. Rossy[4], T. Tabarin[4], J. Gui[1,2], K. Gaus[4], C. Zhu[3], **E. L. Reinherz**[5,1,2];*
[1]Harvard Medical School, Boston, MA, United States, [2]Dana-Farber Cancer Institute, Boston, MA, United States, [3]Georgia Institute of Technology, Atlanta, GA, United States, [4]University of New South Wales, Sydney, Australia, [5]MA, United States.

During the processes of thymic development as well as immune surveillance, the surface molecules on T lineage cells are subject to piconewton scale mechanical forces. We have previously shown that the TCR is an anisotropic mechanosensor, converting mechanical energy into a biochemical signal upon specific but not irrelevant pMHC ligation. Resultant common TCR quaternary change rather than conformational alteration can best facilitate structural signal initiation because of the vast number of distinct TCR molecules. Moreover, in principle, sheer forces can form catch bonds at the TCR-pMHC interface to enhance binding. Given the key role of thymocyte trafficking between cortex and medulla during thymic selection, we further investigated mechanotransduction processes therein. We observed that on developing DP thymocytes, plexinD1 controls surface topology of nanometer-scaled β1 integrin adhesion domains. Furthermore, ligation of plexinD1 by sema3E in trans regulates individual β1 integrin catch bonds. Loss of plexinD1 expression reduces β1 integrin clustering thereby diminishing avidity, whereas sema3E ligation shortens individual integrin bond lifetimes under force to reduce their stability. Both decreased expression of plexinD1 during developmental progression and a thymic medulla-emanating sema3E gradient enhance thymocyte movement towards the medulla, thus enforcing the tightly-orchestrated lymphoid trafficking required for effective immune repertoire selection. In the absence of this regulated mechanobiology, autoreactivity develops. Our results demonstrate plexin-tunable molecular features of integrin adhesion relevant to many cellular processes.

S.6.02
Analysis of T cell fate and reactivity

***T. N. Schumacher**;*
The Netherlands Cancer Institute, Amsterdam, Netherlands.

There is strong evidence that manipulation of T cell immunity can have clinically meaningful effects, not only in the field of infectious diseases but also in oncology. We have set out to develop and exploit technologies that can be utilized to dissect disease- and therapy-induced T cell responses in mice and men. First, to understand how the T cell based immune system can recognize human cancer, we have developed MHC-based technology to measure T cell reactivity against hundreds of (potential) T cell epitopes. Experiments that exploit this approach in conjunction with cancer exome sequencing to dissect T cell recognition of the consequences of the DNA damage in melanoma will be presented. Second, to understand more fundamental aspects of the generation of T cell responses, and in particular T cell diversity, we have developed technology for in vivo lineage tracing at the single cell level. Data obtained demonstrate that the fate of individual naïve T cells is highly discordant, with respect to initial clonal expansion and differentiation, and with respect to their ability to participate in recall responses. From these experiments we conclude that the reproducibility of T cell responses that we are used to see at the cell population level is due to the averaging of highly divergent cellular behaviors. Furthermore, the data demonstrate that asymmetric division of T cells is by itself insufficient to explain the generation of distinct cellular outcomes within the T cell lineage.

S.6.04
The role of self recognition in the development of various T cell subsets

***K. A. Hogquist**;*
University of Minnesota, Minneapolis, MN, United States.

The healthy adaptive immune system is responsive to foreign antigens, and tolerant to self. However, several types of T cells have, and even require, substantial self-reactivity for their particular functions in immunity: nTreg cells, iNKT cells, and nIELs. We used a Nur77GFP reporter mouse to understand the self-reactivity of various T cell populations, and examine the consequences of NKT cell self-reactivity in particular. We identified a specific subset of iNKT cells that produces IL-4 in the steady state, particularly early in life. Through examination of lineage specific transcription factors, we define 3 subsets of iNKT cells_NKT1, NKT2, and NKT17, which exhibit substantial inter-strain variation in numbers. In several strains of mice, NKT2 cells are abundant and stimulated by self-ligands to produce IL-4. This steady state IL-4 conditioned CD8 T cells to become “memory-like”, increased serum IgE levels, and caused dendritic cells to produce chemokines. These data show that steady state IL-4 produced by self-stimulation alters immune properties under normal physiological conditions

S.6.05
Butyrophilin 3A1 binds phosphorylated antigens and stimulates human γδ T cells

***G. De Libero**[1,2], L. Mori[1];*
[1]SIgN, Singapore, Singapore, [2]University of Basel, Basel, Switzerland.

Human T cell receptor Vγ9Vδ2-expressing cells recognise phosphorylated prenyl metabolites (P-Ags) as antigens in the presence of antigen-presenting cells but independently of major-histocompatibility-complex, MR1 and CD1 molecules. We used genetic approaches to identify the molecule that binds and presents P-Ags. We used TCR Vγ9Vδ2 transgenic T cells as responders to stimulation with mouse-human hybrid somatic cell lines as antigen-presenting cells. Using a combination of somtic hybrids containing individual human chromosomes, we mapped the presence of the gene encoding the antigen-presenting molecule to human chromosome 6, in a position telomeric to MHC locus. By microarray we identified genes commonly expressed in antigen-presenting cells and found butyrophilin 3A1 (BTN3A1) as the molecule involved in activation of TCR Vγ9Vδ2 cells.
BTN3A1 bound P-Ags with low affinity, at 1:1 stoichiometry as detected by surface plasmon resonance and mass spectrometry. The structures of the BTN3A1 distal domain in complex with host- and microbe-derived P-Ags revealed an immunoglobulin-like fold, in which the antigens bound within a shallow pocket. Soluble Vγ9Vδ2 TCR interacted specifically with BTN3A1-antigen complex as shown by surface enhanced Raman scattering. Accordingly, BTN3A1 represents an antigen-presenting molecule for the activation of Vγ9Vδ2 T cells.

TLR-ligand peptide conjugates for superior therapeutic vaccination against immunogenic cancers

***C. J. M. Melief**[1], G. G. P. Zom[2], D. V. Filippov[3], W. J. Krebber[4], F. Ossendorp[2];*
[1]ISA Pharmaceuticals, Leiden, Netherlands, [2]Tumorimmunology, Dept of Immunohematology and Blood Transfusion, Leiden University Medical Center, Leiden, Netherlands, [3]Bio-organic Synthesis,, Leiden, Netherlands, [4]ISA Pharmaceuticals,, Leiden, Netherlands.

High-risk HPV type 16 is the most oncogenic virus type that cause cervical, vulvar and head and neck cancer. Therapeutic vaccination with a set of 13 overlapping synthetic long peptides (SLP) covering the entire sequences of the E6 and E7 oncoproteins of HPV16

resulted in complete or partial regression of premalignant lesions in >50% of women presenting with premalignant HPV16-positive vulvar intraepithelial neoplasia (VIN) (Kenter et al. NEJM 2009). In preclinical mouse models TLR ligand-peptide conjugates performed better as therapeutic vaccines than long peptides mixed with the same TLR ligands. Notably, covalent attachment of TLR ligands to synthetic long peptides allows superior Dendritic cell (DC) targeting with antigen and DC activation in vitro and in vivo, resulting in superior T cell priming and tumor control in these animal models. Subsequently D Filippov and colleagues developed a proprietary TLR1/2 ligand, based on knowledge of the crystal structure of its interaction with the TLR1/2 receptor.
In 2013 we will conduct a phase I/II toxicity/immunogenicity clinical trial in HPV16-positive head and neck cancer patients with a vaccine formulation consisting of synthetic long peptides conjugated to the improved TLR-ligand. Two peptides were selected from the set of 13 HPV16 SLP based on immunogenicity in vaccinated patients in previous trials. When these novel TLR ligand-HPV peptide conjugates were functionally tested *in vitro*,they both induced significant mouse and human DC maturation, as determined by IL-12 production and the upregulation of co-stimulatory molecules and other activation markers. Moreover, as determined by specific T-cell proliferation and cytokine production, the epitopes present in the peptides of both conjugates were much more efficiently recognized by HPV-specific human T-cell clones derived from VIN patients in comparison to mixtures of SLP and the same TLR ligand.Taken together, these results provide a solid basis for the further clinical development of proprietary TLR ligand -SLP conjugates.

S.8.02
NLRs and inflammasomes in intestinal homeostasis, cancer and metastasis

M. Saleh*;*
McGill University, Montreal, QC, Canada.

Sensing of microbial products and/or host-derived danger signals by pattern recognition receptors (PRRs) of the innate immune system is a key physiological response required to maintain homeostasis at the steady state and to induce defense mechanisms in pathological situations. However PRR responses need to be tightly regulated, as their aberrant activation is often associated with immunopathologies. The Nod-like receptors (NLRs), which constitute a subset of PRRs, are especially critical for ensuring host resistance, as evidenced by the high association of mutations and single nucleotide polymorphisms in NLR genes with human diseases. We have investigated NLR regulation, signaling mechanisms and effector functions in the gut. At the ICI, I will discuss how NLRs and associated inflammasomes are regulated, and will present our findings on the role of the inflammasome-IL-18 axis in intestinal homeostasis, colorectal cancer and metastasis to the liver. We show that in addition to maintaining intestinal homeostasis and preventing intestinal inflammatory pathologies, the inflammasome mediates tumor immune surveillance through NK cells and suppresses colorectal cancer growth in the liver. The mechanistic bases of these observations will be discussed.

S.8.03
Human NK cell receptors and pathogen infection

A. Moretta*;*
Dipartimento di Medicina Sperimentale Università di Genova, Genova, Italy.

It is well established that Natural killer (NK) cells play a crucial role in early immunity after hematopoietic stem cell transplantation because they are the first lymphocyte subset recovering after the allograft. Interestingly, in different patients undergoing umbilical CB transplantation discrete patterns of NK-cell development can be identified. In this context, we showed that , in a group of patients, a relevant fraction of NK cells already expressed a mature phenotype characterized by the KIR+NKG2A- signature 3-6 months after transplantation. In other patients, most NK cells maintained an immature phenotype even after 2 months. A possible role for cytomegalovirus in the promotion of NK-cell development was suggested by the observation that a more rapid NK-cell maturation together with expansion of NKG2C+ Siglec-7-NK cells was confined to patients experiencing cytomegalovirus reactivation. Our data support the concept that cytomegalovirus infection accelerates NK-cell development after HSCT leading to fully mature KIR+ NK cells displaying potent alloreactivity against KIR ligand mismatched targets.

S.8.04
Variable Natural Killer cell Receptors and Human Evolution

P. Parham*;*
Stanford University, Stanford, CA, United States.

Natural killer (NK) cells have distinctive roles in immunity and reproduction, which are controlled by variable receptors that recognize MHC class I molecules. The variable NK cell receptors present in human populations – the Killer-cell Immunoglobulin-like Receptors (KIR) - are specific to simian primates, species in which the KIR have progressively coevolved with MHC class I molecules. The emergence of the *MHC-A, B* and *C* genes in hominids drove the evolution of a system of KIR that recognises MHC-C molecules, which is currently most highly elaborated in chimpanzees. By contrast, the human system of KIR that recognise HLA-C appears to have been subject to different selection pressures that have acted in competition on the immunological and reproductive functions of MHC class I molecules. It is speculated that this compromise facilitated the development of the bigger brains that enabled archaic and modern humans to migrate out of Africa and populate other continents. Comparison of modern human populations reveals extraordinary diversity in their systems of KIR and HLA class I ligands.

S.9 Genetic and epigenetic control

S.9.01
A genomic framework for macrophage identity and functional specialization

G. Natoli*;*
IFOM-IEO Campus, Milan, Italy.

Cell identity is determined by a complex and highly dynamic interplay between cell intrinsic and lineage restricted developmental pathways on the one hand, and cell extrinsic and tissue specific micro environmental signals on the other. In this context, macrophages are a paradigmatic cell population in that their functional specialization in vivo reflects the impact of the local microenvironment onto the intrinsic macrophage differentiation program. This complex interaction leads to a variety of specialized macrophage types in different tissues as well as in physiological and pathological conditions. Genomic approaches developed in the last five years, and specifically the combination of RNA sequencing and Chromatin Immunoprecipitation (ChIP)-sequencing, have enabled an integrated and high resolution view of players and mechanisms that control macrophage plasticity in the context of different environmental conditions and at the same time enforce macrophage identity in spite of a changing environment. Principles of genomic regulation inferred from these experiments will be discussed.

S.9.02
Histone Mimicry and Antiviral Response

A. Tarakhovsky*;*
The Rockefeller University, New York, NY, United States.

In my presentation I will discuss histone mimicry and its potential physiological significance. Histone mimicry describes a phenomenon of structural and functional similarity between the N-terminal domain of histones and the non-histone proteins of distinct origin. I will

discuss how the presence of histone mimics in mammalian and viral proteins contributes to the regulation of gene expression. I will also discuss how synthetic compounds that mimic the histone function can regulate gene expression in model systems.

S.9.03
Metabolism, epigenetics and miRNAs - an unholy trinity controlling innate immunity

***L. O'Neill**;*
Trinity College Dublin, Dublin, Ireland.

In the field of inflammation research, the most important advances in the past 10 years has been in the uncovering of multiple pathways involved in innate immunity. Glucose metabolism has been shown to be required for induction of IL-1beta mRNA by TLR4. Succinate is a signal from the mitochondria elevated in response to TLR signalling, which is required for IL-1beta gene transcription via activation of HIF1alpha. The so-called Warburg effect of aerobic glycolysis is a feature of cells activated during inflammation (including Th17 cells) providing an added level of complexity to signalling pathways activated by TLRs during inflammation (1). One important output from these changes will be epigenetic modification, as histone and DNA modification depends on metabolic products such as acetylCoA and alpha ketoglutarate. MicroRNAs also participate in these processes, two examples being miR107, whose expression is decreased by LPS and which is involved in insulin resistance, and miR-210 which can target succinate dehyrdogenase. There is therefore likely to be important interactions between metabolism, epigenetics and miRNAs during innate immunity and inflammation.

S.9.04
Regulation of T lymphocyte effector functions by non-coding RNAs

*M. Pagani, G. Rossetti, R. Bonnal, V. Ranzani, A. Arrigoni, I. Panzeri, E. Provasi, R. Rossi, P. de Candia, **S. Abrignani**;*
INGM, Istituto Nazionale Genetica Molecolare, Milan, Italy.

$CD4^+$ T-lymphocytes orchestrate adaptive immune responses by differentiating into various subsets of effector T-cells such as Th1, Th2, Th17, and Treg. These subsets have been described by master transcription factors that dictate the expression of cytokines and receptors, which ultimately define lymphocyte effector functions. However, the view of T lymphocyte subsets as stable and terminally differentiated lineages has been challenged by increasing evidence of functional plasticity within $CD4^+$ T-cell subsets, which implies flexible programming of effector functions depending on time and space of T cell activation. Among the mechanisms which define the plasticity of effector functions, regulatory non-coding RNAs appear to play a key role. Not only microRNAs have been proven to be important for $CD4^+$ T-cell differentiation, but it is also likely that the overall T cell functioning is the result of a multilayered network composed by coding RNAs and by short and long non-coding RNAs. Interestingly, activated lymphocytes release microRNAs that can be monitored in the bloodstream, and we have found that some serum miRNAs can be detected as biomarkers of vaccination and more in general of adaptive immune responses. Furthermore, the prompt reduction of intracellular level of some miRNAs linked to their release in the external milieu suggests that the selective extracellular disposal of miRNAs can be a rapid way to regulate gene expression during lymphocyte activation. In conclusion, the integrated study of all the nodes of this network will provide a comprehensive view of the molecular mechanisms underlying T cell functions in health and disease.

S.10 T and B cell repertoires

S.10.01
Thymic microenvironments that shape T cell repertoire

***Y. Takahama**;*
University of Tokushima, Tokushima, Japan.

During development in the thymus, a virgin repertoire of diverse TCR-alpha/beta recognition specificities in immature T cells is selected to form a functionally competent and self-tolerant repertoire of mature T cells. Positive selection supports the survival of potentially useful self-MHC-restricted thymocytes upon low-affinity TCR engagement, whereas negative selection deletes potentially harmful self-reactive thymocytes upon high-affinity TCR engagement. Recent advances in the biology of thymic stromal cells have indicated that a proximal interplay among developing T cells, dendritic cells, and thymic medullary epithelial cells that promiscuously express tissue-specific self-antigens is essential for the establishment of a self-tolerant TCR repertoire. It has also been pointed out that the formation of an immunocompetent TCR repertoire requires positive selection by thymic cortical epithelial cells that express unique protein degradation machineries, including the beta5t-containing thymoproteasome. These results suggest the vital role played by self-peptide repertoires specifically expressed by multiple thymic microenvironments in the development of an immunocompetent and self-tolerant T cell repertoire.

S.10.03
Control of early B cell development by the transcription factor Ikaros

*T. Schwickert, H. Tagoh, S. Gültekin, A. Dakic, B. Werner, E. Axelsson, M. Jaritz, **M. Busslinger**;*
Research Institute of Molecular Pathology, Vienna, Austria.

The zinc-finger transcription factors Ikaros (Ikzf1) is an essential regulator of B-cell development, which is arrested at an early lymphoid progenitor stage in *Ikzf1*$^{-/-}$ mice. Here, we have investigated the role of Ikaros in early B-cell development.
Conditional loss of Ikaros in *Cd79a*-Cre *Ikzf1*$^{fl/-}$ mice stringently arrested B-cell development at a transitional c-Kit^{low} pro-B cell stage. These pro-B cells did not proliferate although they expressed Igμ and surrogate light chains. ChIP- and RNA-sequencing identified 130 activated and 180 repressed Ikaros target genes, which code for cell surface receptors, signal transducers and transcription factors. Consequently, Ikaros-deficient pro-B cells did not undergo pre-B cell receptor signaling. Consistent with the identification of Ikaros target genes implicated in cell migration and adhesion, Ikaros-deficient pro-B cells failed to migrate in response to CXCL12 stimulation, but strongly adhered to VCAM1-coated surfaces in contrast to control pro-B cells.
At the genome-wide level, Ikaros bound to active promoters and enhancers. DNase I hypersensitive (DHS) site mapping and profiling of active histone marks revealed that Ikaros binding silenced the promoters of repressed Ikaros target genes. In contrast, Ikaros promoted transcriptional elongation and activated enhancers at activated target genes. Together, these data identified Ikaros as an important regulator of early B-cell development.

S.11 Viral infections

S.11.01
Viral regulation of inhibitory and activating Ly49 receptors

***S. Jonjic**;*
Faculty of Medicine University of Rijeka, Rijeka, Croatia.

Natural killer (NK) cells play an important role in the control of cytomegalovirus (CMV) infection. NK cells effector functions are mediated through a fine interplay between activating and inhibitory NK receptors. Ly49 is a family of mouse NK cell receptors which contains both inhibitory and activating members. Inhibitory Ly49 receptors screen the cells for the presence of MHC class I molecules

and play their part in the control of viral infection through the "missing-self" recognition mechanism. On the other hand, activating Ly49 receptors can recognize stand-alone viral proteins or viral proteins expressed with MHC class I molecules. We have previously shown that, in addition to Ly49H which recognizes virally encoded m157 protein, activating Ly49P, L and D2 receptors also play a role in the specific recognition of cells infected by mouse CMV (Pyzik M et al. *Journal of Experimental Medicine* 208:1105, 2011). MCMV encoded m04/gp34 was shown to be necessary, but not sufficient for a successful recognition of MCMV infected cells via these activating receptors. In this talk I will present our results on characterization of viral component needed for an efficient recognition of infected cells by several activating Ly49 receptors. The biological significance of viral regulation of various Ly49 receptors in virus control *in vivo* will be discussed.

S.11.03
Cytokine regulation of NK and CD8 T cell responses to acute viral infections

***C. A. Biron**;*
Brown University, Providence, RI, United States.

There is limited genetic information available to deal with protection against an almost limitless range of infectious agents and against disease resulting from immune responses to infection. To deal with the challenge, the immune system has evolved remarkable flexibility in shaping endogenous responses. Work focusing on elements controlling cytokine effects on NK and CD8 T cells during viral infections will be reviewed. In particular, two mechanisms sensing infection conditions to induce intrinsic cellular changes altering cytokines responses will be discussed. The first is through modifying total protein levels of individual signal transducers and activators of transcriptions (STATs) to change functions of cytokines with preferred STATs but flexibility to use other STATs for activation. The second is the role for proliferation in changing responses to cytokines from immune enhancing with interferon (IFN) gamma production, to immunoregulating with IL-10 production. The mechanisms are being characterized in NK and CD8 T cell responses to type 1 IFNs and IL-12 during infections of mice with lymphocytic choriomeningitis virus (LCMV) and/or murine cytomegalovirus (MCMV). Taken together, the studies are making unexpected discoveries about the biological importance of experience for conditioning intrinsic cell responses to shape immunity and promote health during viral infections. Supported by the National Institutes of Health, USA.

Toward a genetic theory of childhood infectious diseases

***J. Casanova**;*
The Rockefeller University, New York, NY, United States.

The hypothesis that inborn errors of immunity underlie infectious diseases is gaining experimental support. However, the apparent modes of inheritance of predisposition or resistance differ considerably between diseases and between studies. A coherent genetic architecture of infectious diseases is lacking. We suggest here that life-threatening infectious diseases in childhood, occurring in the course of primary infection, result mostly from individually rare but collectively diverse single-gene variations of variable clinical penetrance, whereas the genetic component of predisposition to secondary or reactivation infections in adults is more complex. This model is consistent with (i) the high incidence of most infectious diseases in early childhood, followed by a steady decline, (ii) theoretical modeling of the impact of monogenic or polygenic predisposition on the incidence distribution of infectious diseases before reproductive age, (iii) available molecular evidence from both monogenic and complex genetics of infectious diseases in children and adults, (iv) current knowledge of immunity to primary and secondary or latent infections, (v) the state of the art in the clinical genetics of non-infectious pediatric and adult diseases, and (vi) evolutionary data for the genes underlying single-gene and complex disease risk. With the recent advent of new-generation deep resequencing, this model of single-gene variations underlying severe pediatric infectious diseases is experimentally testable.

Recurrent bacterial and fungal infections, eczema and elevated serum IgE levels characterize patients with the hyper-IgE syndrome (HIES). Known genetic causes for HIES are mutations in proteins involved in signal transduction pathways, namely STAT3 and DOCK8. However, glycosylation defects have not been described in these patients. One crucial enzyme in a glycosylation pathway is Phosphoglucomutase 3 (PGM3), which catalyzes a key step in the synthesis of UDP-GlcNAc which is required for the biosynthesis of N-glycan and other essential glycopolymers. Aim of our study was to elucidate the genetic cause in patients who do not have mutations in STAT3 or DOCK8. Genetic linkage analysis revealed an 11.9 Mb linkage region on chromosome 6. Mutation detection in the positional candidate genes identified one homozygous mutation per family (L83S and E340del) in PGM3 (Phosphoglucomutase 3) that segregated perfectly with affection status and recessive inheritance. Sanger sequencing of PGM3 identified two additional HIES patients from Morocco with the homozygous L83S mutation and a Turkish patient with a third homozygous mutation (D502Y). Functional studies showed that these mutations are hypomorphic and leave intact the enzyme's phosphoglucomutase activity, but impact on the biosynthetic reactions involving UDP-GlcNAc. Glycomics analysis revealed an aberrant glycosylation pattern in leukocytes exemplified by a reduced branching of complex-type N-glycans. We concluded that the impairment of PGM3 function leads to a novel primary (inborn) error of immunity, as biallelic hypomorphic mutations are associated with impaired glycosylation and a hyper-IgE-like syndrome.

S.12.04
Immunoglobulin class switch recombination deficiencies

S. Kracker[1], M. Di Virgilio[2], J. Schwartzentruber[3], C. Cuenin[4], B. Grimbacher[5], N. Kutukuler[6], S. L. Seneviratne[7], N. Jabado[8], M. Nussenzweig[9], ***A. Durandy***[1];
[1]INSERM U768, Imagine Institute, Descartes-Sorbonne Paris cité University, Paris, France, [2]Laboratory of molecular biology, Rockefeller University New York, NY, United States, [3]Department of Human Genetics,, McGill University and Genome Quebec Innovation Cen, QC, Canada, [4]International Agency for Research on Cancer, Lyon, France, [5]Centre of Chronic Immunodeficiency, University Medical Center Freiburg and University, Germany, [6]Department of Pediatric Immunology, Ege University Faculty of Medicine, 35100 Bornova,, Turkey, [7]Department of Clinical Immunology, Royal Free Hospital, London,, United Kingdom, [8]Department of Pediatrics,, McGill University Health Centrer Montreal, QC, Canada, [9]Laboratory of Molecular Immunology,, The Rockefeller University, New York, NY, United States.

Immunoglobulin class-switch recombination deficiencies (Ig-CSR-Ds) are rare primary immunodeficiencies characterized by defective switched isotypes' (IgG/IgA/IgE) production. Depending on the molecular defect in question, the Ig-CSR-D may be combined with an impairment in somatic hypermutation (SHM). Some of the mechanisms underlying Ig-CSR and SHM have been described by studying natural mutants in humans. This approach has revealed that T cell-B cell interaction (resulting in CD40-mediated signaling), intrinsic B-cell mechanisms (activation-induced cytidine deaminase-induced DNA damage), and complex DNA repair machineries (including uracil-N-glycosylase and mismatch repair pathways) are all involved in class-switch recombination and SHM. We herein describe INO80 deficiency as a new cause of mild CSR-D. INO80 is a key protein in an evolutionarily conserved chromatin remodelling complex that functions in DNA replication, repair and transcriptional regulation. We identified hypomorphic *INO80* mutations in two Ig-CSR-D patients. These mutations were associated with fibroblast hyper-radiosensitivity, which was corrected by wild-type INO80 expression. In CH12-F3 cells, down-regulation of INO80 and its partners Reptin and Pontin was associated with lower CSR. Finally, an abnormal separation of sister chromatids was observed upon INO80 downregulation in CH12-F3 cells, suggesting a defect in cohesin. Since INO80 and cohesin were shown to accumulate at Sα and Eμ regions of the IgH locus, we propose that the INO80 complex modulates cohesion function that could be required during switch region synapsis.

Primary Biliary Cirrhosis: The Environment and Autoimmunity

M. Gershwin*;*
University of California at Davis School of Medicine, Davis, CA, United States.

Environmental stimulation is a major factor in the initiation and perpetuation of autoimmune diseases. We have addressed this issue and focused on primary biliary cirrhosis (PBC), an autoimmune disease of the liver. Immunologically, PBC is distinguished by immune mediated destruction of the intra hepatic bile ducts and the presence of high titer antimitochondrial autoantibodies (AMA) directed against a highly specific epitope within the lipoic acid binding domain of the pyruvate dehydrogenase E2 subunit (PDC-E2). Using quantitative structure activity relationship (QSAR) analysis on a peptide-xenobiotic conjugate microarray platform, we have demonstrated that when the lipoyl domain of PDC-E2 was modified with specific synthetic small molecule lipoyl mimics, the ensuing structures displayed highly specific reactivity to PBC sera, at levels often higher than the native PDC-E2 molecule. Furthermore, data on the immunological characterization of antigen and Ig isotype specificities against one such lipoic acid mimic; 6,8-bis(acetylthio)octanoic acid (SAc), when compared with rPDC-E2, strongly support a xenobiotic etiology in PBC. This observation is of particular significance in that approximately one third of patients who have taken excessive acetaminophen (APAP) developed AMA with same specificity as patients with PBC, suggesting that the lipoic domain are a target of APAP electrophilic metabolites such as NAPQI. We submit that in genetically susceptible hosts, electrophilic modification of lipoic acid in PDC-E2 by acetaminophen or similar drugs can facilitate loss of tolerance and lead to the development of PBC.

S.13.05
Genetic and Environmental Contributions to Human Autoimmune Disease

D. Hafler*;*
Yale School of Medicine, New Haven, CT, United States.

GWAS identified genetic associations between common SNPs and risk of autoimmune diseases. We evaluate the extent of sharing for 107 disease-risk SNPs in seven diseases and developed a novel statistic for which detects association of a SNP to multiple phenotypes. We find evidence that 47/107 (44%) immune-mediated disease risk SNPs are associated to multiple immune-mediated diseases. Distinct groups of interacting proteins are encoded near SNPs that predispose to the same subsets of diseases; we propose these as the mechanistic basis of shared disease risk. We have begun efforts to identify the biologic effects of disease causing SNPs at non-coding regions of the genome where it has been difficult to assign function to DNA sequence and to compare these effects across different autoimmune diseases. We use fine-mapping genetic data to identify causal mutations and integrate these data with chromatin maps of ten defined human CD4+ T-cell populations and 56 additional cell-types. These investigations identified risk variants disrupting the enhancers of distinct cell types among the different autoimmune diseases. Finally, autoimmune disease results from untoward interactions between genetics and the environment. We recently showed that salt boost the induction of Th17 cells mediated by SGK1. The Th17 cells generated under high-salt display a pathogenic cytokine phenotype. Mice fed with a high-salt diet develop a severe form of EAE. Identifying specific sites where a single, non-coding nucleotide variant is responsible for disease risk may pinpoint specific disruptions of consensus transcription factor binding sites that ultimately define disease risk as related to environmental factors.

NKT cells as an ideal target for anti-tumor immunotherapy

M. Taniguchi*[1], S. Fujii[1], Y. Okamoto[2];*
[1]RIKEN Center for Integrative Medical Sciences(IMS-RCAI), Yokohama, Japan, [2]Chiba University Graduate School of Medicine, Chiba, Japan, Chiba, Japan.

Human NKT cells bearing an invariant Vα24Jα18 antigen receptor, the counterpart of murine Vα14Jα18 NKT cells, mediate strong adjuvant activity by their production of IFN-γ upon stimulation with a specific ligand, α-GalCer. In the animal model, administration of α-GalCer-pulsed DCs into tumor bearing host completely eradicates metastatic tumors within a week. IFNγ produced by α-GalCer-activated NKT cells mediates strong adjuvant activity acting on NK cells and CD8 killer T cells at the same time to increase in their numbers and to enhance their cytotoxic function. Also, NKT cells induce maturation of immature DCs in the presence of α-GalCer, resulting in the recovery from immunodeficiency in the tumor-bearing host.
Based on the efficient anti-tumor effects of NKT cell-targeted immune cell therapy in the animal model, we conducted phase I/IIa clinical trials in patients with head & neck tumors (10 cases). No severe adverse event related to the treatment was observed. After the injection of α-GalCer-pulsed PBMC-DCs (10^8) into nasal submucosa together with $5x10^7$ in vitro activated autologous NKT cells, all patients responded well to be SD in 5 cases and PR in 5 cases. Tumor infiltrating lymphocytes (TIL) in PR and SR cases were significantly increased (10-100 times increase over untreated controls) 28 days after the NKT cell targeted therapy, which efficiently

recruits endogenous NKT cells. iPS-derived NKT cells are also effective to eradicate tumors. These results are encouraging and warrant further evaluation of the survival benefit of this NKT cell-targeted immunotherapy.

Chemokines: tails from the clinic

***P. M. Murphy**;*
NIAID, NIH, Bethesda, MD, United States.

Knowledge about the chemokine system has advanced from molecules to mice to man, with CCR5 and CXCR4 antagonists maraviroc and plerixafor now on the market for HIV/AIDS and hematopoietic stem cell mobilization, respectively. CXCR4 blockade is also a rational therapeutic strategy in WHIM syndrome, a rare congenital immunodeficiency disorder characterized by warts, hypogammaglobulinemia, infections, and myelokathexis (neutropenia due to impaired egress from the bone marrow) that is caused by gain-of-function mutations in CXCR4. We have developed a Phase I clinical trial to repurpose plerixafor in WHIM syndrome. In addition to defining parameters of safety and efficacy in this disease, the trial has identified new patient groups and a potential role for CXCR4 in G6PC3 deficiency, a newly discovered inherited disorder of glucose homeostasis that like WHIM syndrome is characterized by severe congenital neutropenia and myelokathexis. This trial is providing basic new insights about the role of CXCR4 in leukocyte trafficking in man, as well as information about the utility of plerixafor in WHIM syndrome and the feasibility of chronic blockade of this essential receptor in any disease where it may play a role in pathogenesis.

S.15.02
Chemokine Guidance in the Lymph Node Imprints Adaptive Immune Responses

***A. Luster**;*
Massachusetts General Hospital and Harvard Medical School, Boston, MA, United States.

The differentiation of naïve CD4+ T cells into T helper cells is critical for generating adaptive immune responses. This process occurs in the lymph node (LN) where naïve CD4+ T cells are activated by cognate antigen loaded dendritic cells (DC) and differentiate into one of several lineages of helper T cell subsets, such as T helper type 1 (Th1), Th2, Th17, and T follicular helper (Tfh). While the cytokines and transcription factors that control this process are relatively well understood, far less is known about how this process is temporally and spatially orchestrated within LNs *in vivo*, where it initially takes shape. We have shown that the CXCR3 chemokine system is required for the optimal generation of interferon gamma secreting Th1 cells *in vivo*. Using a newly generated CXCR3 chemokine ligand CXCL9 and CXCL10 reporter transgenic mouse, called REX3 for Reporter Expression CXCR3 chemokine ligands, we have found that following immunization with LPS and poly I:C or infection with influenza, stromal cells in the interfollicular region of the LN predominately express CXCL9 while hematopoietic cells in the medullary and interfollicular regions express CXCL10. Dendritic cell-derived CXCL10 facilitates T cell-DC interactions in LNs during T cell priming and CXCL9 and CXCL10 guide the intranodal positioning of CD4+ T cells to interfollicular and medullary zones, respectively, in the LN following immunization and influenza infection. Thus, the CXCR3 chemokine system guides priming CD4+ T cells into specialized niches in the reactive LN that facilitate Th1 cell differentiation.

S.15.05
Dynamisms and regulation of tumor-associated myeloid cells

***K. Matsushima**[1,2];*
[1]The University of Tokyo, Tokyo, Japan, [2]JST, CREST, Tokyo, Japan.

Tumor growth is often associated with the aberrant systemic accumulation of mononuclear phagocytes, which have the potential to support tumor growth. The accumulation of tumor-associated macrophages (TAMs) is a dynamic process associated with medullary and extramedullary monopoiesis and subsequent chemokine-mediated cellular migration. Recent studies suggest that spleen-pool monocytes are a source of TAMs. However, the relative contribution of spleen- versus bone marrow (BM)-pool monocytes to the TAM population remains unclear.
Here, we track spleen- and BM-pool Ly-6Chi monocytes in tumor-bearing mice in which myeloid cells express KikGR, a fluorescent protein that is irreversibly converted from green to red upon exposure to violet light. Irradiation of either the BM (femur) or spleen allowed us to track the redistribution of Ly-6Chi monocytes from each of these pools over a 24 h period. Within 1 h, significant numbers of red cells appeared in the peripheral blood from each pool, and began to redistribute to the BM, spleen, and tumor. However, many more BM-pool cells than spleen-pool cells accumulated in the tumor due to intrinsic differences in the ability of spleen- and BM-pool monocytes to infiltrate and survive within tumors. Experiments using Fucci transgenic mice that express cell-cycle indicator proteins demonstrated that the BM remains the major site of monopoiesis even in the tumor-bearing state.
These findings provide evidence that the contribution of BM-pool monocytes to the TAM population is considerably greater than that of spleen-pool monocytes.

S.16 Antigen processing and presentation

S.16.01
Genome-wide analyses define new factors controlling MHC class I and MHC class II antigen presentation

***J. Neefjes**;*
The Netherlands Cancer Institute, Amsterdam, Netherlands.

MHC class I present mainly peptides generated in cells by the proteasome to present a blueprint of the intracellular proteome to immune cells. MHC class II molecules perform an analogous job but present mainly peptides generated in endosomes to the immune system. The two systems are thus complementary and in assembly cover the entire proteome for presentation. Fully understanding these processes is important as it may allow manipulation and then skewing of immune responses. Various proteins have been identified that support peptide generation, transfer, folding and loading of MHC molecules. We will report technologies and results from genome-wide genetic screens for additional molecules controlling antigen presentation by MHC class I or MHC class II molecules. These define new biology but also define new and unique targets for manipulation of antigen presentation by MHC molecules, as will be illustrated.

S.16.02
Molecular Aspects of MHC class I-restricted Antigen Processing

***P. Cresswell**;*
HHMI; Yale University School of Medicine, New Haven, CT, United States.

The recognition of virus-infected cells or tumor cells by CD8-positive T lymphocytes relies on the formation of complexes of MHC class I molecules with virus-derived or tumor specific peptides, respectively. The peptides are generated in the cytosol and are translocated into the endoplasmic reticulum (ER), where peptide binding occurs, by the dimeric ATP-dependent Transporter associated with Antigen Processing (TAP). TAP is a component of the multi-subunit Peptide Loading Complex (PLC). The PLC also incorporates the glycoprotein tapasin, a product of an MHC-linked gene, which physically links MHC class I-[[Unsupported Character - Symbol Font ]]$_2$-microglobulin dimers to the PLC. The preferential association of MHC

class I molecules with high affinity peptides is mediated by tapasin and is facilitated by an adaptation of the calnexin/calreticulin quality control cycle that normally facilitates the proper folding of a variety of glycoproteins in the ER prior to transport. The lectin chaperone calreticulin and the thiol oxidoreductase ERp57, two components of this folding pathway, are also associated with the PLC and play a critical role in the peptide binding process. The mechanism of action of the PLC and the nature of the quality control mechanisms underlying the formation of MHC class I-peptide complexes will be discussed.

S.16.04
Antigen crosspresentation in dendritic cells

***S. Amigorena**;*
Institut Curie / INSERM U932, Paris, France.

Dendritic cells represent a highly specialized hematopoietic lineage, whose main role is to sense infections in tissues and to activate specific T lymphocytes in lymphoid organs to mount immune responses adapted to the threat. The mode of dendritic cell activation defines a series of maturation programs that influence T cell activation deeply. To activate T lymphocytes, dendritic cells need to present peptides derived from infectious antigens on MHC molecules on their plasma membrane. The activation of CD8+ T cells to mount cytotoxic immune responses requires the loading of peptides from either endogenous (self or viral) or internalized (endocytosed or phagocytozed) antigens. The latter process, called cross presentation, is more efficient in dendritic cells than in other antigen presenting cells, at least in part due to specialization of dendritic cell's endocytic pathway. Indeed, antigen cross presentation involves several steps of intracellular membrane traffic, including the export of the internalized antigens to the cytosol, low levels of phagosome-lysosome fusion and the recruitment of ER-resident proteins to phagosomes. We have initiated the analysis of the effect of various inducers of dendritic cell maturation on these different steps of membrane traffic.

S.16.05
Regulatory T cells control Th1 priming by inhibiting CD70 expression: a role for intercellular transfer of CD27?

***M. Moser**[1], C. Coquerelle[1], M. Dhainaut[1], H. Yagita[2], J. Borst[3];*
[1]Université Libre de Bruxelles, Bruxelles, Belgium, [2]Juntendo University School of Medicine, Tokyo, Japan, [3]The netherlands cancer Institute, Amsterdam, Netherlands.

Naturally occurring regulatory T cells (nTregs) ensure the integrity of the host by controlling reactivity to self as well as to foreign antigens. We sought to determine the mechanism by which nTreg restrict the development of MHC class I and class II-rectricted IFN-γ-producing cells *in vivo.* Here, we show that regulatory T cells selectively inhibit the CD70/CD27 pathway, while sparing interleukin 12 production. Consistent with a role for CD70, $CD27^{-/-}$ mice did not show enhanced Th1 Responses under conditions of regulatory T cell depletion.Our data reveal a novel mechanism of immune regulation in which intercellular transfer of intact CD27 results in CD70 downregulation on dendritic cells and impaired Th1-prone costimulation. The molecular mechanism of this transfer remains elusive and may include trogocytosis and/or tunneling nanotubes. In conclusion, our data indicate that nTreg control the expression of CD70 on dendritic cells, which has been shown to act as master regulator of tolerance versus immunity.

S.17 Complement and soluble mediators

S.17.01
Complement: more than a "guard" against invading pathogens

***J. D. Lambris**;*
University of Pennsylvania, Philadelphia, PA, United States.

Nearly a century after the significance of the human complement system was recognized, we have come to realize that its functions extend far beyond the elimination of microbes. It is increasingly perceived as an intricate network of effectors, regulators and regulators that not only drives core cascade functions in health and disease but also extensively communicates with associated physiological pathways ranging from immunity and inflammation to homeostasis and development. A steady stream of experimental data reveals new fascinating connections at a rapid pace; while opening unique opportunities for research discoveries, and therapeutic interventions against various diseases and clinical conditions. I will discuss our updated view of the function, structure and dynamics of the complement network, highlight its interconnection with immunity at large and with other endogenous pathways, and illustrate its multiple roles in homeostasis and disease. Finally, I will discuss the current status of complement therapeutics and various approaches for complement based therapies.

S.17.02
Functional aspect of the lectin complement pathway

***T. Fujita**[1,1], M. Takahashi[2], H. Sekine[2];*
[1]Fukushima Prefectural General Hygiene Institute and, Fukushima City, Japan, [2]Department of Immunology, Fukushima Medical University, Fukushima City, Japan.

The complement system is an effector mechanism in both innate and adaptive immunity. It is activated through three pathways, the classical, alternative and lectin pathways. The lectin pathway plays a role in innate immunity. It is initiated by the binding of mannose-binding lectin (MBL) or ficolins to carbohydrates on the surfaces of pathogens. In the lectin pathway, mannose-binding lectin (MBL) and ficolins act as pattern recognition molecules for pathogens, resulting in the activation of MBL- associated serine proteases (MASPs; MASP-1, MASP-2 and MASP-3). Among these proteases, MASP-2 is a key enzyme that cleaves C4 and C2 to assemble a C3 convertase (C4b2a). To investigate the roles of MASP-1 and MASP-3, we generated a MASP-1- and MASP-3-deficient (M1/3 KO) mouse model, and found that the deficient mice lacked alternative pathway activation, because factor D (Df) remained as a proenzyme in the serum. MASP-1 and MASP-3 were able to convert the proenzyme of Df to an active form in vitro and in vivo. Last year, Degn et al. reported that in human serum neither MASP-1 nor MASP-3 is required for alternative pathway function using 3MC MASP-1/3 deficient sera (J Immunol 2012). We claimed this point and found that in human MASP-1/3 deficient sera human Df is still proDf by Western blotting. In human and mouse sera, thus, MASP-1 and MASP-3 seems to be involved in activation of both the lectin and alternative pathways.

S.17.03
Trick or treat - how do pathogens deal with the complement system?

***S. Meri**, D. Ho, T. Meri, K. Haapasalo, H. Jarva, S. Jokiranta;*
Department of Bacteriology and Immunology, Haartman Institute, University of Helsinki, Helsinki, Finland.

Despite the potent antimicrobial effects of the complement (C) system many pathogenic microbes are resistant to opsonophagocytosis or direct C-mediated killing. The pathogens escape C killing e.g. by expressing surface proteins that bind soluble C inhibitors, notably factor H or C4bp. More than ten different types of microbes (borrelia, pneumococci, group A and B streptococci, meningococci and many invasive Gram-negative enteropathogens) express factor H binding proteins (FHBP). Interestingly, FHBPs of microbes often have the same binding sites on factor H, either in domains 6-7 or 20. The importance of FHBPs is exemplified by the facts that 1) a polymorphic variant in domain 7 that predisposes to age-related macular degeneration protects individuals from group A streptococcal infections, 2) the site in domain 20 is used by a number of microbes extending from Gram-negative and positive bacteria to the yeast *Candida albicans* and 3) the FHBPs can be used as vaccines. As a novel C evasion mechanism we have found an ability of pathogenic bacteria to bind the key C components C3 and C4 in a form that prevents their activation. Microbial proteins that bind C3 and C4 noncovalently have been discovered e.g. from *Borrelia burgdorferi*, *Salmonella* and *Yersinia*. The ability to escape C is thus a key feature

in the pathogenicity and invasiveness of disease-causing bacteria. Complement resistance may also explain the species-specificity spectra of some of the pathogens. At an individual level, those who carry protective alleles of their C regulator genes may have survival benefit against microbial infections.

S.17.04
The complement system: friend or foe?

*R. Bulla[1], C. Agostinis[2], **F. Tedesco**[1];*
[1]Department of Life Sciences, University of Trieste, Italy, [2]Institute for Maternal and Child Health, IRCCS Burlo Garofolo, Italy.

Embryo implantation into the maternal decidua represents a real challenge for the maternal immune system during pregnancy. The system provides protection against pathogens and other noxious agents that may impair the progression of pregnancy and at the same time avoids attacking the developing fetus despite recognition of paternal antigens expressed on fetal trophoblast. These goals are achieving mainly through the contribution of the cellular component of the innate immune system, in particular NK cells and macrophages. However, recent data suggest that the complement system is also implicated in these processes. Most complement components and regulators are present in the decidual tissue and may originate both from the circulation and from local synthesis by various cell types including macrophages, fibroblasts, endothelial cells and extravillous trophoblasts. Their expression is regulated by cytokines that contribute to embryo implantation site inducing vascular remodeling. Recent findings have disclosed a novel role of C1q, the first complement component, which is synthesized by decidual endothelial cells (DECs) and invading extravillous trophoblast. C1q expressed on DECs promotes adhesion of endovascular trophoblast followed by partial replacement of endothelium, while C1q secreted by trophoblasts favors their migration through the decidua.
Local complement activation may impair fetal survival if it were uncontrolled by regulators expressed at critical sites in the feto-placental unit. However, unrestricted complement activation may overcome the protection of complement inhibitors resulting in tissue damage and poor pregnancy outcome. Anti-phospholipid syndrome and pre-eclampsia are two examples of pathologic pregnancies that are contributed to a large extent by complement activation.

S.18 Bacterial infections

S.18.01
Activation of inflammasomes by bacterial pathogens

***R. E. Vance**;*
University of California, Berkeley, CA, United States.

Inflammasomes are multiprotein complexes that assemble in the cytosol of cells in response to infection or other noxious stimuli. Once assembled, inflammasomes initiate downstream signaling by activation of downstream proteases, most notably Caspase-1 and Caspase-11. Once activated, these caspases initiate downstream signaling events that stimulate inflammation. For example, inflammasome activation results in processing of cytokines (interleukins-1beta and -18), production of eicosanoids, and a rapid lytic cell death called pyroptosis. There are several distinct inflammasomes, each of which responds to different stimuli. However, the mechanisms by which these stimuli actually lead to inflammasome assembly are poorly understood. In my talk I will discuss recent advances in our understanding of inflammasome activation in response to bacteria. Our data, and that of several other labs, support the idea that the mechanisms of inflammasome activation are surprisingly diverse. An important question that will be considered is whether there are any general principles underlying these diverse mechanisms.

S.18.02
Card9 Signaling Complexes in Innate Immunity

***J. Ruland**;*
Technische Universität Münche, München, Germany.

Card9 is a non-redundant adapter protein that functions in the innate immune system in the assembly of multifunctional signaling complexes. These complexes are engaged upon bacterial, fungal, or viral recognition, and they are essential for host protection. Loss of function mutations in Card9 lead to immunodeficiencies in mice and man. Moreover, Card9 polymorphisms are commonly associated with human inflammatory diseases such as inflammatory bowel diseases. Card9 is required to link Syk-coupled C-type lectin receptors to NF-kappaB activation. Card9 signaling also responds to intracellular danger sensors, such as RIG-I-like receptors and Nod2. Mechanistically, Card9 cooperates with Bcl10 and the paracaspase, Malt1 for the activation of pro-inflammatory cascades. A better understanding of the mechanisms of Card9 activation will enable the development of agonists or antagonists, which might be useful in vaccination and therapies of immunopathologies, Here, we discuss recent insights into the molecular regulation of Card9 signaling and the function of Card9 in host defense and immune homeostasis.

S.18.03
Type I interferon suppresses Type II interferon-triggered human anti-mycobacterial responses

***R. Modlin**;*
UCLA, Los Angeles, CA, United States.

The immune mechanisms that control resistance vs. susceptibility to mycobacterial infection in humans were investigated by studying leprosy skin lesions, the site where the battle between the host and the pathogen is joined. Using an integrative genomics approach, we found an inverse correlation between IFN-β and IFN-γ gene expression programs at the site of disease. The Type II IFN, IFN-γ and its downstream vitamin D-dependent antimicrobial genes were preferentially expressed in the lesions from patients with the self-healing tuberculoid form of the disease and mediated antimicrobial activity against the pathogen, Mycobacterium leprae, in vitro. In contrast, the Type I IFN, IFN-β, and its downstream genes, including IL-10, were induced in monocytes by M. leprae in vitro, and were preferentially expressed in the lesions of disseminated and progressive lepromatous form. The IFN-γ-induced macrophage antimicrobial response was inhibited by IFN-β and IL-10, by a mechanism involving blocking the generation of bioactive 1,25-dihyroxyvitamin D as well as inhibiting induction of antimicrobial peptides cathelicidin and DEFB4. The ability of IFN-β to inhibit the IFN-γ-induced vitamin D pathway including antimicrobial activity was reversed by neutralization of IL-10, suggesting a possible target for therapeutic intervention. Finally, a common IFN-β and IL-10-associated gene signature was identified in both the skin lesions of leprosy patients and in the peripheral blood of active tuberculosis patients. Together these data suggest that the ability of IFN-β to downregulate protective IFN-γ responses provides one general mechanism by which some bacterial pathogens of humans evade protective host responses and contribute to pathogenesis.

S.19.02
Integrating immune and vascular signaling programs through lectin-glycan interactions

***G. A. Rabinovich**;*
Instituto de Biología y Medicina Experimental (IBYME/ CONICET), Ciudad de Buenos Aires, Argentina.

In the postgenomic era, the study of the ‘glycome’- the whole repertoire of saccharides in cells and tissues- has enabled the association of unique glycan structures with specific physiological and pathological processes. The responsibility for deciphering this biological information is assigned, at least in part, to endogenous

glycan-binding proteins or lectins whose expression is regulated at sites of inflammation and tumor growth. With the overarching goal of generating more rational therapeutic strategies, our laboratory investigates the molecular interactions between endogenous lectins and N- and O-glycans leading to the control of immune tolerance, inflammation and angiogenesis in the tumor microenvironment. In the past years we have identified an essential role for galectin-1, an endogenous lectin with specificity for poly-N-acetyllactosamine-enriched glycans in promoting tumor-immune escape in several tumor models by selectively eliminating Th1 and Th17 responses, by instructing the differentiation of tolerogenic dendritic cells (DCs) and by promoting the expansion of FoxP3+ T regulatory cells. In the presence of galectin-1, DCs acquired an interleukin 27 (IL-27)-dependent regulatory function and promoted IL-10-mediated T cell tolerance. More recently, we found that interactions between galectin-1 and specific target N-glycans may couple tumor hypoxia to angiogenesis through mechanisms that are independent of HIF-1α. Targeted disruption of galectin-1-glycan interactions prevented hypoxia-driven angiogenesis and suppressed tumorigenesis in several models. Our results suggest a major role for lectin-glycan interactions in integrating immunoregulatory to vascular signaling programs during tumor growth and metastasis

S.20 T and B cell subsets

S.20.02
Transcriptional network controlling Th17 cell differentiation

V. Kuchroo*;*
Harvard Medical School, Boston, MA, United States.

Upon activation, T cells undergo distinct developmental pathways, attaining specialized properties and effector functions. T-helper (TH) cells are traditionally thought to differentiate into TH1 and TH2 cell subsets. Recently, a subset of interleukin (IL)-17-producing T cells (TH17) distinct from TH1 or TH2 cells was described and shown to have a crucial role in the induction of autoimmune tissue injury. Accumulating data suggests that there are three distinct steps in Th17 differentiation: Induction, Amplification and Stabilization mediated by distinct cytokines and loss of any of the cytokines (TGF-b, IL-6, IL-21 or IL-23) in the pathway results in a defect in generation of Th17. However not all Th17 cells are pathogenic and induce autoimmunity, IL-23 is a key cytokine that induces pathogenicity in Th17 cells. Using expression profiling at very high temporal resolution, novel computational algorithms and innovative nano-wire based “knock-down” approaches, we have developed a regulatory network that governs the development of Th17 cells. The Th17 transcriptional network consists of two self-enforcing but mutually antagonistic modules, which are essential for maintaining a balance between Th17 and other CD4 T cell subsets. Using these approaches we have identified Serum Glucocorticoid Kinase-1 (SGK-1) a key kinase induced during IL-23R signaling. High concentration of NaCl also induces SGK-1 and promotes Th17 differentiation, therefore supporting the possibility that high salt diet promotes Th17 differentiation and provides a trigger for inducing autoimmune disease on a genetically susceptible background.

Development and function of dendritic cell subsets

K. M. Murphy*[1], R. Tussiwand[1], W. KC[2], A. T. Satpathy[2], C. Briseno[2], N. Kretzer[2], X. Wu[2], G. Grajales[2], T. L. Murphy[2];*
[1]Howard Hughes Medical Institute at Washington University School of Medicine, St. Louis, MO, United States, [2]Washington University School of Medicine, St. Louis, MO, United States.

The BATF members of the AP-1 transcription factor family mediate lineage decisions and functions of several types of immune cells. Batf is required for TH17 development, for T follicular helper (TFH) function by controlling c-Maf and Bcl6 expression, and in B cells, for AID expression and activation of transcription of the I-region promoters. Batf3 controls terminal differentiation and viability of the Irf8-dependent $CD8\alpha^+/CD103^+$ subsets of conventional dendritic cells required for cross-priming of CD8 T cells and innate defense against Toxoplasma gondii. The unique lineage-specific functions of BATF family members depends on the interaction of their leucine zipper domains to interact with non-AP-1 factors, specifically Irf4 and Irf8, in forming complexes on compound recognition elements. Although this unique interaction clearly operates in many BATF-specific transcriptional circuits, additional non-IRF-dependent activities are apparent that are still unique and not mediated by other AP-1 factors, such as in the regulation of the immunosuppressive cytokine IL-10. While homeostatic development of $CD8\alpha^+$ DCs is Batf3-dependnet, we identified a novel physiologic pathway that operates during infections by intracellular pathogens and that employs Batf and Batf2 for molecular compensation of Batf3 function in DC progenitors. This compensatory pathway serves to expand this protective DC subset during infections by intracellular pathogens. The seminar will discuss this and other unique and recently identified aspects of dendritic cell physiology.

Co-stimulation of natural killer cells overcomes anergy

W. M. Yokoyama*;*
HHMI/Washington University, St. Louis, MO, United States.

Natural killer (NK) cells are well known to integrate signals received from their activation and inhibitory receptors that recognize ligands on their cellular targets but our understanding of NK cell activation is still incomplete. These concepts are well illustrated by NK cell responses to murine cytomegalovirus (MCMV) which contains several open reading frames (ORFs) that down-regulate expression of MHC class I molecules on infected cells, presumably to evade virus-specific MHC class I-restricted T cells while releasing the MHC class I-specific inhibitory receptors on NK cells, making the infected cells more vulnerable to NK cells. However, NK cells do not directly attack MCMV-infected cells unless they express m157, a virus-encoded molecule that is a ligand for the Ly49H NK cell activation receptor. Yet, the transgenic expression of m157 does not lead to widespread NK cell activation and instead leads to “anergy” of Ly49H+ NK cells, a form of tolerance. Here I will describe our progress in understanding how interactions between Ly49H and m157 lead to NK cell activation during MCMV infection but anergy during non-inflammatory conditions. In essence, “co-stimulation” of NK cells by signals from other molecules and pathways overcomes “anergy” from activation receptor engagement alone.

S.21.02
Adaptive reconfiguration of the human NK-cell compartment in response to cytomegalovirus

*A. Muntasell[1], C. Vilches[2], A. Angulo[3], **M. Lopez-Botet**[4];*
[1]IMIM (Hospital del Mar Medical Research Institute), Barcelona, Spain, [2]Hospital Universitario Puerta de Hierro, Majadahonda, Madrid, Spain, [3]Institut d’Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain, [4]Univ. Pompeu Fabra. IMIM (Hospital del Mar Medical Research Institute), Barcelona, Spain.

Human Cytomegalovirus (HCMV) infection promotes in healthy individuals a persistent expansion of a functionally competent NK-cell subset expressing high surface levels of the CD94/NKG2C activating receptor. $NKG2C^{bright}$ NK cells are NKG2A- CD16+, display inhibitory KIR and LILRB1 receptors for self HLA class I molecules, but bear low levels of NKp46 and NKp30 activating receptors. Only minor proportions of $NKG2C^{dim}$ NK cells with a distinct phenotypic profile are detected in HCMV seronegative as well as in a number of HCMV+ subjects.
The expansion of $NKG2C^+$ NK cells reported in other infectious diseases is systematically associated to HCMV co-infection. The reconfiguration of the NK cell compartment appears particularly marked in immunocompromised patients and in symptomatic congenital HCMV infection, suggesting that it is inversely related with the efficiency of the T cell response.
An *NKG2C* gene deletion has been reported in different populations (~4% $NKG2C^{del/del}$). *NKG2C* zygosis appears related with the

magnitude of the steady-state NK cell redistribution, and functional studies support that the genotype influences the response of $NKG2C^+$ cells to engagement of the receptor.
This feature of HCMV infection is reminiscent of the response of murine $Ly49H^+$ NK cells against MCMV, and it has been hypothesized that an interaction of the CD94/NKG2C receptor with HCMV-infected cells may drive the NK subset expansion. Yet, the role of $NKG2C^+$ cells in the control of HCMV infection, the molecular mechanisms underlying the reconfiguration of the NK cell compartment, and its putative influence on the immune response to other pathogens or tumours remain open issues.

S.21.04
Natural Killer cells, Innate Lymphoid cells and Immunity

***E. Vivier**;*
Centre d'Immunologie de Marseille-Luminy, INSERM/CNRS/Aix Marseille University, France.

Innate Lymphoid cells represent an emerging group of cells that participates to innate and adaptive immune responses. Natural Killer (NK) cells belong to group 1 ILCs. NK cell distinguish normal cells that they spare, from target cells that they contribute to eliminate, through a variety of cell surface activating and inhibitory receptors, the engagement of which regulates NK cell activities. Among NK cell activating receptors, NK cell express the Natural Cytotoxicity Receptors (NCR), which have been shown since more than a decade to be involved in the activation of NK cells by tumor cells. The NCR family includes NKp46, NKp44 and NKp30. A subset of gut Innate Lymphoid Cells (NCR+ ILC3) also express NKp46 in human and mice. We generated a NKp46-iCre knock-in mice that allow us to selectively target genes in NK cells and NCR+ ILC3. Using this genetic model, we will present data on the mechanisms by which these cells adapt to their environment.

Molecular mechanisms of differentiation of pro-inflammatory gamma-delta T-cells

***B. Silva-Santos**;*
Instituto de Medicina Molecular, Lisboa, Portugal.

Gamma-delta T-cells are innate-like lymphocytes that share many functional properties with NK cells. Among them, we have recently demonstrated that human gamma-delta cells employ NKG2D and natural cytotoxicity receptors (especially NKp30) to target hematological tumors. The anti-tumor function of gamma-delta cells is also tightly linked to their abundant secretion of interferon-gamma (IFN-g). On the other hand, we and others have shown that gamma-delta cells make a large contribution to the production of interleukin-17 (IL-17) in murine models of infection, autoimmunity and cancer. We further demonstrated that IL-17 versus IFN-g producing gamma-delta cells differentiate in the murine thymus and can be segregated on the basis of CD27 expression levels. However, the molecular determinants of their functional potential in the periphery remained unknown. We have now conducted a genome-wide characterization of histone H3 modifications, integrated with mRNA levels of transcription factors that control *Il17* or *Ifng* expression, in peripheral gamma-delta cell subsets. This revealed a large set of potential new players in type 1 (IFN-g) or type 17 (IL-17-producing) cell differentiation *in vivo*. Furthermore, it allowed us to show that CD27(+) gamma-delta cells are stably committed to express *Ifng* but not *Il17*, whereas CD27(-) gamma-delta cells display permissive chromatin configurations at both type 17 and type 1 gene loci and can differentiate into IL-17/ IFN-g double producers in IL-1b/ IL-23-rich microenvironments. We will discuss the implications of these findings for gamma-delta T-cell responses in infection, autoimmunity and cancer.

The role of CTLA-4 in regulating T cell responses

***D. M. Sansom**[1,2];*
[1]UCL, London, United Kingdom, [2]University College London, London, United Kingdom.

The T cell immune system exists in a state of balance, poised to react to invading pathogens but at the same time constantly being restrained from attacking our own tissues. Several strategies are employed in order to minimise our own self-reactivity. First amongst these processes is the deletion of T cells in the thymus, however this process is incomplete and self-reactive T cells still populate our immune systems. A second layer of control is exerted by regulatory T cells (Treg) which act to restrain self-reactivity by dominantly suppressing T cell responses. How Treg function to prevent autoimmunity is therefore of considerable interest. The protein CTLA-4 is highly expressed on Treg and we have recently identified a novel molecular basis for CTLA-4 function where CTLA-4 acts as a molecular “hoover” removing stimulatory ligands from antigen presenting cells[1]. This talk will discuss the mechanisms of CTLA-4 function, the predictions generated by this mechanism of action and the implications for regulatory T cell function.

Neutrophil microparticles activate tissue protective signals. Mauro Perretti Barts and The London School of Medicine

***M. Perretti**, L. Norling, S. Headland, J. Dalli, T. Montero-Melendez;*
Barts and The London School of Medicine, London, United Kingdom.

Altered plasma neutrophil microparticle levels have recently been implicated in a number of vascular and inflammatory diseases, yet our understanding of their actions is very limited. We have recently detailed the proteome of neutrophil microparticles observing presence of >300 proteins, which varied in large part in function of the mode of neutrophil stimulation (Dalli, Montero-Melendez et al., Mol Cell Prot 2013). Heterogeneity of vesicles released from the same cell type was also reflected in distinct modulation of target cells, like the endothelial cells. These data set the scene for further analyses in human samples, like septic plasma and rheumatoid arthritis synovial fluids. It was noted that microparticles generated in settings that mimic vascular inflammation seem to propagate and accentuate the inflammatory response whereas microparticles that mimic those produce by neutrophils in an exudate are able to active tissue protective circuits. The latter is being studies in the contact of joint inflammatory disease. Specific determinants for the bioactions afforded by these microparticles have been identified and are exploited for therapeutic opportunities.

Vita-PAMPs: Signatures of microbial viability

***J. Blander**;*
Icahn School of Medicine at Mount Sinai, New York, NY, United States.

Can the innate immune system detect and respond to microbial viability? Using bacteria as a model, we found that indeed the very essence of microbial infectivity, viability itself, can be detected, and notably, in the absence of the activity of virulence factors. The microbial molecule that serves as the signature of viability is bacterial messenger RNA (mRNA), common to all bacteria, and without which bacteria cannot survive. Prokaryotic mRNAs also differ from eukaryotic mRNAs in several ways, and as such, these features all

fulfill the criteria for a pathogen-associated molecular pattern (PAMP) as originally proposed by Charles Janeway. Because these mRNAs are lost from dead bacteria, they belong to a special class of PAMPs, which we call vita-PAMPs. Here we discuss the possible receptors and pathways involved in the detection of bacterial mRNAs, and thus microbial viability. We also consider examples of vita-PAMPs other than bacterial mRNA.

Reprogramming the immune environment in cancer via dendritic cells

***A. K. Palucka**, J. Banchereau;*
Baylor Institute for Immunology Research, Dallas, TX, United States.

T cells can reject established tumors when adoptively transferred into patients thereby demonstrating that the immune system can be harnessed for cancer therapy. Active immunotherapy with vaccines has the potential to induce tumor-specific effector and memory T cells that might control tumor outgrowth on the long term. Vaccines act through dendritic cells (DCs), which induce, regulate and maintain T cell immunity. The goal is to generate high-quality, high-sensitivity, poly-functional effector $CD8^+$ T cells that reject tumors and memory $CD8^+$ T cells that prevent relapse by targeting distinct DC subsets. Our pre-clinical studies demonstrate that Langerhans cells are superior to other DC subsets in their capacity to prime high-affinity $CD8^+$ T cells that can kill tumors. Our recent studies demonstrated the presence in breast cancer Th2 inflammation, which fosters breast cancer development. This is driven by the cytokine TSLP, which induces and maintains pro-tumor $CD4^+$ T cells via OX40L-expressing DCs. Thus, a better understanding of DC biology within the tumor environment will allow us to design novel immunotherapeutic strategies that reprogram DCs to induce tumor-rejecting Th1-mediated acute inflammation and strong tumor-specific $CD8^+$ cytotoxic T cells.

Immunity and tolerance to fungi: The contribution of gut microbiota via tryptophan catabolism

***L. Romani**[1,2], T. Zelante[2], R. G. Iannitti[2], C. Cunha[2], A. De Luca[2], G. Pieraccini[3], C. Massi-Benedetti[2], F. Fallarino[4], A. Carvalho[2], P. Puccetti[2];*
[1]Italy, [2]Department of Experimental Medicine and Biochemical Sciences, University of Perugia, Perugia, Italy, [3]Mass Spectrometry Centre (CISM) of the University of Florence, Florence, Italy, [4]Department of Experimental Medicine and Biochemical Sciences, University of Perugia, Perugia, Perugia, Italy.

Candida albicans is a commensal fungus of the oro-gastrointestinal tract, vagina and skin. In concomitance with defects in the innate and adaptive immune systems or microbial dysbiosis, the fungus may shift from a state of commensalism to parasitism and can cause severe chronic mucosal infections. IL-22, driven by intestinal microbiota, exerts a fine control over the initial fungal growth and tissue homeostasis at mucosal surfaces. This prompted us to decipher the signaling mechanism(s) linking the bacteria-fungal population dynamics with the mammalian host at mucosal surfaces. Endogenous tryptophan metabolites from resident microbiota have an important role in mammalian gut immune homeostasis, yet their potential contribution to fungal colonization and/or infection has never been addressed. We discovered a metabolic pathway whereby tryptophan metabolites from the microbiota balance antifungal mucosal reactivity in mice. Switching from sugar to tryptophan as an energy source−e.g., under conditions of unrestricted tryptophan availability−highly adaptive lactobacilli are expanded and produce an AhR ligand that contributes to AhR-dependent *Il22* transcription. The resulting balanced mucosal response provides colonization resistance to *C.albicans* and mucosal protection from inflammation. Thus, our study identifies a tryptophan metabolic pathway that is exploited by certain lactobacilli to optimize host immune homeostasis and fungal adaptation in vertebrate hosts and may offer a plausible explanation not only for susceptibility to infection in certain clinical settings but also for the strain-specific effects observed with probiotic lactobacilli administration, the empirical use of which as probiotics−to prevent *Candida* infection−has long been recommended but never mechanistically explained.

Treg induction by a rationally selected Clostridia cocktail from the human microbiota

***K. Honda**;*
RIKEN Center for Integrative Medical Sciences (IMS RCAI), Yokohama, Japan.

Manipulation of the gut microbiota holds great promise for treating inflammatory and allergic diseases. Although numerous probiotic microorganisms have been identified to date, there is a compelling need to discover organisms that elicit more robust therapeutic responses, are compatible with the host, and can affect a specific arm of the host immune system in a well-controlled, physiological manner. Here we used a rational approach to isolate CD4+Foxp3+ regulatory T cell (Treg)-inducing bacterial strains from the human indigenous microbiota. Starting with a healthy human faecal sample, a sequence of selection steps was applied to obtain mice colonised with human microbiota enriched in Treg-inducing species. From these mice, we isolated and selected 17 strains of bacteria based on their high potency in enhancing Treg cell abundance and inducing important anti-inflammatory molecules, including interleukin 10 (IL-10) and inducible T-cell co-stimulator (ICOS), in Treg cells upon inoculation into germ-free (GF) mice. Genome sequencing revealed that the 17 strains fall within clusters IV, XIVa and XVIII of Clostridia, which lack prominent toxins and virulence factors. The 17 strains act as a community to both provide bacterial antigens to T cells and to help polarize the T cells to become Treg cells by inducing the generation of a TGF-β-rich environment. Oral administration of the cocktail to adult mice attenuated disease in models of colitis and allergic diarrhoea. Use of the isolated strains may allow for tailored therapeutic manipulation of human immune disorders.

Mucosal T cells: Modelled to fit the challenges

*Y. Huang[1], D. Mucida[1,2], M. M. Husain[1], S. Muroi[3], F. van Wijk[1,4], M. Teitell[5], W. Ellmeier[6], M. Kronenberg[1], I. Taniuchi[7], **H. Cheroutre**[1];*
[1]Division of Developmental Immunology, La Jolla Institute for Allergy & Immunology, La Jolla, CA, United States, [2]Current address: Laboratory of Mucosal Immunology, The Rockefeller University, New York, NY, United States, [3]for Transcriptional Regulation, RIKEN Research Center for Allergy and Immunology, Yokohama, Kanagawa, Japan, [4]Department of Pediatric Immunology, University Medical Center, Utrecht, Netherlands, [5]Department of Pathology and Laboratory Medicine, David Geffen School of Medicine at University of California Los Angeles, Los Angeles, CA, United States, [6]Institute of Immunology, Center for Physiology, Pathophysiology and Immunology, Medical University of Vienna, Vienna, Austria, [7]Laboratory for Transcriptional Regulation, RIKEN Research Center for Allergy and Immunology, Yokohama, Kanagawa, Japan.

The T cells that reside as intraepithelial lymphocytes (IEL) within the epithelium of the gastrointestinal tract constantly face a plethora of foreign antigens. This challenge requires rapid and effective protection, however, with the least damage to the epithelium. Furthermore, since the majority of antigens are diet- or commensal-derived antigens, a strict requirement for maintaining a balance between protection and tolerance represents another challenge.
Most IEL are CD8αβ effector memory T cells (T_{EM}) with immediate protective functions. Unlike lymphoid memory cells, mucosal T_{EM} are controlled by an environmental-driven process that optimizes effective immunity by selectively preserving the highest affinity CD8αβ cytotoxic T lymphocytes (CTL). The selective accumulation of high

affinity CD8αβ T_{EM} provides a first line of defense with exceedingly responsive sentinels that can eliminate invading pathogens, before the pathogens or the systemic immune system can jeopardize the barrier integrity. In addition to the CD8αβ CTL, there are also CD4 T cells with a cytotoxic phenotype and recently we showed that these CD4 CTL are progeny of conventional CD4 Th cells that lost the Th transcription factor, ThPOK and post-thymically terminated the Th program and acquired the CTL phenotype instead. Both, the selective accumulation of high affinity CD8αβ T_{EM} and the functional switch of CD4 Th cells to CTL, are processes driven by the challenges imposed by the mucosal environment to keep a balance between optimal immune protection in the face of immune tolerance.

Trained immunity: innate immune imprinting of host-microbe interaction

***M. G. Netea**;*
Radboud University Nijmegen Medical Center, Nijmegen, Netherlands.

The inability of innate immunity to build an immunological memory, considered one of the main characteristics differentiating it from adaptive immunity, has been recently challenged by studies in plants, invertebrates, and mammals. Long-term reprogramming of innate immunity, that induces adaptive traits and has been termed trained immunity characterizes prototypical innate immune cells such as natural killer cells and monocytes, and provides protection against reinfection in a T/B-cell-independent manner. In contrast, trained immunity has been shown to be able to induce protection against reinfection in a monocyte-independent manner. Non-specific protective effects dependent on trained immunity have also been shown to be induced after BCG vaccination in humans. Specific signaling mechanisms including the dectin-1/Raf1 and NOD2-mediated pathways induce trained immunity, through induction of histone methylation and epigenetic reprogramming of monocyte function. Complex immunological and metabolic circuits link cell stimulation to a long-term epigenetic reprogramming of its function. The concept of trained immunity represents a paradigm change in immunity and its putative role in infection and inflammation may represent the next step in the design of future vaccines and immunotherapeutic approaches.

The endogenous microbiome controls development of spontaneous autoimmunity to immunologically privileged neuroretina

*C. R. Zárate-Bladés[1], R. Horai[1], J. Chen[1], P. B. Silver[1], P. Dillenburg-Pilla[2], H. Yamane[3], C. Chan[1], K. Honda[4,5], **R. R. Caspi**[1];*
[1]National Institutes of Health, NEI, Bethesda, MD, United States,
[2]National Institutes of Health, NIDCR, Bethesda, MD, United States,
[3]National Institutes of Health, NIAID, Bethesda, MD, United States,
[4]University of Tokyo, Tokyo, Japan, [5]RIKEN Institute, Tokyo, Japan.

Autoimmune uveitis that targets the neuroretina and is thought to be driven by a T cell response to retinal antigens is a significant cause of human blindness. Since retinal antigens are not expressed outside the eye, a major unanswered question is where do retina-specific T cells become activated to acquire the ability to enter the eye. Microbial triggers have been suspected, but never proven. R161H mice, which express a transgenic T cell receptor (TCR) specific for the retinal antigen IRBP, develop spontaneous uveitis by 2 months of age. If treated with a broad-spectrum antibiotic cocktail, or reared under germ-free conditions, these mice exhibit a marked delay in uveitis onset and intensity. Analysis of cells from the gut lamina propria of antibiotic-treated or untreated R161H mice, crossed to various reporter strains, demonstrated presence of IRBP-specific Th17 cells, which appear to become activated in the gut by signals that depend on the presence of microbiota. Activation is not dependent on IRBP, but nevertheless appears to involve the TCR. Upon adoptive transfer to RAG2-/- recipients, these lamina propria lymphocytes induced uveitis. We interpret these data to mean that commensal microflora or its metabolites activate autopathogenic retina-specific T cells, possibly through a process involving at least in part a TCR-mediated signal. We hypothesize that such effects might not be restricted to IRBP-specific T cells and uveitis. Our findings may help to explain the postulated connection in humans between microbial triggers and uveitis, and could have implications also other autoimmune diseases.

S.27.02
Class and specificity of the human T cell response to commensals, pathogens, and allergens

***F. Sallusto**;*
Institute for Research in Biomedicine, Bellinzona, Switzerland.

To interrogate the naive and memory T cell repertoires we developed a high throughput cellular screening method based on T cell libraries of polyclonally activated and expanded T cells. These libraries are then interrogated, in an iterative fashion, to identify antigen-specific T cells and determine frequency, fine specificity, and cross-reactivity, and to isolate T cell clones. The T cell library method is not limited by the complexity of the antigen, neither by the HLA of the donor, and allows the detection of T cells specific for naturally processed antigens, even whole pathogens. Using this method we have been able to identify antigen-specific T cells in the naive repertoire and measure the distribution of memory T cells within distinct subsets of Th1, Th2, Th17 and Th22 cells. I will discuss how the new high-throughput methodological approaches that are becoming available may lead to a better understanding of the class and specificity of the human immune response, the lineage relationship between T cell subsets and their plasticity, and will be instrumental to increase our understanding of the immune response to commensal and pathogenic microbes as well as environmental allergens.

S.27.03
Origins of CD4+ memory T cells

*R. W. Nelson, D. Kotov, **M. K. Jenkins**;*
University of Minnesota, Minneapolis, MN, United States.

We studied the relationship between memory cell formation and protective immunity by tracking microbial peptide:MHCII-specific CD4+ T cells during a transient Listeria infection that is not controlled by CD4+ T cells and a persistent Salmonella infection that is. We found that CD4+ memory T cell population generated by transient Listeria infection declined with a half-life of 60 days after the bacteria were cleared. The memory cell population consisted of non-cytotoxic Th1 and Tfh subsets. In contrast, CD4+ memory T cells generated by low-level persistent Salmonella infection did not decline over a year unless the infection was eliminated with antibiotics. The memory population consisted exclusively of Th1 cells, some of which expressed Granzyme B and were cytotoxic. Thus, an infection that is controlled by CD4+ T cells generated cytotoxic Th1 cells that were stably maintained by peptide:MHCII presentation. These results suggest that vaccines that are cleared from the body will not produce protection from infections that are controlled by CD4+ T cells because these cells will not persist or acquire the necessary microbicidal functions.

S.27.04
TFH heterogeneity, memory and plasma cell survival niches

***D. Gray**, T. Barr, S. Brown, V. Morrison, M. Trüb;*
IIIR, University of Edinburgh, Edinburgh, United Kingdom.

The formation of optimal helper T cell memory during Salmonella infection is dependent on BCR-mediated recognition of the bacteria by B cells and their subsequent antigen presentation to T cells. The

formation of stable T follicular helper cell (TFH) populations has similar requirements of B cells. In addition, both seem to depend on expression of Bcl6 and ICOS ligation. However, the CXCR5+, ICOS+, bcl6+, PD1+ TFH formed early in Salmonella infection are not classical, in that they do not enter germinal centres (none form until much later) and nor do they support early, extra-follicular antibody production which is largely T-independent. We have characterised these Tfh-like cells to ask whether they resemble, classical TFH, short-lived effector cells or memory precursor effector cells. We have asked about the importance of follicular entry and interaction with B cells by constructing chimeric mice in which T cells cannot enter follicles. We will discuss this data in the context of the contrasting requirements for T cell follicular migration in the generation of effector T cell and memory responses after bacterial infection compared to immunization with non-replicating antigens.

Getting to the center of the immunological synapse

M. Dustin[1], *K. Choudhuri*[1], *J. Llodra*[1], *D. Skokes*[1], *C. Hioe*[1], *E. Roth*[1], *S. Gordo*[2], *K. Wucherpfennig*[2], *J. Tsai*[3], *L. Kam*[3];
[1]*New York University School of Medicine, New York, NY, United States,* [2]*Dana Farber Cancer Institute, Boston, MA, United States,* [3]*Columbia University, New York, NY, United States.*

The recognition events that mediate adaptive cellular immunity depend on intercellular contacts between T cells and antigen presenting cells (APC). T cell signaling is initiated at these specialized junctions between T cells and APCs, known as the immunological synapse (IS), when surface-expressed antigen receptors (TCR) recognize peptide fragments of pathogens (pMHC) on APCs [1]. Using high resolution optical and electron microscopy, optical-EM correlation, and electron-tomography, we show that centrally accumulated TCR at the IS is located on the surface of extracellular microvesicles that bud at the IS center and are recognized by APC bearing cognate antigen. An early endosomal-sorting complex required for transport (ESCRT) sorts TCR for inclusion in microvesicles, while terminal ESCRT components mediate scission of microvesicles from the T cell plasma membrane. The HIV polyprotein GAG co-opts this process by displacing TCR from microvesicles, resulting in release of virus-like particles at the antigen-dependent IS. We conclude that post-signaling TCR accumulates at the IS center and is released in extracellular microvesicles by an ESCRT-dependent mechanism triggered by T cell activation. These microvesicles mediate intercellular communication in immune cell collaboration, and can be co-opted by HIV GAG for viral transmission across antigen-dependent synapses.

What determines the directionality of leukocyte transendothelial migration?

R. Alon[1], *L. Stoler-Barak*[1], *S. Barzilai*[1], *Z. Shulman*[1], *N. Ben-Chetrit*[1], *C. Moussion*[2], *E. Shezen*[1], *S. W. Feigelson*[1], *M. Sixt*[2];
[1]*The Weizmann Institute of Science, Rehovot, Israel,* [2]*IST, Klosterneuburg, Austria.*

Directional guidance is a hallmark of immune cell trafficking. Although chemokines are critical for directional leukocyte crossing of endothelial barriers, it is still unclear how these cytokines drive this complex migration process. It is believed that transendothelial migration (diapedesis) is mediated by signals from endothelial-presented chemokines which trigger serial low affinity integrin-mediated adhesions coupled to highly dynamic actin-driven protrusions. Whether steep chemokine gradients are obligatory for diapedesis is still unclear. The blood vessel cells that promote leukocyte diapedesis produce their own chemokines or actively transport chemokines across endothelial barriers. One plausible mechanism for generation of chemokine gradients across these barriers is extensive washing of chemokines from the lumenal vessel aspects. In addition, we find a sharp enrichment of heparan sulfates (HS) at the basolateral aspects of lymphoid and non lymphoid post capillary venules. We propose that this basolateral pool of potential chemokine scaffolds can generate different chemokine gradients across variably inflamed endothelial barriers. While most leukocyte diapedesis depends on these HS scaffolds, subsets of effector T cells respond to endothelial produced inflammatory chemokines independently of endothelial HS. Strikingly, the ability of these lymphocytes to squeeze their nuclei through endothelial junctions does not depend on endothelial myosin-II mediated contractility. Thus, leukocyte transendothelial migration is guided by endothelial chemokines, integrin ligands and unique endothelial machineries that couple transient and confined endothelial barrier rupture events to directional leukocyte motility from the apical endothelial surface towards the endothelial basement membrane.

S.28.04
Visualizing and regulating the traffic of pathogenic CD8+ T cells within the liver

L. G. Guidotti[1,2];
[1]*San Raffaele Scientific Institute, Milan, Italy,* [2]*The Scripps Research Institute, La Jolla, CA, United States.*

Hepatitis B virus (HBV) causes a liver disease of variable duration and severity. HBV replicates noncytopathically in the hepatocyte and most of the liver injury associated with this infection reflects the immune response. Virus-specific effector CD8 T cells play a major role in the development of liver disease and the resolution of HBV infection during self-limited acute viral hepatitis. Viral persistence reflects the failure to induce CD8 T cells with full antiviral capacity, so that the infection is not cleared from the liver and a CD8 T cell-dependent chronic necroinflammatory process begins, often resulting in cirrhosis and hepatocellular carcinoma (HCC). The use of dedicated animal models coupled with advanced in vivo imaging helped us to show that the hepatic recruitment of pathogenic effector CD8 T cells is promoted by platelets. This effect appears to depend on platelets that - after having adhered to liver sinusoidal endothelial cells and become activated - provide a preferential surface onto which CD8 T cells arrest their passage within the hepatic microcirculation. CD8 T cells eventually detached from platelets start to crawl up and down the liver sinusoids in search of viral antigens. That platelets represent key players in the pathogenesis of viral hepatitis is also indicated by experiments we recently performed in a mouse model of chronic HBV infection. There, a continuous aspirin/clopidogrel therapy inhibiting platelet activation was shown to limit the hepatic accumulation of pathogenic effector CD8 T cells and the consequent liver disease, ultimately preventing the development of cirrhosis and HCC.

Using Advanced Dynamic and Multiplex Static Imaging to Probe Innate and Adaptive Immunity In Vivo

R. N. Germain, *M. Y. Gerner, W. Kastenmüller, T. Laemmermann, P. Torabi-Parizi, T. Honda, J. G. Egen;*
NIAID, NIH, Bethesda, MD, United States.

Immune responses involve multiple cell-cell interactions within lymphoid tissues, trafficking of activated cells to sites of effector function, and the migration of such effector cells within peripheral tissues. To gain a more detailed appreciation of the relationship among cell movement, tissue architecture, and immune function, we have used intravital multiphoton microscopy and a novel immunohistochemical method to analyze immune cell dynamics and functional tissue micro-anatomy.
Our data show that T cells follow stromal pathways during migration in lymph nodes, which enhances interactions with DCs attached to the same FRC network. Additional chemokine guidance cues facilitate interactions among rare antigen-presenting and antigen-recognizing cells. Adhesive interactions regulating the duration of cell-cell association are also critical to for adaptive immune responses. In tissue sites, effector cells stop when they perceive adequate antigen and undergo transient local activation and polarized cytokine release, followed by tuning of their response to exisitng antigen levels. Innate

immune (neutrophil) responses have been dissected at the molecular level. The role of cell localization in both innate defense and adaptive immunity has been addressed using both dynamic imaging and a new method called histo-cytomtery that reveals at high resolution the spatial positioning of cells with complex phenotypes throughout lymphoid tissues. These observations show the power of in situ imaging in the acquisition of a more accurate picture of the molecular, cellular, spatial, and temporal aspects of cell function and signaling events in host immune responses.

Role of tissues in immune regulation in allergic inflammation

C. A. Akdis[1,2]*;*
[1]*Swiss Institute of Allergy and Asthma Research (SIAF), University of Zurich, Zurich, Switzerland,* [2]*Christine Kühne Center for Allergy Research and Education (CK-CARE), Davos, Switzerland.*

In chronic allergic inflammation, dermis in the atopic dermatitis skin and submucosa in the asthmatic lung act like a peripheral lymphatic organ, where dendritic cells, T cells and B cells contact each other. This is followed by a second step of antigen-presentation and activation in the inflamed tissue. Immune system cells and their cytokines interact with resident tissue cells, which leads to a series of tissue events leading to proinflammatory cytokine and chemokine release from both sides. Some of these events seem to be part of the immune pathology, such as basement membrane thickening, epithelial death, desquamation and spongiosis, however, they also act as mechanisms that control the severity of tissue inflammation. These can be listed as: keep away effects; wash away effects and immune suppression. “Keep away“ effects play a role in allergen ignorance by decreasing the allergen burden. They are lamina reticularis thickening and allergen-specific secretory IgA, in addition to cough and mucociliary activity. “Wash away“ effects that decrease the intensity of inflammation are epithelial apoptosis, spongiosis, leakage and wash of proinflammatory cytokines and inflammatory cells away from the tissues towards the lumen. Direct “suppression” is taking place by allergen-specific B and T regulatory cells as well as “regulation” of B cells for the production of non-inflammatory antibody isotypes (more IgG4 and IgA, less complement activating antibodies and IgE).

S.30 Tolerance and transplantation

S.30.01
Immunoregulation in Transplantation

K. Wood*;*
University of Oxford, Oxford, United Kingdom.

Immune regulation is fundamental to any immune response to ensure that it is appropriate for the perceived threat to the host. Strategies for the induction of specific unresponsiveness to donor alloantigens currently under investigation in the clinic take advantage of two of the major mechanisms for the induction of tolerance to self antigens - deletion and immunoregulation/suppression.
We have demonstrated that human regulatory T cells expanded ex vivo can protect human allografts (skin and vessels) from rejection (2, 3). Together with other leukocyte populations, including regulatory T cells, B cells and macrophages as well as myeloid derived suppressor cells and dendritic cells, Treg contribute to the regulation of immune responses in vivo after cell or solid organ transplantation (1).
The identification and characterisation of Treg that can control immune responsiveness to alloantigens has opened up exciting opportunities for new therapies in transplantation. Phase1/2a clinical trials are in progress - www.onestudy.org.

Mechanisms of Allograft Tolerance Achieved with Hematopoietic Cell Transplantation

M. Sykes*;*
Columbia University Medical Center, New York, NY, United States.

Immune tolerance would avoid the need for chronic immunosuppressive therapy, with all of its toxicities, that is currently required to prevent graft rejection. Following upon studies in rodents and large animals, we have performed combined HLA-mismatched (haploidentical) related donor kidney and bone marrow transplantation (CKBMT) to induce chimerism and tolerance in patients with renal failure in an ITN-sponsored trial. CKBMT recipients have tolerated their allografts for >3 to >10 years without immunosuppressive medication and developed donor-specific unresponsiveness in in vitro assays. Donor chimerism was present for less than 3 weeks in these patients. Tregs were enriched in PBMC CD4 cell populations in the first few months post-transplant and some of the patients’ PBMCs drawn within the first year revealed residual anti-donor reactivity in vitro when Tregs were depleted. However, MLR, CML and limiting dilution assays at later time points were suggestive of a deletional mechanism of tolerance. Assessing deletional tolerance directly has previously been impossible due to the unavailability of markers for the many thousands of T cell clones responding to HLA alloantigens. We have developed a new strategy for tracking the fate of donor-reactive T cell clones and preliminary data supporting a deletional mechanism of tolerance will be presented. This tolerance requires an active role for the kidney graft. Because other organs are less effective than kidneys at promoting tolerance in combination with transient mixed chimerism, our current studies in large animals aim to achieve durable mixed chimerism without toxicity. Encouraging preliminary data will be presented.

S.30.03
Clinical and Immunological Relevance of Antibodies in Transplantation

N. K. Mehra*, J. A. Siddiqui, A. K. Baranwal, D. K. Bhat, S. Goswami, V. K. Bansal, S. K. Agarwal;*
All India Institute of Medical Sciences, New Delhi, India.

The detection and characterization of anti HLA antibodies in organ transplantation and the clinical impact of their occurrence is an area of immense interest. In recent years, it has become clear that several HLA antibodies that develop post transplantation and are not necessarily donor specific, are also associated with poor graft survival. Indeed the presence of circulating anti-HLA antibodies along with positive C4d staining on allograft biopsies has been reported to have strong correlation with the development of chronic rejection in kidney transplant recipients. Our experience indicates that renal transplant patients who develop anti-HLA antibodies *de novo*, even though they are not donor specific (cross-match negative) have significantly poor graft survival as compared to the negative group. Further, the impact of non-HLA antibodies including MICA (MHC class I related chain A), angiotensin II type 1 receptor, vimentin, collagen V etc. have been documented in solid organ transplant outcome. It is now agreed that MICA antigens expressed on endothelial cells are an important antibody target towards graft destruction. Patients who develop both anti HLA and MICA antibodies reject their grafts more frequently than those having either of these antibodies. The current data also indicates that identification of *de novo* donor specific antibodies with the help of most accepted and sensitive luminex based single antigen assay is an important tool in addition to other cell based assays. Thus, the HLA and non-HLA

antibodies could not only be predictive of allograft failure, but also as an important prognostic marker in transplant subjects.

Specification of innate type-2 lymphocytes by the transcriptional determinant Gfi1

***C. J. Spooner**, J. Lesch, D. Yan, A. Abbas, M. Xu, J. DeVoss, H. Singh;*
Genentech, Inc., South San Francisco, CA, United States.

Innate type-2 lymphoid cells (ILC2s) play a pivotal role in protective immune responses against helminth parasites and are implicated in the pathophysiology of allergic inflammation. ILC2s are activated by the epithelial-derived cytokines IL-33 and IL-25 and are a prominent source of the type-2 effector cytokines IL-5 and IL-13. However, regulatory networks that orchestrate the generation and effector state of ILC2s are poorly understood. Here we report that the transcription factor Growth factor independence-1 (Gfi1) functions to control the development, activation, and proper specification of the ILC2 effector state. Accordingly, IL-33- or *Nippostrongylus brasiliensis*-instigated inflammation was severely impaired in the absence of Gfi1. Genetic and molecular analyses of ILC2s reveals a stringent requirement for Gfi1 in response to IL33, not IL-25, as Gfi1 directly targets and activates the IL-33 receptor. Strikingly, loss of Gfi1 in activated ILC2s results in a unique hybrid effector state, which is characterized by derepression of the IL-17 inflammatory program while retaining expression of genes associated with type-2 inflammation, including IL-13. Given that Gfi1 is implicated in reciprocally regulating Th2 and Th17 cell fates, our results reveal it to be a conserved regulatory component which functions in both innate and adaptive immune cells to sustain a type-2 cytokine response while repressing the IL-17 effector state. These findings may have important implications for the pathophysiology of severe asthma, which manifests deregulation of these two inflammatory states in a subset of patients.

LB1.02
Identification of a common monocyte progenitor

***J. Hettinger**[1], D. M. Richards[1], J. Hansson[2], M. M. Barra[1], A. C. Joschko[1], J. Krijgsveld[2], M. Feuerer[1];*
[1]German Cancer Research Center (DKFZ), Heidelberg, Germany, [2]European Molecular Biology Laboratory (EMBL), Heidelberg, Germany.

Monocytes, macrophages and dendritic cells (DCs) are critical immune regulators and part of the mononuclear phagocyte system (MPS), a body-wide, cellular system of phagocytic cells. The MPS is multi-functional and involved in various biological processes, such as the maintenance of tissue homeostasis, pathogen defense and wound healing, as well as many pathological conditions including infectious diseases, cancer and atherosclerosis.
Monocytes and DCs are heterogeneous populations and sub-divided into distinct subsets. For monocytes, classical Ly6C-high and non-classical Ly6C-low monocytes, and for DCs, classical DCs (cDCs) and plasmacytoid DCs (pDCs) are the major subsets. From a developmental perspective, monocytes/macrophages and DCs share a common origin, having the macrophage/dendritic cell progenitor (MDP) as common precursor. Unlike for DCs, the distal differentiation pathways from the MDP towards monocytes/macrophages are currently not fully elucidated.
We now demonstrate in mice the existence of a clonogenic, monocyte/macrophage-restricted progenitor, termed the common monocyte progenitor (cMoP). Derived from the MDP, the cMoP is a proliferating cell found in the bone marrow, which generates both major monocyte subsets and macrophages, but not DCs. Using in-depth quantitative proteomics, we characterized the proteome changes during monocyte differentiation, giving insights into the molecular principles of developing monocytes such as their functional maturation. Thus, monocytes/macrophages can renew independently from DCs from a committed progenitor.

LB1.03
Distinct TLR4-expressing cell compartments control neutrophilic and eosinophilic airway inflammation

***J. W. McAlees**[1], G. S. Whitehead[2], I. Harley[1], M. Cappelletti[1], C. L. Rewerts[1], A. Holdcroft[1], S. Divanovic[1], C. L. Karp[1,3], D. N. Cook[2];*
[1]Cincinnati Children's Hospital Research Foundation, Cincinnati, OH, United States, [2]National Institutes of Health, Research Triangle Park, NC, United States, [3]Gates Foundation, Seattle, WA, United States.

Stimulation of TLR4 expressed by hematopoietic and airway epithelial cells can contribute to the airway immune response to lipopolysaccharide (LPS) and allergens such as house dust mite (HDM) or ovalbumin (OVA), however, the specific contribution of these cell compartments to the airway inflammatory responses remains under-defined. We used newly developed *Tlr4*$^{fl/fl}$ mice along with reciprocal bone marrow chimera techniques to define the relative contributions of airway epithelial and hematopoietic cell *Tlr4* expression to LPS- and allergen-induced airway inflammation. Our data indicate that airway epithelial cell *Tlr4* expression is required for the development of Th2-mediated eosinophilic airway inflammation following airway sensitization and challenge with HDM or OVA/LPS. Conversely, hematopoietic cell *Tlr4* expression is required for Th1- and Th17-mediated cytokine production and for neutrophilic responses to these same allergens, or in response to acute LPS challenge. Thus, *Tlr4* expression by hematopoietic and airway epithelial cells controls distinctive aspects of the airway immune response to inhaled allergens.

LB1.04
Seeing is believing: visualization of the thymic T-cell development in a quantitative and non-invasive manner

***B. Bajoghli**[1], D. Inoue[2], M. Rauzi[1], P. Kuri[1], N. Aghaallaei[2], Y. Taniguchi[3], A. Toyoda[4], J. Wittbrodt[2], M. Leptin[1];*
[1]EMBL, Heidelberg, Germany, [2]COS-University of Heidelberg, Heidelberg, Germany, [3]Keio University, Tokyo, Japan, [4]National Institute of Genetics, Mishima, Japan.

The optical transparency of the thymus in medaka fish facilitates the in vivo characterization of molecular and cellular principles that underlie the development of the T-lymphocytes using high-resolution imaging. To investigate the dynamics of thymocyte movement within the thymus in real time, we use medaka fish transgenic reporter lines to visualize either thymocytes at different developmental stages or thymic stromal cells (e.g. thymic epithelial cells and dendritic cells). We have analyzed the migration of individual thymocytes into (and out of) defined areas within the thymus. Lymphocyte progenitors, which require a high level of chemokine receptor Ccr9a for thymus homing, begin to express the chemokine receptor ccr9b after interaction with cortical thymic epithelial cells through Notch1b/Dll4a signaling, after which they move to the center of thymus. Thymocytes in the central area do not proliferate and are less motile. Dendritic cells in the thymus can interact simultaneously with several thymocytes and are able to engulf one of the latter in less than thirty minutes. We have observed single dendritic cells containing up to five phagocytosed thymocytes. Taken together, we will illustrate how advanced genetic tools allow the visualization and tracking of cells to study the cellular processes associated with T-cell development in the thymus in a quantitative and non-invasive manner.

LB1.05
A global approach to study viral antigen presentation using immunoproteomics

*N. P. Croft[1], D. C. Tscharke[2], **A. W. Purcell**[1];*
[1]Monash University, Clayton, Australia, [2]Australian National University, Canberra, Australia.

Current knowledge about the dynamics of antigen presentation to T cells during viral infection is very poor despite being of fundamental importance to our understanding of anti-viral immunity. We have used advanced mass spectrometry to simultaneously quantify the presentation of vaccinia virus peptide-MHC complexes (epitopes) on infected cells and the amounts of their source antigens at multiple times after infection. The results show a startling 10,000-fold range in abundance as well as strikingly different kinetics across the epitopes monitored. The tight correlation between onset of protein expression and epitope display for most antigens provides the strongest support to date that antigen presentation is largely linked to translation and not later degradation of antigens[1]. In depth interrogation of MHC bound peptides identified over 100 new vaccinia virus derived peptides, over 70% of which were immunogenic and some bearing unanimated post-translational modifications. This highlights the utility of a peptidomics strategy to map T cell epitopes, particularly for complex pathogens. Finally, using data independent acquisition approaches (SWATH-MS) we have monitored all viral and host cell proteins providing a global view of viral antigen expression and host cell responses. This study highlights the complexity of viral antigen presentation and demonstrates the weakness of simple models that assume total protein levels are directly linked to epitope presentation and immunogenicity.

LB1.06
Molecular characterization of a novel antigen specific, immunoglobulin expressing cell in immunized animals with phenotypic characteristics of both granulocytes and lymphoctes

***J. D. Berry**[1,2], E. Chronopoulou[1], A. Uribe-Benninghoff[1], J. Fisher[1], X. Ji[1], J. Elia[1], P. Waterman[1], D. Stupack[3];*
[1]BD Biosciences, La Jolla, CA, United States, [2]University of Manitoba, Winnipeg, MB, Canada, [3]UCSD, La Jolla, CA, United States.

Scientists seek improved methods of generating antigen specific antibodies important for use in therapeutics, diagnostics and creating immune reagents. Here we used flow sorting to examine antigen specific cells from immunized mice. Following immunization with protein antigens, a novel immunoglobulin- bearing antigen-specific cell population was identified and named "V cells". This cell population lacks surface expression of B-cell lineage specific markers such as B220, CD19, as well as T-cell, natural killer (NK)-cell, NK T (NKT)-cell, basophil, and stem-cell specific markers as determined by flow cytometric analysis. The dual IgG/IgE expression in V cells was confirmed via confocal microscopy and Z-stack analysis. V cells have a polymorphonuclear giemsa staining pattern which resolves as a “donught” shape under confocal and electron microscopy. They cycle in the spleen, bone marrow, and blood of immunized mice, but not other tissues. Antigen-specific V cells appear following protein immunization as early as 7 to 14 days. Molecular analysis of mRNA from sorted V cells of individual animals has shown rearranged and mutated IgG/E and Kappa by RT-PCR. The dual IgG/IgE expression in V cells contradicts long standing theories molecular expression and cellular classification. V cells, bearing antigen specific IgG and IgE, have some central role in protective immunity, homeostasis and/ or allergy as they are engendered commonly in response to protein antigens.

LB.2 Late Breaking Session - Translational Research

LB2.01
Identification of specific markers for type 2 (pro-allergic) human dendritic cells: interest as follow-up markers for immunotherapy

***L. Mascarell**, C. Gueguen, H. Moussu, P. Moingeon, V. Baron-Bodo; Stallergenes, Antony, France.*

Dendritic cells (DCs) are involved in the initiation of regulatory and effector adaptive immune responses. Thus, markers of polarized DCs represent promising molecules to monitor immune responses following immunotherapy. Herein, we aimed to identify specific markers for type 2 DCs (DC2), ie. monocyte-derived dendritic cells (MoDCs) which promote Th2 allergic responses.
After screening more than one hundred biological and pharmaceutical agents, a cocktail of molecules capable of differentiating DC2 was selected. Such DC2 were confirmed to support the differentiation of IL-5 and IL-13 secreting $CD4^+$ T cells. While DC1 produced IL-1β, IL-6, IL-8, IL-10, IL-12p70 as well as TNF-α, DC2 secreted a distinct panel of effector cytokines ($IL\text{-}1\beta^-$, $IL\text{-}12p70^-$, $TNF\text{-}\alpha^-$, $IL\text{-}10^{low}$, $IL\text{-}6^+$ and $IL\text{-}8^+$). Both DC1 and DC2 over-expressed effector genes (e.g. MX1, NMES1, FSCN1 and IRF4) while down-regulating the expression of regulatory genes (e.g. C1QA, CATC, GILZ, STAB1 and RALDH1) specific for DCreg. Whole genome transcriptome comparison of DC1, DC2 and DCreg revealed extensive differences between these three DC subsets. When compared to non-treated MoDCs, DC1, DC2 and DCreg up-regulated 1617, 1493 and 186 genes and down-regulated 1917, 1882 and 197 genes, respectively. Interestingly, in DC2, 104 and 36 genes were specifically over-expressed and under-expressed, respectively, when compared with DC1 and DCreg.
Specific DC2 markers have been identified, allowing to distinguish such cells from effector DC1 or regulatory DC subsets. Those markers are being tested as follow-up read outs of efficacy for allergen immunotherapy.

LB2.02
Double-stranded RNA of intestinal commensal but not pathogenic bacteria triggers production of protective IFN-β

***N. M. Tsuji**[1], T. Kawashima[2,1], H. Yan[1,3], Z. Guo[4], J. Carreras[1,5], R. Uchiyama[6], R. Fukui[7], T. Kaisho[8], S. Akira[9], K. Miyake[7], H. Tsutsui[6], T. Saito[4];*
[1]National Institute of Advanced Science and Technology (AIST), Tsukuba, Japan, [2]Research and Development Division, Kikkoman Corporation, Noda, Japan, [3]The Fifth Hospital of Shijiazhuang, Shijiazhuang, China, [4]RIKEN, Yokohama, Japan, [5]Tokai University, Isehara, Japan, [6]Hyogo College of Medicine, Nishinomiya, Japan, [7]The Institute of Medical Science, The University of Tokyo, Tokyo, Japan, [8]WPI Immunology Frontier Research Center, Osaka University, Suita, Japan, [9]WPI Immunology Frontier Research Center, Osaka University, Tsukuba, Japan.

The small intestine harbors a substantial number of commensal bacteria and is sporadically invaded by pathogens, but the response to these microorganisms is fundamentally different. We identified a discriminatory sensor using Toll-like receptor 3 (TLR3). Double-stranded RNA (dsRNA) of one major commensal species, lactic acid bacteria (LAB), triggered IFN-β production from dendritic cells (DCs) and protected mice from experimental colitis. Endosomal TLRs are required for this protective mechanism, because Tlr3-/- as well as Unc93b13d mice, in which endosomal TLR3, 7, and 9 are dysfunctional, were not affected by oral administration of LAB in colitis model. While digestion of dsRNA canceled in vivo effects, suggesting TLR3 initiates the anti-inflammatory process, we also found that cooperation of TLR3 and TLR9 maximized IFN-β production in vitro. Compared to LAB, pathogenic bacteria contained less dsRNA and induced much less IFN-β. Moreover, dsRNA was not involved in pathogen-induced IFN-β induction. These results identify TLR3 as a sensor to small intestinal commensal bacteria and contribute to the maintenance of immunological homeostasis.

LB2.03
Human antigen-specific CD4+CD25+CD134+CD39+ T cells are enriched for regulatory T cells and comprise a substantial proportion of CD4+ T cell antigen recall responses

L. Cook[1,2], *N. Seddiki*[3], *C. Munier*[1,2], *J. Zaunders*[1], *A. D. Kelleher*[1,2];
[1]*The Kirby Institute for Infection and Immunity in Society, Sydney, Australia,* [2]*St Vincent's Centre for Applied Medical Research, Sydney, Australia,* [3]*INSERM U955 and Université Paris Est Créteil, Creteil, France.*

Human antigen-specific CD4+ T cells can be detected through the dual expression of CD134 (OX40) and CD25 after 44 hours stimulation with cognate antigen. We show that differential surface expression of CD39 on these cells enables isolation of a CD39+ Treg-enriched cell population. We have demonstrated that the majority of these CD4+CD25+CD134+CD39+ T cells originate from the peripheral memory CD4+CD45RO+CD25hiCD127loCD39+ Treg population. Dose response studies also revealed that the CD4+CD25+CD134+CD39+ Treg-enriched cell population responds to lower doses of antigen than the effector-like CD4+CD25+CD134+CD39− T cells. Across recall responses to a wide range of antigens, these Treg-enriched CD4+CD25+CD134+CD39+ T cells consistently formed a substantial proportion of the CD4+ T cell response. Viable, antigen-specific Treg enriched CD25+CD134+CD39+ T cells were isolated and expanded in vitro as T cell clones, that stably retained their antigen specificity and a Treg phenotype with high Foxp3, CD25, CTLA-4 and CD39 expression. Importantly, these clones could suppress autologous effector T cell proliferation and the magnitude of suppression positively correlated with CD39, Foxp3 and CTLA-4 expression. Collectively, our data show that antigen-specific CD4+CD25+CD134+CD39+ T cells are highly enriched for Tregs, form a surprisingly large component of CD4+ T cell recall responses and maintain a Treg-like phenotype upon in vitro expansion. Identification and isolation of these cells enables the role of Tregs in memory responses to be further defined, a greater understanding of disease pathogenesis and paves the way for developing this methodology as a novel immunotherapy.

LB2.04
Human memory Helios- FOXP3+ Treg encompass induced Treg that express Aiolos and respond to IL-1β by down-regulating their suppressor functions

M. Ayyoub*, C. Raffin, P. Pignon, C. Celse, D. Valmori;*
INSERM UMR 1102, Nantes-Saint Herblain, France.

FOXP3$^+$ Treg are critical regulators of self-tolerance and immune homeostasis. In mice and humans, two subsets of FOXP3$^+$ Treg have been defined based on their differential expression of Helios, a transcription factor of the Ikaros family. Whereas the origin, specificity and differential function of the two subsets are yet controversial, their characterization has been thus far limited by the absence of surface markers that distinguish them. Here, we show that human memory Helios$^+$ and Helios$^-$ Treg are phenotypically distinct and can be separated *ex vivo* based on their differential expression of IL-1RI, that is restricted to Helios$^-$ Treg, in combination with CCR7. The two populations isolated using this strategy are distinct with respect to the expression of other Ikaros family members. Namely, whereas Eos, that has been reported to mediate FOXP3-dependent gene silencing, is expressed in Helios$^+$ Treg, Aiolos, that is involved in the differentiation of T_H17 and induced Treg, is instead expressed in Helios$^-$ Treg. In addition, whereas both subsets are suppressive *ex vivo*, Helios$^-$ Treg display increased suppressive capacity than Helios$^+$ Treg, but respond to IL-1β by down-regulating their suppressive activity. Together, these data support the concept that human Helios$^-$ memory Treg encompass induced Treg that can readily respond to changes in the environment by modulating their suppressive capacity.

LB2.05
B lymphocytes undergo TLR2-dependent apoptosis upon Shigella infection mediated by the virulence factor IpaD

K. Nothelfer[1], *E. T. Arena*[1], *L. Pinaud*[1], *M. Neunlist*[2], *I. Belotserkovsky*[1], *C. Parsot*[1], *R. Raqib*[3], *B. Mozeleski*[1], *P. J. Sansonetti*[1], *A. Phalipon*[1];
[1]*Institut Pasteur, Paris, France,* [2]*INSERM U913, CHU Hotel Dieu, Nantes, France,* [3]*ICDDR, B, Dhaka, Bangladesh.*

Shigella is a gram-negative enteroinvasive bacterium and the causative agent of bacillary dysentery, an acute recto-colitis. Antibody-mediated natural immunity to Shigella requires several episodes of infection to get primed and is short-lasting, suggesting that the B cell response is functionally impaired. Here we show that upon ex vivo infection of human colonic tissue, invasive S. flexneri interacts with and invades B lymphocytes. We observe the induction of a type three secretion apparatus (T3SA)-dependent B cell death in vitro, both in lamina propria B lymphocytes and the human CL-01 B cell line. This cell death and the parallel reduction of the B cell pool can also be observed in an in vivo mouse infection model. Intriguingly, Shigella-induced B cell death does not require bacterial invasion or injection of virulence effectors via the T3SA in vitro. Instead, the virulence factor IpaD triggers mitochondrial B cell apoptosis in the presence of bacterial co-signals that render B lymphocytes prone to die. We provide evidence that IpaD binds to and induces apoptosis via TLR2, a signaling pathway that has thus far only been considered as a mitogenic stimulus for B lymphocytes. Apoptotic B lymphocytes in close contact with Shigella displaying IpaD are also detected in isolated lymphoid follicles of rectal biopsies of naturally-infected individuals. These findings reveal a novel mechanism of T3SA action to induce B cell death by the binding of a virulence factor and reveal an efficient strategy by which entero-invasive pathogens could impair the priming of a protective immune response.

LB2.06
CD14+CD16-, CD14+CD16+ and CD14dimCD16++ monocyte subsets are changed in obesity

M. Renovato-Martins[1,2], *E. Devevre*[2], *K. Clément*[2], *A. Basdevant*[2], *C. Sautes-Fridman*[2], *I. Cremer*[2], *C. Poitou*[2];
[1]*State University of Rio de Janeiro, Rio de Janeiro, Brazil,* [2]*INSERM U872, Paris, France.*

Introduction: Obesity is associated with a low-grade inflammation in which monocytes play an important role. Three subpopulations of monocytes have been described: classical CD14+CD16- (CM), intermediary CD14+CD16+ (IM) and non classical CD14dimCD16++ (NCM) monocytes. We previously showed increased percentages and numbers of IM and NCM in obese subjects that decreased with weight loss. Here we characterize gene expression profile of the monocyte subpopulations in obesity.
Subjects and Methods: The CM, IM and NCM of 7 obese subjects (OB) before and after gastric bypass and 7 lean subjects (C) were sorted by flow cytometry. The expression of genes involved in monocyte functions including migration, adhesion, phagocytosis and cytokines production, was analyzed by Taq Man Low Density Array.
Results: The gene expression of CX3CR1 (fractalkine receptor) and TLR8 (Toll Like Receptor 8) was highly increased in the CM, IM and NCM of the OB group and decreased after surgery. The three subsets displayed different gene expression profiles in the OB group compared to the C group: the NCM expressed high levels of CSF1R (Colony Stimulating Factor 1 receptor), SELPLG (selectin P ligand) and IL1β, the IM were characterized by over-expression of CCR5 (C-C chemokine receptor type 5), TNFα and MCP1 and the CM expressed high levels of CCR2 and CD36.
Conclusion: In obese subjects, the three subpopulations display different gene expression pattern of molecules involved in migration, inflammation and antibody capture. CX3CR1 and TLR8 could be considered as a molecular signature reflecting modified functions of monocytes in obesity.

Role of NADPH oxidase-derived reactive oxygen species in human neutrophil IL-1 beta secretion

*M. L. Gabelloni[1], F. Sabbione[1], C. Jancic[1], I. Keitelman[1], L. Iula[1], M. Oleastro[2], J. Geffner[1], **A. Trevani**[1,3];*
[1]IMEX-CONICET, Academia Nacional de Medicina, Buenos Aires, Argentina, [2]Hospital Nacional de Pediatría "Juan P Garrahan", Buenos Aires, Argentina, [3]Facultad de Medicina, Universidad de Buenos Aires, Buenos Aires, Argentina.

Interleukin-1β (IL-1β) is a major pro-inflammatory cytokine synthesized in the cytoplasm as a precursor that has to be proteolytically processed to become biologically active. We determined that in response to LPS and LPS plus ATP, human neutrophil IL-1β processing is dependent on caspase-1 and on elastase and/or proteinase-3. The role of reactive oxygen species (ROS) in IL-1β processing remains still controversial and has not been studied in neutrophils. We found that upon stimulation, NADPH oxidase-deficient neutrophils activated caspase-1 and did not exhibit differences in NALP3 expression as compared to healthy neutrophils, indicating that ROS are neither required for inflammasome activation nor for its priming, as has been reported in macrophages. Strikingly, ROS exerted opposite effects on the processing and secretion of IL-1β; whereas ROS negatively controlled caspase-1 activity, as reported in mononuclear phagocytes, they were found necessary for IL-1β secretion, a role never previously described. The complex ROS-mediated regulation of neutrophil IL-1β secretion might constitute a physiological mechanism to control IL-1β-dependent inflammatory processes where neutrophils play a crucial role.

IL1.01.02
Characterization of cytosolic proliferating cell nuclear antigen (PCNA) in neutrophils: anti-apoptotic role of the monomer

*A. De Chiara, **V. Witko-Sarsat**;*
INSERM U1016, Institut Cochin, Université Paris Descartes, Paris, France.

Neutrophils are deprived of proliferative capacity and have a tightly controlled lifespan to avoid their persistence at the injury site. We have previously described that the proliferating cell nuclear antigen (PCNA), a nuclear factor involved in DNA replication and repair of proliferating cells is a key regulator of neutrophil survival (J Exp Med 2010). The nuclear-to-cytoplasmic relocalization occurring during granulocytic differentiation was dependent on a nuclear export sequence that was exposed only in monomeric PCNA (J Biol Chem 2012). Nuclear PCNA functions are tightly linked to its ring-shaped structure, which allows PCNA to bind to numerous partner proteins to orchestrate DNA-related processes. We tested the hypothesis that monomeric PCNA could have a biological role in neutrophils. Using a combination of cross-linking and gel filtration experiments, both trimeric and monomeric PCNA were detected in neutrophil cytosol. The promyelocytic cell line PLB985 stably transfected to express the monomeric PCNAY114A mutant showed an enhancement of granulocytic differentiation as evidenced by an increased percentage of CD11b- and gp91phox-positive cells compared with the wild type trimeric PCNA. However, both trimeric and monomeric PCNA displayed a similar anti-apoptotic activity following treatment with gliotoxin or TRAIL compared to control PLB985. The molecular basis through which cytoplasmic PCNA exerts its anti-apoptotic activity in mature neutrophils may, at least in part, be independent of the trimeric conformation. Through an intimate comprehension of the functions of cytosolic PCNA, novel pathways regulating neutrophil survival can be unraveled and innovative agents can be developed to dampen inflammation where it proves detrimental.

W1.01.01
Chromatin configurations correlate with the differential capacity of human neutrophils and monocytes to express IL-6 in response to LPS

***M. Zimmermann**, N. Tamassia, M. Castellucci, M. Rossato, F. Bazzoni, M. A. Cassatella;*
University of Verona, Verona, Italy.

IL-6 is a pleiotropic cytokine with a broad range of pro- and anti-inflammatory functions that is produced by appropriately stimulated monocytes. However, whether human neutrophils do so, remains still controversial in the literature. To clarify such issue, we explored with additional studies at epigenetic level, whether human neutrophils express IL-6 in response to lipopolysaccharide (LPS), which in autologous monocytes represents a major IL-6 inducer.
We found that highly purified (> 99,7 %) neutrophils stimulated at 5 million/ml with 100 ng/ml ultrapure LPS for 24 h released no or very negligible (< 20 pg/ml) amounts of IL-6, unlike autologous monocytes (50 ng/ml/2,5 million/ml). Neutrophils neither expressed IL-6 mRNA or IL-6 primary transcripts at time points (up to 6 h) in which they were maximally produced in autologous monocytes. Consistent with the lack of any IL-6 transcriptional activity, no increase of IL-6 promoter activity could be observed in neutrophils incubated with LPS for 4 h, as revealed by formaldehyde-assisted isolation of regulatory elements (FAIRE). In contrast, a 10-fold increase of nucleosome free DNA levels was detected at the IL-6 promoter of autologous monocytes treated as neutrophils. Furthermore, by chromatin immunprecipitation (ChIP) no H4Ac (an epigenetic marker of transcriptionally active chromatin) was detected at the IL-6 locus (spanning a 30 kb range) of neutrophils incubated with LPS for up to 5 h, in large contrast to monocytes.
Taken together, these results suggest that the differential capacity of human neutrophils and monocytes to express IL-6 upon LPS activation is likely controlled by epigenetic mechanisms.

W1.01.02
Influence of CD137L signalling in myelopoiesis during acute and chronic inflammation

***Q. Tang**[1], D. Jiang[2], J. M. M. Gomez[1], S. Alonso[1], A. Pant[1], D. M. Kemeny[1], L. Chen[3], H. Schwarz[1];*
[1]National University of Singapore, Singapore, Singapore, [2]University of Ulm, Ulm, Germany, [3]Yale University, New Haven, CT, United States.

CD137 is a costimulatory molecule expressed on activated T cells. The signalling of CD137 into T cells upon ligation by its ligand, CD137L expressed on antigen presenting cells (APC), can potently enhance the activation of T cells. Reversibly CD137 can also induce signalling into APC via CD137L to promote activation and proliferation. The aim of this project is to investigate the role of CD137L on myelopoiesis under inflammatory condition. Our data show that in vivo CD137 represents a novel and potent growth and differentiating factor for murine myeloid cells during inflammation. In an acute peritonitis model there is a significantly larger increase of proliferating myeloid cells in the bone marrow of wild type (WT) than of CD137-/- mice. Further investigations revealed that the sources of CD137, which drives the enhanced myelopoiesis during inflammation, are CD4+ T cells. In vitro, WT activated CD4+ T cells induced higher expression of myeloid marker as well as enhanced proliferation of lineage negative progenitor cells than CD137-/- activated CD4 T cells. Interestingly, in an ageing model where mice experienced chronic inflammation, WT mice also have enhanced myelopoiesis and increased number of CD137+CD4+ T cells compared to CD137-/- mice, further strengthening the link between CD137 and myelopoiesis during inflammation. It is hypothesized that when inflammation is induced, T cells are activated and home to the bone marrow and interact with CD137L-expressing progenitor cells and myeloid cells. Future experiments will focus on exploiting the potential of CD137-CD137L interaction in monitoring myelopoiesis during different pathological conditions.

W1.01.03
Neutrophils have a negative impact on DC activation and disease progression following Leishmania major infection

S. Schuster[1,2]*, B. Hurrell*[1,2]*, D. Ashok*[1]*, H. Acha-Orbea*[1]*, F. Tacchini-Cottier*[1,2]*;*
[1]Department of Biochemistry, University of Lausanne, Epalinges, Switzerland, [2]WHO Immunology Research and Training Center, University of Lausanne, Epalinges, Switzerland.

Neutrophils arrive rapidly and massively at the site of *Leishmania major* inoculation in the skin. They participate in shaping the immune response by the secretion of numerous factors including cytokines and chemokines and by interactions with antigen-presenting cells such as dendritic cells (DC). More specifically, neutrophils participate in the attraction of DCs to the site of infection and can either promote or inhibit their activation. In this study, we investigated the impact of neutrophils on the activation of DCs during the first days following *L. major* inoculation at the site of infection and the draining lymph node (dLN) in *Leishmania*-susceptible BALB/c mice and evaluated the consequences on disease progression. Transient depletion of neutrophils led to increased activation of DCs in the dLN three days post *L. major* infection whereas no detectable differences in DC activation were found at the site of infection. Moreover, mice depleted of neutrophils developed significantly smaller lesions and harbored decreased numbers of parasites in infected ears six weeks post *L. major* infection. Collectively, these data indicate that neutrophils have a negative impact on DC activation and disease progression in BALB/c mice during the onset of *L. major* infection.

Novel neutrophil-T-cell interactions: Hormones and the regulation of T-cell responses

S. Nadkarni*, F. Marelli-Berg, M. Perretti;*
William Harvey Research Institute, London, United Kingdom.

Novel cellular cross-talk within the immune system is gaining new ground. Specifically, the interaction between cells of the innate and adaptive immune systems appear to have important implications in the maintenance of tolerance.
We have reported that the pre-menopausal estrogen, estradiol, induces a protective, anti-inflammatory phenotype in human neutrophils, modulating adhesion molecule expression and reducing their recruitment to sites of inflammation, *via* non-genomic modulation of the anti-inflammatory protein, Annexin-A1.
In the present study, we provide new evidence that treatment of neutrophils with the pregnancy hormones estriol (E3) and progesterone (P4) can induce a regulatory-like phenotype in T-cells. Briefly, neutrophils were treated with 100ng/ml of E3 and P4 for 30 min, washed and co-cultured with autologous T-cells (stimulated with anti-CD3/anti-CD28) for 5 days. We found that neutrophils treated with E3 and P4 did *not* suppress T-cell proliferation. Closer analyses revealed T-cells co-incubated with E3+P4-treated neutrophils (but not with neutrophils without hormone treatment), released high levels of IL-2 and IL-10, and expressed the Treg transcription factor, FOXP3. These IL-10-producing $FOXP3^{+ve}$ T-cells were also functionally *suppressive*.
Taken together, we provide evidence for a novel cellular cross-talk, where neutrophils, in the presence of pregnancy hormones E3 and P4, induce and expand a functionally suppressive regulatory T-cell population. These results could have important implications in our understanding of maternal-foetal tolerance during pregnancy.

Neutrophil Extracellular Trap (NET) formation in the pathogenesis of *Staphylococcus aureus* sepsis

E. Kolaczkowska[1,2]*, P. Kubes*[1]*;*
[1]University of Calgary, Calgary, AB, Canada, [2]Jagiellonian University, Krakow, Poland.

Sepsis remains a serious condition, associated with multiple organ dysfunction syndrome, often resulting in mortality. Neutrophils are one of the first cells which detect systemic infection as they continuously patrol the blood. During sepsis, neutrophils are often immobilized in the lungs and liver for yet unclear reasons. One possibility for this sequestration is to allow neutrophils to form neutrophil extracellular traps (NETs), composed of extracellular DNA, histones and granular proteins, including proteases. Although NETs are well characterized *in vitro*, their *in vivo* characteristics remain unclear. NETs function to trap and immobilize pathogens and subsequently contribute either directly, or indirectly to pathogen elimination. Persistent presence of NETs in vasculature, however, might also lead to bystander cell damage due to prolonged exposure to anti-microbial and proteolytically active NET components. We report here that systemic infection with *Staphylococcus aureus* led to profound neutrophil infiltration in the liver and strong NET formation. These processes occur within the first few hours and are observed, in real time, using spinning-disk confocal intravital microscopy. Interestingly, some NETs persisted in vasculature for several hours and this was associated with profound damage to the liver, a phenomenon that could be reduced by systemic DNase treatment. Importantly, the liver damage was not exclusively NET-dependent as the observed damage was also diminished in mice injected with transgenic *S. aureus* not encoding *a*-toxin. Thus we can conclude that NET formation during *S. aureus* infection partially contributes to liver damage. EK is supported by FP7-PEOPLE-2010-IOF (grant No.273340) from EU.

W1.01.06
Activated basophils form extracellular DNA traps able to kill bacteria

M. Morshed[1]*, D. Simon*[2]*, T. Kaufmann*[1]*, R. Hlushchuk*[3]*, V. Djonov*[3]*, H. Simon*[1]*, S. Yousefi*[1]*;*
[1]Institute of Pharmacology, University of Bern, Bern, Switzerland, [2]Department of Dermatology, Inselspital, University Hospital Bern, Bern, Switzerland, [3]Institute of Anatomy, University of Bern, Bern, Switzerland.

Background: Basophils represent a small population of blood leukocytes constituting less than 1% of total leukocytes. They have been primarily associated with the pathophysiology of allergic diseases and parasitic infections. Basophils release granule proteins and some Th2 cytokines (IL-4/IL-13) following immunological and non-immunological activation; such secretion can be enhanced upon priming with IL-3. Moreover, basophils can bind various bacteria even in the absence of opsonizing antibodies.
Objective: To investigate whether basophils are able to form extracellular DNA traps able to kill bacteria.
Results: Basophils were able to form extracellular DNA traps containing mitochondrial DNA and the granule protein basogranulin following immunological and non-immunological activation in the absence of cell death. Although basophils have been described to express no functional NADPH oxidase, the generation of reactive oxygen species (ROS) was required for the formation of these extracellular DNA-containing structures. While basophils were unable to kill bacteria intracellularly owing to their inability to perform phagocytosis, basophil extracellular traps (BETs) exhibited bactericidal activity *in vitro*. BETs were present in inflammatory human and mouse skin.
Conclusions: Basophils mediate IgE-mediated and -independent antibacterial immune responses involving extracellular DNA traps.

Mast cells and regulatory cells: a dialogue that can last a lifetime

***C. Pucillo**;*
Laboratory of Immunology, Department of Medical and Biological Science, University of Udine, Udine, Italy.

Mast cells (MC) have been considered for long time only for their role in the allergy, and for the patients the most hated cells in the body. In the past, some researchers have also proposed eradicating them to avoid suffering. However, MCs reputation has been turned around with progress in our understanding of their role in immune response. In fact, we have learned that the MCs play many roles as sentinels that regulate the immune response on invading bacteria. Moreover, they have a fundamental role in link the innate with adaptive immune system. Our recent studies and literature data on MC interactions with other cells of immune system point to their importance in the cross-talk with regulatory cells, mediating the maintenance of the regulatory T cell-dependent peripheral tolerance during skin allografts. Additionally, they have a continuous dialogue, influencing the development and activity of other regulatory cells too, as the recently discovered subset of B cells, the IL10-competent B cells. However, a membrane-studded of receptors do not limit the MCs to have interactions with only few cellular types, but allow those cells to enlist all the cell of the immune system and to be present in normal and pathological tissue with a different behavior. This capability added to the power of thousands of compounds that the MCs can release is useful to coordinate the activity of immune system but can be fickle allies too.

IL1.02.02
Basophils: new key players in lung and intestinal Th2 or Th17-associated chronic inflammatory disorders.

***M. Sarfati**;*
CRCHUM, Université de Montréal, Montreal, QC, Canada.

Basophils, a rare type of cells, are typically implicated in Th2-associated diseases through IgE- dependent mediators/cytokines release and amplification of dendritic cell-induced naïve T cell development into Th2 effectors. Here, we report that basophils accumulated in the lungs of mice with allergic asthma. Passive transfer of highly purified pulmonary basophils to sensitized but non asthmatic mice induced airway inflammation, lung production of type 2 cytokines and unexpectedly, IL-17 release. Murine pulmonary as well as human circulating basophils directly acted on autologous memory CD4 T cells to enhance *in vitro* Th2, Th17 and Th17/Th1 memory T cell responses. Accordingly, IL-3 or IL-33-activated basophils amplified IL-4 or IL-17 release in effector memory (T_{EM}), central memory (T_{CM}) as well as in $CRTh2^+$ and $CCR6^+$ CD4 T cells, respectively. Mechanistic analysis revealed that enhancing effect of cytokine production by basophils did not require the presence of Ag, APC or TCR triggering and was partially mediated by histamine via H2 and H4 histamine receptors. We next demonstrate that basophils were not only detected in lungs of cystic fibrosis patients but also accumulated at inflamed sites in intestinal tissues of patients with the Crohn's disease and Ulcerative Colitis. Thus, we propose that basophils are key innate players in chronic inflammatory disorders beyond Th2 and IgE-associated allergic diseases.

Seven color flow cytometry analyses of Allergin-1 expression and function on human primary bronchoalveolar and nasal mast cells

***K. Nagai**[1,2], S. Tahara-Hanaoka[1,2], A. Shibuya[1,2];*
[1]Department of Immunology, Division of Biomedical Sciences, University of Tsukuba, Tsukuba, Ibaraki, Japan, [2]Japan Science and Technology Agency, CREST, Tokyo, Japan.

We have recently reported a novel inhibitory immunoglobulin-like receptor, Allergin-1, expressed on mast cell (MC) and showed that mouse Allergin-1 inhibited FcεRI-mediated signal and degranulation from MC in vitro and in vivo (Hitomi, et al, *Nat Immunol.* 2010). Unlike mouse Allergin-1, human Allergin-1 consists of three splicing isoforms, including Allergin-1L, Allergin-1S1, and Allergin-1S2. However, the expression and function of each Allergin-1 on human primary MCs have not been determined due to a hard acquisition of primary human MC. To overcome this problem, we established an analytical method of very small number of human MCs in broncoalveolar lavage fluid (BAL-MCs) and nasal scratching sample (N-MCs) by using seven color flow cytometry. We defined MCs as $PI^-CD45^+Lin^-c\text{-}Kit^+Fc\varepsilon RI\alpha^+$ cells and characterized BAL-MCs and N-MCs by using two monoclonal antibodies (mAb) specific to Allergin-1S1 or Allergin-1S2. MCs accounted for 0.164 ± 0.049% (n=21) in the BAL fluid cells of patients with variable respiratory diseases and 0.535 ± 0.112% (n=9) in nasal scratching sample from allergic rhinitis patients. We also demonstrate that BAL-MCs and N-MCs preferentially expressed Allergin-1S1, but not Allergin-1L and Allergin-1S2. To examine the function of Allergin-1S1 on BAL-MCs, BAL-MCs were sensitized with TNP-specific IgE and then stimulated with either TNP-conjugated control mAb or TNP-conjugated anti-Allergin-1S1 mAb. The proportion of $CD107a^+$ cells in the BAL-MCs were analyzed by flow cytometry. Comparing to TNP-conjugated control mAb, TNP-conjugated anti-Allergin-1S1 mAb significantly decreased the $CD107a^+$ population. These results first demonstrate that human bronchial MCs express Allergin-1S1, which inhibits FcεRI-mediated signal and degranulation from MC.

W1.02.02
Soluble CD14 is necessary for lipopolysaccharide-mediated signalling in human intestinal mast cells

***S. A. Brenner**, S. C. Bischoff, A. Lorentz;*
University of Hohenheim, Stuttgart, Germany.

Mast cells are known to be involved in pathogen recognition and host immune defence. At the gastrointestinal barrier, mast cells are confronted with a huge microbiota and the challenge to tolerate commensal microorganisms and to recognize and eliminate potential pathogens. Here, we examined the role of CD14 in lipopolysaccharide (LPS) mediated signalling in human intestinal mast cells (hiMC). HiMC were isolated from intestinal tissue and cultured with SCF and IL-4. Using cytometry, TLR-4, but not CD14, was detectable on hiMC. Consistently, triggering with LPS alone failed to stimulate degranulation or cytokine expression in hiMC. To investigate the relevance of CD14 in LPS-mediated signalling, hiMC were treated with LPS [1 µg/ml] alone or combined with 1 ng/ml - 1µg /ml soluble CD14 (sCD14). We found a dose dependent induction of the proinflammatory cytokines/chemokines IL-1β, IL-6, and IL-8 measured by real-time RT-PCR. Noteworthy, the chemokines MCP-1, MIP-1α, and -1β were not expressed in response to LPS/sCD14 stimulation. Moreover, an increased cytosolic content of IL-8 and IL-1β and the release of IL-8 was measured by ELISA upon combined activation of hiMC with LPS and sCD14. In summary, hiMC are not sensitive towards LPS alone due to the missing CD14 receptor. In contrast, LPS triggering in the presence of sCD14 results in a selective expression and release of proinflammatory cytokines. In vivo, sCD14 may be derived by other LPS provoked cells and consequently activate hiMC at the gastrointestinal barrier.

W1.02.03
Siglec-7 is an Inhbitory receptor on Human mast cells

***S. Mizrahi**[1], B. F. Gibbs[2], L. Karra[1], M. Ben-Zimra[1], F. Levi-Schaffer[1];*
[1]The Hebrew University of Jerusalem, Jerusalem, Israel, [2]Medway School of Pharmacy, University of Kent, Kent, United Kingdom.

Allergic inflammation (AI) is a multiphase process which is involved in pathological disorders such as asthma and allergic rhinitis. AI is typically initiated when IgE-bearing tissue dwelling mast cells (MC) bind to an allergen throw the FcεRI -bound IgE. This leads to cross-linking of the FcεRI and activates the MC to release their mediators and to orchestrate the immediate, early phase of the allergic response. The subsequent recruitment and activation of inflammatory cells, particularly eosinophils (Eos) causes a late phase allergic response which often results in the chronic perpetuation of the

inflammatory reaction. Due to their key role in the initiation of AI a lot of research is focus on understanding the mechanism controlling MC and especially on the ones that inhibit them. Siglec-7 belongs to a family of lectins that recognize sialic acid. We have found that Siglec-7 is expressed in MC as a 75 kDa protein and can be found on MC grown from bone marrow derived precursors (CBMC) and on the MC-lines: HMC-1 and LAD-2. Siglec-7 activation, by cross-linking it with Abs, can only inhibit FcεRI-induced MC activation when Siglec-7 is coupled to FcεRI. Siglec-7 activation and coupling to FcεRI inhibited the release of mediators from all three major groups of soluble mediators released by MC: arachidonic acid metabolites, newly synthesized and preformed mediators. Activation of Siglec-7 leads to phosphorylation of tyrosine residues on Siglec-7 and associated molecules. In conclusion, the discovery of new inhibitory receptor on MC will enable the development of new treatments to allergy.

W1.02.04
The S1P/S1PR$_2$ axis controls T-cell infiltration in a mast cell-dependent mouse model of acute pulmonary inflammation

*M. M. Price[1], Y. T. Falanga[2], J. J. Ryan[2], R. Sabbadini[3], S. Spiegel[4], **C. A. Oskeritzian**[5];*
[1]Virginia Commonwealth University School of Medicine Department of Biochemistry and Molecular Biology, Richmond, VA, United States, [2]Virginia Commonwealth University Department of Biology, Richmond, VA, United States, [3]LPath Inc., San Diego, CA, United States, [4]Virginia Commonwealth School of Medicine Department of Biochemistry and Molecular Biology, Richmond, VA, United States, [5]University of South Carolina School of Medicine Department of Pathology, Microbiology and Immunology, Columbia, SC, United States.

Mast cells promote allergic inflammation by first secreting vasoactive mediators, including histamine and sphingosine-1-phosphate (S1P). However, the pathophysiology of acute allergic inflammation and its molecular mechanisms still remain unclear. We show that preventing signaling through the type 2 receptor for S1P (S1PR2) on mast cells by neutralizing its ligand S1P with a highly selective antibody Sphingomab^{TM} improved many inflammatory features associated with antigen (Ag) exposure, including circulating levels of histamine and chemokines and lung mast cell degranulation. Moreover, kinetic studies revealed that T cells and a few macrophages were recruited very early around pulmonary blood vessels within minutes after Ag challenge. This unexpected early T cell infiltration was accompanied with increased serum levels of RANTES/CCL-5 and suppressed in the absence of mast cells, S1PR2 or intact S1PR2 signaling. Optimal RANTES/CCL5 secretion by IgE/Ag-activated mast cells also required functional S1PR2. We propose that perturbing S1PR2 signaling in mast cells might constitute an effective therapeutic strategy to prevent early T cell infiltration associated with allergic inflammation and therefore its persistency. Supported by NIH grants R01 AI50094 to SS and U19 AI077435 to SS and JJR and K01AR053186 and R01 AI095494 to CAO.

W1.02.05
IgE-dependent mast cell hyperplasya in the intestine of cystic fibrosis mouse model needs KCNN4 channel activity

*T. T. Riquelme, L. P. Cid, F. V. Sepúlveda, **C. A. Flores**;*
Centro de Estudios Cientificos (CECs), Valdivia, Chile.

Cystic fibrosis (CF) primary dysfunction in epithelial transport concurs with deregulation of the immune system in human patients and animal models. We observed that when the KCNN4 channel is genetically silenced in the CF mouse lethality is drastically reduced with no improvement of intestinal function. The KCNN4 channel is broadly expressed including the immune system. We aim to test if KCNN4 channel inhibition is involved in immune system dysfunctions associated with CF.
CF animals presented a 4-fold increase of intestinal mast cells, the value obtained in the KCNN4-null/CF mice was lower and comparable to controls. IgE-induced migration was 2-fold increased in control and CF mast cells compared with non-stimulated cells. Migration was blocked when the KCNN4 specific inhibitor TRAM-34 was used. Migration was completely impaired in the KCNN4-null and KCNN4-null/CF cells. Serum IgE level was increased in the CF as in the KCNN4-null/CF mice.
Inhibition of KCNN4 blocks migration in control and CF mast cells. Hyperplasia of mast cells in the CF mice is localized in the intestinal tissue and can be due to increased migration induced by the higher levels of IgE. Mast cell reduction on intestine of KCNN4-null/CF mice is due to the impairment in migration of mast cells and not to reduced IgE levels. The origin of IgE in the CF mice remains a matter of investigation. KCNN4 inhibtion can be a useful pharmacological target on inflammatory CF disease where mast cells can act as enhancers of inflammation.

Mast cells determine the adaptive immune response in contact hypersensitivity

***A. Dudeck**[1], J. Dudeck[1], M. Gunzer[2], A. Roers[1];*
[1]University of Technology Dresden, Medical Faculty, Institute for Immunology, Dresden, Germany, [2]University Hospital Essen, University Duisburg-Essen, Essen, Germany.

Contact allergens trigger a rapid inflammatory response of skin resident innate immune cells. By these inherent adjuvant-properties, sensitizing compounds elicit allergic-specific T cell responses. However, the mechanisms by which organic sensitizers trigger innate immunity are incompletely understood. Mast cells are considered important sentinel cells of innate immunity at body surfaces. Conflicting results were published on the role of mast cells in contact allergy based on mast cell-deficient kit mutant mice. We used our novel Cre/loxP-based mouse models of mast cell deficiency and mast cell-specific gene inactivation to study mast cell functions in contact allergy. We found that in the absence of mast cells, allergic responses to organic haptens were massively reduced. Mast cell-deficiency abrogated the early innate response to contact allergens as determined by quantification of vasodilatation, vessel permeability and neutrophil influx. Importantly, we demonstrated that DC migration from sensitized skin to lymph nodes and expansion of T lymphocytes was reduced in the absence of mast cells, and that the CD8$^+$ T cell response to secondary allergen encounter was impaired in mast cell-depleted mice. To address mechanisms of the mast cell effect on contact hypersensitivity, we generated mice lacking TNF selectively in mast cells. Also these animals featured reduced CD8$^+$ T cell-mediated inflammatory responses of allergen-challenged skin. However, we found that mast cell-derived TNF selectively supports migration and maturation of CD8$^+$ DCs responsible for CD8$^+$ T cell priming. In summary, we demonstrate that mast cell responses to contact allergens are essential for the induction of the pathogenic T cell response.

W1.03 NK cells and NK receptors

IL1.03.01
Cross-talk bethween human natural killer cells and macrophages

*F. Bellora[1], R. Castriconi[1], A. Doni[2], A. Mantovani[3], A. Pessino[4], A. Moretta[1], **C. Bottino**[5];*
[1]University of Genova, Genova, Italy, [2]Istituto Clinico Humanitas IRCCS, Rozzano (MI), Italy, [3]Istituto Clinico Humanitas IRCCS and University of Milano, Rozzano (MI), Italy, [4]IRCCS Azienda Ospedaliera Universitaria San Martino-IST, Genova, Italy, [5]University of Genova and G.Gaslini Institute, Genova, Italy.

We investigate the molecular pathways involved in the interaction between NK cells and unpolarized or polarized macrophages. M0 and M2 are unable to trigger NK cell function. Following exposure to microbial products (LPS or BCG), M1 polarizing M0 and M2 (but not endotoxin tolerant macrophages), induce strong activation of resting NK cells resulting in CD69, CD25 and CCR7 expression, IFN-γ production and acquisition of anti-tumor cytotoxicity. NK cells also enhance the “editing” capability becoming capable of killing iDC, M0 and M2, which express low, non protective amounts of HLA-I. NK cell activation mostly depends on the interaction of NKp46, DNAM-1 and 2B4 receptors (on NK) with their ligands on macrophages, and on the

IL-18R (on NK) that binds small amounts of IL-18 released by M0 and M2 upon TLR engagement (PNAS 2010). We also showed that M-CSF induces the expression of mIL-18 membrane-bound form of IL-18 (mIL-18) in a subset of M-CSF primed macrophages differentiating from both CD16- and CD16+ monocytes. Inhibition of caspase-1 reduces mIL-18 expression suggesting the requirement of an assembled inflammasome for IL-18 surface expression. While M2 polarization does not modify mIL-18 expression, M1 polarization induces the protease(s)-mediated shedding of mIL-18. Soluble IL-18 (sIL-18) acts in close cell-to-cell contact and is crucial for CCR7 expression and IFN-γ release by resting NK cells (EJI 2012). Recently we analyzed the functional outcome of the interaction between NK cells and Tumor-associated macrophages (TAM) from ascites of ovarian cancer patients.

IL1.03.02
Functionally distinct subsets of human NK cells

G. Deniz*;*
Istanbul University, DETAE, Department of Immunology, Istanbul, Turkey.

Natural killer cells not only exert cytotoxic activity against tumor cells or infected cells, but also act to regulate the function of other immune cells by secretion of cytokines and chemokines. The major functional properties of NK cells are cytotoxicity and cytokine production. NK cells express a wide range of activating receptors, as well as inhibitory receptors that regulate NK cell activation and tolerance, and their functions are governed by a balance between activating messages transmitted by their activating receptors and inhibitory signals transmitted by their inhibitory receptors. Similar to the Th1 and Th2 subsets of $CD4^+$ and also $CD8^+$ T cells, NK cells are also divided into NK1 and NK2 subpopulations according to the profile of cytokine secretion. NK cells that are exposed to IL-12 *in vitro* (NK1) produce predominantly IFN-γ, whereas NK cells stimulated with IL-4 (NK2) produce IL-5 and IL-13. Similar to suppression of both cytokine production and antigen-specific proliferation of Th1 and Th2 cells by IL-10, IL-10-secreting NK cells suppress both allergen-stimulated T cells and PPD-stimulated T cell proliferation, whereas IFN-γ secreting NK cells did not show any suppression. Findings suggest the *in vivo* existence of a regulatory NK cell subset, which indeed may play an immune regulatory and suppressor role.

W1.03.01
NK cell subsets isolated from human thymus differ from peripheral blood NK cells in their phenotype and their cytotoxic and cytokine secreting capabilities

S. Krieg[1], W. Kroeger[2], G. Heidkamp[2], K. Winterling[1], A. Purbojo[2], R. Cesnjevar[2], A. Mackensen[2], D. Dudziak[2], ***E. Ullrich****[1,2];*
[1]Children's Hospital, Frankfurt, Germany, [2]University Hospital Erlangen-Nuremberg, Erlangen, Germany.

Little is known about the functional role of human NK subpopulations in different lymphoid organs beyond blood. We therefore aim to characterize the phenotypical and functional profile of human NK cell subsets from different organs with special interest in thymic NK cells.
Human NK cells can be classified according to the expression of CD56 and CD16 into immunoregulatory and cytotoxic NK cells. In this study, we observed that especially the composition of NK subpopulations in the thymus differs from peripheral blood of both adult and children. Thymic NK cells have not only a lower CD56-expression but also a different ratio of $CD16^{high}$ / $CD16^{dim}$ NK cells. Extensive phenotypical analysis revealed significant alterations in expression patterns of KIRs, NCRs and other maturation or differentiation markers on thymic NK cells. Furthermore, functional assays revealed important differences of $CD16^{high}$ and $CD16^{dim}$ thymic NK cells. Whereas thymic $CD16^{high}$ NK cells showed high killing capacity of K562 tumor cells, $CD16^{dim}$ NK cells required an increased stimulation period with IL-2 to gain cytotoxic function. Dependent on IL-2 both subsets could reach the killing capability of unstimulated adult peripheral blood NK cells. Remarkably, only $CD16^{dim}$ NK cells were able to produce few amounts of IFN-γ upon stimulation with IL-2.

In summary, this comparative study of NK cell subsets provides important insight on the development and function of NK cells that will be of great value for the optimization of cellular therapy.

W1.03.02
Neuraminidase-mediated, NKp46-dependent, immune evasion mechanism of influenza viruses

Y. Bar-On*, O. Mandelboim;*
Hebrew University, Jerusalem, Israel.

Natural killer (NK) cells play an essential role in the defense against influenza virus infections, one of the deadliest respiratory viruses known today. The natural killer receptor (NKp46), expressed by NK cells is critical in controlling influenza virus infections, as influenza-virus infected cells are eliminated through the recognition of the viral hemagglutinin (HA) protein by NKp46. Here we describe a novel immune evasion mechanism of influenza viruses that is mediated by the viral neuraminidase (NA) protein. We show, by using various NA blockers, that NA removes sialic acid residues from NKp46 and that this leads to reduced recognition of HA. Furthermore, we provide in vivo and in vitro evidence for the existence of this novel NA-mediated, NKp46-dependent immune evasion mechanism and demonstrate that NA inhibitors, which are commonly used for the treatment of influenza infections, are useful not only as blockers of virus budding but also as boosters of NKp46 recognition.

W1.03.03
NK cells from malignant pleural effusions are not anergic but produce cytokines and display strong anti-tumor activity on short-term IL-2 activation

P. Vacca*[1], S. Martini[2], L. Moretta[3], M. C. Mingari[1];*
[1]University of Genoa, Genoa, Italy, [2]IRCCS AOU San Martino-IST (National Institute for Cancer Research), Genova, Italy;, Genoa, Italy, [3]Giannina Gaslini Institute, Genova, Italy.University of Genoa, Genoa, Italy.

NK cells are a major component of the innate immunity and exert a potent anti-tumor effect both in vitro and in vivo. However, tumor infiltrating natural killer (NK) cells have been shown to display severely impaired functional properties. In this study, we analyzed NK cells isolated from pleural effusions (PE) in patients with primary or metastatic tumors of different origin (including mesotheliomas, lung carcinomas, breast, colon gastric and liver carcinomas). Freshly isolated PE-NK cells displayed a CD56bright phenotype and expressed normal levels of both activating receptors and HLA-Class I-specific inhibitory receptors. In addition, they rapidly released large amounts of IFN-γ and TNF-α upon stimulation. After short- or long-term culture in IL-2, they acquired a potent cytolytic activity against both allogenic and autologous tumor cells. Tumor cell lysis was primarily mediated by NKG2D and by NKp30 and, in part, by NKp46 and DNAM-1, in agreement with the expression of the corresponding ligands on tumor cells. The finding that PE-NK cells are not functionally impaired and can efficiently kill tumor cells upon IL-2 activation may offer an important clue for novel approaches in tumor immunotherapy.

W1.03.04
Unique CD56bright CD16+ NK cells infiltrate regional metastatic Lymph Nodes from stage III melanoma patients

M. Messaoudene*[1], G. Fregni[2], E. Fourmentraux-Neves[1], J. Chanal[3], M. Avril[3], A. Caignard[1];*
[1]INSERM, Paris, France, [2]Lausanne University, Lausanne, Switzerland, [3]AP-HP, Paris, France.

Over the past decades, the incidence of melanoma has been constantly increasing. Malignant melanoma has a high metastatic potential with limited treatment options. There are numerous arguments indicating that melanomas are immunogeneic and that the immune system can control the tumor growth in certain conditions.

We focus our interest on Natural Killer (NK) cells, potent cytotoxic effectors that control metastases in several murine tumor models.
We have investigated the ex vivo phenotype and function of NK cells infiltrating 21 metastatic lymph nodes (M-LN) from 16 stage III B/C melanoma patients. The tumor burden in the samples was assessed by the percentages of CD45- cells in the LN suspensions. Interestingly, the expression of NKp30 and NKG2D correlate with the proportions of CD45- cells (likely melanoma cells) that invaded the M-LN. Moreover, among M-LN NK cells, we have identified a subset of CD56brightCD16+ cells that express high level of activating NK receptors. Our results showed that M-LN NK cells required PMA/Iono to degranulate and produce IFNγ ex vivo, and the proportion of CD107a was inversely correlated to the percentage of CD45- cells. Immunoselected NK cells from M-LN and donor LN were activated for 6 days with IL-2 or IL-15. These cytokine activated NK cells efficiently and rapidly lysed metastatic melanoma cell lines.
The presence of mature CD56brightCD16+NCR+NKG2D+ NK cells subset in M-LN from melanoma patients and their high anti-tumor potential after cytokine activation are strong arguments for NK cell based therapy in patients with positive sentinel lymph node.

NK cells targeting of human and mouse Cancer Initiating Cells

R. Tallerico[1]*, S. Di Franco*[2]*, C. Maccalli*[3]*, L. Conti*[4]*, S. Lanzardo*[4]*, C. Garofalo*[1]*, R. Sottile*[1]*, M. Todaro*[2]*, G. Stassi*[2]*, F. Cavallo*[2]*;*
[1]University Magna Graecia of Catanzaro, Catanzaro, Italy, [2]University of Palermo, Palermo, Italy, [3]San Raffaele Foundation Scientific Institute, Milan, Italy, [4]Molecular Biotechnology Center (MBC), Turin, Italy.

Tumor cell populations have been recently proposed to be composed by two compartments: cancer-initiating cells (CICs) characterized by a slow and asymmetrical growth and the differentiated cancer cells with a fast and symmetrical growth. CICs play a crucial role in tumor recurrence. The resistance of CICs to drugs and irradiation often allows them to survive traditional therapy. Natural Killer (NK) cells are potent cytotoxic lymphocytes that can recognize tumor cells in human and mice.
Human: The NK cell recognition of tumor target cells derived from the two cancer cell compartments of human colon adenocarcinoma lesions. Our data demonstrate that freshly purified human allogeneic NK cells can recognize and kill Colorectal Carcinoma CICs while the tumors either autologous or allogeneic is less susceptible to NK cells. This difference in the NK cell susceptibility correlates with higher expression on CICs of ligands for NKp30 and NKp44 in the NCR group of activating NK receptors. In contrast CICs express lower levels of MHC class I, known to inhibit NK recognition, on their surface than the related tumor cells.
Mouse: The NK cell recognition of tumor target cells derived from the two cancer cell compartments of murine mammary carcinoma. Our data demonstrate so far in vitro that NK cells purified from C57/BL6 and Balb/c mice, selectively recognize the CICs derived from an epithelial murine ErbB-2+ positive tumor cell line, named TUBO.
This study strengthens the idea that biology based therapy harnessing NK cells could be an attractive opportunity in solid tumors.

W1.03.06
Novel mouse models reveal how expression of NKG2D and its ligands on various cell subsets affects immune responses

M. G. Morvan[1]*, M. Champsaur*[2]*, N. L. Johnson*[3,1]*, V. Sexl*[4]*, L. L. Lanier*[1]*;*
[1]University of California, San Francisco, CA, United States, [2]UCB Pharma, Brussels, Belgium, [3]California State University East Bay, Hayward, CA, United States, [4]Veterinärmedizinische Universität, Wien, Austria.

NKG2D is an activating receptor expressed by all Natural Killer (NK) cells, a subset of T cells, and activated macrophages. NKG2D and its ligands, which are expressed on stressed or damaged cells, play important roles during viral infections, cancers, and autoimmune diseases, both in mouse and human. While NKG2D is well studied in NK cells, its function on other cells remains unclear, particularly in vivo. In this study, we examine the consequences of cell-specific ablation of NKG2D, or tissue-specific expression of its ligand Rae-1, on innate and adaptive immunity, using two novel mouse models. By crossing Cre expressing strains to our two newly generated mice bearing a floxed allele of NKG2D, or a Rosa26-LSL-Rae-1 transgene, we obtain conditional knockouts of NKG2D, or mice that express Rae-1 in a cell-specific manner. We are now able to dissect the contribution of each cell subset expressing NKG2D in models of viral infection, tumor rejection, and autoimmunity. In addition, we observed that NK cells chronically interact with myeloid cells in vivo, since expression of Rae-1 on these subsets, but not others, leads to down-modulation of NKG2D expression and impaired NKG2D-dependent functions. Data from these two new mouse models provide a better understanding of the role of NKG2D by defining its impact on different immune cell functions, and by mimicking physiopathological situations of patients in which a human counterpart of Rae-1 is expressed on various tissues.

W1.03.07
Regulation of the activating NKp30 ligand B7-H6 in tumor cells

N. Fiegler[1]*, S. Textor*[1]*, A. Arnold*[1]*, A. Rölle*[1]*, I. Oehme*[1]*, K. Breuhahn*[2]*, G. Moldenhauer*[1]*, M. Witzens-Harig*[2]*, A. Cerwenka*[1]*;*
[1]German Cancer Research Center, Heidelberg, Germany, [2]University Hospital Heidelberg, Heidelberg, Germany.

Natural Killer (NK) cells are innate immune cells sensing and eliminating stressed cells by an array of specialized cell surface receptors. Stressed, transformed or infected cells downregulate inhibitory ligands and upregulate ligands for activating NK cell receptors, resulting in target cell killing. The natural cytotoxicity receptor NKp30 plays an important role in the induction of NK cell responses against tumor cells. Recently, the ligand for NKp30 on the surface of tumor cells has been identified to be the novel B7-family member B7-H6. Due to the lack of B7-H6-specific monoclonal antibodies (mAbs), the expression pattern of B7-H6 has so far only poorly been explored. The regulation of B7-H6 surface expression on tumor cells also remains unknown.
Here, we describe two novel B7-H6-specific mAbs generated in our laboratory. These mAbs specifically bind recombinant B7-H6 in ELISA and B7-H6 expressed on the surface of B7-H6-positive cells in flow cytometry.
Using these mAbs, we demonstrate that B7-H6 is expressed on the surface of various tumor cell lines but not on healthy PBMCs and keratinocytes. B7-H6 regulation was studied by treating tumor cell lines with different reagents. The treatments with the strongest effect on B7-H6 surface expression were further investigated for the mechanisms involved. Finally, the consequences of B7-H6 modulation on NK cell effector functions were assessed.Our findings show that certain treatments have the capability to modulate B7-H6 expression on the surface of tumor cells which has important implications for the activation of NK cells

W1.03.08
Human M1 macrophages activate resting NK cell antitumoral activities through IL-15/IL-15RA transpresentation

I. Mattiola*, M. Pesant, P. Tentorio, D. Mavilio, M. Locati;*
Humanitas Clinical and Research Center, Rozzano, Italy.

Natural killer (NK) cells are important effectors of innate immune responses, providing cellular immunity against tumor-transformed and virally-infected cells. Although NK cell-DC crosstalk is well established, information on NK cells interactions with macrophages is scanty.
Autologous human NK cells and monocyte-derived macrophages were obtained from buffy coats of healthy donors. Macrophages were polarized into M0, M1, M2 and Tumor Associated Macrophages (TAMs). The influence of polarized macrophages on NK cell anti-tumoral activities was analyzed treating NK cells with macrophage-conditioned media or performing direct NK cell-macrophage co-culture. NK cell activating receptors and degranulation levels were evaluated by FACS, IFNγ production was quantified by RT-PCR and ELISA.
Among the panel of activating receptors we evaluated, resting NK cells treated with M1-conditioned medium upregulated specifically

NKG2D, NKp44 and CD69. Additionally, they expressed enhanced levels of IFNγ transcript and released high amount of IFNγ. This effect was partly abolished by neutralizing IL-15/IL-15Rα. Moreover, M1-treated NK cells killed more efficiently the erythroleukemia cell line K562 in a NKG2D-dependent but IL-15/IL-15Rα-independent fashion. Direct co-culture experiments showed that M1-primed NK cells secreted high amounts of IFNγ. They further displayed higher cytotoxic activities towards K562, which was decreased by NKG2D neutralization and totally impaired by further blocking IL-15Rα.
In conclusion, we demonstrate in a human model an important role and a dual effect of IL-15/IL-15Rα complex in the crosstalk between NK cells and M1 macrophages: the soluble complex induces NK cell IFNγ secretion, whereas membrane trans-presentation enhances NK cell cytotoxicity towards tumor cells.

W1.03.09
Natural killer cell distribution and trafficking in normal and neoplastic human tissues

P. Carrega[1], *I. Bonaccorsi*[2], *E. Di Carlo*[3], *M. Mingari*[4], *L. Moretta*[1], *G. Ferlazzo*[2];
[1]*Giannina Gaslini Institute, Genoa, Italy,* [2]*University of Messina, Messina, Italy,* [3]*"G. d'Annunzio" University, Chieti, Italy,* [4]*University of Genoa, Genoa, Italy.*

Although natural killer (NK) cells have been detected in various lymphoid and non-lymphoid organs in mice, limited data are available regarding the distribution and trafficking of NK cells among human solid organs. To increase the current knowledge regarding the presence of NK cells in both healthy and pathological conditions, we analyzed a wide array of normal as well as neoplastic tissues derived from different human compartments. We found that NK cells were broadly distributed in most solid tissues, although, in general, the amount of NK cells significantly varied depending on the tissue/organ analyzed. Interestingly, NK cell distribution appeared to be subset-specific since some tissues were preferentially populated by CD56bright perforinlow NK cells while, others by the CD56dim perforinhigh cytotoxic counterpart. Accordingly, the gene expression level of chemotactic factors in the tissues analyzed matched the expression of chemokine receptors in the NK cell subsets infiltrating the tissues. Remarkably, the chemokine expression pattern of many human tissues resulted modified after neoplastic transformation. As a result, the relative proportion of the NK cell subsets infiltrating the tissues was different, in most cases toward a tumor- infiltrating NK cell population enriched in CD56bright perforinlow cells. Besides solid tissues, a CD3negCD56bright NKp46+ cell population was also detected in seroma fluids, which represents an accrual of human afferent lymph, suggesting that NK cells might leave peripheral solid tissues. Overall, our results support the notion that distinct subsets of NK cells populate, and recirculate through, the majority of human peripheral tissues driven by organ-specific chemokine expression patterns.

W1.03.10
The viral KSHV chemokine vMIP-II inhibits the migration of naive and activated human NK cells by antagonizing two distinct chemokine receptors

R. Yamin*, N. Stanietsky-Kaynan, A. Glasner, Y. Bar-On, S. Elias, C. Gur, O. Mandelboim;*
Hebrew University, Jerusalem, Israel.

NK cells are cells of the innate immune system able to rapidly kill virus-infected and tumor cells. Two NK cell populations are found in the blood; the majority (90%) expresses the CD56 receptor in intermediate levels (CD56Dim) while the remaining 10% express it in high levels (CD56Bright). NK cells are resident in some tissues and traffic to various infected organs through the usage of different chemokines and chemokine receptors. KSHV, like other viruses of the herpes family, is master of immune evasion having numerous sophisticated and versatile strategies to escape the attack of immune cells such as NK cells. Here, we investigate the role of the KSHV derived cytokine (vIL-6) and chemokines (vMIP-I, vMIP-II, vMIP-III), in immune modulation. Using transwell migration assay and fusion and recombinant proteins, we showed that out of the four cytokine/chemokines encoded by the KSHV, vMIP-II is the only one that binds to the majority of NK cells. We demonstrate that vMIP-II binds to two different receptors, CX3CR1 and CCR5, expressed on the naïve CD56Dim NK cells and on activated NK cells, respectively, and that the binding of vMIP-II to CX3CR1 and CCR5 blocks the binding of the natural ligands of these receptors, Fractalkine (Fck) and Rantes, respectively. Finally, we show that vMIP-II inhibits the migration of naïve and activated NK cells towards Fck and Rantes. Thus, the present study indicates a very dominant role for vMIP-II in preventing NK cell migration.

W1.03.11
Innate immunity driving tumor angiogenesis: the role of Natural Killer cells in non-small cell lung cancer

A. Bruno[1,2], *F. Chiara*[3], *A. Pagani*[2], *I. Andrea*[4], *M. Spagnoletti*[5], *C. Capella*[6], *G. Ferlazzo*[7], *L. Mortara*[2], *D. Noonan*[2,1], *A. Albini*[3,8];
[1]*Scientific and Technology Park, IRCCS MultiMedica, Milan, Italy,* [2]*Department of Biotechnology and Life Sciences, University of Insubria, Varese, Varese, Italy,* [3]*Research and Statistics Infrastructure, IRCCS Arcispedale Santa Maria Nuova, Reggio Emilia, Italy,* [4]*Department of Surgical and Morphological Sciences, University of Insubria, Varese, Varese, Italy,* [5]*Center for Thoracic Surgery, University of Insubria, Varese, Italy,* [6]*Department of Surgical and Morphological Sciences, University of Insubria, Varese, Italy,* [7]*Department of Human Pathology, University of Messina, Messina, Italy,* [8]*IRCCS MultiMedica, Milan, Italy.*

Natural Killer (NK) cells are innate effector lymphocytes that potentially can control tumors by their cytotoxic activity. However, in cancer patients innate immune cells often show polarization to a proangiogenic protumor phenotype. The role of NK cells in tumor angiogenesis remains to be defined.
Here we investigated phenotype, function and subset distribution of NKs in tumor, adjacent normal tissue and peripheral blood and the correlation with proangiogenic factor production, i.e. VEGF, PlGF and IL-8/CXCL8 from patients with non-small cell lung cancer (NSCLC).
The CD56brightCD16- NK phenotype predominated in NSCLC samples while the CD56dimCD16+ cytotoxic NK phenotype prevailed in adjacent normal tissues and in non-oncologic lung tissues. The CD56+CD16- NK subset was associated with angiogenic cytokine production including VEGF, PlGF and IL-8. Patients with squamous cell carcinoma histotype (SQK) showed higher NK angiogenic factor production compared to those from adenocarcinoma (ADC) and control tissues.
Supernatants derived from NSCLC infiltrating CD56+CD16- NKs induced in vitro endothelial cell chemotaxis and formation of capillary-like structures, particularly evident in SQK specimens. As TGFβ1 expression has been associated with poorer survival in NSCLC SQK patients and polarization of peripheral NK cells towards an angiogenic decidual NK phenotype, we evaluated whether TGFβ1 could induce proangiogenic factor production. Exposure of NK cells of peripheral blood from healthy subjects to TGFβ1 induced up-regulation of VEGF and PlGF production.
Our data suggest that NK cells in NSCLC can be switched to a proangiogenic phenotype, particularly evident for SQK patients and partly mediated by TGFβ1.

W1.03.12
Defining the Lethal Hit: Perforin Forms Transient Pores on the Target Cell Plasma Membrane to Facilitate Rapid Access of Granzymes During Killer Cell Attack

J. A. Lopez[1], *O. Susanto*[1], *M. R. Jenkins*[1], *N. Lukoyanova*[2], *V. R. Sutton*[1], *R. H. P. Law*[3], *J. C. Whisstock*[3], *H. R. Saibil*[2], *J. A. Trapani*[1], *I. Voskoboinik*[1];
[1]*Peter MacCallum Cancer Centre, East Melbourne, Australia,* [2]*Crystallography, Institute for Structural and Molecular Biology, Birkbeck College, London, United Kingdom,* [3]*The ARC Centre of Excellence in Structural and Functional Microbial Genomics, Monash University, Melbourne, Australia.*

Cytotoxic lymphocytes serve a key role in immune homeostasis by eliminating virus-infected and transformed target cells through the perforin-dependent delivery of pro-apoptotic granzymes. However,

the mechanism of granzyme entry into cells remains unresolved. Using biochemical approaches combined with time-lapse microscopy of human primary cytotoxic lymphocytes engaging their respective targets, we defined the time course of perforin pore formation in the context of the physiological immune synapse. We show that upon recognition of targets, calcium influx into the lymphocyte led to perforin exocytosis and target cell permeabilisation in as little as 30-sec. Within the synaptic cleft, target cell permeabilisation by perforin resulted in the rapid diffusion of extracellular milieu derived granzymes. Repair of these pores was initiated within 20-sec and completed within 80-sec, thus limiting granzyme diffusion. Remarkably, even such a short timeframe was sufficient for the delivery of lethal amounts of granzymes into the target cell. Rapid initiation of apoptosis was evident from caspase-dependent target cell rounding within 2-min of perforin permeabilisation. The current study defines the final sequence of events controlling cytotoxic lymphocyte immune defence, in which perforin pores assemble on the target cell plasma membrane, sufficient to ensure efficient delivery of lethal granzymes.

W1.03.13
Gap Junction intercellular communication induces NK cell activation and modulates cytotoxic capacity

I. J. Guerrero[1,2]*, A. Tittarelli*[1]*, A. Mendoza-Naranjo*[3]*, M. Farías*[1]*, M. López*[1,2]*, B. Chambers*[4]*, F. Salazar-Onfray*[1,2]*;*
[1]Institute of Biomedical Sciences, Faculty of Medicine, University of Chile, Santiago, Chile, Santiago, Chile, [2]Millennium Institute on Immunology and Immunotherapy, University of Chile, 8380453 Santiago, Chile, Santiago, Chile, [3]University College London, Santiago, United Kingdom, [4]Karolinska Institute, Stockholm, Sweden.

Gap junctions (GJ) mediate intercellular communication between adjacent cells. Previously, we showed that connexin 43 (Cx43), the main GJ protein in the immune system, mediates antigen transfer between human DCs, being also recruited to the immunological synapse during T cell priming. This crosstalk contributed to T cell activation, intracellular Ca^{2+} responses, and cytokine release. However, the role of GJ in NK cell activation by DCs and NK cell-mediated cytotoxicity against tumor cells, remain unknown. Here, NK cells and monocyte-derived DCs were obtained from peripheral blood. A human melanoma cell line (Mel2) and K562 cells were used as target. Cx43 localization was quantified on NK-DCs and NK-tumor cell co-cultures by flowcytometry and immunofluorescence. GJIC was evaluated using Calcein transfer and GJ inhibitors. Cytotoxicity and Granzyme-B activity was evaluated and the induction of Ca^{2+} signaling detected with FLUO-4AM. We found that NK cells form functional Cx43-GJ with DC and tumor cells. Polarization of Cx43 at the NK/DCs and NK/tumor cells contact site was detected. Cx43-mediated communication between NK and DCs was bidirectional, although blocking Cx43-GJIC inhibited NK cell activation not affecting DCs phenotype or function. Blocking of Cx43, by an analogue peptide or RNA silencing, inhibited CD69, CD25 and IFN-γ-release by NK. Moreover, Cx43-GJIC blocking strongly inhibited tumor lysis by NK associated to Granzyme-B activity and Ca^{2+} influx inhibition. Thus, our data suggest that Cx43-GJIC may play an important role in the NK cell interactions with other immune cells as well as in the NK anti-tumor effector function.

W1.03.14
Analyzing and modeling the dynamics of differentiating and adoptively transferred NK cells in patients undergoing hematopoietic stem cell transplantation (HSCT)

M. Killig[1]*, B. Friedrichs*[2]*, J. Meisig*[3]*, M. Luetke-Eversloh*[1]*, L. Uharek*[2]*, C. Romagnani*[1]*;*
[1]Deutsches Rheumaforschungszentrum, Berlin, Germany, [2]Clinic for Hematology and Oncology - Charité Berlin, Berlin, Germany, [3]Institute for Medical Systems Biology - Charité Berlin, Berlin, Germany.

Mature NK cells are able to display graft versus leukemia, without inducing graft versus host disease. These unique properties make NK cells an ideal additional lymphocyte-graft, especially in haploidentical HSCT. Here, we combine multiparameter flow-cytometry and mathematical algorithms to monitor patients undergoing haploidentical HSCT followed by NK cell adoptive transfer in the frame of a phase I/II clinical trial. Acute myeloid leukemia patients were transplanted with $CD34^+$ cells followed by transfer of $CD3^-$ $CD56^+$ NK cells derived from the same haploidentical donor. NK cells were monitored between day 0 and 150 after transplantation by multiparameter flow-cytometry and data was analyzed applying principle component analysis (PCA). In the first week after transplantation, we could separately track NK cells transferred from the donor, those reconstituting from donor $CD34^+$ cells, as well as recipient ones. Transferred NK cells largely displayed a mature phenotype and their proliferative ability *in vivo* was restricted to the $CD62L^+$ subset. In the second week after transplantation, we detected a peak of highly proliferating immature NK cells derived from $CD34^+$ cells, which progressively differentiated into mature NK cells, gradually losing the expression of CD62L, CD56 and NKG2A, while acquiring KIR, CD16, and CD57. PCA defined a clear direction of maturation and supported the concept of NK cell
differentiation as a non synchronized continuum. Mathematical clustering led to a model in which 3 distinct phases can be distinguished during time. Hence, transferred NK cells are detectable, proliferate in vivo and represent the only circulating lymphocyte population early after haploidentical HSCT.

W1.04 NKT cells

IL1.04.01
Regulatory role of iNKT cells, from viral infection to type 1 diabetes

A. Lehuen[1,2]*, L. Ghazarian*[1,2]*, Y. Simoni*[1,2]*, L. Beaudoin*[1,2]*, J. Diana*[1,2]*;*
[1]Institut Cochin, INSERM U1016, Paris, France, [2]Université Paris Descartes, Labex Inflamex, Paris, France.

Invariant natural killer T (iNKT) cells are regulatory T cells that can both inhibit autoimmune T cell responses and promote T cell responses to pathogens such as viruses. Since converging data in humans and mouse models suggest that viral infections influence the development of type 1 diabetes, we have investigated whether iNKT cells could prevent type 1 diabetes (T1D) during viral infections using LCMV, and Coxsackievirus B4 that has been implicated in the etiology of T1D. iNKT cells inhibit the development of diabetes upon both infections. After LCMV infection, iNKT cells promote CD8 antiviral response in the spleen required for the clearance of the virus. In the pancreas iNKT cells interact with plasmacytoid dendritic cells (pDC) to induce a strong type I IFN production to inhibit viral replication. In a second step, iNKT cells activate pDC to produce TGF-beta that induces anti-islet Treg cells thereby preventing local damage and diabetes development. Upon CVB4 infection, iNKT cells inhibit the development of diabetes by another mechanism. Locally in the pancreas, CVB4-induced diabetes is associated with a massive recruitment of inflammatory macrophages. However iNKT cells alter macrophage function and induce IDO expression that inhibits anti-islet T cell function and prevents diabetes onset. While these two studies highlight the regulatory role of iNKT cells, a subset of iNKT cells producing IL-17 is locally activated in the pancreas and can exacerbate the development of diabetes. Altogether these data reveal the complex role of iNKT in T1D and prompt further studies in patients.

IL1.04.02
Therapeutic potential of NKT cell adjuvant-based therapies for the treatment of B-cell lymphoma

T. J. Webb*, J. Li, W. Sun, P. B. Subrahmanyam, C. Page, M. Frieman, Q. Chen, A. S. Kimball;*
University of Maryland School of Medicine, Baltimore, MD, United States.

Natural killer T (NKT) cells are a unique subset of T lymphocytes that serve as a link between the innate and adaptive immune system through their ability to recognize lipid antigens presented in the context of the non-classical MHC class I molecule, CD1d and rapid release of cytokines following activation. NKT cells can mediate tumor immune-surveillance; however, NKT cells are numerically reduced

and functionally impaired in lymphoma patients. Unlike other cancers, most hematologic malignancies express CD1d molecules and co-stimulatory proteins needed to induce anti-tumor immunity by NKT cells, yet most tumors are poorly immunogenic. In this study, we assessed NKT cell function throughout lymphomagenesis in two spontaneous, *myc* oncogene-driven mouse models of B-cell lymphoma. At early stages, NKT cell responses were enhanced in lymphoma-bearing animals compared to disease-free animals. In lymphoma- bearing animals with splenomegaly, lymphadenopathy, and high cyclin D1 expression, NKT cells were physically and functionally reduced. Treatment of tumor bearing mice with a potent NKT cell agonist, α-galactosylceramide (α-GalCer), resulted in a significant decrease in tumor burden. *Ex vivo* studies demonstrated that NKT cells from α-GalCer treated mice remained responsive to α-GalCer stimulation unlike the anergic NKT cells from vehicle-control treated mice. These data demonstrate an important role for NKT cells in their capacity to directly mediate tumor regression. Therefore, vaccination strategies utilizing NKT cell agonists in combination with other targeted therapies may be an effective means to stimulate effective anti-tumor immunity in patients with hematologic malignancies.

W1.04.01
Development of MAIT cells in the human fetus

E. Leeansyah[1], *L. Loh*[2,3], *D. F. Nixon*[2], *J. K. Sandberg*[1];
[1]*Center for Infectious Medicine, Karolinska Institutet, Stockholm, Sweden,* [2]*Division of Experimental Medicine, University of California San Francisco, San Francisco, CA, United States,* [3]*Department of Microbiology and Immunology, University of Melbourne, Melbourne, Australia.*

Mucosal-associated invariant T (MAIT) cells are innate-like T cells that are abundant in mucosal tissues, liver and peripheral blood. Human MAIT cells express a semi-invariant TCR Vα7.2-Jα33 Vβ2/13, and recognise microbial vitamin B metabolites restricted by the evolutionarily-conserved MHC-Ib-related (MR1) protein. MAIT cells are identified as Vα7.2+ CD161hi T cells coexpressing IL-18Rα and the transcription factor PLZF. The majority of MAIT cells are CD8α+, coexisting as CD8αα or CD8αβ, with minor CD4+ or CD8/4 double-negative populations. Human MAIT cells are thought to expand and mature following the establishment of gastrointestinal microbiota after birth. However, there is no study on human MAIT cell development prior to birth and microbiota establishment.
Here we studied, for the first time, the development of MAIT cells in second trimester human fetal tissues. Fetal MAIT cells were present in the thymus predominantly as an immature CD8αβ single-positive population, with similar observations in the spleen and mesenteric lymph node. In contrast, acquisition of maturation markers and expansion of CD8αα population were found in fetal small intestine, liver and lung. Fetal MAIT cells readily proliferated and produced cytokines in response to Escherichia coli stimulation in vitro. Our results thus indicate that human fetal MAIT cells become functionally mature in peripheral/mucosal tissues, likely in the absence of established gut microbiota.

W1.04.02
miRNA regulation of iNKT cell development

M. Fedeli[1], *V. Maselli*[1], *M. Riba*[1], *G. Rossetti*[2], *M. Pagani*[2], *S. Abrignani*[2], *A. Liston*[3], *E. Stupka*[1], *P. Dellabona*[1], *G. Casorati*[1];
[1]*San Raffaele Scientific Institute, Milan, Italy,* [2]*INGM-National Institute of Molecular Genetics, Milan, Italy,* [3]*VIB - Katholieke Universiteit, Leuven, Belgium.*

iNKT cells are a separate subset of T lymphocytes displaying innate effector functions. We have previously shown that microRNAs (miRNAs) control the unique iNKT cell developmental program. iNKT cells, and not T cells, are dramatically reduced and blocked at an immature stage in mice with a conditional deletion of Dicer, the RNAse III enzyme that produce mature miRNAs. Accordingly, thymic mature iNKT and T cells display distinct miRNA signatures. To unravel the miRNA-mRNA interaction network underlying iNKT cell development, we determined the gene expression profiles of miRNA-sufficient or -deficient thymic iNKT cells and T cells. Consistent with a tight dependence of iNKT cells on miRNA control of gene expression, we find that the absence of miRNA dramatically affect iNKT but not T cell transcriptome. We identify genes upregulated in iNKT cells lacking miRNAs compared to WT cells, which are involved in cell proliferation, DNA integrity at G1/S transition during cell cycle, thymic development and positive regulation of apoptosis. Amongst the transcripts modulated by the absence of miRNAs, we sought to enrich for genes targeted by single miRNAs expressed by iNKT cells. In this manner, we are now trying to characterize the genes that could be critically involved in the genetic program controlling iNKT cell development via miRNA regulation.

The role of NKT cell TCR β-chain on antigen specificity

G. Cameron[1], *K. S. Wun*[2], *O. Patel*[2], *D. G. Pellicci*[1], *A. P. Uldrich*[1], *A. R. Howell*[3], *A. G. Brooks*[1], *S. A. Porcelli*[4], *J. Rossjohn*[2], *D. I. Godfrey*[1];
[1]*The University of Melbourne, Parkville, Australia,* [2]*Monash University, Clayton, Australia,* [3]*The University of Connecticut, Storrs, CT, United States,* [4]*Albert Einstein College of Medicine, New York, NY, United States.*

The prototypic Natural Killer T (NKT) cell ligand, α-galactosylceramide (α-GalCer) has been shown to provide anti-tumour effects in various disease models, and is currently in clinical trials as an anti-cancer therapeutic. Despite maintaining a semi-invariant TCR repertoire, NKT cells have been demonstrated to respond to a range of different glycolipid antigens, with different antigens eliciting distinct responses, however the molecular basis for antigen discrimination by the NKT cell receptor is unclear. Utilizing a range of structurally distinct glycolipids we have demonstrated that modifications in the glycosyl headgroup directly impacted TCR interactions, which affected the NKT cell cytokine response. Although these glycolipid analogues were capable of activating both Vβ7 and Vβ8 NKT cells, those with an altered 4'-OH on the sugar biased the expansion of NKT cells expressing Vβ7. Modifications in the acyl chain did not appear to affect TCR interactions, however truncation of the phytosphingosine chain resulted in an induced fit mode of TCR binding, which reduced TCR affinity. Vβ7+ NKT cells have also been shown to preferentially respond to the endogenous glycolipid antigen isoglobotrihexosylceramide (iGb3), a potential tumour antigen. Data will be presented demonstrating that recognition of iGb3 is specific to a subset of the NKT cell population, which is biased towards those expressing Vβ7 and also appears to be favoured by particular TCR-Jβ regions. The specificity of iGb3 recognition supports the possibility that other antigen specific populations may be present within the NKT cell population despite the semi-invariant nature of the NKT cell TCR.

W1.04.04
Bacterial CD1d restricted glycolipids induce IL-10 production by human Tregs upon crosstalk with iNKT cells

K. Venken, *T. Decruy, S. Aspeslagh, S. Van Calenbergh, B. N. Lambrecht, D. Elewaut;*
Ghent University, Ghent, Belgium.

Invariant natural killer T cells (iNKT) and CD4+CD25+FOXP3+ regulatory T cells (Tregs) are important immune regulatory T cells with antigen reactivity towards glycolipids and peptides respectively. However, the functional interplay between these cells in humans is poorly understood. In this study we therefore investigated a reciprocal interaction between human Tregs and iNKT cells in function of pathogen related mechanisms of iNKT stimulation. Specifically, we explored iNKT activation by diacylglycerols derived from *Borrelia burgdorferi* (responsible for Lyme's disease) and *Streptococcus pneumonia* (causative agent of pneumonia). In addition, innate like activation of iNKT cells relying on IL-12/IL-18, was also evaluated. We show that Tregs suppress iNKT cell proliferation induced by CD1d restricted glycolipids and by innate like activation. Inhibition was related to the potency of iNKT agonists, making diacylglycerol iNKT responses very prone towards suppression. Cytokine production by iNKT cells was differentially modulated by Tregs as IL-4 production was more profoundly reduced as compared to IFN-γ. A compelling observation was the significant production of IL-10 by Tregs after cell-contact with iNKT cells, in particular in the presence of bacterial diacylglycerols. These iNKT-primed Tregs showed an

increased FOXP3 expression and superior suppressive function. Suppression of iNKT cell but not conventional T cell responses was IL-10 dependent, suggesting that there is a clear difference in mechanism between the Treg mediated inhibition of these cell types. Our data highlight a physiologically relevant interaction between human iNKT and Tregs upon pathogen derived glycolipid recognition with significant impact on the design of iNKT cell based therapeutics.

W1.04.05
CD1d-restricted phosphatidic acid-reactive T cells selectively inhibit glycolipid-reactive T cells and protect against inflammatory liver disease

***R. C. Halder**, C. Tran, R. R. Singh;*
University of California, Los Angeles, Los Angeles, CA, United States.

Lipid antigens bind CD1d and activate T-cells. Extensive work on T-cells reactive with glycolipid antigens such as αGalCer has identified their pathogenic or protective roles in inflammation, infection and cancer. Little is known about the biology and functions of T-cells reactive to phospholipid antigens such as phosphatidic acid (PA). Here, we used CD1d-phosphatidic acid (CD1d-PA) tetramers to identify T-cells in various lymphoid and other organs of mice. We found that 0.5-2% of lymphocytes in liver and 0.3-1% of lymphocytes in spleen stained for TCRβ and CD1d-PA tetramers. CD1d-PA tetramer+ cells did not stain with CD1d/αGalCer tetramers and did not respond to glycolipid antigen αGalCer. Upon in vivo priming with PA, TCRβ+CD1d-PA tetramer positive cells secreted IFN-γ. Intriguingly, activation of CD1d-PA tetramer+ T-cells markedly reduced the proliferation of αGalCer-reactive T-cells in vitro, ex vivo, and in vivo. We further found that in vivo activation of CD1d-PA T-cells reduced Concanavalin A-induced hepatitis that is known to be mediated by αGalCer-reactive T-cells. Thus, PA-reactive T-cells are a subset of CD1d-restricted T-cells that are phenotypically and functionally distinct from αGalCer-reactive T-cells. CD1d-PA T-cells also negatively regulate the function of αGalCer-reactive T-cells. Ongoing studies will investigate mechanisms whereby PA-reactive T-cells inhibit the function of glycolipid-reactive T-cells.

W1.04.06
Invariant NKT cells in Response to Dengue Virus Infection in Human

***P. Matangkasombut**[1], W. Chan-in[1], P. Pongchaikul[1], N. Tangthawornchaikul[2], S. Vasanawathana[3], W. Limpitikul[4], P. Malasit[1,2], T. Duangchinda[2], J. Mongkolsapaya[1,5];*
[1]Mahidol university, Bangkok, Thailand, [2]BIOTEC, NSTDA, Bangkok, Thailand, [3]Konkaen Hospital, Konkaen, Thailand, [4]Songkhla hospital, Songkhla, Thailand, [5]Imperial College, London, United Kingdom.

Dengue infection is a global health problem without vaccine and specific treatment. Clinical severity varies from asymptomatic, dengue fever (DF) to a more severe dengue hemorrhagic fever (DHF). Adaptive immune responses were shown to be pathogenic in severe disease. Invariant NKT (iNKT) cells represent innate-like lymphocytes that play a critical role in several viral infections but their contribution in human dengue infection is not known.
In this study, PBMC from dengue infected patients (n=35) with varying severity and at various timepoints were analyzed by flow cytometry. iNKT cells were identified by PBS57loaded-CD1d tetramer and CD3. iNKT cell activation and subset were evaluated by the expression of CD69 and CD4/CD8 respectively. Data were also compared with other febrile illness (OFI) and healthy controls.
The percentage of $CD69^+$ iNKT cells was significantly higher during acute febrile illness than at 2 weeks after the infection in both DF and DHF but not in OFI group. Furthermore, DHF group showed significantly higher % $CD69^+$ iNKT cells when compared to DF, OFI or healthy control. The percentage and subset of iNKT cells neither change during the course of infection nor differ in various disease severity conditions.
Therefore, during the acute febrile stage of dengue infection, iNKT cells are activated. The level of activation correlates with the disease severity. Our finding suggests that iNKT cells play a role in immune response against dengue viral infection in human. Further study is being performed to delineate the detailed mechanisms of how iNKT cells contribute to the pathogenesis of this disease.

Functional Education of iNKT Cells by Dendritic Cell Tuning of SHP-1

***P. Dellabona**, A. Napolitano, G. Casorati;*
San Raffaele Scientific Institute, Milano, Italy.

iNKT cells play key roles in host defense by recognizing lipid antigens presented by CD1d. iNKT cells are activated by bacterial-derived lipids and are also strongly autoreactive towards self-lipids. iNKT cell responsiveness must be regulated to maintain effective host defense while preventing uncontrolled stimulation and potential autoimmunity. CD1d-expressing thymocytes support iNKT cell development, but thymocyte-restricted expression of CD1d gives rise to antigen hyper-responsive iNKT cells. We hypothesized that iNKT cells require functional education by CD1d+ cells other than thymocytes to set their correct responsiveness. In mice that expressed CD1d only on thymocytes, hyper-responsive iNKT cells in the periphery expressed significantly reduced levels of tyrosine phosphatase SHP-1, a negative regulator of TCR signaling. Accordingly, heterozygous SHP-1 mutant mice displaying reduced SHP-1 expression developed a comparable population of antigen hyper-responsive iNKT cells. Restoring non-thymocytes CD1d expression in transgenic mice normalized SHP-1 expression and iNKT cell reactivity. Radiation chimeras revealed that CD1d+ dendritic cells supported iNKT-cell up-regulation of SHP-1 and decreased responsiveness following thymic emigration. Hence, dendritic cells functionally educate iNKT-cells by tuning SHP-1 expression to limit reactivity.

W1.05.01
TSLP induces corticosteroid resistance of natural helper cell and evokes severe asthma

***K. Moro**[1,2], H. Kabata[3], K. Asano[4], S. Koyasu[1,5];*
[1]Laboratory for Immune Cell System, RCAI, RIKEN, Yokohama, Japan, [2]PRESTO, JST, Tokyo, Japan, [3]Division of Pulmonary Medicine, Keio University School of Medicine, Tokyo, Japan, [4]Division of Pulmonary Medicine, Tokai University School of Medicine, Kanagawa, Japan, [5]Department of Microbiology and Immunology, Keio University School of Medicine, Tokyo, Japan.

Asthma is a common chronic lung disease from which 230 million people suffer. Although corticosteroid is an effective treatment for most patients, ~5% of patients respond poorly to a normal dose of corticosteroid. IL-33, an epithelial cell-derived cytokine, induces airway inflammation in the absence of acquired immune system during asthma. Natural Helper (NH) cell, a new member of innate immune system, produces a large amount of IL-5 and IL-13 in response to IL-33, and induces eosinophilia and goblet cell, both of which are prominent symptom of asthma. In this study, we examined the effect of corticosteroid on NH cells during asthmatic responses. NH cells induced to the lung by a classic antigen-induced asthma model or by intranasal injection of IL-33 were efficiently despaired by intraperitoneal injection of dexamethasone. On the other hand, airway inflammation induced by addition of IL-33 to a classic antigen-induced asthma model was resistant to dexamethasone. We found that induction of NH cells with eosinophilia and goblet cell hyperplasia triggered by IL-33 plus thymic stromal lymphopoietin (TSLP) was not blocked by dexamethasone treatment, suggesting that TSLP modifies the corticosteroid-sensitivity of NH cells. In fact, *in vitro* experiments showed that dexamethasone completely inhibits the proliferation and Th2 cytokine production of IL-33-stimulated NH cells, but addition of TSLP dampened the effect of dexamethasone. Our results collectively indicate that TSLP produced by epithelial cells causes corticosteroid resistance of NH cells and exacerbate the airway inflammation in asthma.

W1.05.02
Group 2 innate lymphocytes are critical for Th2 cell-mediated allergic lung inflammation

*T. Y. F. Halim, L. Matha, C. A. Steer, **F. Takei**;*
British Columbia Cancer Agency, Vancouver, BC, Canada.

Group 2 innate lymphoid cells (ILC2), also termed natural helper cells, are stimulated by epithelial cell-derived IL-33 and TSLP. Activated ILC2 produce large amounts of IL-5 and IL-13, but not IL-4. Intranasal administration of the protease allergen papain activates lung ILC2 and induces T cell-independent allergic lung inflammation. We generated ILC2-deficient mice by transplanting bone marrow cells from the RORα mutant *Staggerer* mice to lethally irradiated mice and tested the effects of ILC2-deficiency on Th2 cell responses. Repeated intranasal administration of the protease allergen papain into normal mice induced Th2 cell generation, high titre serum IgE and allergic lung inflammation. In contrast, Th2 cell generation by papain, which was IL-4-independent, was severely impaired in ILC2-deficient mice. The initial sensitization of control mice with papain activated ILC2 and induced an accumulation of activated DCs expressing CD40 in draining mediastinal lymph node (mLN) where naive T cells differentiated into Th2 cells, whereas the accumulation of $CD40^+$ DCs and Th2 cell differentiation in mLN was impaired in ILC2-deficient mice. The effects of IL-13 neutralization in control mice and IL-13 injection into ILC2-deficient mice showed that ILC2-derived IL-13 is critical for the accumulation of $CD40^+$ DC in mLN and Th2 cell differentiation. Thus, ILC2 not only produce Th2 type cytokines and mediate T cell-independent allergic inflammation but they also play a critical role in the initiation of Th2 cell-mediated allergic lung inflammation.

W1.05.03
Identification of IL-17+RORgt+CD34+ as lineage-committed progenitors of IL-22+NCR+RORgt+ Innate lymphoid cells

***E. Montaldo**[1], L. G. Teixeira[2], L. Moretta[3], M. C. Mingari[1,4], C. Romagnani[2];*
[1]Department of Experimental Medicine-University of Genova, Genova, Italy, [2]Innate Immunity-Deutsches Rheuma-Forschungszentrum-Leibniz-Gemeinschaft, Berlin, Germany, [3]Giannina Gaslini Institute, Genova, Italy, [4]Azienda Ospedaliera Universitaria San Martino–Istituto Nazionale per la Ricerca sul Cancro, Genova, Italy.

The innate lymphoid cell (ILC) family includes Natural Killer (NK) cells, RORgammat+ ILC and ILC2. Due to their shared developmental requirements, such as dependence on Id2 and gamma-chain cytokines, a common ILC progenitor has been postulated. Distinct stages have been described for NK cell but not for RORgt+ ILC differentiation. We identified a new population of human CD34+ hematopoietic progenitor cells (HPC) characterized by the ex vivo expression of RORgt, CD117, alpha4beta7 integrin and ability to produce IL-17A and IL-17F. CD34+ RORgt+ HPC reside in tonsils and give rise to IL-22 producing RORgt+ ILC, but not to NK cells upon in vitro culture. Conversely, tonsil CD34+ RORgt- CD117- HPC can still differentiate either towards IL-22 producing RORgt+ ILC or towards NK cells. Our data indicate that CD34+ RORgt+ cells are lineage-specified progenitors of IL-22+ RORgt+ ILC and that tonsils may represent a preferential site not only for NK cell, but also for RORgt+ ILC differentiation.

W1.05.04
T-bet is required for the development of NKp46+ innate lymphoid cells (ILCs) via a notch dependent pathway

***L. C. Rankin**;*
Walter and Elize Hall Institute of Medical Research, Parkville, VIC, 3052, Australia.

Rorγt+ innate lymphoid cells (ILCs) are found enriched in the intestinal mucosa of adults and are crucial for maintaining the delicate balance of tolerance, immunity and inflammation in the gastrointestinal tract. Rorγt+ ILCs include CD4+ LTi cells, CD4- LTi cells and the NK cell receptor expressing NKp46+ ILCs. The developmental relationship between these subsets and the transcription factors regulating their differentiation is controversial. We have found that the transcription factor T-bet (encoded by Tbx21) is essential for the development of NKp46+ ILCs, but not for LTi cells. Furthermore, NKp46+ ILCs differentiated solely from the CD4- and not the CD4+ LTi population in a Notch and T-bet dependent manor. In line with this finding, Notch was able to rescue this defect in the absence of T-bet. Collectively, our data provides a developmental link between CD4- LTi and NKp46+ ILCs controlled by the actions of Notch and T-bet distinct from CD4+ LTi.

W1.05.05
Reduced MAIT cell frequency associated with enhanced cell death in systemic lupus erythematosus

***A. Chiba**[1], N. Tamura[2], E. Hayashi[2], R. Matsudaira[2], T. Yamamura[1], Y. Takasaki[2], S. Miyake[1];*
[1]Department of Immunology, National Institute of Neuroscience, NCNP, Tokyo, Japan, [2]Department of Internal Medicine and Rheumatology, Juntendo University School of Medicine, Tokyo, Japan.

Background: Mucosal-associated invariant T (MAIT) cells are restricted by the MHC-related molecule-1 (MR1) and express an invariant TCRα chain: Vα7.2-Jα33 in humans and Vα19-Jα33 in mice. Like other innate-like lymphocytes, MAIT cells have been suggested to play both proinflammatory and regulatory roles in autoimmune models. In this study, we sought to investigate whether MAIT cells are relevant to systemic lupus erythematosus (SLE).
Methods: Peripheral blood MAIT cells were identified as $CD3^+\gamma\delta TCR^-V\alpha7.2^+TCR^+CD161^{high}$ cells by FACS. The usage of Vα7.2-Jα33 TCR of single-cell sorted cells was analyzed by PCR. Peripheral mononuclear cells (PBMC) were stimulated with anti-CD3mAb and anti-CD28mAb or various types of cytokines, and 6-7 days later, the cell proliferation was analyzed.
Results: The percentages of MAIT cells from SLE patients were about 10-fold lower compared with those from healthy subjects. Single-cell PCR analysis indicated that the decrease of MAIT cells in SLE patients was not a result of downmodulation of surface markers. Although MAIT cells from healthy subjects as well as lupus patients proliferated upon TCR or cytokine stimulation, repeated stimuli reduced MAIT cell frequency. Lupus MAIT cells had higher percentages of FAS^{high} cells and active caspase-3 or 7-AAD positive cells, suggesting that more MAIT cells are undergoing cell death.
Conclusions: This study demonstrates that increased cell death of activated MAIT cells may be responsible for reduced frequency of MAIT cells in SLE. As increased serum concentrations of various cytokines have been reported in SLE, the decrease of MAIT cells may reflect such pathological condition of the disease.

W1.05.06
The SLAM family receptor Ly9 (CD229) is a negative regulator of marginal zone B cells response

***M. Cuenca**, X. Romero, J. Sintes, P. Engel;*
University of Barcelona, Barcelona, Spain.

Homophilic interactions between the SLAM family receptors are required for the development of innate-like T lymphocytes. Recently, we have shown that Ly9 differs from the other SLAMF members by acting as an inhibitory regulator of iNKT cell development and activation. Splenic marginal zone B cells are innate-like lymphocytes that are known to mount rapid and intense antibody responses to blood-borne pathogens. Here, we test the hypothesis whether Ly9 also plays a regulatory role in the function of these cells. Analysis of the B cell development in a *Ly9*-deficient ($Ly9^{-/-}$) mice (BALB/c genetic background) showed no major alterations in bone-marrow B cell subsets. In contrast, the absence of Ly9 lead to an expansion of splenic $B220^+$ B cells as compared to wild-type mice (62.12% ± 0.51 vs 50.20% ± 0.93). Interestingly, an increased number of marginal zone B cells was also observed in the $Ly9^{-/-}$ mice. *In vivo* humoral response was assessed by immunizing $Ly9^{-/-}$ mice with T-dependent (TNP_{31}-KLH), T-independent type I ($TNP_{0.3}$-LPS) and T-independent type II (TNP_{65}-Ficoll) antigens. Our data revealed that Ly9 deficiency resulted in a striking increase of hapten-specific antibody levels,

especially IgG2a, IgG2b and IgG3 following TNP-Ficoll immunization (days 7 and 14). This effect was concomitant with a greater marginal zone B cell expansion. In contrast, responses against T-independent type I and T-dependent antigens were not significantly affected in *Ly9*-deficient mice. In conclusion, Ly9 emerges as an inhibitory cell-surface receptor involved in marginal B cell development and effector function.

W1.06.01
Stabilin-1/CLEVER-1, defines an immune suppressive monocyte population

S. Palani[1,2,3], *K. Elima*[1,3,4], *M. Salmi*[1,4], *S. Jalkanen*[1];
[1]*Medicity Research Laboratory, University of Turku, Turku, Finland,*
[2]*Turku Graduate School of Biomedical Sciences, Turku, Finland,*
[3]*Turku Doctoral Programme of Molecular Medicine, Turku, Finland,*
[4]*Department of Medical Biochemistry and Genetics,University of Turku, Turku, Finland.*

Stabilin-1/CLEVER-1 is a multidomain protein present in lymphatic and vascular endothelial cells and Type II immunosuppressive macrophages. It functions in scavenging, endocytosis and in leukocyte adhesion to and transmigration through the blood vascular and lymphatic endothelial cells. In this study, we have identified for the first time Stabilin-1/CLEVER-1 expression on blood monocytes in healthy individuals. We investigated the gene expression profile and functional difference between Stabilin-1/CLEVER-1 high and low/negative expressing monocytes. Microarray analysis from RNA of sorted CLEVER-1 high and low/negative revealed differences in the gene profile. However, SiRNA mediated suppression of CLEVER-1 on the monocytes did not result in any alteration in the selected genes, suggesting that CLEVER-1 does not directly regulate the synthesis of the differentially expressed genes. Tetanus toxoid stimulation assays showed that when co-cultured with T-cells in ELISPOT plate CLEVER-1 high monocytes produced less of IFN-gamma compared to CLEVER-1 low/negative monocytes. When monocytes were differentiated in vitro to type I and II macrophages by cytokine stimulation, CLEVER-1 expression was induced on type II macrophages whereas no expression in type I macrophages was detected**.** We also found that CLEVER-1 expression is reduced in blood monocytes, placental macrophages and macrophages in placental bed in pre-eclampsia (involving many proinflammatory changes) compared to normal pregnancy. Collectively, these findings suggest that CLEVER-1 high monocytes play an immune suppressive role in circulating blood.

W1.06.02
Mice depleted of neutrophils develop chronic inflammation and deregulated adaptive immunity

R. Parsa*, H. Lund, X. Zhang, A. O. G. Cacais, A. M. Georgoudaki, M. Karlsson, R. A. Harris;*
Karolinska Institute, Stockholm, Sweden.

Neutrophils are an important cell type in innate immune reactions. They are one of the first cells engaged in an inflammatory response and thus have the ability to orchestrate both adaptive and innate responses.There has been an intensive research focus to understand the regulation of inflammation by neutrophils, and one way to address this is to deplete them in vivo. In this study we depleted neutrophils by using the diphtheria toxin A (DTA) stopflox system. A selective depletion of neutrophils was noted but othermyeloid cells in different organs were unaffected. Mice lacking neutrophils developed a chronic systemic inflammation with inflamed lymph nodes and splenomegaly after immune triggering. Deregulation of both T and B cell functions was observed, with increased numbers of Th1 and Th17 cells, plasma cells and high titers of serum antibodies. These results indicate a hitherto unreported immunohomeostatic function of neutrophils.

W1.06.03
Glucocorticoid-induced leucine zipper (GILZ) inhibits inflammatory activation in macrophages via reduced MAPK signalling: role in endotoxin tolerance

J. Hoppstädter[1], *T. Stadter*[1], *S. Bruscoli*[2], *C. Riccardi*[2], *A. K. Kiemer*[1];
[1]*Saarland University, Saarbruecken, Germany,* [2]*University of Perugia, Perugia, Italy.*

Induction of glucocorticoid-induced leucine zipper (GILZ) by glucocorticoids plays a key role in their anti-inflammatory action, whereas GILZ expression is reduced under inflammatory conditions. Thus, we aimed to investigate the role of GILZ in LPS-induced inflammation and LPS tolerance in human alveolar macrophages (AM) and murine bone marrow-derived macrophages (BMDM).
Treatment of AM and BMDM with LPS resulted in a rapid decrease of GILZ mRNA and protein levels. To assess the functional significance of GILZ downregulation we generated mice with a macrophage-specific GILZ knockout (GILZ KO) using the *Cre-loxP* system. GILZ KO BMDM displayed a higher responsiveness towards LPS, as shown by increased and prolonged IL-1β- and TNF-α-expression. LPS-mediated ERK activation was significantly enhanced in GILZ KO cells, whereas inhibition of ERK repressed the induction of proinflammatory mediators upon LPS challenge, suggesting that GILZ modulates inflammation *via* the ERK pathway.
Interestingly, GILZ downregulation was abrogated in LPS-tolerized AM, which was independent of endogenous glucocorticoid production and associated with increased GILZ mRNA-stability. In line with this finding, LPS-tolerant cells were not able to induce the mRNA-binding protein TTP, which was previously shown to be involved in GILZ mRNA-downregulation. LPS tolerance resulted in a diminished expression of proinflammatory mediators accompanied by an almost complete abrogation of ERK, p38 and SAPK/JNK activation. In contrast, MAPK signalling was preserved in LPS-tolerized GILZ KO BMDM. Accordingly, LPS-tolerant GILZ KO cells retained their ability to induce TNF-α, indicating that GILZ downregulation not only increases macrophage activation, but also critically influences their deactivation.

W1.06.04
CD300a is a new hypoxia-inducible gene and a regulator of proinflammatory cytokine production in human monocytes and macrophages

F. Raggi*, F. Blengio, L. Varesio, M. Bosco;*
Laboratory of Molecular Biology/Institute G.Gaslini, Genova, Italy.

Peripheral blood monocytes are recruited to inflammatory and tumor lesions where they undergo terminal differentiation into macrophages. Monocytes/macrophages integrate stimulatory and inhibitory signals present in the microenvironment through a defined repertoire of cell surface receptors, and deregulated expression of these molecules may result in amplification of inflammation or establishment of immune escape mechanisms. Characterization of the effects of pathologic stimuli on the expression and function of these receptors may, thus, contribute to our understanding of monocytic lineage cell functions in diseased tissues. A common feature at pathologic sites and an important regulator of monocyte/macrophage proinflammatory functions is represented by low partial oxygen pressure (hypoxia). We recently identified by gene expression profiling the leukocyte membrane antigen, CD300a, a member of the Ig-like CD300 superfamily of immunoreceptors, as a new hypoxia-inducible gene in primary human monocytes. In this study, we demonstrate that CD300a mRNA and surface protein are upregulated by hypoxia and the hypoxia-mimetic agent, desferrioxamine, in both monocytes and monocyte-derived macrophages. Stimulatory effects are reversible, being counteracted by cell reoxygenation or addition of iron sulfate. Interestingly, CD300a ligation by an agonist Ab delivers both inhibitory and activating signals in these cells, differentially affecting the production of the chemotactic and proangiogenic cytokines, CCL20 and VEGF, driven by hypoxia and desferrioxamine. These findings point to a role for this molecule in the regulation of monocyte/macrophage inflammatory and angiogenic activity at hypoxic sites, with potential implications for inflammatory diseases and cancer pathogenesis.

W1.06.05
Physical interaction between miR-155 and miR-146a gene loci: Co-regulation during macrophage activation and induction of endotoxin tolerance

C. Doxaki[1]*, A. Eliopoulos*[2]*, C. Spilianakis*[2]*, C. Tsatsanis*[1]*;*
[1]*Medical School, Heraklion, Crete, Greece,* [2]*IMBB-FORTH, Heraklion, Crete, Greece.*

MiRNA expression profile of macrophages is altered during activation, contributing to the regulation of the inflammatory response. MiR-155 and miR-146a are induced upon activation of macrophages by LPS. Previous work from our group has shown that several miRNAs are regulated by Akt kinases and control the magnitude of the inflammatory response and their polarization (M1/M2) phenotype. Akt1 ablation results in hyper-responsiveness to LPS and abrogates development of endotoxin tolerance via upregulation of miR-155 (Androulidaki et al., Immunity 2009), while ablation of Akt2 gives rise to an anti-inflammatory phenotype, via miR-155 and miR-146a (Arranz et al., PNAS 2012 and unpublished results). Herein, we analyzed the mechanism that controls expression of miR-155 and miR-146a in response to LPS in naïve and tolerant primary macrophages and RAW264.7 cell line. Pri-miR-155 and pri-miR-146a were induced upon LPS stimulation. When macrophages became LPS tolerant, the expression of pri-miR-155 and pri-miR-146a was decreased, while upon a subsequent LPS stimulus, their expression is rapidly induced. ChIP analysis revealed that their genomic loci are regulated by the same transcription factors, namely C/EBPβ, NFkB and Bach2, while FISH experiments showed a monoallelic inter-chromosomal interaction between miR-155 and miR-146a at the stage of endotoxin tolerance. Genetic ablation of Akt1 or Akt2 differentially affected expression of miR155 and miR-146a and association of their gene loci. In conclusion, our data suggest that miR-155 and miR-146a are coordinately regulated at the transcriptional level and physical interaction of their genomic loci is observed in mesophasic nuclei at the stage of endotoxin tolerance.

W1.06.06
Single cell dynamics of macrophage activation and signalling

J. S. Bagnall*, L. Schmidt, D. Spiller, M. R. H. White, P. Paszek;*
University of Manchester, Manchester, United Kingdom.

Macrophages display a remarkable ability to decode inflammatory cues by adapting their physiology. In response, they propagate such cues by activating specific gene expression programs that involves secretion of pro- and anti-inflammatory cytokines. This signalling is coordinated by a set of molecular and cellular networks including the Nuclear Factor kappa B (NF-κB) and Signal Transducers and Activators of Transcription (STATs) systems downstream of Tumour Necrosis Factor α, Interleukins, and Interferon. Here, we apply an interdisciplinary systems biology approach to build a quantitative picture of macrophage-mediated inflammatory signalling at a single cell level. We investigate classical and alternative macrophage activation using Raw 264.7, J774 and bone marrow derived macrophages as a model system. Using live cell microscopy with cells expressing NF-κB and STAT fluorescent fusion proteins we characterise the dynamical interaction between the two systems. These are correlated with temporal patterns of cytokine expression. Finally, in a co-culture we investigate the signalling between activated macrophages and a reporter fibroblast cell line, demonstrating that classically activated macrophages have a reduced capacity to propagate NF-κB signalling across the reporter fibroblast cell line. Our analyses suggest a complex relationship between macrophage ability to decode and propagate inflammatory cues and dynamics of underlying molecular and cellular signalling networks. A more quantitative picture of these non-intuitive interactions could provide better understanding of inflammatory signalling.

W1.06.07
Revisiting the ontogeny of the mononuclear phagocyte system: embryonic and adult hematopoietic contributions

G. Hoeffel, ***F. Ginhoux****;*
Singapore Immunology Network, Singapore, Singapore.

The mononuclear phagocyte system (MPS) constitutes a network of heterogeneous cell populations that play a crucial role in tissue homeostasis and immunity and include monocytes, macrophages and dendritic cells (DCs). Macrophages and DCs are highly heterogeneous in phenotype and function and multiple subsets of these cells have been described. Our findings show that heterogeneity is also reflected in the origin of DCs and macrophages. Macrophages and DCs are thought to derive from a common adult bone marrow (BM) progenitor. However, certain subpopulations such as the Langerhans cells (LCs), the DCs of the epidermis, and microglia, the resident macrophages of the central nervous system (CNS) seem to arise from embryonic hematopoietic precursors that respectively seed the skin and the CNS prior to birth, before the onset of BM hematopoiesis. The origin of these embryonic precursors has remained unclear. We recently showed that post-natal hematopoietic progenitors do not significantly contribute to adult LCs and microglia and that both LCs and microglia develop from yolk sac (YS)-derived primitive macrophages. However, in contrast to microglia, which remain of YS origin throughout life, YS-derived LC precursors are largely replaced by fetal liver monocytes during late embryogenesis, establishing the dual origin of LCs. Similarly, fetal liver monocytes contributed to other tissue phagocytes during late embryogenesis and superseded YS contribution. Our results highlight the importance of embryonic myeloid development in the formation of tissue macrophages, key elements of the adult immune system.

W1.06.08
CX3CR1hi Ly6C- monocytes play an anti-inflammatory role during liver inflammation

Y. Morias[1]*, C. Abels*[1]*, D. Laoui*[1]*, E. Van Overmeire*[1]*, E. Schouppe*[1]*, F. Tacke*[2]*, P. De Baetselier*[1]*, A. Beschin*[1]*;*
[1]*Myeloid Cell Immunology, Vrije Universiteit Brussel (VUB) / VIB, Brussels, Belgium,* [2]*Med. Klinik III, RWTH-University Hospital Aachen, Aachen, Germany.*

Two major subsets of blood monocytes can be distinguished, namely $Ly6C^{hi}CCR2^{+}CX_3CR1^{int}$ 'inflammatory' monocytes and $Ly6C^{-}CCR2^{-}CX_3CR1^{hi}$ 'patrolling' monocytes. Both $Ly6C^{hi}$ and $Ly6C^{-}$ monocytes are recruited to inflammation sites where they can differentiate into macrophages and/or DCs and exert protective or detrimental roles depending on the pathogenic trigger. We use experimental African trypanosomiasis as a model to study the role of these monocyte subsets in infection-associated liver inflammation. We have reported that $Ly6C^{hi}$ monocytes are recruited to the liver of *Trypanosoma congolense* infected mice and differentiate in classically activated monocytic cells (M1, including TIP-DCs and macrophages). By secreting TNF, these cells contribute to liver cell apoptosis/necrosis, resulting in organ failure and early death. IL-10, as suppressor of M1 pathogenic immune responses, plays a critical role in limiting liver injury and prolonging survival.We now document that $Ly6C^{-}$ monocytes were increasingly recruited to the liver of *T.congolense* infected mice. These IL-10 producing cells do not own a gene signature reflecting an alternative, M2 activation status and do not differentiate into macrophages/DCs. Using adoptive transfer, we revealed that $Ly6C^{-}$ monocytes could suppress production of TNF by $Ly6C^{hi}$ monocytes during infection, favor the differentiation of the latter cells towards M2-type macrophages and protect liver integrity.These data illustrate a regulatory role for Ly6C- monocytes in parasite-induced liver pathogenicity by limiting the pro-inflammatory capacities of $Ly6C^{hi}$ monocyte and skewing them to a M2 phenotype. Hereby, $Ly6C^{-}$ monocytes protect the liver from damage caused by a persistent pathogenic immune response.

W1.06.09
Targeting MIF/CD74 signaling pathway to dampen acute inflammation in autoimmune diabetes

H. Korf[1], *B. Stijlemans*[2], *K. Ciotkowski*[1], *J. Laureys*[1], *M. Gilis*[1], *C. Gysemans*[1], *C. Mathieu*[1];
[1]*KULeuven, Leuven, Belgium,* [2]*VUB, Brussels, Belgium.*

Autoimmunity leads to the activation of innate effector pathways, proinflammatory cytokine production, and end-organ injury. In type 1 diabetes (T1D), autoaggressive T cells and infiltrating monocytes/macrophages secrete cytotoxic parameters that trigger beta cell damage and promote further inflammation. Recently, macrophage migration inhibitory factor (MIF) has been identified as an upstream activator of the innate immune response that mediates the recruitment and retention of monocytes/macrophages via its receptor, CD74. However, up to date, a contribution of MIF/CD74 signaling pathways in T1D pathogenesis remains incompletely explored. Here we identified a population of monocytes/macrophages from non-obese diabetic (NOD) animals with a hyper-inflammatory status and elevated levels of CD74. Interestingly, the induction of this unique monocyte/macrophage phenotype, translated into their increased ability to activate islet-antigen reactive $CD4^+$ T cells. Moreover, a similar inflammatory signature and elevated CD74 expression was observed in $CD14^{high}CD16^{low}$ monocytes from T1D patients. Exposure of human T1D monocytes to danger signals revealed that the majority of monocytes producing high levels of intracellular TNFa also uniquely expressed CD74. The physiological importance of this cell subset is further supported by the abundance of $CD74^+$ cell subsets within inflamed pancreatic islets of diabetic prone animals and even more so in animals with established disease. Further studies are ongoing to investigate whether interference in the MIF/CD74 signaling cascade could prevent the onset of- or protect against established autoimmune diabetes.

W1.06.10
Role of M1 and M2 macrophages in phagocytosis and degradation of amyloid-beta in Alzheimer's disease transgenic mice

H. Lund*, X. Zhang, R. A. Harris;*
Karolinska Institutet, Stockholm, Sweden.

Microglia and brain-infiltrating monocytes are functionally distinct cells with non-redundant roles in the CNS during injury and inflammation. In the brain of APP/PS1 transgenic mice, a model of Alzheimer's disease (AD), blood derived monocytes are of critical importance in restricting amyloid-beta (Aβ) plaque growth, whereas microglia can be completely depleted without any effect on amyloid deposition. There is also evidence that the microglial population is skewed from an alternatively activated (M2) phenotype to a proinflammatory (M1) phenotype as mice age. These studies highlight the importance of monocyte derived macrophages in AD mice, but the individual roles of M1 and M2 phenotypes in restricting amyloid deposition remains to be elucidated. Here we show that macrophages that are transplanted into the hippocampus of aged APP mice retain the ability to migrate toward amyloid plaques. Interestingly, we found M1 macrophages to be better at phagocytosis and degradation of Aβ. Surprisingly, although M2-stimulation increased scavenger receptor expression, which has been implicated in Aβ-binding, it did not correlate with increased Aβ phagocytosis in our assay. These data suggest that a certain degree of inflammation might be beneficial in reducing Aβ deposition in the brain of APP mice.

W1.06.11
Interleukin 17 receptor A regulates renal inflammation and aggravates fibrosis

S. Ge*, B. Hertel, H. Haller, S. von Vietinghoff;*
Medizinische Hochschule Hannover, Hannover, Germany.

Background: The T cell cytokine IL-17 is an important pro-inflammatory mediator. We have previously shown IL-17 receptor expression on monocytes and a role of IL-17 in macrophage accumulation in peritonitis. We here investigated the role of the IL-17 receptor on myeloid cells in chronic renal inflammation and fibrosis.
Methods: Renal interstitial fibrosis was induced by unilateral urethral obstruction in mice reconstituted with *Il17ra*$^{-/-}$ or control bone marrow or a mixture of both. Renal leukocytes were assessed by flow cytometry, and kidney damage was scored by HE and sirius red staining.
Results: *Il17ra*$^{-/-}$ macrophages were significantly less abundant than wt cells in in the control, and much more markedly the obstructed kidney. Obstruction increased CD11c and F4/80 expression. This phenotype was significantly less pronounced in the cells deficient in IL-17 signaling. The proportion of fibrotic tissue area was significantly lower in mice reconstituted with *Il17ra*$^{-/-}$ bone marrow than mice with *wt* bone marrow.
Conclusion: Lack of IL-17 receptor A on the myeloid cells significantly alters inflammation and diminishes fibrosis in renal obstruction.

W1.06.12
IL-4 stimulates macrophage soluble Flt-1 and inhibits murine experimental choroidal neovascularisation

W. Wu[1], *L. B. Nicholson*[1,2], *D. O. Bates*[3], *A. D. Dick*[1,2];
[1]*School of Cellular and Molecular Medicine, University of Bristol, Bristol, United Kingdom,* [2]*School of Clinical Sciences, University of Bristol, Bristol, United Kingdom,* [3]*School of Physiology and Pharmacology, University of Bristol, Bristol, United Kingdom.*

Monocyte/macrophages contribute to pathological retinal and choroidal angiogenesis. The exact role myeloid derived cells play in neovascularisation remains poorly understood. We have found that IL-4-conditioned macrophages have therapeutic anti-angiogenic properties, notably soluble Flt-1 production. To interrogate the therapeutic potential of IL-4 to inhibit angiogenesis, laser-induced choroidal neovascularization (CNV) was performed with IL-4 intravitreal administration.
Bone marrow derived macrophages (BMDM) conditioned with IL-4 were assessed for sFlt-1 expression. The activity of HUVEC in IL-4-conditioned BMDM supernatant was assessed to determine the anti-angiogenic capacity of sFlt-1, whilst specificity of sFlt-1 function was confirmed following sFlt-1 siRNA knockdown. To determine the effects of IL-4 inhibition on angiogenesis in vivo, IL-4 was administrated intravitreally during CNV development. Resident macrophages and CD11b+ isolated retinal microglia were also examined for sFlt-1 production in response to IL-4. We found that IL-4 or IL-13-conditioned BMDM media significantly suppresses VEGF-mediated HUVEC activity, and the effect was reversed when sFlt-1 was knocked down in those conditioned BMDM. In vivo, giving IL-4 intravitreally during CNV decreased angiogenesis. In the retina, CD11b+, but not CD11b- cells, express sFlt-1, arginase-1 and YM-1 in the presence of IL-4.
We have shown that IL-4 induced macrophage sFlt-1 expression which in turn significantly decreased VEGF-mediated endothelial cell activity. IL-4 administration inhibited angiogenesis in laser-induced CNV. Retinal CD11b+ cells responded to IL-4, inferring that the macrophage is critical for the sFlt-1-mediated IL-4 inhibitory response. Our study supports the therapeutic potential of IL-4 to suppress pathological angiogenesis via induction of sFlt-1 from macrophages.

W1.06.13
CCR2 expression by macrophages promotes tumor progression through induction of IL-10 production

N. Caronni[1,2], *B. Savino*[1], *M. Locati*[1], *R. Bonecchi*[1];
[1]*University of milan, rozzano, Italy,* [2]*Istituto Clinico Humanitas, Rozzano, Italy.*

Chemokines are well known to play a major role in tumor progression and metastasis. In particular CCL2 and its receptor CCR2 are over-expressed in several human cancers and their higher levels correlate with poor prognosis and shorter outcomes. Whereas CCR2 has been demonstrated to recruit monocytic cells such as tumor-associated macrophages (TAM), little is known about its role in macrophage polarization. In order to directly investigate this aspect wt and $CCR2^{-/-}$ macrophages were polarized with M1 and M2 stimuli and analyzed

for gene expression and cytokines production. While no difference was found in M2 polarized macrophages, $CCR2^{-/-}$ M1 or LPS activated macrophages showed higher expression of inflammatory genes and reduced production of the anti-inflammatory cytokine IL-10 and of the pro-angiogenic cytokine VEGF when compared to wt macrophages. After LPS and CCL2 co-stimulation, $CCR2^{-/-}$ macrophages showed reduced activation of NF-kB and of p38 MAPK when compared to wt macrophages indicating a cross talk between CCR2 and TLR4 signaling pathways. The contribution of CCR2 to cancer growth was evaluated with a trasplantable lung cancer model that grew slower when co-injected with $CCR2^{-/-}$ macrophages. Taken together these data indicate that CCR2 expression by macrophages not only induce their recruitment to tumor site but also affect their polarization and anti-tumoral potential.

W1.06.14
Matrix reprogramming of immune cells and its disturbance in tumor

I. Malyshev*;*
Moscow State University of Medicine and Dentistry, Moscow, Russian Federation.

The rapid response of the immunity to new pathogens is due to the fact that immune mechanisms need not be formed de novo but are quickly reproduced from a ready-made immune matrix available for immune cell interactions in response to pathogens. Matrix points contain various immune cells. For interdependent reprogramming of different cells of the immune matrix, we suggest the term “matrix reprogramming”. The architecture of the immune matrix clearly demonstrates the homeostatic mechanism, including the sensor (macrophages), the regulator (APCs, Tregs and MDSCs) and the effector (lymphocytes), which eliminate pathogens and restore homeostasis. We describe matrix reprogramming as applied to an adequate immune response or its disorder in tumors. The tumor can affect any component of the matrix and transform the homeostatic mechanism into protumor programs. As a result, the immune matrix fails to restore homeostasis. Macrophages play a key role in the protumor transformation of matrix. Thus, macrophages are a very attractive target for pharmacology and biotechnology. We are developing a new cell biotechnology focused on the creation of macrophages with a stable antitumor phenotype. The first approach utilizes the blockade of macrophage receptors to reprogramming cytokines released by the tumor. The second approach is based on ramification of the intracellular signaling pathway and possibility to create a “smart” macrophage, which would not only prevent the protumor transformation of the immune matrix but would additionally enhance the antitumor response. The third approach also create a “smart” macrophage and based on incorporation of chimeric heteroreceptors into the macrophage membrane.

STIM2 is the essential STIM protein in non-SOCE calcium responses of macrophages in vitro and in vivo

G. Sogkas[1]*, S. Syed*[1]*, E. Rau*[1]*, D. Stegner*[2]*, T. Vögtle*[2]*, B. Nieswandt*[2]*, R. Schmidt*[1]*, E. Gessner*[1]*;*
[1]*Hannover Medical University, Clinic for Immunology and Rheumatology, Hannover, Germany,* [2]*Chair of Experimental Biomedicine, University Hospital and Rudolf Virchow Center, DFG Research Center for Experimental Biomedicine, University of Würzburg, Würzburg, Germany.*

Macrophage physiology critically depends on Ca^{2+} signalling. STIM isoforms are mediators of the most common mode of calcium influx in non-excitable cells, Store-Operated Ca^{2+} Entry (SOCE). Here, the relative dependence of key aspects of macrophage physiology on the mobilization of Ca^{2+} from the internal stores and/or the extracellular compartment was evaluated. Among the functions studied, cytokine responses to TLR ligands and chemokine elicited motility were mainly dependent on the mobilization of intracellular Ca^{2+}. In contrast, FcγR-mediated phagocytosis, apart from internal stores, depends on Ca^{2+} influx and SOCE. STIM2, in addition to contributing in SOCE, is involved in the maintenance of the internal ER-store of Ca^{2+}. The consequences of STIM2 deficiency in these Ca^{2+} dependent functions were characterized and contrasted with the effect of STIM1 deficiency. The SOCE dependent FcγR-mediated phagocytosis was reduced in case of STIM2 deficiency. However, the resulting defect was smaller as compared to the consequences of STIM1 deficiency. Moreover, genetic deletion of STIM2 had no effect on the phagocytosis-promoting function of C5a in vitro and in a model of autoimmune hemolytic anemia in vivo. Effective cytokine production downstream of TLRs and elicited motility, however, strictly depends on the presence of STIM2. In vivo, *Stim2*$^{-/-}$ mice exhibited milder LPS-induced sepsis and thioglycollate-elicited peritonitis. Interestingly, none of these SOCE-independent functions were reduced in case of STIM1 deficiency, suggesting their being specifically mediated by STIM2.

Glomerular deposition of myeloperoxidase and NETs in human anti ANCA associated vasculitis correlates with DTH effector cell accumulation

K. M. O'Sullivan*, S. L. Ford, C. Lo, A. R. Kitching, S. R. Holdsworth; Monash University, Melbourne, Australia.*

Myeloperoxidase (MPO) autoimmunity underlies most cases of anti-neutrophil cytoplasmic antibody (ANCA) associated vasculitis and glomerulonephritis. We sought evidence for the hypothesis that glomerular injury is initiated by ANCA induced neutrophil accumulation, degranulation and NET formation. This is substantially exacerbated by anti-MPO CD4 T cells recognising extracellular MPO then directing DTH effector macrophages. Forty eight renal biopsies from ANCA MPO positive patients with clinically active glomerulonephritis were examined by confocal microscopy for leukocytes and MPO. A significant infiltration of MPO+CD15+ neutrophils and MPO+CD68+ monocytes/macrophages was present in all biopsies. Significant correlation was found for simultaneous glomerular infiltration of CD4 T cells and MPO expressing cells ($P<0.05$), and simultaneous infiltration of CD15 and MPO positive cells, and CD68 and MPO positive cells ($P=0.004$, $P=0.035$ respectively). Interstitial CD15 positive cells and the total number of MPO positive cells correlated inversely with estimated glomerular infiltration rate at time of biopsy and at 1 year ($P<0.05$ and, $P<0.01$, respectively.) Extracellular MPO was found in 93% of all glomeruli and made up 23% of the total proportion of MPO observed within glomeruli and 31% of all the MPO in the interstitium. Neutrophil extracellular traps (NETs) were present in 61.3% of MPO-ANCA biopsies and there was a significantly more CD15 cells, total MPO expression and extracellular MPO in the glomeruli of patients with the presence of NETs ($P< 0.05$). This study provides evidence to support the hypothesis that neutrophil derived extracellular MPO acts as a planted autoantigen in glomeruli inducing T cell mediated DTH type injury.

W1.07.03
Leishmania inhibits antigen crosspresentation by cleaving VAMP8

N. Moradin[1]*, D. Matheoud*[2]*, M. Desjardins*[2]*,* ***A. Descoteaux***[1]*;*
[1]*INRS- Institut Armand-Frappier, Laval, QC, Canada,* [2]*Universite de Montreal, Montreal, QC, Canada.*

Soluble N-ethylmaleimide-sensitive-factor attachment protein receptor (SNARE) proteins mediate membrane fusion events involved in vesicular trafficking associated to phagocytosis and phagolysosome biogenesis. Targeting these proteins may therefore provide a potent immune evasion strategy to several pathogens, including Leishmania, as it may interfere with phagosome functions. Here we report that VAMP8 and other phagosomal SNAREs were cleaved upon infection with Leishmania promastigotes, and that this cleavage was mediated by the Leishmania surface zinc-metalloprotease GP63. In addition, we found that Leishmania promastigotes efficiently inhibited antigen crosspresentation in a GP63-dependent manner. Using cells from VAMP8 null mice, we found that this SNARE was required for antigen

crosspresentation. In the absence of VAMP8, phagosomal assembly of the NADPH oxidase complex was impaired, leading to a defective phagosomal proteolysis. Thus, we uncovered the existence of a novel mechanism used by Leishmania promastigotes to subvert an important phagosome immune function, whereby these parasites proteolytically degrade key regulators of vesicular trafficking.

W1.07.04
The inhibitory effect of secretory leukocyte protease inhibitor (SLPI) on formation of neutrophil extracellular traps

K. Zabieglo[1]*, A. Wlodarczyk*[1]*, M. Kapinska-Mrowiecka*[2]*, A. Dubin*[3]*, J. Cichy*[1]*;*
[1]Department of Immunology, Faculty of Biochemistry, Biophysics and Biotechnology, Jagiellonian University, Krakow, Poland, [2]Department of Dermatology, Zeromski Hospital, Krakow, Poland, [3]Department of Analytical Biochemistry, Faculty of Biochemistry, Biophysics and Biotechnology, Jagiellonian University, Krakow, Poland.

Neutrophil extracellular traps (NETs), a web like structures composed of DNA and antibacterial proteins provide efficient means of eliminating invading microorganisms but can also present potential threat to host, as a likely source of autoantigens, for example. Therefore, it is important to understand not only how the NETs are generated but also to identify mechanism(s) that inhibit NET formation. Translocation of neutrophil elastase (NE) from primary granules into nucleus followed by NEdependent histone processing and chromatin decondensation is one of the key events implicated in NET release. Since neutrophils contain inhibitors of NE such as secretory leukocyte protease inhibitor (SLPI) and α_1-Proteinase inhibitor (α_1-PI), we hypothesized that these inhibitors would play a role in restricting NET generation. Here we demonstrate, that exogenous human recombinant SLPI but not α_1-PI dramatically inhibited NET formation in human and mouse neutrophils. Moreover, neutrophils isolated from SLPI-/ mice were much more efficient in generating NETs compared with neutrophils derived from wild-type (WT) mice. Finally, endogenous SLPI was found to co-localize with NE in the nucleus of human neutrophils *in vitro*, as well as *in vivo* in an inflamed skin of psoriasis patients. Since SLPI is considered a cytosolic and/or granule protein, its co-localization with NE in the nucleus might further support a role of SLPI in restricting NEmediated histone processing. Taken together, our findings identify controlling role of SLPI in NET generation.

The role of iRhom2 (rhbdf2) during immune activation

P. A. Lang[1]*, D. R. McIlwain*[1]*, D. Häussinger*[1]*, K. Lang*[2]*, P. S. Ohashi*[3]*, T. Maretzky*[4]*, P. Darshinee*[4,5]*, J. Salmon*[4,5,6]*, C. P. Blobel*[7,6,8]*, T. W. Mak*[3]*;*
[1]Department of Gastroenterology, Hepatology and Infectious Diseases, Dusseldorf, Germany, [2]Institute for Immunology, Essen, Germany, [3]Ontario Cancer Institute, Toronto, ON, Canada, [4]Hospital for Special Surgery, New York, NY, United States, [5]Department of Immunology, New York, NY, United States, [6]Department of Medicine, Weill Cornell University, New York, NY, United States, [7]Department of Special Surgery, New York, NY, United States, [8]Department of Physiology, Biophysics and Systems Biology, Weill Cornell University, New York, NY, United States.

Innate immune responses are vital for pathogen defence but can result in septic shock when excessive. A key mediator of septic shock is TNF, which is shed into intercellular spaces after cleavage from the plasma membrane by the TNF convertase (TACE). Here we report that the rhomboid family member iRhom2 interacts with TACE and regulates TNF shedding in vitro and in vivo. In particular, iRhom2 is critical for TACE maturation and trafficking to the cell surface in hematopoietic cells. Compared to controls, gene-targeted iRhom2-deficient mice show reduced serum TNF after LPS challenge and can survive a lethal LPS dose. Furthermore, iRhom2-deficient mice fail to adequately control the replication of Listeria monocytogenes and thus succumb to even mild infections. Our study has identified iRhom2 as a novel regulator of innate immunity that may be an important target for modulating sepsis and pathogen defense. Moreover, iRhom2 may be a critical trigger for immune activation and disease pathogenesis.

W1.07.06
FAM19A4: a novel cytokine promotes phagocytosis of zymosan but negatively regulates TNF-α secretion associated with NF-κB pathway in macrophages

W. Wang*, P. Wang, T. Li, X. Wang, W. Yuan, H. Zhang, Y. Zhang, D. Ma, W. Han;*
Peking University Center for Human Disease Genomics, Department of Immunology, School of Basic Medical Science, Peking University Health Science Center, Beijing, China.

Cytokines play a key role in the immune system. When pathogen infection occurs, macrophages undergo phagocytosis first, accompanied with inflammatory cytokines secretion. FAM19A4 is a novel cytokine identified by the strategy of immunogenomics. It is a classical secreted protein which can be inhibited by BFA. It is low expressed in most normal human tissues, but is up-regulated in inflammatory stimulated monocytes-macrophages both in THP-1 cells and human peripheral monocytes derived macrophages. FAM19A4 can enhance phagocytosis of murine macrophages against zymosan both in vitro and in vivo not only the percentage of cells that phagocytized zymosan, but also the number of zymosan particles phagocytized by one single cell. FAM19A4 leads to noticeably increasing the phosphorylation of Akt on basis of zymosan stimulation, but reduces TNF-α secretion in zymosan-challenged macrophages by impacting activation of p38 and ERK1/2 in NF-κB pathway, due to the degradation of p65 both in nucleus and cytoplasm. These findings provide a novel cytokine FAM19A4 expressed by stimulated macrophages, which can promote phagocytosis of macrophages by activating Akt, but impact TNF-α increasing with challenge by inhibiting NF-κB pathway.

Increased numbers of monocyte-derived DC in the lymph node during successful tumor treatment with immune activating agents

S. Kuhn, E. Hyde, F. Rich, J. Harper, J. Kirman, ***F. Ronchese****;*
Malaghan Institute of Medical Research, Wellington, New Zealand.

Local treatments with selected TLR ligands or bacteria such as Bacillus Calmette-Guerin increase anti-tumor immune responses and delay tumor growth. It is thought that these treatments may act by activating tumor-associated DC, and supporting the induction of anti-tumor immune responses. However, common parameters of successful immune activation have not been identified.
We compared treatments with different immune activating agents for ability to delay tumor growth, improve priming of tumor-specific T cells, and induce early cytokine production and DC activation. Treatment with poly I:C or a combination of monosodium urate crystals (MSU) and Mycobacterium smegmatis (M. smeg) was effective at delaying the growth of subcutaneous tumors, and reducing lung metastases. In contrast, LPS, and MSU or M. smeg alone had no activity.
Effective treatments required both NK cells and CD8+ cells, and led to increased T cell priming and the infiltration of NK cells and CD8+ T cells in tumors. Unexpectedly, both effective and ineffective treatments increased the expression of costimulatory molecules on DC in the tumor-draining lymph node. In contrast, only effective treatments induced the rapid appearance of a monocyte-derived DC population in the lymph node, early release of IL-12 and IFN-gamma, and low IL-10 in the serum.
Our results suggest that the activation of existing DC subsets is not sufficient for the induction of anti-tumor immune responses, whereas early induction of Th1 cytokines and monocyte-derived DC are features of successful activation of anti-tumor immunity.

IL1.08.02
Innate sensing of bacterial and endogenous nucleic acids by plasmacytoid dendritic cells: a novel role for interleukin 26

*S. Meller[1], J. Di Domizio[2], **M. Gilliet**[2];*
[1]Department of Dermatology, Heinrich-Heine University, Düsseldorf, Germany, [2]Department of Dermatology, Lausanne-CHUV, Lausanne, Switzerland.

Plasmacytoid dendritic cells (pDC) are professional IFN-α producing cells with the ability to sense viral infections via endosomal TLR7 and TLR9. While efficiently responding to viral nucleic acids transported into the cell during the infectious process, extracellular microbial or self-nucleic acids are unable to activate pDC due to the intracellular seclusion of these receptors. We found that interleukin-26, a Th17-derived cytokine belonging to the IL-20 family, is a highly cationic amphiphatic antimicrobial protein capable of directly killing bacteria such as pseudomonas, enterococcus, and staphylococcus via the mechanism of membrane pore formation. Upon killing of bacteria, IL-26 was found to bind the microbial DNA released into the extracellular compartment and to promote the internalization of the DNA complexes into endosomal compartments, leading to activation of TLR9 in pDC. Similarly, Th17-derived IL-26 was found to form complexes with DNA released by dying host cells and trigger innate immune activation of pDCs with production of IFN-α. These results identify a role of IL-26 as an antimicrobial protein and a regulator of innate immune activation extracellular microbial and self-nucleic acids, providing new insights into the potent antimicrobial and pro-inflammatory function of Th17 cells.

Characterization of human afferent lymph dendritic cells from seroma fluids

***B. Morandi**[1], I. Bonaccorsi[2], R. Conte[3], G. Costa[2], R. Iemmo[4], S. Ferrone[5], C. Cantoni[1], M. Mingari[1], L. Moretta[6], G. Ferlazzo[2];*
[1]University of Genoa, Genoa, Italy, [2]University of Messina, Messina, Italy, [3]IRCCS A.O.U. San Martino-IST-Istituto Nazionale per la Ricerca sul Cancro, Genoa, Italy, [4]Cellular Therapy Program, University Hospital - A.O.U. Policlinico, Messina, Italy, [5]Department of Surgery, Massachusetts General Hospital, Boston, MA, United States, [6]Istituto G.Gaslini, Genoa, Italy.

Dendritic cells (DCs) migrate from peripheral tissues to secondary lymphoid organs (SLO) through afferent lymph. Due to limitations in investigating human lymph, DCs flowing in afferent lymph have not been properly characterized in humans until now. In this study, DCs contained in seroma, an accrual of human afferent lymph occurring after lymph node surgical dissection, were isolated and analyzed in detail. Two main DC subsets were identified in seroma corresponding to the migratory DC subsets described in lymph nodes, i.e. $CD14^+$ and $CD1a^+$. The latter also included $CD1a^{bright}$ Langherans cells. The two subsets appeared to share the same precursor and be developmentally related; both of them spontaneously released high levels of TGFβ and displayed similar T cell activating properties. On the other hand, they differed in membrane molecule expression, including TLRs, in their phagocytic activity and in the expression of proteins involved in antigen processing and presentation. It is worth noting that while both subsets were detected in seroma in the post-surgical inflammatory phase, only $CD1a^+$ DCs migrated via afferent lymph in steady state conditions. Therefore, the large amount of DCs contained in seroma fluids allowed us a proper characterization of human DCs migrating via afferent lymph.

W1.08.02
Plasmacytoid, conventional and monocyte-derived dendritic cells undergo a profound and convergent genetic reprogramming during their maturation

*T. Vu Manh[1,2,3], Y. Alexandre[1,2,3], T. Baranek[1,2,3], K. Crozat[1,2,3], **M. Dalod**[1,2,3];*
[1]Centre d'Immunologie de Marseille-Luminy (CIML), CNRS UMR7280, Marseille, France, [2]UNIV UM2, Aix Marseille Université, Marseille, France, [3]Inserm, UMR1104, Marseille, France.

Dendritic cells (DC) express receptors sensing microbial, danger or cytokine signals, which combination triggering drives DC maturation and functional polarization. Maturation was proposed to result from a discrete number of modifications in conventional DC (cDC) contrasting to a cell-fate conversion in plasmacytoid DC (pDC). cDC maturation is generally assessed by measuring cytokine production and membrane expression of MHC class II and co-stimulation molecules. pDC maturation complexity was demonstrated by functional genomics. Here, pDC and cDC were shown to undergo profound and convergent changes in their gene expression programs *in vivo* during viral infection. This observation was generalized to other stimulation conditions and DC subsets, by public microarray data analyses, PCR confirmation of selected gene expression profiles, and gene regulatory sequence bioinformatics analyses. Thus, maturation is a complex process similarly reshaping all DC subsets, including through the induction of a core set of NFKB- or interferon-stimulated genes irrespective of stimuli. This work received funding from CNRS, Inserm, Agence Nationale de la Recherche (ANR) (pDCphysiology, ANR-07-MIME-018-01; EMICIF, ANR-08-MIEN-008-02 and PhyloGenDC, ANR-09-BLAN-0073-02), and the European Research Council under the European Community's Seventh Framework Programme (FP7/2007-2013 Grant Agreement no. 281225).

W1.08.03
The dendritic cells of the bone marrow

***B. R. Fancke**[1,2], J. Pooley[1], M. O'Keeffe[1,2];*
[1]Burnet Institute, Melbourne, Australia, [2]Monash University, Melbourne, Australia.

Dendritic cells (DC) are antigen presenting cells that are vital for initiating immune responses. They are found throughout the body and within all secondary lymphoid organs however those that might be found in the bone marrow (BM) have not been characterised. Here, for the first time, we reveal the 5 distinct DC subsets found in murine BM. We show that all of these DC subsets display unique functions, including the pathogens they recognise, the type of T cell they activate, and the proinflammatory cytokines and chemokines they produce upon activation. We identify that certain DC subsets of the BM show homology to those found in the spleen through their ability to cross present antigen to CD8 T cells or promote CD4 T cell expansion. However, both phenotypical and functional differences are evident between the DC of both organs. Unlike those of the spleen, certain DC of the BM produce large amounts of the neutrophil chemoattractant CXCL1 suggesting their importance, not only as antigen presenting cells, but as promoters of cell migration to and within the BM microenvironment itself. The BM is known to harbour latent HIV and cytomegalovirus. Recently it has also been shown to be a hideout of *Mycobacterium tuberculosis*. Our elucidation of the DC subsets within the BM identifies novel cellular targets for clinical manipulation of immune responses within the BM to overcome persistent infections by pathogens such as these. The DC of the BM may also be important targets in the prevention of graft versus host disease.

W1.08.04
Unraveling the fingerprint of human tolerogenic DC-10, a dendritic cell subset involved in the establishment of peripheral tolerance

*M. Comi[1], D. Tomasoni[1], M. Villa[1], M. Pala[2], M. Floris[2], A. Bulfone[3], M. Roncarolo[1,4], **S. Gregori**[1];*
[1]San Raffaele Telethon Institute for Gene Therapy (HSR-TIGET), Milan, Italy, [2]CRS4, Technology Park Polaris, Pula, (CA), Italy, [3]CRS4, Technology Park Polaris, Pula (CA), Italy, [4]Vita-Salute San Raffaele University, Milan, Italy.

Dendritic cells (DCs) are critically involved in limiting immunity and in promoting tolerance. We identified DC-10, a subset of human tolerogenic DCs characterized by the high IL-10/IL-12 ratio and the co-expression of high levels of the tolerogenic molecules HLA-G and immunoglobulin-like transcript (ILT)4. DC-10 are potent inducers of adaptive type 1 regulatory T (Tr1) cells, well known to promote and maintain peripheral tolerance.
To characterize DC-10 and to investigate their tolerogenic potential, we compared DNA microarray-based transcriptional profiling of in vitro generated tolerogenic DC-10 and immunogenic mature myeloid DC (mDC). Through the screening of gene differentially expressed by human DC-10 we identified a unique pattern of DC-10-specific markers which will be used to improve their identification *in vivo*, and thus to better define the biology of *in vivo*-occurring DC-10. Moreover, DC-10 showed a molecular signature of anti-inflammation, immuno-modulation, and pro-angiogenesis. DC-10 show up-regulated IL-10- and Tissue Growth Factor (TGF) beta-dependent pathways, whereas down-modulate the signaling of pro-inflammatory cytokines. Moreover, DC-10 have an interesting matrix remodeling signature, that places them as hypothetical determinants of the tolerogenic environment in peripheral tissues.
These results represent the first step forward to further dissect the biology of DC-10 and will be instrumental to design novel approach for improving their in vitro generation for clinical use.

W1.08.05
In vivo roles of XC chemokine receptor 1-expressing dendritic cells

***T. Ohta**[1], H. Hemmi[1,2], C. Yamazaki[3,2], M. Sugiyama[1,2], I. Sasaki[1,2], K. Hoshino[1,2,4], T. Kaisho[1,2];*
[1]WPI Immunology Frontier Research Center Osaka University, Suita, Japan, [2]RIKEN Research Center for Allergy and Immunology, Yokohama, Japan, [3]Okayama University, Okayama, Japan, [4]Kagawa University, Takamatsu, Japan.

Dendritic cells (DCs) are professional Ag presenting cells linking innate and adaptive immunity. DCs consist of various subsets, which exert subset-specific functions. Murine splenic CD8α$^+$ DCs are characterized by high ability to produce proinflammatory cytokines, to ingest necrotic cells and to cross-present antigens for inducing CD8 T cell responses. But, it still remains largely unknown how this DC subset is involved in various immune responses or inflammatory processes in vivo. In order to address this issue, the system for specific ablation of this DC subset in mice is quite useful. A chemokine receptor, XC chemokine receptor 1 (XCR1), is highly and selectively expressed in CD8α$^+$ DCs. We have first generated the mutant mice in which Diphtheria toxin A subunit (DTA) was designed to be expressed only in XCR1 expressing cells (XCR1-DTA mice). In XCR1-DTA mice, CD8α$^+$ DCs subset was constitutively ablated, but not in any other cells. In other tissues, including lymph node (LN) and intestinal lamina propria, CD103$^+$ DCs, which are closely related to splenic CD8α$^+$ DCs, were also ablated. XCR1-DTA mice showed no sign of autoimmune diseases or myeloproliferative disorder, which can be seen in the mutant mice lacking all CD11c$^+$ cells. XCR1:DTA mice should be useful for elucidating in vivo functions of XCR1 expressing DCs including CD8α$^+$ and CD103$^+$ DCs. Analysis on XCR1-DTA mice will be presented.

W1.08.06
Resident CD11b+Ly6C- lung dendritic cells are responsible for allergic airway sensitization to house dust mite in mice

*C. Mesnil, C. M. Sabatel, T. Marichal, M. Toussaint, D. Cataldo, P. Drion, P. Lekeux, F. Bureau, **C. J. Desmet**;*
University of Liege, Liège, Belgium.

Conventional dendritic cells (DCs) are considered as the prime initiators of airway allergy. Yet, it remains unclear whether specific DC subsets are preferentially involved in airway allergic sensitization. Here, we systematically assessed the respective pro-allergic potential of individually sorted lung DC subsets isolated from house dust mite antigen (HDM)-treated donor mice, following transfer to naïve recipients. Transfer of lung CD11c+CD11b+ DCs, but not CD11c+CD11b-CD103+ DCs, was sufficient to prime airway allergy. The CD11c+CD11b+ DC subpopulation was composed of CD11c+CD11b+Ly6C+ inflammatory monocyte-derived cells, whose numbers increase in the lungs following HDM exposure, and of CD11c+CD11b+Ly6C- DCs, which remain stable. Counterintuitively, only CD11c+CD11b+Ly6C- DCs, and not CD11c+CD11b+Ly6C+ DCs, were able to convey antigen to the lymph nodes and induce adaptive T cell responses and subsequent airway allergy. Our results thus support that lung resident non-inflammatory CD11c+CD11b+Ly6C- DCs are the essential inducers of allergic airway sensitization to the common aeroallergen HDM in mice.

W1.09 Dendritic cell differentiation and function

IL1.09.01
Dendritic cells identified in the human system

***G. Ferlazzo**;*
Laboratory of Immunology and Biotherapy, University of Messina, Messina, Italy.

Most of the knowledge available on dendritic cell (DC) ontogeny, differentiation and functions has so far been derived from either mouse models or DCs generated ex vivo from human precursors employing different combinations of cytokines. As a result, the depiction of DCs present in the human body, in several aspects, remained vague.
Lately, we gained access to substantial information on human DC compartments, starting to identify the different roles of migratory and lymphoid tissue resident DCs as well as their peculiar molecular patterns. Notably, even in the absence of inflammation, specific subsets of human DCs continuously migrate from peripheral tissues to secondary lymphoid organs via afferent lymph, possibly playing relevant roles in the maintenance of peripheral tolerance to self antigens.
These recent studies open the way to further work on the functional role of distinct human DC subsets migrating from peripheral tissues to secondary lymphoid organs to exert their protective or tolerogenic immune functions, most likely depending on signals received in peripheral tissues.
This field of investigation might strongly contribute to the improvement of modern vaccination strategies as well as other immune-based therapies for human diseases.

IL1.09.02
Molecular regulators of DC function

***P. S. Ohashi**, E. F. Lind, D. Johnson, D. Dissanayake;*
Campbell Family Institute for Breast Cancer Research, Princess Margaret Cancer Centre, Departments of Medical Biophysics and Immunology, University of Toronto, Toronto, ON, Canada.

In order to fully understand mechanisms of autoimmunity and immune surveillance, my lab has been exploring a variety of molecular mechanisms that regulate the ability of dendritic cells to induce CD8 immunity. To follow the induction of CD8 cells in vivo, we have generated a new way to induce a tissue specific response using our RIP-GP mouse model. RIP-GP transgenic mice express the

lymphocytic choriomeningitis virus glycoprotein (LCMV-GP) on the [[Unsupported Character - Symbol Font ]]-islet cells of the pancreas directed by the rat insulin promoter. Our previous studies have shown that virus infection in RIP-GP mice, or P14/RIP-GP double transgenic mice treated with peptide and DC maturation signals (anti-CD40, TLR, HSP-70) leads to the induction of tissue specific immunity and diabetes. We have recently developed a model showing that TLR matured bone marrow derived DCs pulsed with GP peptides can induce diabetes in RIP-GP single transgenic mice within 10 days. This allows us to evaluate the importance of various molecules expressed by DCs, using bone marrow derived DCs from various gene deficient mice.
Although conventional pathogen derived signals are important for DC maturation and the subsequent activation of CD8 immunity, there are other ways to alter DC function and allow the activation of CD8 T cells in vivo. I will present data on our recent studies using a variety of knock out DCs. Data suggests that there are multiple factors that maintain steady state DCs, and the molecular programming of DCs is a critical step that regulates immunity.

W1.09.01
Defining Dendritic Cells by Ontogeny

B. Schraml*, J. van Blijswijk, S. Zelenay, P. Whitney, A. Filby, N. Rogers, C. Reis e Sousa;*
Cancer Research UK, London, United Kingdom.

Mononuclear phagocytes sample the environment for signs of damage or infection. The classification of these cells as macrophages or dendritic cells (DC) has traditionally been done on the basis of differences in cell morphology, expression of specific markers or of select functional attributes. However, these attributes are not absolute and often overlap, leading to difficulties in cell type identification. To circumvent these issues, we have generated a model to define DC based on their ontogenetic descendence from a committed precursor. We show that in mice precursors of conventional DC but not other leukocytes are marked by expression of DNGR-1/CLEC9A. We generated a mouse model to genetically label Clec9a-expressing conventional DC precursors and their progeny with yellow fluorescent protein (YFP). Genetic labeling of these cells and their progeny specifically traces cells traditionally ascribed to the DC lineage and the restriction is maintained after infection. Notably, in some tissues cells previously thought monocytes/macrophages are in fact descendants from DC precursors. These studies provide the first in vivo model for lineage tracing of DC and allow the definition of DC based on ontogenetic rather than phenotypic, morphological or functional criteria. These studies establish DC as an independent immune lineage and distinguish them from other leukocytes, thus paving the way to unraveling the functional complexity of the mononuclear phagocyte system.

W1.09.02
Lymphatic endothelium forms Integrin-engaging 3D structures during DC transit across inflamed lymphatic vessels

Á. Teijeira[1]*, S. Garasa*[1]*, R. Pelaez*[1]*, C. Aubá*[2]*, C. Alfaro*[1]*, R. Magda*[3,4]*, S. Vallituti*[4]*, R. Ana*[1]*, M. Ignacio*[1]*;*
[1]CIMA University of Navarra, Pamplona, Spain, [2]Clinica Universidad de Navarra, Pamplona, Spain, [3]INSERM U1043, Toulousse, Spain, [4]INSERM U1043, Toulouse, France.

Dendritic cell (DC) transmigration across the lymphatic endothelium (LEC) is critical for the initiation and sustenance of immune responses. Under non-inflammatory conditions DC transit across LEC has been shown to be integrin-independent. In contrast, there are increasing evidences on the participation of integrins and their ligands in DC transit across lymphatic endothelium under inflammation. In this sense, we describe the formation of ICAM-1 (CD54) -enriched 3D structures on LEC/DC contacts, as these DC adhere to inflamed skin lymphatic vessels and transmigrate into them. In vitro imaging revealed that under inflammation, ICAM-1 accumulated on microvilli projections surrounding 60% of adhered DC. In contrast, these structures were scarcely formed in non-inflammatory conditions. Besides, the ICAM-1-enriched microvilli were important for promoting DC transendothelial migration (TEM) and DC crawling over the LEC surface. Microvilli formation was dependent on the presence of integrins and of their high affinity epitopes on the DC side. Finally, we observed that LEC microvilli structures appeared in close vicinity to CCL21 depots, being their assembly partially inhibited by CCL21-neutralizing antibodies. Therefore, under inflammatory conditions, integrin ligands form 3D membrane projections around DCs. These structures, offer docking sites for DC transit from the tissue towards the lymphatic vessel lumen.

W1.09.03
MyD88 signaling drives steady-state intestinal CD103+ DC migration to draining mesenteric lymph nodes

K. Hägerbrand*, B. Johansson-Lindbom, W. Agace;*
Lund University, Lund, Sweden.

Intestinal homeostasis and induction of systemic tolerance to fed antigens (i.e. oral tolerance) relies on steady-state migration of small intestinal lamina propria dendritic cells (DCs) into draining mesenteric lymph nodes. $CD103^+$ DCs are the major migratory antigen-presenting cell population in the small intestine and appear to play a central role in initiating immune responses to soluble luminal antigens and inducing expression of gut-homing receptors on T cells. Here we demonstrate that the steady-state mobilization of $CD103^+$ DCs into the MLN is governed by the Toll-like receptor (TLR) signaling adaptor molecule MyD88 and occurs independently of TNF-α. Likewise, TLR signaling through the adaptor molecule TRIF and downstream production of type I interferon are not required. Experiments on CD11c-Cre x $MyD88^{fl/fl}$ mice lacking MyD88 selectively in $CD11c^+$ cells resulted in impaired steady-state $CD103^+$ DC migration, indicating a potential role for DC intrinsic MyD88 signaling in driving intestinal DC migration in the steady state.

W1.09.04
IL-27 in human secondary lymphoid organs attracts myeloid DC and impairs their HLA class I-restricted antigen processing and presentation

F. Morandi[1]*, E. Di Carlo*[2]*, S. Ferrone*[3]*, V. Pistoia*[1]*, I. Airoldi*[1]*;*
[1]Istituto Giannina Gaslini, Genova, Italy, [2]G. d'Annunzio" University and Ce.S.I. Aging Research Center, "G. d'Annunzio" University Foundation, Chieti, Italy, [3]Massachusetts General Hospital, Harvard Medical School, Boston, MD, United States.

DC are the most potent professional APC that in the immature state are positioned throughout the peripheral tissues by acting as sentinels and sensing the presence of antigens. When activated, DC migrate to lymphatic vessels and into lymph nodes, where they can direct antigen-specific T cell responses. Different cytokines play crucial role in inflammation and in polarizing immune responses, including IL-27 that may exert pro-and anti-inflammatory functions. Although the activity of IL-27 is well characterized in T, NK and plasma cells, only limited information is available on the role of IL-27 on human DC. Since the latter cells act as a key players in both adaptive and innate immunity, we have investigated the effects of IL-27 on human DC. We provide the first evidence that i) in human secondary lymphoid organs macrophages are the major source for IL-27, ii) immature and mature human DC express functional IL-27R, ii) IL-27 exerts immunosuppressive activity by crippling the antigen processing machinery in immature DC under steady-state conditions and after pulsing with a viral antigen, and iii) IL-27 is chemotactic for human DC. Our results highlight novel immunoregulatory functions of IL-27 that may be relevant in immune responses during infection and cancer.

W1.09.05
The kindlin-3-beta2 integrin interaction controls dendritic cell activation and Th1/Th2 priming

V. L. Morrison[1]*, M. MacPherson*[1]*, K. Grzes*[1]*, P. Cook*[2]*, C. Gawden-Bone*[1]*, A. Prescott*[1]*, A. S. MacDonald*[2]*, S. C. Fagerholm*[1]*;*
[1]University of Dundee, Dundee, United Kingdom, [2]University of Edinburgh, Edinburgh, United Kingdom.

Beta2 integrins play fundamental roles in leukocyte trafficking and signaling, but integrin proximal events in these processes remain

poorly characterized. Here, we show that mutation of the kindlin-3 binding site in the beta2 integrin cytoplasmic domain caused a loss of dendritic cell firm adhesion to integrin ligands. Surprisingly, the loss of beta2 integrin-mediated adhesion and cytoskeletal organization resulted in increased Syk and downstream signaling, and an elevated dendritic cell activation phenotype in terms of cytokine production and MHC class II and co-stimulatory molecule expression. This elevated dendritic cell activation state resulted in increased priming of CD4 T cell responses both *in vitro,* in a co-culture with TCR transgenic T cells, and *in vivo*, using a dendritic cell adoptive transfer model. Specifically, we found that in the absence of kindlin-3-beta2 integrin interactions in dendritic cells, Th1 priming *in vivo* was enhanced whilst Th2 responses were severely impaired. Thus, beta2 integrin binding to kindlin-3 integrates the cell exterior to the actin cytoskeleton, which restricts signaling in dendritic cells, thereby dampening their activation status and modulating *in vivo* immune responses.

W1.09.06
Deletion of IL-4 receptor alpha on dendritic cells renders mice hypersusceptible to Leishmania major infection

***F. Brombacher**;*
ICGEB, Cape Town, South Africa.

Susceptibility to Leishmania major infection in BALB/c mice is driven by T helper 2 (Th2) responses producing interleukin (IL)-4 and IL-13, which share a common receptor subunit, the IL-4 receptor alpha chain (IL-4Ra). However, global abrogation of IL-4Ra is not sufficient to confer complete resistance to L. major, specific abrogation of IL-4Ra on CD4+ T cells leads to resistance, indicating a protective role for IL-4Rα signalling on non-CD4+ T cells. To investigate this further, CD11ccreIL-4Ra-/lox BALB/c mice were generated by gene targeting and cre/loxP recombination under control of the CD11c promoter. DNA, protein and functional characterisation demonstrated abrogated IL-4Ra expression on dendritic cells and alveolar macrophages only. Following infection with L. major, CD11creIL-4Ra-/lox mice became hyper susceptible to disease, showing earlier and increased footpad swelling, necrosis and parasite burden, increased Th2 cytokine and i type 2 antibody responses, as well as impairment in classical activation of macrophages, measured by iNOS expression. Hyper susceptibility in CD11ccreIL-4Ra-/lox mice was accompanied by a striking increase in parasite burdens in peripheral organs such as the spleen, liver and even brain. CD11b+ inflammatory DCs were the major infected cell population and showed deficiencies in iNOS production and increased parasite loads. IL-4Ra-deficient DCs produced reduced IL-12 but increased IL-10 due to impaired DC instruction and had increased mRNA expression of IL-23p19 and activin A. Together, these data suggest that abrogation of IL-4Ra signaling on DCs is detrimental to the host, leading to rapid disease progression, dissemination, and increased survival of parasites in infected CD11b+ DCs.

W1.09.07
Chronic hypoxia reprograms human immature dendritic cells by inducing a proinflammatory phenotype and TREM-1 expression

***D. Pierobon**[1,2], M. C. Bosco[3], F. Blengio[3], F. Raggi[3], A. Eva[3], T. Musso[4], F. Novelli[1,2], P. Cappello[1,2], L. Varesio[3], M. Giovarelli[1,2];*
[1]Department of Molecular Biotechnology and Health Sciences, University of Torino, Torino, Italy, [2]Center for Experimental Research and Medical Studies (CERMS), A.O. Città della Salute e della Scienza di Torino, Torino, Italy, [3]Laboratory of Molecular Biology, G. Gaslini Institute, Genova, Italy, [4]Department of Public Health and Pediatric Sciences, University of Torino, Torino, Italy.

Dendritic cells (DCs) are powerful antigen-presenting cells central in the orchestration of innate and acquired immunity. DC development, migration, and activities are intrinsically linked to the microenvironment. DCs migrate through pathologic tissues before reaching their final destination in the lymph nodes. Hypoxia, a condition of low partial oxygen pressure, is a common feature of many pathologic situations, capable of modifying DC phenotype and functional behavior. We studied human monocyte-derived immature DCs generated under chronic hypoxic conditions (H-iDCs). We demonstrate by gene expression profiling the up-regulation of a cluster of genes coding for antigen-presentation, immunoregulatory, and pattern recognition receptors, suggesting a stimulatory role for hypoxia on iDC immunoregulatory functions. In particular, we show that H-iDCs express TREM-1, a member of the Ig superfamily of immunoreceptors and an amplifier of inflammation. This effect is reversible because H-iDC reoxygenation results in TREM-1 down-modulation. TREM-1 engagement promotes upregulation of T-cell costimulatory molecules and homing chemokine receptors, typical of mature DCs, and increases the production of proinflammatory, Th1/Th17-priming cytokines/chemokines, resulting in increased T-cell responses. These results suggest that TREM-1 induction by the hypoxic microenvironment represents a mechanism of regulation of Th1-cell trafficking and activation by iDCs differentiated at pathologic sites.

W1.09.08
The mitochondrial protein, TCAIM, abolishes T cell priming of dendritic cells by inhibiting TLR-induced IL-2 expression

***S. Vogel**[1], S. Schlickeiser[1], I. Panov[1], M. Schröder[2], M. Lutz[3], K. Vogt[1], G. Grütz[1], B. Sawitzki[1];*
[1]Charite Institute for Medical Immunology, Berlin, Germany, [2]National University of Ireland, Institute of Immunology, Maynooth, Ireland, [3]Julius-Maximilans-Universität Würzburg, Institute of Virology and Immunobiology, Würzburg, Germany.

We previously showed that TCAIM, T cell activation inhibitor - mitochondrial, is highly expressed in CD11c+ dendritic cells (DCs) of tolerance developing recipients and that the encoded protein is exclusively localized within mitochondria. Recently the importance of mitochondria in the regulation of host innate immune signaling, e.g. importance of TRAF6 translocation to mitochondria upon TLR1/2/4 stimulation resulting in release of mROS, has been demonstrated. Here we show that LPS-stimulated Ad-TCAIM transduced DCs failed to induce proliferation of and cytokine expression by allogeneic CD4+ and CD8+ T cells. A transcriptional profiling revealed a dramatically reduced IL-2 mRNA expression in LPS-stimulated TCAIM overexpressing DCs as compared to control-transduced DCs. This was accompanied by reduced mROS formation. Addition of IL-2 to DC-T cell co-cultures nearly completely restored T cell priming capacity of TCAIM overexpressing DCs. Thus TCAIM interferes with mitochondria-dependent events of TLR signaling in DCs and subsequently impairs their T cell priming capacity.

W1.09.09
PAF induces regulatory DCs through two independent mechanisms: amplification of COX2/PGE2 loop and induction of IL10

***M. M. Koga**, F. J. O. Rios, B. Bizzarro, A. Sá-Nunes, S. Jancar;*
Biomedical Sciences Institute - University of Sao Paulo, Sao Paulo, Brazil.

The platelet activating factor receptor (PAFR) is a G-protein coupled receptor present in plasma and nuclear membranes of leukocytes. In macrophages, activation of PAF-R is associated to a suppressor phenotype. In the present study we investigated whether it has a similar effect on dendritic cells (DCs) and the mechanisms involved. Murine (BALB/c) bone marrow-derived dendritic cells were obtained after 6 days culture with GM-CSF. Maturation was induced by LPS. The PAFR-antagonists WEB2170 and PCA4248 and the prostaglandin (PG) synthesis inhibitors, Indomethacin and NS-398 were added to DCs 30 min before LPS. The agonist, methylcarbamyl-PAF (cPAF), was added together with LPS. RT-PCR and ELISA were employed to measure mRNA and protein for COX2, IL10 and IL12. PAF-R mRNA and protein is expressed in both types of DCs. PAFR-antagonists significantly increased lymphocyte proliferation in an antigen-specific proliferation assay and reduced IL10 and PGE2 production, indicating that PAFR engagement in DCs promotes suppressor functions through these molecules. PAFR-antagonists did not affect the expression of DCs MHCII and co-stimulatory molecules. IL10 was potentiated by cPAF and unaffected by PG synthesis inhibitors. IL12 was not affected by PAFR agonist nor antagonists. PAFR-antagonists did not affect COX2 mRNA but reduced PGE2 while cPAF potentiated its production. We propose that PAF is involved in two independent suppressor mechanisms in DCs: amplification of the loop COX2/PGE2 through its production induced

by LPS and potentiation of IL10, shifting DCs towards a regulatory phenotype. By increasing the antigen-presenting function of DCs PAFR-antagonists may be valuable co-adjuvants in vaccines.

W1.09.10
Glucocorticoid-Induced Leucine Zipper expression in dendritic cells controls Treg induction in vivo

J. Calmette[1,2], *T. Tran*[1,2], *S. Karaki*[1,2], *M. Ellouze*[1,2], *M. Pallardy*[1,3], *F. Bachelerie*[1,2], *R. Krzysiek*[1,2], *D. Emilie*[1,2], *G. Schlecht-Louf*[1,2], *V. Godot*[4,5,1];
[1]*INSERM UMR-S 996, Clamart, France,* [2]*Université Paris-Sud, Faculté de Médecine, Le Kremlin Bicêtre, France,* [3]*Université Paris-Sud, Faculté de Pharmacie, Chatenay Malabry, France,* [4]*INSERM U955, Créteil, France,* [5]*Université Paris Est Créteil, Faculté de Médecine, Créteil, France.*

We have previously demonstrated that human dendritic cells (DCs) treated in vitro with glucocorticoids, IL-10 or TGF-β up-regulate the glucocorticoid-induced leucine zipper (GILZ) protein. We further established that GILZ over-expression turns DCs into a regulatory phenotype, generating CD25hiFoxP3+CTLA-4+ IL-10-producing antigen-specific regulatory T cells (Tregs) that inhibit T cell responses in an IL-10 dependent manner. To gain insight into the in vivo importance of GILZ expression in DCs for Tregs induction, we generated CD11c-GILZ transgenic mice. DCs from these mice constitutively overexpress GILZ to the same extent as glucocorticoid treated DCs. They display normal DC subsets distribution in both spleen and lymph nodes. GILZhi DCs phenotype is not different from that observed in DCs from control littermates, and their antigen uptake and processing capacity is not significantly modified. Tregs characterization in young mice hosted in an EOPS animal facility does not show any accumulation nor activation of these cells. However, Tregs analysis in older mice reveals a significant increase of CD4+FoxP3+ Tregs in the thymus, spleen and in the skin draining and mesenteric lymph nodes. Furthermore, when OVA-loaded GILZhi BMDCs and OT-2 T-cells are adoptively transferred in mice, in vivo OVA-specific T cell proliferation and activation are reduced, and this is associated with an increase in the CD25+FoxP3+ T cell population. Thus, our work shows that GILZ overexpression in DCs is sufficient to impede their capacity to activate T cells in vivo, most probably through Treg induction by a mechanism that does not require DCs phenotypic alteration or reduced antigen capture/processing.

W1.09.11
The inhibitory NK receptor Ly49Q protects plasmacytoid dendritic cells from TLR9-triggering cell death by assuring lysosomal integrity

N. Toyama-Sorimachi[1], *M. Tanaka*[1], *T. Kobayashi*[1], *A. P. Makrigiannis*[2], *K. Inaba*[3];
[1]*National Center for Global Health and Medicine, Tokyo, Japan,* [2]*University of Ottawa, Ottawa, ON, Canada,* [3]*Kyoto University, Kyoto, Japan.*

Ly49Q is an ITIM-bearing lectin-type NK receptor highly expressed in plasmacytoid DCs (PDCs), and associates with classical MHC class I in cis-configuration. We have reported that Ly49Q-/- mice showed impaired production of TLR9-mediated type I IFN production and diminished protection to mouse CMV infection. We also have revealed that Ly49Q colocalized with TLR9/CpG-ODN at the endosomes/lysosomes and affects their trafficking, which is shown to be important for TLR9 signaling.
We here show that Ly49Q is crucial for protection of lysosome-dependent PDC death under TLR9 stimulation. We found that Ly49Q-deficient (Ly49Q-/-) and an ITIM-less Ly49Q-expressing transgenic mice showed failure of intrasplenic redistribution of PDCs after CpG-ODN stimulation. Such anomalous Ly49Q-/- PDCs behavior was partly due to their decreased migration ability, but largely due to cell death. CpG-ODN-induced Ly49Q-/- PDC death was accompanied by cathepsin B leakage into the cytoplasm, and inhibited by cathepsin B- or caspase-1-inhibitor. These results suggest that CpG-ODN-induced Ly49Q-/- PDC death is lysosome-dependent process, and that Ly49Q exerted an influence on lysosomal integrity. It has been demonstrated that such cathepsin B- and caspase 1-dependent inflammatory cell death, so-called “pyroptosis”, causes IL-1β production through inflammasome activation. We also found that Ly49Q-/- PDCs secreted increased amounts of IL-1β after CpG-ODN stimulation. β2m-/- PDCs stimulated with CpG-ODN also showed pyroptotic cell death and produce IL-1β. These results strongly suggest that Ly49Q-MHC class I interaction facilitates PDCs survival through regulation of lysosomal integrity.

W1.09.12
Membrane transfer from tumor cells generates plasmacytoid dendritic cells cross-dressed with exogenous antigens

I. Bonaccorsi[1,2], *B. Morandi*[3], *G. Costa*[1,2], *D. Oliveri*[1,2], *R. Conte*[4], *G. Pezzino*[1,2], *M. Mingari*[3,4], *G. Ferlazzo*[1,2];
[1]*University of Messina, Messina, Italy,* [2]*Cellular Therapy Program, University Hospital - A.O.U. Policlinico, Messina, Italy,* [3]*University of Genoa, Genoa, Italy,* [4]*IRCCS A.O.U. San Martino-IST-Istituto Nazionale per la Ricerca sul Cancro, Genoa, Italy.*

The potential contribution of plasmacytoid dendritic cells (pDCs) in the presentation of tumor cell antigens still remains to be elucidated and some controversies currently exist regarding the ability of pDCs to phagocyte particulate antigens and cross-present them to MHC class I-restricted T lymphocytes.
Here, we show that human pDCs are prone to acquire membrane patches and associated molecules from cancer cells of different histotypes. Conversely, pDCs were not able to internalize cell membrane fragments by phagocytosis. The transfer of membrane patches to pDCs occurs in a very short time and require cell-to-cell contact interactions. Remarkably, HLA complexes were also transferred from tumor cells and the acquired antigens could efficiently be recognized by antigen-specific T cells on pDCs.
The exchange of exogenous antigens between pDCs and tumor cells appears to occur also *in vivo*, as pDCs isolated from human colon cancer tissues displayed a strong surface expression of Epithelial Cell Adhesion Molecule.
These data demonstrate that pDCs are particularly prone to acquire membrane patches from contiguous tumor cells by a cell-to-cell contact-dependent mechanism that closely resembles “trogocytosis”. This phenomenon may allow pDCs to proficiently present tumor cell-derived antigens despite their limited properties of endo-phagocytosis.

W1.09.13
Myeloid cells in the islets of Langerhans are key players in presentation of islet antigens and trophic function: identification of their phenotype and ontogeny

B. Calderon, *E. R. Unanue;*
Washington University School of Medicine, St. Louis, MO, United States.

The entry of autoreactive T cells to their target organ is important in autoimmunity since this initiates the inflammatory process. Islets of Langerhans contain a monocyte/macrophage-derived cell with important features and properties. This islet myeloid cell plays a central role in the interaction with diabetogenic T cells. We have studied in-depth the phenotype of the islet myeloid cells in the NOD and non-diabetic mouse strains and find 2 myeloid subsets: one subset (~85%), expressing MHC-II, CD11c, CD11b, F4/80 and LysM; and a minor subset, (~15%) expressing MHC-II, CD11c, CD11b, CD103, BTLA and LysM. Islet myeloid cells are stable in numbers and decrease 30% 7 days after whole body irradiation. Studies testing eGFP bone marrow transplantation has shown that islet myeloid cells can be replaced as early as 2 weeks post-transplant. Finally, we consider that in addition to their role of antigen presentation, the islet myeloid cell has a different and perhaps a more important role in islet physiology, which is to maintain the health of the islet. When a genetic mutation affects the presence of myeloid cells in islets (CSF-1-deficient mice), islets are reduced in size and show an altered glucose homeostasis. Our findings highlight the importance of the islet myeloid cell as central in presentation of islet antigen and trophic function of the islet. Their phenotype, ontogeny and trophic identification, will bring insights into diagnostics and point of interventions in diabetes.

W1.09.14
Dendritic cells partake in regulation of ovarian physiology

A. Cohen-Fredarow[1], *A. Tadmor*[1], *T. Raz*[1], *N. Meterani*[1], *M. Neemam*[1], *G. Mor*[2], *N. Dekel*[1];
[1]*weizmann, Rehovot, Israel,* [2]*Yale University School of Medicine,, New Haven,, CT, United States.*

Ovulation and inflammation share common attributes including the invasion of immune cells. We hypothesized that these cells, specifically dendritic cells (DCs), play a role in ovulation and corpus luteum formation. To follow the ovarian DCs we used transgenic mice, in which the expression of CD11c is conjugated to YFP. To explore their origin we transplanted WT ovaries under the kidneys capsule of YFP-CD11c transgenic hosts. For their conditional ablation, we injected diphtheria toxin into transgenic females, in which the expression of simian diphtheria toxin receptor is under the control of the CD11c promoter. We found a small ovarian resident CD11c positive- F4/80 negative-cells, apparently DCs prior to ovulation. Following the ovulatory stimulus, DCs are recruitment from the circulation and massively accumulate in the newly formed corpus luteum. We further revealed that CD11c positive cells are essential for expansion of the cumulus oocytes complex, the release of the ovum from the ovarian follicle, as well as for the formation of a functional corpus luteum. These effects of CD11c positive cells are mediated by upregulation of ovulation-essential genes and stimulation of lymphangiogenesis. Unexpectedly, we detected a remarkable anti-inflammatory capacity of the CD11c positive cells, which seemingly serves to restrict the ovulatory-associated inflammation. Our results provide strong evidence for the involvement of DCs in the ovulatory response. Moreover, the novel reported functions of ovarian dendritic cells unveil the wide diversity in their activities, beyond their classical immunologic role, which is most likely relevant to many biological systems as well as pathological conditions.

IL1.10.02
Association of TIR domains underlying immunosuppression in bacterial infection and activation of MyD88 mediated cell signaling associated with B-cell lymphoma

O. Fekonja[1], *M. Avbelj*[1], ***R. Jerala***[2,1,3];
[1]*National institute of chemistry, Ljubljana, Slovenia,* [2]*University of Ljubljana, Ljubljana, Slovenia,* [3]*EN-FIST centre of excellence, Ljubljana, Slovenia.*

Cells participating in innate immune system respond to pathogen associated molecules by activating Toll-like receptor (TLR) signaling pathways leading the inflammatory response. Excessive and/or inappropriate TLR signaling pathway activation can on the other hand lead to different acute or chronic inflammatory disease development including sepsis, rheumatoid arthritis, systemic lupus erythematosus and cancer. TLR and TIR-domain containing adaptor interactions represent potential sites for specific TLR signaling pathway inhibition. Expression of proteins with TIR domains are used by bacteria and viruses to suppress activation of TLR signaling response to infection. On the other hand mutations within the TIR domain of MyD88 are associated with lymphoma. We demonstrate that coiled-coil mediated dimerization of TIR domain TcpB of Brucella potentiates inhibition and prevents constitutive activation of innate immune response. Genetic fusion of TIR domains of human TLRs and MyD88 adaptor inhibits activation, similar to the monomeric TIR domain but leads to the constitutive activation of TLR signaling pathway at overexpression. We were able to design a TIR domain containing protein that lacks the constitutive activation and is superior to any described TIR-domain-containing protein in inhibiting TLR activation. Additionally those properties of dimeric TIR domain proteins provide an additional insight into the molecular mechanism of intracellular TLR signaling pathway, which is also used by the constitutive activity of MyD88 mutations found in B-cell lymphoma.

IL1.10.01
The long pentraxin PTX3: a paradigm for humoral pattern recognition molecules

C. Garlanda*;*
Humanitas Clinical and Research Center, Rozzano, Italy.

Soluble pattern recognition molecules (PRMs) are components of the humoral arm of innate immunity; they recognize pathogen-associated molecular patterns (PAMP) and are functional ancestors of antibodies, promoting complement activation, opsonization, and agglutination. In addition, several PRMs have a regulatory function on inflammation.
Pentraxins are a family of evolutionarily conserved PRMs characterized by a cyclic multimeric structure, and on the basis of structure, they have been divided into short and long families. C-reactive protein (CRP) and serum amyloid P component are prototypes of the short pentraxin family, while pentraxin 3 (PTX3) is a prototype of the long pentraxins. PTX3 is produced by somatic and immune cells in response to proinflammatory stimuli and Toll-like receptor engagement, and it interacts with several ligands and exerts multifunctional properties. PTX3 gene organization and regulation have been conserved in evolution, thus allowing its pathophysiological roles to be evaluated in genetically modified animals. Gene targeting of PTX3 has unequivocally defined functional roles of this molecule in innate immunity and inflammation. The molecular mechanisms underlying these properties indicate that PTX3 plays a role similar to that of antibodies, including in complement activation, opsonization, and glycosylation-dependent regulation of inflammation. In addition, recent data show that PTX3 is involved in the orchestration of tissue repair and remodeling, thus suggest that matrix and microbial recognition are common, ancestral features of the humoral arm of innate immunity.

W1.10.01
Viral inhibition of DNA-PK-dependent DNA sensing

B. J. Ferguson[1], *N. E. Peters*[2], *D. S. Mansur*[2], *M. Mazzon*[1], *H. Ren*[1], *A. S. Fahy*[2], *E. Krysztofinska*[2], *R. Arribas-Bosacoma*[3], *L. H. Pearl*[3], *G. L. Smith*[1];
[1]*University of Cambridge, Cambridge, United Kingdom,* [2]*Imperial College, London, United Kingdom,* [3]*University of Sussex, Brighton, United Kingdom.*

The host response to DNA virus infection includes the direct detection of viral DNA by the innate immune system which then initiates an inflammatory response. The pattern recognition receptors responsible for DNA sensing are under intensive research and, although several putative sensors have been proposed, in most cases their biological relevance is currently unknown. Here we show that DNA-dependent protein kinase (DNA-PK) can act as a DNA sensor in fibroblasts and in vivo and is important for sensing DNA viruses such as vaccinia (VACV) and herpes simplex virus (HSV) 1. In addition we present the discovery that a VACV protein, C16, can inhibit DNA sensing by directly binding DNA-PK and disrupting its ability to interact with foreign DNA. Removal of the gene which encodes C16 from VACV attenuates the virus in vivo and results in a more potent innate immune response to the infection. This discovery not only validates the biological relevance of DNA-PK as a DNA sensor for DNA viruses but furthers our understanding of how viruses such as VACV evolve to combat the host immune response.

W1.10.02
Hepatitis C virus degrades Riplet ubiquitin ligase to escape host innate immune response

H. Oshiumi*, M. Matsumoto, T. Seya;*
Hokkaido University, Sapporo, Japan.

The innate immune system is essential for controlling viral infections. RIG-I is a cytoplasmic viral RNA sensor and triggers the signal to induce type I interferon production through IPS-1 adaptor molecule. Riplet ubiquitin ligase is essential for RIG-I activation and mediates K63-linked polyubiquitination of RIG-I C-terminal region. Hepatitis C

virus (HCV) is a major cause of hepatocellular carcinoma. HCV NS3-4A protease has the ability to suppress host innate immune response. The NS3-4A protease cleaves a peptide bond just after Cys-805 of IPS-1 to abrogate RIG-I signaling, and an IPS-1 C508A mutant protein is resistant to NS3-4A cleavage. Interestingly, we found that NS3-4A could reduce RIG-I signaling in response to HCV RNA even in the presence of the IPS-1 C508A mutant protein. We found that the Riplet protein level was severely reduced in human hepatocyte cell lines that contains HCV full-length replicons. Moreover, ectopic expression of NS3-4A reduced the Riplet protein level and abrogated Riplet-mediated RIG-I polyubiquitination. Within Riplet RING-finger domain is a sequence similar to NS3-4A target consensus sequence. Mutations within Riplet RING-finger domain rendered the Riplet protein resistant to NS3-4 protease activity. Although Riplet was required for RIG-I foci formation in cytoplasm in response to viral infection, RIG-I foci were not detected in cells infected with HCV JFH1. Taken together, our data indicate that HCV degrades Riplet ubiquitin ligase to escape host innate immune response.

W1.10.03
Lysosomal Dnase2a is required for the autophagic clearance of self damaged nuclear DNA

Y. Lan[1,2,3], *D. Londono*[1], *N. Hacohen*[1,2,3];
[1]*Massachusetts General Hospital, Charlestown, MA, United States,* [2]*Broad Institute, Cambridge, MA, United States,* [3]*Harvard Medical School, Boston, MA, United States.*

Deficiencies in nucleases that degrade DNA lead to accumulation of self DNA, activation of innate immune responses and development of autoimmune disorders in mice and humans. How undegraded DNA accumulates and leads to immune responses in these deficiencies is not well understood. Here, we investigate the cell type specificity, source and sub-cellular localization of accumulated DNA in the absence of the major lysosomal DNA degradation enzyme, Dnase2a. Deletion of this nuclease results in inflammation and chronic polyarthritis that resembles human. We find that high levels of undegraded DNA accumulate in both phagocytic and non-phagocytic cells of Dnase2a-deficient mice. This excess DNA is of nuclear origin and co-localizes outside the nucleus with γ-H2AX that marks damaged double-stranded DNA, and increases in abundance after induction of DNA damage. DNA appears to escape from the nucleus via nuclear buds and speckles and requires autophagosomes and lysosomes for degradation. A deficiency in autophagy leads to higher levels of extra-nuclear DNA. Furthermore, an innate immune response is induced in either Dnase2a-deficient or autophagy-deficient cells, but is abolished upon depletion of the Sting-mediated cytosolic nucleic acid sensing pathway. Our results reveal a process by which damaged nuclear DNA is transported via nuclear buds and autophagosomes from the nucleus to the lysosome where it is degraded by Dnase2a, thus preventing self DNA recognition and activation of innate immune responses. Such a process may help explain how inflammation is regulated in diverse conditions, including cancer, chemotherapy and aging when damaged DNA is generated at high levels.

W1.10.04
Commensal microbiota monitoring by RLRs regulates contact hypersensitivity response

E. Plantamura[1], *L. Moudombi*[1], *S. Djebali*[1], *C. Macari*[1], *S. Lippens*[2], *A. Dzutsev*[3], *G. Trinchieri*[3], *J. Marvel*[1], *M. C. Michallet*[1];
[1]*Centre International de Recherche en Infectiologie (CIRI), INSERM U1111 - CNRS UMR5308, Université de Lyon 1, ENS de Lyon, Lyon, France,* [2]*Molecular Signaling and Cell Death Unit, Department for Molecular Biomedical Research, VIB, Ghent, Belgium,* [3]*Laboratory of Experimental Immunology, Center for Cancer Research, NCI/NIH, Frederick, MD, United States.*

RIG-I like receptors (RLRs) play a major role in response to cytosolic viral RNAs by initiating an antiviral immune response through the recruitment of the mitochondrial adaptor protein MAVS. A novel regulatory role of the RLRs pathway in sterile inflammation has been recently identified in a murine model of experimental colitis. Using another sterile inflammation model, Contact Hypersensitivity (CHS) to the strong hapten 2,4-dinitrofluorobenzen (DNFB), we showed that MAVS-deficient mice developed an exacerbated response. We characterized this inflammatory response at the challenge site of MAVS-deficient mice and demonstrated a higher oedema due to an increase of immune cell infiltrate with higher proportion of cytotoxic CD8+ T cells and an enhanced production of inflammatory cytokines. As it has been suggested that the monitoring of commensal bacteria by RLRs may be involved in the regulation of intestinal inflammation, we evaluated the role of the microbiota in the enhanced CHS response in MAVS-deficient mice. We performed cohousing experiments and showed that the inflammatory phenotype of MAVS-deficient mice can be transferred to WT mice. Moreover, antibiotic treatment of MAVS-deficient mice strongly inhibited the increased CHS response, confirming the importance of commensal microbiota in the regulation of CHS. Altogether, our results highlight that monitoring of commensal microbiota by RLRs is involved in the regulation sterile inflammatory CHS response.

W1.10.05
Essential role for Bruton's tyrosine kinase outside the B cell compartment in bacterial infection

A. F. De Vos[1], *J. Pater*[1], *R. De Beer*[1], *S. Terpstra*[1], *C. Van 't Veer*[1], *R. Hendriks*[2], *T. Van Der Poll*[1];
[1]*Academic Medical Center, Amsterdam, Netherlands,* [2]*ErasmusMC, Rotterdam, Netherlands.*

Bruton's tyrosine kinase (Btk) is a key component in B-cell receptor and Toll-like receptor signaling. Lack of functional Btk renders humans and mice highly susceptible to infections. Aim of our study was to determine the role of Btk in the host defense response against the capsulated bacterium *Klebsiella pneumoniae*.
Btk-KO mice inoculated intranasally with *K.pneumoniae* were highly susceptible to infection as reflected by increased bacterial counts in the lung, increased dissemination of bacteria to other organs within 24-36 hour and increased mortality. Impaired bacterial clearance was associated with elevated inflammation. Natural IgM antibodies against *K.pneumoniae* were found in WT mice (but not in Btk-KO mice) and these antibodies facilitated phagocytosis of *K.pneumoniae* by alveolar macrophages. Strikingly, Btk-KO mice of which the B cell compartment was 'rescued' by reinforced expression of Btk (Btk-KO/CD19-Btk Tg mice, with normalised natural IgM levels), were not protected against *K.pneumoniae* infection and demonstrated similar susceptibilty as Btk-KO mice. Moreover, B-cell deficient (muMT) mice displayed similar bacterial clearance in lungs and other organs as WT mice. Finally, Btk-KO mice with reinforced expression of Btk in $MHCII^+$ cells (Btk-KO/MHCII-Btk Tg mice), i.e. B cells and macrophages, showed an almost complete reversal in susceptibility to *K.pneumoniae*.
These data demonstrate that B cells and natural IgM antibodies contribute little to nothing to the early host defense response against *K.pneumoniae.* Moreover, these data indicate that Btk is essential for receptor signaling outside the B-cell compartment during *K.pneumoniae* infection and suggest an important role for Btk in myeloid cells during bacterial infection.

W1.10.06
Genetic variants in donor *PTX3* impair antifungal immunity and predispose to invasive aspergillosis after stem cell transplantation

C. Cunha[1], *F. Aversa*[2], *A. Mantovani*[3], *L. Romani*[1], ***A. Carvalho***[1];
[1]*Department of Experimental Medicine and Biochemical Sciences, University of Perugia, Perugia, Italy,* [2]*Department of Clinical and Experimental Medicine, University of Parma, Parma, Italy,* [3]*Istituto Clinico Humanitas IRCCS, University of Milan, Milan, Italy.*

Invasive aspergillosis is a major complication associated with hematopoietic stem cell transplantation, although individual risk varies considerably. Given the pivotal role of the long pentraxin 3 (PTX3) in antifungal immunity, we investigated the contribution of genetic variation in PTX3 to risk of invasive aspergillosis in a discovery cohort of 229 recipients of allogeneic hematopoietic stem cell transplants and their donors. The analysis was validated in a large multicenter study involving 107 cases of invasive aspergillosis and 223 matched

controls. A donor homozygous haplotype (h2/h2) in PTX3 increased risk for invasive aspergillosis in the discovery (adjusted hazard ratio, 3.15; P=0.002) and validation (adjusted odds ratio, 2.78; P=0.03) studies. Functionally, the h2/h2 haplotype led to decreased expression of PTX3 in neutrophils, presumably due to impaired mRNA stability, resulting in defective phagocytosis and clearance of the fungus. PTX3 deficiency was confirmed in bronchoalveolar lavage and lung specimens from transplant recipients with h2/h2 donors. In conclusion, our findings disclose a crucial role of PTX3 to human antifungal immunity and point to PTX3 deficiency as an important risk factor for invasive aspergillosis in stem cell transplant recipients.

W1.11 Toll-like and pattern recognition receptors

IL1.11.01
Regulation of the innate immune responses in wild mice

A. Poltorak[1]*, T. Volkova*[2]*, I. Kurbatova*[2]*, V. Ilyuha*[2]*, U. Bagina*[2]*, D. Ram*[1]*;*
[1]Tufts University, Boston, MA, United States, [2]Petrozavodsk State University, Petrozavodsk, Russian Federation.

Immune response leads to inflammation, which, if excessive, can often lead to the programmed death. How do genes control the balance between inflammation and cell death? To answer this question, we have elected to study the immune responses in so called wild-derived mice (WDM), which evolved from common ancestor with classical laboratory mice more than a million years ago and therefore share only 11% of their genome with laboratory mice. Such divergence of WDM results in phenotypic differences between WDM and classical laboratory mice, which we investigate by means of classical genetic analysis. In the last few years, we established several genetic screens in the WDM including hyper- and hypo-responsiveness to TLR-agonists, resistance to TLR-mediated necroptosis, in vitro responses to infectious pathogens, resistance to septic shock in vivo. In our published and ongoing research, we show that forward studies in WDM provide insights into human biology that would not be available without access to this largely untapped reservoir of genetic diversity. Because we have not exhausted the genetic diversity available in the WDM, we propose to further explore it in newly established genetic screens.

W1.11.01
Emerging roles of an innate immune regulator TAPE in the endosomal Toll-like receptor (TLR) and cytosolic RIG-I-like receptor (RLR) pathways

P. Ling[1]*, K. Chen*[1]*, C. Yang*[2]*, Y. Lo*[1]*, C. Huang*[2]*, T. Tan*[2]*;*
[1]National Cheng-Kung University, Tainan, Taiwan, [2]National Health Research Institutes, Zhunan, Taiwan.

Pattern-recognition receptors (PRRs) function to trigger innate immune defenses upon sensing pathogen-associated molecular patterns (PAMPs) from pathogen infection. Of these PRRs, endosomal TLRs, cytosolic RLRs, and DNA sensors are implicated in detecting microbial nucleic acids. Upon ligand stimulation, these PRRs activate major downstream pathways leading to the production of inflammatory cytokines and type I IFNs. Remarkable progress has been made in defining the importance of PRRs in innate immunity. Yet, signaling networks underlying these PRR pathways still remain complex. Our recent work has led to uncover an innate immune regulator termed TAPE (TBK1-Associated Protein in Endolysosomes), also known as CC2D1A/Freud-1/Aki-1. TAPE is located in the endolysosomal compartments. TAPE interacts and synergizes with TBK1 and TRIF to enhance IFN-β activation. TAPE knockdown abolishes the TLR3 and TLR4 pathways to IFN-β production. Furthermore, we extend the biological role of TAPE to the regulation of RLR signaling. TAPE functionally and physically interacts with RIG-I, MDA5 and IPS-1/MAVS to regulate IFN-β activation. TAPE impairment blocks IFN-β production upon RLR ligand stimulation or RNA virus infection. Our data demonstrate a critical role for TAPE in linking TLR3, TLR4, and RLRs to innate immune responses. Furthermore, we have generated immune cell-specific TAPE conditional knockout mice to explore in vivo roles of TAPE in regulating the endosomal TLR, RLR, or other innate sensing pathways.

W1.11.02
Smurf2 negatively regulates RIG-I-like receptor -mediated immune signaling

Y. Pan*, J. Zhang;*
Peking University Health Science Center, Beijing, China.

The primary role of the innate immunityis to limit the spread of infectious pathogens, by recognition by Toll-like receptors (TLR) and RIG-like receptors (RLR).Innate immune response is under tight control to avoid unwanted tissue damage. Here, we identified smurf2, one of the Smad ubiquitin regulator factor proteins (the HECT family of E3 ligase members), as an important negative regulator of virus-triggered type I IFN signaling. Overexpression of Smurf2 inhibits Sendai virus-induced IFN and ISRE activation and the expression of downstream molecules. The E3 ligase defective mutant Smurf2 C716A loses the ability to suppress virus-induced type I IFN signaling, suggesting that this effect is dependent on the ubiquitin ligase activity of smurf2.Compared to WT cells, Smurf2 knockout MEF cells dramatically promote SeV induced IFN and ISRE activation and the production of Interferon-β. It promotes the K48 ubiquitination of target proteins. Further studies are ongoing to charaterize the signaling molecules which Smurf2 targets.

W1.11.03
PIAS1 negatively modulates virus triggered type I IFN signaling by blocking the DNA binding activity of IRF3

R. Li, Y. Pan, D. Shi, Y. Zhang, ***J. Zhang****;*
Peking University Health Science Center, Beijing, China.

During viral infection, production of proinflammatory cytokines including type I interferons (IFNs) is under stringent control to avoid detrimental overreaction. The protein inhibitor of activated STAT (PIAS) family proteins have been recognized as anti-inflammatory molecules by restraining type I IFN induced amplifying signaling. Here we identified PIAS1 as an important negative regulator of virus-triggered type I IFN signaling. Overexpression of PIAS1 repressed virus-or RIG-I like receptor stimulated type I IFN transcription, whereas knockdown of PIAS1 expression augmented virus-induced production of type I IFNs. PIAS1 with a mutation in the SAP domain retained the inhibitory function in virus-induced IFN transcription, but abolished the inhibition in IFN-stimulated signaling. SUMO E3 ligase activity dead mutant PIAS1/C350S still had the comparable inhibitory function with WT PIAS1.Further study indicated that PIAS1 interacted with IRF3 and inhibited the DNA binding activity of IRF3. Therefore,PIAS1 is important in maintaining proper amounts of type I IFNs and restrains its magnitude when the antiviral response intensifies.

W1.11.04
The evolutionary landscape of the NLR family is reflected in the species-specific response to infection

T. P. Monie*, L. Hopkins, J. Boyle, W. Amos, C. Bryant;*
University of Cambridge, Cambridge, United Kingdom.

Activation of the NLR family of cytoplasmic pattern recognition receptors initiates an innate immune response to a wide range of exogenous and endogenous ligands. This leads to a pro-inflammatory response via NFκB and stress kinase signalling pathways; and/or the secretion of interleukin-1β following caspase-1 processing by a multi-protein complex termed the inflammasome.
Humans possess 22 NLR proteins, but this number varies in other species. We have analysed the evolutionary patterns of the NLRs across a range of vertebrate species including mammals, birds, amphibians and fish. There are clear species specific expansions, and losses, of subsets of this receptor family including one pair of

receptors that have undergone linked genetic retention or loss across multiple species. The key inflammasome forming NLRs are almost entirely restricted to mammals; birds possess a very limited subset of receptors; fish show extensive receptor specific expansions; and the coelacanth is an evolutionary midpoint in NLR evolution. In addition a putative new NLR protein has been identified bioinformatically.
Functional analysis of the cellular response to ligand stimulation in different species supports the crucial role of these receptors in the innate immune response and provides a rationale for the different susceptibilities of species to infections such as Salmonella.

W1.11.05
CD14 as a key regulator of TLR-mediated responses of microglia

H. Janova[1], *T. Regen*[2], *D. van Rossum*[1], *A. Götz*[1], *W. Brück*[1], *U. Hanisch*[1];
[1]*Universitaetmedizin Goettingen, Goettingen, Germany,*
[2]*Universitaetsmedizin der Johannes Gutenberg-Universitaet, Mainz, Germany.*

Toll like receptor 4 (TLR4) is best-known for its recognition of lipopolysacharide (LPS), the cell wall component of Gram-negative bacteria. Binding of this ligand to TLR4 triggers the response via both MyD88- and TRIF-dependent signalling pathways, leading to production of cyto- and chemokines and thereby alarming and attracting the peripheral immunocompetent cells to invade into the site of insult. However, TLR4 is only fully functional in complex with several co/receptors, such as CD14. Our latest data show that CD14 increases the sensitivity towards LPS in a cell type-specific manner, making microglia far more sensitive to LPS than bone marrow and peritoneal macrophages. While application of low dose LPS into striatum of CD14ko brains reveals minor neutrophil recruitment compared to wildtypes, high LPS leads to augmented neutrophil influx. This phenomenon correlates well with *in vitro* data, revealing CD14 absence in microglia upon high LPS challenge to result in excessive but selective chemokine production, with highest impact on the neutrophil chemoatractant CXCL1. For such regulatory abilities, CD14 requires its membrane insertion and prolonged functionality, pointing to an involvement of signalling. Thus far we excluded the role of Syk and PLC that in comparison to dendritic cells do not have a contribution in CD14-dependent signalling in microglia. Importantly, we found various factors regulating the expression of CD14 receptor itself, which could thereby determine the extent and impact of a CD14-mediated control over TLR4 functions. Supported by the DFG (FOR1336).

W1.11.06
Bruton's tyrosine kinase plays an essential role in TLR-dependent human DC activation

V. Lougaris*, M. Vitali, M. Baronio, G. Tampella, L. Tassone, A. Soresina, R. Badolato, A. Plebani;*
Pediatrics Clinic and Laboratory for Molecular Medicine "A.Nocivelli", University of Brescia, Brescia, Italy.

Bruton's tyrosine kinase (btk) plays an essential role in various biological functions of different cell types. Mutations in btk lead to the X-linked form of Agammaglobulienmia (XLA) in humans or in the xid phenotype in mice. However, in recent years the important physiological function of btk has been investigated in various cell types , such as macrophages, NK cells, neutrophils and others, mainly by using the animal models (xid mice). Furthermore, btk was recently linked to the innate immune system, in particular the TLR pathway. However, the TLR9 pathway in dendritic cells from XLA patients has not been investigated yet. We decided therefore to investigate whether Btk influences human DC responses upon TLR engagement. We show that btk plays an essential role in moDC responses to CpG: although responses to LPS/TLR4 induce normal DC activation in terms of up-regulation of activation markers, the CpG/TLR9 pathway is completely impaired in XLA patients. Furthermore, cytokine production upon TLR9 activation in XLA patients is radically impaired in terms of IL-6, IL-10, IL-12 and TNF-a production. Interestingly, btk resulted essential for STAT1 up-regulation in a TLR9-dependent manner. The important role of btk in human DC activation was confirmed after incubation of healthy DCs with the specific btk inhibitor resulting in impairment of TLR9 responses as seen in XLA patients. These findings may be of important significance for better understanding and managing clinical complications in different clinical conditions, such as agammaglobulinemia and lymphoid malignancies.

W1.11.07
Lysosomal oligopeptide transporter SLC15A4 regulates Toll-like receptor 7/9-mediated autoantibody production

T. Kobayashi*, T. Okamura, N. Toyama-Sorimachi;*
National Center for Global Health and Medicine, Tokyo, Japan.

Lysosome is a key compartment that regulates the signaling from Toll-like receptors. We have reported that Solute Carrier family (SLC) 15A4, a lysosomal oligopeptide transporter expressed in the immune and nervous cells, played crucial roles in TLR7-, TLR9- and NOD1-mediated cytokine production in dendritic cells (DCs).
We here show that SLC15A4 is also expressed in B cells, and plays crucial roles in B cell functions. Lack of SLC15A4 reduced the serum IgG2c antibody level, which was caused by inability of SLC15A4-deficient B cells to produce IgG2c antibody in response to TLR stimulation. When SLC15A4-deficient B cells were stimulated by TLR7 or TLR9 ligand, cytokine production such as IFN-beta or IL-6 was impaired. We next examined TMPD-induced SLE model whether SLC15A4 was involved in autoantibody production since IgG2c antibody is thought to be one of the pathogenic factors in mouse autoimmune disease. SLC15A4-deficient mice failed to produce autoantibody such as anti-RNP and anti-DNA IgG antibodies. These results indicated that SLC15A4 contributes to pathogenesis of TLR7- or TLR9-dependent autoimmune diseases.
SLC15A4 gene is reportedly associated with the autoimmune disorders such as inflammatory bowel diseases and systemic lupus erythematosus in human. Although further investigation should be necessary, our findings suggest that SLC15A4 could be a novel therapeutic target for the autoimmune diseases.

W1.11.08
NLRC5-mediated regulation of MHC class I immune responses

K. S. Kobayashi[1,2,3], *I. Downs*[1], *A. Biswas*[1,2,3], *T. Meissner*[2,3], *Y. Liu*[2], *K. Lee*[2,3], *A. Li*[2];
[1]*Texas A&M Health Science Center, College Station, TX, United States,* [2]*Dana-Farber Cancer Institute, Boston, MA, United States,* [3]*Harvard Medical School, Boston, MA, United States.*

MHC class I and class II molecules are critical for the activation of human adaptive immune responses. Although a master regulator of MHC class II genes, CIITA (MHC class II transactivator) has been recognized for nearly two decades, the mechanism of MHC class I expression has been largely unknown until recently. We found one of NLR protein, NLRC5 is a MHC class I transactivator (CITA). Whereas CIITA can strongly induce MHC class II and related genes such as invariant chain, NLRC5 can specifically associate with and activate promoters of both classical (HLA-A, B, C) and non-classical MHC class I genes. Strikingly, NLRC5/CITA regulates not only MHC class I, but also regulates functionally related genes such as TAP1, LMP2 and b2microglobulin. In NLRC5 deficient mice, the expression of MHC class I and related genes is selectively downregulated and CD8 T cell responses are impaired. Therefore, NLRC5/CITA and CIITA regulate concerted expression of genes in MHC class I and class II pathways, respectively.

W1.11.09
Co-ligation of TLR3 and Dectin-1 agonists potentiates Th1 polarization capability on monocyte derived Langerhans cells in vitro

I. Rajkovic[1], *A. Dragicevic*[2], *S. Vasilijic*[1,2], *D. Vucevic*[1,2], *B. Bozic*[3], *D. Mihajlovic*[1], *M. Markovic*[2], *M. Colic*[1];
[1]*Medical Faculty of the Military Medical Academy, University of Defense in Belgrade, Belgrade, Serbia,* [2]*Institute for Medical Research, Military Medical Academy, Belgrade, Serbia,* [3]*Institute for Physiology and Biochemistry, Faculty of Biology, University of Belgrade, Belgrade, Serbia.*

Langerhans cells represent the first dendritic cell subtype that encounters foreign pathogens due to its localization in skin and stratified mucosa. Their potential to initiate T-cell responses has recently been challenged. Since viral and fungal infections are among the most common in these tissues, we have studied effects of Toll-like receptor 3 (TLR3) and Dectin-1 agonists, polyinosinic:polycytidylic acid (poly I:C) and curdlan, respectively, on maturation of their in vitro counterparts, monocyte derived Langerhans cells (MoLCs). Immature (im)MoLCs were generated in the presence of GM-CSF, IL-4 and TGF-β1 and then treated with polyI:C, curdlan or their combination for 2 days. Both single or combined treatments elicited phenotypic maturation of imMoLCs with increased allostimulatory capacity. Poly I:C-treated MoLCs up-regulated both the production of IFN-γ and IL-17 by alloreactive CD4+ T cells while curdlan-treated MoLCs stimulated only the production of IFN-γ, compared to imMoLCs. Poly I:C+curdlan-treated MoLCs produced higher concentrations of IL-12 and IL-10 and stimulated more strongly the production of IFN-γ by alloreactive CD4+ T cells then curdlan-treated MoLCs. At the same time, poly I:C+curdlan-treated MoLCs produced more IL-23 but less IL-27 and were weaker stimulators of IL-17 by alloreactive CD4+ T cells then poly I:C-treated cells. Poly I:C+curdlan-treated MoLCs showed higher expression of CD40 and CCR7 then both poly I:C- and curdlan-treated MoLCs. Ligation of both TLR3 and Dectin-1 agonists on imMoLCs upregulated their Th1 polarization capability compared to single agonists. This finding suggests that MoLCs could be considered for their potential use in immunotherapy.

W1.11.10
TLR-9 dependent dendritic cells activation by filamentous bacteriophage targeting DEC-205

R. Sartorius[1], *L. D'Apice*[1], *M. Trovato*[1], *G. De Leo*[2], *A. De Matteis*[2], *P. Barba*[3], *P. De Berardinis*[1];
[1]*Institute of Protein Biochemistry, C.N.R., Naples, Italy,* [2]*TIGEM-Telethon Institute of Genetics and Medicine, Naples, Italy,* [3]*Institute of Genetics and Biophysics "Adriano Buzzati Traverso", C.N.R., Naples, Italy.*

Based on a modification of the phage display technology, we developed and described an antigen delivery system based on the filamentous bacteriophage fd, able to elicit full-spectrum of antigen-specific immune responses. We improved this system by constructing phage particles displaying a single chain antibody fragment known to bind the mouse dendritic cells (DC) surface molecule DEC-205, and thus enabling direct delivery of phage particles to DC. We demonstrated that targeting DCs via DEC-205 delivers phage particles into late endosome/lysosome LAMP-1 positive compartments. Moreover we observed that DCs targeted by fd virions via DEC-205 upregulate accessory molecules, produce IFN-alpha and IL-6, and mediate an increased antigen presentation. We found that these activities of fd-antiDEC-205 phage particles were TLR-9 dependent. Since to become active TLR-9 translocate into LAMP-1 positive compartments, we suggest that phage particles, containing a single strand DNA genome reach in CpG motifs, are able to intercept and trigger the active TLR-9 innate immune receptor and thus to enhance the immunogenicity of the displayed antigenic determinants.

W1.11.11
Bacterial 23S rRNA is recognized by the endosomal TLR13 unless it is modified to constitute erythromycin resistance

A. Krüger[1], *M. Oldenburg*[1], *R. Ferstl*[2], *A. Kaufmann*[3], *G. Nees*[3], *J. Buer*[1], *H. Wagner*[2], *S. Bauer*[3], *H. Hochrein*[4], *C. J. Kirschning*[1];
[1]*Institute of Medical Microbiology, University of Duisburg-Essen, Essen, Germany,* [2]*Institute of Medical Microbiology, Immunology and Hygiene, Technical University of Munich, Munich, Germany,* [3]*Institute for Immunology, Philipps University of Marburg, Marburg, Germany,* [4]*Department of Research Immunology, Bavarian Nordic GmbH, Martinsried, Germany.*

The innate immune system, being very sensitive, tends to over-amplify inflammatory signals. Accordingly, bacterial infections often cause septic shock. Major intiators of sepsis are bacterial infections with Escherichia coli and Staphylococcus aureus. Analyzing their interaction with the host, we observed recognition of a segment within bacterial 23S ribosomal (r) RNA through TLR13 in mice. The same segment is a target for antibiotics like macrolide, lincosamide and streptogramin group (MLS) antibiotics (including erythromycin). As a resistance mechanism bacteria prevent binding of MLS antibiotics to 23S rRNA by inducing N-methylation at a specific adenosine (A) upon acquisition of a distinct erythromycin resistance related methyltransferase (e.g. ErmB or ErmC) via horizontal gene transfer. Next to post transcriptional RNA modification, mutation of the specific A (e.g. A→G, found also in eukaryotic 28S rRNA) renders bacteria resistant. Of note, both RNA alterations abrogated activation of TLR13, thereby enabling immune evasion.
Utilizing Tlr23479-/- mice, we observed Gram negative bacterial total RNA to be non TLR13 activating in contrast to purified Gram negative bacterial 23S rRNA. We speculate that it is another RNA subspecies that inhibits the stimulative capacity of 23S rRNA.

W1.11.12
TLR triggered MAPK signalling is responsible for the regulatory phenotype of macrophages in response to Schistosoma mansoni cercarial secretions

D. E. Sanin, *A. P. Mountford;*
Centre for Immunology and Infection, University of York, York, United Kingdom.

The interaction between antigen presenting cells in the skin with molecules secreted by cercariae of *Schistosoma mansoni* constitutes the first point of contact between the host's immune system and the pathogen. Macrophages (MΦ) may play a pivotal role in modulating the immune response in the skin as they readily take up the molecules secreted by cercariae upon invasion.
MΦ produce high levels of IL-10 when exposed to cercarial excreted/secreted (E/S) products, but it is unknown what signalling pathway(s) drive the production of IL-10 rather than IL-12 , or how they are linked to innate recognition of E/S antigens. Our findings demonstrate that TLRs, particularly TLR-4 and TLR-2, play a fundamental role in the induction of IL-10. Furthermore, MyD88 is essential for the activation of multiple MAPK pathways which in turn control E/S product induced IL-10. Selective chemical inhibition of specific pathways allowed us to determine the contribution of each signalling cascade. We determined that the activation of the MEK/Erk and p38 induced the production of IL-10, whilst it negatively affected IL-12. Furthermore, p38 activation leads to the phosphorylation of CREB, which is likely responsible for the observed effects on both IL-10 and IL-12. Finally, we show that TLR-4 and TLR-2 are directly implicated in the activation of these pathways.
From these findings we propose a mechanism by which *S. mansoni* E/S products induce a specific MAPK signalling cascade that triggers IL-10 production in MΦ by binding their TLRs, thus polarizing the immune response in the skin.

W1.11.13
Redox-based control of synergy and antagonism among TLRs modulates cytokine production by monocytes

***R. Lavieri**, L. Delfino, P. Piccioli, E. Repaci, P. Castellani, A. Rubartelli;*
Cell Biology Unit, IRCCS AOU San Martino - IST, Genoa, Italy.

In human monocytes, single stimulation of different TLRs results in induction of IL-1β and of cytokines downstream of it. The process is tightly regulated by redox signaling. Here we show that the simultaneous administration of agonists of TLR 2, 4 and 7, at doses providing optimal monocyte activation when used individually, strongly enhances IL-1β but severely impairs IL-1Ra and IL-6 secretion and induces oxidative stress. Antioxidants restore IL-1Ra and IL-6 secretion, demonstrating the functional link between generation of oxidative stress and impairment of secretion of cytokines downstream of IL-1β. When TLRs are concomitantly triggered by lower doses of the three agonists, which are unable to induce monocyte activation if provided individually, oxidative stress is prevented and cytokine secretion is maintained. Thus, multiple triggering of TLRs and sustained doses of single agonists concur to the loss of redox control and the consequent block of secretion of cytokines downstream of IL-1β. In conclusion, we have identify a novel redox-mediated mechanism responsible for the correct development of TLR-triggered inflammatory response. This mechanism provides a molecular basis to the unbalance between pro- and anti-inflammatory circuits occurring in pathologic conditions such as sepsis and chronic diseases, and open the way to new strategies for controlling inflammation.

W1.11.14
A TNFα-CCL20-CCR6 axis drives Nod1-induced B cell recruitment

***J. H. Fritz**;*
McGill University, Montreal, QC, Canada.

Innate immune responses provoke the accumulation of leukocytes at sites of inflammation. In addition to monocytes and granulocytes, B cells also participate in anti-microbial innate immune responses, however the mechanisms for recruitment of B cells to sites of inflammation are not well understood. To study B cell accumulation following systemic inflammation, we used a model synthetic ligand that stimulates a specific pattern recognition molecule, Nod1. Upon exposure to Nod1 agonists, both B cells and neutrophils rapidly accumulate within the spleen and dendritic cells migrate into the periarterial lymphoid sheath. Nod1 stimulation led to a marked increase in several chemokines within the spleen, including CXCL13, CCL2 and CCL20. While the Lymphotoxin pathway was critical for the induction of the B cell chemoattractant CXCL13 in response to Nod1 agonists, B cell accumulation within the spleen following Nod1-induced systemic inflammation was independent of the Lymphotoxin pathway. In contrast, a CCR6/CCL20 chemokine loop instructed rapid B cell recruitment to the spleen in response to systemic administration of Nod1 agonists in a TNFα-dependent manner. These results reveal a novel mechanism for rapid mobilization of B cells during inflammation, and shed light on how B cells participate in innate immune responses to microbial stimulation.

Galectins in Inflammation and Immunity

***F. Liu**[1,2];*
[1]Institute of Biomedical Sciences, Academia Sinica, Taipei, Taiwan, [2]Department of Dermatology, University of California-Davis, Sacramento, CA, United States.

Galectins are a family of β-galactoside-binding proteins. They can bind to cell-surface glycans, thereby affecting a variety of cellular processes. They are also present in the cytosol and nucleus and can influence cellular functions through interacting with other regulators in a non-glycan-dependent fashion. Recombinant galectin-1 and -9 have been shown to induce apoptosis in T cells, by engaging cell surface glycoproteins, and suppress certain inflammatory responses when administered in vivo. Recombinant galectin-3 has been shown to promote the inflammatory responses by activating various leukocytes and inducing migration of monocytes/macrophages.
We demonstrated that endogenous galectin-3 is recruited to the cytoplasmic side of the immunological synapse in activated T cells and promotes HIV-1 viral budding in a fashion that is dependent on Alix. We also found galectin-3 suppresses the bacteriocidal effects of macrophages on Listeria monocytogenes and that the protein is accumulated around the bacteria that are escaping the phagosomes.
We demonstrated that galectin-3 negatively regulates the Th cell response in the Th1 and Th17 directions through dendritic cells. By using galectin-3-deficient mice, we established that galectin-3 promotes allergic airway inflammation and airway hyperresponsiveness, as well as allergic skin inflammation, through promoting the Th2 response.
Galectin-7 is down-regulated in human psoriatic lesions compared with non-lesional sites. We demonstrated that knocking down galectin-7 expression in the human keratinocyte cell line HaCaT resulted in increased production of the inflammatory cytokines IL-6 and IL-8, in response to various immune stimuli. Additional results suggest that galectin-7 has a suppressive effect on the inflammatory response in keratinocytes.

IL1.12.02
Molecular interplay between sialic acids and siglecs in subversion of host innate immune response by Pseudomonas aeruginosa

***C. Mandal**, B. Khatua;*
Council of Scientific and Industrial Research (CSIR)-Indian Institute of Chemical Biology, Kolkata, India.

Pseudomonas aeruginosa (PA) is an opportunistic pathogen and associated with immune-compromised host. We have demonstrated PA (PA+Sias) adsorbed both α2,3- and α2,6-linked Sias from the host serum. Sialic acid-binding immunoglobulins like lectins (siglecs) are usually present on different immune cells. They are important in cellular interactions with pathogens and functional consequences of the engagement of notorious pathogen like PA with siglecs are unclear. Innate immune cells mainly neutrophils and macrophages generally express receptor like siglec-1, siglec-5 and siglec-9 on their surface. PA+Sias interact maximally with NK-cells and monocytes through siglec-7 and siglec-9 via α2,6- and α2,3-linked sialic acid respectively. Adsorbed Sias on PA also show association with both human macrophages and neutrophils mainly via α2,3-linked sialic acid-siglec-9 dependent manners. In contrast PA shows negligible binding with both B- and T-cells. Both macrophages and neutrophils also exhibits enhance phagocytosis of PA+Sias compared to PA-Sias. The interaction of PA with neutrophils shows reduced oxidative burst, releases of elastase and enhances expression of IL-10 in transcriptional and translational levels. All these events result decreased NETs formation thus establishing the role of adsorbed Sias that can weaken neutrophil's protective activity. Enhanced survivality of PA demonstrated by significant increased in CFU counts supported strongly for their resistance towards NETs. It may consider as a general mechanism for pathogens that cannot synthesize Sias in order to subvert immunity. Such Sias-siglec interaction also may be accompanied by modulation of Th1 and Th2 cytokines which may likely be due to the function of TLR and its downstream signaling.

W1.12.01
C-type lectin MCL is a receptor for mycobacterial cord factor TDM and is critical for Mincle induction

***Y. Miyake**[1], K. Toyonaga[1], D. Mori[1], S. Kakuta[2], Y. Hoshino[3], Y. Iwakura[4], S. Yamasaki[1];*
[1]Kyushu University, Fukuoka, Japan, [2]Tokyo University, Tokyo, Japan, [3]National Institute of Infectious Diseases, Tokyo, Japan, [4]Tokyo University of Science, Tokyo, Japan.

We have previously reported that Mincle is a receptor for mycobacterial tuberculosis. Mincle recognizes mycobacterial glycolipid, trehalose dimycolate (TDM) and triggers inflammatory

responses such as cytokine/chemokine production and lung granuloma formation. These TDM responses were totally abolished in Mincle-deficient mice, suggesting that Mincle is a dominant receptor for TDM. Although Mincle expression was barely detected under steady-state conditions, TDM stimulation strongly induced Mincle expression. These data prompted us to hypothesize that an alternative TDM receptor expressing under resting conditions may promote the initial induction of Mincle. We have searched for the novel TDM receptor and finally identified MCL (macrophage C-type lectin, also called clec4d, clecsf8) as a candidate receptor. MCL is constitutively expressed in myeloid cells. MCL directly bound to TDM and transduced activation signals via ITAM-bearing adaptor molecule FcRgamma. We generated MCL-deficient mice and analyzed the function of MCL in TDM responses. MCL-deficient mice failed to induce Mincle expression upon TDM stimulation. As a result, TDM-induced inflammatory responses including cytokine/chemokine production and lung granuloma formation were significantly impaired in MCL-deficient mice. Finally, we analyzed the function of MCL against mycobacterial infection. MCL-deficient cells showed the significant reduction of Mincle induction and compromised immune responses against mycobacterial infection.
In summary, MCL is a dominant TDM receptor at resting stage and triggers Mincle induction for efficient immune responses against mycobacteria.

W1.12.02
Targeting C-type Lectin receptors on dendritic cells for neonatal adjuvant setting

***S. Lemoine**, B. Jaron, E. Deriaud, C. Leclerc, R. Lo-Man;*
Pasteur Institute, Paris, France.

Early life is characterized by a high susceptibility to infection, poor innate responses, and biased CD4 T cell response to many vaccines to TH2. New adjuvant settings should take into consideration these particularities of the neonatal innate immune system, such as its poor capacity to respond to TLR activation. We are thus investigating alternative innate pathways to TLRs for dendritic cell activation, such as C type lectin receptors (CLRs) that signal through the Syk/CARD9 pathway, to prime TH1 protective response in neonates.
Among CLRs, targeting Dectin-1 was evaluated using curdlan, a beta 1-3 glucan, as an adjuvant in neonatal vaccination inducing strong Th1 and Th17 responses. In a subunit vaccine including TB10.4 antigen and curdlan, protective response were induced against aerosol challenge with Mycobacterium tuberculosis H37Rv. The efficiency of Curdlan relies on the mobilization of dermal dendritic cells as well as RORgt-gamma-delta T cells in the dermis of neonatal mice.
The potency of beta-glucans was also evaluated on human neonatal dendritic cells for their capacity to induced appropriate inflammatory responses.
This work illustrates the potency of Dectin-1 as an emerging adjuvant candidate. We showed that Dectin-1 triggering can induce pro-inflammatory cytokines both in mice and in humans. Signal through Dectin-1 was able to induce protective TH1/TH17 response in newborn mice and protect them from MTB infection. These results show the potential of CLR related pathways as a relevant target for future adjuvant development.

W1.12.03
A novel role of beta-glucan in improving anti-tumorimmunity by regulating monocytic myeloid-derived suppressor cells

***J. Tian**[1], K. Ma[1], H. Guo[1], J. Chen[2], H. Xu[1], S. Wang[1];*
[1]Department of Immunology, Jiangsu University, Zhenjiang, China,
[2]Department of Laboratory Medicine, The Affiliated People's Hospital, Jiangsu University, Zhenjiang, China.

Accumulating evidence has shown that a population of cells with suppressive activity called myeloid-derived suppressor cells (MDSCs) contributes to the negative regulation of immune responses and plays an essential role in tumor-induced immunosuppression. Promoting MDSCs differentiate into mature myeloid cells without suppressive capacity might be considered one of the most promising approaches in cancer immunotherapy. β-Glucans have been reported to function as potent immunomodulators to stimulate innate and adaptive immune responses, which contributes to their anti-tumor property. We firstly found the expression of dectin-1 (receptor of β-glucan) on MDSC. Therefore, we hypothesized that WGP (whole β-glucan particles) treatment through dectin-1 pathway may circumvent MDSC-mediated immune suppression.
Here we investigated the effect of particulate β-glucans on MDSCs and found that β-glucan treatment could promote the differentiation of M-MDSCs (monocytic MDSCs) into a more mature $CD11c^{+}$ $F4/80^{+}$ $Ly6C^{low}$ population via dectin-1 pathway in vitro, which is NF-κB dependent, and the suppressive function of M-MDSCs was significantly decreased. Treatment of orally administered yeast-derived particulate β-glucan drastically down-regulated MDSCs but increased the infiltrated DCs and macrophages in tumor-bearing mice, thus eliciting CTL and Th1 responses, inhibiting the suppressive activity of regulatory T cells, thereby leading to the delayed tumor progression.
We show here for the first time that β-glucans induce the differentiation of MDSCs and inhibit the regulatory function of MDSCs, therefore revealing a novel mechanism for β-glucans in immunotherapy and suggesting their potential clinical benefit.

Soluble CD52 is a negative regulator in the innate immune system

***M. Rashidi**, Y. Zhang, E. Bandala-Sanchez, J. M. Wentworth, J. Vince, L. C. Harrison;*
The Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia.

CD52 is a small, heavily glycosylated molecule comprising a short peptide linked to the cell membrane via a GPI anchor. The physiological role of CD52 has been elusive, but we have recently shown that T cells with high expression of CD52 are immunosuppressive via the release of soluble CD52. In the current study, we investigated the effect of recombinant soluble CD52 (CD52-Fc) in the innate immune system.
In response to LPS, CD52-Fc in a nanomolar dose-response range inhibited cytokine production by human and mouse monocytes and dendritic cells. Similarly, CD52-Fc inhibited responses to other innate immune stimuli including Pam3CSK, CPG, Lysteria monocytogenes, Poly I:C, and the inflammasome activators monosodium urate, alum and nigericin.
Cleaving the sialylated N-linked oligosaccharides of CD52 reversed the inhibitory effect of CD52 on LPS-induced IL-1β secretion, demonstrating the requirement of the oligosaccharide moiety for the inhibitory effect of CD52. Moreover, the inhibition was dependent on sialic acid, because desialylation with A. ureafaciens neuraminidase also reversed the inhibitory effect of CD52-Fc. In accord with this finding, preliminary studies showed that CD52-Fc interacts with the lectin receptor, Siglec 10.
The inhibitory effect of CD52-Fc was applied to a model of sepsis in C57Bl/6 mice: CD52-Fc (10 μg/kg) markedly reduced plasma cytokine concentrations 2 h following i.p. injection with, or up to one hour, after LPS (15 mg/kg).
Our findings demonstrate that soluble CD52 suppresses innate immune responses and is a candidate immunotherapeutic agent.

W1.12.05
Galectin-3 promotes cell-to-cell transmission of HIV-1

*S. F. Wang[1,2], D. K. Hsu[1,3], Y. M. A. Chen[2,4], **H. Y. Chen**[1,3], F. T. Liu[1,3];*
[1]Institute of Biomedical Sciences, Academia Sinica, Taipei, Taiwan, [2]AIDS Prevention and Research Center, National Yang-Ming University, Taipei, Taiwan, [3]Department of Dermatology, University of California, Davis, CA, United States, [4]Department of Microbiology, Faculty of Medicine, College of Medicine,Kaohsiung Medical University, Kaohsiung, Taiwan.

Galectin-3 (Gal3), a β-galactoside-binding lectin, has been reported to regulate various immune functions. Furthermore, reports indicate that Gal3 expression is greatly induced by HIV-1 infection in T cells. However, the role of Gal3 in HIV-1 infection remains unclear. Lipid raft integrity plays a critical role in virological synapse formation during HIV infection, and previously we have demonstrated that endogenous Gal3 is accumulated in lipid rafts of dendritic cell surface membrane. Therefore, we hypothesized that galectin-3 may play a role in viral cell-to-cell transmission during virological synapse formation. Here, we show that Gal-3 was co-localized with Gag and Env in lipid raft at cell-to-cell junction of HIV-1-infected Magi5 (HeLa cells expressing CD4, CXCR4 and CCR5) and Hut78 $CD4^+$ T cells. In addition, results from conventional cell-to-cell transmission assay indicate that HIV-1 transmission efficacy is significantly attenuated in Gal3 knockdown Magi5 and Hut78 T cells ($p<0.05$). On the other hand, HIV-1 transmission efficacy is significantly increased by overexpression of Gal3 in Jurkat T cells ($p<0.05$). Moreover, Gal3-promoted HIV-1 cell-to-cell transmission efficacy is positively correlated with the expression level of Gal3 in the effector cells ($p<0.05$). Time-lapse confocal microscope indicates colocalization of Gal3-EGFP and HIV Gag-iCherry at virological synapses between effector and target cells. In addition, both Gal3-EGFP and Gag-iCherry were cotransmitted from the effector cells to the target cells via virological synapses. These results were confirmed by using human primary $CD4^+$ T cells. Altogether, our studies demonstrated an active role of Gal3 in HIV-1 cell-to-cell transmission and revealed a potential target for HIV-1 therapy.

Galectin 3 affects DCs:NKT cell interaction in the development of αGalCer-induced hepatitis

V. B. Volarevic[1]*, M. Milovanovic*[1]*, B. Simovic Markovic*[1]*, S. Bojic*[1]*, M. Stojanovic*[1]*, N. Arsenijevic*[1]*, G. Besra*[2]*, M. L. Lukic*[1]*;*
[1]Centre for Molecular Medicine and Stem Cell Research Faculty of Medical Sciences University of Kragu, Kragujevac, Serbia, [2]School of Biosciences, University of Birmingham, Birmingham, United Kingdom.

We used α-galactosylceramide (αGalCer) induced liver injury, well established murine models of NKT cell mediated hepatitis, to study the role of Galectin 3 (Gal-3) in acute liver injury.
We tested susceptibility to αGalCer-induced hepatitis in galectin-3-deficient (Gal-3KO) mice and wild-type (WT) C57BL/6 mice.
One microgram/mouse of αGalCer i.v. significantly enhanced expression of Gal-3 on dendritic cells (DCs) and NKT cells of WT mice. Gal-3KO mice were less sensitive to αGalCer-induced hepatitis as evaluated by liver enzyme test, histology, cytokine production and intracellular staining of immune cells in the liver. The level of IL-10 in the sera and percentage of IL-10-producing NKT cells were significantly higher in αGalCer-treated Gal-3KO mice. Percentage of liver infiltrating CD11c (+) DCs, CXCR3(+) DCs, CD1d(+) DCs and TNFα-, IFNγ-, and IL-12-producing DCs was significantly lower in αGalCer-treated Gal-3KO mice. In vitro, αGalCer-loaded DCs, isolated from livers of untreated Gal-3KO mice, produced significantly higher amounts of IL-10 and significantly lower amounts of IFNγ compared to DCs from WT mice confirming that. αGalCer-induced production of IL-10 and IFNy by DCs is Gal-3 dependent. Liver DCs (5x105/mouse) of untreated WT mice, but not from Gal-3KO mice, transferred in Gal-3KO recipient significantly enhanced αGalCer-induced hepatitis. Pretreatment of WT mice with a selective inhibitor of Gal-3 led to the attenuation of αGalCer-induced liver injury and provided similar effect as Gal-3 deletion.
Gal-3 plays an important pro-inflammatory role in αGalCer-induced hepatitis by affecting DCs:NKT cell interaction in the liver.

Inside-out and outside-in Fc receptors: impact on antibody therapy of cancer

J. H. W. Leusen*;*
University Medical Center Utrecht, Utrecht, Netherlands.

Fc receptors are an important bridge between the cellular and humoral branches of the immune system. Residing on monocytes, granulocytes, platelets, B lymphocytes, NK cells and dendritic cells, triggering of Fc receptors by complexed antibodies can lead to e.g. phagocytosis, respiratory burst, cytokine production and antigen presentation. Over the past decades, Fc receptors got more attention because of their important role in antibody therapy. Immunotherapy using monoclonal antibodies (mAb) has emerged as an excellent therapeutic strategy for cancer, immune deficiencies, immune regulation and autoimmunity. The first FDA-approved antibody for human neoplasia was Rituximab, targeting B-cell CD20 for treatment of non-Hodgkin's lymphoma and immune diseases.
An important mechanism of action of rituximab is antibody-dependent cellular cytotoxicity (ADCC), depending on Fc receptor bearing effector cells, such as NK cells and macrophages. In vitro also complement dependent cytotoxicity (CDC) and apoptosis induction are described as important mechanisms. The Immunotherapy group investigates the importance of these distinct effectormechanisms in vivo, including the possibility of apoptosis induction by crosslinking of Fc-receptors. For the latter purpose an transgenic mouse was developed, with normal expression of Fc receptors, but without the signaling of these receptors.(de Haij et al, Cancer Research 2010). Also the effectiveness of IgA as a novel isotype in antibody therapy is being explored in vivo (EMBO MM, in press). Knowledge of the biology of both IgG and IgA receptors is essential for these investigations.

IL1.13.02
Fc gamma Receptors: a 50 year anniversary

C. Sautes Fridman*;*
Centre de Recherche des Cordeliers, Paris, France.

Fcgamma R are an heterogeneous family of molecules of the Ig superfamily with effector and immunoregulatory functions. The Fcgamma RI bind IgG with high affinity whereas FcgRII, FcgRIII and FcgRIV (in the mouse) bind IgG immune complexes. They comprise several activating receptors characterized by an Immunoreceptor Tyrosine Activation Motif (ITAM) in their intracytoplasmic region or in their associated chains, and a unique single chain inhibitory receptor, FcgRIIB, with an Immunoreceptor Tyrosine Inhibition Motif (ITIM) in the intracytoplasmic domain.
Fcgamma R are expressed by most if not all cells of the immune system. The innate cell subpopulations co-express activating and inhibitory Fcgamma R, whereas B cells selectively express inhibitory FcgRIIB and NK cells mostly FcgRIII. Expression of FcgRII can be found on T lymphocytes as well. The ectopic expression of FcgRIIB can be found on some cancer cells such as in human metastatic melanoma.
I will present the FcgR family members and their functions to introduce the workshop.

W1.13.01
Role of IgG, IgG receptors and neutrophils in anaphylactic reactions

F. Jönsson[1,2]*, D. A. Mancardi*[1,2]*, P. Bruhns*[1,2]*;*
[1]Institut Pasteur, Paris, France, [2]Inserm U760, Paris, France.

Allergic reactions are generally considered to be triggered by the activation of mast cells or basophils, when IgE antibodies bound to their receptors (FcεRI) get crosslinked by specific antigens. Challenging this dogma, we could recently demonstrate that a murine model of allergic shock (anaphylaxis) depended primarily on IgG, IgG receptors and the activation of neutrophils (JCI 2011). Anaphylaxis was abolished in mice lacking all activating IgG and IgE receptors (FcRγ-/- mice). Interestingly, transfer of human neutrophils into

antigen-immunized FcRγ-/- mice restored a shock upon antigen challenge, suggesting a) that neutrophils alone can induce anaphylaxis, and b) that human neutrophils bare IgG receptors (FcγRs) responsible for this reaction.
Human neutrophils constitutively express FcγRIIA (CD32A) and can induce FcγRI (CD64) expression under inflammatory conditions. As both receptors are activating IgG receptors, we hypothesized that hFcγRIIA and/or hFcγRI could contribute to allergic reactions.
Using unique models of hFcγR-transgenic mice, we could show that both hFcγRIIA and hFcγRI were sufficient to induce anaphylactic reactions in mice. hFcγRI-induced anaphylaxis depended on the activation of neutrophils (Blood 2013), whereas both neutrophils and monocytes contributed to hFcγRIIA-triggered reactions. Supporting a role for these IgG receptors and neutrophils in human anaphylaxis, we found that human neutrophils released anaphylactogenic mediators upon stimulation with IgG immune complexes (Blood 2012).
Together our data suggest that IgG antibodies as well as their receptors, e.g. hFcγRIIA or hFcγRI, may contribute to these afflictions in humans and might therefore be novel targets for anti-allergic therapy.

W1.13.02
Role of the phagocytic synapse in the recognition of bacteria and the subsequent induction of Th17-responses

***M. N. Habets**, Z. Yang, H. elMoussaoui, M. I. de Jonge, D. A. Diavatopoulos;*
Radboud University Medical Centre, Nijmegen, Netherlands.

Airway infections caused by extracellular bacterial pathogens such as *Staphyloccus aureus* and *Streptococcus pneumoniae* cause millions of deaths every year. In response to pneumococcal replication, bacterial lysis occurs which leads to the release of many pathogen-associated molecular patterns. Immune cells may recognize soluble ligands (released during lysis) or intact bacteria and induce a local Th17 response, ultimately leading to bacterial clearance. The presence of opsonizing antibodies may also be relevant, as cross-talk between Fc gamma receptors and pattern recognition receptors signaling pathways may affect the ensuing cellular response.
The aim of this study is therefore to examine the immune response to soluble and particulated bacterial components and examine the effects of IgG. In the presence or absence of purified human IgG, primary human immune cells (PBMCs) were stimulated with surface-coated or soluble TLR/CLR ligands, including whole bacterial lysate. We then examined the early innate response (IL-6, TNFa, IL-23 and IL-1b) as well as the late cytokine response (IL17a, IFNg). Our results suggest that stimulation of PBMCs with surface-coated, but not soluble IgG induces production of TNFa, IL-1b and IL-17A. Co-stimulation with surface-bound IgG and Pam-3-CSK (either soluble or surface-bound) induced a synergistic IL-1b response compared to co-stimulation with either Pam-3-CSK or IgG alone, suggesting molecular cross-talk between FcγR and TLR signaling pathways. Currently, experiments are ongoing to identify the exact innate signaling pathways that lead to this synergistic effect in the context of the 'phagocytic synapse'.

W1.13.03
Anti-inflammatory activity of IVIg mediated through the activating FcγRIII (CD16) is induced by ITAMi signaling

***S. Ben Mkaddem**, M. Aloulou, U. Blank, R. C. Monteiro;*
Inserm U699, Paris, France.

Fc receptors are critical components of the innate immune system responsible for the recognition of cross-linked antibodies and the subsequent clearance of pathogens. However, in autoimmune diseases, these receptors play a role in the deleterious action of self-directed antibodies and as such are candidate targets for therapeutic approaches. Intravenous immunoglobulin (IVIg) has been used in the treatment of several autoimmune and inflammatory diseases. However, its mechanism of action remains incompletely understood. Here, we hypothesized that IVIg might induce its anti-inflammatory effects through inhibitory ITAM (ITAMi) signaling targeting activating Fc receptors bearing an ITAM in the FcR signaling adaptor. We demonstrated that interaction of FcR-associated mouse or human FcRIII with IgG1 or IVIg, or with bivalent anti-FcRIII $F(ab')_2$ reduced calcium responses, ROS production, endocytosis and phagocytosis, induced by heterologous activating receptors on monocytes/macrophages and $FcRIII^+$ transfectants. This inhibition required the ITAMi configuration of the FcRIII-associated FcR subunit and SHP-1 recruitment as shown by the formation of intracellular "inhibisome" clusters containing FcRIII and the targeted heterologous activating receptor. *In vivo,* anti-FcγRIII $F(ab')_2$ and IVIg lead to reduced renal inflammation and improved immune thrombocytopenic purpura in mice lacking FcRIIB. These results suggest that circulating IgG may continuously interact with FcRIII inducing ITAMi signaling to maintain immune homeostasis. These data support a new mechanism of action for IVIg and demonstrate the therapeutic potential of FcRIIIA targeting in inflammation and autoimmune diseases.

W1.13.04
Antibody opsonised pathogens profoundly alter secondary immune responses through cross-talk of TLRs and FcgammaRs

***J. Bakema**[1], K. Tuk[1], S. van Vliet[1], S. bruijns[1], J. Vos[1], S. Letsiou[2], C. Dijkstra[1], Y. van Kooyk[1], A. Brenkman[3], M. van Egmond[1];*
[1]VUMC, Amsterdam, Netherlands, [2]UmCu, Utrecht, Netherlands, [3]UMCU, Utrecht, Netherlands.

Cell-mediated mechanisms of the host defense, involving innate immunity and adaptive immune responses, are of crucial importance for the control of infectious pathogens. Pathogen recognizing receptors (PRR) play an essential role during innate or primary responses. In contrast, the presence of pathogen-specific antibodies during re-encounter with the same pathogen induces rapid uptake through binding to Fc-receptors (FcR) with concomitantly rapid clearance. The individual importance of these different classes of receptors is well studied. However, as immune cells will encounter antibody-opsonized bacteria during secondary responses, it's a challenging thought that simultaneous binding of their respective ligand can evoke cross-talk between the two receptor types.
We investigated this hypothesis during infection of dendritic cells with antibody-opsonized pathogens and by determining protein and metabolite profiles of the differentially activated dendritic cells as well as T_H-cell polarization. We demonstrate that antibody-opsonised pathogens evoke cross-talk between TLRs and FcRs, which induced profoundly altered release of multiple inflammatory cytokines, as well as eicosanoids metabolites. We observed redirection of T_H-1-subset towards T_H-17-subtype and intriguingly skewing towards GM-CSF producing T_H-cells. Furthermore, altered inflammatory cytokine profile was regulated on both transcription and post-transcriptional levels depending on the distinct cytokine. Finally, cross-talk was promiscuous between several TLRs and FcRs and was not constrained to dendritic cells.
These findings generate novel insights how secondary infections are resolved and that antibody opsonisation of bacteria particularly induces an inflammatory profile that favours recruitment, activation and prolonged survival of neutrophils at inflammatory sites.

Monocytes rather than NK-cells contribute to antibody mediated protection from MCMV infection

***A. Bootz**[1], T. Winkler[2], M. Mach[1];*
[1]Institute for Clinical and Molecular Virology, Friedrich-Alexander University Erlangen-Nürnberg, Erlangen, Germany, [2]Nikolaus-Fiebiger-Center for Molecular Medicine, Friedrich-Alexander University Erlangen-Nürnberg, Erlangen, Germany.

Cytomegalovirus is a clinically important pathogen. Previously we could show using murine cytomegalovirus (MCMV) that the adoptive transfer of immune serum into B- and T-cell deficient Rag-/- mice was highly effective against MCMV-induced morbidity and mortality. Antibodies can act either by direct neutralization of extracellular virus and/or by Fcγ receptor (FcγR)-mediated effector functions e.g. antibody-dependent cellular cytotoxicity (ADCC) and/or complement-dependent cytotoxicity (CDC).
To analyze the contribution of the FcγRs we used animals lacking the FcRγ-chain (FcγRxRag-/-), which is the accessory chain of the activating murine IgG receptors FcγRI, FcγRIII and FcγRIV. Following

serum therapy, FcγRxRag-/- mice developed high viral titers and showed a significantly shorter survival compared to the Rag-/- control mice indicating a substantial contribution of the Fcγ receptors in antibody protection. Animals lacking FcγRI, FcγRIII or FcγRIV individually were completely protected after immune serum therapy. Thus, NK cells which express only the FcγRIII seem not to participate significantly in antibody-mediated protection from MCMV. The depletion of NK cells in recipient mice confirmed this assumption. Mice lacking both, the FcγRIV and FcγRIII receptor developed high viral titers following serotherapy indicating redundant functions of the various FcγRs. Interestingly, adoptively transferred CD115+ monocytes from Rag-/- donors, bearing all activating Fc-receptors, into FcγRxRag-/- mice several days after immune serum treatment resulted in reduced viral titers in the recipient animals compared to the FcγRxRag-/- control mice. These results suggest an important role of monocytes in antibody mediated protection from MCMV infection.

W1.13.06
Swiprosin-1/EFhd2 is involved in the initial reaction of the IgE Fc receptor signal

Y. Mitsuhashi[1], *M. Hachiya*[2], *T. Aradate*[3], *Y. Yamanoi*[4], *M. Kanamori*[5], *A. Muraguchi*[6], *D. Mietenz*[7], *T. Katagiri*[4];
[1]*Dept Human Science 1 (Faculty of Medical Sciences) University of Toyama, Toyama, Japan,* [2]*Dept. Biology (Faculty of Pharmaceutical Sciences) University of Toyama, Toyama, Japan,* [3]*Dept. Medical Biology (Faculty of Pharmaceutical Sciences) University of Toyama, Toyama, Japan,* [4]*Dept. Biology (Faculty of Pharmaceutical Sciences) University of Toyama, Toyama, Japan,* [5]*Dept Human Science 1, (Faculty of Medical Sciences) University of Toyama, Toyama, Japan,* [6]*Dept. Immunology (Faculty of Medical Sciences) University of Toyama, toyama, Japan,* [7]*Nikolaus Fiebiger Center, University of Erlangen-Nürnberg, Erlangen, Germany.*

To elucidate the initial mechanism of IgE Fc receptor signaling, we searched novel molecules which localization in lipid rafts was increased by antigen stimulation. As a result, we identified a protein, Swiprosin-1. In this study, we aimed to reveal the function of Swiprosin-1 in FcεRI signaling. We knocked down Swiprosin-1 in rat basophilic leukemia 2H3 (RBL-2H3) cells, and analyzed the effect to degranulation. As a result, It was suppressed in KD cells, whereas ionomycin, PMA stimulation was not. To examine the function of Swiprosin-1 in more detail, we measured Ca^{2+} response. As a result, antigen-induced Ca^{2+} transient was suppressed in KD cells. However, ionomycin-induced Ca^{2+} response pattern was the same as WT cells. To investigate the effect to the upstream signal, we examined tyrosine phosphorylation signaling induced by stimulation FcεRI. Total protein tyrosine phosphorylation induced by antigen stimulation was suppressed in KD cells. However, TNF-α production, downstream of tyrosine phosphorylation, was not affected by KD. We used immunoprecipitation method to detect Swiprosin-1 associate protein(s), and found Approximately 50kDa tyrosine phosphorylated protein that was significantly appeared in stimulated RBL-2H3. Besides, we analyzed Swiprosin-1 associated proteins by MALDI TOF-MS and detected Vimentin. This result raises the possibility that the interaction between Swiprosin-1 and Vimentin regulates allergic reaction including IgE-mediated degranulation. Thus, elucidation of associated proteins and interaction leads to reveal the mechanism of allergic regulation.

W1.14 Cytokines and other regulatory mediators of inflammation

IL1.14.01
Endotoxin tolerance as a novel defence strategy in infectious diseases

F. Fallarino[1,1], *M. Gargaro*[1], *A. Bessede*[2], *D. Matino*[1], *G. Servillo*[1], *L. Tissi*[1], *L. Romani*[1], *U. Grohmann*[1], *P. Puccetti*[1];
[1]*University of Perugia, Perugia, Italy,* [2]*University of Bordeaux, Bordeaux, France.*

Analysis of disease tolerance pathways could provide new approaches for treating infections and other inflammatory diseases. Candidate pathways include sensors of pathogen presence, host metabolism, and intrinsic danger- or damage-associated molecules. Typically, an initial exposure to bacterial Lipopolysaccharide (LPS) induces a state of protective tolerance to further LPS challenge ("endotoxin tolerance"). The complex events
underlying this phenomenon remain poorly understood. Here we demonstrate that endotoxin tolerance reprograms Toll-like receptor 4 signaling *via* the combined effects of tryptophan catabolism, the ligand-operated Transcription factor aryl hydrocarbon receptor, and the cytokine transforming growth factor β. The protective, LPS-triggered tolerant state is not restricted to LPS-or gram-negative bacteria-induced immunopathology, in that it also specifically targets the inflammasome in a *Streptococcus*-induced multifocal septic arthritis model. Thus interfering with the trade-offs that the defense systems in both pathogens and their hosts impose on host fitness could ultimately help to selectively enhance pathways responsible for strong and rapid inflammatory responses that lead to fast pathogen clearance, yet do not involve immunopathology.

W1.14.01
Expression and regulation of IL-35 in human tolerogenic dendritic cells and its role in regulating T cells responses

K. O. Dixon[1], *S. van der Kooij*[1], *N. Schlagwein*[1], *D. Vignali*[2], *C. van Kooten*[1];
[1]*LUMC, Leiden, Netherlands,* [2]*St Jude`s Children`s Research Hospital, Memphis, TN, United States.*

IL-35 is a novel cytokine of the IL-12 family, existing as a heterodimer of IL-12p35 and EBV-induced gene 3 (Ebi3). IL-35 has regulatory properties and is produced by regulatory T cells in humans and mice, where it seems required for optimal suppression. Distinct from other IL-12 family members, expression of IL-35 has not been clearly described in antigen presenting cells. In view of its regulatory properties, we investigated the expression, regulation and function of IL-35 in human dendritic cells (DC) and tolerogenic DC (tolDC).
We generated tolDC by culturing monocyte-derived DCs in the presence of dexamethasone. These tolDCs did not produce detectable levels of bioactive IL-12p70 or the homodimer IL-12p40. In line with this, we demonstrate by Q-PCR that tolDC completely lack the expression of IL-12p40. However, tolDC maintain mRNA expression of IL-12p35 and Ebi3. Using intracellular FACS and western blot we confirm that tolDC maintain protein expression of both Ebi3 and IL-12-p35, which can be further enhanced upon stimulation with IFNγ, LPS and CD40 ligation. It was previously demonstrated that tolDC have the capacity to suppress T cell activation. We demonstrate that suppression can also be obtained with supernatant derived from tolDCs. Preliminary experiments using blocking antibodies and siRNA knockdown in tolDCs suggest that IL-35 contributes to regulatory function of tolDC.
Taken together, our results suggest that aside from increased expression of previously described tolerance inducing markers (B7-H1, ILT3) and increased IL-10 production, tolDC produce IL-35, providing an additional novel mechanism by which these cells elicit their tolerogenic potential.

W1.14.02
The BAFF/Th17 axis in Helicobacter pylori infection

F. Munari[1], *M. Fassan*[2], *M. Cassatella*[3], *M. de Bernard*[1];
[1]*Venetian Institute of Molecular Medicine, Padova, Italy,* [2]*Uninversity of Padova Department of Pathology, Padova, Italy,* [3]*Uninversity of Verona Department of Pathology, Padova, Italy.*

H. pylori (HP) infects the stomach and causes gastric pathologies such as chronic and autoimmune gastritis (AIG), ulcers, gastric MALT lymphoma and gastric cancer. Interestingly, studies carried out in humans and mice reveal that HP infection is followed by a mixed Th1/Th17 inflammatory response in gastric mucosa. Th17 cells are T lymphocytes with strong inflammatory effects that are involved in the pathogenesis of autoimmune diseases (AID).
B cells activating factor (BAFF), also is a crucial cytokine in B-cell development and survival but it is also up regulated in several AID. Recently, a relationship between the up regulation of BAFF and the rising of a Th17 response in AID in mice has been proposed, however the axis BAFF/Th17 in humans remains unknown.

In our study, we found that BAFF is up-regulated in macrophages infiltrating the gastric mucosa of HP infected patients; accordingly, IL-17, marker for the Th17 response, is similarly up-regulated in the presence of HP. We confirm that HP infected macrophages release BAFF in vitro. Other in vitro data show that BAFF could polarize human T cells toward the Th17 profile thorough an indirect action of monocytes; indeed, BAFF-treated monocytes release high amount of pro-Th17 cytokines (IL-6, TGF-β, IL-1β, and IL-23). These data are the first evidence for an involvement of BAFF in the Th17 cells differentiation in humans and suggest that the axis BAFF/Th17 inflammatory response in gastric mucosa could be the trigger of AIG in HP infected patient.

W1.14.03
Molecular basis of signaling through the IL-36 receptor

***E. J. Sundberg**;*
Institute of Human Virology, University of Maryland School of Medicine, Baltimore, MD, United States.

The IL-36 subfamily of cytokines and receptors, members of the larger IL-1 family, have recently been described as potent activators of BMDCs and TH1 cells and play a key role in psoriasis, a common severe skin disease. The IL-36 receptor (IL-36R) uses the IL-1 receptor accessory protein (IL-1RAcP) as a secondary receptor for signaling, the same RAcP as do IL-1 family receptors (e.g., IL-1R itself and ST2 - the IL-33 receptor). As it is engaged by three agonist interleukins (IL-36alpha, IL-36beta and IL-36gamma) and two antagonist interleukins (IL-36Ra and IL-38), IL-36R represents the most diverse axis for agonism and antagonism within the IL-1 receptor family. This group of interleukins likely follows similar mechanisms as do IL-1 and IL-33 to promote or inhibit interaction with IL-1RAcP. We have now solved the high-resolution X-ray crystal structures of human IL-36gamma and IL-38, providing insights to molecular mechanisms of agonism and antagonism of signaling through IL-36R. We have further dissected the requirements for differential signaling through interleukin loop swapping and mutagenesis coupled with interaction and functional analyses. These results suggest strategies for developing novel psoriasis therapeutics and refine the general model of activating and inhibitory IL-1 family receptor complexes.

W1.14.04
Intracellular signalling involved in IL-22 release by Dendritic Cells

***M. Foti**[1,2], S. Fumagalli[1], S. Citterio[1], C. Ripamonti[1];*
[1]University of Milano-Bicocca, Milano, Italy, [2]Genopolis Consortium, University of Milano-Bicocca, Milano, Italy.

The role of cytokines in immunoregulation and inflammation is well established and anticytokine terapies are now common in the treatment of chronic inflammatory diseases. However, it is necessary to define how cytokine function and how signalling pathways are regulated in different types of immune cells to understand underlying disease mechanisms. Here we show that dendritic cells (DCs) produce the cytokine IL-22 in response to Pattern Recognition Receptors (PRRs) stimulation and we characterize the signalling pathways that are engaged. Although it is known that innate lymphoid cells produce IL-22 under different conditions data on DCs are still unclear. The ability of DCs to produce IL-22 in response to TLRs and c-Type lectins receptors activation and their adaptor molecules has been characterized. We show that Jnk and Erk MAP kinases play a major role in IL-22 production whereas p38 is not implicated. By blocking NFkB with the inhibitor Bay11-7085, we confirmed that it takes part together with AP-1 in IL-22 production in DCs. Finally, we tested the activity of the aryl hydrocarbon (AhR) and RORgt receptors confirming a crucial role for AhR but not for RORgt. The data pointed out different intracellular IL-22 regulation mechanisms operating in DCs compared to innate lymphoid cells. In conclusion, our study provides the first evidence that DCs are able to produce IL-22 upon PRRs stimulation. Since IL-22 is highly dysregulated in chronic inflammatory conditions and correlated with disease activity, a better understanding of its regulation is important for development of IL-22 as a potential drug target.

W1.14.05
Environmental conditions perceived by the brain alter CD4+ T cell responses through an adiponectin-dependent mechanism

***M. M. Canali**, J. A. Soria, E. Murris, J. Chabry, A. Guyon, A. Paitel, N. Zsürger, E. Mougneau, N. Glaichenhaus;*
IPMC CNRS, Sophia Antipolis, Valbonne, France.

We are interested in elucidating how the brain controls the immune system. To this aim, we have established and validated an environmental enriched (EE) paradigm in which C57BL/6 mice experience higher levels of sensory, motor, social, and cognitive stimuli, compared to animals housed in a standard environment (EE). In agreement with previous studies, we found that EE increased hippocampal neurogenesis and synaptogenesis at the cellular level, and decreased anxiety and increases exploratory activity at the behavioral level. EE housing did not result in gross alterations in the frequency of neutrophils, dendritic cells (DC), macrophages, Natural Killer (NK), CD4(+) and CD8(+) T cells and B lymphocytes in the lymphoid organs of immunologically naïve animals. However, both DC and NK cells expressed a more mature phenotype in EE animals. Furthermore, EE mice exhibited both a Th2-biaised T response upon immunization with OVA and a more robust memory T cell response. To elucidate the mechanisms that were responsible for these latter phenomena, we compared the levels of various metabolites in the serum of EE and SE mice. Compared to SE mice, EE animals exhibited increased levels of adiponectin, a cytokine that is mainly secreted by adipose tissue and that modulates a number of metabolic processes, including glucose regulation and fatty acid oxidation. Most importantly, adiponectin-deficient mice housed in EE did not exhibit the Th2-biaised immune response that was observed in wild-type (wt) mice therefore suggesting a critical role of this cytokine in EE-induced immune alterations.

W1.14.06
The non-specific and sex-differential immunological effects of the Bacillus Calmette-Guerin (BCG) vaccine in infants

***K. J. Jensen**[1,2], N. Larsen[3], S. Biering-Sørensen[1,2], H. B. Eriksen[1,2], M. J. Jørgensen[1], D. Hougaard[3], K. Flanagan[4], P. Aaby[5], C. S. Benn[1,2];*
[1]Bandim Health Project, Copenhagen, Denmark, [2]Center for Vitamins and Vaccines, Copenhagen, Denmark, [3]Statens Serum Institut, Copenhagen, Denmark, [4]Monash University, Melbourne, Australia, [5]Bandim Health Project, Bissau, Guinea-Bissau.

Introduction: Vaccine efficacy is almost exclusively evaluated based on specific effects. However, investigation of overall effects of vaccines is pivotal, as it can help optimizing current vaccine programs, especially in countries with high disease burden. The Bacillus Calmette-Guerin (BCG) vaccine against tuberculosis is one of the most widely used vaccines in the world. A recent randomized trial from Guinea-Bissau found that BCG provided at birth to low-birth-weight (LBW) neonates reduces neonatal mortality by 45%. Our observations cannot be explained by protection against tuberculosis; the main causes of death were septicaemia and pneumonia, and the effects occurred too quickly to be related to tuberculosis. Hence, BCG has beneficial non-specific effects on the immune system. Whereas the overall effect may be stronger in girls, the reduction in mortality is apparent already within 3 days after BCG particularly in boys, suggesting that non-adaptive mechanisms are involved.
Objective: The present study will shed light on how BCG modulates fundamental immunological functions in infants in a non-specific and possibly sex-differential manner.
Methods: 400 LBW infants in Guinea-Bissau were randomized to BCG at birth or the usual postponed BCG. The infants were bled at 4 weeks (before the control group received BCG) and at 10 weeks of age. Pro-inflammatory, Th1-, Th2-, Th17-related, and anti-inflammatory cytokine responses to common recall antigens and innate agonists are investigated in whole-blood assays. Moreover, common haematological and cytochemical values are analysed.
Results: The laboratory analyses are ongoing. Data will be presented at the congress.
Conclusion: Yet awaiting results of the analyses.

W1.15 Inflammasome

IL1.15.01
Role of inflammasomes for chronic inflammatory diseases

E. Latz[1,2];
[1]*Institute of Innate Immunity, University of Bonn, Bonn, Germany,*
[2]*UMass Medical School, Worcester, MA, United States.*

Innate immunity evolved to recognize microbial infection and to respond to danger signals that appear under disease conditions. The most recently described innate immune receptor family is the Nod-like receptor (NLR) family. The NLR member NLRP3 and the adapter protein ASC form a multi-molecular complex termed the NLRP3 inflammasome. Inflammasomes control the activity of caspase-1, which cleaves and activates the pro-form of the inflammatory cytokines IL-1b and IL-18. The NLRP3 inflammasome can be activated by various membrane active bacterial toxins or after phagocytosis of crystalline materials. In addition, various microbes can activate the NLRP3 inflammasome. The mechanisms by which the NLRP3 inflammasome is activated by physico-chemical diverse activators are not well understood.
We demonstrated that crystals activate the NLRP3 inflammasome in a process that requires phagocytosis and we found that crystal uptake leads to lysosomal damage and rupture. Furthermore, sterile lysosomal damage was also sufficient to induce NLRP3 activation and inhibition of phagosomal acidification or inhibition or lack of cathepsins impaired NLRP3 activation. These results indicate that the NLRP3 inflammasome can sense lysosomal damage as an endogenous danger signal. Using different approaches including chemical biology screens, interactome analysis and RNA interference we are currently studying the mechanisms of NLRP3 activation.

IL1.15.02
Inflammasome activators induce the secretion of IL-1α via two distinct pathways displaying differential requirement for a protease activity-independent function of caspase-1

O. Groß;
Klinikum rechts der Isar, München, Germany.

Through their capacity to sense danger signals and to generate active IL-1β, inflammasomes occupy a central role in the inflammatory response. In contrast to IL-1β, little is known about the regulation of IL-1α activity. Unexpectedly, we find that inflammasome activators also induce the regulated secretion of IL-1α, thus leading to the co-secretion of both IL-1 cytokines. Depending on the type of inflammasome activator, release of IL-1α is inflammasome/caspase-1-dependent or -independent. Unlike for IL-1β, calcium influx, induced by the opening of cation channels such as TRPV2, suffices for the inflammasome-independent IL-1α activation. In both cases IL-1α is released primarily in a processed form, caused by a calpain-like protease. Remarkably, caspase-1-dependent release of IL-1α and IL-1β is independent of caspase-1 catalytic activity, defining a novel function for caspase-1. Considering the involvement of inflammasomes in chronic inflammatory diseases such as gout and diabetes, the use of IL-1α antagonists may be beneficial in the treatment of these disorders.

W1.15.01
Cytosolic cathepsin inhibitor Stefin B (Cystatin B) regulates NLRP3 inflammasome activation

K. Maher, *B. Jeric, B. Turk, N. Kopitar Jerala;*
Jozef Stefan Institute, Ljubljana, Slovenia.

Pathogen-associated molecular patterns are recognized by innate immune receptors that are membrane bound Toll-like receptors (TLRs) and cytosolic Nod-like receptors (NLRs). Members of NLR family and adaptor ASC form inflammasomes, required for pro-inflammatory caspase-1 self activation and interleukin (IL)-1β maturation.
Cathepsins are proteases responsible for protein breakdown within lysosomes, recently cathepsin B was suggested to be involved in inflammasome activation. Cathepsin inhibitor stefin B (cystatin B) is located in the cytosol and nucleus, where it has protective role. Mutations in the gene of stefin B are associated with the neurodegenerative disease known as progressive myoclonus epilepsy (EPM1). Recently, it was reported that early microglial activation precedes neuronal loss in the brain of the stefin B deficient mice.
In our study, we demonstrate that Stefin B deficient mice secrete significantly higher amounts of pro-inflammatory cytokines (IL-1β, TNF-α, IL-6) upon LPS challenge. We further show that stefin B-/- bone marrow macrophages (BMM) exhibit increased caspase-1 and 11 activation and better IL-1β processing upon NLRP3 inflammasome activation. Moreover, in ATP stimulated BMM we observed lysosomal destabilization (but not disruption) and release of the lysosomal content. Cytosolic cathepsin B activity was higher in stefin B-/- BMM and cathepsin inhibition resulted in attenuated IL-1β levels.
We hypothesize that the same signalling pathways determined in macrophages are also functional in microglia that are important in the pathology of neurodegenerative disease. Elucidation of the stefin B role on cytokine synthesis in macrophage model will contribute to the better understanding of the pathology of the EPM1 disease.

W1.15.02
The inflammasome adaptor ASC forms a prion-like danger signal that perpetuates inflammation

B. S. Franklin[1], *D. De Nardo*[1], *G. Horvarth*[1], *S. Zimmer*[2], *S. Hornemann*[3], *A. Aguzzi*[4], *E. Latz*[1,5];
[1]*Institute of Innate Immunity, University of Bonn, Bonn, Germany,* [2]*4Department of Medicine/Cardiology, University of Bonn, Bonn, Germany,* [3]*Institut für Molekularbiologie und Biophysik, ETH Zürich, Zürich, Switzerland,* [4]*UniversitätsSpital Zürich, Institute of Neuropathology, Department of Pathology, Zurich, Switzerland,* [5]*University of Massachusetts Medical School Division of Infectious Diseases & Immunology, Worcester, MA, United States.*

Upon activation, most of the inflammasome sensors interact with the adaptor molecule Apoptosis associated speck-like containing a CARD domain (ASC) which, in turn, recruits procaspase-1 leading to its autoproteolytic activation. ASC recruitment to the inflammasome sensors is followed by its rapid self-assembly into a large protein complex, the so-called “speck” or “pyroptosome”. Activation of caspase-1 in the ASC pyroptosome results in a special type of cell death, termed pyroptosis. Although it is well known that such cell death is accompanied by release of cellular content into the extracellular medium, the fate of the assembled ASC pyroptosome after cell demise remains unknown. Here we show that shortly after inflammasome activation, ASC specks containing a whole inflammasome assembly of ASC, NLRP3 and pro-caspase-1 are released from pyroptotic cells into the extracellular space. The released ASC specks remain biologically active in the extracellular medium and are capable of amplifying inflammation by processing pro-caspase-1 and pro-IL-1β into their mature forms. Furthermore, extracellular specks are sensed as danger signals and phagocyted by surrounding immune cells. Phagocyted ASC specks induce lysosomal rupture and potentiate production of IL-1β in recipient cells. Moreover, pre-aggregated ASC specks have prion-like properties and can recruit and nucleate endogenous ASC in recipient cells. Finally, extracellular specks are found in bronchoalveolar lavage from patients with chronic obstructive pulmonary disease (COPD). Together, our results reveal an important and unprecedented feature of the inflammasome adaptor ASC and extend our understanding of its function in innate immunity.

W1.15.03
The NLRP3 inflammasome links complement-mediated inflammation and IL-1β release

F. Laudisi[1], *R. Spreafico*[1], *M. Evrard*[1], *B. Mandriani*[1], *S. Baalasubramanian*[2], *A. Mortellaro*[1];
[1]*Singapore Immunology Network (SIgN), A*STAR, Singapore, Singapore,* [2]*Singapore Institute for Clinical Sciences (SICS), A*STAR, Singapore, Singapore.*

The complement system is a potent component of the innate immune response, promoting inflammation and orchestrating defense against

pathogens. However, dysregulation of complement is critical to several autoimmune and inflammatory syndromes, including lupus, rheumatoid arthritis, glomerulonephritis, vasculitis and angioedema. Elevated expression of the pro-inflammatory cytokine IL-1β is often also linked to such diseases. In this study we reveal the mechanistic link between complement and IL-1β secretion using murine dendritic cells. IL-1β secretion occurs following intracellular caspase-1 activation by large multi-protein complexes, named inflammasomes. Here we show that complement elicits secretion of both IL-1β and IL-18 in vitro and in vivo via the NLRP3 inflammasome. This effect is dependent on the inflammasome components NLRP3 and ASC, and caspase-1 activity. Interestingly, sub-lethal complement membrane attack complex formation, but not the complement activation products C3a and C5a, activated the NLRP3 inflammasome and promoted IL-1β release by transient K+ efflux and production of reactive oxygen species. These findings provide insight into the molecular processes underlying complement-mediated inflammation and highlight the possibility of targeting IL-1β to control complement-induced disease and pathological inflammation.

W1.15.04
Fas-mediated inflammatory response in *Listeria monocytogenes* infection

***R. Uchiyama**, H. Tsutsui;*
Hyogo college of Medicine, Department of Microbiology, Nishinomiya, Japan.

The molecular mechanisms of Fas (CD95/Apo-1)-mediated apoptosis are increasingly understood. However, the role of Fas-mediated production of pro-inflammatory cytokines such as IL-18 and IL-1β in bacterial infection is unclear. In this study, we demonstrate the importance of Fas-mediated signaling in IL-18/IL-1β production following infection with *Listeria monocytogenes* (LM). *Fas*$^{-/-}$ mice were more susceptible to LM infection than normal mice *in vivo*, and the elevation of IL-18 was lower in sera from *Fas*$^{-/-}$ mice infected with LM than from normal mice. In addition, IL-18/IL-1β production in LM-infected peritoneal exudate cells (PECs) from Fas-deficient mice was lower than those from Wt mice *in vitro*, indicating that Fas-signaling contributes to cytokine production in response to LM infection. LM infection induced Fas ligand (FasL) expression on NK cells, which stimulates Fas expressed on the infected macrophages, leading to the production of IL-18/IL-1β. This was independent of caspase-1, -11, and nucleotide-binding domain- and leucine-rich repeat-containing receptors (NLRs) such as Nlrp3 and Nlrc4, but dependent on apoptosis-associated speck-like protein containing a caspase recruitment domain (Asc). Upon infection with LM, Wt cells exhibited caspase-8 activation, while Fas deficient cells did not. LM-induced caspase-8 activation was abrogated by inhibitor for intracellular reactive oxygen species (ROS), *N*-acetyl-$_L$-cysteine (Nac). These results indicate the possibility that LM infection induced the activation of caspase-8 via Fas signaling in ROS-dependent manner, and the activated caspase-8 cleaved pro-IL-18/IL-1β to produce active cytokines. This study revealed a novel role of Fas in the induction of the inflammatory response against LM infection.

W1.15.05
TLRS-induced PAI-2 expression suppresses NLRP3-dependent caspase-1 activation and IL-1B processing

***L. Hsu**, S. Chuang, C. Yang, C. Lee, C. Chou;*
National Taiwan University, Taipei, Taiwan.

The NLRP3 inflammasome, a multiprotein complex, triggers caspase-1 activation and maturation of proinflammatory cytokines IL-1β and IL-18 upon sensing a wide range of pathogen- and damage-associated molecules. Dysregulation of NLRP3 inflammasome activity contributes to the pathogenesis of many diseases, but its regulation remains poorly defined. Plasminogen activator inhibitor 2 (PAI-2), a member of a large group of proteins that inhibit serine proteases, is regulated by IKKβ-dependent activation of the transcription factor NF-κB. Previous studies demonstrated that mice with *Ikkβ* deletion in myeloid cells are hypersusceptible to endotoxin (LPS)-induced septic shock, and increased LPS susceptibility is associated with elevated plasma IL-1β. Reconstitution of *Ikkβ*-deficient macrophages with PAI-2 blocks IL-1β release after LPS stimulation. To further elucidate the physiological role of PAI-2 in LPS-induced septic shock, we generated transgenic mice that specifically express PAI-2 in myeloid cells, and then crossed this transgenic mice with myeloid-deleted *Ikkβ* mice. PAI-2 expression decreased plasma IL-1β in myeloid-deleted *Ikkβ* mic after LPS challenge. In addition, PAI-2 transgenic mice showed a decrease in circulating IL-1β level upon *Escherichia coli* infection. We also demonstrated that depletion of PAI-2 in macrophages resulted in NLRP3- and ASC-dependent caspase-1 activation and IL-1β secretion in macrophages in response to TLR activators and *E. coli* infection with no need of a second stimulus. Together, our data identify a new tier of TLR signaling in controlling NLRP3 inflammasome activation.
This work was supported by grants from National Science Council, Taiwan (NSC100-2320-B-002-096-MY3).

W1.15.06
NLRP3 controls Trypanosoma cruzi infection through a caspase-1-dependent IL-1R-independent NO production.

***K. R. Bortoluci**[1], V. M. Gonçalves[1], K. C. Matteucci[1], B. H. Miollo[1], C. L. Buzzo[1], D. Ferrante[1], J. M. Alvarez[2], M. M. Rodrigues[1];*
[1]Federal University of São Paulo, Sao Paulo, SP, Brazil, [2]University of São Paulo, Sao Paulo, SP, Brazil.

Introduction: *Trypanosoma cruzi* is an intracellular protozoan parasite and etiological agent of Chagas disease, a severe and chronic infectious illness that affects millions of people in the world. Although the role of TLR and Nod1 in controlling infection by *T. cruzi* is well established in the literature, there is no data about the involvement of inflammasomes. **Methods and Results:** In this study, we evaluated the participation of NLRP3 and caspase-1 in host response to *T. cruzi* infection and found that NLRP3$^{-/-}$ and caspase1$^{-/-}$ mice are susceptible to infection. Although inflammatory cytokines IL-6 and IFN-γ were found in spleen cells from NLRP3$^{-/-}$ and caspase1$^{-/-}$ infected mice, these mice displayed a defect in the production of nitric oxide (NO), which impairs the parasitic capacity of their macrophages. In fact, macrophages from NLRP3$^{-/-}$ and caspase-1$^{-/-}$ are more permissive to *T. cruzi* replication than the MyD88$^{-/-}$ ones. The inhibition of caspase-1 with z-YVAD-fmk, but not the neutralization of IL-1R abrogated the NO production by WT and MyD88$^{-/-}$ macrophages and renders them as susceptible as NLRP3$^{-/-}$ and caspase-1$^{-/-}$ cells to *T. cruzi* replication. **Conclusion:** Taken together our results demonstrate the role of iNLRP3 inflammasome for the control of *T. cruzi* and point out the caspase-1-dependent NO production as a new effector mechanism for these innate receptors.

Microbial manipulation of select host signaling pathways to disengage immune bacterial clearance from inflammation

***G. Hajishengallis**[1], T. Maekawa[1], J. L. Krauss[2], K. B. Hosur[1], J. D. Lambris[1];*
[1]University of Pennsylvania, Philadelphia, PA, United States, [2]University of Louisville, Louisville, KY, United States.

Porphyromonas gingivalis (Pg) is a keystone pathogen that enhances the pathogenicity of the multispecies periodontal community through the disruption of host-microbe homeostasis. In so doing, Pg manipulates select host signaling pathways to impair host immunity without significantly affecting the host inflammatory response, which serves the nutritional needs of the bacteria (inflammatory tissue breakdown products and hemin-derived iron). However, the molecular mechanism(s) by which Pg can selectively inhibit immune elimination without blocking inflammation has remained obscure. I will present our latest data that support a model according to which Pg can disarm and disassociate a host-protective TLR2-MyD88 pathway from a TLR2-PI3K proinflammatory pathway that promotes Pg survival. Specifically, our findings indicate that Pg causes MyD88 degradation in a C5a receptor- and TLR2-dependent manner, resulting in decreased killing of Pg by neutrophils. Moreover, the same Pg-

induced C5aR-TLR2 crosstalk induces PI3K signaling which inhibits Pg phagocytosis by neutrophils and promotes the induction of a non-host protective proinflammatory response. This subtle manipulation of host signaling pathways is a matter of life and death for Pg and co-habiting species. If Pg caused generalized immunosuppression, this would inhibit bacterial killing, but would also deprive the bacteria of critical nutrients derived from inflammatory tissue breakdown. These findings indicate that periodontal bacteria have evolved to evade host immunity in an inflammatory environment that is essential to their persistence but - at the same time- causes collateral damage to the tissues causing periodontitis.

W1.16.01
C3 opsonisation enhances apoptotic cell-associated antigen presentation by DCs by controlling the endocytic handling

L. Baudino[1], *A. Sardini*[2], *M. Ruseva*[1], *L. Fossati-Jimack*[1], *D. Scott*[1], *T. Cook*[1], *M. Botto*[1];
[1]*Centre for Complement and Inflammation Research, Department of Medicine, Imperial College, London, United Kingdom,* [2]*Molecular Sciences, Institute of Clinical Science, Imperial College, London, United Kingdom.*

Apoptotic cells are considered a potential source of auto-antigens and can efficiently deliver an antigen load to dendritic cells (DCs). *In vivo* they are rapidly removed by macrophages and defective clearance may lead to autoimmunity. Complement has been shown to contribute to the uptake of apoptotic cells by macrophages but not by DCs. Complement C3-deficient (C3-/-) DCs have been shown to exhibit reduced potency to stimulate T cell responses but the underlying mechanism(s) remains unclear. Here, we investigated the role of C3 in the T cell response to apoptotic cell-associated antigens by feeding C3-deficient or C3-sufficient DCs from C57BL/6 mice ($H2\text{-}A^b$) with allogeneic $H2\text{-}E^+$ apoptotic B cells (from BALB/c mice) and assessing presentation and priming using the Y-Ae monoclonal antibody (specific for a peptide from the MHC molecule $H2\text{-}E^+$ molecule presented by $H2\text{-}A^b$) and 1H3 TCR transgenic T cells (same specificity as the Y-Ae mAb). Using this model we found that the lack of C3 did not affect the uptake of apoptotic cells by DCs but rather controlled the intracellular trafficking by accelerating the association of the apoptotic cargo with lysosomes. Consistent with this, C3 deficiency resulted in reduced antigen-specific T cell proliferation *in vitro* and *in vivo*. Notably, pre-opsonisation of apoptotic cells with exogenous C3 rectified the trafficking and T cell priming defects in C3-/- DCs. These data indicate that activated C3 may act as a "chaperone" in the intracellular processing of apoptotic cells and may modulate the fate of self-antigens displayed on dying cells.

Follicular dendritic cells are essential for maintenance of autoreactive B cells

B. A. Heesters[1,2], *P. Chatterjee*[1], *N. Dwivedi*[1], *A. Das*[1], ***M. C. Carroll***[1,3];
[1]*The Program in Cellular and Molecular Medicine, Boston Children's Hospital, Boston, MA, United States,* [2]*Medical Microbiology, University Medical Center Utrecht, Utrecht, Netherlands,* [3]*Harvard Medical School, Department of Pediatrics, Boston, MA, United States.*

Formation of germinal centers within secondary (and tertiary) lymphoid tissues is a hallmark of an ongoing B cell response to foreign and self-antigen. Recently, we identified a novel pathway by which FDC endocytose and cycle foreign antigen via complement receptors CD21/CD35 and periodically present it to cognate B cells. To test whether this pathway was required for maintenance of autoreactive B cells, we have used multiple approaches to disrupt FDC retention of self-antigen. For example, in 564 Igi knock-in mice (Berland et al 2006 *Immunity*), that are specific for nucleolar RNP such as SSB/LA, a small fraction of autoreactive B cells escape anergy, mature and form GC in spleen and lymph nodes in a TLR 7-dependent pathway. Strikingly, ablation of FDC, disruption of their maturation or blockade of the CD21 receptor in the 564 Igi mice leads to a rapid loss of mature autoreactive B cells relative to endogenous non-autoreactive B cells. We propose that autoreactive B cells are highly sensitive to the presence of self-antigen retained by FDC and that disruption of their contact leads to rapid elimination. Although not mutually exclusive, it is possible that FDC secretion of cytokines, *e.g.* IL-6, IFNγ, or growth factors such as BAFF are critical for survival of the autoreactive B cells. Current studies are in progress to dissect the role of FDC in maintenance of the lupus-antigen specific B cells.

Response gene to complement-32 mediates C5b-9 induced cell cycle activation and migration in endothelial cells

C. A. Tegla[1,2], *C. D. Cudrici*[1], *T. Ito*[1], *V. Nguyen*[1], *V. Rus*[1], *F. Niculescu*[1], *H. Rus*[1,3,2];
[1]*University of Maryland School of Medicine, Baltimore, MD, United States,* [2]*Veterans Affairs Maryland Health Care System, Baltimore, MD, United States,* [3]*Veterans Administration Multiple Sclerosis Center of Excellence East, Baltimore, MD, United States.*

Proliferation of endothelial cells (EC) and smooth muscle cells (SMC) are critical events involved in angiogenesis and atherosclerosis. We have previously shown that activation of complement and assembly of sublytic C5b-9 induced cell cycle activation in both aortic EC and SMC. We also found that sublytic C5b-9 induces the expression of Response Gene to Complement (RGC)-32 and that its overexpression leads to cell cycle activation. We investigated the role of endogenous RGC-32 in cell cycle activation by C5b-9. Silencing of RGC-32 expression, using siRNA, abolished C5b-9 induced DNA synthesis indicating that RGC-32 is required for cell cycle activation and S-phase entry in human aortic EC. In addition we found that RGC-32 is involved in C5b-9 induced EC migration. In order to identify the genes that are regulated by RGC-32 and involved in cell cycle activation we used gene array analysis and investigated the effect of RGC-32 knockdown on gene expression in human aortic EC. Of the 234 genes that were differentially expressed after RGC-32 knockdown, a group of genes involved in cell adhesion and cell cycle growth were the most significantly regulated by RGC-32. RGC-32 knockdown induced a decrease in the expression of cyclin D1, cyclin D3, Akt, ROCK1, Rho GDP dissociation inhibitor alpha and profilin. RGC-32 appears to mediate aortic EC migration through regulation of RhoA and ROCK1 expression. Since RGC-32 seems to play an important role in human aortic EC proliferation and migration, targeting RGC-32 is a potential therapeutic intervention in angiogenesis and atherosclerosis.

W1.16.04
Soluble GC1QR is an autocrine signal which induces bradykinin receptor 1 (B1R) expression on activated endothelial cells

B. Ghebrehiwet[1,2], *Y. Jl*[1], *K. Hosszu*[1], *A. Valentino*[1], *E. I. B. Peerschke*[2];
[1]*Stony Brook University, Stony Brook, NY, United States,* [2]*Memorial Sloan-Kettering Cancer Center, New York, NY, United States.*

The endothelial cell (EC) receptor complex for high molecular weight kininogen (HK) comprises cytokeratin 1, urokinase-type plasminogen activator receptor (uPAR), and the receptor for the globular heads of C1q (gC1qR), and is essential for the assembly and activation of the kinin-kallikrein system (KKS). Of these, gC1qR serves as high affinity site for HK—the bradykinin (BK) precursor—and plays a critical role in triggering the KKS leading to the generation of bradykinin (BK). Bradykinin, which belongs to the kinin family of proinflammatory peptides, is one of the most potent vasodilator agonists known, and induces its activity via two G-protein-coupled receptors: bradykinin receptor 1 (B1R) and B2R. While B2R is constitutively expressed on many healthy cell types, IL-1 induces B1R after tissue damage. Because gC1qR is secreted by activated ECs, and soluble gC1qR (sgC1qR) binds to cells, we hypothesized that sgC1qR may serve as an autocrine/paracrine signal for the induction of B1R. Our results show that: 1) sgC1qR binds to microvascular ECs via a highly conserved gC1qR domain (aa174-180), and deletion of this domain abolishes sgC1qR binding as assessed by deconvolution fluorescence microscopy. 2) Incubation of ECs (2h and 24h) with sgC1qR resulted in a dose-dependent B1R expression (24h>2h) in a manner that suggested *de novo* synthesis. 3) More importantly, a

peptide corresponding to residues 174-180 also mimicked the effects of sgC1qR. Therefore at sites of EC activation, sgC1qR may provide an additional signal for B1R expression and could represent a potential target for therapy against BK-mediated inflammation and vascular permeability.

W1.16.05
Role of the long Pentraxin PTX3 in fibrosarcoma development and progression

E. Bonavita[1]*, S. Gentile*[1]*, N. Polentarutti*[1]*, F. Feruglio*[1]*, F. Pasqualini*[1]*, M. Nebuloni*[2]*, S. Jaillon*[1]*, A. Mantovani*[1,3]*, C. Garlanda*[1]*; [1]Humanitas Clinical and Research Center, Rozzano (MI), Italy, [2]L. Sacco Department of Medical Sciences,University of Milan, Milan, Italy, [3]Department of Translational Medicine, University of Milan, Milan, Italy.*

Pentraxins (PTXs) are prototypic components of the humoral arm of innate immunity and constitute a superfamily of multifunctional multimeric proteins phylogenetically conserved from arachnids to mammals. The prototypic long pentraxin PTX3 plays a fundamental role in innate immunity, in regulation of the inflammatory response and in tissue remodeling, through different molecular mechanisms, including Complement regulation, P-selectin-dependent leukocyte recruitment and FGF2-regulation.
Inflammatory responses play decisive roles at different stages of tumor development, including initiation, promotion, malignant conversion, invasion and metastasis. PTX3 is produced by diverse cell types present in the tumor stroma such as leukocytes, endothelial cells and fibroblasts. To define the role of PTX3 in tumor development, we investigated the susceptibility to 3-Methylcholanthrene-induced fibrosarcoma or transplanted fibrosarcomas in Ptx3-/- and wild type mice. PTX3-deficiency was associated with increased tumor incidence, fast tumor growth and higher inflammatory response (e.g leukocyte recruitment, inflammatory cytokines). Furthermore, the analysis of tumors reveled increased complement C3 and reduced Factor H deposition in PTX3-deficient mice, in agreement with the complement-regulatory function of PTX3. Finally, the genetic analysis of “hot” genes Tp53 and K-ras, classically mutated by 3-MCA, showed that PTX3-deficiency was associated with higher mutation frequency, possibly due to polyclonality of the lesions.
All together, these results suggest that the regulation of inflammation mediated by PTX3 could play a crucial role in fibrosarcoma development. Mechanisms potentially involved in the mentioned phenotypes, which range from regulation of angiogenesis, complement deposition, leukocyte recruitment and gene instability are currently under investigation.

W1.16.06
Dendritic cell alternative pathway production is differentially regulated by Interferons & IL-27

J. O`Flynn*, K. Dixon, N. Klar Mohamad, M. R. Daha, C. van Kooten; Leiden University Medical Centre, Leiden, Netherlands.*

Dendritic cells (DCs) and complement are both key members of the innate immune system, and recent experimental mouse models have shown that production of alternative pathway (AP) components by DCs strongly affects local T cell populations. The diverse functions of DCs are not only dependent on their mode of activation,but also strongly influenced by intrinsic differences between subtypes. In this study we investigated the production and regulation of factor P (fP), and H (fH), integral components of the AP, by both human DC and tolerogenic DCs (tolDCs).
We demonstrated by Q-PCR and ELISA that tolDCs expressed significantly elevated levels of fP and fH compared to DCs. Moreover FACS analysis and confocal imaging showed that DC, and particularly tolDC, derived fP was functionally active as shown by binding to necrotic cells and C3b.
We investigated the possible regulators of DC derived AP factors and found that IFNγ possesed a dual role, downregulating fP while also upregulating fH. Stimulation with TLR agonists including LPS did not effect either fP or fH.
IL-27 has been shown to share some functional characteristics with IFNγ. Interestingly while IFNγ (type II IFN) and IL-27 significantly increased production of fH in both DCs, IFNβ (type I IFN) significantly downregulated fH production. While fP production was significaty downregulated by IFNγ in both DC subsets this was not observed for IL-27 or IFNβ.
In summary, this study reveals a novel role of IFNs and IL-27 in regulating local complement production by DCs through differential affects on fP and fH.

W1.17.01
Novel regulatory control of IgE antibody responses in vivo

D. Butt*, T. Chan, R. Brink;*
Garvan Institute of Medical Research, Sydney, Australia.

IgE antibodies bind to receptors on mast cells and basophils priming them to degranulate and release inflammatory mediators upon interaction with cognate antigen. IgE antibody responses offer protective immunity against parasite infection, though they are best known for their critical role in the acute and severe reactions suffered by patients with asthma and other allergies. Despite the central role of IgE in asthma pathogenesis, relatively little is known about the regulation of IgE production in vivo. Whilst investigations into the role of T helper (TH) cells and the innate immune system have shown some promise a detailed knowledge of the nature of the IgE-switched B cells and plasma cells together with the mechanism underlying their differentiation will be critical to the development of more effective strategies for asthma treatment and prevention. To gain greater insight into the biology of IgE-switched B cells we have developed and made use of a powerful in vivo mouse model to characterise antigen-specific IgE-switched B cells within the context of the local environmental and molecular cues that guide their differentiation. Using this experimental system our results reveal a novel role for a mutated protein previously not known to be involved in the regulation of IgE antibody production in vivo suggesting a new paradigm for considering the causes of allergies and the development of treatments for these diseases. Our ongoing studies to interrogate the unique function of this gene in tuning B cell responses to suppress IgE production within the germinal center microenvironment will be presented.

W1.17.02
Basophil-derived mouse mast cell protease 11 is involved in the development of IgE-mediated chronic allergic inflammation

H. Deki*, Y. Kawano, S. Yoshikawa, M. Iki, M. Egawa, T. Ohta, H. Karasuyama;*
Department of Immune Regulation,Tokyo Medical and Dental University, Tokyo, Japan.

Basophils are the least common granulocytes, and had long been considered as minor relatives of mast cells. However, recent studies have illustrated non-redundant roles for basophils in various immune responses, including allergic reactions and protective immunity against parasites. We previously demonstrated that basophils but not mast cells play an important role in the development of IgE-mediated, delayed-onset allergic inflammation in the skin, designated IgE-CAI. However, it remains elusive how basophils trigger the skin inflammation. In this study, we focused on mast cell protease 11 (mMCP-11) that shows a tryptase activity, and is expressed by basophils rather than mast cells. In order to elucidate the role for mMCP-11 in IgE-CAI, we generated engineered mice deficient for mMCP-11, in that the number of basophils was comparable to that in wild-type mice. Their basophils expressed normal levels of other proteases including mMCP-8 and surface FcεRI, and normally degranulated upon stimulation with IgE plus antigens, as judged by β-hexosaminidase release assay. Of note, skin swelling elicited by the IgE-CAI reaction was reduced in mMCP-11-deficient mice to half of that in wild-type mice. Moreover, the number of proinflammatory cells accumulating skin lesions, including eosinophils and neutrophils, was significantly reduced in mMCP-11-deficient mice. Thus, mMCP-11

released by basophils is a key effector molecule in the development of IgE-CAI.

W1.17.03
Analysis of NK cell subsets in children with atopic dermatitis

G. Deniz[1], *E. Aktas Cetin*[1], *N. Akdeniz*[1], *B. Safa*[2], *M. Kosker*[3], *Y. Camcioglu*[3], *&. Barlan*[2];
[1]*Istanbul University, The Institute of Experimental Medicine, Department of Immunology, Istanbul, Turkey,* [2]*Marmara University, Division of Pediatric Allergy and Immunology, Istanbul, Turkey, Istanbul, Turkey,* [3]*Istanbul University, Cerrahpasa Faculty of Medicine, Department of Pediatric Infections Disease, Istanbul, Turkey, Istanbul, Turkey.*

Atopic dermatitis (AD) is a frequent chronic inflammatory skin disease which is often complicated by recurrent microbial superinfections. Numerous studies demonstrated increased frequency of allergen-specific Th2 cells producing increased IL-4, IL-5 and IL-13 in the peripheral blood of AD patients, however little is known about the role of natural killer (NK) cells. In this study, NK1, NK2 and NK regulatory cytokine profiles, the expression of activatory receptors as well as the cytotoxic activity of NK cells in AD were investigated. The study group consists of children with AD (n=14, mean age=7 ± 3.8) and healthy subjects (n=14, mean age=10 ± 4). The patients were multisensitized to at least one aeroallergen and had high serum total IgE levels. Cytotoxic activity, expression of $CD16^{bright}CD56^{dim}$ and $CD16^{dim}CD56^{bright}$ NK cell subsets, NK cell activatory receptors and intracellular IL-4, IL-10 and IFN-γ levels were determined by flow cytometry. In AD patients the percentages of $CD3^{-}CD16^{+}CD56^{+}$, $CD16^{bright}CD56^{dim}$ NK cell subsets and expression of activatory receptors of NKG2D cells were significantly decreased compared to healthy subjects (p=0.000, p=0.000 and p=0.04, respectively). Although, IL-10 secreting regulatory and IL-4 secreting NK2 cells were increased, IFN-γ secreting NK1 cells and cytotoxic activity of NK cells were found to be decreased in AD patients (p=0.000, p=0.000, p=0.014 and p=0.016, respectively). Our results suggested that impaired NK cell functions such as decreased expression of $CD16^{bright}$ subset, NKG2D expression as well as cytotoxic activity, high secretion of L-10 & IL-4 might play a role in the pathogenesis of AD.

W1.17.04
Novel IL-9-producing Innate Helper Cells Promote Oral Antigen-induced Anaphylaxis

Y. Wang, *C. Chen, J. Lee, B. Liu, F. Finkelman, S. Hogan;*
Cincinnati Children's Hospital, Cincinnati, OH, United States.

IgE-mediated food allergy is manifested by an overactive T-helper 2 immune response to dietary antigens in the gastrointestinal (GI) tract. Interleukin (IL)-4, IL-13, and IL-9 promote IgE antibody production, intestinal mucus secretion, and mastocytosis, respectively, which allow the development of oral antigen-induced anaphylaxis in an experimental model. However, little is known about the primary cellular sources of IL-9 or the mechanisms that promote intestinal mastocytosis. Here, we report the identification of multifunctional IL-9-producing innate helper cells (IHC9) that promote intestinal TH2 inflammation and mastocytosis that drives oral antigen-induced anaphylaxis. Distinct from ILC2, IHC9 exhibit non-lymphoid cell attributes and can secrete prodigious amount of IL-9 and other TH2 cytokines, IL-4 and IL-13 in lesser amount. Histologic and electron microscopic analysis reveal that IHC9 display morphologic characteristics of innate helper cell lineages. Repeated intragastric antigen challenge induces accumulation of intestinal IHC9, which correlate positively with symptoms and susceptibility to oral antigen-induced anaphylaxis. The failure of irradiated mice reconstituted with STAT6-deficient bone marrow to generate IHC9 in response to challenge was accompanied by reduced serum MCPt-1, intestinal mastocytosis, and goblet cell hyperplasia and loss of allergic diarrhea. Thus, IHC9 represent a new type of innate helper cell lineage and play a pivotal role in the development of IgE-mediated food allergy. (This work is supported by grant NIH-P30 DK078392)

W1.17.05
Lack of PTX3 enhanced airway inflammation and hyperresponsiveness in a murine model of asthma

J. Balhara, L. Shan, ***A. Soussi Gounni****;*
Department of Immunology, University of Manitoba, Winnipeg, MB, Canada.

Pentraxin-3 (PTX3) is a member of the long pentraxins family, which activates the innate and adaptive immune systems in a coordinated manner. It plays an important role in providing immunity against pulmonary infections such as aspergillosis, pneumonia, tuberculosis and Psuedomonas aeroginosa infection. Considering its role in fostering lung immunity, we examined the role of PTX3 in asthma. We have recently demonstrated an enhanced expression of PTX3 in bronchial biopsies of allergic asthmatics that correlated with the disease severity. In this report, we assessed the effect of PTX3 deficiency on OVA-induced experimental asthma in a murine model. The magnitude of increase in airway and tissue resistance of OVA sensitized/challenged mice in response to methacholine (MCh) is found to be greater in PTX3 KO mice in contrast to their WT counterparts. We observed an increase in the infiltration of inflammatory cells in BALF obtained from PTX3 KO mice upon OVA sensitization/challenge as compared to their WT littermates. However peribronchial and perivascular inflammation and goblet cells hyperplasia showed no significant difference in both mouse strains. Further we found an enhanced induction of IL-4, IFN-γ, IL-17A and IL-10 production in the lungs of PTX3 KO mice as compared to WT mice upon OVA challenge. In lymph node, IL-17A recall response was greater in PTX3 KO mice than WT mice but no difference was observed in term of IL-4, IFN-g and IL-10. Taken together, our data suggest that lack of PTX3 predisposes mice to airway hyperresponsiveness and an enhanced inflammation.

W1.17.06
MicroRNA-155 augments local Th2 response in a mouse model of allergic airway inflammation

C. Malmhäll*, S. Alawieh, Y. Lu, M. Sjöstrand, A. Bossios, M. Eldh, M. Rådinger;*
University of Gothenburg/Inst of Medicine/Krefting Research Centre, Gothenburg, Sweden.

Background: Allergic inflammation and tissue remodeling in allergic asthma is driven by a type 2 immune response to inhaled allergens. The molecular mechanisms associated with the allergen induced immune response remain largely unclear. MicroRNAs **(**miRNAs) are important regulators of gene expression in the immune system and miR-155 has previously been shown to regulate T cell responses.
Aim: To investigate the regulatory role of miR-155 in a model of allergen induced airway inflammation.
Methods: Wild type (WT) and miR-155 knockout (miR-155 KO) mice were sensitized and airway challenged to OVA. Differential cell counts, cytokine and chemokine production were evaluated. T helper (Th) cell populations and co-expression of master regulatory transcription factors in lung Th cells were determined by flow cytometry.
Results: miR-155 deficiency resulted in a decreased eosinophilic inflammation in the lung, Th2 cytokine production and airway mucus hypersecretion and further virtually abolished allergen-induced airway eotaxin-2/CCL24 and periostin levels. These characteristics were accompanied by a significant reduction in Th2 ($CD4^{+}GATA\text{-}3^{+}$) cells as well as reduced number of Th cells co-expressing additional master regulatory transcription factors in the lung of allergen challenged miR-155 KO mice compared to WT mice.
Conclusions: Our data provides evidence that miR-155 is involved in the regulation of allergen-induced airway inflammation, possibly through the regulation of Th2 cells locally in the airways. Targeting miR-155 may be beneficial both in the acute phase response and the more long-term effect of remodelling.

W2.01.01
The recruitment and activation of phosphatidylinositol 4-phosphate 5-kinases α critically regulate CD28-dependent signaling responses

***L. Tuosto**, M. Muscolini, C. Camperio, C. Capuano, S. Caristi, E. Piccolella, R. Galandrini;*
Sapienza University, Rome, Italy.

CD28 is one of the most relevant costimulatory receptors that delivers both TCR-dependent and TCR-independent signals regulating a wide range of signaling pathways crucial for cytokine and chemokine gene expressions, T cell survival and proliferation. Most of the CD28-dependent signaling functions are initiated by the recuitment and activation of class IA PI3Ks, which catalyze the conversion of phosphatidylinositol 4,5-biphosphate (PIP2) into phosphatidylinositol 3,4,5-triphosphate (PIP3), thus generating the docking sites for key signaling proteins. Hence, PIP2 is a crucial substrate in driving the PI3K downstream signaling pathways and PIP2 turnover may be an essential regulatory step to ensure the activation of PI3K following CD28 engagement. Despite some data evidence that CD28 augment TCR-induced turnover of PIP2, its direct role in regulating PIP2 metabolism has never been assessed. Here we show that CD28 regulates PIP2 turnover by recruiting and activating phosphatidylinositol 4-phosphate 5-kinases α (PIP5Kα) in human primary CD4+ T lymphocytes. This event leads to the neo-synthesis of PIP2 and to its consumption by CD28-activated PI3K. We also evidenced that PIP5Kα activation is required for both CD28 unique signals regulating IL-8 gene expression as well as for CD28/TCR-induced Ca2+ mobilization, NF-AT nuclear translocation and IL-2 gene transcription. Our findings elucidate a novel mechanism that involves PIP5Kα as a key modulator of CD28 costimulatory signals.

W2.01.02
Terminal transport of lytic granules to the immune synapse is mediated by the kinesin-1/Slp3/Rab27a complex

***G. Menasche**[1], M. Kurowska[1], N. Goudin[1], N. Nehme[1], M. Court[2], J. Garin[2], A. Fischer[1], G. de Saint Basile[1];*
[1]INSERM, Paris, France, [2]INSERM-CEA, Grenoble, France.

Cytotoxic T lymphocytes (CTLs) kill target cells via the polarized secretion of cytotoxic granules at the immune synapse (IS). The lytic granules are initially recruited around the polarized microtubule-organizing center (MTOC). In a dynein-dependent transport process, the granules move along microtubules towards the MTOC in the minus-end direction. Here, we show that (i) polarized granule transport over the small remaining distance to the plasma membrane and (ii) delivery of the granules' contents at the IS depend on the conventional molecular motor kinesin-1. We found evidence to suggest that the Rab27a effector synaptotagmin-like protein 3 (Slp3) is expressed in CTLs and interacts with the tetratricopeptide repeat of the kinesin-1 light chain. We found that kinesin-1 regulates a very late step in the transport of Rab27a/Slp3-associated vesicles that is required for lytic granule secretion. Our data provide further molecular insights into the key functional and regulatory mechanisms underlying the terminal transport of cytotoxic granules and the latter's secretion at the IS.

W2.01.03
The potassium channel KCNK3 determines calcium signaling pathways in T lymphocytes

***S. Bittner**, H. Wiendl, S. G. Meuth;*
University of Münster, Münster, Germany.

Ion channels are known to influence the activation and effector functions of T lymphocytes. Recently, a role for members of the two-pore domain potassium channel family (K2P channels, e.g. KCNK3, KCNK5, KCNK9) could be described for autoimmune neuroinflammation. KCNK3-/- mice showed a significantly ameliorated disease course in myelin oligodendrocyte glycoprotein peptide induced experimental autoimmune encephalomyelitis (EAE), an animal model of multiple sclerosis. However, the underlying intracellular pathways in T cells have not yet been addressed. Therefore, we intended to investigate the influence of KCNK3 to intracellular T cell signaling.
Murine and human CD4+ T lymphocytes were stained with the calcium-sensitive dye Fura-2. Pharmacological blockade of KCNK3 with A293, a novel selective blocker, reduced the extracellular calcium influx upon T cell receptor (TCR) crosslink. These results could be confirmed with KCNK3-/- cells which displayed a significantly reduced calcium increase compared to wildtype mice. A293 had no additional effect on KCNK3-/- cells. The reduced calcium levels led to a reduced activation of calcineurin and therefore a reduced dephosphorylation and nuclear translocation of the calcium-dependent signaling protein nuclear factor of activated T-cells (NFAT) as detected by western blotting experiments. In contrast, upstream signaling proteins such as ZAP70 or LAT showed higher phosphorylation levels in KCNK3-/- mice than in wildtype mice both under basal and stimulated conditions.
In summary, we were able to demonstrate a crucial influence of KCNK3 on calcium signaling pathways in T cells. Further studies are needed to explore the molecular pathways in more detail.

W2.01.04
Molecular tuning of telomerase activity in highly differentiated human primary CD28−CD27− T cells

***A. Lanna**, S. M. Henson, D. Escors, A. N. Akbar;*
University College London, London, United Kingdom.

Telomerase is a RNA-dependent DNA polymerase re-expressed by T cells mounting an immune response upon antigenic stimulation. Highly differentiated $CD28^{-}CD27^{-}$ (DN) T cells are an end-stage sub-population progressively accumulating in the elderly, in patients with autoimmune disorders, cancer and chronic viral diseases. These cells have short telomeres and show proliferative defects as a result of defective telomerase activity, due in part to active MAPK p38 signalling. Most interestingly telomerase activity and cell survival can be re-established following MAPK p38 blockade in DN T cells. Therefore key senescent features of the human memory T cell compartment are reversible. Although repeated antigenic stimulation is considered one of the main drivers of T cell senescence, metabolic dysfunctions and cytokine priming have been postulated to negatively impact the biochemical features of end-stage T cell sub-populations. However the molecular evidence for such a mechanism linking chronic inflammation, due to cytokines and/or metabolic impairment, and T cell senescence has not yet been elucidated. We report here an alternative mechanism regulating MAPK p38 activation in highly differentiated DN T cells. The mechanism described here provides a target for manipulation of telomerase activity in a T cell compartment specific manner, reducing the risk of malignancies. This may result in the design of novel immunotherapy strategies aimed at reversing T cell senescence and boosting T cell mediated immune responses.

W2.01.05
The expression and phosphorylation of HS1 protein are finely tuned in normal and leukemic B cells

***C. Scielzo**[1], E. ten Hacken[1], M. T. S. Bertilaccio[1], M. Ponzoni[2], U. Restuccia[3], A. Bachi[3], P. Ghia[4], F. Caligaris-Cappio[5];*
[1]Fondazione Centro San Raffaele, Division of Molecular Oncology, Unit of Lymphoid Malignancies, Milano, Italy, [2]Fondazione Centro San Raffaele, Division of Molecular Oncology, Pathology Unit, Milano, Italy, [3]Fondazione Centro San Raffaele, Division of Genetics and Cell Biology , Biomolecular Mass Spectrometry Unit, Milano, Italy, [4]Fondazione Centro San Raffaele, Division of Molecular Oncology, Unit of B Cell Neoplasia, Università Vita-Salute San Raffaele, Milano, Italy, [5]Fondazione Centro San Raffaele, Division of Molecular Oncology, Unit of Lymphoid Malignancies, Università Vita-Salute San Raffaele,, Milano, Italy.

We demonstrated that HS1 is a pivotal molecule in the signal transduction pathway triggered by the B-cell receptor (BCR), serving as a central interactor of several cytoskeletal components and being involved in tissue trafficking and homing in neoplastic B lymphocytes, namely in Chronic Lymphocytic Leukemia (CLL). Interestingly, HS1

protein shows a differential expression in the bone marrow as compared to the peripheral blood of CLL patients. That parallels what we also observed in normal B cells subpopulations where HS1 is expressed at very low level in Pre and Pro-B cell lineages while it is expressed at a higher level in mature B cells.
Rather than the expression of the protein, HS1 phosphorylation appears to be important as it correlates with prognosis in CLL and is modulated in normal B cells. As we aimed at defining the nature of HS1 phosphorylation in B cells, we analyzed cells form CLL patients and we found that HS1 is constitutively phosphorylated at the activatory site Tyr397 in a sizable fraction of patients, while this site is phosphorylated in normal B cells only after BCR stimulation. By mass spectrometry analysis we found new additional HS1 phosphorylation sites on Serine and Threonine residues, in a subset of patients, probably mediating the inactivation of the protein, in clear contrast with normal B cells.
The modulation of the expression and activation of the molecule in CLL cells and infiltrated tissues can help to better characterize the function of HS1 in B-cell ontogeny and CLL development.

W2.01.06
The impact of arginine methylation on BCR signaling

S. Infantino[1]*, A. Light*[1]*, K. O'Donnell*[1]*, S. Richard*[2]*, D. Tarlinton*[1]*;*
[1]*Walter and Eliza Hall Institute, Melbourne, Australia,* [2]*Lady Davis Institute for Medical Research, McGill University, Montreal, QC, Canada.*

Signals through the B cell receptor (BCR) are transmitted by a multitude of molecules, many of which undergo post-translational modification. In BCR signaling, arginine methylation, a characterized post-translational modification, has been suggested to control B cell development. Specifically, Protein Arginine Methyl-Transferase 1 (PRMT1) has been shown to methylate Ig-α and consequently to modulate BCR signal.
We have examined the consequence of a conditional deletion of the prmt1 gene in B cells. We find that PRMT1 regulates B cell maturation by shaping the pre-B cell compartment and modulating the subsequent transition to the immature B cell stage. By deleting PRMT1 at the CD23+ stage of B cell development, we find that, while follicular B cells were not affected, marginal zone B cells were lost. When activated, PRMT1-deficient B cells displayed an altered proliferation and survival capacity. Arginine methylation mediated by PRMT1 is required in B cells for humoral immunity. Indeed, in response to protein antigen, B cells lacking PRMT1 failed to form germinal centre. Moreover, the T-independent immune response against a polysaccharide antigen was also severely impaired in mice lacking PRMT1 in B cells. Thus PRMT1 plays a critical, B-cell intrinsic role in specifying the outcome of humoral immune responses and in fine-tuning B cell development.

Modulation of TCR signaling and T cell activation by glucocorticoids: facts and hypotheses

C. T. Baldari*;*
University of Siena, Siena, Italy.

Glucocorticoids (GC) have the ability to regulate gene transcription through the glucocorticoid receptor, a cytosolic transcription factor that translocates to the nucleus upon ligand binding. GCs have long been known to inhibit T cell activation through the GC receptor mediated transcriptional regulation of several immunosuppressive genes. Recent evidence has however revealed that, in addition to this slow mode of action, GC also elicit rapid, transcription independent responses at the onset of T cell activation. These non-genomic activities, which are mediated by cytosolic and/or membrane bound GC receptors, involve suppression of T cell signaling independently of transcription. The unligated GC receptor has been indeed shown to interact with the activated TCR complex, which associates with the kinases Lck and Fyn. Upon GC short-term treatment this interaction is disrupted, leading to the dissociation of Lck and Fyn from the TCR and thereby suppressing TCR signaling. In my talk I shall summarize our current understanding of the cross-talk of GC receptors with the TCR, discussing the the immune synapse as a potential target of GC dependent immunosuppression.

Antagonistic actions of Rcor proteins refine LSD1 activity and restrain cellular differentiation

A. H. Chowdhury, G. Upadhyay, D. Kim, ***S. Saleque****;*
The City College of New York, New York, NY, United States.

The histone demethylase LSD1/Kdm1a demethylates histone3-lysine4 residues on nucleosomal histones in collaboration with the adaptor protein CoREST/Rcor1. Both proteins are obligate co-factors of, and mediate repression of the gene targets of, the transcription factors Gfi1 and Gfi1b during hematopoiesis. Two other Rcor paralogs, Rcor2 and Rcor3, also interact with LSD1 and Gfi1/1b. However, while Rcor2 exhibits biochemical activities and physiological properties analogous to Rcor1 and facilitates LSD1 mediated processes, Rcor3 inhibits LSD1 enzymatic activity and antagonizes its cellular function. Appending the SANT2 domain of Rcor1 to Rcor3 transforms it into an activator of LSD1. Thus Rcor3 functions as a naturally occurring dominant-negative inhibitor of LSD1 function in vitro and in vivo owing to its lack of the critical SANT2 domain. Endogenous levels of Rcor3 rise sharply in maturing erythroid cells, while that of LSD1 and Rcor1/2 remain relatively uniform, likely enabling Rcor3 to dampen LSD1 activity during hematopoietic development. These results reveal that LSD1 together with Rcor1/2 "drive" hematopoietic differentiation, while Rcor3 "brakes" it, by opposing or disrupting LSD1-Rcor1/2 function. This study highlights a general mechanism of refining the enzymatic and physiological activity of a widespread epigenetic modifier (LSD1), and restraining its cellular differentiation potential both in hematopoiesis and other developmental contexts.

W2.02.02
Estradiol promotes functional responses in inflammatory and steady state dendritic cells through differential requirement of activation function-1 of estrogen receptor α

S. Laffont[1]*, C. Seillet*[1]*, N. Rouquié*[1]*, A. Krust*[2]*, P. Chambon*[2]*, J. Arnal*[3]*, J. Guéry*[1]*;*
[1]*INSERM U1043, CPTP, Toulouse, France,* [2]*IGBMC, CNRS-INSERM-ULP-Collège de France, Illkirch, France,* [3]*INSERM U1048, I2MC, Toulouse, France.*

Estradiol (E2) has been shown to regulate cytokine-driven dendritic cell (DC) differentiation through estrogen receptors (ER) -signaling in myeloid progenitors (MP). ER regulates transcription of target genes through two distinct activation functions (AFs), AF-1 and AF-2 which requirement for transcriptional activities is dependent on the cell-type and promoter context. We investigated the role of ER AFs in the development and effector functions of inflammatory DCs, steady state conventional DCs (cDCs) and plasmacytoid DCs (pDC), using mouse lacking either AF1 ($ERAF1^0$) or AF2 ($ERAF2^0$). In agreement with previous works, we showed that E2 fostered the differentiation and effector functions of inflammatory DC through ER-dependent up-regulation of IRF-4 in GM-CSF-stimulated MPs. Interestingly, whereas AF-1 was required for IRF-4 upregulation, it was dispensable for the E2-mediated increase in the differentiation of the more functional Ly6C- subsets of DC. By contrast, no specific response to E2 was seen with progenitors from either $ERAF2^0$ or $ER^{-/-}$ mice. These results suggest that AF-1-independent activation of ER genomic effects promotes additional pathways in MP that synergize with low levels of IRF-4 to sustain GM-DC differentiation. By contrast, in Flt3L-driven DC subsets, ER AF1 was required for the E2-mediated effects on the development and innate functions of both cDCs and pDCs. Moreover, lack of ER AF-1 blunted the TLR-7 mediated IFN-response of female pDCs *in vivo*. Thus, ER uses AF1 differently in steady state and inflammatory DC lineages to regulate their innate functions, suggesting that selective ER modulators could be used to target specific DC subsets.

Identification of TREM-1 as a novel target of Nuclear Receptor ligands in Dendritic Cells

R. Fontana[1,2], *N. Di Meglio*[3,2], *C. Battaglia*[4], *M. Mattioli*[4], *M. Cella*[5], *C. Doglioni*[1,6], *C. Traversari*[7], *M. Colonna*[5], *V. Russo*[2];
[1]*Università Vita-Salute Ospedale San Raffaele, Milan, Italy,* [2]*Cancer Gene Therapy Unit, Program of Immunology and Bio Immuno Gene Therapy of Cancer, Division of Molecular Oncology, Scientific Institute San Raffaele, Milan, Italy,* [3]*Università Vita-Salute Ospedale San Raffaele, Milano, Italy,* [4]*Department of Medical Biotechnology and Translational Medicine, Postgraduate School of molecular medicine, University of Milan, Milan, Italy,* [5]*Department of Pathology, Washington University in St. Louis, St.Louis, MO, United States,* [6]*Department of Pathology, Scientific Institute San Raffaele, Milan, Italy,* [7]*MolMed S.p.A., Milan, Italy.*

Dendritic cells (DCs) are antigen-presenting cells playing a crucial role in the regulation of innate and adaptive immune responses. DCs initiate adaptive immune responses after their migration to secondary lymphoid organs, a process dependent on the expression of the chemokine receptor CCR7. Our group has recently demonstrated that tumors produce LXR ligands/oxysterols, which are able to dampen DCs migration to secondary lymphoid organs by inhibiting CCR7 expression. We have recently analyzed the transcriptome profile of DCs undergoing maturation in the presence of the oxysterol 22R-Hydroxycholesterol (22R-HC), identifying more than 1500 genes modulated upon the treatment. Among them the triggering receptor expressed on myeloid cells (TREM)-1 and some genes belonging to its pathway were found markedly up-regulated by oxysterol.
The expression of TREM-1, a strong amplifier of immune responses, induced by oxysterols on maturing DCs was confirmed by qRT-PCR and by flow cytometry. Since LXRs form heterodimers with RXR, we tested the effect of the combination of 22R-HC and 9-cis Retinoic Acid, and found an additive effect on TREM-1 induction. Moreover, also the ligands for the nuclear receptors RAR and VDR raised TREM-1 expression, while ligands for PPAR, FXR and PXR have no effect. This modulation was specific for DCs and was functional, as the triggering of TREM-1 strongly increased TNF release. Interestingly, several tumor-conditioned supernatants were able to induce TREM-1 expression. We are performing experiments *in vivo* to evaluate the biologic role of nuclear receptor ligand-induced TREM-1 up-regulation in DCs.

Retinoic acid-rich microenvironment provides clonal survival cues for tumor and bacteria-specific CD8+ T cells

Y. Guo*, K. Pino-Lagos, R. Noelle;*
The Geisel School of Medicine at Dartmouth, Lebanon, NH, United States.

While studies have implicated a role of vitamin A (VA) in host resistance to infectious disease, little is known as to the role of VA and its active metabolite, retinoic acid (RA) in host defense against cancer. Herein, it is shown for the first time that local RA production within the tumor microenvironment (TME) is increased up to 5-fold compared to naïve surrounding tissue, with a commensurate increase in RA signaling to regionally infiltrating tumor-reactive T cells. Tumor-specific CD8+ T cells deficient in RA signaling (by specific over-expression of dominant negative Retinoic Acid Receptor α in CD8+ T cells) failed to accumulate and control tumor growth. Specific deletion of RARα, RARβ and RARγ in CD8+ T cells further demonstrated that RARα is required for CD8+ T cell survival/homeostasis and RA-induced gut-homing receptor (α4β7 and CCR9) expression, whereas RARβ is indispensable for bacteria-specific CD8+ T cell expansion in response to Listeria monocytogenesis infection. These studies established a novel function of RA essential for both anti-tumor and infection CD8+ T cell immunity.

W2.02.05
Th17-mediated B cell activation contributes to splenomegaly in PPARγ hypomorphic mice

Y. Liu[1], *Y. Tsai*[2], *P. Tsai*[3];
[1]*Institute of Basic Meidcal Science, National Cheng Kung University, Tainan, Taiwan,* [2]*Institute of Clinical Medicine, National Cheng Kung University, Tainan, Taiwan,* [3]*Department of Medical Laboratory Science and Biotechnology, National Cheng Kung University, Tainan, Taiwan.*

PPARγ is a nuclear transcription factor that modulates diverse biofunctions, including lipid biosynthesis, glucose metabolism and inflammation. However, the specific role of PPARγ in immune function *in vivo* has not been fully explored. We have previously generated PPARγ hypomorphic mice with about 25% expression of PPARγ (*Pparg*$^{C/-}$ mice). Interestingly, we found that splenomegaly was observed from young to old of *Pparg*$^{C/-}$ mice, and young *Pparg*$^{C/-}$ mice with splenomegaly without relocation of hematopoiesis to the spleen. Moreover, old mice displayed gross splenomegaly accompanied by increased autoantibody production and renal immune complex deposition. We found that increased autoantibody production was caused by increased B cell activity. *In vitro* assay revealed splenic *Pparg*$^{C/-}$ CD4^{+} T cells showed increased proliferation and survival. Indeed, co-culture of wild type B cells with activated *Pparg*$^{C/-}$ CD4^{+} T cells promoted increased plasma cells and IgG production, compared that with wild type CD4^{+} T cells. Further evaluation of CD4^{+} subsets in *Pparg*$^{C/-}$ mice, the signature Th17-type factors, RORγt and IL-17A, were increased in the spleen of *Pparg*$^{C/-}$ mice. Also, *Pparg*$^{C/-}$ CD4^{+} T cells from *Pparg*$^{C/-}$ mice exhibited enhanced polarization toward Th17 phenotype in response to αCD3/CD28. Wild type B cells and CD4^{+} T cells co-culture system supplied with conditional medium from activated *Pparg*$^{C/-}$ CD4^{+} T cells with IL-17A depletion showed that lower IL-17A level decreased B cell activity. Our results indicated splenomegaly in young *Pparg*$^{C/-}$ mice was contributed by increased activation of B cells with the help of Th17, suggesting PPARγ has a new beneficial role in immunomodulation.

W2.02.06
Expression levels of mRNA for GRα, GRβ, 11βHSD1 and GRα/β ratio in peripheral blood mononuclear cells (PBMC) from patients with pulmonary tuberculosis, throughout the 6-month course of etiological treatment and 3 month following its completion

L. D. D'Attilio[1], *A. Díaz*[1], *B. Bongiovanni*[1], *N. S. Santucci*[1], *G. Dídoli*[1], *W. Gardeñez*[2], *A. Del Rey*[3], *H. Besedovsky*[3], *O. A. Bottasso*[1], ***M. L. Bay***[1];
[1]*Institute of Immunology, School of Medical Sciences, National University of Rosario, Rosario, Argentina,* [2]*Department of Pneumonology, Provincial Hospital of the Centenary, Rosario, Argentina,* [3]*Department of Immunophysiology, Institute of Physiology and Pathophysiology, Marburg, Germany.*

Patients with pulmonary tuberculosis (TB) show several immune-endocrine alterations, like decreased plasma levels of dehydroepiandrosterone (DHEA) together with augmented concentrations of proinflammatory cytokines and cortisol. The latter continues to be increased throughout treatment, whereas IL-6 and IFN-γ fall to control values and DHEA concentrations normalize. Studies on the expression of mRNA for glucocorticoid receptor isoforms (GRα and β) and enzymes regulating cortisol availability (11beta-hydroxysteroid dehydrogenase type 1; 11βHSD1 and type 2; 11βHSD2) in PBMC indicate a lower GRα/β ratio and higher 11βHSD1 in severe pulmonary TB. Extending this analysis we now analyzed the expression of mRNA for GRα, GRβ, 11βHSD1 and GRα/β ratio in PBMC from 16 TB -HIV negative- patients, bled at diagnosis (T0), two (T2), four (T4) and 6 months (T6) of treatment as well as 3 months later (T9) and 19 age- and sex-matched healthy controls (HCo), for comparison purposes. Transcript levels for GRα at T0 remained within controls values, rose significantly throughout treatment ($p<0.05$) decreasing to normal levels by T9. Conversely, the GRβ expression, that was augmented at diagnosis ($p<0.03$), decreased significantly in the remaining time-point evaluations ($p<0.02$). This resulted in a significantly reduced GRα/β ratio at T0 ($p<0.03$), reaching values similar as those of HCo from T2 and

thereafter (p<0.02). Expression of 11βHSD1 was augmented at T0 (p<0.05), but further evaluations during and after specific treatment showed levels within the normal range (p<0.02). Clinical improvement and decreased inflammation resulting from specific treatment coexist with a milieu more suitable for the immunomodulatory effects of endogenous GC.

W2.03 Epigenetic control of immune responses

IL2.03.01
Epigenomic and transcriptional regulation of human Th cell differentiation

***R. Lahesmaa**;*
Turku Centre for Biotechnology, University of Turku, Turku, Finland.

T helper (Th) cell subsets with distinct cytokine secretion profiles and function play a crucial role in host defense as well as in pathological disorders such as allergy and chronic inflammatory and autoimmune diseases. To complement extensive knowledge on mouse Th cell differentiation, comprehensive studies in the human system are urgently needed for mechanistic understanding of human immune mediated diseases providing a key basis for translational research (Scand. J Immunol. 2013 doi: 10.1111/sji.12071. Aiming at identifying new regulators of Th cell differentiation we have analysed the epigenomic changes during the initiation of human Th cell differentiation.
The first human genome-wide maps of histone modifications that reveal enhancer elements at an early stage of polarization toward Th1 and Th2 lineages were generated (. Global Chromatin State Analysis Reveals Lineage-Specific Enhancers during the Initiation of Human T helper 1 and T helper 2 Cell Polarization, Immunity (2013), http://dx.doi.org/10.1016/ j.immuni. 2013.05.011). Our analysis indicates that even at this very early time point, cell-specific gene regulation and enhancers are at work directing lineage commitment. Further examination of lineage-specific enhancers identified known and novel transcription factors as putative drivers of lineage-specific gene expression. Lastly, an integrative analysis of immunopathogenic associated SNPs suggest a role for distal regulatory elements in the disease pathogenesis.

W2.03.01
Regulatory non-coding RNAs as modulators of human lymphocytes differentiation

***V. Ranzani**, A. Arrigoni, R. J. Bonnal, G. Rossetti, S. Curti, E. Sugliano, E. Provasi, V. Parente, S. Abrignani, M. Pagani;*
Istituto Nazionale di Genetica Molecolare, Milano, Italy.

Most of the immune cell subsets can be purified by flow-cytometry, making it an interesting and powerful model system to study the role of non-coding RNAs in human primary cells. In particular we focused our studies on two classes of non-coding RNAs: microRNAs and large intergenic non-coding RNAs (lincRNAs). As little is known on expression of lincRNAs, in functional subsets of human immune system, we performed a comprehensive transcriptome analysis of 13 purified primary human cell subsets (belonging to T-CD4+, T-CD8+ and B lymphocytes) by RNA-seq using Illumina platform. We assembled ~2 billion RNA-seq reads across 63 cell samples, using both Cufflinks and Oases algorithms for Reference Annotation Based and de-novo assembly respectively. lincRNAs were identified taking into account length, structural, coding potential, and orthology features. Here we show that different lincRNAs are preferentially expressed in specific lymphocyte subsets and that their expression patterns change during the functional T cell differentiation. We identified lincRNA signatures of the selected lymphocytes subsets. Experiments of loss/gain of function suggest the role of these lincRNAs in lymphocytes' cell identity and maintenance. To investigate microRNAs role in human immune system, we have recently performed a microRNA profiling in seventeen lymphocyte subsets (Rossi et al. Nature Imm. 2011 12:796), providing an 'atlas' of microRNA expression in human lymphocytes, defining subset-specific signatures and their target genes, and indicating that T-cell naive state is enforced by microRNAs. We are exploring the interplay between microRNAs and lincRNAs as a new dynamic regulatory layer of non-coding RNAs controlling lymphocyte plasticity.

W2.03.02
Bromodomain inhibition enhances tolerogenic properties in dendritic cells

***R. Schilderink**[1], L. E. Nijhuis[1], F. W. Hilbers[1], R. K. Prinjha[2], W. J. de Jonge[1];*
[1]Tytgat Institute for Liver and Intestinal Research, Academic Medical Center, Amsterdam, Netherlands, [2]Epinova DPU, Immuno-Inflammation Centre of Excellence for Drug Discovery, GlaxoSmithKline, Stevenage, United Kingdom.

Inhibition of acetylated-lysine reader enzymes, the bromodomain and extra-terminal domain (BET) proteins, is effective in specific downregulation of secondary response inflammatory genes and ameliorates lethal inflammatory states in several animal models. In this study we analyzed the effects of BET-inhibitor I-BET151 on dendritic cell function.
Bonemarrow derived dendritic cells (BMDC) were cultured from C57BL/6 mice by exposure to GM-CSF for 8 days. I-BET151 was tested at 1nM up to 1000nM against DMSO vehicle. Effect of I-BET151 on maturation, cytokine secretion and ovalbumin specific CD4+ CD62L+ naive T cell skewing was analyzed. Regulatory T-cell suppression assays were performed using 3-H thymidine incorporation.
I-BET151 treatment during maturation of BMDC resulted in lower expression of CD40, CD80, CD86 and MHC-II. Secretion of IL-6, IL-12 and IL-10 was abrogated (11%, 0.5% and 1.6% of vehicle, respectively; all p<0.001), whereas TNF-alpha secretion was still present (83% of vehicle). A 2 hour incubation of 1000nM I-BET151 to ovalbumin loaded matured BMDC, prior to addition of T naive T cells, did not affect IFN-gamma Th1 cell skewing, but led to a 3-fold increase in foxp3 expressing T cells (p<0.001). PMA/ionomycin stimulation of the T cells resulted in higher IL-10 levels in I-BET151 treated compared to the vehicle treated BMDC (p<0.01). These cells were able to suppress proliferation of naïve T cells.
We conclude that the epigenetic modifier I-BET151 histone mimic tolarizes DCs and enhances their potential to skew suppressive Treg by inhibiting maturation and inflammatory cytokine secretion.

W2.03.03
The Polycomb group protein Ezh2 regulates the germinal center B cell response

***S. Casola**[1], M. Caganova[1,2], C. Carrisi[1], F. Zanardi[1], F. Mainoldi[1], L. George[3], M. Ponzoni[4], K. M. Toellner[3], I. Su[5];*
[1]IFOM Foundation, the FIRC Institute of Molecular Oncology Foundation, Milano, Italy, [2]Italian Institute of Technology (IIT), Milan, Italy, [3]MRC Centre for Immune Regulation, School of Immunity and Infection, University of Birmingham, Birmingham, United Kingdom, [4]Unit of Lymphoid Malignancies, Department of Onco-Haematology, San Raffaele Scientific Institute, Milano, Italy, [5]Division of Genomics and Genetics, School of Biological Sciences, Nanyang Technological University, Singapore, Singapore, Singapore.

In mammals, Polycomb group (PcG) proteins exert and essential function in the control of stem cell self-renewal, pluripotency, and cell lineage determination. PcG proteins are recruited within Polycomb Repressive Complexes (PRC) to promote transcriptional repression of target genes through post-translational modifications of lysine residues within histone tails. Ezh2, as part of PRC2, promotes the trimethylation of lysine-27 on Histone H3 (H3K27me3).
In mature B cells, Ezh2 is up regulated upon entry into the germinal center (GC) reaction, during a T-cell dependent immune response. Importantly, Ezh2 gain-of-function mutations are often identified in GC-derived Non Hodgkin B-cell lymphomas.
We used conditional gene targeting to study the role of Ezh2 in GC B cells. Inducible Ezh2 inactivation in GC B cells resulted in marked apoptosis of the cells, leading to poor antibody responses and fewer high-affinity memory B cells. Strikingly, Ezh2 protected GC B cells from genotoxic damage caused by AID. Global identification of

H3K27me3 targets in GC B cells revealed a significant enrichment for developmental regulators and BCL6 repressed genes. Ezh2 inactivation in GC B cells caused the up-regulation of H3K27me3 targets, including the plasma cell determinants IRF4 and Blimp1. This resulted in a significant enhancement of plasma cell differentiation in response to IL-21 stimulation. All together these results show that Ezh2 sustains AID-dependent antibody diversification and limits IL-21 dependent terminal differentiation of GC B cells, to sustain high affinity antibody responses. Our findings are relevant to understand how deregulated Ezh2 activity may contribute to lymphomagenesis.

W2.03.04
Loss of an Igκ gene enhancer in mature B cells results in rapid gene silencing and partial reversible de-differentiation

*X. Zhou, Y. Xiang, **W. T. Garrard**;*
UT Southwestern Medical Center, Dallas, TX, United States.

We address here whether there is cellular memory of a transcriptional enhancer once it has served its purpose to establish an active chromatin state. We have previously shown that the mouse Igκ gene's downstream enhancers, E3′ and Ed, are essential but play redundant roles for establishing transcriptional activity in the locus during B cell development. To determine if these enhancers are also necessary for the maintenance of transcriptional activity, we conditionally deleted E3′ in mature B cells that possessed Ed -/- alleles. For these studies we bred F/F E3′ Ed -/- mice with either tamoxifen-inducible Cre mice, or with mice specifically expressing CD23-Cre in mature B cells. Successful deletion of E3′ in these cases generated E3′-/-Ed-/- mice, which have single LoxP and Frt sites in place of E3′ and Ed, respectively. Upon E3′ deletion, the locus became rapidly silenced, lost positive histone epigenetic marks, and the mature B cells partially de-differentiated, induced RAG-1 and -2 along with certain other pro-B cell makers, and then re-differentiated after triggering Igλ gene rearrangements. We conclude that the Igκ gene's downstream enhancers are essential for both the establishment and maintenance of transcriptional activity, and that there is no cellular memory of previous transcriptional activity in this locus. Furthermore, upon enhancer loss the mature B cells unexpectedly underwent reversible retrograde differentiation. This result establishes that receptor editing can occur in mature B cells, and raises the possibility that this may provide a tolerance mechanism for eliminating autoreactive B cells in the periphery.

W2.03.05
Regulation of CD4 T helper cell differentiation and plasticity by the histone methyltransferase Ezh2

***D. J. Tumes**[1], A. Onodera[1], C. Iwamura[1], H. Hosokawa[1], H. Koseki[2], K. Tokoyoda[1], Y. Suzuki[3], T. Nakayama[1];*
[1]Department of Immunology, Chiba University, Chiba, Japan, [2]RIKEN Research Center for Allergy and Immunology, Yokohama, Japan, [3]Department of Medical Genome Sciences, University of Tokyo, Kashiwa, Japan.

Upon encountering antigen, naïve CD4 T cells rapidly differentiate into discrete subsets of effector T helper (Th) cells that direct immune responses to different types of infection. Polarizing cytokines induce the expression of lineage-specifying genes (*Tbx21* for Th1 cells and *Gata3* for Th2 cells) that control differentiation. We found that the histone H3K27 methyltransferase Ezh2 controls differentiation of Th1 and Th2 cells, and that inactivation of Ezh2 enhances plasticity of both of these subsets. *Tbx21* and *Gata3* experienced large changes in Ezh2 occupancy during Th differentiation, and inactivation of Ezh2 depleted H3K27-trimethylation (H3K27-Me3) at these loci. Additionally, loss of Ezh2 enhanced the ability of Th2 cells to cause pathology in a mouse model of allergic asthma, and CD4 T cell-specific deletion of Ezh2 resulted in the progressive accumulation of memory phenotype Th2 cells *in vivo*. This study establishes a functional link between Ezh2 and transcriptional regulation of lineage-specifying genes in terminally differentiated peripheral T cells via H3K27-Me3. These data may therefore contribute to the development of therapies that target this pathway to enhance or repress immune responses in human disease.

W2.03.06
Unique epigenetic signatures are associated with the induction, silencing and re-expression of CD8 during T cell development and activation

***K. L. Charlton**[1], E. B. Day[1], B. E. Russ[1], S. H. Apte[2], S. J. Turner[1], A. Kelso[1,3];*
[1]Department of Microbiology and Immunology, The University of Melbourne, Parkville, Victoria, Australia, [2]Queensland Institute of Medical Research, Brisbane, Queensland, Australia, [3]World Health Organization Collaborating Centre for Reference and Research on Influenza, North Melbourne, Victoria, Australia.

The CD8 co-receptor is a powerful modulator of T cell activation and function whose levels are regulated by various stimuli. Here we show that initiation, maintenance and silencing of CD8 expression during murine T cell development in the thymus were associated with complex changes in DNA methylation across the *Cd8a* locus. In peripheral $CD8^+$ T cells, CD8 down-regulation following activation in type 2-polarizing conditions was accompanied by a distinct pattern of *Cd8a* remethylation, which was stable long-term. A combination of activation and certain cytokine signals could induce a subset of apparently committed type 2 $CD8^{low}$ cells to re-express CD8; this reactivation correlated with reduced DNA methylation at specific regions of *Cd8a*. Thus, T cells display a unique epigenetic signature at the *Cd8a* locus at each stage in their development, polarization and reprogramming, suggesting complex, differential DNA modification in response to changing external signals. Notably, type 2-polarized $CD8^{low}$ cells induced to re-express CD8 switched to a type 1 effector phenotype. Therefore, CD8 co-receptor re-expression is one of a suite of functions that can be re-programmed after primary effector differentiation. We conclude that even strongly polarized effector $CD8^+$ T cells have the capacity to adapt to a new environment and tailor their phenotype and function accordingly. Such plasticity may be harnessed for treatment strategies targeting chronic diseases such as HIV or chronic B cell lymphocytic leukaemia, where $CD8^+$ T cells displaying type 2 cytokine production and low CD8 co-receptor expression have been reported and may be linked to poorer disease outcomes.

TCD8+ suppressor cells produce antigen-specific exosomes carrying miRNA-150 to inhibit contact sensitivity response

*K. Bryniarski[1,2], **K. Nazimek**[1], E. Sikora[1], M. Ptak[1], P. W. Askenase[2], W. Ptak[1,2];*
[1]Department of Immunology Jagiellonian University College of Medicine, Krakow, Poland, [2]Department of Internal Medicine, School of Medicine, Yale University, New Haven, CT, United States.

Introduction: T suppressor cells (Ts) release the exosomal suppressor factor (TsF) that inhibit murine contact sensitivity reaction (CS). The antigen specificity of exosomes is warranted by coating with immunoglobulin light chains produced by B1 lymphocytes.
The research is aimed to define Ts phenotype and to determine the exact structure of exosome cargo conditioning suppressive activity of TsF.
Materials & Methods: Mice tolerized with high intravenous doses of antigen produce suppressive exosomes isolated in standard ultracentrifugation procedure. Their biological activity is estimated in adoptive transfer of CS effector cells or active hapten immunization and assessed as ear swelling response in CS test. To characterize Ts the negative and positive selection tests and DEREG mice depleted of FoxP3+ T regulatory cells (Tregs) were used. To define the RNA compound of TsF, appropriate miRNA inhibitors and knock-out (KO) mice were used.
Results: TsF exosomes from DEREG mice suppressed CS transfer similarly to wild-type mice. RNA cargo from chromatographically purified suppressive exosomes was sequenced which lead to the assumption that miR150 is the suppressive particle. This hypothesis was verified by using miR150 inhibitor and miR150 KO mice that produce non-suppressive exosomes. Supplementation of exosomes from miR150 KO mice with miR150 restored their suppressive activity.

Conclusions: TsF exosomes are produced by TCD3+CD8+ suppressor lymphocytes that are not Tregs. Their immunoregulatory activity is mediated by miR150 molecules equipped in antigen recognition system. To our knowledge, this is the first evidence of immunoregulation orchestrated in vivo by antigen-specific exosomes carrying inhibitory information coded in a short RNA particle.

W2.04.02
The role of microRNA-142-5P in experimental colitis

***A. A. te Velde**, M. M. W. Slaman, F. H. van Dooren, C. Kunne, S. L. Meijer, K. Fluiter, E. W. Vogels, P. D. Moerland;*
Academic Medical Center, Amsterdam, Netherlands.

The pivotal role of microRNAs in the regulation of gene expression, in particular genes involved in the immune response, indicates that they play a role in the pathogenesis of inflammatory bowel disease (IBD) as well. MicroRNAs, by their mechanism of action, are promising new therapeutic agents or targets.
Experimental colitis in severe combined immunodeficiency (SCID) mice shares many features of human inflammatory bowel disease (IBD). In this model in which transfer of CD4CD45RB^{high} T cells results in colitis we found a number of microRNAs upregulated during development of experimental colitis, among these microRNA-142-5p (miR-142-5P). The aim of this study is to determine the effect and the target genes of the upregulated microRNA.
We administered locked-nucleic-acid-modified (LNA) oligonucleotide anti-miR-142-5p or anti-scr-microRNA at the moment the mice demonstrated the first signs of disease 3 weeks after the transfer of the CD4CD45RB^{high} T cells. We determined the course of the disease and performed an mRNA analysis (Illumina, Service SX, Leiden) of the spleen and colon.
Blocking anti-miR-142-5p resulted in a higher survival rate compared to mice treated with anti-scr-microRNA (p=0.0026). In a separate experiment mRNA analysis demonstrated that four of the top ten genes that show upregulation in the spleen after blocking miR-142-5p are found in a pathway related to mast cell biology. In the colon the upregulated genes after blocking miR-142-5p are related to diverse signalling pathways (PPAR, TLR), early stage of cancer and metalloproteases.
Various potential interesting pathways are involved in the diminution of chronic experimental colitis after blocking miR-142-5P.

W2.04.03
Investigating the impact of individual miRNAs on Treg conversion

***S. C. Warth**[1], A. Hiekel[2], V. Heissmeyer[2];*
[1]Helmholtz zentrum Munich, Munich, Germany, [2]Ludwigs-Maximilians-Universität München, Munich, Germany.

T cell differentiation is imposed by transcriptional changes initiated by signaling events upon T cell activation. Induction of regulatory T cells (Treg) further depends on post-transcriptional mRNA regulation by Argonaute-loaded microRNAs, as shown by strongly impaired Treg differentiation in the absence of microRNAs in Dicer-knockout T cells.
Post-transcriptional gene regulation may be most important early after T cell activation before shortening of transcript 3'UTRs and downregulation of Argonaute protein expression occur. To elucidate the function of individual microRNAs on Treg induction during the initial activation phase, we employed adenoviral gene transfer into CD4 T cells, which transgenically express the coxsackie adenovirus receptor. This allowed overexpression of microRNAs in naive CD4 T cells before T cell activation. Based on a screen of 150 T cell-expressed microRNAs we identified a number of microRNAs that significantly affected Treg conversion. To discriminate specific effects of these microRNAs, we also determined their effect on Th17 differentiation. MicroRNA-99a promoted Treg and interfered with Th17 differentiation. Since mTOR is a known reciprocal regulator of Treg and Th17 differentiation we tested its regulation as a predicted miR-99a target. We show an inverse correlation between microRNA-99a overexpression and mTOR mRNA levels during Treg induction as well as a functional repression through the mTOR 3'UTR by microRNA-99a. In summary, our data suggest a role for microRNA-99a as part of a larger miRNA network, which specifically downregulates mRNAs like mTOR to control the reciprocal differentiation towards Treg and Th17 subsets early after antigen-recognition by naive T cells.

W2.04.04
IL-10-induced microRNA-187 negatively regulates TNFα, IL-6 and IL-12p40 production in TLR4-stimulated monocytes

***M. Rossato**[1], G. Curtale[2], N. Tamassia[1], M. Castellucci[1], L. Mori[2], S. Gasperini[1], B. Mariotti[1], M. A. Cassatella[1], M. Locati[2,3], F. Bazzoni[1];*
[1]University of Verona, Verona, Italy, [2]Istituto Clinico Humanitas IRCCS, Rozzano, Italy, [3]University of Milano, Milan, Italy.

Interleukin (IL)-10 is a potent anti-inflammatory molecule that, in phagocytes, negatively targets cytokine expression at transcriptional and post-transcriptional levels. Post-transcriptional checkpoints also represent the specific target of a recently discovered, evolutionary conserved class of small silencing RNAs known as microRNAs (miRNAs), which display the peculiar function of negatively regulating mRNA processing, stability and translation. In this study, we report that activation of primary human monocytes upregulates the expression of miR-187, both *in vitro* and *in vivo*.
Accordingly, we identify miR-187 as the first IL-10-dependent miRNA playing a role in IL-10-mediated suppression of TNFα, IL-6 and IL-12p40 produced by primary human monocytes following TLR4 activation. Ectopic expression of miR-187 consistently and selectively reduces TNFα, IL-6 and IL-12p40 produced by LPS-activated monocytes. Conversely, the production of LPS-induced TNFα, IL-6 and IL-12p40 is significantly increased when miR-187 expression is silenced. Our data demonstrate that miR-187 directly targets TNFα mRNA stability and translation, and indirectly decreases IL-6 and IL-12p40 expression via downmodulation of IκBζ, a master regulator of the transcription of these latter two cytokines. These results uncover a novel miRNA-mediated pathway controlling cytokine expression and demonstrate a central role of miR-187 in the physiological regulation of IL-10-driven anti-inflammatory responses.
This study was supported by research grants from the Ministero dell'Istruzione dell'Università e della Ricerca, the University of Verona, Fondazione Cariverona, the Italian Association for Cancer Research and Regione Lombardia.

MiR-146a promotes IVIg-mediated inhibition of NFκB activation in LPS-treated human monocytes

***L. Loubaki**, D. Chabot, I. Paré, R. Bazin;*
Héma-Québec, Québec, QC, Canada.

Background: Monocytes are key players of the innate immune response and recent studies have shown that their differentiation and functions involve microRNA which act through the inhibition of protein translation. Among them, miR-146a has been shown to supress NF-κB activity and consequently, to inhibit NF-κB target genes. Therefore, miR-146a could lead to anti-inflammatory effects similar to those reported for IVIg, a therapeutic preparation of polyclonal human IgG isolated from the plasma of thousands of healthy donors. Indeed, IVIg has been shown to abrogate pro-inflammatory cytokines while increasing the expression of anti-inflammatory cytokines in monocytic cells.
Objectives: To evaluate whether miR-146a is involved in the anti-inflammatory effects of IVIg following LPS stimulation of human monocytes.
Methods: Human monocytes were obtained from the blood of healthy volunteers and treated with LPS (1 µg/mL) or IVIg (15 mg/mL) alone or alternatively, pretreated with LPS followed by addition of IVIg. Then, miR-146a, IRF3, IFN-β, TGF-β1 and IL-1Ra expression was measured by qPCR while NF-κB and IRAK1 expression was measured by Western blotting.
Results: Addition of IVIg to LPS-pretreated monocytes induced a significant up regulation of miR-146a expression associated with a significant reduction of its target IRAK1 and consequently of NF-κB activation. Furthermore the expression of IRF3 and IFN-β was reduced in LPS-pretreated monocytes following treatment with IVIg, whereas TGF-β1 and IL-1Ra expression were increased, thus

skewing the balance between proinflammatory vs anti-inflammatory cytokine towards an anti-inflammatory pathway.
Conclusion: Our data suggest that miR-146a may contribute to the anti-inflammatory effects of IVIg in human monocytes.

MicroRNA regulation of bacterial infection in the lung

***H. L. Tay**, G. E. Kaiko, P. M. Hansbro, P. S. Foster;*
University of Newcastle, Newcastle, Australia.

RATIONALE MicroRNAs (miRNAs) are small non-coding RNA that can bind to multiple target mRNA to repress protein production. While the expressions of specific miRNAs are known to be dysregulated in multiple human diseases, the role of miRNAs during bacterial infection in the lung remains unknown. Lung pathogens, such as non-typeable Haemophilus Influenzae (NTHi), activate different TLR signalling pathways and inflammatory cytokines. Our aim is to investigate the roles of miRNA in regulating these processes.
METHODS Lung miRNAs that were differentially expressed following bacterial challenge were identified by microarray. miRNA in primary macrophages and neutrophils were knocked down using miRNA inhibitors (antagomirs) in vitro, to investigate the role of miRNA in regulating bacterial clearance by these immune cells. In vivo, antagomir-treated macrophages and neutrophils were adoptively transferred into naïve recipient mice. These mice were then challenged with bacterial. Following bacterial challenge, bacterial loads in lung were measured.
RESULTS Upon NTHi infection, 20 miRNAs were up-regulated while 52 were down-regulated by > 2.5 fold. Interestingly, knockdown of a specific miRNA in vitro resulted in significantly decreased bacterial load and increased phagocytosis by macrophages and neutrophils. Similarly, transfer of macrophages or neutrophils deficient in miRNA into naïve recipient mice leads to enhance clearance of the bacteria in vivo. This enhance clearance is independent of cellular infiltration. Inhibiting miRNA may play a protective role by enhancing the function of innate immune cells during bacterial infection.
CONCLUSION Our study suggests that miRNA may play important roles in regulating the innate immune response to bacterial infection.

Genetic Regulation of Longevity in Memory CD4 T cells in Aged mice

***S. Sadegh-Nasseri**, S. Khoruzhenko, N. Song, S. Sonder;*
Johns Hopkins University, Baltimore, MD, United States.

While memory T-cells represent a hallmark of adaptive immunity, little is known about regulation of memory CD4 T-cell survival. A major challenge has been in finding and characterization sufficient numbers of antigen-specific CD4 memory T-cells that survive several months post immunization. Previously, we have shown that presentation of low doses of antigen to memory CD4+ T-cells induce a state of anergy. B cells specific for the protein antigen induce a dormant state in memory CD4 cells that is reversible upon re-infection. Here, by taking advantage of a sensitive technology, we have studied gene expression dynamic profile of specific CD4 cells in mice. We explored mechanisms that allow survival of memory DO11.10 CD4 T-cells throughout mouse life. We analyzed the dynamic patterns of gene expression at multiple time points post Vaccinia-OVA infection up to 11 months comparing it to the gene expressions in naïve cells in young mice, and to age-matched naïve cells in aging mice. The results demonstrated a striking pattern of changes in cellular metabolism as well as pro-survival and other factors that appear to work in synergy to achieve the biological goal of extending the longevity of memory CD4 T-cells. We show a pattern of gene expression that is specific for survival of memory, but not naïve cells in aging mice. Understanding this pattern of gene expression can be used in developing strategies for extending survival of memory CD4 T-cells, or repressing them for improved outcomes in transplantation.

Senescene associated cells in human CD8+ T-lymphocytes

***O. O. Onyema**[1], L. N. Forti[1], R. Njemini[1], I. Bautmans[1], J. Aerts[2], M. De Waele[3], T. Mets[1,4];*
[1]Gerontology Department, Vrije Universiteit, Brussel, Belgium, [2]Immunology and Physiology Department, Vrije Universiteit, Brussel, Belgium, [3]Hematology Department, Universitair Ziekenhuis, Brussel, Belgium, [4]Geriatrics Department, Universitair Ziekenhuis, Brussel, Belgium.

The expression of CD57 and the absence of CD28 on T-lymphocytes have been used as "senescence" markers. The association of these markers with characteristics of senescence that emerge during in vitro cellular aging is, however, not clear. Using flow cytometry, CD8+ T-cells were analyzed in old and young human subjects for their expression of CD57 and CD28. The subpopulations were tested for various markers of cellular senescence, apoptosis, homing and differentiation, and for their proliferation capacity and tendency for apoptosis. Significantly higher proportions of CD28+CD57+ and CD28-CD57+ cells were found in old subjects. CD28+CD57+ cells lacked proliferation, had the highest intensity of expression of p16, p21, Bcl-2 and CD95, and the highest frequency of Bcl-2 and CD95 expressing cells. The combined expression of these proteins favour their likely role in promoting senescence in CD28+CD57+ cells despite the significantly higher proportion of CD28+CD57+ cells positive for the apoptosis indicator, Annexin-V, compared with other subpopulations. The frequency of CD45RO and CCR5 expressing cells was also highest in CD28+CD57+ cells, and are highly expressed by T-cell populations believed to be dominated by senescent cells. Notably, our observation of a subpopulation of CXCR2+ cells among CD28-CD57+ cells indicates the possibility of a subpopulation of CD28-CD57+ cells that might represent a more pronounced senescent phenotype. We conclude that among CD8+ T-lymphocytes, characteristics that correspond to a senescent cell type are most prominent in CD28+CD57+ cells, thus providing further evidence for the existence of senescent cells in vivo and their possible importance in aging.

Characterization of the role of distinct plasma cell-free DNA (cf-DNA) species in age-associated inflammation and frailty

***J. Jylhävä**;*
University of Tampere, Medical school, Dept. Microbiology and immunology, Tampere, Finland.

Self-DNA that circulates in plasma as cell-free DNA (cf-DNA) has recently emerged as a potential biomarker of age-associated systemic inflammation and cell death. cf-DNA may also promote autoinflammation in certain cass. Because the total cf-DNA pool comprises different cf-DNA species, we quantified the plasma levels of gene-coding cf-DNA, Alu repeat cf-DNA, mitochondrial DNA (mtDNA) copy number and the amounts of unmethylated and total cf-DNAs. We identified the relationships between these cf-DNA species and age-associated inflammation, immunosenescence and frailty. In addition, we determined the cf-DNA species-specific genome-wide transcriptomic signatures in blood mononuclear cells to elucidate the age-linked leukocyte responses to cf-DNA. The study population consisted of n=144 nonagenarian participants of the Vitality 90+ Study and n=30 young controls. In the nonagenarians, higher levels of total and unmethylated cf-DNAs were associated with systemic inflammation and increased frailty. The plasma mtDNA copy number was also directly correlated with increased frailty but not with inflammation. None of the cf-DNA species were associated with immunosenescence. The transcriptomic pathway analysis revealed that higher levels of total and unmethylated cf-DNAs were associated with immunoinflammatory activation in the nonagenarians but not in the young controls. The plasma mtDNA appeared to be inert in terms of inflammatory activation in both the nonagenarians and young controls. These results demonstrate that the plasma levels of total and unmethylated cf-DNA could serve as biomarkers of age-associated systemic inflammation and frailty. We suggest that circulating self-DNA, assessed as total or unmethylated cf-DNA, might aggravate immunoinflammatory reactivity in very old individuals.

Assessing human TCRB CDR3 repertoire by a RACE-PCR-sequencing method

H. Li, T. Hiroi, Y. Zhang, G. Chen, S. De, E. J. Metter, W. H. Wood III, E. G. Becker, ***N. P. Weng****;*
National Institute on Aging, Baltimore, MD, United States.

The T cell receptor (TCR) repertoire is a blueprint and record of the adaptive immune system in humans. The great diversity and proper distribution of the TCR repertoire is essential for a competent immune system that is capable of responding effectively to the vast universe of antigens/pathogens. However, neither the actual size of the diversity nor the distribution of specific TCR in man has been adequately determined. Here, we describe a RACE-PCR- next generation sequencing (RAP-Seq) method that allows a direct assessment of the size and distribution of the TCRβ CDR3 repertoire of T cells. We have also developed computational algorithms for data processing and analysis. From analysis of the TCRβ CDR3 repertoire of peripheral blood from 16 adults (21-94 years old), including 7 adults with longitudinal samples, we found that the size of the TCRβ CDR3 diversity of CD4+ T cells ranges from 2.6-3.7 x105, which was more than twice that of CD8+ T cells. With age, expansion of highly abundant TCRβ CDR3 clones as well as reduction in TCRβ CDR3 diversity size was observed in old adults (>late 60s). Remarkably, a significant number of TCRβ CDR3 retained over a decade including some public TCRβ CDR3 against known viral antigens. Together, these findings reveal for the first time the actual age-associated changes of the TCRβ CDR3 repertoire (reduced diversity and altered distribution) in humans, which could serve as a measure of immune competency and a guide for intervention in the elderly.

W2.05.04
Memory B cell repertoire changes with age.

D. K. Dunn-Walters*;*
King's College London School of Medicine, London, United Kingdom.

Diversity of repertoire is a necessity for effective function of the immune system. We have previously shown that repertoire diversity can be compromised in old age and that this correlates with poor health. We have also investigated the repertoire changes during vaccination in older people and have seen that age-related perturbations of the repertoire can be seen at different stages of the response. Closer analysis, following the expansion of Ig genes in samples of peripheral blood, show that the IgA response in particular seems to be much delayed, to the extent that there is not much expansion of IgA cells at day 7 after vaccination in old compared to young, and where the young group had resolved the IgA expansions by day 28, the old group still had significant Ig gene expansion. Since plasma cells have many more copies of Ig mRNA than B cells these studies likely reflect changes in peripheral blood plasma cells. Cell sorting to investigate age-related changes in different B cell subsets (by CD27 and IgD phenotype) has indicated that the repertoire of IgG memory B cells also changes with age, such that it acquires characteristics that we previously reported were distinguishing features of so-called IgM memory cells.

W2.05.05
Memory immune response to booster vaccination in old age depends on adequate priming earlier in life

B. Weinberger*[1], C. Neuner[2], M. Schirmer[3], R. Mateucci Gothe[4], B. Grubeck-Loebenstein[1];*
[1]Research Institute for Biomedical Aging Research, University Innsbruck, Innsbruck, Austria, [2]Public Health Department, Federal State of Tyrol, Innsbruck, Austria, [3]Department of Internal Medicine I, Medical University Innsbruck, Innsbruck, Austria, [4]Department of Public Health and Health Technology Assessment, UMIT – University for Health Sciences, Medical Informatics and Technology, Hall i. T., Austria.

Regular booster vaccinations against tetanus and diphtheria are recommended for adults and older persons in many European countries. Vaccine-induced immune responses are generally weaker and antibody decline over time is more pronounced in the elderly. We therefore investigated immune responses to booster vaccinations against tetanus and diphtheria in older adults. 87 persons over 60 years received two consecutive booster vaccinations against tetanus and diphtheria and antibody concentrations were measured before and 4 weeks after the vaccinations. After the second boost tetanus- and diphtheria-specific circulating plasmablasts and cytokine secreting T cells were determined. The proportion of persons without protective antibody concentrations (0.1 IU/ml) against diphtheria was lower prior to the second compared to the first boost probably due to the shorter booster interval. Four weeks after vaccination all participants had protective antibodies against tetanus, but 14% or 7% had no protective antibodies against diphtheria after the first and the second vaccination, respectively. Individual antibody responses were very similar after the first and the second boost, but responses against tetanus and diphtheria were only weakly linked. Antibody responses were independent of gender, health status, CMV-status, inflammatory status and specific T cell responses. However, there was a strong correlation between antibody responses and the size of the memory B cell pool as indicated by the number of specific circulating IgG-plasmablasts 7 days after booster vaccination. Our results show that older persons respond similar to consecutive booster vaccinations and that vaccination history and primary responses are determining factors for the quality of booster responses.

W2.05.06
Human B cell response to the influenza vaccine is predicted by AID and decreased by inflammaging

B. B. Blomberg*, A. Diaz, M. Romero, A. Landin, D. Frasca;*
University of Miami Miller School of Medicine, Miami, FL, United States.

Deficits in immune responses in the elderly contribute to their mortality and morbidity. In order to develop predictive markers for a beneficial humoral immune response, we evaluated the in vivo and in vitro response to the seasonal influenza vaccine in young and elderly individuals. We measured serum antibody response and associated this with the in vitro B cell response to the vaccine, measured by AID (activation-induced cytidine deaminase). AID is a measure of immunoglobulin class switch recombination (CSR), the process that generates protective antibodies and memory B cells, and is a good measure of B cell function. Both responses decrease with age, are significantly correlated, and measures of AID in activated (mitogen) B cells at t0 (before vaccination) predict ability to respond to the vaccine. We hypothesized that the increased pro-inflammatory status of the elderly, called inflammaging, directly impacts B cell function, thus impairing the capacity of the individual to make protective antibodies and to respond to vaccination. Our data indicate that aged B lymphocytes themselves make TNF-α before vaccine challenge and this correlates with their impaired function, including reduced AID expression after B cell stimulation. Our results reveal new molecular mechanisms which contribute to reduced antibody responses in aging and suggest that these will have an impact for crucial development of effective vaccines to protect the elderly from infectious and other debilitating diseases.

Clathrin light chain subunits control actin organization during infection and lymphocyte migration

F. M. Brodsky*[1], M. Bonazzi[2], P. Cossart[3], P. Parham[4], S. Majeed[1];*
[1]UCSF, San Francisco, CA, United States, [2]CPBS-CNRS, Montpellier, France, [3]Institut Pasteur, Paris, France, [4]Stanford University, Stanford, CA, United States.

The self-assembly of clathrin into a lattice-like coat on membranes is mediated by the clathrin heavy chain (CHC) subunits, which form a triskelion-shaped molecule. The classical function of the clathrin coat is to sort proteins into vesicles during receptor-mediated endocytosis and organelle biogenesis. Our work now defines novel functions for

clathrin on both sides of host-pathogen interactions and these new roles are dependent on the clathrin light chain (CLC) subunits. While these subunits contribute to assembly regulation, they also provide a functional link between the clathrin lattice and the actin cytoskeleton. This link occurs via the Hip family proteins (Hip1R, Hip1 or Sla2p in yeast), which bind to CLC and actin. During infection by bacteria that co-opt actin for host uptake or adhesion, clathrin is exploited as a platform for actin organization and this requires CLC and Hip, as well as tyrosine phosphorylation of the CHC. CLC-Hip-actin interactions also contribute to cell migration and this is dramatically illustrated by a lymphocyte migration defect in mice that are genetically deleted for the CLCa isoform. Most tissues express both CLC isoforms, and the CLCb isoform can substitute for many CLCa functions. However, lymphocytes predominantly express CLCa and do not compensate by increased CLCb expression in the CLCa-deleted animals, so their lymphocytes are effectively CLC negative. In these animals, lymphocytes are defective in directional migration towards chemokine signals, demonstrating a major role for clathrin in lymphocyte response to infection. Thus, the clathrin-actin connection contributes to immune defense, as well as pathogen subversion.

W2.06.02
DOCK8 is a Cdc42 activator critical for interstitial dendritic cell migration during immune responses

Y. Harada[1,2], *Y. Tanaka*[1,2,3], *M. Terasawa*[1,2], *J. V. Stein*[4], *T. Kinashi*[2,5], *Y. Fukui*[1,2,3];
[1]*Division of Immunogenetics , Medical Institute of Bioreguration, Fukuoka, Japan,* [2]*Japan Science and Technology agency, CREST, Tokyo, Japan,* [3]*Research Center for Advanced Immunology, Kyushu University, Fukuoka, Japan,* [4]*Theodor Kocher Institute, University of Bern, Bern, Switzerland,* [5]*Department of Molecular Genetics, Institute of Biomedical Science, Kansai Medical University, Osaka, Japan.*

To migrate efficiently through the interstitium, dendritic cells (DCs) constantly adapt their shape to the given structure of the extracellular matrix and follow the path of least resistance. It is known that this amoeboid migration of DCs requires Cdc42, yet the upstream regulators critical for localization and activation of Cdc42 remain to be determined. In this study, we show that DOCK8 is a Cdc42-specific guanine nucleotide exchange factor critical for interstitial DC migration. By generating the knockout mice, we found that in the absence of DOCK8, DCs failed to accumulate in the lymph node parenchyma for T-cell priming. Although DOCK8-deficient DCs migrated normally on 2-dimensional surfaces, DOCK8 was required for DCs to crawl within 3-dimensional fibrillar networks and to transmigrate through the subcapsular sinus floor. This function of DOCK8 depended on the DHR-2 domain mediating Cdc42 activation. DOCK8 deficiency did not affect global Cdc42 activity. However, Cdc42 activation at the leading edge membrane was impaired in DOCK8-deficient DCs, resulting in a severe defect in amoeboid polarization and migration. These results indicate that DOCK8 regulates interstitial DC migration by controlling Cdc42 activity spatially.

W2.06.03
All-trans retinoic acid and rapamycin synergize with transforming growth factor-β to induce regulatory T cells but confer distinct in vivo migratory capacities

G. Raimondi[1], *S. Jhunjhunwala*[2], *L. C. Chen*[3], *E. E. Nichols*[4], *Y. T. Nicholson*[3], *A. W. Thomson*[3], *S. R. Little*[5];
[1]*Johns Hopkins School of Medicine, Baltimore, MD, United States,* [2]*Massachusetts Institute of Technology, Boston, MA, United States,* [3]*Starzl Transplantation Institute - University of Pittsburgh School of Medicine, Pittsburgh, PA, United States,* [4]*University of Pittsburgh, Pittsburgh, PA, United States,* [5]*Department of Chemical Engineering and McGowan Institute - University of Pittsburgh, Pittsburgh, PA, United States.*

Regulatory T cells (Treg) hold great promise for immunoregulation. However, being the frequency of naturally-occurring Treg extremely low, inducing Treg (iTreg) from non-Treg is a viable alternative. We have then compared the functional and migratory properties of iTreg induced in presence of all-trans retinoic acid (RA) or rapamycin (Rapa) - two molecules that synergize with TGF-β to induce stable iTreg.
Addition of RA or Rapa during activation of mouse CD4+CD25- T cells increased the conversion to Foxp3+ cells over TGF-β alone. No significant differences were found in the expression of Treg-associated markers: CTLA-4, CD25, and GITR. All three iTreg types had similar in vitro suppressive capacity. Major differences were evident, however, in the expression of chemokine receptors and integrins: TGFβ-iTreg were CCR9loCD103hi; RA-iTreg were CCR9hiCD103hi, and Rapa-iTreg were CCR7hiCCR9loCD103lo - suggesting different migratory properties. Bioluminescent imaging of adoptively- transferred luciferase-expressing iTreg confirmed that Rapa-iTreg had a greater tendency to accumulate in lymph nodes, while RA-iTreg accumulated outside of lymphoid tissues. In a mouse model of inflammatory bowel disease (based on adoptive transfer of T cells with or without iTreg), Rapa-iTreg exerted the strongest protective effect, correlating with their ability to suppress the activation of colitogenic T cells in mesenteric lymph nodes.
Overall, although RA and Rapa are considered interchangeable in promoting stable iTreg, they confer a different migratory potential that translates in different abilities to control local immune responses. We then envision interventions that employ iTreg "optimized" for the specific type and stage of disease to be treated.

W2.06.04
The transporter Spns2 is required for secretion of lymph but not plasma sphingosine-1-phosphate

A. Mendoza[1], *B. Breart*[1], *W. D. Ramos-Perez*[1], *L. A. Pitt*[1], *M. Gobert*[1], *M. Sunkara*[2], *J. J. Lafaille*[1], *A. J. Morris*[2], ***S. R. Schwab***[1];
[1]*Skirball Institute, New York University School of Medicine, New York, NY, United States,* [2]*Gill Heart Institute, University of Kentucky, Lexington, KY, United States.*

Plasma sphingosine-1-phosphate (S1P) regulates vascular permeability, and plasma and lymph S1P guide lymphocyte egress from lymphoid organs. S1P is made intracellularly, and little is known about how S1P is delivered into circulatory fluids. Here, we find that mice without the major facilitator superfamily transporter Spns2 have a profound reduction in lymph S1P, but only a minor decrease in plasma S1P. Spns2-deficient mice have a redistribution of lymphocytes from the spleen to lymph nodes and a loss of circulating lymphocytes, consistent with normal egress from the spleen directed by plasma S1P and blocked egress from lymph nodes directed by lymph S1P. Spns2 is needed in lymphatic endothelial cells to supply lymph S1P and support lymphocyte circulation. As the first differential requirement for lymph and blood S1P to our knowledge, Spns2 may be an attractive target for immune suppressive drugs.

W2.06.05
D6 is a β-arrestin-biased signaling chemokine scavenger receptor

C. Cancellieri[1], *E. M. Borroni*[1], *A. Vacchini*[1], *Y. Benureau*[2], *F. Bachelerie*[2], *F. Arenzana-Seisdedos*[2], *K. Mizuno*[3], *A. Mantovani*[1], *R. Bonecchi*[1], *M. Locati*[1];
[1]*Departement of Medical Biotechnologies and Translational Medicine, University of Milan, Humanitas Research and Cancer Center, Rozzano-Milan, Italy,* [2]*Unité de Pathogénie Virale Moléculaire, Institut Pasteur, Paris, France,* [3]*Department of Biomolecular Sciences, Tohoku University, Sendai, Japan.*

The atypical chemokine receptor D6 is a scavenger for inflammatory CC chemokines with a non-redundant role in the control of inflammatory processes. Being unable to sustain cell migration and activate signal transduction pathways triggered by classical chemokine receptors, such as CCR5, D6 is currently classified as a "silent" receptor. Our previous data showed that, differently from CCR5, ligand induces D6 up-regulation on plasma membrane through a rapid mobilization of receptor from recycling endosomes, thus improving its scavenging performance. Here we report that in cells expressing D6 or CCR5, ligand engagement causes a massive actin cytoskeleton reorganization and changes receptors colocalization with actin filaments in a completely opposite fashion. Both receptors signal to actin cytoskeleton by phosphorylating cofilinA

through the Rac1-PAK1-LIMK1-dependent pathway. However, opposite to CCR5, D6 activates this pathway via a beta-arrestin-dependent, G protein-independent mechanism. Inhibition of each component of this signaling cascade completely abrogates D6 adaptive upregulation and scavenging activity. Altogether these results provide the first evidence that D6 scavenging activity relies on unique signaling properties and raise the intriguing possibility to extend our observations to the others members of atypical chemokine receptors subfamily, in order to understand if the beta-arrestin-dependent triggering of Rac1-PAK1-LIMK1-cofilin pathway represents a general signaling feature which specifically defines this particular subfamily and contributes to explain their peculiar activities aimed at chemokine gradient shaping instead of prompt cell migration.

A mechanism of the skin-infiltration of basophils that is essential for the acquired protective immunity to tick infestation

S. Yoshikawa[1], *T. Ohta*[1], *K. Ishiwata*[2], *K. Horiguchi*[1], *L. Li*[1], *K. Miyake*[1], *Y. Kawano*[1], *H. Kanuka*[2], *N. Watanabe*[2], *H. Karasuyama*[1];
[1]*Department of Immune Regulation, Tokyo Medical and Dental University Graduate School, Tokyo, Japan,* [2]*Department of Tropical Medicine, Jikei University School of Medicine, Tokyo, Japan.*

Blood-sucking ticks are ectoparasites that transmit a wide variety of microorganisms to humans and animals, leading to serious infectious disorders including Lyme disease. Many animal species show resistance to tick re-infestation, and thereby have less chance of pathogen transmission. We recently reported that basophils are recruited to tick-feeding sites during the 2nd infestation, and that basophil depletion abolishes the manifestation of tick resistance, illustrating a pivotal role for basophils in acquired protective immunity against tick infestation. However, it remains elusive how basophils are recruited to tick-feedingsites during the 2nd but not 1st infestation. We found that IL-3-deficient mice exhibited impairment in protective immunity against ticks and basophil infiltration to tick-feeding sites during the 2nd infestation. While Rag2-/- mice deficient for T and B cells, failed to accumulated basophils at tick-feeding sites during the 2nd infestation, adoptive transfer of T cells isolated from wild-type but not IL-3-deficient mice restored the basophil accumulatiuon. Of note, the-pretreatment with IL-3 but not TSLP conferred the ability to accumulate basophils on Rag2-/- mice even in the 1st infestation, in spite of the absence of T cells. These results suggest that in the 2nd infestation, T cells specific to tick antigen produce IL-3, which in turn promotes basophil recruitment to the tick-feeding sites.

Regulatory T cells that developed *via* central tolerance mechanisms in the thymus play a major role in maintenance of peripheral tolerance. For inducing tolerance to an immunogenic protein therapeutic, we customized the immune repertoire during ontogeny of the immune system by exploiting the physiological process of maternal IgG transcytosis to fetal circulation *via* neonatal FcRn receptor. To this end, mouse Ig-Fc-fusion chimeric molecules were developed using domains of FVIII (A2-Fc, C2-Fc) and hemagglutinin (HA1-Fc), with biochemical and functional characterisation. ELISA and *in vivo* imaging validated the placental transfer of the proteins to the fetuses during gestation. The functional avidity, presentation by thymic APCs, time window and therapeutic dose were determined in HA-TcR transgenic mice, where $HA_{111-119}$ specific T cells can be identified using anti-clonotypic antibody. Intravenous injection of 100µg protein during gestational day 16 to 18 was sufficient to significantly induce HA1-specific Tregs and to delete autoreactive T cells in the progeny. These validated parameters were then applied to a mouse model of hemophilia A (FVIII $^{-/-}$) utilizing A2-Fc, C2-Fc and monoclonal IgG1 as control. The progeny of A2-Fc and C2-Fc treated mothers was challenged with therapeutic doses of the FVIII neo-antigen at 6 weeks of age. The data show an induction of FVIII-tolerance in the progeny with drastic reduction in the levels of total anti-FVIII IgG and abrogation of FVIII-specific T cell proliferation. Our study provides the first proof of concept towards exploiting the materno-fetal interface to shape the immune repertoire and to induce tolerance in allo-immune pathological conditions.

W2.07.02
Ly9 (CD229) cell surface receptor ameliorates autoimmune response

X. Romero*, J. de Salort, P. Engel;*
Univerity of Barcelona, Barcelona, Spain.

Systemic lupus erythematosus (SLE) is a multisystem autoimmune disease characterized by a major immunological stigmata, the production of antibodies against own cell nuclear components. Genetic predisposition is a central element for the development of SLE. A fine mapping of Sle1 region defined a gene interval of 0.9Mb, termed Sle1b, as the most potent segment implicated in the generation of autoantibodies. Interestingly, this segment includes seven signaling activation molecules family (SLAMF) cell surface receptor genes. Ly9 is a cell surface molecule that belongs to the SLAMF receptors. Here, we use *Ly9*-deficient mice backcrossed to B6 and BALB/c backgrounds to determine the role of Ly9 receptor in autoantibody development. Our findings revealed that the absence of Ly9 receptor *per se* initiates the spontaneous development of autoantibodies. By contrast, a chemically induced lupus model, injecting pristane, showed that both wt and *Ly9*-deficient strains (*BALB/c.129*) developed equally high titers of auto-antibodies. We further demonstrate that *Ly9* gene ablation in *BALB/c* background results in disturbed B and T cell subsets involved in autoimmunity, with major differences observed in Tfh cells and GC B cells. In summary, the data presented in this study shed light on the inhibitory function of Ly9 cell surface receptor, suggesting that this molecule is involved in maintenance of peripheral cell tolerance by serving as a negative regulator of immune response.

W2.07.03
An Agonistic Anti-BTLA mAb (3C10) Induced Generation of IL-10 Dependent Regulatory CD4$^+$ T Cells and Prolongation of Murine Cardiac Allograft

M. Uchiyama[1,2], *X. Jin*[2,3], *Q. Zhang*[2], *L. Yu*[2], *H. Bashuda*[1], *H. Matsuda*[1], *H. Yagita*[1], *M. Niimi*[2];
[1]*Juntendo University, Tokyo, Japan,* [2]*Teikyo University, Tokyo, Japan,* [3]*Harbin Medical University, Harbin, China.*

Background: The co-inhibitory receptor B and T lymphocyte attenuator (BTLA) has been implicated in the regulation of autoimmunity and may potentially play an important role in allograft tolerance. We investigated the effect of an agonistic anti-BTLA mAb (3C10) in the fully MHC-mismatched murine cardiac transplantation.
Methods: CBA mice underwent transplantation of C57BL/6 hearts and received one dose of 3C10 on the day of transplantation (day 0) or four doses of 3C10 on day 0, 3, 6 and 9. Adoptive transfer studies were performed to determine whether regulatory cells were generated. Moreover, to confirm the requirement for regulatory T cell and Th-2 cytokines, we administrated anti-interleukin (IL)-2 receptor

alpha antibody (PC-61) or anti-IL-10 antibody (JES-2A5) to 3C10-treated CBA recipient.
Results: CBA mice treated with one and four doses of 3C10 prolonged allograft survival (median survival times [MSTs], 43 and >100 days, respectively). Secondary CBA recipients given whole splenocytes or $CD4^+$ cells from primary 3C10-treated CBA recipients had significantly prolonged survival of C57BL/6 hearts (MSTs, >100 in both). Also, flow cytometry studies showed an increased $CD4^+CD25^+Foxp3^+$ cell population in 3C10-treated mice. Additionally, IL-2 and interferon-γ production were suppressed in 3C10-treated mice, and IL-4 and IL-10 from 3C10-treated CBA mice increased. Moreover, 3C10 directly suppressed allo-proliferation in a mixed leukocyte culture. However, administration of PC-61 or JES-2A5 clearly attenuated prolonged survival of 3C10-treated mice (MSTs, 15.5 and 13.5 days, respectively).
Conclusion: 3C10 could control acute rejection by its suppressive effect on alloreactive T cells and induction of IL-10 dependent regulatory $CD4^+$ T cells.

Upregulation of inhibitory molecules in T cells is associated with altered functions of dendritic cells by HIV-1 and activation of the P38MAPK/STAT3 pathway

E. M. Shankar[1], *K. F. Che*[2], *M. Larsson*[3];
[1]*Department of Medical Microbiology, Faculty of Medicine, University of Malaya, Kuala Lumpur, Malaysia,* [2]*Institute for Environmental Medicine, Karolinska Institutet, Stockholm, Sweden,* [3]*Division of Molecular Virology, Department of Clinical and Experimental Medicine, Linkoping University, Linkoping, Sweden.*

HIV-1 reportedly augments the expression of certain negative costimulatory and inhibitory molecules on T cells, leading to immune impairment. The signaling mechanisms underlying the induction of suppressor molecules and subsequent onset of T-cell impairment in HIV infection remain ambiguous. Our experiments with both autologous and allogeneic T cells exposed to HIV-pulsed dendritic cells showed increased expression of LAG-3, TIM-3, CD160 CTLA-4, TRAIL, and certain suppression-associated transcription factors, namely Blimp-1, DTX1 and FoxP3, whose recruitments were closely regulated by P38MAPK/STAT3 signal transduction pathways. Blockade of P38MAPK/STAT3 significantly decreased the expression of the inhibitory molecules studied and significantly restored T-cell proliferation. The P38MAPK/STAT3 proteins had a higher degree of phosphorylation in the HIV-1-primed cells. We also found that IL-6 and IL-10, and certain other growth factors commonly known to activate STAT3 signaling events were not responsible for STAT3 activation. Blockade of viral CD4 binding and fusion with DCs significantly reduced the negative effects DCs imposed on primed T cells. We concluded that HIV-1 negatively modulate DC functions, causing the activation of the P38MAPK/STAT3 pathway in T cells, leading to recruitment of inhibitory molecules and subsequent onset of T-cell impairment.

W2.07.05
Interleukin 15 reverses age-related CD8+ T cell inactivation with increasing interferon-gamma production and improves survival in aged septic mice

S. Inoue[1], *K. Suzuki-Utsunomiya*[1], *Y. Komori*[1], *S. Inokuchi*[2], *K. Hozumi*[3], *T. Sato*[3];
[1]*Institute of Innovative Science and Technology, Tokai University, Isehara, Kanagawa, Japan,* [2]*Department of Emergency and Critical Care Medicine, School of Medicine, Tokai University, Isehara, Kanagawa, Japan,* [3]*Department of Immunology, School of Medicine, Tokai University, Isehara, Kanagawa, Japan.*

Background: Aging plays an important role in sepsis, a systemic inflammatory response to infection with immunosuppression. Elderly patients with sepsis show reduced immunocompetent T cells. Interleukin 15 (IL-15) is a pluripotent antiapoptotic cytokine that promotes lymphocytes activation and proliferation. We examined whether IL-15 increases T-cell activation and improves survival of aged septic mice. Method: In vitro study Splenocytes from young (6-8 weeks) and aged (20-22 months) C57/B6 mice were stimulated overnight using an anti-CD3 antibody with/without recombinant mouse IL-15. We performed flow cytometric analysis for T]-cell activation and measured interferon-gamma (IFN-γ) levels in the supernatants. In vivo study Aged mice underwent cecal ligation puncture (CLP) or sham treatment. We subcutaneously injected 1.5 μg IL-15 or phosphate-buffered saline at 3 h after CLP. Mice were killed at 24 h after CLP for peritoneal lavage and blood collection. We measured cytokine levels, counted bacterial colonies in the peritoneal cavity, and performed a 7-day survival test. Results: In vitro stimulation of splenocytes showed that compared to young mice, aged mice showed impaired T-cell activation (68% reduction in both CD4+ and CD8+ T cells, $p < 0.01$). IL-15 reversed this impaired CD8+T cells l activation in aged mice and increased IFN-γ levels dose dependently. Furthermore, IL-15 increased bacterial clearance and IFN-γ levels in the peritoneal cavity in vivo. IL-15 also improved the 7-day survival after sepsis in aged mice (67% vs 0%, $p = 0.015$). Conclusion: IL-15 reverses age-related T-cell inactivation with increasing IFN-γ production and improves survival in aged septic mice.

W2.07.06
Upregulation of glucocorticoid-induced leucine zipper by hepatocyte growth factor promotes tolerogenic dendritic cells and inhibits experimental autoimmune encephalomyelitis

M. Benkhoucha, *N. Molnarfi, M. Santiago-Raber, G. Schneiter, P. Lalive;*
Faculty of Medicine. Department de Pathology and Immunology - CMU, Geneva, Switzerland.

Objective: To unravel the immunomodulatory mode of actions of hepatocyte growth factor (HGF) in experimental autoimmune encephalomyelitis (EAE), a mouse model of multiple sclerosis (MS).
Background: We previously showed that CNS-restricted expression of HGF, a factor known for both neuronal and oligodendrocytic protective properties, decreased EAE immunopathogenesis by promoting tolerogenic dendritic cells (tDCs) (Benkhoucha M. et al., *PNAS*, 2010). Expression of glucocorticoid-induced leucine zipper (GILZ), a transcriptional regulator, was reported to correlate with the regulatory activity of tDCs, conferring a possible mechanism by which HGF could exert regulatory activities on DCs.
Design/Methods: Systemic HGF (50 μg) treatment was applied s.c. two days before EAE induction (myelin oligodendrocyte glycoprotein p35-55). DC functions were evaluated *ex vivo*. Using DCs in which GILZ expression was selectively suppressed, we assessed the ability of HGF to induce tDCs.
Results: Mice treated with HGF developed reduced disease and had in the periphery decreased frequencies of both Th1 and Th17 cells but increased proportion of Tregs. DCs from HGF-treated mice produced high levels of GILZ. RNAi-mediated knock-down approach demonstrated that GILZ is critical for HGF in driving tDC differentiation. Using adoptive transfer experiments, we established that HGF treatment of DCs from wild-type, but not from GILZ knock-out mice, conferred significant protection to recipient mice with established EAE.
Conclusion/Relevance: These results indentify GILZ as a critical factor for effective suppression of T-cell-mediated CNS inflammation by HGF via the induction of tDCs, a mechanism that may be exploited for therapeutic benefit in pathology of autoimmune diseases such as MS.

W2.08 Antigen receptor signaling

IL2.08.01
Novel assignments for the CD43 molecule

*M. E. Bravo-Adame[1], M. Sandoval-Hernández[1], N. A. Fierro[2], E. Pérez-Rueda[1], J. Carneiro[3], R. Vera[1], B. Barkla[1], M. E. Cruz-Munoz[1], **Y. Rosenstein**[1];*
[1]Instituto de Biotecnología, UNAM, Cuernavaca, Mor., Mexico, [2]Centro Universitario de Ciencias de la Salud, Hosp. Civil de Guadalajara, Guadalajara, Jal., Mexico, [3]Instituto Gulbenkian, Oreiras, Portugal.

CD43 is the most abundant costimulatory molecule on the T cell surface; it transduces activation signals through its cytoplasmic domain, modulating the outcome of T cell responses. CD43 signals lower the threshold for TCR-dependent activation by controlling different regulatory loops. Particularly, CD43 engagement restricts the c-Cbl and Cbl-b inhibitory effects on TCR signaling as well as the participation of SHP-1, ultimately increasing the intensity and the duration of downstream signals. Recently, we undertook a series of projects aimed at identifying new signaling pathways and novel functions modulated by CD43. The analysis of protein expression profiles of normal human CD4+ T cells stimulated through TCR and CD43 uncovered changes in proteins involved in a variety of biological processes such as cell migration, cell signaling, apoptosis, cell cycle, gene expression and metabolism, with glucose metabolic processes significantly represented. Data will be shown supporting the participation of CD43 in glucose metabolism, as well as in activating moonlight functions of pyruvate kinase PKM2. In addition, we will show how a predictive analysis of the transcription factors (TFs) that would regulate the promoters of a panel of 42 cytokines, chemokines, and growth factors [the expression of which is upregulated in response to the combined signals of CD43 and the TCR] led us to identify a group of TFs as “global” regulators. Thus, in addition to strengthen TCR signals, CD43 modulates gene transcription and metabolism, two important processes for a cell to decide whether pursuing a differentiation program is wise.

W2.08.01
Antigen-specific TCR-pMHC catch bond enables force to trigger T cell signaling

C. Zhu[1], *B. Liu[1], W. Chen[1], B. Evavold[2];*
[1]Georgia Institute of Technology, Atlanta, GA, United States, [2]Emory University, Atlanta, GA, United States.

T cell receptor (TCR) binding to the peptide-major histocompatibility complex (pMHC) initiates adaptive immune responses. Mechanical force may be applied to TCR-pMHC bonds, thereby triggering T-cell signaling. However, it is not known how force regulates the stability of TCR-pMHC bonds and how such regulation impacts T cell triggering. Using a single-bond mechanical assay, here we show that force unexpectedly stabilizes TCR-pMHC interaction via an agonist-specific catch bond, where bond lifetime is prolonged by force. Concurrent Ca^{2+} imaging and binding measurement demonstrates that a 10-piconewton durable force applied via agonist pMHC to a TCR is sufficient and necessary to trigger intracellular Ca^{2+} flux. Single cell analysis revealed that Ca^{2+} signaling strength best correlates with total bond lifetime accumulated in the first minute during repeated force application through TCR-pMHC bond. For T cells with similar cumulative bond lifetimes, a greater number of short lifetimes corresponds to a lower level of Ca^{2+} flux. Therefore, our data support a T cell triggering model, where a mechanical force applied to the TCR delivers either an activating or inhibitory signal depending on the bond lifetime, such that agonists form catch bonds with the TCR to rapidly accumulate long lifetimes to activate the T cell, whereas antagonists form short-lived slip bonds that attenuate activation.

W2.08.02
Regulation of the Ras-Erk cascade during T-cell activation

*M. Poltorak[1], B. Schraven[2], **I. Simeoni**[1];*
[1]Otto-von-Guericke University, Institute of Molecular and Clinical Immunology, Magdeburg, Germany, [2]Otto-von-Guericke University, Institute of Molecular and Clinical Immunology, Magdeburg, Germany.

The duration and/or the magnitude of Erk activation are known to regulate cell-fate decisions. In lymphoid cell lines, the Ras-Erk cascade is activated by the action of two GEFs, the ubiquitously expressed Sos1 and the lymphoid-specific RasGRP1. Here, we have assessed how Ras-Erk is activated upon TCR triggering in primary human T cells. We used two different stimuli, CD3 mAbs cross-linked in solution (sAbs) or immobilized on microbeads (iAbs). sAbs induce a transient Erk signaling and an anergic-like, unresponsive state, whereas iAbs induce sustained Erk activation and T-cell proliferation. In order to evaluate the role of Sos1 and RasGRP1 in transient vs. sustained Erk activation, we suppressed Sos1 or RasGRP1 expression using siRNA. Surprisingly, we have found that transient Erk activation does not depend on Sos1 but requires RasGRP1. Conversely, sustained Erk signaling depends on both Sos1 and RasGRP1. In summary, our data show that the two GEFs expressed in T cells are differentially involved in the regulation of the duration of Erk activation and in the generation of T-cell responses (the work was supported by DFG SFB854 and GRK1167).

W2.08.03
Kidins220/ARMS associates with B-Raf and the TCR promoting sustained Erk signaling in T cells

G. J. Fiala[1,2,3], *S. Deswal[1,2,3], A. Meyer[1,4], A. E. Eisenhardt[2,5], L. C. Schmitt[2,5], M. Salek[6], T. Brummer[2,5], O. Acuto[6], S. Minguet[1,4], W. W. A. Schamel[1,2,4];*
[1]Department of Molecular Immunology, Institute of Biology III, University of Freiburg and Max Planck Institute of Immunobiology and Epigenetics, Freiburg, Germany, [2]BIOSS Centre for Biological Signaling Studies, University of Freiburg, Freiburg, Germany, [3]Spemann Graduate School of Biology and Medicine, SGBM, University of Freiburg, Freiburg, Germany, [4]Centre for Cronic Immunodeficiency CCI, University Clinics Freiburg and Medical Faculty, University of Freiburg, Freiburg, Germany, [5]Institute for Molecular Medicine and Cell Research, University of Freiburg, Freiburg, Germany, [6]T Cell Signalling Laboratory, Sir William Dunn School of Pathology, University of Oxford, Oxford, United Kingdom.

The activation kinetics of the mitogen activated protein kinase (MAPK) Erk is critical for T cell activation and development. In particular, sustained Erk signalling is required for T-cell activation, such as IL-2 production. While Raf-1 triggers transient Erk activation, B-Raf is implicated in sustained Erk signaling after TCR stimulation. However, how B-Raf activation is coupled to the TCR in unknown. Using mass spectrometry, we identified Kidins220/ARMS as novel B-Raf interaction partners. Kidins220, a protein so far studied only in neuronal and melanoma cells, was associated with the pre-TCR, αβTCR and γδTCR. In mature T cells, Kidins220 is required for TCR-induced sustained, but not transient, Erk activation. Consequently, expression of the transcription factors c-Fos and Erg-1 was impaired and upregulation of the activation markers CD69, IL-2 and IFN-γ was reduced, as we reported recently (1).
Next, we want to investigate the in vivo function of Kidins220 in T cell development. We generated chimeric mice in which a T cell-compromised host was reconstituted with fetal liver-derived cells from the embryonic lethal Kidins220-deficient mice. Thymocytes derived from Kidins220-/- cells exhibited a block at the double-positive stage. Moreover, the transition to CD4+ single-positive thymocytes, where sustained ERK is required, was drastically reduced.
In conclusion, we describe Kidins220 as a novel TCR-interacting protein that couples B-Raf to the TCR. Kidins220 is mandatory for sustained Erk signaling and thus, it is crucial for TCR-mediated T cell activation and development.

W2.08.04
Dual-specificity phosphatase 14 negatively regulates TAK1 signaling and immune responses

C. Yang[1], *T. Tan*[2];
[1]*Immunology Research Center,National Health Research Institutes, Miaoli County, Taiwan,* [2]*Immunology Research Center, National Health Research Institutes, Miaoli County, Taiwan.*

Dual-specificity phosphatase 14 (DUSP14, also named MKP-6) is a general mitogen-activated protein (MAP) kinase (MAPK) phosphatase *in vitro*. Here we show that overexpression of DUSP14, but not a phosphatase-dead DUSP14 mutant, reduced T-cell receptor (TCR) induced TAK1, JNK and IKKα/β activation; knockdown of DUSP14 by RNA interference enhanced these activations. To elucidate the *in vivo* function of DUSP14, we generated DUSP14-deficient mice. The subsets of thymic, spleen and lymph node T cells in DUSP14-deficient mice were indistinguishable from those in wild-type mice. DUSP14-deficient T cells displayed increased T-cell proliferation, enhanced cytokine production, and enhanced up-regulation of the activation markers upon anti-CD3 antibody stimulation. DUSP14 inactivated TAK1, leading to attenuation of IKK and JNK activation. Also, DUSP14-deficient mice exhibited enhanced *in vivo* T cell-mediated immunity and were more susceptible to experimental autoimmune encephalomyelitis (EAE) induction. The molecular mechanism of DUSP14 modification in TCR signaling will also be discussed. Taken together, our results indicate that DUSP14 is a negative regulator of TAK1 signaling and immune responses. (Supported by NHRI-98A1-IMPP01-014)

W2.08.05
Lysophosphatidic acid (LPA) receptor 5 inhibits B cell antigen receptor signaling and antibody response

R. M. Torres[1], *J. Hu*[1], *S. Oda*[1], *A. Al-Shami*[2], *Y. Fujiwara*[3], *G. Tigyi*[4], *T. Oravecz*[2], *R. Pelanda*[1];
[1]*University of Colorado School of Medicine and National Jewish Health, Denver, CO, United States,* [2]*Lexicon Pharmaceuticals, The Woodlands, TX, United States,* [3]*University of Tennessee Health Sciences Center, Memphis, TN, United States,* [4]*University of Tennessee Health Sciences Center, M, TN, United States.*

The development, trafficking and function of lymphocytes is dependent on signaling by sphingosine-1-phosphate G-protein coupled receptors (GPCR). Lysophosphatidic acid (LPA) is another major lysophospholipid found systemically that also signals via distinct GPCR expressed by B and T lymphocytes. Notably, LPA levels are found to be significantly elevated in certain pathological settings such as certain cancers and infections. We have found that BCR signal transduction by mature B cells is inhibited upon LPA engagement of the LPA5 receptor via a Gα12/13 - Arhgef1 signaling axis. The inhibition of BCR signaling by LPA5 manifests by impaired intracellular calcium store release and most likely by interfering with inositol 1,4,5-trisphosphate receptor activity. We further show that LPA5 also limits antigen-specific induction of CD69 and CD86 expression and that LPA5-deficient B cells display enhanced antibody responses. Thus, these data show that LPA engagement of LPA5 negatively regulates BCR signaling, B cell activation and immune response. These findings extend the influence of lysophospholipids on immune function beyond directing lymphocyte trafficking and suggest that alterations in LPA levels as found in certain pathological conditions likely influence adaptive humoral immunity.

W2.08.06
Negative regulation of chemokine receptor signaling and B cell chemotaxis by p66Shc

N. Capitani[1], *L. Patrussi*[1], *E. Cannizzaro*[1], *F. Finetti*[1], *O. Lucherini*[1], *P. Pelicci*[2], *C. T. Baldari*[1];
[1]*University of Siena, Siena, Italy,* [2]*European Institute of Oncology, Milan, Italy.*

Shc adaptors are ubiquitous components of the signaling pathways triggered by tyrosine kinase-coupled receptors. In lymphocytes, similar to other cell types, the p52 and p66 isoforms of ShcA/Shc participate in a self-limiting loop where p52Shc acts as a positive regulator of antigen receptor signaling by promoting Ras activation, while p66Shc limits this activity by competitively inhibiting p52Shc. Based on the fact that many signaling mediators are shared by antigen and chemokine receptors, including p52Shc, we have assessed the potential implication of p66Shc in the regulation of B cell responses to chemokines, focusing on the homing receptors CXCR4 and CXCR5. The results identify p66Shc as a negative regulator of the chemotactic responses triggered by these receptors, including adhesion, polarization and migration. We also provide evidence that this function is dependent on the ability of p66Shc to interact with the chemokine receptors and promote the assembly of an inhibitory complex that results in impaired Vav-dependent reorganization of the actin cytoskeleton, and map this function to the phosphorylatable tyrosine residues in the CH1 domain. The results identify p66Shc as a negative regulator of B cell chemotaxis and suggest a role for this adaptor in the control of B cell homing.

W2.09 MHC and other polymorphic genes in health and disease

IL2.09.01
MHC and other polymorphic genes in health and disease

J. A. Frelinger[1], *D. Jaraquemada*[2];
[1]*University of Arizona, Tucson, AZ, United States,* [2]*Universitat Autònoma de Barcelona, Bellaterra, Spain.*

The Major Histocompatibility complex (MHC) is critical in the regulation of immune responses. This gene complex comprises about 4 Mbp in human and mouse. The MHC encodes genes that are critical to the generation and display of antigenic peptides on the cell surface for recognition by T cells. These include proteins that bind peptides. The are the class I genes that usually bind endogenously synthesized peptides and class II the bind exogenously derived peptides. The also include proteins in the immunoproteosome, LMP and in the transport pathway. In addition important innate effectors also map in the MHC. Finally MHC related proteins such as CD1 are also important in immune regulation. Because of its critical role in the presentation of antigen it impacts how the immune responses recognizes pathogens and how the pathogens can escape.
In the session here we have outstanding presentation that demonstrate the interplay between host immunity and pathogen immune evasion as well as the interaction between pathogens and the induction of autoimmunity.

W2.09.01
Tapasin facilitation of MHC-I separates closely related allomorphs, is strongly influenced by peptide length and depends on stability

L. Geironson[1], *C. Thuring*[1], *M. Harndahl*[2], *M. Rasmussen*[2], *S. Buus*[2], *G. A. Røder*[2], ***K. M. Paulsson***[1];
[1]*Experimental Medical Science, Lund University, Lund, Sweden,* [2]*Experimental Immunology, University of Copenhagen, Copenhagen, Denmark.*

Only a small fraction of the peptides inside a cell are eventually presented by HLA-I on the cell surface. The presented peptides have HLA-I allomorph-specific motifs and length restrictions. Tapasin influences HLA-I antigen presentation both qualitatively and quantitatively to different degrees depending on both peptide sequence and HLA-I allomorph. The tapasin-dependence in cellular context has been shown to correspond to the facilitation of peptide-HLA-I complex formation by the first 87 amino acids of tapasin (Tpn1-87) (i.e., tapasin-facilitation = Bmax Tpn1-87/Bmax Ctrl) in a biochemical assay. Both peptide length and tapasin-facilitation are important for HLA-I antigen presentation and we here set out to study if these two parameters relate to each other. We used a luminescent oxygen channeling assay and seven different peptide libraries (X7-X13) to study 16 HLA-A and -B allomorphs and the results show a broad spectrum of tapasin-facilitation of HLA-I allomorphs and that HLA-A allomorphs were generally less restricted than -B allomorphs

to peptides of the classical lengths of 8-10 amino acids. Since both stability and tapasin-facilitation have been suggested as discriminators of immunogenic peptides we used a scintillation proximity based assay to study the stability of peptide-HLA-I complexes formed with peptides of different lengths. The results demonstrate an inverse correlation between tapasin-facilitation and stability valid for different peptide mixes of specific lengths but also on the level of HLA-I allomorphs, suggesting that molecules of poor stability are either not in a conformation that allows tapasin to interact or have a conformation where association has no effect.

W2.09.02
NLRC5 controls basal MHC class I gene expression in an MHC-enhanceosome dependent manner

*A. Neerincx[1], G. Rodriguez[2], V. Steimle[2], **T. Kufer**[1];*
[1]University of Cologne, Köln, Germany, [2]Université de Sherbrooke, Sherbrooke, QC, Canada.

Nuclear binding domain, leucine rich repeat containing proteins (NLRs)play important roles in innate immune responses as pattern recognition receptors (PRRs). While most NLRs act in cell autonomous immune pathways, some do not function as classical PRRs. One such NLR is the MHC class II transactivator (CIITA), the master regulator of MHC class II gene transcription. Here we report that human NLRC5, which we recently showed to be involved in viral-mediated type I interferon responses, shuttles to the nucleus and activates MHC class I gene expression. Knock-down of NLRC5 in different human cell lines and primary dermal fibroblasts leads to reduced MHC class I expression, while introduction of NLRC5 into cell types with very low expression of MHC class I augments MHC class I expression to levels comparable to those found in lymphocytes. Expression of NLRC5 positively correlates with MHC class I expression in human tissues. Functionally, we show that both the N-terminal effector domain of NLRC5 and its C-terminal LRR (leucine rich repeat) domain are needed for activation of MHC class I expression. Moreover, nuclear shuttling and function depends on a functional Walker A motif. Finally, we identified a promoter sequence in the MHC class I promoter, the X1-box, to be involved in NLRC5-mediated MHC class I gene activation. Taken together this suggests that NLRC5 acts in a manner similar to CIITA to drive MHC expression and revealed NLRC5 as an important regulator of basal MHC class I expression.

W2.09.03
TAPBPR uses the same residues as tapasin to associate with MHC class I

***C. Hermann**, L. M. Strittmatter, L. H. Boyle;*
Department of Pathology, Cambridge Institute for Medical Research, Cambridge, United Kingdom.

In order to induce an appropriate T cell response, MHC class I molecules must be loaded with high affinity peptide. The key player for peptide loading is the MHC class I dedicated chaperone tapasin. Recently we have found a tapasin related protein called TAPBPR which is an additional component of the antigen presentation system. Like tapasin, TAPBPR binds to a heterodimer of MHC class I heavy chain and β2m. In contrast to tapasin, TAPBPR is not a component of the peptide loading complex and is not required for peptide loading. However, it controls the ER export rate of MHC class I molecules.
Here we have characterised the interaction between TAPBPR and MHC class I. Residues in the N-terminal and IgC domain of tapasin which are important for its association with MHC class I are highly conserved in TAPBPR. Site-directed mutagenesis of these residues followed by immunoprecipitation of TAPBPR revealed that mutation of I282 or E226, R228, Q230, Q293 in the N-terminal domain and R335, Q336 and S337 in the IgC domain abolishes binding of TAPBPR to MHC class I. Tapasin is known to associate with specific residues on MHC class I such as T134, D227 and E229. We have identified that these residues are also essential for TAPBPR binding to MHC class I. The identification of TAPBPR as an additional MHC class I specific chaperon which binds to MHC class I in a similar way as tapasin has significant implications on our understanding of MHC class I biology.

W2.09.04
Usage of a genome-wide shRNA-based lentiviral screen and targeted siRNA knockdown to identify host cell proteins involved in US2- and US11-mediated degradation of major histocompatibility complex class I molecules

***D. C. Chapman**[1], P. Stocki[2], F. Teusel[2], D. B. Williams[2,1];*
[1]Department of Immunology - University of Toronto, Toronto, ON, Canada, [2]Department of Biochemistry - University of Toronto, Toronto, ON, Canada.

Human cytomegalovirus (HCMV) utilizes multiple mechanisms to disrupt peptide presentation by major histocompatibility complex class I molecules (MHC I). US2 and US11 are two HCMV proteins that target MHC I for degradation through ER-associated degradation (ERAD), each dependent on different cellular factors to carry out this activity. To identify host proteins involved in US11 function, a genome-wide shRNA screen was used to identify knockdown targets that increased surface MHC I levels (as shown by fluorescence-assisted cell sorting) in cells expressing US11. Hits identified in the screen were filtered using gene ontology (GO) term associations, replication by independent shRNAs, and statistical approaches. Subsequent validation of hits by flow cytometry and western blotting identified new potential players in ERAD, and linked MHC I to these as an ERAD substrate. In addition to this screen-based approach, individual targets of interest were investigated. This led to the identification of cyclophilin C (cypC) as an ER-localized peptidyl-prolyl cis-trans isomerase involved in US2 mediated degradation of MHC I. Knockdown of cypC increased both surface and total expression of MHC I in cells expressing US2. This effect was not due to a general ER unfolded protein response (as measured by XBP-1 splicing), but more likely a direct effect on US2 itself, since an interaction between cypC and US2 could be detected. Our results suggest that cypC is involved early in US2 mediated-degradation of MHC I, and may act to bridge US2 to other proteins of the ERAD pathway.

W2.09.05
Comparative analysis of DQA1*05/DQB1*02 mRNAs and DQ2 heterodimer expression in relation to antigen presentation

*L. Pisapia[1], A. Camarca[2], P. Barba[1], S. Picascia[2], G. Del Pozzo[1], **C. Gianfrani**[2];*
[1]Institute of Genetics and Biophysics-IGB, Naples, Italy, [2]Institute of Food Sciences-CNR, Avellino, Italy.

HLA is the main genetic risk factor in autoimmunity. The DQ2 heterodimer, coded by DQA*05/DQB*02 alleles, and located in cis conformation in DR3-DQ2 haplotype, restrict T cell response to gluten peptides in the great majority of celiac disease-(CD) patients. We have investigated the correlation between DQA1*05 and DQB1*02 mRNAs and the surface expression of DQ2 in respect to the ability to present immunodominant gluten peptides to intestinal T cells from CD patients carrying the DR3-DQ2 haplotype in homozygousity or in heterozygousity. We first evaluated DQA*05 and DQB1*02 mRNAs amount by RT-qPCR in EBV-transformed lymphoblastoid B cells (EBV-B), obtained by CD patients either DR3/DR3 or DR3/DR1 positive. Then, the surface expression of DQA1*05 and DQA1*01 chains was analysed by specific antibodies and flow cytometry. Our data showed that mRNAs of these alleles are more abundant compared to DQA1*01 and DQB1*05. Furthermore, flow cytometry analysis confirmed a greater surface expression of DQA1*05 respect to DQA1*01 chain, in agreement with RT-qPCR data. Preliminary results showed no statistical differences in the T cell activation, measured as IFNγ production, when DR3/3, DR3/5, and DR3/1 positive EBV-B were used to present suboptimal amount of DQ2-glia-γ1 peptide to celiac T cells, thus contrasting the expected T cell activation on the base of an unbiased combination of the alfa and beta chains in the APC, i.e: DR3/3 (100% DQ2), DR3/5 (50% DQ2) DR3/1 (25% DQ2), and DR1/1 (0% DQ2). Our results provide a molecular basis for the high penetrance of DR3-DQ2 haplotype in autoimmune diseases.

W2.09.06
Novel HLA-B27-restricted epitopes from Chlamydia trachomatis suggest a role of molecular mimicry in reactive arthritis

C. Alvarez-Navarro[1], *J. Cragnolini*[1,2], *H. G. Dos Santos*[1], *E. Barnea*[3], *A. Admon*[3], *A. Morreale*[1], *J. López de Castro*[1];
[1]*Centro de Biología Molecular Severo Ochoa (CSIC-UAM), Madrid, Spain,* [2]*Whitehead Institute for Biomedical Research, Cambridge, MA, United States,* [3]*Faculty of Biology, Technion - Israel Institute of Technology, Haifa, Israel.*

The spondyloarthropathies are a group of rheumatic diseases strongly associated with HLA-B27, which include ankylosing spondylitis (AS) and reactive arthritis (ReA). This latter disease can be triggered by diverse bacteria, *Chlamydia trachomatis* being among the most prominent ones. However, its pathogenetic significance, autoimmune potential, and relevant epitopes are unknown. The purpose of this study was to directly identify *Chlamydia*-derived HLA-B27 ligands processed and presented *in vivo*, and to examine their potential as mediators of molecular mimicry. A methodology is described for studying the endogenous processing and presentation of chlamydial epitopes, which includes stable transfection of bacterial proteins and purification of the peptide-MHC complexes from HLA-B27-positive cells, followed by high-throughput comparative and targeted peptide sequencing for detecting specific bacterial ligands in the HLA-B27 peptidome. The use of mass spectrometry techniques with high resolution and sensitivity allowed us to detect peptides derived from the bacterial ClpC (CT286), NQRA (CT634) and DNA primase (C794) proteins, including some recognized by CTL of ReA patients. These peptides showed high homology to human protein sequences fulfilling the HLA-B27 binding motif. The DNAP(211-223) peptide was shown, through molecular dynamics simulation, to adopt a striking conformational similarity with a self-derived and highly flexible peptide, B27(309-320). The use of high-resolution and sensitivity MS techniques provided a major improvement in the detection of *Chlamydia*-derived antigens and shed new light about the pathogenetic role of molecular mimicry in this disease.

IL2.10.02
Regulation of inflammation and cell-death trough interactions of RHIM-domain protein kinases with caspase-8

D. Wallach[1], *T. Kang*[2], *S. Yang*[1], *B. Toth*[1], *A. Rajput*[1], *J. Kim*[1], *A. Kovalenko*[1];
[1]*Department of Biological Chemistry, The Weizmann Institute of Science, Rehovot, Israel,* [2]*Department of Biotechnology, College of Biomedical and Health Science, Konkuk University, Chungju, Republic of Korea.*

Caspase-8 was discovered as the proximal enzyme in the 'extrinsic cell-death pathway'- one of the main mechanisms by which immune killer cells impose apoptotic cell death. This pathway is restricted by signaling for activation of NF-κB - transcription factors that also control inflammatory genes. Cell vulnerability to death induction by the extrinsic pathway is therefore likely to decrease in association with induction of inflammation. Conversely, once the extrinsic death pathway does become activated various proteins that signal for NF-κB activation are cleaved and thus inactivated, resulting in arrest of induction of inflammation. The apoptotic process itself restricts inflammation by safeguarding against release of damage-associated molecular patterns from the dying cell and by immunosuppressive effects of apoptotic cell membrane structures. Studies of recent years revealed that caspase-8 also blocks inflammation by additional mechanisms. One common denominator to the signaling complexes mediating the induction of those mechanisms is that they all encompass the RHIM-domain containing protein kinase RIPK1. Some also contain the RHIM-domain kinase RIPK3. In all these complexes, the inhibitory effect of caspase-8 is associated with proteolytic cleavage of these kinases, which arrests signaling by these complexes and yields proteolytic fragments of the kinases that may act as signaling inhibitors. Consistent with these functions of caspase-8, in several transgenic mice models its deficiency was found to prompt severe inflammation. Recent advances in elucidating the mechanisms for the anti-inflammatory function of caspase-8 will be presented.

W2.10 Autophagy and cell death in the immune system

IL2.10.01
Understanding symptomatic infections in order to avoid initiation of autoimmunity

C. Munz;
University of Zurich, Zurich, Switzerland.

Primary infection with the human herpesvirus Epstein Barr virus (EBV) can result in infectious mononucleosis, a self-limiting disease caused by massive lymphocyte expansion, which predisposes for the development of multiple sclerosis. It remains unclear why some individuals experience this symptomatic primary EBV infection, while the majority acquires the virus asymptomatically. Using a mouse model with reconstituted human immune system components, we could demonstrate that depletion of human natural killer (NK) cells enhances symptoms of infectious mononucleosis, mainly due to loss of immune control over lytic EBV infection. Particularly, an early NK cell differentiation stage expanded after EBV infection and loss of this particular NK cell subset increased viral load and CD8+ T cell expansion after infection with wild-type EBV, but not a recombinant virus, deficient in lytic replication. These data suggest that failure of innate immune control by human NK cells augments symptomatic lytic EBV infection, which drives lymphocyte expansion and features of infectious mononucleosis. Therefore, older EBV negative individuals with decreased NK cell reactivity against lytic EBV replication could benefit from vaccination to decrease their risk for infectious mononucleosis and the associated development of multiple sclerosis.

W2.10.01
Human and mouse mononuclear phagocytes are the only leukocyte subset expressing functional death receptors for Trail

C. Belgiovine, *M. Liguori, G. Germano, C. Buracchi, A. Mantovani, P. Allavena;*
Humanitas Research Institute, Rozzano, Italy.

It is believed that TRAIL-induced apoptosis spares normal cells and selectively kills neoplastic cells. In a careful analysis of TRAIL-R expression in leukocyte subsets we found that monocytes express discrete levels of signaling TRAIL-Rs (DR4 and DR5) and lack the non-signaling decoy receptor DcR1. In contrast neutrophils and lymphocytes predominantly express the decoy receptor and have very low levels of signaling receptors. Accordingly, TRAIL-ligand induced the activation of caspase 8 exclusively in monocytes.
Macrophages differentiated in vitro with M-CSF, and in particular M2-polarized macrophages, were also confirmed to express functional TRAILRs. The expression of TRAIL receptors is modulated in monocytes stimulated with selected pro or anti-inflammatory stimuli.
Similar findings were observed in mouse mononuclear phagocytes, where inflammatory Ly6Chigh blood monocytes were found to express high DR5, and neutrophils and lymphocytes had low or negative expression. In murine fibrosarcoma, DR5 expression co-localized with F4/80+ macrophages and not with Gr1+ MDSC or CD31+ vessels. These results imply that monocytes and macrophages are selectively susceptible to this killing mechanism. In several tumor types, the presence of Tumor-Associated Macrophages (TAM) correlates with poor clinical outcome and resistance to conventional treatment and targeting of tumor macrophages is considered a promising therapeutic strategy. The differential susceptibility of mononuclear phagocytes to TRAIL-induced apoptosis could be exploited to selectively target monocytes/macrophages in the tumor micro-environment.

W2.10.02
Target cell death is necessary for cytotoxic T cell detachment and serial killing

***M. R. Jenkins**, J. A. Lopez, J. A. Rudd-Schmidt, I. Voskoboinik, J. A. Trapani;*
PeterMacCallum Cancer Centre, East Melbourne, Australia.

Cytotoxic CD8+ T lymphocytes (CTL) play a critical role in the cell-mediated immune response against virus-infected and cancerous cells. Following specific target cell (TC) recognition and formation of an immune synapse, CTLs release perforin and granzymes and the TC is destroyed through these synergistic actions. CTL can sequentially kill several TCs, a process that requires the periodic breaking of synapses. We can now visualise a functional synapse and delivery of perforin in real time, using live cell microscopy. For example, calcium signalling within the CTL and analysis of the subsequent kinetics and morphological changes associated with TC death, allows us to define the lethal hit for the first time. We demonstrate that upon delivery of the lethal hit, TC death is necessary for CTL to detachment. Therefore, the act of degranulation itself is not sufficient for a synapse breaking. Synapses formed with CTL from genetic-modified mice deficient in either perforin or both granzymes A and B, showed sustained calcium signalling and a striking delay in target cell detachment. One important consequence is elevated cytokine production by perforin-null CTL; this may serve as a model for the clinical manifestation of perforin deficiency in human patients with FHL2, who succumb to a 'cytokine storm' following vial challenge. We conclude that CTL/TC detachment is a regulated process and is dependent on feedback from the TC following effector molecule delivery. This study highlights the importance of a CTL rapidly detaching to facilitate further rounds of killing, and controlling an efficient and balanced immune response.

W2.10.03
The switch in T cell survival: Cross-regulation between homeostasis and antigen-induced activation

***S. Heinzel**, P. Koenen, J. Zhang, A. Strasser, P. Hodgkin;*
Walter and Elisa Hall Institute for Medical Research, Parkville, Australia.

The survival of mature T cells in the periphery is a tightly regulated process governed by two major processes: homeostasis of naïve T cells mediated by IL-7 and antigen-induced activation. How the transition between these two states is controlled is not well understood. Here we investigated the events controlling survival of T cells shortly after antigen activation before cells enter the proliferative state. We found that T cell survival is reprogrammed upon TCR-mediated stimulation by actively inhibiting homeostatic survival signals while initiating a new, dominant survival program. Activation through the TCR antagonised IL-7/IL-7R mediated STAT5 phosphorylation and Bcl-2 expression and induced pro-apoptotic molecules Bim and Bax, while simultaneously promoting survival through induction of alternative anti-apoptotic Bcl-2 family members A1 and Bcl-xL. Stimulation strength determined the kinetics of the transition between the survival programs. Calcineurin or MEK pathway inhibitors prevent the initiation of the new survival program while permitting the dominant repression of Bcl-2. Thus, in the presence of these drugs the response to antigen receptor ligation is cell death. Using calcineurin inhibitors Cyclosporin A or FK506 we were able to induce antigen specific loss of activated T cells in-vitro and in-vivo.Our results identify a molecular switch that can serve as an attractive target for inducing antigen-specific tolerance in treating autoimmune disease patients and transplant recipients.

W2.10.04
IFN-γ induces an autophagy-mediated antimicrobial response against Mycobacterium leprae in human monocytes

***B. J. Silva**, P. R. Andrade, T. P. Amadeu, V. Diniz, S. Côrte-Real, V. C. Valentim, H. Ferreira, J. A. C. Nery, E. N. Sarno, R. O. Pinheiro;*
Oswaldo Cruz Institute - FIOCRUZ, Rio de Janeiro, Brazil.

Leprosy is a chronic infectious disease caused by the intracellular pathogen *Mycobacterium leprae* (ML). Previous data suggest that the establishment of different clinical forms is driven by host innate mechanisms. While in multibacillary (LL) patients there are highly infected macrophages, in paucibacillary (BT) rare or few bacilli are found. In the present study we evaluated the role of autophagy in the immune response to ML. Ultrastructural analysis showed a higher number of autophagosomes in isolated skin lesion cells from BT patients compared to LL patients. The increase of LC3-II expression observed in skin biopsies from BT patients was associated with higher gene expression of cathelicidin and β-defensin 2. Previous studies have demonstrated that IFN-γ induces autophagy in human monocytes and that the levels of IFN-γ were significantly raised in BT patients when compared to LL. Here, we demonstrated that IFN-γ treatment in ML-stimulated THP-1 cells decreased the interaction of the bacilli with the host cell and increased LC3-II and Atg3 expression. There was an increase on LC3-II expression in BT macrophages when compared to LL, in the presence or absence of IFN-γ. IFN-γ treatment promotes ML/LC3-II co-localization in THP-1 macrophages and leads to increased levels of IL-15 in the culture supernatants. The pre-treatment with wortmannin or 3-MA was able to reduce IFN-γ-induced LC3-II expression and led to decreased IL-15 levels after stimulation with IFN-γ and ML. These data indicate that IFN-γ induces IL-15 in ML-stimulated macrophages, which contributes to increase the microbicidal activity in host cells by autophagy induction.

W2.10.05
p53 contributes to T cell homeostasis through the induction of pro-apoptotic SAP

***H. S. Madapura**[1,2], D. Salamon[1], K. G. Wiman[2], S. Lain[1], G. Klein[1], E. Klein[1], N. Nagy[1];*
[1]Dept. of Microbiology, Tumor and Cell Biology (MTC), Karolinska Institutet, Stockholm, Sweden, [2]Dept. of Oncology-Pathology (CCK), Karolinska Institutet, Stockholm, Sweden.

Lack of functional SAP protein, due to gene deletion or mutation, is the cause of X-linked lymphoproliferative disease (XLP), characterized by functionally impaired T and NK cells and a high risk of lymphoma development. We have demonstrated earlier that SAP has a pro-apoptotic function in T and B cells. Deficiency of this function might contribute to the pathogenesis of XLP. We have also shown that SAP is a target of p53 in B cell lines. In the present study, we show that activated primary T cells express p53, which induces SAP expression. p53 is functional as a transcription factor in activated T cells and induces the expression of p21, PUMA and MDM2. PARP cleavage in the late phase of activation indicates that T cells expressing high levels of SAP undergo apoptosis. Modifying p53 levels using Nutlin-3, which specifically dissociates the MDM2-p53 interaction, was sufficient to upregulate SAP expression, indicating that SAP is a target of p53 in T cells. We also demonstrated p53's role as a transcription factor for SAP in activated T cells by ChIP assays. Our result suggests that p53 contributes to T cell homeostasis through the induction of the pro-apoptotic SAP. The involvement of p53 and SAP in activation induced T cell death (AICD) is poorly understood. High levels of p53 and SAP is necessary for the activation-induced cell death that is pivotal in termination of the T cell response.

W2.10.06
Autophagy facilitates TLR4,3-triggered migration and invasion of lung cancer cells by promoting chemokine and IL-6 production through maintaining TRAF6 ubiquitination

***Z. Zhan**[1], X. Zhang[2], H. Fan[1], Z. Liu[1];*
[1]Research Center for Translational Medicine & Institute of heart failure; Shanghai East Hospit, Shanghai, China, [2]School of Medicine and Public Health; University of Newcastle, NSW, Australia.

Toll-like receptors (TLRs) expressed in cancer cells have been shown to function in tumor progression and immune escape. Autophagy is also known to exert effects on cancer cell survival and development under stress condition. However, the link between TLR signaling and autophagy as well as its role in tumor invasion remain largely undefined. Here we report that TLR4 and TLR3 both induced autophagy through TRIF adaptor, which promote migration and invasion of lung cancer cells by maintaining TLR4,3-triggered TRAF6

ubiquitination and TAK1 activation. Autophagy appeared essential for TLR4,3-induced production of chemokines and immunosuppressive factors including MCP-1, MIP-3α, IL-6, VEGF and MMP-2, in that inhibition of autophagy abolished release of these cytokines and the increased migration and invasion of lung cancer cells which mostly related to roles of these cytokines. Together with that IL-6 blockade significantly decreased the TLR4,3-induced release of VEGF and MMP-2, this seemed that IL-6 production was critical for enhanced invasion of lung cancer cells triggered by TLR4,3-induced autophagy. Strikingly, autophagy maintained TLR4, 3-triggered TRAF6 ubiquitination and TAK1 activation, which resulted in the enhanced activation of MAPK and NF-κB signaling, and inhibitor of MAPK and NF-κB signaling reversed the increased production of IL-6. The effect of autophagy on TLR4, 3-triggered activation of MAPK and NF-κB signaling were confirmed with siRNA knockdown of Atg5. Therefore, our study demonstrates that autophagy-dependent production of chemokines and IL-6 as a consequence of TRAF6 ubiquitination and downstream signaling activation are essential for TLR-triggered migration and invasion in lung
cancer cells.

W2.12 Signalling in immune cells

IL2.12.01
T-cell signaling via adaptor regulation of the nuclear pore complex (NPC)

***C. E. Rudd**;*
University of Cambridge, Cambridge, United Kingdom.

T cell activation is mediated by a complex array of intracellular signaling events that lead to transcription and effector functions. In addition to the CD4- and CD8-p56lck complexes and their initiation of the tyrosine phosphorylation cascade in T-cells involving ZAP-70, recent studies have identified adaptor proteins that integrate responses. Several of these such as LAT (Linker for the activation of T-cells) and SLP-76 (SH2 domain containing leukocyte protein of 76kDa) regulate calcium mobilization, while others such as ADAP (adhesion- and degranulation-promoting adapter protein) and SKAP1 (Src kinase-associated phosphoprotein 1) account of integrin adhesion of T-cells. SKAP1 binds to the Rap1 binding protein to ensure membrane localization and interaction with LFA-1 cytoplasmic tail. This pathway regulates both the activation of integrins as well as the 'stop' signal needed for T-cell interaction with dendritic cells. The talk will outline recent new findings on the role of adaptors in motility as well as in the modulation of nuclear pore complex (NPC) mediated transport by binding and regulation of exchange factor RanGAP.

W2.12.01
GRAIL targets CDC37 to maintain CD4 T cell unresponsiveness

***C. C. Whiting**, D. Gomez-Martin, J. M. Schartner, L. Su, C. Fathman; Stanford University, palo alto, CA, United States.*

GRAIL (gene related to anergy in lymphocytes, also known as RNF128), an ubiquitin-protein ligase (E3), plays a central role in CD4 T cell unresponsiveness. We recently demonstrated that GRAIL is expressed in resting CD4 T cells as well as in anergic CD4 T cells suggesting that GRAIL might hold CD4 T cells in cell cycle arrest. Applying a novel E3 substrate screen we developed, we identified cdc37 (a G1-specific cyclin) as a potential target of GRAIL. Specifically, CDC37 can be ubiquitinated by GRAIL. CDC37 interacts with GRAIL in a co-immunoprecipitation assay and confocal microscopy shows both proteins co-localize predominantly in Rab7+ endosomes. Additional studies demonstrate that induced GRAIL expression leads to diminished CDC7 expression. Inversely, primary T cells lacking GRAIL have higher levels of CDC37 compared to wildtype T cells under resting as well as with TCR stimulation. These data together suggest that GRAIL ubiquinates and targets CDC37 for degradation and thus, maintains CD4 T cells in G1/S interphase arrest. This is consistent with published data demonstrating that GRAIL knock out T cells are hyperproliferative compared to wild-type T cells upon TCR engagement. Results from these studies highlight a role for CDC37 in GRAIL-mediated cell cycle regulation and CD4 T cell proliferation.

W2.12.02
TRAF6 regulates TCR signaling via interaction with and modification of LAT adapter

*J. Xie[1], J. Liang[1], L. Diao[1], A. Altman[2], **Y. Li**[1];*
[1]Sun Yat-sen University, Guangzhou, China, [2]La Jolla Institute for Allergy and Immunology, San Diego, CA, United States.

TNF receptor-associated factor 6 (TRAF6) is an essential ubiquitin E3 ligase in immune responses, but its function in adaptive immunity is not well understood. Here we show that TRAF6 is recruited to the peripheral ring of the T cell immunological synapse in Jurkat T cells or human primary $CD4^+$ T cells conjugated with SEE-pulsed B cells. This recruitment depends on TRAF6 interacting with linker for activation of T cells (LAT) via its TRAF domain. Although LAT was indispensable for TCR/CD28-induced TRAF6 ubiquitination and its ligase activity, RNA interference-induced TRAF6 knockdown in T cells decreased TCR/CD28-induced LAT ubiquitination, tyrosine-phosphorylation and association with tyrosine kinase ZAP70. Overexpression of TRAF6 or its catalytically inactive form C70A promoted and decreased, respectively, LAT tyrosine phosphorylation upon stimulation. Moreover, LAT was ubiquitinated at Lysine-88 by TRAF6 via K63-linked chain. In addition, TRAF6 was required for and synergized with LAT to promote the TCR/CD28-induced activation of NFAT. These results reveal a novel function and mechanism of TRAF6 action in the TCR-LAT signaling pathway distinct from its role in TCR-induced NF-κB activation, indicate LAT also play an adapter role in TCR/CD28-induced activation of TRAF6.

W2.12.03
TNF reverse signaling induces translocation of CKIP-1

***E. Duda**[1], K. Juhasz[2], A. Zvara[3], Z. Balogi[2], A. Sonnleitner[2], A. Borsodi[4];*
[1]Inst. Medical Biology, Szeged, Hungary, [2]Center for Advanced Bioanalysis GmbH, Linz, Austria, [3]Biological Research Center, Szeged, Hungary, [4]BioTargeting Ltd., Szeged, Hungary.

When the transmembrane form of tumor necrosis factor (mTNF) interacts with its cognate receptors or agonistic antibodies signaling pathways are activated in the ligand expressing cells. This "reverse signaling" appears to be a fine-tuning control mechanism in the immune response. We have shown that ligation of mTNF leads to nuclear translocation of the N-terminal cytoplasmic fragment (Nterm) of TNF. We found that over-expression of Nterm is enough to elicit the reverse signal. Using the cytoplasmic domain of TNF as bait in a Y2H system TNF-interacting protein(TIP)/casein kinase-2 interacting protein-1 (CKIP-1) was identified. We found that CKIP-1 expression was elevated upon LPS challenge in THP-1 monocytes. Over-expression of CKIP-1 triggered activation of THP-1 cells and up-regulated the human TNF promoter, especially when co-expressed with c-Jun in HEK293 cells. TNF reverse signaling induced the translocation of CKIP-1 from the plasma membrane to intracellular compartments in THP-1 cells. Expression of the Nterm of mTNF also elicited the re-localization of CKIP-1 in HEK293 cells. CKIP-1-triggered activation of THP-1 cells was antagonized by TNF reverse signaling. Similarly, the presence of the Nterm of mTNF inhibited CKIP-1 mediated TNF promoter activation in HEK293 cells. Reverse signaling in THP-1 monocytes and expression of the Nterm of mTNF in HEK293 cells induced apoptosis that could be prevented by over-expression of CKIP-1. Our findings demonstrate that CKIP-1 activates pro-inflammatory pathways and interferes with TNF reverse signaling-induced apoptosis, while reverse signaling blocks CKIP-1-induced activation of the TNF promoter in human monocytes.

W2.12.04
PI 3-kinase sub-pathways in lymphocyte activation: regulation and functions of phosphatidylinositol (3,4)-bisphosphate

***A. Marshall**, N. Jayachandran, H. Li, I. Landego, S. Pauls, S. Hou; University of Manitoba, Winnipeg, MB, Canada.*

Activation of PI3-kinase enzymes is essential for lymphocyte development and function. Active PI3Ks generate several types of D3 phosphoinositides (PI), including PI(3,4,5)P3 and PI(3,4)P2. These PIs are under distinct regulation by PI phosphatases, have distinct protein binding partners and distinct functions in cell biology. We are assessing the regulation of the PI(3,4)P2 sub-pathway via phosphatases SHIP1 and INPP4A, as well as the functions of PI(3,4)P2-binding proteins TAPP1, TAPP2, Bam32/DAPP1 and lamellipodin. Function of TAndem PH domain containing Proteins (TAPPs) have been assessed using knock-in mutant mice in which both TAPP1 and TAPP2 are uncoupled from PI(3,4)P2. We found that these TAPP KI mice exhibit elevated serum antibody levels and also develop autoantibodies and kidney pathology resembling that of lupus. TAPP KI B cells show increased responses to BCR stimulation associated with elevated Akt activation. TAPP KI mice show evidence of chronic lymphocyte activation in vivo and generated elevated germinal center (GC) responses upon immunization. We hypothesize that TAPP adaptor binding to PI(3,4)P2 contributes a novel regulatory mechanism controlling B cell activation. We further find that PI(3,4)P2 can positively contributes to some B cell functions, particularly migratory responses to chemokine stimulation. We found that selective degradation of PI(3,4)P2 by INPP4A impairs B cell migration and have implicated PI(3,4)P2-binding proteins TAPP2 and lamellipodin as important regulators of lymphocyte migration. Together these results indicate that distinct PI pathways activated by PI3K contribute to different aspects of B cell activation.
Funding provided by the Canadian Institutes of Health Research and the Canadian Cancer Society.

W2.12.05
Interleukin-7 signaling is motorized in human CD4 T-cells

***B. Tamarit**[1,2], F. Bugault[1], A. Pillet[1,2], V. Lavergne[1], P. Bochet[1,3], J. Thèze[1], T. Rose[1];*
[1]Institut Pasteur, Paris, France, [2]Université Pierre et Marie Curie, Paris, France, [3]CNRS UMR3525, Paris, France.

Interleukin(IL)-7 is the main homeostatic regulator of CD4 T-lymphocytes (helper) at both central and peripheral levels. Upon activation by IL-7, several signalling pathways, mainly Jak/STAT, PI3K/Akt and MAPK, induce the expression of genes involved in T-cell differentiation, activation and proliferation. We have analyzed the early events of CD4 T-cell activation by IL-7. We have shown that IL-7 in the first few minutes induces the formation of cholesterol-enriched membrane microdomains that compartmentalize its activated receptor and initiate its anchoring to the cytoskeleton supporting the formation of the signalosome on the IL-7-receptor cytoplasmic-domains.
We describe by stimulated emission depletion (STED) microscopy, the key roles played by membrane microdomains and cytoskeleton transient organization in the IL-7-regulated Jak/STAT signalling pathway. We image phospho-STAT5 and cytoskeleton components along IL-7-activation kinetics using appropriate inhibitors. Lipid raft inhibitors delay and reduce IL-7-induced Jak1 and Jak3 phosphorylation. Drug-induced disassembly of cytoskeleton inhibits phospho-STAT5 formation, transport and translocation into the nucleus that controls the transcription of genes involved in T-cell activation and proliferation.
We fit together the results of these quantitative analyses and propose the following mechanism: activated IL-7-receptors embedded in membrane microdomains induce actin-microfilament meshwork formation, anchoring microtubules that grow radially from rafted receptors to the nuclear membrane. STAT5 phosphorylated by signalosomes are loaded on kinesins and glide along the microtubules across the cytoplasm to reach the nucleus two minutes after IL-7-stimulation. Radial microtubules disappear 15 minutes later while transversal microtubules, independent of phospho-STAT5 transport, begin to bud from the microtubule-organization-center.

W2.12.06
Molecular profiling of LFA-1 signalling in T-cells identifies novel genomic signatures implicated in Th1, Th17 and iTreg polarization

*N. K. Verma[1], E. Dempsey[1], S. P. Barry[1], A. Davies[1], **A. Long**[1], P. G. Fallon[1], Y. Volkov[1], D. Kelleher[2];*
[1]Trinity College Dublin, Dublin, Ireland, [2]Imperial College London, London, United Kingdom.

Background: T-cell expression of functional phenotypes is dependent on a range of interacting signals. Here we demonstrate molecular mechanisms by which LFA-1-mediated signalling associated with lymphocyte migration modulates T-cell differentiation into Th1, Th17 or iTreg.
Methods: Primary human or mouse T-cells were stimulated via LFA-1 by incubating on immobilised recombinant ICAM-1. Affymetrix GeneChip® microarrays and Ingenuity Pathway Analysis were performed. Biochemical and imaging techniques including real-time PCR, Western-blotting, ELISA, siRNA-mediated gene silencing, confocal microscopy and High Content Analysis were utilised.
Results: Molecular profiling of LFA-1-stimulated T-cells identified genomic signatures defining both Notch and TGF-β signalling pathways. We further demonstrate that LFA-1/ICAM-1 interaction activates Notch signalling by nuclear translocation of its cleaved intracellular domain and up-regulation of target genes Hey1 and Hes1. This interaction also up-regulates a subset of molecules associated with reduced TGF-β responsiveness, including Smad7, Smurf2 and Ski. The increased expression of these molecules in T-cells significantly attenuates TGF-β-mediated phosphorylation of Smad2 and/or suppression of IL-2 secretion. While LFA-1/ICAM-1 favours Notch-dependent Tbet+ Th1 polarization, LFA-1-stimulated T-cells are refractory to TGF-β-mediated induction of Foxp3+ iTreg or RORγt+ Th17 differentiation. Pre-treatment of T-cells with blocking anti-LFA-1 antibody, specific inhibitors or siRNA against identified genes substantially antagonises LFA-1/ICAM-1-mediated effects on functional phenotypes and restores their TGF-β sensitivity.
Conclusion: This study establishes a crucial role of LFA-1-mediated signalling in immunoregulation concurrent with lymphocyte motility, involving both Notch and TGF-β pathways. Our findings suggest a rational basis for novel selective and “tunable” therapeutic approaches aimed to modulate immune functions in inflammatory diseases.

W3.01 Lymphoid organogenesis and lineage commitment

IL3.01.01
TNF and both soluble and membrane-bound lymphotoxins have distinct functions in GALT organogenesis and in intestinal immunity

*A. A. Kruglov[1,2], **S. A. Nedospasov**[1,2,3];*
[1]German Rheumatism Research Center, a Leibniz Institute, Berlin, Germany, [2]Lomonosov Moscow State University, Moscow, Russian Federation, [3]Engelhardt Institute of Molecular Biology, Russian Academy of Sciences, Moscow, Russian Federation.

TNF and lymphotoxin are known to be involved both in the development and in the maintenance of lymphoid organs’ microstructure, and various cellular sources of these cytokines may contribute to these functions. In this study we addressed distinct contributions of TNF, membrane-bound LTα1β2 and soluble LTα3 produced by RORγt+ innate lymphoid cells (ILC) in the intestinal immune system. We generated novel mice with cell type-restricted ablation of TNF, LTβ and LTα in RORγt+ cells and found that ILC-derived TNF and both types of LT are distinctly required for GALT development. Furthermore, we found that ILC-derived soluble LTα3, but not TNF or heterotrimeric LTα1β2, is critical for IgA induction in the lamina propria. There appears to exist two distinct mechanisms of IgA induction by ILC: a T-cell-independent pathway that is critically dependent on ILC-derived LTα1β2 expression and a novel T cell-dependent pathway that relies on a non-redundant function of sLTα3 produced by ILC. Finally, ILC-derived sLTa3 is important for control of microbiota composition.

W3.01.01
The layered immune system: adult hematopoietic stem cells cannot fully reconstitute all of the functionally distinct immune cell subsets

E. E. B. Ghosn[1], *R. Yamamoto*[2], *S. Hamanaka*[3], *Y. Yang*[1], *L. Herzenberg*[1], *H. Nakauchi*[4], *L. Herzenberg*[1];
[1]*Stanford University, School of Medicine, Stanford, CA, United States,* [2]*University of Tokyo, Institute of Medical Science, Tokyo, Japan,* [3]*University of Tokyo, Institute of Medical Science, ERATO, Tokyo, Japan,* [4]*University of Tokyo, Institute of Medical Science, ERATO, Stanford, Japan.*

The mammalian immune system develops progressively during ontogeny. In both mice and humans, the types of immune cells that develop in fetuses/neonates differ from those that develop in adulthood. Among lymphocytes, B-1, γδT, and iNKT cells are the earliest to emerge and persist at low frequencies thereafter. In contrast, B-2, marginal zone B (MZB) and αβT cell emerge later but rapidly rise to predominance in adults. The accepted dogma has been that a single hematopoietic stem cell (HSC) from either neonatal or adult bone marrow (BM) can give rise to all of these developmentally distinct immune cell subsets.
However, in studies here, we finally demonstrate that individual HSC sorted from adult BM and transferred to lethally irradiated recipients clearly gives rise to B-2, MZB and B-1b but does not detectably reconstitute B-1a. These findings place B-1a in a separate lineage derived from HSC that are rare or missing in adults. In addition, we surprisingly show that HSC harvested from fetal/neonatal BM similarly fail to fully reconstitute B-1a in adoptive recipients, while E12 yolk sac cells fully reconstitute all B cell subsets.
In conclusion, we have now demonstrated that *certain lymphocytes can originate from an unsuspected developmental pathway that is independent of both neonatal and adult BM HSC*. This finding is poised to introduce dramatic changes into the current understanding of the developmental landscape of the immune system, and to impact human regenerative therapies in which HSC are used to restore hematopoiesis.

W3.01.02
Deletion of the atypical chemokine receptor CCX-CKR alters thymic stroma, impairs thymocyte development and promotes autoimmunity.

S. R. McColl[1], *M. Bunting*[1], *N. Seach*[2], *M. Hammett*[2], *D. L. Asquith*[3], *H. Korner*[4], *R. L. Boyd*[2], *R. J. B. Nibbs*[3], *I. Comerford*[1];
[1]*The University of Adelaide, Adelaide, Australia,* [2]*Monash University, Clayton, Australia,* [3]*University of Glasgow, Glasgow, United Kingdom,* [4]*The University of Tasmania, Hobart, Australia.*

The atypical chemokine receptor CCX-CKR regulates bioavailability of CCL19, CCL21 and CCL25, homeostatic chemokines that play crucial roles in thymic lymphopoiesis. Deletion of CCX-CKR results in accelerated experimental autoimmunity induced by immunization. Here we show that CCX-CKR-deletion also increases incidence of a spontaneous Sjögren's syndrome-like pathology, characterised by lymphocytic infiltrates in salivary glands and liver of CCX-CKR-/- mice, suggestive of a defect in self-tolerance when CCX-CKR is deleted. This prompted detailed examination of the thymus in CCX-CKR-/- mice. Negatively selected mature SP cells were less abundant in CCX-CKR-/- thymi, yet expansion of both DP and immature SP cells was apparent. Deletion of CCX-CKR also profoundly reduced frequencies of DN3 thymocyte precursors and caused DN2 cells to accumulate within the medulla. These effects are likely driven by alterations in thymic stroma as CCX-CKR-/- mice have impaired expansion of cTECs, the cell population that expresses the highest level of CCX-CKR in the thymus. A profound decrease in CCL25 within the thymic cortex was observed in CCX-CKR-/- thymi, likely accounting for their defects in thymocyte distribution and frequency. These findings identify a novel role for CCX-CKR in regulating cTEC expansion, which promotes optimal thymocyte development and selection important for self-tolerant adaptive immunity.

W3.01.03
Identification of thymic epithelial stem cells ensuring lifelong central T-cell tolerance

M. Sekai[1,2], *Y. Hamazaki*[1], *N. Minato*[1,2];
[1]*Department of Immunology and Cell Biology, Graduate School of Medicine, Kyoto University, Kyoto, Japan,* [2]*Department of Immunology and Cell Biology, Graduate School of Biostudies, Kyoto University, Kyoto, Japan.*

The thymus consists of two distinct compartments, the cortex and the medulla, each containing functionally different thymic epithelial cells (cTECs and mTECs). mTECs are crucial for establishing immunological self-tolerance by promiscuous expression of tissue-specific self antigens (TSAs) in part via Autoimmune regulator (Aire). mTECs show high turnover rate, promoting cross-presentation of the TSAs by dendritic cells and effective deletion of autoreactive T cells. However, the mechanism for sustaining regeneration of functional mTECs to ensure lifelong T-cell self-tolerance remains unknown. Here we demonstrate that self-renewing mTEC stem cells capable of sustaining a functional thymic medulla throughout postnatal life are generated during early embryonic stage. Implantation of purified wild type embryonic Claudin-3,4^{+} mTEC progenitor fraction into *aly/aly* thymic microenvironment completely restored thymic medulla including Aire^{+} mTECs and suppressed the autoimmune manifestation for nearly life-long. A SSEA-1^{+} fraction within the embryonic Claudin-3,4^{+} mTEC progenitor population contained self-renewable clonogenic TECs in culture, which could specifically regenerate mature mTECs *in vivo*. While the mTEC stem cell activity was markedly diminished after birth in concordance with physiological thymic involution in normal mice, it was sustained at high levels in adult RAG2$^{-/-}$ mice. Our results demonstrate that life-long central T cell tolerance is ensured by the stem cells specified for a mTEC lineage, albeit the stem cell activity is declined postnatally under robust T cell development in the thymus. These findings provide an important clue for developing strategies for maintaining TEC stem cells and cell-based therapies against autoimmunity related to thymic dysfunction in diseases and aging.

W3.01.04
Dissecting the cellular and molecular requirement for Lymphotoxin in orchestrating B cell accumulation in ectopic follicle like structures in a rodent model of Multiple Sclerosis

N. Pikor, *G. Galicia, D. Ng, J. Gommerman;*
University of Toronto; Department of Immunology, Toronto, ON, Canada.

Multiple Sclerosis (MS) is a T cell dominated inflammatory disease of the central nervous system (CNS). Nevertheless, recent studies have implicated B cells as disease modifiers, including B cell depletion studies and the correlation of B cell rich, meningeal follicle like structures (FLS) with increased CNS neuropathology. While ectopic FLS are common to many chronic inflammatory diseases, the cellular and molecular instigators supporting FLS in the CNS remain unclear. Preliminary studies in the rodent model of MS, Experimental Autoimmune Encephalomyelitis (EAE) have implicated the Tumor Necrosis Factor family member Lymphotoxin (LT) in FLS formation, complementary to its role in orchestrating the architecture of secondary lymphoid organs. In this study we use the SJL model of EAE to evaluate the requirement of B cells and LT signaling as drivers of meningeal FLS in CNS inflammation. First, using a B cell depletion strategy we determined that despite their abundance in the follicles, meningeal FLS can form in the absence of B cells. Next, we used a combination of pharmacological and genetic approaches to dissected the requirement of LT on different cell populations to support FLS formation in the CNS. We consistently observed a pronounced decrease in B cell accumulation within the FLS as well as less compact morphology of meningeal follicles, dependent on LT receptor expression by a non-hematopoeitic cell population. Taken together these results shed light on the cellular requirements of lymphotoxin signaling in supporting meningeal FLS in a model of CNS autoimmunity.

W3.01.05
Pbx1 restrains myeloid maturation while preserving lymphoid potential in hematopoietic progenitors

F. Ficara[1,2], *L. Crisafulli*[1,2], *C. Lin*[3], *M. Iwasaki*[3], *L. Zammataro*[4], *M. L. Cleary*[3];
[1]*Istituto di Ricerca Genetica e Biomedica, Consiglio Nazionale delle Ricerche, Milan, Italy,* [2]*Humanitas Clinical and Research Center, Rozzano (MI), Italy,* [3]*Stanford University School of Medicine, Stanford, CA, United States,* [4]*Center for Genomics Science@SEMM, Istituto Italiano di Tecnologia, Milan, Italy.*

The capacity of the immune system to promptly respond to peripheral demands relies on adequate pools of progenitors able to transiently proliferate and differentiate in a regulated manner. However, little is known about factors that may restrain progenitor maturation to maintain their reservoirs. In addition to a profound defect in hematopoietic stem cell (HSC) self-renewal, conditional knockout mice for the Pbx1 proto-oncogene have a significant reduction in lineage-restricted progenitors, as well as aberrant size, cell number and microscopic structure of thymus and spleen. Through analysis of purified progenitor proliferation, differentiation capacity and transcriptional profiling, we demonstrate that Pbx1 regulates the lineage-specific output of multipotent and oligopotent progenitors. In the absence of Pbx1 multipotent progenitor (MPP), including lymphoid-primed multipotent progenitors (LMPPs), and common myeloid progenitor (CMP) pools are reduced due to aberrantly rapid myeloid maturation. This is associated with premature expression of myeloid differentiation genes and decreased maintenance of proto-oncogene transcriptional pathways including reduced expression of Meis1, a Pbx1 dimerization partner, and its subordinate transcriptional program. Conversely, Pbx1 maintains lymphoid differentiation potential of LMPPs and common lymphoid progenitors (CLPs), whose reduction in the absence of Pbx1 is associated with a defect in lymphoid priming that is also present in CMPs, which persistently express lymphoid and HSC genes underlying a previously unappreciated lineage promiscuity that is maintained by Pbx1. These results demonstrate a role for Pbx1 in restraining myeloid maturation while maintaining lymphoid potential to appropriately regulate progenitor reservoirs.

W3.01.06
Survivin inhibition disturbs Bcl-6 and Blimp-1 control of lymphocyte differentiation

M. Bokarewa*, S. Andersson, M. N. Svensson, M. Erlandsson, I. Jonsson, K. M. Andersson;*
University of Göteborg, Göteborg, Sweden.

Survivin is a proto-oncogene and an inhibitor of apoptosis regulating cell division. In normal tissue survivin is critical for development of CD34+ stem cells and for beta-selection of early T cells. In the present study we assessed if inhibition of survivin affects antigen-induced maturation of T cells.
Survivin transcription was inhibited by shRNA-lentiviral construct (shSurv, 10^6-10^7 particles /mouse) provided as a single injection on the day of immunization. This resulted in significant survivin inhibition within T and B populations of bone marrow and spleen compared to mice received non-targeting construct (shNT).
Survivin inhibition was inversely correlated to an increase of transcription repressors Bcl-6 and Blimp-1. In consistence with overexpression of Blimp-1, shSurv mice had low levels of IL-2, suppressed proliferation response and increased populations of the effector (CD62l-CD44hi) CD4+ and CD8+ cells, followed by high IL-6 production. shSurv mice had increased populations of Tregs (CD4+Foxp3+) and Th2 cells supported by high mRNA of Foxp3 and GATA3, and high release of IL-10 and IL-4.
shSurv mice had small CXCR5+CD4+ and CXCR5+B220+ populations, suggesting insufficient Bcl-6 and poor Tfh development despite high expression of IL-21. Bcl-6 was sufficient to suppress production of TNFα, IFNγ, and IL-17A and to impair development of Th1, and Th17 subsets.
In conclusion, Survivin expression is an essential modulator of lineage commitments. Inhibition of survivin favours Blimp-1-driven development of Tregs and Th2 cells and impairs formation of Tfh.

W3.02 Role of the stroma in innate and adaptive immunity

IL3.02.01
Role of Lymph node structure in adaptive immunity to influenza virus

M. C. Woodruff[1,2], *C. H. Herndon*[1], *S. S. Turley*[3,4], ***M. C. Carroll***[1,5,2];
[1]*Boston Children's Hospital, PCMM, Boston, MA, United States,* [2]*Graduate Program in Immunology, Harvard Medical School, Boston, MA, United States,* [3]*Dana Farber Cancer Institute, Boston, MA, United States,* [4]*Harvard Medical School, Department of Microbiology and Immunobiology, Boston, MA, United States,* [5]*Harvard Medical School, Department of Pediatrics, Boston, MA, United States.*

In order to understand the dynamics of localization and uptake of an influenza vaccine within skin draining LNs, we have used a murine model in which mice are injected sub-cutaneously with fluorescent-labeled UV-inactive influenza virus (recombinant strain PR8 bearing the OT-II epitope). Combining two-photon live imaging with three-dimensional (3 -D) reconstruction of draining lymph nodes, viral particles were tracked within the afferent lymphatics over the first six hours. Results identified labeled virus resolving in medullary projections within inter-follicular regions (IFRs). These specialized sites, which are located adjacent to B cell follicles, are marked by a transition of sinus lining macrophages from sub-capsular macrophages to medullary macrophages. Further, 3-D analysis over a 6-12 hour period of LN isolated from immunized mice revealed large scale repositioning of the LN resident DC (LNDC) to the IFR. With a slightly delayed kinetics, viral specific CD4+ T cells are identified within IFRs where they make direct contact with LNDC and viral antigen. Strikingly, viral specific (but not naïve) CD4+ T cells express activation markers CD69 and CXCR3 and develop a Th 1 phenotype prior to skin draining DC arrival.
Together, we believe that these data elucidate the importance of LN structure and the localization of lymph borne viral antigen to the specialized IFR in the development of effective humoral immunity to influenza vaccination.

Stroma-derived Hyaluronan induces CD44-dependent apoptosis in diabetic insulin-secreting cells

D. Naor[1], *N. Assayag-Asherie*[2], *E. A. Turley*[3], *I. Raz*[4];
[1]*Hebrew University, Faculty of Medicine, Jerusalem, Israel,* [2]*The Hebrew University, Faculty of Medicine, Jerusalem, Israel,* [3]*London Region Cancer Center ,Canada, London, ON, Canada,* [4]*Hadassah University Hospital ,Israel, Jerusalem, Israel.*

We showed that the development of type 1 diabetes (T1D) in NOD mice is highly dependent on interaction between cell surface CD44 and its ligand hyaluronic acid (HA) (Proc. Natl. Acad. Sci. USA. 97, 285- 290,2000) generated by pancreatic islet stromal cells. Yet, the mechanism of action underlined this finding has not been elucidated. Here we show that the balance between CD44-dependent low mobility of inflammatory cells and CD44-dependent high susceptibility of insulin-secreting β cells to apoptosis dictates the activity of T1D in NOD mice. The reduced mobility of wild type (WT; $CD44^+$) diabetic inflammatory cells has been proven by the low rates of their *in vivo* islet invasion and *in vitro* cell migration, when compared with the CD44-deficient phenotype, indicating that the WT cells are firmly adhere to the HA substrate. This anti-diabetic effect is counter-balanced by the susceptibility of WT (but not CD44-null) insulin-secreting β cells to the autoimmune attack. The relative resistance of CD44-deficient β cells to pro-inflammatory cytokine attack *in vitro* or autoimmune attack *in vivo* has been evident by the decrease of their inducible nitric oxide (NO) synthase (iNOS) and caspase-3 signals, as well as by decline of their NO release and increase in glucose-stimulation insulin secretion, when compared with the WT phenotype. Hence, the balance between the reduced mobility of CD44-positive inflammatory cells and the enhanced susceptibility of β cells to programmed cell death dictates whether the mouse is diabetic or free of diabetes.

W3.02.01
Endocytosis and recycling of immune complexes by follicular dendritic cells enhances B cell binding and activation

B. A. Heesters[1,2]*, P. Chatterjee*[1]*, Y. Kim*[1]*, S. F. Gonzalez*[3]*, M. P. Kuligowski*[4]*, T. Kirchhausen*[1]*, M. C. Carroll*[1]*;*
[1]Harvard Medical School, Boston, MA, United States, [2]Utrecht University, Utrecht, Netherlands, [3]Institute for Research in Biomedicine, Bellinzona, Switzerland, [4]Centenary Institute of Cancer Research and Cell Biology, Newtown, Australia.

Follicular dendritic cells, which are stromal derived, are centrally located within B cell follicles of secondary lymphoid tissues, including the spleen and lymph nodes. Here they are a major reservoir for antigen that is essential for formation of germinal centers, the site where memory and effector B cells differentiate. A long-standing question is how the follicular dendritic cells retain antigen in its native form for extensive periods and how they display it to specific B cells. We find that follicular dendritic cells take-up complement-coated immune complexes directly from non-cognate B cells via complement receptors (CD21/CD35) and rapidly internalize them by an actin dependent pathway. Immune complexes are retained intact within a cycling compartment and are displayed periodically on the cell surface where they are accessible to antigen-specific B cells. After antigen-acquisition these cognate B cells are activated, as expected. Thus, internalization of immune complexes into a non- degradative compartment and periodic cycling of the intact immune complex to the cell surface would explain the long standing question how antigens are retained for extensive periods of time and made available to B cells.

W3.02.02
Dynamics of plasma cell survival niches in the bone marrow

S. Zehentmeier[1]*, K. Roth*[1]*, Ö. Sercan*[1]*, H. Chang*[1]*, Z. Cseresnyes*[1]*, R. Niesner*[1]*, A. Radbruch*[1]*, **A. E. Hauser***[2]*;*
[1]Deutsches Rheumaforschungszentrum, Berlin, Germany, [2]Charité Universitätsmedizin, Berlin, Germany.

The maintenance of long-lived bone marrow PC is guaranteed by a special bone marrow microenvironment termed survival niche. This niche consists of stromal components as well as hematopoietic cells (e.g. eosinophils), which have been reported to secrete plasma cell survival factors such as APRIL and IL-6.
We have investigated the dynamics of reticular stroma cells and bone marrow eosinophils in the microanatomical context of the plasma cell survival niche. We studied the turnover of both stromal cells and accessory niche cells in T-dependent secondary immune responses. 30 days after secondary immunization of mice, we found 80% of bone marrow PC in direct contact to reticular bone marrow stroma cells. Studying the proliferation of reticular stroma cells by EdU pulse-chase labeling in vivo, we found that mesenchymal cells of the bone marrow do not respond to immunization by increased proliferation and that reticular stroma cells localized next to PC do not proliferate in the first 12 days after immunization. This indicates that reticular stroma cells are stable components of the plasma cell survival niche. In strong contrast to reticular stroma cells, eosinophils in the vicinity of PC have a high turnover, reflected by the incorporation of EdU during the pulse and complete loss of EdU within 18 days after the pulse. These findings support the idea of a dynamic PC survival niche, comprised of hematopoietic accessory cells with a high turnover like eosinophils, and stable organizers of the niche such as reticular stroma cells.

W3.02.03
Galectin-1-expressing stromal cells constitute a specific niche for pre-BII cell development in mouse bone marrow

J. Tellier[1,2]*, F. Mourcin*[2]*, C. Breton*[2]*, P. Narang*[3]*, L. Chasson*[2]*, A. Jorquera*[2]*, M. Coles*[3]*, S. Mancini*[2]*, C. Schiff*[2]*;*
[1]Walter and Eliza Hall Institute, Parkville, Australia, [2]Centre d'immunologie Marseille Luminy, Marseille, France, [3]Center of Immunology and infection, York, United Kingdom.

In the bone marrow (BM), stromal cells constitute a supportive tissue indispensable for the generation of pro-B/pre-BI, pre-BII, and immature B lymphocytes. IL-7-producing stromal cells constitute a cellular niche for pro-B/pre-BI cells, but no specific stromal cell microenvironment was identified for pre-BII cells expressing a functional pre-B cell receptor (pre-BCR). However expression of the pre-BCR represents a crucial checkpoint during B-cell development. We recently demonstrated that the stromal cell derived-galectin1 (GAL1) is a ligand for the pre-BCR, involved in the proliferation and differentiation of normal mouse pre-BII cells. Here we show that nonhematopoietic osteoblasts and reticular cells in the BM express GAL1. We observed that pre-BII cells, unlike the other B-cell subsets, were specifically localized in close contact with GAL1(+) reticular cells. We also determined that IL-7(+) and GAL1(+) cells represent 2 distinct mesenchymal populations with different BM localization. These results demonstrate the existence of a pre-BII specific stromal cell niche and indicate that early B cells move from IL-7(+) to GAL1(+) supportive BM niches during their development.

W3.02.04
Local Complement Activation Abrogates the Tumor-Endothelial Barrier and Mediates T Cell Homing and Tumor Immune Attack

A. Facciabene*, F. De sanctis, K. Balint, P. Magotti, J. Lambris, G. Coukos;*
University of Pennsylvania, Philadelphia, PA, United States.

Given the survival advantage associated with T cell infiltration of tumor implants, this association has implications for clinical outcome. Cancer immune therapy does not only depend on the ability of the patients to mount an anti-cancer immuneresponse but also to the capability of the effector cells to infiltrate tumors through the endothelial barrier. Here, we show that tumor infiltration by antitumor T cells in vivo requires local endothelial complement activation and anaphylatoxin release. Th1 cytokines, released by tumor-reactive T cells, induce endothelial C3 expression, local complement activation, and C5a anaphylatoxin release. This promotes the upregulation of ICAM-1 and VCAM-1 and T-cell adhesion to the endothelium, circumventing the endothelial barrier in vivo and in vitro. We conclude that a sufficiently potent T cell response succeeds in overcoming the tumor endothelial barrier, and that local complement activation, acting via C5a, is a critical mechanism by which effector T cells disrupt this barrier.

W3.02.05
Alterations in stromal cell compartment during thymus atrophy induced by P. brasiliensis infection

T. Alves da Costa*, R. Di Gangi, C. Francelin, R. Thomé, L. Verinaud; UNICAMP, Campinas, Brazil.*

Thymus is the development site of T lymphocytes, which are important cells of the specific immune response. To perform its function, the thymic microenvironment must be preserved. Despite its importance, the thymus is a target organ for many infectious diseases, including paracoccidioidomycosis, the most prevalent systemic mycosis in Latin America, caused by the fungus *Paracoccidioides brasiliensis* (Pb). We have already demonstrated in experimental models that Pb invades the thymic microenvironment, inducing severe atrophy characterized by organ weight decrease and loss of corticomedullary delimitation. We have also reported that such atrophy is related to the increased death of immature lymphocytes and to the premature migration of these cells to the periphery. However, the possibility that thymic atrophy during the paracoccidioidomycosis infection is also associated to alterations in non-lymphoid cells, which include dendritic cells (DCs), thymic cortical (cTECs) and medullary epithelial cells (mTECs) cannot be discarded. In this study, we examined the stromal cell compartment of thymuses from BALB/c mice infected with the Pb virulent isolate (Pb18) during the acute phase of the disease. By immunofluorescence technique, our results show an altered pattern of distribution of DCs as well as mTECs (Keratin-5^{+} cells) and cTECs (Keratin-8^{+}) in thymuses from Pb-infected animals. Also, by flow cytometry technique, we observed phenotypic alterations in DCs and severe reduction in the number of mTECs and cTECs. Altogether, these findings show that the stromal compartment is also deeply

affected during thymic atrophy caused by Pb infection, complementing previous studies of our laboratory.

W3.02.06
A quasi clone specific mechanism for the regulation of the size of the primary CD8 T cell response

***R. W. Dutton**, T. Zou;*
UMass.Med.Sch, Worcester, MA, United States.

Previous studies suggested that the control of the size of the primary CD8 T cell response was clone specific (Kemp et al., 2004, J.Immunol. 173: 2923-27) and that regulation was achieved by controlling the number of progeny that survive. We now propose that the availability of the thymic positive selecting self peptide for recognition by a responding T cell clone is a factor in the control of clonal burst size. The recognition of the selecting peptide distinguishes members of the clone from members of other clones specific for the same epitope but which were selected on different thymic peptides. We have developed an in vivo - in vitro model in which the addition of CD45 negative stromal cells and the thymic selecting peptide can enhance, in a clone specific manor, the survival of CD8 T cells from transgenic mice responding to cognate peptide antigen. We hypothesize that T cells interact with Fibroblastic Reticular Cells in a selecting peptide dependent manor and receive a very locally available survival signal, such as IL-7, that increases the number of progeny that can survive. The mechanism proposed can serve to stabilize the repertoire of T cells responding to a particular epitope in the face of other selective pressures.

IL3.03.01
Role of the affinity of TCR-self peptide interaction in commitment to $CD4^+Foxp3^+$ and $CD4^+Foxp3^-$ T cells and in shaping their TCR repertoires

*L. Wojciech[1], L. Ignatowicz[1], **P. Kisielow**[2];*
[1]Center for Biotechnology and Genomic Medicine, Georgia Regents University, Augusta, GA, United States, [2]Institute of Immunology and Experimental Therapy, Wroclaw, Poland.

Binding of class II MHC presented peptides by TCRs on immature $CD4^+8^+$ thymocytes results in their deletion (negative selection) or in differentiation (positive selection) into two functionally different kinds of CD4+T cells: $Foxp3^+$ regulatory and $Foxp3^-$ non-regulatory effectors. Previous studies suggested that commitment towards $CD4^+Foxp3^+$ lineage requires higher affinity of TCR interaction with the selecting MHC/peptide complex than commitment to $CD4^+Foxp3^-$ lineage, which could explain differences in their TCR repertoires. To study the role of the affinity of TCR-self peptide interaction we analyzed the TCR repertoires of $CD4^+Foxp3^-$ and $CD4^+Foxp3^+$ thymocytes in mice with restricted TCR repertoire (TCR^{mini}) that expressed class II MHC molecules (A^b) bound exclusively with one peptide recognized with either low (Ep) or high (Ep63K) affinity by multiple TCRs from this repertoire. In "single peptide" $A^bEp\ TCR^{mini}$ mice, the TCR repertoires of $CD4^+Foxp3^+$ and $CD4^+Foxp3^-$ thymocytes are diverse but share large proportion of identical TCRs. In contrast, in "single petide" $A^bEp63KTCR^{mini}$ mice fewer TCRs are shared by corresponding repertoires, which are more dissimilar and less diverse as a consequence of negative selection of thymocytes recognizing self peptide with higher affinity. Our results indicate that intrathymic commitment into $CD4^+Foxp3^+$ or $CD4^+Foxp3^+$ lineage is not dictated by different affinity of TCR-self peptide interaction and that negative selection plays dominant role in separating their TCR repertoires.

IL3.03.02
Anti-cytokine autoantibodies in APECED correlate with chronic mucocutaneous candidiasis

***P. Peterson**, J. Kärner, K. Kisand;*
University of Tartu, Tartu, Estonia.

Autoimmune polyendocrinopathy candidiasis ectodermal dystrophy (APECED) is a monogenic autoimmune disease caused by mutations in the Autoimmune Regulator (AIRE). AIRE is a transcriptional regulator expressed in thymic epithelial cells where it promotes the expression of tissue-specific antigens. APECED patients commonly have chronic mucocutaneous candidiasis, hypoparathyroidism, Addison's disease and multiple other autoimmune disorders including type 1 diabetes. The autoantibodies in patient sera recognize many organ-specific targets. In particular, they are reactive to type I interferons; IFNalpha and IFNomega and to Th17 cell-associated cytokines; IL-17 and IL-22. These autoantibodies are neutralizing, occur in extremely high titers, are disease-specific and, in addition to APECED, have been only reported in patients with thymomas. We found that the immunoglobulins responsible for neutralizing type I IFNs and IL-22 belong to IgG with dominant subtypes of IgG1 and IgG4, the latter possibly having immune regulatory rather than inflammatory function. We also found neutralizing autoantibodies to IL-17 in aged Aire-deficient mice, which is the first antigen to which reactivity is seen in both human and mouse AIRE-deficiency states. We conclude that autoimmunization against IFN and Th17 cytokines in AIRE-deficiency is closely related to the disease initiation.

W3.03.01
Novel role for heparan sulfate in thymic development of CD8+ T cells

***D. Simon Davis**, C. R. Parish;*
The John Curtin School of Medical Research, Australian National University, Canberra, Australia.

A remarkable feature of adaptive immunity is the process of positive and negative selection of T cells in the thymus that results in self-MHC restricted T cells with minimal autoreactivity. Our recent studies have provided new insights into this important process. It has been known for decades that murine CD4+CD8+ (double positive (DP)) thymocytes form multicellular conjugates with autologous erythrocytes in vitro, a phenomenon termed autorosetting. We have recently identified CD8β as the thymocyte autorosetting receptor and heparan sulfate (HS) as the autorosetting ligand on erythrocytes. Furthermore, a subpopulation of thymic cells, probably of stromal origin, has been identified that expresses extraordinarily high levels of cell surface HS, exhibits very high MHC expression and rosettes with thymocytes. Immunohistochemical studies showed that these HShi cells are located in small 'islands' throughout the thymic cortex. Additional in vitro studies demonstrated that high molecular weight HS mimetics, such as dextran sulfate 500-kDa (DxS-500), are capable of inducing a strong and prolonged intracellular calcium flux in DP thymocytes that is CD8β and SLP76, but not Zap70, dependent and lowers the thymocyte TCR activation threshold. In contrast, sialylation of CD8β expressed by single positive thymocytes and peripheral CD8+ T cells results in a dramatic reduction in HS binding and loss of the DxS-500 induced calcium flux. Collectively these data imply that the interaction of CD8β on DP thymocytes with HS expressed by thymic HShi stromal cells triggers an intracellular calcium flux that aids the positive selection of thymocytes with low affinity for self-MHC.

W3.03.02
B cells engender thymic Tregs

***S. N. Walters**[1], K. E. Webster[1], S. Daley[2], S. T. Grey[1];*
[1]Garvan Institute, Sydney, Australia, [2]Australian National University, Canberra, Australia.

Although B cells have been reported in the thymus the exact role they play is unclear. Here we observe that B cells can modulate thymic production of $Foxp3^+$ $CD4^+$ T cells (Tregs). BAFF transgenic mice harbor increased numbers of peripheral-Tregs whose expansion is B

cell dependent. BAFF did not enhance Treg survival, proliferation or conversion in the periphery but promoted a ~3 fold increase in thymic Helios$^+$ Treg numbers. Interestingly BAFF also increased thymic B cells. Thymic-Treg expansion was lost in BAFF-Tg/µMT$^{-/-}$BM chimeras and B cell null µMT$^{-/-}$ mice exhibited decreased numbers of thymic Tregs. There was also a direct correlation between the amount of thymic B cells and thymic Tregs. Based on the surface markers IgM, CD21 and CD23, four distinct populations of intra-thymic B cells could be determined, reminiscent of splenic B cell populations. CD19$^+$ B cells accumulated in the thymic medulla region close to medullary thymic epithelial cells suggesting a role in thymic Treg selection. Further to this thymic B cells were observed in close proximity to Foxp3$^+$ T cells. In the absence of B cell surface MHC class II, thymic Treg expansion did not occur, indicating the possibility of direct B-Treg interactions in the thymus. Further, thymic Treg expansion did not occur in BAFF-Tg/IgHEL BCR BM chimeras demonstrating a requirement for antigen-specificity. Thus, we present a model whereby intra-thymic B cells provide a source of cognate signals to modulate thymic Treg production. This results in increased numbers of peripheral Tregs that allow for allograft acceptance.

W3.03.03
Involvement of commensal bacteria in thymic Aire expression

A. Nakajima[1]*, N. Negishi*[1]*, H. Tsurui*[1]*, M. Nanno*[2]*, H. Yagita*[1]*, K. Okumura*[1]*, S. Habu*[1]*;*
[1]*Juntendo University, Tokyo, Japan,* [2]*Yakult Central Institute, Tokyo, Japan.*

Autoimmune regulator (Aire) expression in thymic epithelial cells (TECs) is involved in negative selection of self-antigen reactive T cells. However, little is known about how Aire expression is regulated. In this study, we found that Aire expression is reduced in TECs in germ-free (GF) mice in which commensal bacteria are absent, in comparison to specific pathogen-free (SPF) mice, allowing us to predict that components of commensal bacteria are involved in promoting Aire expression in TECs. Mutant mice lacking Nod1, an intracellular pattern recognition receptor of bacteria-derived molecules, also revealed reduced Aire expression in TECs. In the organ culture system of fetal thymus (FTOC) of wild type mice in the presence of synthetic ligand of Nod1, Aire expression was reciprocally increased in TECs. Staphylococcal enterotoxin B (SEB) produced from *Staphylococcus aureus* also induced Aire up-regulation in FTOC, which was reduced when thymic lobes were co-cultured with blocking antibody against the cytokine RANK ligand (RANKL). These observations indicate that intestinal bacterial components are involved in promoting Aire expression in TECs *in vivo* and *in vitro*, suggesting the novel possibility that commensal bacteria contribute to intrathymic negative selection through Aire induction.

W3.03.04
A Key Role for PTPN22 in Setting the Threshold for Natural and Inducible Regulatory T Cell Development

G. Fousteri[1]*, I. Debernardis*[1]*, T. Jofra*[1]*, S. Stanford*[2]*, N. Bottini*[2]*, M. Battaglia*[1]*;*
[1]*San Raffaele Scientific Institute, Milan, Italy,* [2]*La Jolla Institute for Allergy and Immunology, La Jolla, CA, United States.*

Regulatory T cells (Tregs) represent a vital component of the adaptive immune response securing peripheral tolerance. During positive selection in the thymus, a stable population of FOXP3-expressing natural Tregs (nTregs) develops as a result of strong agonist recognition. In addition to nTreg development, a fraction of conventional CD4+ T cells can acquire de novo FOXP3 expression in the periphery developing into inducible Tregs (iTregs). For both natural and inducible Treg development combined signals through the TCR, CD28, IL-2 and TGF-beta promote the upregulation of FOXP3. How FOXP3 expression is induced and maintained during Treg development is poorly understood. Here we demonstrate that mice deficient for PTPN22, a protein tyrosine phosphatase that inhibits TCR signaling, had increased frequency and number of nTregs in thymus and secondary lymphoid organs. We found that in the absence of PTPN22, the induction of TGF-beta-driven FOXP3 expression by conventional CD4 T cells was dependent on the degree of TCR activation. While PTPN22 antagonized FOXP3 at low TCR-mediated activation, it augmented FOXP3-inducing signals at higher TCR activating conditions. Since iTregs can be elicited from conventional CD4 T cells in response to lymphopenia, we employed this model to study the contribution of PTPN22 in iTreg development in vivo. iTreg induction by PTPN22-deficient CD4 T cells was reduced at two weeks after transfer in lymphopenic hosts, which, however, was increased at six weeks post transfer. Altogether, our results identify PTPN22 as indispensable factor for setting the proper threshold for natural and inducible Treg development in vitro and in vivo.

W3.03.05
Aire-mediated central tolerance includes naïve but not post-translational modified self antigens

B. Raposo*, P. Merky, R. Holmdahl, J. Bäcklund;*
Karolinska Institutet, Stockholm, Sweden.

The autoimmune regulator (Aire) controls ectopic expression of peripheral tissue-restricted antigens (TRAs) in medullary thymic epithelial cells, and is involved in mediating deletion of autoreactive T cells in the thymus. Despite the relevant role of Aire in regulating tolerance to TRAs, autoreactive T cells are frequently observed within the mature T cell repertoire. Many self-antigens are naturally subjected to post-translational modifications, such as glycosylation, and it is possible that such modified TRAs are not sufficiently presented to induce tolerance in the thymus. Here we have investigated the regulation of tolerance to type II collagen (CII), a self-antigen naturally subjected to glycosylation. Using an autologous collagen-induced arthritis model, where the transgenic expression of CII is Aire-dependent, we show that tolerance to CII is restricted to the non-modified version of the autoantigen, whereas T cells specific for the glycosylated version escape central tolerance. This finding explains earlier observations that the glycosylated form of CII constitutes the immunodominant epitope, despite that peripherally expressed self-CII appears uniformly glycoslylated. However, as many self-antigens are naturally subjected to post-translational modifications or may become altered over time either spontaneously or due to traumas, our data points out a possible general mechanism whereby T cells may escape an otherwise efficient tolerogenic mechanism.

W3.03.06
Functional study of WW domain-containing oxidoreductase in T cells

T. Chang*, L. Hsu;*
Taiwan National Cheng Kung University, Tainan, Taiwan.

WW domain-containing oxidoreductase (known as WOX1) has been shown to promote stress-induced cancer cell death and function as a tumor suppressor. Previous studies indicated that WOX1-deficient mice exhibit preweaning lethality, abnormal bone formation and growth retardation. However, whether WOX1 plays a role in the immune system is unknown. In this study, we investigated the functional role of WOX1 in lymphoid organs and found thymus atrophy in WOX1-deficient mice. Using cleaved caspase-3 staining and TUNEL assay, we examined higher levels of caspase activation and apoptosis in WOX1-deficient thymus. After ex vivo culture for 24 hours, WOX1-deficient thymocytes showed higher percentages of cell death than control, as determined by annexin-V and propidium iodide staining. The presence of a pan-caspase inhibitor, Z-VAD, in cultures partially prevented apoptosis in WOX1-deficient thymocytes. These results suggest that WOX1-deficient thymocytes are prone to cell death. To explore the intrinsic or extrinsic defect that causes extensive apoptosis in WOX1-deficient thymocytes, wild-type or WOX1-deficient bone marrow cells carrying CD45.2 were transferred into CD45.1+ NOD.SCID mice. Our results demonstrated that wild-type bone marrow cells differentiated into mature T cells and showed normal distribution of thymocyte subpopulations in NOD.SCID recipients 6 weeks after adoptive transfer. However, WOX1-deficient bone marrow cells failed to differentiate into mature T cells in recipient mice. In summary, we show here that WOX1-deficient

thymocytes exhibit intrinsic defects in sustaining cell differentiation and survival. These in vivo findings run against the role of WOX1 as a pro-apoptotic protein and unravel a novel function of WOX1 in thymocyte development.

IL3.04.01
Combinatorial H3K9acS10ph histone modifications in IgH locus S regions target 14-3-3 adaptors and AID to specify antibody class switch DNA recombination

P. Casali[1], *G. Li*[2];
[1]*Institute for Immunology, University of California, Irvine, CA, United States,* [2]*University of California, Irvine, CA, United States.*

Class switch DNA recombination (CSR) is central to effective antibody responses. By recombining an upstream (donor) S region and a downstream (acceptor) S region, it changes an antibody IgH constant region and endows it with news biological effector functions. 14-3-3 adaptors recruited/stabilize to/on S regions AID, which is critical for CSR. 14-3-3 a high affinity for 5'-AGCT-3' repeats, which recur at a high density in all S regions. How 14-3-3 and the AID-centered CSR machinery target exclusively the S regions that will undergo recombination is poorly understood. We hypothesized that histone posttranslational modifications play an important role in CSR targeting. We showed that "primary" (CD154 or LPS) CSR-inducing stimuli induced histone methyltransferases and acetyltransferases, which catalyzed H3K4me3 and H3K9ac/K14ac modifications in S regions as well as germline IH-S-CH transcription (specified by cytokines) were associated with but did not precisely predict the S region targets of CSR. By contrast, the combinatorial H3K9acS10ph histone modification marked only the donor Sμ and acceptor S regions that were set to recombine. H3K9acS10ph was introduced into the recombining S regions by CD154- or LPS-induced pGcn5 and Pcaf histone acetyltransferases and specifically recruited 14-3-3 (and AID), as determined by free H3K9acS10ph peptide competition. Thus, the combinatorial H3K9acS10ph histone code is "written" by primary stimuli-induced histone-modifying enzymes, specifically marks the S regions that will undergo recombination and is "read" by 14-3-3 adaptors, thereby targeting the AID-centered CSR machinery to "transduce" CSR as specific functional outcome. Supported by NIH AI079705, AI105813, AI045011 and AI060573 grants to P.C.

Proteostasis in the exocytic compartment: synthesis, folding and transport of antibodies as intracellular signals

S. Cenci[1], *T. Anelli*[1], *M. Bertolotti*[1], *E. Milan*[1], *N. Pengo*[1,2], ***R. Sitia***[1];
[1]*Division of Genetics and Cell Biology. Università Vita Salute San Raffaele Scientific Institute, Milan, Italy,* [2]*Present adress: University College, London, United Kingdom.*

Immunoglobulin subunits act as powerful signaling devices during the entire B cell developmental program. At the B cell level, for instance, the antigen receptor is essential for survival also in the absence of nominal antigen. Upon encounter with antigen in a suitable context, however, the B cell receptor delivers signals that induce B lymphocytes to differentiate into antibody secreting plasma cells. Most of these undergo apoptosis after a few days of intense immunoglobulin production, so as to limit antibody responses. Real professional secretors, plasma cells allow dissecting the mechanisms that maintain protein homeostasis (proteostasis) in the exocytic compartment, the stresses that the exuberant production and transport of antibodies along the exocytic route entail, as well as their roles in signaling. Our data reveal how proteotoxic stresses physiologically contribute to regulate the biogenesis, function and lifespan of B and plasma cells, and explain in part why multiple myeloma cells are exquisitely sensitive to proteasome inhibitors.

W3.04.01
A novel DNA break and phosphorylation-dependent positive feedback loop promotes class switch recombination

J. Chaudhuri;
Memorial sloan Kettering Cancer Center, New York, NY, United States.

Activation induced cytidine deaminase (AID) is essential for class switch recombination (CSR), a deletional-recombination reaction that occurs between repetitive DNA elements, termed switch (S) regions, in the immunoglobulin heavy chain (*Igh*) locus. The ability of AID to mediate CSR is significantly dependent on its phosphorylation at serine-38 (S38); however, the trigger that induces AID phosphorylation and the mechanism by which phosphorylated AID drives CSR have not been elucidated. We have used catalytically-inactive AID and mice impaired in processing deaminated DNA to demonstrate that AID phosphorylation at S regions is induced by DNA breaks. Conversely, in the absence of AID phosphorylation, DNA breaks are not efficiently generated at S regions due to a failure of AID to interact with the apurinic/apyrimidinic endonuclease APE1. Additionally, Ataxia telangiectasia mutated (ATM) deficiency impairs AID phosphorylation and interaction with APE1. Our results uncover a novel positive feedback loop for amplification of DNA breaks at S regions through a phosphorylation- and ATM-dependent interaction of AID with APE1.

AID-dependent IgV hypermutation requires a splice isoform of the SR protein SRSF1

N. Kanayama[1], *Y. Kanehiro*[1], *K. Todo*[1], *Y. Kawaguchi*[1], *S. Miyazaki*[1], *K. Watanabe*[1], *H. Tokumitsu*[1], *J. L. Manley*[2], *M. Magari*[1], *H. Ohmori*[1];
[1]*Department of Biotechnology, Okayama University, Okayama, Japan,* [2]*Department of Biological Science, Columbia University, New York, NY, United States.*

Somatic hypermutation (SHM) of IgV genes in B cells is crucial to generate high-affinity antibodies during immune responses. Both IgV transcription and activation-induced cytidine deaminase (AID) are required for SHM. However, it remains unclear how IgV genes are much more sensitive to AID-induced mutagenesis than other genes and what links the action of AID with IgV transcription in SHM. We found an essential role for a splice isoform of the prototypical serine/arginine-rich (SR) protein splicing factor SRSF1, termed SRSF1-3, in AID-induced SHM in a hypermutating chicken B cell line DT40. We unexpectedly found that both SHM and gene conversion (GCV) did not occur in a DT40 line lacking SRSF1-3 expression (DT40-ASF), while they are readily detectable in parental wild-type DT40 cells. In DT40-ASF cells, the endogenous SRSF1 gene is disrupted and a tet-regulated SRSF1 cDNA is introduced. Importantly, reconstitution of SRSF1-3 in DT40-ASF cells completely restored SHM and GCV without increasing off-target mutations. In contrast, overexpression of AID in DT40-ASF cells led to a large increase in off-target mutations, while marginally affected IgV mutation. ChIP analysis showed that SRSF1-3 bound preferentially to the IgV gene and inhibited processing of the Ig transcript, but reconstitution of SRSF1-3 did not enhance the recruitment of AID on the IgV gene. Our findings define an unexpected and important role for SRSF1, specifically for its splice variant, in enabling AID to specifically attack its natural substrate during IgV hypermutation.

Effect of the 3'Regulatory Region insulation on B cell development and DNA rearrangements at the Immunoglobulin heavy chain locus

F. Braikia, ***C. Conte****, M. Moutahir, A. khamlichi;*
CNRS UMR5089-IPBS / University of Toulouse, Toulouse, France.

The Immunoglobulin heavy chain locus (IgH) undergoes a series of developmentally-regulated DNA rearrangements, named V(D)J recombination.
Regulation of these events is effected by various cis-acting elements among which the Eμ enhancer plays a major role. Another important

cis-element is the 3' Regulatory Region, located downstream of the IgH locus, and which was suggested to interact with Eμ enhancer. CTCF-binding elements have been described at the IgH locus and are thought to mediate the formation of large loops that may be important for various processes linked to V(D)J recombination.
In this study, we have adopted an insulation approach by inserting the well-characterized cHS4 insulator of the chicken β-globin locus, upstream of the IgH 3'RR. We generated two mouse lines in which either the wild-type, CTCF-binding, cHS4 insulator was used or a mutated version of it devoid of CTCF-binding site.
We will present our recent results on the long-range effect of 3'RR insulation on B cell development, V(D)J recombination, allelic exclusion and IgH expression.

W3.04.04
Genetic variation and positional biases influence rearrangement of lymphocyte receptor genes

***M. J. Kidd**, A. M. Collins;*
University of New South Wales, Kensington, Australia.

An important source of the diversity of lymphocyte receptors is combinatorial diversity - the joining of gene segments to produce functional lymphocyte receptor genes. Estimates of the size of the primary human immunoglobulin repertoire generally assume that functional genes of the same type (V, D or J) are equally likely to be present in any V(D)J rearrangement. However, there are clear biases in gene usage, and some studies have even suggested that there are weak positional biases in the pairings of different DJ and V(DJ) heavy chain genes. Using 454 pyrosequencing, we have studied repertoires of V(D)J rearrangement in 30 individuals. Each dataset included at least 5000 sequences. The data show that the frequencies with which different IGHD genes partner with each IGHJ gene are subject to strong, though complex, positional biases. Techniques that allow the inference of both chromosomal sets of germline genes in an individual have allowed us to separately analyze rearrangements of each chromosome. IGHD/IGHJ haplotypes associated with different IGHD and IGHJ alleles show stronger or weaker but still predictable positional biases. Furthermore, individuals who carry IGHD gene deletion polymorphisms on one chromosome show a predictable overutilization of DJ pairings with those D genes on the second chromosome. Incorporating these positional biases into models of repertoire development will be essential if we are to understand individual variation in immunocompetence.
The primary repertoire may be more comprehensible and predictable than previously reports have suggested, and genetic variation may account for individual differences in the primary antibody repertoire.

W3.04.05
Secondary immunoglobulin heavy chain rearrangements in IgA cloned mice

***R. Kumar**[1], O. Kanagawa[2], S. Fagarasan[2], S. Casola[1];*
[1]The FIRC Institute of Molecular Oncology Foundation (IFOM), Milano, Italy, [2]Research Center for Allergy and Immunology,RIKEN Yokohama Institute, Yokohama, Japan.

The generation of a diversified repertoire of Immunoglobulin Heavy (IgH) chains requires RAG-mediated VDJ recombination. Recent reports have suggested that secondary IgH rearrangements both in humans and mice contribute to the complexity of the primary antibody repertoire. Secondary IgH rearrangements have been preferentially studied under conditions where B cells express either non-functional or autoreactive IgH chains, raising the question of the physiological relevance of this process. This study estimated the contribution of secondary IgH rearrangements to primary antibody diversification under physiological conditions. We employed a novel mouse strain generated through the reprogramming of terminally differentiated intestinal IgA plasma expressing a non-autoreactive BCR. Heterozygous IgA (IgAH/+) mice allowed us to easily track secondary VH rearrangements. Surprisingly, almost 20% of peripheral B cells in IgAH/+ cloned mice expressed IgM instead of IgA. Sequencing of IgA rearrangements in sorted IgM+ B cells of IgAH/+ mice indicated that both VH replacement and direct VH-to-JH joining contributed to the disruption of the original VH rearrangement. The presence of n-nucleotides in the CDR3 region of secondary VH rearrangements indicated that these events occurred in pro-B cells. Interestingly, analysis of V-gene usage in secondary IgH rearrangements revealed a strong bias for V-genes proximal to the pre-rearranged VH gene. The preferential use of proximal VH genes for secondary VH rearrangements correlated with higher levels of germline transcripts detected in pro-B cells. Altogether these results reveal a major contribution of secondary IgH rearrangements to the diversification of the primary antibody repertoire under conditions of unperturbed B-cell development.

W3.04.06
The conservation of immunoglobulin genes: an evolutionary link between autoreactivity and innate response against pathogens

***A. M. Vale**[1], P. Kapoor[2], T. I. Mahmoud[2], C. Zemlin[2], M. Zemlin[2], P. D. Burrows[2], J. F. Kearney[2], D. E. Briles[2], A. Nobrega[1], H. W. Schroeder[2];*
[1]Instituto de Microbiologia Prof Paulo de Goes, Rio de Janeiro, Brazil, [2]University of Alabama at Birmingham, Birmingham, AL, United States.

Selection and physiologic production of protective natural antibodies (NAbs) have been associated with exposure to endogenous antigens. The extent to which this association depends on germline NAb sequence is uncertain. To test the role of natural selection of germline sequence in this cross-protection, in mice with gene-targeted alterations of DH sequence we evaluated responses against a hazardous self antigen, oxidized low density lipoprotein (OxLDL), and against phosphorylcholine (PC), a bacterial cell wall component. Here, we show that alterations in germline DH sequence can sever the association between the production of self-reactive NAbs and NAbs that afford protection against a pathogen. In unmanipulated hosts, the availability of the evolutionarily conserved DFL16.1 gene segment sequence profoundly affected the serum levels of NAbs against bacterial phosphorylcholine (PC), but not OxLDL. Mice with partially altered DFL16.1 sequence could use N nucleotides to recreate the amino acid sequence associated with the classical protective T15 idiotype positive NAbs, whereas those without DFL16.1 could not. DFL16.1 gene deficient mice proved more susceptible to challenge with live Streptococcus pneumoniae. We present data that support the moderating concept that natural selection of conserved DH sequence, and self-antigen driven somatic selection operate in concert to create a protective, functional NAb repertoire reactive with a bacterial cell wall component. In remarkable contrast, NAb reactivity and function in the case of an endogenous antigen representative of molecular debris does not show this dependence on evolutionarily conserved DH sequences. The potential relevance of these findings for the rational design of vaccines is discussed.

Compartment cross-talk controlling phagosome maturation and exogenous antigen presentation in dendritic cells

***P. van Endert**[1,2], M. Weimershaus[2], J. Babdor[2], D. Descamps[2], A. Lennon-Dumenil[3], M. Zwick[4], T. Brocker[4], L. Saveanu[2];*
[1]France, [2]INSERM, U1013; Université Paris Descartes, Paris, France, [3]INSERM, U932; Institut Curie, Paris, France, [4]Institute for immunology, Ludwig-Maximilians-Universität, Munich, Germany.

Dendritic cells (DC) process internalized material in a manner optimized for simultaneous extraction of antigenic information for stimulation of adaptive immune responses and controlled activation of innate signaling. This optimization is thought to depend on DC-specific attenuated phagosome maturation due to fusion events with the endoplasmic reticulum-Golgi intermediate compartment (ERGIC) on the one hand, and with inhibitory lysosome-related organelles on the other hand. Here we report a critical role of a specific slowly recycling endosomal compartment in DC-specific phagosome maturation. Formation and stability of the compartment requires a number of proteins including the aminopeptidase IRAP and Rab14.

Upon destabilization of the compartment by IRAP deletion or expression of Rab14 mutants, phagosome maturation is accelerated, associated with functional consequences described in the accompanying abstract by Saveanu et al. Interestingly, knockdown of Sec22b, described to mediate ERGIC-fusion with phagosomes, profoundly affects formation of the compartment. Our results point to a central role of a specific endosomal storage compartment in triggering of adaptive and innate immune responses by DCs.

W3.05.01
The true story of how MHC peptides are produced

A. Admon[1], *L. Gutter-Kapon*[1], *E. Milner*[1], *D. Bourdetsky*[1], *E. Barnea*[1], *I. Beer*[2];
[1]*Technion-Israel Institute of Technology, Haifa, Israel,* [2]*Haifa IBM Research Laboratory, Haifa, Israel.*

The cellular proteolytic pathways leading to the formation of the MHC peptidome were analyzed by dynamic metabolic labeling of cultured cells with stable heavy isotope heavy amino acids, followed by large-scale immunopeptidome and proteome analyses. The MHC molecules were immunoaffinity purified and the bound peptides were analyzed by capillary chromatography and mass spectrometry (dynamic-SILAC immunopeptidome analysis). Specific proteolysis inhibitors were used to define the relative contribution of the proteolytic pathways that produce the immunopeptidomes. Surprisingly, the proteasomes inhibitors, epoxomicin and bortezomib, affected the rate of synthesis of the cellular proteins and of their degradation products, the MHC peptides in a complex manner. While (as expected) the proteasome inhibitors reduced the rates of degradation of many cellular proteins, they increased the degradation (and synthesis) rates of others. Correlating between the rates of production of the source proteins and their derived HLA peptides suggests that the contribution of the proteasomal proteolysis to the production of the HLA peptidome should be reevaluated. It is possible that the proteasomal proteolysis contributes more significantly to the production of HLA peptides derived from newly synthesized proteins, possibly including defective ribosome products (DRiPs) and short lived proteins (SLiPs), while non-proteasomal pathway (such as the autophagosomal pathway) contribute more to the production of HLA peptides derived from stable, long-lived proteins.

ER-resident editors optimize distinct features of the peptide cargo loaded onto MHC class I molecules

T. Kanaseki[1], *K. C. Lind*[2], *H. Escobar*[3], *N. Nagarajan*[2], *E. Reyes-Vargas*[3], *B. Rudd*[3], *L. Van Kaer*[4], *N. Sato*[1], *J. Delgado*[3], ***N. Shastri***[2];
[1]*Sapporo Medical University, Sapporo, Japan,* [2]*University of California Berkeley, Berkeley, CA, United States,* [3]*University of Utah School of Medicine, Salt lake City, UT, United States,* [4]*Vanderbilt University School of Medicine, Nashville, TN, United States.*

Effective CD8+ T cell responses depend upon presentation of a stable peptide repertoire by MHC I molecules on the cell surface. The overall quality of pMHC I is determined by poorly understood mechanisms that generate and load peptides with appropriate consensus motifs onto MHC I. Here we show that both tapasin, a key component of the peptide loading complex, and ERAAP, the ER aminopeptidase associated with antigen processing, are quintessential editors of distinct structural features of the peptide repertoire. The T cell responses elicited by the pMHC I showed that absence of tapasin or ERAAP independently altered the peptide repertoire by causing loss as well as gain of new pMHC I. Changes in amino acid sequences of MHC bound-peptides revealed that ERAAP and tapasin respectively defined the characteristic amino and carboxy termini of canonical MHC I peptides. Thus, the optimal pMHC I repertoire is produced by two distinct peptide editing steps in the ER..

A CD74-dependent MHC class I endolysosomal cross-presentation pathway

W. A. Jefferies[1], *G. Basha*[1], *K. D. Omilusik*[2], *A. Chavez-Steenbock*[1], *A. T. Reinicke*[3], *N. Lack*[1], *K. Choi*[1];
[1]*University of British Columbia, Vancouver, BC, Canada,* [2]*University of California, San Diego, San Diego, CA, United States,* [3]*University of Lübeck, Lübeck, Germany.*

Immune responses are initiated and primed by dendritic cells (DCs) that cross-present exogenous antigen. The chaperone CD74 (invariant chain) is thought to promote DC priming exclusively in the context of major histocompatibility complex (MHC) class II. However, we demonstrate here a CD74-dependent MHC class I cross-presentation pathway in DCs that had a major role in the generation of MHC class I–restricted, cytolytic T lymphocyte (CTL) responses to viral protein– and cell-associated antigens. CD74 associated with MHC class I in the endoplasmic reticulum of DCs and mediated the trafficking of MHC class I to endolysosomal compartments for loading with exogenous peptides. We conclude that CD74 has a previously undiscovered physiological function in endolysosomal DC cross-presentation for priming MHC class I–mediated CTL responses.
Our observations have defined a previously unknown pathway for the priming of immune responses; future studies should completely elucidate this process. Our results are of considerable clinical relevance and suggest that targeting vaccine candidates to the endolysosomes of DCs would enhance priming for both MHC class I and MHC class II antigens and thereby improve the immunogenicity and efficacy of vaccines.

W3.05.04
IRAP endosomes are an intracellular crossroad of innate and adaptive immunity

L. Saveanu[1,2], *M. Weimershaus*[1,2], *J. Babdor*[1,2], *M. Tohme*[1,2], *P. Vargas*[3], *A. Lennon-Dumenil*[3], *D. Descamps*[4,2], *B. Manoury*[4,5], *P. van Endert*[4,2];

An efficient immune response depends on tight cooperation between innate and adaptive immunity. Such cooperation requires dendritic cells (DCs) that detect pathogens via innate immune receptors including TLRs, and present antigens to specific T cells. Coupling TLR signaling to antigen presentation depends on cellular mechanisms that are still poorly understood. Here, we demonstrate that these mechanisms implicate a previously uncharacterized endosomal DC compartment bearing the features of storage endosomes. These endosomes contain, and are formed in the presence of the antigen trimming aminopeptidase IRAP (Insulin Responsive AminoPeptidase). We show that they are important for regulating the dynamics of phagosomal maturation and TLR9 signaling in DCs, in addition to the previously described role of IRAP in antigen trimming during cross-presentation. Destabilization of the endosomal storage compartment by IRAP deletion led to accelerated phagosome maturation, as documented by premature loss of early endosomal markers and accelerated acquisition of phagolysosome markers such as Lamp1 and V-ATPase. This was associated with faster degradation of phagocytosed antigen, enhanced acidification and increased killing of internalized microbes. IRAP deletion also affected the trafficking of TLR9, as illustrated by steady state mis-localization of the receptor to lysosomes. Altered TLR9 trafficking was correlated with a hyper-inflammatory phenotype of IRAP deficient mice, which displayed increased mortality during Pseudomonas aeruginosa infection. These data suggest a major role of IRAP in maintaining a functional storage endosome compartment required both for innate and adaptive immunity.

W3.05.05
CD4 T cell receptor transgenic mice recognizing an unstable peptide of insulin are directly recruited into islets bypassing local lymph nodes

***J. F. Mohan**, B. Calderon, E. R. Unanue;*
Washington University School of Medicine, Saint Louis, MO, United States.

In the NOD model of autoimmune diabetes, a predominant component of the islet autoreactive CD4 T cell repertoire is directed against the B:9-23 segment of the insulin beta chain. Previous studies have established that the overwhelming majority of insulin reactive T cells specifically recognize a weak peptide-MHC binding register within the B:9-23 peptide. These T cells are uniquely stimulated when the B:9-23 peptide but not the insulin protein is offered to APC. Strong evidence suggests that these T cells are intimately involved in the autoimmune response leading to diabetes. Within the islets, resident APC routinely take up free peptides derived from the insulin protein found in the secretory granules of beta cells. As a result, islet APC constitutively present insulin peptides and have the capacity to trigger these T cells during disease development. To study these unconventional insulin reactive T cells in greater detail we generated a TCR transgenic (8F10) mouse. The peptide specific CD4 T cells in 8F10 mice are not negatively selected despite being actively recruited to the islets and being highly pathogenic. Additionally, we have found that the local lymph nodes are dispensable for the migration of 8F10 T cells into islets, indicating that these T cells can bypass an initial priming stage in the pancreatic lymph node previously thought to be critical prior to islet T cell entry. We believe these findings are highly relevant to the study of autoimmunity and provide new insight into the anatomical location of disease initiation in autoimmune diabetes.

W3.05.06
Structural basis of human beta-cell killing by CD8+ T cells in Type 1 diabetes

***D. K. Cole**;*
Cardiff University, Cardiff, United Kingdom.

Autoreactive T-cells play a role in type 1 diabetes (T1D) by killing insulin producing beta cells in the pancreas, although the mechanism has not been fully resolved. The antigen specific interaction between the T-cell receptor (TCR), on the T-cell surface, and peptide-major histocompatibility complexes (pMHCs) on the target cell surface, govern T-cell mediated immunity. Thus, we examined how T-cells kill human islet beta cells by solving the atomic structure of an autoreactive-TCR (1E6) specific for a MHC-restricted glucose-sensitive preproinsulin peptide (A2-ALW).
Rigid 'lock-and-key' binding underpinned the 1E6-A2-ALW interaction, whereby 1E6 docked similarly to most MHCI-restricted TCRs. However, this interaction was extraordinarily weak, due to limited contacts with MHCI. Thus, highly focused peptide-centric interactions associated with suboptimal TCR-pMHCI binding affinities might lead to thymic escape and potential T-cell-mediated autoreactivity.
This first sight of how T-cells target insulin producing beta cells has increased our understanding of how T1D arises. This knowledge will be used in the future to help predict who might get the disease, and also to develop new approaches to prevent it. Our aim is to catch the disease early before too many insulin-producing beta cells have been damaged.
This study has been recently published in Nature Immunology (Nature Immunology. 2012 Jan 15;13(3):283-9) and was featured in the News and Views section of the same issue.

IL3.06.01
Autonomous CD28 signalling pathways in the regulation of T lymphocyte survival and pro-inflammatory functions

***L. Tuosto**;*
Istituto Pasteur-Fondazione Cenci Bolognetti, Department of Biology and Biotechnology Charles Darwin, Sapienza University, Rome, Italy.

CD28 costimulatory receptor is a crucial determinant of the outcome of T lymphocyte activation. The engagement of CD28 by its natural ligands, B7.1/CD80 or B7.2/CD86, expressed on the surface of professional APC, lowers TCR activation threshold, thus leading to the enhancement of early signalling events necessary for efficient cytokine production, cell cycle progression, survival and regulation of T cells effector responses. CD28 is also able to act as a unique signalling receptor and to deliver TCR-independent autonomous signals, which account for its critical role in the regulation of pro-inflammatory cytokine/chemokine production and T cell survival.
In the last years, we extensively worked on the characterization of CD28 autonomous signalling and we found that CD28 stimulation by B7 expressed on APCs, in the absence of TCR engagement, is able to recruits and activates IKKα and a non-canonical NF-κB2-like cascade leading to both the production of pro-inflammatory cytokine/chemokines and the activation of survival genes, which protect cells from apoptosis and ensure their long-term survival. The mechanisms and molecules coupling CD28 to NF-κB signaling pathway as well as their functional relevance in immune diseases will be discussed.

IL3.06.02
Viruses and type 1 diabetes - the good and the bad

***M. G. Von Herrath**[1,2,3];*
[1]La Jolla institute and NovoNordisk, La Jolla and Seattle, WA, United States, [2]Diabetes Center La Jolla Institute, La Jolla, CA, United States, [3]NovoNordisk T1D R&D Center, Seattle, WA, United States.

We have been studying the histopathology of human type 1 diabetes as part of the nPOD consortium (www.jdrf.nPOD.org). This has offered important insight into the development of human type 1 diabetes including some surprises, which could make us rethink therapeutic priorities in some cases. Three interesting, yet unexplained, findings indicate the potential involvement of viral infections in triggering or re-igniting insulitis that then leads progressively to beta-cell loss: First, insulitis cannot be consistently documented prior to the onset of diabetes clinically, raising the possibility that human diabetes in its development is a relapsing-remitting disorder. Second, many human islet over-express uniformly MHC class I after diagnosis of diabetes (a phenomenon not present in healthy controls or type 2 diabetes), which is not seen that pronounced and uniformly in mouse models, the cause for this being unknown. Last, human diabetes appears develop in a lobular fashion and not randomly affecting islets throughout the pancreas, as this is usually seen in rodent models. Thus, we have to consider that enteroviral (or possibly even herpes virus) infections could constitute at least an additional factor that contributes to diabetes pathogenesis. On the other hand, studies in experimental animal models clearly show that viral infections can also prevent diabetes (enteroviruses, rotaviruses). This occurs through mechanisms that 'reset' the immune system, eliminate autoreactivity and enhance immune regulation, which are byproducts of successfully overcome viral infections. Systematic studies in humans such as the ones initiated by nPOD-V, VIDIS and PEVNET will be critical in resolving this important dilemma.

W3.06.01
Mechanical Insights into the functional impacts of interactions between antigen-presenting cells and T cells

T. Lim[1]*, A. Mortellaro*[1]*, C. Lim*[2]*, G. J. Hämmerling*[3]*, P. Ricciardi-Castagnoli*[1]*;*
[1]Singapore Immunology Network, Singapore, Singapore, [2]National University of Singapore, Singapore, Singapore, [3]German Cancer Research Center DKFZ, Heidelberg, Singapore.

Antigen recognition and discrimination by T lymphocyte are essential in initiating appropriate immune responses. The mechanisms underlying exquisite sensitivity and specificity of antigen discrimination are not fully elucidated but involved physical intercellular interactions between T cell and antigen-presenting cell (APC) including dendritic cells (DCs) and B cells. Using single cell force spectroscopy (SCFS), we have successfully probe mechanical interactions between DC and T cells in response to a panel of altered peptide ligands (APLs). In the presence of different type of APLs, DC:T conjugate displays different ranges of mechanical forces that match their corresponding T cell responsiveness. Strong cell-cell interaction forces are contributed not only by surface adhesion molecules including TCR:pMHC, CD28:B7 and ICAM-1:LFA-1 interaction pairs, but also dependent on the integrity of membrane cholesterol and cytoskeleton dynamics. As compared to B:T interactions, stronger DC:T cell-cell interactions are likely to provide a mechanically stable environment that induces potent functional T cell activation, suggesting that the measurement of mechanical forces could be a significant predictor of T cell functional activation efficacy. Our SCFS studies provide mechanical insights into the adhesive roles of cell surface proteins in regulating APC:T cell-cell interactions. Functional roles of TLR ligands in regulating APC:T interactions and T-cell responses will be discussed.

W3.06.02
Basilic, a lymphoid-specific protein essential for CD28 costimulation and regulatory T cell development

M. Malissen[1]*, L. Yinming*[1]*, M. Cucchetti*[1]*, R. Roncagalli*[1]*, T. Yokosuka*[2]*, T. Saito*[2]*, C. Wuelfing*[3]*, B. Malissen*[1]*;*
[1]Centre d'Immunologie de Marseille Luminy, Marseille, France, [2]Laboratory for cell signaling, RIKEN Research Center for Allergy and Immunology, Yokohama, Japan, [3]chool of Cell and Molecular Medicine, University of Bristol, Bristol, United Kingdom.

Background: Early studies have led to a "two-signal model" of T cell activation in which the first signal is delivered via the T cell antigen receptor following recognition of antigenic peptides bound to class I and II molecules of the major histocompatibility complex. This signal provides antigen specificity to T cell responses. The second signal is known as the costimulatory signal and is delivered by the CD28 molecule upon recognition of the CD80 and CD86 ligands that are expressed on antigen presenting cells.
Methods: By using an N-ethyl-N-nitrosourea-mutagenesis screen aiming at discovering effectors of CD28-mediated costimulatory signals, we identified a mutation in the functionally uncharacterized Basilic gene.
Results: We showed that Basilic is a T cell-specific protein that is essential for CD28 costimulation and regulatory T cell development. TCR-CD28 engagement at the immune synapse resulted in the spatial colocalization of CD28 with wild-type and mutant Basilic forms. However, the Basilic mutant form prevented CD28 signaling by abrogating the connection between CD28 and protein kinase C-θ and Carma1, two key effectors of CD28 costimulation.
Conclusions: Our findings provide a more complete model of CD28 costimulation in which Basilic plays an essential role.

W3.06.03
Human memory T-cell subsets require distinct costimulatory signals to efficiently expand ex vivo

V. Volpin[1,2]*, N. Cieri*[1,2]*, C. Bonini*[1]*;*
[1]San Raffaele Scientific Institute, Milan, Italy, [2]Università Vita-Salute San Raffaele, Milan, Italy.

Costimulation plays a critical role for activation of T cells in response to pathogens, cancer and in alloreactive immune responses. However, costimulatory requirements of memory T cell responses have been much less studied than those for primary response generation, especially in humans. In the present work, we evaluated the ability of several costimulatory molecules (the CD28-family member CD28 and ICOS, and the TNFR-family members 4-1BB, OX40, GITR, CD27, CD30, HVEM) in expanding ex-vivo human memory T-cell subsets. We assessed the effect of these costimulatory molecules on central memory (TCM), effector memory (TEM) and on the recently identified memory stem T cells (TSCM). Memory T-cell subsets were FACS-sorted, according to the expression of CD45RA/CD62L and CD95, activated by coated anti-CD3 antibody in the presence of anti-costimulatory molecules antibodies and cultured with low dose homeostatic cytokines. The efficacy of costimulatory molecules was measured in terms of T-cell expansion and preservation of the original surface phenotype. Strikingly, we found that each memory T-cell subset best responded to distinct costimulatory signals. TSCM lymphocytes expanded, while maintaining a higher fraction of cells with the original and less-differentiated phenotype, when stimulated in the presence of OX40- and GITR-mediated signals, while TCM best performed when CD28- and 4-1BB-costimulated. Finally, TEM cells expanded to higher numbers in response to CD27 costimulation. We are currently evaluating the cytokine secretion profile of differentially costimulated T-cell subsets. Altogether, these findings may help in designing new strategies to boost immunity against immune-evading pathogens and tumors, as well as to increase vaccine efficacy.

W3.06.04
Differential usage of costimulatory/coinhhibitory pathways by antigen-specific CD8+ T cells in patients with chronic hepatitis C

S. Owusu Sekyere*, P. Suneetha, V. Schlaphoff, M. Manns, M. Cornberg, H. Wedemeyer;*
Hannover Medical School, Hannover, Germany.

The function of antigen-specific T cells is regulated by a sophisticated network of co-stimulatory/inhibitory receptors. Particularly, hepatitis C virus (HCV), Epstein-Bar virus (EBV) and cytomegalovirus (CMV) that establish lifelong infections show upregulation of an expanding repertoire of distinct coinhibitory receptors on virus-specific CD8+ T cells. The differential usage of costimulatory pathways by CMV, EBV and HCV-specific CD8+ T cells has not been studied thus far. It also remains unknown if antigen-specific CD8+ T cell responses to CMV and EBV are altered in the face of secondary infections such as chronic hepatitis C. To investigate these, we assessed the proliferation, degranulation and cytokine production of CMV-, EBV- and HCV-specific CD8+ T cells after *in vitro* blockade of PD-1, CTLA-4, Tim-3 and 2B4 in varying combinations in PBMC of healthy blood donors and chronic HCV patients. We also analysed expression of different costimulatory molecules by virus-specific CD8+ T cells *ex vivo* by flow cytometry. We found that at the individual level, a 'private pattern' of co-stimulatory receptor usage determines the functionality of CMV-, EBV- and HCV-specific CD8+ T cells in chronic HCV patients. Notwithstanding, we observed that regulation of virus-specific CD8+ T cell responses by costimulatory molecules is similar between CMV and EBV but distinctly different from HCV at the level of proliferation and interferon-γ production. Finally we report that CMV or EBV-specific CD8+ T cells in chronic HCV patients and healthy individuals use similar patterns and hierarchies of costimulatory molecules.

W3.06.05
PD-1 controls effectors but not the generation or function of natural or induced regulatory T-cells

K. K. Ellestad*, G. Thangavelu, C. L. Ewen, C. C. Anderson;*
University of Alberta, Edmonton, AB, Canada.

During T cell activation, the balance of co-stimulatory and co-inhibitory interactions plays an important role in shaping the resulting T cell response. Co-inhibitory signals help maintain peripheral immune tolerance, and thus animals with defective co-inhibitory molecules, such as PD-1 KO mice, are predisposed to autoimmunity. Unlike PD-1 KO mice, which develop mild autoimmunity, adult Rag KO recipients of PD-1 KO hematopoietic stem cells (HSC) succumb

to rapid and severe multi-organ autoimmune disease soon after newly generated T cells emerge from the thymus, implicating PD-1 as an especially critical controller of T cell self-reactivity during lymphopenia induced homeostatic proliferation (LIP). While we have found no reduction in absolute numbers of FoxP3+ regulatory T cells (Treg) in diseased PD-1 KO vs. wild type (WT) HSC recipients, some studies have indirectly suggested that PD-1 deficiency may inhibit the conversion of conventional T cells to induced Treg (iTreg) in the periphery. We therefore investigated whether PD-1 deficiency results in an intrinsic inability of T cells to convert to iTreg in vivo, which could underlie disease in PD-1 KO HSC recipients. Surprisingly, our findings show that PD-1 deficiency increases the numbers of iTreg and does not reduce Treg suppressive function. In the context of LIP, co-inhibitor deficient effector T cells cause disease primarily by expanding beyond the ability of Treg to control them. The finding that PD-1 restrains the effector response rather than promoting iTreg may guide application of immunotherapeutics currently under investigation to block human PD-1 in cancer.

W3.06.06
Immunogenic, but not steady-state, antigen presentation permits Treg control of CD8+ T-cell effector differentiation through IL-2 modulation

***R. J. Steptoe**, A. McNally, R. Thomas;*
University of Queensland, Woolloongabba, Australia.

One proposed mechanisms of Treg suppression is absorption of IL-2 by Treg and in vivo experimental evidence for this has recently been obtained. While modulation of IL-2 bioavailability controls CD8+ effector differentiation under strongly immunogenic conditions it is not known whether this modulates CD8+ T cell responses under steady-state conditions. Here we assess this using a model in which dendritic cells (DC) are manipulated to present cognate antigen to CD8+ T cells either in the steady-state or when activated. Our observations show Treg exert a check on expansion and effector differentiation of CD8+ T cells, under strongly immunogenic conditions associated with TLR ligand activation of DC and this is mediated by limiting IL-2 availability. In contrast, when DC remained unactivated, depletion of Treg had little apparent effect on effector differentiation or IL-2 homeostasis. We conclude that while modulation of IL-2 homeostasis is an important mechanism by which Treg control CD8+ effector differentiation under immunogenic conditions, this mechanism plays little role in modulating CD8+ T-cell differentiation under non-immunogenic or tolerogenic conditions.

W3.07.01
The Ras/Erk/PI3K pathways during positive selection of primary B cells

***C. Babolin**, L. Sinik-Teodorovic, R. Torres, R. Pelanda;*
National Jewish Health and University of Colorado Denver, Denver, CO, United States.

Expression and signaling of the B cell antigen receptor (BCR) guide the differentiation and selection of immature B cells. The BCR is also able to signal in the absence of ligand binding, a response called "tonic". We have found that tonic BCR signaling in immature B cells propagates via Erk and PI3K through a pathway that can be activated by Ras. These pathways promote the differentiation of non-autoreactive immature B cells and their selection into the peripheral B cell pool. Here, we propose that alterations of the Ras/Erk/PI3K pathways can modify the selection of immature B cells and the composition of the peripheral B cell pool, potentially increasing the frequency of autoreactive B cells. We demonstrate that these pathways are less active in autoreactive cells than in non-autoreactive cells. Morevover, we show that activation of the tonic BCR signaling cascade within autoreactive immature B cells breaks central tolerance and leads to the differentiation into transitional B cells via the same Erk and PI3K pathways. Our findings support a model whereby arrest in differentiation and central B cell tolerance are caused by the absence of tonic BCR signaling rather than the presence of self-antigen-mediated signals.

W3.07.02
Characterization of Umbilical Cord Blood CD34+CD43+CD19+CD38lo/int Cells Suggests a Common Progenitor for Human B1 And B2 Cells

***T. D. Quach**[1], N. E. Holodick[1], R. Vuyyuru[2], T. Manser[2], T. L. Rothstein[1];*
[1]NSLIJ The Feinstein Medical Research Institute, Manhasset, NY, United States, [2]Kimmel Cancer Center, Thomas Jefferson University, Philadelphia, PA, United States.

Recently Vuyyuru et. al. reported that human Umbilical Cord Blood hematopoietic stem cells (UCBHSC) engrafted NSG (HIS) mice generate protection against Borrelia hermsii, which causes relapsing fever in infected humans, and is counteracted by murine B1b cells in WT mice. A substantial number of HIS B cells displayed the human B1-phenotype, CD19+CD27+CD43+CD70-. Importantly, we confirmed that only these B cells spontaneously secreted IgM antibody, a characteristic of B1 cell function. Together, we found that CD34+ UCBHSC can give rise to both B1 and B2 cells. To further identify human B1 potential progenitors, we characterized the phenotype of human CD34+ UCBHSC utilizing multi-color flow cytometry. Ex vivo analysis of CD34+ UCBHSC cells showed that 90% of CD34+CD38lo/int cells express CD43. As cells differentiated into B cell lineage, identified by the dual expression of CD19 and CD10, most early B cells lost CD43 while gaining higher CD38 and surface Ig expression. Interestingly, a small fraction of B lineage committed cells retained CD43 while gaining CD38 and surface Ig expression. To investigate the progenitor potential of CD34+CD38lo/int and CD34+CD38int/hi, we co-cultured sorted CD34+CD38lo/int and CD34+CD38int/hi cells with human primary stromal cells. We found that sorted CD34+CD38lo/int cells gave rise to both CD34+CD19+10+CD43+CD38hi and CD34+CD19+CD10+CD43-CD38hi cells, whereas sorted CD34+CD38hi cells generated mostly CD34+CD19+CD10+CD43-CD38hi B cells. Our findings suggested CD34+CD43+CD19+CD38lo/int as the common progenitors for both human B1 and B2 cells, and as these cells developed, B2 cells lost both CD34 and CD43 expression, whereas B1 cells only lost CD34 expression while sustaining CD43 expression.

W3.07.03
A human marginal zone B cell precursor

***M. Descatoire**[1,2], S. Weller[1], S. Irtan[3], J. C. Weill[1], C. A. Reynaud[1];*
[1]INSERM U783, paris, France, [2]Faculté Paris Descarte, Paris, France, [3]Hopital Necker-enfants malades, paris, France.

In mice, marginal zone B cells (MZB) represent a distinct B cell lineage which arises in the spleen where marginal zone precursor cells (MZP) differentiate under the control of the Notch2 pathway. In humans, the existence of such a lineage is still controversial. We propose here that in humans, blood IgM+IgD+CD27+ B cells represent circulating splenic MZB cells with a differentiation pathway that could be conserved at least in part between mice and humans. We identified in human spleen a putative MZP subset, characterized by its capacity to differentiate into MZB-like cells through Notch2 activation *in vitro*. This subset which is IgM^{high} IgD^{high} $CD27^{neg}$ $ABCB1^{pos}$ $CD24^{int}$ and $CD1c^{int}$, can be distinguished from naive cells by the presence of a glycosylated variant of the CD45RB molecule. It accounts on average for 5% of total splenic B cells in children and decreases throughout life. A transcriptomic analysis confirmed that MZP represent an intermediate differentiation stage between naive and MZB cells. A Notch induction signature predominated among genes discriminating MZP from naive B cells, a signature further developed among MZB cells. We next analyzed the blood of three patients with an inactivating mutation in one Notch2 allele (a subset of Allagille syndrome) and observed a specific decrease of IgM+IgD+CD27+ MZB cells whereas switched memory B cells were not impacted, similarly to the phenotype seen in Notch2-

haploinsufficient mice Altogether, our results suggest that the early development of human blood and splenic MZB cells, proceeds, as in the mouse, through a Notch2-dependent differentiation pathway..

The ELL-associated factor 2 negatively regulates germinal center B cell survival and humoral immune responses

Y. Li[1]*, Y. Takahashi*[2]*, S. Fujii*[3]*, J. Wang*[1]*;*
[1]*Laboratory for Immune Diversity, RIKEN Yokohama Institute, Yokohama, Japan,* [2]*National Institute of Infectious Diseases, Tokyo, Japan,* [3]*Research Unit for Cellular Immunotherapy, RIKEN Yokohama Institute, Yokohama, Japan.*

The germinal center (GC) B cells undergo Ig gene hypermutation and those with increased affinity for antigen are selected to survive and differentiate into plasma or memory cells whereas those with deleterious/nonsense mutations are eliminated by apoptosis. It is not well understood how GC B cell survival is regulated. We found that the ELL-associated factor 2 (EAF2) is selectively and highly expressed in GC B cells. Mice deficient in EAF2 contained a higher frequency of GC B cells than did WT mice after immunization with the T-dependent (TD) antigen NP-CGG (4-hydroxy-3-nitrophenyl-acetyl coupled to chicken gamma-globulin). Immunohistochemical staining of spleen sections revealed that EAF2-deficient mice had a 2-fold increase in the size of GC and decreased $TUNEL^+$ apoptotic cells compared with WT mice. In addition, GC B cells isolated from EAF2-deficient mice exhibited enhanced survival compared with WT GC B cells under *in vitro* culture conditions. These results collectively suggest that EAF2 promotes the apoptosis of GC B cells. Consistently, EAF2-deficient mice produced increased levels of NP-specific antibodies in response to NP-CGG than WT mice. Furthermore, the mutant mice also showed elevated antibody production against the T-independent (TI) antigen NP-Ficoll than did WT mice. These results demonstrate that EAF2 mediates apoptosis of GC B cells and negatively regulates humoral immune responses against both T-D and T-I antigens.

W3.07.05
Epstein-Barr virus-encoded Latent membrane protein 2A impairs B cell selection in germinal centers (GCs) but not GC formation

T. Minamitani*, S. Sakakibara, T. Yasui, H. Kikutani;*
Research Institute for Microbial Diseases, WPI Immunology Frontier Research Center, Osaka University, Suita, Japan.

Germinal center (GC) reaction is a critical process for generation of high-affinity B cells. It is known that Epstein-Barr virus (EBV) infect GC B cells and persist in memory B cells and is associated with lymphoid malignancies derived from GC B cell origin. EBV-infected GC B cells express EBV-encoded latent membrane protein 2A (LMP2A) that is known to mimic B-cell antigen receptor signals. To determine whether LMP2A affects GC reaction, we generated knock-in mice expressing LMP2A in GC B cells ($LMP2a^{GCB}$). Normal GC formation and increased numbers of $CD138^+$ plasma cells were observed in spleen of $LMP2a^{GCB}$ mice after immunization with NP-CGG. However, $LMP2a^{GCB}$ mice had markedly reduced number of NP-specific B cells and significantly lower serum levels of NP-specific IgG. Sequencing analysis of Ig heavy chain from NP-specific B cells revealed the significantly reduced frequency of $V_H186.2$ gene usage but not of somatic hypermutation in $LMP2a^{GCB}$ mice. *In vitro* Ig production assay demonstrated that LMP2A inhibited neither Ig production nor Ig class switching. In addition, elevated serum levels of autoantibodies were observed in $LMP2a^{GCB}$ mice. These results suggest that LMP2A-mediated signals perturb GC selection in which low affinity B cell clones such as autoreactive B cells would be generated. We discuss the molecular mechanism by which LMP2A contributes to latent infection of EBV in GC and memory B cells.

W3.07.06
IgE-expressing B cells are restrained by an intrinsic cell fate predisposition

Z. Yang*, C. D. C. Allen;*
University of California, San Francisco, San Francisco, CA, United States.

IgE antibodies are best known for their role in allergic disease. The pathological hypersensitivity reactions mediated by IgE, coupled with the extremely low abundance of IgE in serum, suggest that IgE+ B cell responses are normally tightly regulated. However, direct studies of IgE+ B cells have been hindered by substantial technical challenges in the detection of these rare cells. To overcome these limitations, we have generated IgE reporter mice, in which membrane IgE expression is translationally linked to the expression of the yellow fluorescent protein Venus. In these mice, IgE+ B cells can be readily detected by flow cytometry and microscopy. In addition, we have developed an improved flow cytometry procedure to detect IgE+ B cells in any strains of mice.
We have used these new tools to study the genesis and fate of IgE+ B cells during primary immune responses. Initially, IgE+ B cells differentiated into both plasma cells and germinal center B cells, similar to IgG1+ B cells generated in parallel. However, IgE+ B cells showed an atypical propensity to upregulate the transcription factor Blimp-1 and to undergo accelerated differentiation into short-lived plasma cells, which contributed to the loss of IgE+ B cells from the germinal center. As a result, the duration and affinity maturation of the IgE antibody response were limited. We also observed that the differentiation of activated B cells into plasma cells is affected both intrinsically by the isotype of the B cell receptor that is expressed and extrinsically by the concomitant activation signals.

Crucial role of IL-18R1 signaling in Th1 cell differentiation in mice infected with Trypanosoma cruzi

A. Oliveira[1]*, A. P. Granato*[1]*, J. F. Gomes-Neto*[1]*, C. H. D. Barbosa*[1]*, F. B. Canto*[1]*, R. Fucs*[2]*, A. Nobrega*[1]*,* ***M. Bellio***[1]*;*
[1]*Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil,* [2]*Universidade Federal Fluminense, Niteroi, Brazil.*

The myeloid differentiation protein 88 (MyD88) has been implicated in the polarization to Th1 response through the induction of IL-12 in dendritic cells (DC), following TLR activation. As expected, MyD88-deficient mice are highly susceptible to infection with different intracellular parasites, including the human parasite *Trypanosoma cruzi*, the etiologic agent of Chagas' disease. In fact, IFN-gamma production by $CD4^+$ T cells is severely affected in $MyD88^{-/-}$ mice infected with *T. cruzi.* However, we have shown that CD8 T cell-mediated responses are intact in MyD88-deficient mice, suggesting that DC function is not completely abolished in MyD88-deficient mice. As MyD88 is also an essential adaptor for signaling through IL-1R and IL-18R, we aimed to investigate the intrinsic role of MyD88 expression in CD4 and CD8 T cells during infection with this parasite. In order to answer these questions, we analyzed the production of IFN-gamma by spleen CD4+ and CD8+ T cells in mixed (WT + MyD88KO → WT) bone marrow chimeric mice infected with the Y strain, by intracellular staining and flow cytometry. We also analyzed mixed (WT + $IL\text{-}1R1^{-/-}$ → WT) and mixed (WT + $IL\text{-}18R1^{-/-}$ → WT) bone marrow chimeras and measured CD4+ T cell *in vivo* proliferation by BrDU incorporation. Our results show that MyD88 expression in CD4+ T cells, by signaling through IL-18R1, is necessary for the expansion of the Th1 subset induced during infection with *T. cruzi*.

Pro- and anti-inflammatory cytokine signals control the balance between Th1 and Tfh differentiation during the first few days of viral infection

H. D. Marshall[1], *I. A. Parish*[2], *M. Staron*[1], *B. J. Laidlaw*[1], *J. Ray*[1], *J. Craft*[1], *S. M. Kaech*[1];
[1]*Yale University, New Haven, CT, United States,* [2]*The John Curtin School of Medical Research, The Australian National University, Canberra, Australia.*

During viral infections, anti-viral CD4 T cells receive multiple sometimes opposing cytokine signals, but how these cells interpret and respond to all of these signals is not well understood. We have profiled the T_H1 and T_{FH} responses during acute viral infection from the earliest activation events through memory cell formation. During acute LCMV infection, $Ly6C^{lo}$ effector T_H1 cells gave rise to functional T_H1 memory cells and within the first 2 days of infection, and the earliest activated T cells had already bifurcated into $Ly6C^{hi}$, $CD25^{hi}$, $PSGL1^{hi}$, $T\text{-}bet^{hi}$, $BCL6^{lo}$ (T_H1 precursor) and $Ly6C^{lo}$, $CD25^{lo}$, $PSGL1^{lo}$, $T\text{-}bet^{lo}$, $Bcl6^{hi}$ (T_{FH} precursor) subsets. The T_H1 precursor population was also the greatest IL-2 producer at these very early time points, prior to elaboration of IFN-gamma. Furthermore, the first anti-viral CD4 T cells to exit the T zone into the inflammatory red pulp were T_H1 precursors. Direct IFN-I was not required for T_H1 precursor formation, but was sufficient to promote IL-2 responsiveness and was required for the migration of T_H1 precursor cells out of the white pulp. Gene expression profiling of T_H1 and T_{FH} effector cells revealed a profound TGF-beta signature in anti-viral $FoxP3^-$ T_{FH} cells and indeed, we found that direct TGF-beta signals promoted the differentiation of T_{FH} precursor cells. Together, these studies identify novel pro- and anti-inflammatory signals that control the balance between anti-viral T_H1 and T_{FH} differentiation during the first few days of infection and have a profound impact on the overall effector and memory cells generated.

W3.08.03

CD4+ T cells are both trigger and target of the glucocorticoid response that prevents lethal immunopathology in toxoplasma infection

D. G. Kugler[1], *P. R. Mittlesstadt*[2], *J. D. Ashwell*[2], *A. Sher*[1], ***D. Jankovic***[1];
[1]*LPD, NIAID, NIH, Bethesda, MD, United States,* [2]*LICB, NCI, NIH, Bethesda, MD, United States.*

While synthetic glucocorticoids (GC) are commonly used in the treatment of inflammatory diseases, the role of endogenous GC in the regulation of host-protective immune responses is poorly understood. Here we show that GC are induced during acute *Toxoplasma gondii* infection and directly control the T cell response to the parasite. When infected with toxoplasma, $GR^{lck\text{-}Cre}$ mice that selectively lack GC receptor expression in T cells undergo acute mortality despite displaying parasite burdens indistinguishable from control animals and unaltered levels of the innate cytokines IL-12 and IL-27. Mechanistically, the excessive immunopathology of infected $GR^{lck\text{-}Cre}$ animals was associated with hyperactive Th1 cell function *in vivo*, but not *in vitro*, as revealed by enhanced IFN-g and TNF production. Unexpectedly, these $CD4^+$ T lymphocytes also overexpressed IL-10. Importantly, $CD4^+$ T cell depletion in either wild-type or $GR^{lck\text{-}Cre}$ mice led to ablation of the GC response to infection. Moreover, in toxoplasma infected $RAG2^{-/-}$ animals, adoptive transfer of $CD4^+$ T cells was required for GC induction. These findings establish a novel IL-10-independent immunomodulatory circuit in which Th1 cells trigger a GC response that in turn dampens their own effector function. In the case of *T. gondii* infection, this self-regulatory pathway is critical for preventing collateral tissue damage.

W3.08.04

Blimp-1 triggers the formation of immunoregulatory IL-10 producing Th1 cells during chronic viral infection

I. A. Parish[1,2], *H. D. Marshall*[2], *P. A. Lang*[3,4,5], *A. Brüstle*[3], *J. H. Chen*[2], *W. Cui*[2], *P. S. Ohashi*[3,4,6], *C. T. Weaver*[7,8], *S. M. Kaech*[2,9];
[1]*John Curtin School of Medical Research, Australian National University, Canberra, Australia,* [2]*Yale University School of Medicine, New Haven, CT, United States,* [3]*Campbell Family Institute for Breast Cancer Research, Ontario Cancer Institute, University Health Network, Toronto, ON, Canada,* [4]*Department of Immunology, University of Toronto, Toronto, ON, Canada,* [5]*Department of Gastroenterology, Hepatology, and Infectious Diseases, University of Düsseldorf, Düsseldorf, Germany,* [6]*Department of Medical Biophysics, University of Toronto, Toronto, ON, Canada,* [7]*Department of Pathology, University of Alabama at Birmingham, Birmingham, AL, United States,* [8]*Department of Microbiology, University of Alabama at Birmingham, Birmingham, AL, United States,* [9]*Howard Hughes Medical Institute, New Haven, CT, United States.*

During many chronic viral infections, the anti-viral T cell response becomes attenuated in a process that is partly host regulated. While elevated expression of the immunosuppressive cytokine IL-10 is involved in this process, the relevant cellular sources of IL-10, as well as the pathways responsible for IL-10 induction, remain unclear. In this study, we trace IL-10 production over the course of chronic lymphocytic choriomeningitis virus (LCMV) infection using an IL-10 reporter mouse line. We demonstrate that “exhausted” virus-specific T cells, particularly virus-specific Th1 cells, display elevated IL-10 expression during chronic LCMV infection and that ablation of IL-10 from the T cell compartment can partially restore T cell function and reduce viral loads. We find that Blimp-1 is required for IL-10 expression by Th1 cells and implicate antigen as the likely Blimp-1/IL-10 induction signal. Thus, effector T cells self-limit their responsiveness during persistent viral infection via an IL-10-dependent negative feedback loop.

W3.08.05

RNA-binding protein HuR coordinately regulates GATA-3 and CD4+ Th2 cytokine gene expression in dose-dependent manner

U. Atasoy[1], *M. Gubin*[1], *R. Calaluce*[1], *J. Martindale*[2], *M. Gorospe*[3], *C. Stellato*[4], *V. Casolaro*[4];
[1]*University of Missouri-Columbia, Columbia, MO, United States,*

[3]*National Institute of Aging, NIH, Baltimore, MD, United States,*
[4]*Johns Hopkins University, Baltimore, MD, United States.*

Posttranscriptional control by RNA binding proteins (RBPs) and microRNAs of CD4+ T cells is poorly understood. Asthma is driven by GATA-3, IL-4 and IL-13. The RBP, HuR, posttranscriptionally regulates IL-4 and IL-13. GATA-3 3’ UTR contains AU-rich elements (ARE) which are binding sites for HuR. We identified GATA-3, IL-4 and IL-13 as HuR targets using RNA immunoprecipitation applied to microarrays. We hypothesized that HuR may be coordinately regulating Th2 differentiation. We used a HuR over-expression transgenic mouse, as well as a HuR conditional mouse ($HuR^{fl/fl}$) to ablate HuR in activated T cells, as well as siRNA and lentiviral shRNA to knock-down HuR. HuR over-expression stabilized GATA-3, IL-4 and IL-13 mRNAs, leading to increases in mRNA and protein. Conversely, HuR RNAi produced opposite results. These findings were confirmed in human lymphocytes. We verified GATA-3 is a HuR target by IP and biotin pull-downs and defined binding sites. Th2 polarized cells with reduced HuR levels (26%) from $HuR^{fl/+}$ mice, had significant decreases in IL-4, IL-13 and GATA-3 mRNA but not protein. Surprisingly, Th2 cells from $HuR^{fl/fl}$ mice with HuR knockdown (93%) showed significantly increased IL-4, IL-13 mRNA and protein levels but no changes in GATA-3 or IFNg. We measured mRNA transcription, stability and translation for cytokine mRNAs. IL-4 transcription was increased but not its stability. In contrast, IL-2 and IL-13 transcription were unchanged but their transcripts were stabilized. Polysomal gradient analysis revealed equal rates of translation. Further studies defining how RBPs regulate GATA-3 and Th2 cytokines in asthma will be critical.

W3.08.06
Modifications of the bone marrow microenvironment in the transition from monoclonal gammopathy of undetermined significance to multiple myeloma in Vk*MYC mice

A. Calcinotto[1], *E. Cattaneo*[1], *M. Grioni*[1], *S. Bertilaccio*[1], *M. Chesi*[2], *L. Bergsagel*[2], *G. Casorati*[1], *P. Dellabona*[1], *M. Bellone*[1];
[1]*Fondazione Centro San Raffaele, Milano, Italy,* [2]*Mayo Clinic, Scottsdale, AZ, United States.*

Multiple myeloma (MM) is a neoplastic plasma cell (PC) disorder of the oldest, and it is characterized by clonal proliferation of PC in the bone marrow (BM), monoclonal protein in biological fluids and organ dysfunction. While monoclonal gammopathy of undetermined significance (MGUS) often anticipates MM, the role of the cellular components of the BM microenvironment in the shift from MGUS to MM is unknown. To this aim, we have investigated disease development and progression in the Vk*MYC mouse model of spontaneous MM.
We have found that the BM of Vk*MYC mice is the primary organ of PC accumulation and based on the frequency of PC in the BM and M-spike quantification, we were able to distinguish between MGUS and MM in the Vk*MYC mice. The transition from MGUS to MM in these mice was characterized by increased vascularization of the BM. A comparison between age-matched Vk*MYC and WT mice affected by MGUS revealed precocious alteration of the CD4/CD8 T cell ratio, increased percentage of IL2 and IL4 producing CD4+ T cells, and CD8+ T cells more prone to produce IFNγ in the BM of the former.
In summary, our data suggest that early in disease development, yet unknown factors elicit an inflammatory reaction that significantly modifies the cellular composition of the BM and associates with neoangiogenesis and PC accumulation. Being the pathology in the Vk*MYC mouse similar to the human disease, our data might be relevant to understand the mechanisms of progression from MGUS to MM in humans.

W3.10 Th17 cells

IL3.10.01
Contribution of IL-17 to the chronicity of inflammatory diseases

P. Miossec*;*
University of Lyon, Lyon, France.

IL-17 was first identified as a T cell derived cytokine with effects on inflammation and neutrophil activation. Using the example of Rheumatoid arthritis (RA), it was next shown that its inhibition induced a significant reduction in the production of inflammatory mediators by explants of inflamed synovitis. This effect resulted from synergistic interactions between IL-17 and other proinflammatory cytokines such as TNF or IL-1. In addition to its effect on inflammation and related destruction, the role of IL-17 was shown in RA chronicity through an effect on reduced apoptosis of synoviocytes. Exposure of synoviocytes to IL-17 reduced NO-induced apoptosis. At the same time, enhanced expression of anti-apoptotic molecules such as synoviolin was observed in the blood of RA patients, specifically those not responding well to the TNF inhibitor infliximab. Extension to a mouse model indicated that mice lacking the IL-17R had reduced arthritis, reduced synovium infiltrate but increased local apoptosis. Increased local production of IL-17 may result from local cell-cell interactions. Indeed, interaction between activated T cells with various mesenchymal cells, either from bone marrow, synovium, or skin was found to favor the switch towards the Th17 pathway through a caspase-1 monocyte-driven mechanism. Taken together, these results support the early targeting of IL-17 in chronic inflammation associated with matrix destruction. Reduced effect of IL-17 inhibition can be expected when inflammation had a long term effect on mesenchymal cells. Recent clinical results are in line with these observations.

W3.10.01
Phosphorylation status determines the divergent roles of Smad2 and Smad3 as STAT3 cofactors in Th17 differentiation

J. Yoon[1,2], *K. Sudo*[1], *S. Park*[3], *M. Kuroda*[1], *S. Nakae*[4], *T. Yamashita*[5], *J. Ju*[6], *K. Matsuzaki*[7], *T. Sumida*[8], *M. Mamura*[1];
[1]*Tokyo Medical University, Tokyo, Japan,* [2]*CHA University, Seoul, Republic of Korea,* [3]*Sungkyunkwan University, Suwon, Republic of Korea,* [4]*The University of Tokyo, Tokyo, Japan,* [5]*Azabu University, Kanagawa, Japan,* [6]*Catholic University of Korea, Seoul, Republic of Korea,* [7]*Kansai Medical University, Osaka, Japan,* [8]*University of Tsukuba, Ibaraki, Japan.*

Transforming growth factor-β (TGF-β) and interleukin (IL)-6 are the pivotal cytokines to induce IL-17-producing $CD4^+$ T helper cells (T_H17), which play pathogenic roles in inflammatory diseases. Although crucial roles of IL-6 signaling through STAT3 in T_H17 differentiation have been well demonstrated, roles of TGF-β signaling through Smads are still controversial. Here we show that distinct phosphorylation status of the highly homologous TGF-β receptor-regulated Smads (R-Smads) divergently regulate STAT3-induced T_H17 differentiation. Smad2 deficiency ameliorated murine collagen-induced arthritis (CIA) with decreased T_H17 cells, whereas Smad3 haploinsufficiency exacerbated CIA with increased T_H17 cells. Smad2 and Smad3 exerted the opposite effects on STAT3-induced transcription of IL-17A and the retinoic acid receptor-related orphan nuclear receptor, RORγt (encoded by *Rorc*), an essential transcription factor for induction of IL-17. Smad2 phosphorylated at the linker region, serine 255 interacted with STAT3 to enhance transcription of RORγt and IL-17A. By contrast, Smad3 MH2 domain interacted with STAT3 to suppress STAT3-induced T_H17 differentiation by regulating different sets of genes through distinct C-terminal phosphorylation status: C-terminally unphosphorylated Smad3 recruited protein inhibitor of activated STAT3 (PIAS3) to repress STAT3-induced transcription of RORγt and IL-17A, while C-terminally phosphorylated Smad3 enhanced STAT3-induced transcription of the JAK/STAT inhibitors: SOCS3, SHP1/2. Thus, cite-specific phosphorylation status of R-Smads determines their divergent functions as transcription cofactors of STAT3 to regulate T_H17 differentiation.

W3.10.02
Transcriptional regulation of human Th17 cell differentiation

S. K. Tripathi[1], *Z. Chen*[1], *T. Äijö*[2], *A. Larjo*[3,2], *V. Salo*[1], *S. Tuomela*[1], *H. Lähdesmäki*[1,4], *R. Lahesmaa*[1];
[1]*Turku Centre for Biotechnology, Turku, Finland,* [2]*Department of Information and Computer Science, Aalto University School of Science, Espoo, Finland,* [3]*4Department of Signal Processing, Tampere University of Technology, Tampere, Finland, Tampere, Finland,* [4]*5Department of Information and Computer Science, Aalto University School of Science, Espoo, Finland.*

Dissecting the molecular mechanisms by which naïve CD4+ T cells differentiate to effector Th17 cells is important for understanding the pathogenesis of inflammatory and autoimmune diseases. Most of our current understanding on Th17 cell differentiation relies on studies done in mouse, whereas the molecular mechanisms controlling Th17 cell differentiation program in human are not well defined.
We aim at identifying gene regulatory networks and molecular machinery regulating early stages of human Th17 cell differentiation program through combined RNA interference, genome-wide experimental and computational approaches. As a first step, naïve CD4+ T cells isolated from umbilical cord blood were used to construct detailed kinetics of gene expression after initiation of Th17 differentiation (Tuomela et al. Blood 2012, 119:e151-60). Genome-wide expression analysis of the cells polarizing towards Th17 phenotype, demonstrated differential regulation of several novel and known genes associated with Th17 differentiation. The differential expression of selected candidate genes were further validated at protein level and analyzed for their specificity in initiation of Th17 as compared to initiation of other T helper subsets. Using this dataset as a starting point for constructing the gene regulatory network, we selected to study further the role of STAT3, a transcription factor influencing Th17 polarisation. We have combined RNAi and ChIP sequencing to identify direct and indirect STAT3 targets during Th17 cell differentiation. Further analysis is in progress. Finally, this integrated data set on STAT3-mediated transcriptional network will

provide a basis for modulating Th17 mediated pathogenic and autoimmune immune responses in human.

W3.10.03
Protein C receptor (PROCR) regulates pathogenic phenotype of Th17 cells

Y. Kishi[1], *C. Wang*[1], *C. Wu*[1], *N. Yosef*[1,2], *A. Regev*[2], *N. Joller*[1], *V. Kuchroo*[1];
[1]*Center for Neurologic Diseases, Brigham and Women's Hospital and Harvard Medical School, Boston, MA, United States,* [2]*Broad Institute of MIT and Harvard, Cambridge, MA, United States.*

We performed a temporal microarray analysis of developing Th17 cells to identify cell surface molecules, which are differentially expressed in Th17 cells and regulate the development of Th17 cells. We found protein C receptor (PROCR) to be specifically expressed in Th17 cells. Focusing on the regulation of PROCR expression, we demonstrated that the Th17-specific transcription factors Rorγt, IRF4, and STAT3 bound to the promoter of *PROCR* by chromatin immunoprecipitation (ChIP)-PCR. Furthermore, we found PROCR expression was dramatically reduced in Th17 cells from Rorγt KO, IRF4 KO, or STAT3 KO mice, indicating these Th17-specific transcription factors induce PROCR expression. To elucidate the biological function of PROCR in Th17 cells, we overexpressed PROCR in T cells and observed that PROCR decreased the expression of genes identified as part of the pathogenic signature of Th17 cells, including CXCL3, IL-3, and CCL4. To specifically address the role of PROCR in Th17 cells *in vivo*, we overexpressed PROCR in myelin oligodendrocyte glycoprotein-specific Th17 cells *in vitro* and adoptively transferred these cells to induce experimental autoimmune encephalomyelitis (EAE), a model for multiple sclerosis. In line with our *in vitro* data, PROCR reduced the pathogenicity of Th17 cells as recipients of PROCR expressing Th17 cells displayed ameliorated disease. In conclusion, we identified PROCR as a receptor that is specifically expressed in Th17 cells and regulates the pathogenic phenotype in Th17 cells. Furthermore, we found Rorγt, IRF4, and STAT3 regulated PROCR expression in Th17 cells. Finally, we demonstrated PROCR could reduce Th17 pathogenicity *in vitro* and *in vivo*.

W3.10.04
IL-17A secretion by CD8+ T cells supports Th17-mediated autoimmune encephalomyelitis

M. Huber[1], *S. Heink*[2], *A. Pagenstecher*[3], *K. Reinhard*[1], *J. Ritter*[1], *A. Visekruna*[1], *A. Guralnik*[1], *T. Kamradt*[2], *M. Lohoff*[1];
[1]*Institute for Medical Microbiology, University of Marburg, Marburg, Germany,* [2]*Institute for Immunology, Jena University Hospital, Jena, Germany,* [3]*Dept. Neuropathology, University of Marburg, Marburg, Germany.*

IL-17-producing $CD8^+$ T (Tc17) cells are detectible in multiple sclerosis (MS) lesions; however their contribution to the disease is unknown. To identify functions of Tc17 cells, we induced experimental autoimmune encephalitis (EAE), a murine model of MS, in mice lacking interferon regulatory factor 4 (IRF4). IRF4-deficient mice failed to generate Tc17 and Th17 cells and were resistant to EAE. After adoptive transfer of wild-type $CD8^+$ T cells and subsequent immunization for EAE induction in these mice, the $CD8^+$ T cells developed a Tc17 phenotype in the periphery but could not infiltrate the CNS. Similarly, transfer of small numbers of wild-type $CD4^+$ T cells alone did not evoke EAE, but when transferred together with $CD8^+$ T cells, IL-17-producing $CD4^+$ (Th17) T cells accumulated in the CNS and mice developed severe disease. Th17 accumulation and development of EAE required IL-17A production by $CD8^+$ T cells, suggesting that Tc17 cells are required to promote $CD4^+$ T cell-mediated induction of EAE. Accordingly, patients with early-stage MS harbored a greater number of Tc17 cells in the cerebrospinal fluid than in peripheral blood. Our results reveal that Tc17 cells contribute to the initiation of CNS autoimmunity in mice and humans by supporting Th17-cell pathogenicity.

W3.10.05
Development and stability of human Th17 cells require endogenous NOS2 and cGMPc/GK-dependent NO signaling

N. Obermajer[1], *J. Wong*[1], *K. Chen*[1], *M. Scott*[1], *S. Khader*[1], *J. Kolls*[1], *K. Odunsi*[2], *R. Edwards*[1,3], *T. Billiar*[1], ***P. Kalinski***[1,3];
[1]*University of Pittsburgh, Pittsburgh, PA, United States,* [2]*Roswell Park Cancer Institute, Buffalo, NY, United States,* [3]*University of Pittsburgh Cancer Institute, Pittsburgh, PA, United States.*

Nitric oxide (NO), a mediator of inflammation and immunity, is involved in the pathogenesis of and resistance to cancer, autoimmunity and infectious diseases. We observed that the local markers of Th17 responses in ovarian patients cancer positively correlated with the intarumoral expression of nitric oxide synthase-2 (NOS2/iNOS). While high concentrations of exogenous NO indiscriminately suppressed Th1, Th2, and Th17 responses, the physiologic NO concentrations produced by patients' myeloid-derived suppressor cells (MDSCs) promoted the development of $ROR\gamma t(Rorc)^+IL\text{-}23R^+IL\text{-}17^+$ Th17 cells.
In addition to the positive impact of the exogenous (MDSC-produced) NO, we observed that the development of Th17 cells from naive-, memory-, or tumor-infiltrating $CD4^+$ T cells, driven by IL-1β/IL-6/IL-23/NO-producing MDSCs or by recombinant cytokines (IL-1β/IL-6/IL-23), is associated with the induction of endogenous NOS2 and NO production, and critically depends on NOS2 activity within $CD4^+$ T cells.
Inhibition of NOS2 activity or the canonical cGMP/cGK pathway of NO signaling abolishes the *de novo* induction of Th17 cells and selectively suppresses IL-17 production by established Th17 cells isolated from ovarian cancer patients. Our data indicate that, apart from its previously recognized role as an effector mediator of Th17-associated inflammation, NO is also critically required for the induction and stability of human Th17 responses. The current results provide rationale for targeting NO, NOS2, cGMP, and cGK as new targets to manipulate Th17 responses in cancer, autoimmunity and inflammatory diseases.

W3.10.06
Evidence of a transient nature of the Th17 phenotype of CD4+CD161+ T cells in the synovial fluid of juvenile idiopathic arthritis patients

L. Maggi, *L. Cosmi, V. Santarlasci, M. Capone, V. Querci, M. Rossi, F. Liotta, E. Maggi, F. Annunziato, S. Romagnani;*
University of Florence, Florence, Italy.

Objective: To investigate the phenotype and function of CD4+ T cells in synovial fluid (SF) from the affected joints ofchildren with oligoarticular-onset juvenile idiopathic arthritis (JIA) and to establish a possible link with disease activity. Methods: CD4+ T cells were obtained from the peripheral blood (PB) and SF of 23 children with oligoarticular-onset JIA, as well as from the PB of 15 healthy children and were analyzed for CXCR3, CCR6, CD161 expression and for IFN(interferon)-γ and interleukin-17A (IL-17A) production. Results: The numbers of CD4+CD161+ cells, showing either the type 1 T helper (Th1) or Th17/Th1 phenotype, were higher in SF than in PB of children with JIA. The few Th17 cells from SF of JIA underwent a spontaneous shift to the Th1 phenotype in vitro, whereas Th17 cells from PB of healthy children shifted only in presence of JIA SF; this effect was neutralized by antibody blocked of IL-12 activity. The frequencies of CD4+CD161+ cells, particularly the Th17/Th1 cells, in the JIA SF positively correlated with levels of erythrocyte sedimentation rate and C-reactive protein. Conclusion: These findings suggest that a shifting of CD4+CD161+ T cells from Th17 to the Th17/Th1 or Th1 phenotype can occur in the SF of oligoarticular-onset JIA, and indicate that the accumulation of these cells is correlated with parameters of inflammation. Thus, the results support the hypothesis that these cells may play a role in JIA disease activity.

W3.11 Gamma-delta T cells

IL3.11.01
Regulatory interactions between granulocytes and gamma/delta T cells in response to aminobisphosphonates

D. Kabelitz[1], *V. Chandrasekaran*[2], *T. K. Lindhorst*[2], *S. Kalyan*[1];
[1]*Institute of Immunology, Kiel, Germany,* [2]*Otto-Diehl Institute of Organic Chemistry, Kiel, Germany.*

When Ficoll-Hypaque-separated human peripheral blood mononuclear cells (PBMC) are activated by aminobisphosphonates (n-BP) in the presence of exogenous IL-2, a strong and selective proliferation of Vgamma9/Vdelta2 T-cells ensues. This is commonly attributed to the uptake of n-BP by monocytes and subsequent endogenous production of pyrophosphates due to the inhibitory effect of n-BP on farnesylpyrophosphate synthase. To study the uptake of n-BP in various cell populations, we chemically coupled the n-BP zoledronic acid to CFSE ("FluorZOL"), and analyzed cellular ingestion of FluorZOL by flow cytometry. When using RBC-lysed whole blood (containing all leukocytes) we observed strong uptake of FluoZOL not only in monocytes but also in granulocytes and very little, if any, in lymphocytes. gamma/delta T-cell proliferation was drastically inhibited when total leukocytes rather than PBMC were stimulated with n-BP or FluorZOL, despite highly efficient uptake. The inhibitory effect of granulocytes on gamma/delta T-cell proliferation in response to n-BP could be fully prevented by neutralizing three inhibitory factors of granulocytes. These observations could explain the observed disappearance of gamma/delta T-cells from blood upon prolonged treatment with n-BP (Kalyan et al, J Bone Miner Res 28:728,2013); and, furthermore, these findings may be relevant for the future exploitation of gamma/delta T-cells for immunotherapeutic application.

W3.11.01
Heterogeneity and prognostic influence of tumor- infiltrating γδ T lymphocytes in colon cancer patients

E. Lo Presti[1], *S. Meraviglia*[1], *G. Cicero*[2], *V. Orlando*[1], *S. Buccheri*[1], *M. P. La Manna*[1], *D. Di Liberto*[1], *S. Cutrera*[1], *N. Caccamo*[1], *F. Dieli*[1];
[1]*Dipartimento di Biopatologia e Biotecnologie Mediche e Forensi-Università di Palermo, Palermo, Italy,* [2]*Dipartimento di Discipline Chirurgiche ed Oncologiche-Università di Palermo, Palermo, Italy.*

Tumors grow in a complex and intricated network of epithelial and mesenchymal cells, inflammatory and immune cells and the characterization of the immune contexture is a major prognostic factor for patients survival and represent a target for innovative cancer therapies.
We characterized colon cancer-infiltrating γδ T cells in a cohort of 70 patients in terms of phenotype and effector functions and correlated the immunological analysis with clinicopathological features of colon cancer. Results show that Vδ1 T cells were the predominant population in the vast majority of specimens and upon short term mitogen *in vitro* stimulation produced IL-10, while Vγ9Vδ2 T cells were found uniformly at lower proportion in most of the patients, had a predominant terminally-differentiated effector memory (TEMRA) $CD45RA^{+}CD27^{-}$ phenotype, expressed cytotoxic molecules as perforin and granzyme B and upon short term *in vitro* stimulation with phosphoantigen produced pro-inflammatory cytokines as IL-17 and IFNγ in different combinations.
Correlation with different clinicopathologic features demonstrates that higher percentage of tumor-infiltrating Vγ9Vδ2 T cells are found in well differentiated tumors and in patients with early-stage disease and absence of metastasis; moreover, intratumoral γδ T cell numbers are positively correlated with overall survival of colon cancer patients.
In conclusion, our results highlight the role of γδ T cells against colorectal cancer cells and suggest that immune response mediated by γδ T lymphocytes may contribute to the immunosurveillance of colon cancer. These findings may foster the development of novel alternative or adjuvant therapies targeting γδ T cells for the treatment of colon cancer patients.

W3.11.02
Key role of Free Heavy Chain of HLA class I molecules in HCMV and tumor stress sensing by gamma-delta TCR

R. Marlin[1,2], *S. Netzer*[1,2], *V. Pitard*[1,2], *S. Daburon*[1,2], *C. Harly*[1,2], *T. Bachelet*[1,2], *J. Moreau*[1,2,3], *J. Taupin*[1,2,3], *J. Déchanet-Merville*[1,2];
[1]*CNRS UMR 5164, Bordeaux, France,* [2]*Univ. Bordeaux Segalen, Bordeaux, France,* [3]*Immunology and Immunogenetic laboratory, Bordeaux, France.*

Non-Vδ2 γδ T cell clones isolated from Cytomegalovirus (HCMV)-infected individuals show dual TCR dependent reactivity against tumor cell lines and HCMV-infected cells suggesting recognition of stress-associated self antigens by non-Vδ2 TCRs. In order to identify these uncharacterized ligands, we immunize mice with tumor cells targeted by HCMV-reactive non-Vδ2 TCRs and select mAbs able to specifically abrogate the reactivity of γδ TCR transductants against these targets.
In this study, we focused on a Vγ9Vδ3 TCR, which confers to transductants a restricted reactivity against three tumor B cell lines only. By contrast, several blocking mAbs (LSM) selected to recognize Vγ9Vδ3 antigen, ubiquitously targeted HLA class I (HLA-I) molecules expressed by a wide panel of cells. These results suggested the Vγ9Vδ3 TCR recognition of HLA-I molecules expressed in a particular shape or environment in the three B cell targets. Interestingly, B cell targets and HCMV-infected cells expressed β-2-microglobulin-free HLA-I heavy chains (FHC). Silencing β-2-microglobulin in B cell targets abrogated both HLA-I FHC cell surface expression and Vγ9Vδ3 TCR reactivity, suggesting the recognition of HLA-I FHC by the Vγ9Vδ3 TCR. Moreover, the original Vγ9Vδ3 T clone expressed CD85j and CD158b inhibitory receptors specific for HLA-I, that do not bind FHC, suggesting a regulation of TCR-mediated HLA-I recognition in physiological context. Blocking these receptors markedly increased the Vγ9Vδ3 T clone reactivity against B cell targets and HCMV-infected cells.
Altogether, our results identify HLA-I FHC as a potential stress-associated antigen common to HCMV-infection or cellular transformation that mediate stress surveillance by γδ T cells.

W3.11.03
Implication of gamma delta T cells in the immune response against murine CMV

C. Khairallah, *S. Netzer, M. Juzan, A. Villacreces, V. Praloran, J. Moreau, J. Dechanet-Merville, M. Capone;*
CIRID UMR-CNRS 5164, Bâtiment 1B, Université Bordeaux Segalen, Bordeaux, France.

We previously showed that gamma delta T cells are key contributors to the immune response against CMV in humans, and participate to CMV riddance partially through interferon gamma (IFNgamma) release. The aim of the present study was to use the mouse model of CMV infection in order to dissect in vivo the implication of murine γδ T cells in the control of mouse CMV (MCMV). Using C57BL/6 mice deficient for alpha beta and/or gamma delta T cells, we showed that whichever subpopulation is sufficient to confer protection against MCMV. Viral loads increased with time in all organs tested from CD3epsilon-/- (alpha beta- gamma delta-) infected mice, and the presence of high levels of transaminases in blood was suggestive of liver damage. CD3epsilon-/- ultimately died unlike TCRalpha-/- (alpha beta- gamma delta+) mice that survived with much lower viral loads. In TCRalpha-/- mice, CD27+ gamma delta T cells were increased in the liver 7 days post MCMV-infection suggesting an implication of IFNgamma-secreting gamma delta T cells in the clearance of MCMV in this organ. Finally, bone marrow transfer experiments using TCRalpha-/- donors rendered CD3epsilon-/- mice resistant to MCMV in accordance with a protective anti-viral role for gamma delta T cells. These results which suggest that gamma delta T cells could compensate for the absence of alpha beta T cells during MCMV infection could be of particular relevance in immune-suppressive contexts where alpha beta T cells are more specifically compromised.

W3.11.04
HDAC7 plays a significant role in γδ T-cell development and function

***M. G. MacKenzie**, C. Gawden-Bone, S. Matthews;*
University of Dundee, Dundee, United Kingdom.

In many cellular systems Histone Deacetylases (HDACs) play important roles in the regulation of cell differentiation, proliferation and survival. HDACs regulate chromatin structure and thus gene transcription by reversing histone lysine acetylation. As such they been identified as key players in the development of the immune system with evidence suggesting HDAC7 acts as a gene expression switch regulating T-cell development and function. A small subset of T-cells express TCR chains encoded by the gamma and delta gene loci. A role for HDAC7 in these γδT cell's development and function is yet to be identified. We have bred an HDAC7 floxed/floxed mouse with a vav-cre transgenic mouse in order to delete HDAC7 from all haematopoietic cells. γδ T-cell number in the Thymus of these mice is normal however we have identified a 10-fold increase in γδ T-cell number in the peripheral tissues (spleen and lymph nodes) compared to wild type. Splenocytes from these mice stimulated in-vitro with CD3 and cultured in the presence of IL2 for 6 days preferentially proliferate γδ T-cells to a higher degree than αβ T-cells. Interestingly these activated HDAC7 KO γδ T-cells are functionally competent for producing IFNγ, but not IL-17. Preliminary data also suggests an impairment of γδ T-cells ability to home to epithelial compartments as shown by a 50% reduction of γδ T-cells in the ear epithelia. We propose HDAC7 plays a significant role in the proliferation of γδ T-cells and their ability to produce IL-17 with a further role in γδ T-cell homing.

W3.11.05
A network of High Mobility Group box transcription factors programs innate IL-17 production

***N. Malhotra**[1], K. Narayan[1], O. Cho[1], K. Sylvia[1], H. Melichar[1], M. Rashighi[1], V. Lefebvre[2], J. E. Harris[1], L. J. Berg[1], J. Kang[1];*
[1]UMass Medical School, Worcester, MA, United States, [2]Cleveland Clinic Lerner Research Institute, Cleveland, OH, United States.

All lymphocytes, whether innate or adaptive, can be segregated into effector subsets, based on distinct gene regulatory networks. Innate or innate-like lymphocytes become effectors in their tissue of origin such as thymus (γδ T and iNKT cells) and gut (Lymphoid Tissue inducer-like, LTi, cells) while adaptive lymphocytes acquire specialized functions upon pathogen encounters. Unique gene regulatory networks responsible for the generation of innate lymphocytes were unknown. γδ T cells are the major source of IL-17 and IL-22 (Tγδ17) at the early phases of immune response and are also responsible for inflammatory disorders in the skin. We demonstrate that a transcription factor (TF) network consisting of a quartet of High Mobility Group box TFs, SOX4, SOX13, TCF1 and LEF1, programs the intrathymic differentiation of Tγδ17 cells. While SOX4 and SOX13 positively regulate the two requisite Tγδ17 cell-specific genes, *Rorc* and *Blk*, TCF1 and LEF1 interact with SOX proteins and promote alternate effector subset differentiation. Furthermore, we show that T cell lineage specification factor TCF1 is indispensable for the generation of IL-22 producing gut NKp46$^+$ innate lymphoid cells and restrains cytokine production by LTi-like effectors. These results predict that a shared gene network architecture programs all innate sources of IL-17 and IL-22, independent of anatomical origins and antigen receptor expression.

W3.11.06
Major contribution of gamma delta T cells to IL-17A production and ovarian cancer growth in vivo

***M. Rei**[1,2], T. Lança[1], R. Thompson[3], F. Balkwill[3], H. Kulbe[3], B. Silva-Santos[1], D. Pennington[3];*
[1]Instituto Medicina Molecular, Lisbon, Portugal, [2]Graduate Program in Areas of Basic and Applied Biology, Porto, Portugal, [3]Barts and The London School of Medicine and Dentistry, London, United Kingdom.

A significant body of evidence implicates γδ T cells in tumour immunosurveillance. The anti-tumour function of γδ cells stems from their potent cytotoxicity and their capacity to produce high levels of IFN-γ. However, γδ cells were also recently implicated in promoting tumour growth, possibly as a result of their ability to secrete IL-17A. Considering the ultimate goal of manipulating γδ cells for cancer treatment, we aim to further dissect the pro-tumour mechanisms of γδ cells. We use a transplantable ID8 ovarian cancer cell line, that grows slower upon IL-17A neutralization. Our data show that γδ cells infiltrate ID8 tumour foci and are a major source of IL-17A in the tumour microenvironment. Furthermore, γδ cell-deficient mice (TCRδ-/-) show reduced ID8 tumour burden, which strongly suggests that the pro-tumour role of IL-17A is mediated by γδ cells. A significant fraction of γδ cells is proliferating in situ and accounts for a 2.3-fold increase in γδ cell numbers in the peritoneal cavity, 6 weeks after ID8 cell injection. The majority of these γδ cells display a Vγ1- Vγ4- phenotype, indicating they belong to the Vγ6+ subset which is naturally enriched in the peritoneal cavity. Interestingly, both IFN-γ+ and IL-17A+ γδ cells accumulate in the tumour microenvironment, potentially suggesting a dominance of the pro-tumour effects of IL-17A over the anti-tumour functions of IFN-γ. We are currently generating TCRδ-/- IL-17A-/- mice to further assess the contribution of γδ cells to the IL-17A-mediated tumour growth in this ovarian cancer model.

W3.12 Follicular helper T cells

IL3.12.01
Interleukin-21 directs T follicular helper cell differentiation

*A. Vogelzang, H. McGuire, S. Liu, **C. King**;*
The Garvan Institute of Medical Research, Darlinghurst, NSW 2010, Australia.

T helper cell derived cytokines such as interleukin (IL)-21 play an important role in the generation of antibody forming cells during the germinal center reaction following T dependent immunization. However, several recent studies have questioned whether IL-21 has a CD4$^+$ T cell intrinsic role. Using a variety of approaches including MHC II tetramer-based detection of endogenous antigen specific Tfh cells, we provide evidence that IL-21 acts on antigen specific CD4$^+$ T helper cells to support their survival and differentiation. IL-21 receptor deficient (*Il21r-/-*) "Tfh-like" cells exhibited phenotypic similarities with Tfh cells, but had abnormally high expression of programmed cell death protein 1 (PD-1), selectively differentiated into FoxP3+ regulatory Tfh cells and were functionally deficient as B cell helpers. The propensity for *Il21r-/-* T cells to differentiate into T regulatory cells may reflect the altered balance between responsiveness to IL-2 and IL-21 (Stat5/Stat3) and reinforces the important role for IL-21 in Tfh cell differentiation.

W3.12.01
Functional overlap of ROQUIN-1 and ROQUIN-2 in the repression of mRNAs controlling Tfh cell accumulation and systemic inflammation

*A. Pratama, R. R. Ramiscal, D. G. Silva, S. Das, **V. Athanasopoulos**, X. Hu, J. J. Hogan, C. Goodnow, M. Cook, C. G. Vinuesa;*
John Curtin School of Medical Research, Canberra, Australia.

Accumulation of Tfh cells and excessive production of pro-inflammatory cytokines by myeloid cells lead to autoantibody-driven diseases. ROQUIN-1 (Rc3h1) has been previously shown to repress ICOS and IFNγ and prevent Tfh cell accumulation. Unlike Rc3h1san mice that carry a single mutation in the RNA binding ROQ domain of ROQUIN-1, mice lacking the protein within T cells paradoxically do not display increased T follicular helper (Tfh) cells. We analyzed mice with mutations that eliminate the RING domain from ROQUIN-1 (Rc3h1RING) or its paralog, ROQUIN-2 (Rc3h2). We find that the RING deletion impairs Icos mRNA regulation by ROQUIN-1, but not as dramatically as the ROQ mutation. We propose that in RING-deficient ROQUIN-1 mice, ROQUIN-2 can compensate and largely repress ICOS expression and Tfh cells accumulation. These paralogs, whose common ancestral gene preceded adaptive immunity, also target TNF in non-lymphoid cells. We found that mice carrying the combined mutations Rc3h1san and Rc3h1RING show early lethality, have heightened sensitivity to endotoxic shock and

increased susceptibilty to TNF-dependent autoantibody-induced arthritis. Thus the ROQUIN family emerges as a post-transcriptional brake for both the adaptive and innate immune systems to curtail antibody responses and inflammation.

W3.12.02
Identification of human Tfh-specific miRNAs and investigation of their role in Tfh differentiation and function

***A. Ripamonti**, E. Provasi, G. Rossetti, S. Curti, V. Ranzani, V. Parente, F. Facciotti, M. Moro, S. Abrignani, M. Pagani;*
INGM, Milan, Italy.

Follicular helper T cells (Tfh) are a separate CD4+ T helper subset specialized in provision of help to B cells. They develop independently from other T cell subsets and are critical for humoral immunity, including the generation of long-lived and high affinity plasma cells and memory B cells. Alteration of Tfh-specific genes leads to defects in germinal centers (GCs) formation, with consequent autoimmune or immunodeficiency disorders. The molecular mechanisms underlying Tfh cells differentiation are poorly understood. MicroRNAs (miRNAs) are highly conserved non-coding single-stranded small RNA molecules that control gene expression post-transcriptionally by binding the 3'untranslated region of target mRNA. To investigate the role of miRNAs in Tfh cells biology we performed RT-qPCR and deep sequencing analysis on Tfh and Naive CD4+ T cells sorted from human adenoids. We identified Tfh-specific miRNAs and in vitro validated their predicted targets. We found that Tfh-specific miRNAs regulate transcripts specifically expressed in Tfh cell subset and known to be essential for their function. We are performing gain or loss of function experiments using lentiviral vectors aimed at modulating miRNA expression in human Tfh cells. Through these experiments we will assess how these Tfh specific-miRNAs influence the ability of Tfh cells to help B cells, and elucidate their role in Tfh biology.

W3.12.03
Follicular regulatory T cells migrate to germinal centers via NFAT2-mediated signaling

*M. Vaeth[1], G. Mueller[2], D. Stauss[2], L. Dietz[1], S. Klein-Hessling[1], E. Serfling[1], M. Lipp[2], I. Berberich[3], **F. Berberich-Siebelt**[1];*
[1]Institute of Pathology at the University of Wuerzburg, Wuerzburg, Germany, [2]Max-Delbruck-Center for Molecular Medicine (MDC), Berlin, Germany, [3]Institute of Virology and Immunobiology at the University of Wuerzburg, Wuerzburg, Germany.

Maturation of high affinity B lymphocytes is precisely controlled during the germinal center reaction. This is dependent on $CD4^+CXCR5^+$ follicular helper T cells (T_{FH}) and inhibited by $CD4^+CXCR5^+Foxp3^+$ follicular regulatory T cells (T_{FR}). Since NFAT2 was found to be highly expressed and activated in follicular T cells we addressed its function herein. Unexpectedly, ablation of NFAT2 in T cells caused an augmented GC reaction upon immunization. Consistently, however, T_{FR} cells were clearly reduced in the follicular T cell population due to impaired homing to B cell follicles. This was T_{FR}-intrinsic. The overall frequency of nTreg cells remained unaltered in mice lacking NFAT2 or even NFAT1 plus NFAT2. Furthermore, the suppressive function of both nTreg and iTreg cells was independent on robust NFAT levels, as absence of one or two NFAT members did not alter suppressor activity *in vitro* or during colitis and transplantation *in vivo*. However, the physiological relevance of NFAT2 for humoral (auto-) immunity was corroborated by exacerbated lupus-like disease in the presence of NFAT2-deficient T_{FR}.
This study was funded by the German Research Foundation DFG: SPP1365 (M.V. + F.B.-S.), TRR52/A3 (F.B.-S.), B8 (M.L. & G.M.), and C5 (E.S.), and CRU216 (I.B.) as well as from the Federal Ministry for Education and Research: IZKF in Würzburg, Germany (L.D. + F.B.-S.).

W3.12.04
The inhibitory receptor PD-1 regulates IgA selection and bacterial composition in the gut

***S. Kawamoto**[1], T. H. Tran[1], M. Maruya[1], K. Suzuki[1,2], Y. Doi[1], Y. Tsutsui[1], L. M. Kato[1], S. Fagarasan[1];*
[1]RCAI, RIKEN, Yokohama, Japan, [2]Kyoto University, Kyoto, Japan.

Immunoglobulin A (IgA) is essential to maintain the symbiotic balance between gut bacterial communities and the host immune system. Intestinal IgA production occurs via both T helper cell-dependent and independent pathways. The diversification of IgA repertoire by somatic hypermutation takes place mostly in specialized microenvironments called germinal centers (GCs), in which B cell interaction with T follicular helper (T_{FH}) cells induces the expression of activation-induced cytidine deaminase (AID). T_{FH} cells express high amounts of the inhibitory co-receptor programmed cell death-1 (PD-1), a key receptor for shutting down the ineffective immune responses and maintaining the tolerance. We found that PD-1 regulates the gut microbiota through the appropriate selection of IgA plasma cell repertoires. PD-1-deficiency generates an excess number of T_{FH} cells with pro-inflammatory phenotypes, which affect the selection of IgA precursor cells in GCs of Peyer's patches. Consequently, the IgAs produced in PD-1-deficient mice have reduced bacteria-binding capacity causing alterations of microbial communities in the gut. Interestingly, the altered bacterial composition in PD-1-deficient mice induces systemic activation and induction of GCs where poly- /auto-reactive antibodies could be generated. Thus, we revealed that PD-1 plays a critical role in regulation of antibody diversification required for the homeostasis and prevention of autoimmune diseases.

W3.12.05
Regulation of T Helper Cell-Dependent Antibody Response in Lymphopenic Hosts

***S. Preite**[1], D. Baumjohann[1,2], F. Ronchi[1,3], F. Sallusto[1], A. Lanzavecchia[1,4];*
[1]Institute for Research in Biomedicine, Bellinzona, Switzerland, [2]University of California San Francisco, San Francisco, CA, United States, [3]University of Bern, Bern, Switzerland, [4]Institute of Microbiology, ETH, Zürich, Switzerland.

Cognate interactions between T helper cells and B cells are required for the production of high-affinity antibodies and for the generation of memory B cells and long-lived plasma cells. To gain insight into the nature of signals regulating these different aspects of B cell responses, we set up an experimental system in which CD3e-deficient mice - which lack T cells but have normal B cell development - are reconstituted with small number of TCR-transgenic T cells. We found that adoptively transferred OVA-specific CD4+ T cells induced effective primary antibody responses following immunization with OVA and adjuvant; however, serum antibody levels were not sustained. Further analysis revealed that upon immunization, T cells proliferated extensively and preferentially developed into T follicular helper (Tfh). Although initiation of germinal center (GC) reaction and differentiation of B cells into antibody-secreting short-lived plasma blasts were normal, Tfh cells became dysfunctional and failed to provide help to OVA-specific B cells during late GC events, resulting in impaired affinity-maturation and lack of long lived plasma cells. Instead, hypergammaglobulinemia, hyper-IgE, and production of autoantibodies were observed in the recipients. These data provide a link between overstimulation of Tfh cells and the development of dysregulated humoral immune responses and may have implications for treatment of patients with congenital defects in lymphocyte homeostasis or suffering from diseases involving lymphopenia, such as HIV infection or certain tumors.

W3.12.06
Fate decision of germinal centre B cells is based on asymmetric division

M. Meyer-Hermann[1], *Y. Zhang*[2], *G. D. Victora*[3], *K. Toellner*[2];
[1]*Helmholtz Centre for Infection Research, Braunschweig, Germany,* [2]*University of Birmingham, Birmingham, United Kingdom,* [3]*Whitehead Institute for Biomedical Research, Cambridge, MA, United States.*

Evolution of germinal centre (GC) B cells involves somatic hypermutation and selection. Multi-photon imaging of GC B cells has revealed the migration path of B cells in the GC environment and allowed localisation of critical selection steps. These data are analysed in silico in the framework of a theory of GC B cell selection, divsion, and exit. The analysis unravels so far unappreciated implications of the multi-photon data sets for B cell differentation to plasma cells: B cells, after having received selection signals from T follicular helper cells, always return to the GC dark zone. Thus, the pathway of recylcing, which was not even proven until 3 years ago, turns out to be the exclusive fate of positively selected B cells. In the dark zone, B cells divide and distribute the previously collected antigen asymmetrically onto their daughters. After two divisions one of the four B cells still carries the antigen, enters final differentiation into a plasma cell and leaves the GC in direction of the adjacent T zone. The evidence for this new GC theory, called GC LEDA model, is presented and the implications for the success of the GC reaction is illustrated: Compared to a classical recycling model, the number of plasma cells derived from the GC is ten-fold and affinity maturation is achieved one day earlier. This is of major relevance in time critical immune responses.

W3.13 Regulatory T cells: basic aspects

IL3.13.01
Regulatory T cells fine-tune DC costimulation in vivo to set the threshold for T cell activation

B. Fazekas de St. Groth[1,2], *H. Bolton*[1], *C. Zhu*[1];
[1]*Centenary Institute, Sydney, Australia,* [2]*Discipline of Dermatology, University of Sydney, Sydney, Australia.*

Despite extensive research into their functional properties, the mechanism(s) of regulatory T (Treg) cell action remains controversial. Based on preliminary data indicating that lymph node and spleen dendritic cells (DCs) express abnormally high levels of costimulatory molecules in mice deficient in Tregs, we hypothesised that Tregs exert real-time control over the immunostimulatory function of DCs.
To test whether Tregs reduce the expression of costimulatory molecules in vivo, we set up a mouse model in which immunodeficient animals are reconstituted with pure Tregs, supported by exogenous IL-2. Only when the total number of Tregs reached the number present in normal mice was DC costimulation reduced to normal levels. Using CFSE labelling, we showed that Treg reconstitution prevented fast-phase lymphopaenia-induced proliferation, which is a necessary step in the induction of autoimmune disease in lymphopenic mice. In contrast, reconstitution with conventional CD4 T cells led to an increase in DC costimulation and enhanced lymphopenia-induced proliferation. Treg expression of CTLA-4 was necessary for their ability to normalise DC costimulation and to inhibit lymphopaenia-induced proliferation. Treg expression of CTLA-4 was also responsible for controlling recruitment of antigen-specific CD4 T cells into division.
These data indicate that the activation of self-reactive T cells in lymphopenic mice is a specific result of Treg deficiency, independent of conventional T cells, and that the effect is mediated via control of DC costimulation.

IL3.13.02
Impaired peripheral tolerance as a consequence of disturbed regulatory T cells - dendritic cell interactions

H. Schild, *S. Muth, H. Probst;*
University Medical Center Mainz, Mainz, Germany.

Dendritic Cells (DC) are professional antigen presenting cells (APC) that play a dual role in the control of adaptive immune responses. DC that have been activated through recognition of pathogen- or danger associated molecules can prime naïve T cells. In contrast, non-activated DC in the steady state induce peripheral T cell tolerance. We have recently shown that CD4+Foxp3+ regulatory T cells (Treg) are important for tolerance induction by steady state DC. Depletion of Treg results in an activated phenotype of steady state DC and these DC induce priming instead of tolerance. However, whether DC activation and the concomitant loss of tolerizing capacity is a result of general autoimmunity that develops in the absence of regulatory T cells, or whether direct interactions between DC and Treg are necessary to allow steady state DC to induce tolerance has remained unclear. To address this question in vivo, we have generated mouse models in which cognate DC-Treg interactions or previously reported suppressive Treg-mechanisms are impaired.
We find that in those case where DCs cannot be controlled by regulatory T cells induction and maintenance of peripheral CD8+ T cell tolerance is compromised.

W3.13.01
Low/ negative expression of CD6 in natural T-regulatory cells

C. A. Garcia Santana, *J. W. Tung, S. Gulnik;*
Beckman Coulter, Inc., Miami, FL, United States.

Natural T-regulatory cells, nTreg, are responsible for the maintenance of dominant self tolerance and play an important role in the prevention of autoimmune disorders, allergy, and in the maintenance of fetal maternal tolerance and organ graft tolerance. While the nuclear transcription factor, FOXP3, uniquely defines nTreg, there is a need to identify convenient surface markers that can be used to isolate and expand viable highly enriched nTreg. Several surface markers have been already identified. Among them, CD4, CD25 and CD127 are the most commonly used. In our study healthy blood samples were obtained with informed consent. PBMC were isolated and a 10 color multicolor staining was performed and analyzed on Gallios™ flow cytometer. In addition, labeled Treg cells were isolated using a MoFlo® XDP cell sorter and plated for use in a Treg-suppression assay with allogeneic PBMC stimulated with anti-CD3/CD28 mAbs in a CFSE proliferative assay. Our results show that $CD4^+CD25^{hi}FOXP3^+$ nTreg exhibit low/ negative CD6 expression ($CD6^{lo/-}$). We show that $CD4^+CD25^{hi}CD6^{lo/-}$ and $CD4^+CD25^{hi}CD127^{lo/-}$ cells exhibit similar nTreg-associated marker expression and similar *in vitro* suppression activity on $CD8^+$ T-cell proliferation. Moreover, two major nTreg subpopulations were identified from the analysis of CD6 and CD127 expression on $CD4^+CD25^{hi}$ cells: a $CD6^{lo/-}CD127^{lo/-}$ population, with high expression levels of FOXP3, and a $CD6^+CD127^+$ population, with low FOXP3, high CCR4 and low CD45RA, HLA-Dr and CD39 markers. Lack of CD6 on nTreg cells could participate to Treg anergy response to antigenic stimulus and can contribute to better understanding of biology of nTreg immune regulation.

W3.13.02
Regulatory T cells increase the avidity of CD8+ T cell responses to non-self antigens and promote memory

L. Pace[1], *A. Tempez*[1], *C. Arnold-Schrauf*[2], *F. Lemaitre*[3], *P. Bousso*[3], *L. Fetler*[4], *T. Sparwasser*[2], *S. Amigorena*[1];
[1]*U932, Institut Curie, Paris, France,* [2]*Institute of Infection Immunology, TWINCORE, Hannover, Germany,* [3]*INSERM U668, Institut Pasteur, Paris, France,* [4]*U168 Institut Curie, Paris, France.*

Regulatory T cells (Tregs) suppress autoreactive T cells through multiple effector mechanisms, acting both during the priming and the effector phases of immune responses. In healthy individuals, Treg-mediated suppression does not always compromise T cell responses to infectious, non-self antigens. We show that Tregs play a critical

role during the priming of immune responses in mice. We observed that Treg depletion induced the activation and expansion of an endogenous population of low avidity CD8+ T cells. To study the mechanisms involved in the suppression of low avidity CD8+ T cells, we took advantage of two peptides N4 vs. T4, that are recognized with different affinities by the OT-I TCR. We visualized the early interactions between DCs, OT-I cells and Tregs using dynamic 2-photon microscopy. During the early phases of T cell priming, Tregs established an affinity threshold for CD8+ T cell activation that prevented the activation of low-avidity T cells. We investigated the effects of Treg depletion and the role of CCL-3/4/5 chemokines, on DC-T cell interactions. In the absence of Tregs the over production of CCL-3/4/5 chemokines, stabilized the dynamic interactions between antigen presenting dendritic cells and low avidity CD8+ T cells.
In the absence of Tregs, the avidity of the endogenous primary immune response to Listeria monocytogenes -OVA infection was also impaired, resulting in reduced memory protection.
These results suggest that Tregs are important regulators of CD8+ T cell priming and play a critical role in the induction of high avidity primary responses and effective memory protection.

W3.13.03
Costimulatory requirements for Treg homeostasis and function

*C. Wang, R. Kenefeck, L. Wardzinski, **L. S. Walker**;*
University College London, London, United Kingdom.

We have previously shown that blockade of the CTLA-4 pathway significantly enhances Treg proliferation, presumably by enhancing signaling through the CD28 pathway. We now show using CD28-deficient animals that the effects of anti-CTLA-4 are entirely dependent on CD28 signaling. Analysis of bone marrow chimeric mice, comprising wildtype and CD28-deficient cells, has allowed us to demonstrate that intrinsic CD28 signals are necessary for anti-CTLA-4 induced Treg proliferation. By blocking CD86 and CD80, independently or together, we have been able to dissect the relative requirements for each ligand in maintaining Treg homeostasis. In addition to regulating the strength of CD28 signaling, we have previously shown that Treg-expressed CTLA-4 reduces expression of CD86 and CD80 by a process of trans-endocytosis. Together our data suggest a model in which peripheral Treg control their own pool size by regulation of costimulatory ligand expression.
This work was funded by an MRC Senior Research Fellowship to LSKW

W3.13.04
Continuous interactions with self are required for maintaining regulatory CD4 T-cell numbers and suppressive capacities in the periphery

***A. Delpoux**[1,2], P. Yakonowsky[1,2], A. Pommier[1,2], C. Charvet[1,2], M. Valente[1,2], A. Durand[1,2], B. Martin[1,2], C. Auffray[1,2], B. Lucas[1,2];*
[1]Cochin Institute, INSERM U1016, CNRS UMR 8104, Paris, France, [2]Descartes University, Paris, France.

Thymic development of regulatory Foxp3$^+$ CD4 T cells (Tregs) is instructed by TCR with high avidity for self-peptides bound to self MHC class II molecules (self). In the periphery, Tregs are important for the maintenance of self-tolerance but how their self-reactivity impacts on their homeostasis and suppressive capacities is poorly understood. In this study, we show that, in young mice, peripheral Tregs can be subdivided into two subsets according to Ly-6C expression. Interestingly, almost all thymic Tregs were Ly-6C$^-$ but they gave rise to both Ly-6C$^-$ and Ly-6C$^+$ Tregs after migrating to the periphery. Phenotypic analysis and adoptive transfer experiments of peripheral Ly-6C$^-$ and Ly-6C$^+$ Tregs revealed that the non-expression of Ly-6C by about 60% of peripheral Tregs was dependent on self-recognition. According to their higher ability to interact with self, Ly-6C$^-$ Tregs expressed higher surface amounts of key immunosuppressive molecules such as CD25, CTLA-4, CD39 and CD73 than Ly-6C$^+$ Tregs and were the only ones to produce constitutively anti-inflammatory cytokines. In line with their phenotype, only Ly-6C$^-$ Tregs displayed suppressive capacities both *in vitro* and *in vivo*. Finally, whereas Ly-6C$^-$ Tregs maintained their numbers with age, Ly-6C$^+$ Tregs gradually disappeared. Altogether, our data suggest that both the survival and the function of Tregs rely on continuous interactions with self in the periphery.

W3.13.05
TGF-b signalling is required for CD4+ T cell homeostasis but dispensable for regulatory T cell function

***A. Sledzinska**[1], S. Hemmers[2], F. Mair[1], O. Gorka[3], J. Ruland[3], L. Fairbairn[3], W. Müller[4], A. Waisman[5], B. Becher[1], T. Buch[3];*
[1]Institute of experimental Immunology, Zurich, Switzerland, [2]Memorial Sloan Kettering Cancer Center, New York, NY, United States, [3]Technical University of Munich, Munich, Germany, [4]University of Manchester, Manchester, United Kingdom, [5]Universitätsmedizin der Johannes Gutenberg-Universität, Mainz, Germany.

TGF-β is widely held to be critical for the maintenance and function of regulatory T cells and thus peripheral tolerance. Here we show that inducible deletion of the TGF-β receptor II (TR2) from mature CD4$^+$ T cells does not result in the collapse of the T_{reg} cell population as observed in constitutive models. Instead, it leads to a pronounced enlargement of both Nrp-1$^+$ thymic regulatory and effector memory T cell pools. This T cell expansion is a cell intrinsic process caused by increased T cell receptor sensitivity. Further, the expression of Foxp3 and other regulatory T cells markers was not dependent on TGF-β signalling and the TR2–deficient T_{reg} cells retained their suppressive function both *in vitro* and *in vivo*. We also show that peripheral TR2 ablation from CD4$^+$ T cells does not lead to lethal autoinflammation and transfer of theses T helper cells to lymphopenic recipients results in colitis, but not overt autoimmunity. In contrast, thymic ablation of TR2 receptor in combination with lymphopenia leads to lethal multi-organ inflammation. In summary, our findings indicate that TGF-β regulates the homeostasis of mature CD4$^+$ T cells but is dispensable for peripheral tolerance and T_{reg} function in the adult animal.

W3.13.06
Essential role for Bcl11b in the FoxP3 transcriptional complex and T regulatory cells suppressive function

***M. Hamaguchi**, K. Sakai, N. Ohkura, H. Morikawa, Y. Shimazu, J. B. Wing, S. Sakaguchi;*
Department of Experimental Immunology, World Premier International Immunology Frontier Research Cent, Suita, Japan.

Naturally occurring T regulatory cells (Treg cells) engage in the maintenance of immunological self-tolerance and homeostasis, by expression or repression of lineage specific molecules. Foxp3, which is exclusively expressed by Treg cells, critically controls the development and function of Treg cells; however, the molecular mechanisms by which Foxp3 controls its target genes are still remain elusive. We characterized constituents of the Foxp3 transcriptional complex, and found that the T cell lineage specific transcriptional factor, Bcl11b, was a novel constituent of the Foxp3 transcriptional complex. Treg specific gene regulation and molecule expression, especially CTLA-4 expression, and immune suppressive activity were impaired in Treg cells lacking Bcl11b. Consequently, lethal autoimmunity was observed in Treg-specific Bcl11b conditional knockout mice. Impaired immunesupressive activity in Bcl11b-null Treg cells was rescued by forced expression of CTLA-4 Taken together, Bcl11b is an essential component of the Foxp3 transcriptional complex, which regulates Treg specific gene expression. This model explains how transcriptional complex controls expression of lineage specific gene.

CD4+CD25hiFoxp3+ regulatory T cells (Tregs) are critical mediators of self-tolerance, which is crucial for the prevention of autoimmune disease, but Tregs can also dampen antitumor immunity. Tregs inhibit the proliferation of CD4+CD25− conventional T cells (Tcons), as well as the ability of these cells to produce effector cytokines; however, the molecular mechanisms of suppression remain incompletely understood. We show that human Tregs rapidly suppressed the release of calcium ions (Ca2+) from intracellular stores in response to T cell receptor (TCR) activation in Tcons. The inhibition of Ca2+ signaling resulted in decreased dephosphorylation, and thus decreased activation, of the transcription factor nuclear factor of activated T cells 1 (NFAT1) and reduced the activation of nuclear factor kB (NF-kB). In contrast, Ca2+-independent events in Tcons, such as TCR-proximal signaling and activation of activator protein 1 (AP-1), were not affected during coculture with Tregs. Despite suppressing intracellular Ca2+ mobilization, coculture with Tregs did not block the generation of inositol 1,4,5-trisphosphate in TCR-stimulated Tcons. The Treg-induced suppression of the activity of NFAT and NF-kB and of the expression of IL-2 was reversed in Tcons by increasing the concentration of intracellular Ca2+. Our results elucidate a previously unrecognized and rapid mechanism of Treg-mediated suppression. Ongoing and future studies aim at deciphering new molecules causative for this rapid suppression by next-generation proteomics studies, pathway analyses and computational data integration. This increased understanding of Treg function and Tcon resistance to suppression may be exploited to generate possible therapies for the treatment of autoimmune diseases and cancer.

Selective inhibition of pro-inflammatory T cell responses by TIGIT+ Tregs

N. Joller, *S. Xiao, B. Patel, C. Zhu, J. Xia, F. J. Quintana, V. K. Kuchroo;*
Brigham and Women's Hospital, Harvard Medical School, Boston, MA, United States.

Foxp3$^+$ regulatory T cells (Tregs) are a subset of CD4$^+$ T cells that is key in regulating immune responses and maintaining self-tolerance. Recently the concept has emerged that Tregs are comprised of many specialized subpopulations with distinct regulatory functions. Although the transcription factors that differentially induce the effectors that are required for this specialized suppression have been identified, the molecules that mediate these selective effector functions remain largely unknown. Our results indicate that the co-inhibitory molecule TIGIT, which is expressed on about 30% of nTregs, represents such a mediator.
TIGIT marks a functionally distinct Treg subset that displays increased suppressive capacity and an activated phenotype. Using *in vivo* models of experimental autoimmune encephalomyelitis (EAE) and colitis, we demonstrate that TIGIT$^+$ Tregs specifically suppress pro-inflammatory Th1/Th17 responses yet spare or even enhance Th2 responses. This selective suppression of pro-inflammatory responses (IFN-gamma and IL-17) is mediated by secretion of a soluble Treg specific effector molecule, which is a key factor contributing to the higher suppressive capacity of TIGIT$^+$ Treg and the selective inhibition of Th1/Th17 repsonses. We have identified a transcription factor that is induced by TIGIT that drives the expression of this effector molecule and thereby enables TIGIT$^+$ Tregs to selectively suppress pro-inflammatory effector T cell responses, while sparing or even promoting Th2 effector T cell responses. TIGIT$^+$ Tregs are thus likely to be a specialized Treg subset equipped to specifically suppress inflammatory immune responses and tissue inflammation mediated by Th1/Th17 cells.

W3.13.09
Regulatory T cells suppress the late phase of the immune response in lymph nodes through P-selectin glycoprotein ligand-1

S. Angiari[1], *B. Rossi*[1], *L. Piccio*[2], *B. H. Zinselmeyer*[3], *S. L. Budui*[1], *E. Zenaro*[1], *V. Della Bianca*[1], *A. H. Cross*[2], *M. J. Miller*[3], *G. Constantin*[1];

Regulatory T (Treg) cells maintain tolerance towards self-antigens and suppress autoimmune diseases, although the underlying molecular mechanisms are unclear. In this study we investigated the role of the mucin P-selectin glycoprotein ligand (PSGL)-1 in the suppressor activity exerted by Treg during autoimmune disease development.
RESULTS. We initially found that mice deficient for PSGL-1 develop a more severe form of experimental autoimmune encephalomyelitis (EAE) than wild-type animals, suggesting that PSGL-1 has a role in the negative regulation of autoimmunity. Moreover, Treg cells lacking PSGL-1 were unable to suppress EAE and failed to inhibit T-cell proliferation *in vivo* in the lymph nodes. Using two-photon laser-scanning microscopy in the lymph node, we found that PSGL-1 expression on Treg cells had no role in the suppression of early T-cell priming (day +1 post-immunization) after immunization with antigen. Instead, PSGL-1 deficient Treg cells lost the ability to modulate T-cell movement and failed to inhibit T cell-dendritic cell contacts and T-cell clustering essential for sustained T-cell activation during the late phase of the immune response (day +7 post-immunization). Notably, PSGL-1 expression on myelin-specific effector T cells had no role in T-cell locomotion in the lymph node. In conclusion, our data show that PSGL-1 represents a previously unknown phase-specific mechanism for Treg cell-mediated suppression of the persistence of immune responses and autoimmunity induction.

Visualizing tolerance induction: behavior and function of regulatory T cells during the establishment of materno/fetal tolerance

M. G. Ruocco, *T. Chen, G. Darrasse-Jeze, D. Klatzmann;*
Université Pierre et Marie Curie, Paris, France.

A fetus is inherently antigenic to its mother and yet is not rejected. Our understanding of the mechanisms that regulate materno/fetal tolerance is fragmentary, yet these mechanisms have important therapeutic implications in abnormal pregnancies, organ transplantation and autoimmune diseases.
Recently, regulatory T cells (Tregs) have been suggested to play a pivotal role in preventing the rejection of the fetus during pregnancy, as ablation of Tregs results in increased resorption of the embryos in allogeneic matings in mice. Furthermore, women with repeated spontaneous abortions and preeclampsia were found to display decreased numbers of CD25$^+$CD4$^+$ Tregs.
We have undertaken a comprehensive analysis of the role, activation status and function of Tregs, their spatial and temporal distribution and their interactions with other immune system cells (DCs, Teffs and NK cells) during pregnancy. We found that embryo implantation triggers the early recruitment and proliferation of activated/memory Tregs in the uterine draining lymph nodes. Moreover, Treg proliferation is antigen-driven and self-specific. Finally, low-dose IL-2 treatment prevents abortion in an abortion prone model.
Furthermore, we have developed two-photon *in vivo* imaging approaches to directly visualize T cells at the materno/fetal interface, the decidua. Our data suggest that Tregs are recruited to the decidua upon implantation. Here, they are either motile or big and sessile and these latter are able of long lasting interactions with DCs.

Our results establish novel *in vivo* approaches to study the dynamic interactions of immune cells at the materno/fetal interface and shed light on the establishment of immune tolerance.

Migratory, and not lymphoid-resident, dendritic cells maintain peripheral self-tolerance and prevent autoimmunity via induction of iTreg cells

A. Broggi[1], *C. Vitali*[1], *F. Mingozzi*[1], *S. Barresi*[1], *G. Raimondi*[2], *I. Zanoni*[1], *F. Granucci*[1];
[1]*University of Milan Bicocca, Milano, Italy,* [2]*University of Pittsburgh School of Medicine,Thomas E. Starzl Transplantation Institute, Pittsburgh, PA, United States.*

There is evidence that dendritic cells (DCs) induce peripheral tolerance. Nevertheless, it is not known whether immature DCs in general are able to tolerize CD4 (+) T cells or if this is a prerogative of specialized subtypes. Here we show that, when autoantigen presentation is extended to all conventional mouse DCs, immature lymphoid tissue resident DCs are unable to induce autoantigen-specific regulatory T (iTreg) cell conversion. In contrast, this is an exclusive prerogative of steady-state migratory DCs that are able to induce antigen-specific iTreg cells in an RA-dependent manner. Because only lymph nodes host migratory DCs, iTreg cells develop and are retained solely in lymph nodes, and not in the spleen. Mechanistically, in cutaneous lymph nodes, DC-derived CCL22 contributes to the retention of iTreg cells. The importance of the local generation and retention of iTreg cells is emphasized by their essential role in protecting mice from autoimmunity in a model of autoimmune Herpes Stromal Keratitis.

Functionally distinct T helper cell subsets, such as regulatory T cells (Treg) and T helper 2 (Th2) cells play an important role in allergy. Cumulating evidence indicates that FOXP3+ Treg can be functionally regulated by transcription factors previously thought to be T helper lineage specific, but little data is available for humans. Here, we functionally characterize allergen-specific human T helper cell responses in vitro. We stimulated peripheral blood mononuclear cells (PBMC) of allergic children and non-sensitized healthy controls with purified Der P 1 allergen and analyzed responding cells for GATA3 and FOXP3 transcription factor expression, associated cell surface phenotypes and cytokines production.
In allergic individuals, a typical Th2 response with high GATA3, IL4, IL5 and IL13 expression was observed. Interestingly, a fraction of cells co-expressed GATA3 and FOXP3. These double positive cells were highly proliferative and produced typical Th2 cytokines, but also potently suppressed T cell proliferation and production of non-Th2 cytokines such as IFN-g and TNF-a.
Our data indicate that allergen-specific T helper cells co-expressing GATA3 and FOXP3 have functional features of Th2 and Treg cells. These data indicate that GATA3 and FOXP3 are not exclusive human T helper cell markers and suggest that GATA3+/FOXP3+ T helper cells may contribute to allergic polarization by producing Th2 cytokines while suppressing non-Th2 pathways.

Adoptive transfer of CD4+FOXP3+ regulatory T cells (Tregs) might be an alternative option to achieve tissue specific tolerance without perturbance of general immunocompetence. Polyspecific Tregs can control graft versus host diseases under lymphopenic conditions. However, under non-lymphopenic conditions as in patients after organ transplantation polyspecific Tregs were so far largely ineffective in controlling immune responses. Herein, we describe that the surface molecules latency associated peptide (LAP) and glycoprotein A repetitions predominant (GARP) can specifically identify Tregs activated by their T cell receptor and not in bystander fashion. Using these markers we could show for the first time that the human natural Treg repertoire contains about 10% of alloreactive Tregs. In addition we show that CD154 is neither expressed on resting nor on activated Tregs and can therefore be used to increase the purity of isolated Tregs. The combination of CD154-LAP+ or CD154-GARP+ markers allowed the isolation of highly pure antigen-specific Tregs. The purity, assessed by TSDR methylation analysis, exceeds all other published Treg isolations and identifies furthermore just antigen-specific Tregs. Furthermore, we demonstrated that those LAP+ allospecific Tregs are highly capable in the prevention of potent allospecific DTH responses in humanized mice and in the prevention of rejection of allogeneic cells in immune reconstituted humanized mice.
These results represent a major step forward for the use of adoptively transferred Tregs in non-lymphopenic conditions such as autoimmunity and transplant rejection. As current clinical studies are using CD4+CD25high Tregs, the findings could be of major importance for future clinical trials.

W3.13.14
TCR-independent CD4+CD25+ regulatory T cell activation during immune responses

H. Kojima, *Y. Kashiwakura, M. Hashiguchi, T. Kobata;*
Department of Immunology, Dokkyo Medical University School of Medicine, Mibu, Tochigi, Japan.

To clarify the precise behavior of $CD4^+CD25^+$ regulatory T (Treg) cells during immune responses is important to realize whole truth of immunity. Since activated T cells express CD25 on their surface, it is very hard to distinguish between activated conventional T (Tconv) cells and Treg cells. However, we found that activated Tconv cells were distinguishable from Treg cells by cell-size and the expression levels of CD25. By using this discrimination method, action of Treg cells in mixed lymphocyte culture (MLC) was analyzed in mice. Surprisingly, cell-sizes of the majority of Treg cells enlarged in MLC, although the majority of Tconv cells were still small-sized. TCR-transgenic system indicated that Treg enlargement was not dependent on antigen recognition. Furthermore, a trans-well culture system showed that Treg enlargement required cytokines rather than cell-cell contact. To characterize the large-sized Treg cells in MLC, expression levels of proliferation- and apoptosis-related molecules were assessed. The large-sized Treg cells in MLC expressed Ki-67, a cell-cycle related antigen, and incorporated BrdU as much as Tconv cells. In addition, the large-sized Treg cells expressed Bim, a pro-apoptotic factor, higher than activated Tconv cells. In fact, much apoptotic large-sized Treg cells were found. Taken together, the large-sized Treg cells, which were majority of Treg cells, in MLC were in the situation of both proliferation and apoptosis.
Now we are trying to clarify the trigger by which Treg cells were enlarged, and the regulatory function of large-sized Treg cells in MLC.

W3.14 B cells in autoimmunity and regulatory B cells

IL3.14.01
TACI regulates T-independent marginal zone B cell responses through innate activation-induced cell death

F. Mackay[1,1], *W. Figgett*[1], *A. Strasser*[2], *P. Hertzog*[1], *K. Fairfax*[1], *V. Fabien*[1], *D. Saulep-Easton*[1], *M. Le Page*[1], *L. O'Reilly*[2], *S. Gerondakis*[1];
[1]*Monash University, Melbourne, Australia,* [2]*Walter and Eliza Hall Institute, Melbourne, Australia.*

Activation-Induced Cell Death (AICD) plays a critical role in immune homeostasis and tolerance. In T cell-dependent humoral responses, AICD of B cells is initiated by Fas ligand (FasL) on T cells, stimulating Fas on B cells. In contrast, T cell-independent B cell responses involve innate-type B-lymphocytes, such as marginal zone (MZ) B cells and only little is known about the mechanisms that control AICD during innate B cell responses to TLR activation. Here, we show that MZ B cells undergo AICD in response to TLR4 activation *in vivo*. This process requires engagement of the BAFF/APRIL receptor, TACI, which cooperates with TLR4 signaling to up-regulate expression of both FasL and Fas on MZ B cells and to also repress inhibitors of Fas-induced apoptosis signaling. This process is also dependent on Mal downstream of TLR4. These findings demonstrate an unappreciated role for TACI and its ligands in the regulation of AICD during T-independent B cell responses.

IL3.14.02
Regulatory B and iNKT cells interaction: novel mechanism of Suppression

C. Mauri[1], *A. Bosma*[2], *A. Abdel-Gadir*[2], *E. Jury*[2];
[1]*University College London, London, United Kingdom,* [2]*UCL, London, United Kingdom.*

Currently, dendritic cells (DCs) are believed to be the antigen presenting cells that predominantly present glycolipid antigen and as such are responsible for iNKT cell activation/proliferation. Immunotherapy using lipid presenting cytokine-pretreated dendritic cells to activate iNKT cells has been proposed as a strategy to enhance tumor immunity, infectious diseases or to dampen autoimmune diseases. Given the role for CD19+CD24hiCD38hiCD1dhi B cells in the activation of iNKT cells, and the powerful immunoregulatory properties of these B cells, we propose that lipid presenting Bregs may strongly influence the outcome of iNKT cell based immunotherapy. We have shown that, in healthy individuals, Bregs activate invariant Natural Killer T (iNKT) cells via presentation of lipid antigen, which results in iNKT cell proliferation and cytokine production. We reported also that both CD19+CD24hiCD38hi B cells and iNKT cells are functionally and numerically, deficient in patients with Systemic lupus erythematosus (SLE). In SLE patients, B cells are unable to induce iNKT proliferation or cytokine production, defects that were associated with the rapid internalization and reduced surface expression of CD1d on CD19+CD24hiCD38hi B cells. CD1d expression and iNKT cell function were restored in B cell repopulated patients responding to treatment with rituximab. It is therefore important to further explore the nature of iNKT-Breg interactions during homeostasis, and whether the consequences of these interactions are different during inflammation or following immunotherapy.

W3.14.01
Dual-reactive and autoreactive B cell selection and function in autoimmunity

R. Pelanda[1], *E. Fournier*[1], *L. Teodorovic*[1], *C. Babolin*[1], *S. Rowland*[1], *R. M. Torres*[2];
[1]*National Jewish Health, Denver, CO, United States,* [2]*University of Colorado Denver, Denver, CO, United States.*

Rare dual-reactive B cells expressing two types of Ig light or heavy chains have been shown to participate in immune responses in healthy mice. Using mice bearing Igκ allotypic markers and a wild-type Ig repertoire, we demonstrate that the generation of dual-κ B cells increases with age and disease progression in autoimmune-prone. These dual-reactive cells express markers of activation and are more frequently autoreactive than single-reactive B cells. Moreover, dual-κ B cells represent up to half of plasmablasts and memory B cells in autoimmune mice, whereas they remain infrequent in healthy mice. Furthermore, dual-κ B cells that differentiate into plasmablasts retain the capacity to secrete autoantibodies indicating that they contribute to the autoimmune process. We hypothesize that dual-κ autoreactive B cells mature because an activation of the tonic BCR signaling pathway mediated by the nonautoreactive BCR promotes the differentiation of autoreactive B cells despite the presence of self-antigen-mediated BCR signals. We show that activation of the tonic BCR signaling cascade in autoreactive immature B cells leads to the inhibition of receptor editing via the PI3K pathway and to the differentiation into transitional B cells via the activities of both Erk1/2 and PI3K. Our findings demonstrate that antigen-mediated BCR signals do not block the tonic BCR signaling pathways that travel via Erk and PI3K in immature B cells, and support a model whereby sufficient levels of tonic BCR signaling lead to the inhibition of tolerance and the maturation of low avidity autoreactive B cells.

W3.14.02
The atypical IκB protein IκBNS is important for TLR-induced IL-10 production in B cells

M. Miura, M. Noguchi, ***M. Touma****;*
Niigata University, Niigata, Japan.

Recent studies have revealed an important immune suppressive function of B cells, which is mainly mediated by secretion of the anti-inflammatory cytokine, IL-10. However, the mechanism by which IL-10 is induced in B cells has not been elucidated. Here we report that the atypical IκB protein IκBNS is important for the development of IL-10-producing B cells. We previously reported that IκBNS expression is transiently induced in B cells upon signaling through the BCR, CD40 or TLR and that IκBNS plays a key role in B cell development and antigen-specific antibody production. We also observed that the number of IL-10-producing B cells is reduced in the spleens of IκBNS knockout mice. Analysis of B cells in bone marrow chimeric mice constructed by transferring wild type or IκBNS-deficient bone marrow cells into μMT mice revealed that IκBNS intrinsically controls IL-10 production in B cells. In addition, TLR-stimulated induction of cytoplasmic IL-10-positive cells and IL-10 secretion is significantly reduced in IκBNS-deficient B cells. LPS-induced expression of Il10 is reduced in the absence of IκBNS during the first 24 hours of induction and IL-10 production in IκBNS-deficient B cells is impaired for at least several days, suggesting a role for IκBNS in transcriptional and posttranscriptional regulation of IL-10 production in B cells. These results indicate that IκBNS is required for the development of IL-10-producing regulatory B cells, thus defining an additional important role for IκBNS in control of the immune response.

W3.14.03
Aicda expression in immature B cells, but not in mature B cells is critical for IgG autoantibody production in a model of systemic lupus erythematosus (SLE)

B. Umiker[1], *A. Larbi*[1], *M. Reth*[2], *T. Honjo*[3], *T. Imanishi-Kari*[1];
[1]*Tufts Sackler School of Biomedical Sciences, Boston, MA, United States,* [2]*Max Planck Institute, Freiburg, Germany,* [3]*Kyoto University, Kyoto, Japan.*

Systemic lupus erythematosus (SLE) is a debilitating autoimmune disorder, which is characterized by anti-nuclear antibody. The mechanisms by which B cells produce autoantibodies and avoid tolerance to cause disease are yet to be fully elucidated. 564Igi is a mouse model of SLE that has a heavy and light chain gene for a nucleic acid specific autoantibody knocked-in to the H and L chain loci. On a 564Igi activation induced cytidine-deaminase (*Aicda*) deficient background we conditionally expressed an *Aicda* transgene in all B cells in one mouse model (Mb-1-cre) and only in mature B

cells in another model CD21-cre. CD21-cre mice express no auto-reactive IgG antibodies, while Mb-1-cre mice have high levels of pathogenic IgG anti-RNA antibodies in their sera. Our data demonstrate that AID expression in developing B cells through class switch recombination (CSR) is critical for the production of pathogenic IgG autoantibody. These cells undergo CSR to IgG, avoiding mechanisms of IgM-mediated central tolerance. However, AID in mature B cells does not contribute to CSR of auto-reactive antibody genes. The production of IgG autoantibody is crucial for the etiopathology of SLE.

W3.14.04
Analysis of a wild mouse promoter variant reveals a novel role for FcgammaRIIb in the control of the germinal center and autoimmunity

M. Espeli[1]*, M. Clatworthy*[1]*, S. Boekers*[1]*, K. Lawlor*[1]*, A. Cutler*[1]*, F. Koentgen*[2]*, P. Lyons*[1]*, K. Smith*[1]*;*
[1]*University of Cambridge, Cambridge, United Kingdom,* [2]*Ozgene, Perth, Australia.*

Genetic variants of the inhibitory Fc receptor FcgammaRIIb have been associated with systemic lupus Erythematosus (SLE) in humans and mice. The mechanism by which *Fcgr2b* variants contribute to the development of autoimmunity is unknown and was investigated by "knocking-in" the most commonly conserved wild mouse *Fcgr2b* promoter haplotype, also associated with autoimmune-prone mouse strains, into the C57BL/6 background. We found that in the absence of an AP-1 binding site in its promoter, FcgammaRIIb failed to be up-regulated on activated and germinal center B cells. This resulted in enhanced germinal center responses, increased affinity maturation and autoantibody production. Accordingly, in absence of FcgammaRIIb activation-induced up-regulation, mice developed more severe collagen-induced arthritis and spontaneous glomerular immune-complex deposition. Our data highlight how natural variation in *Fcgr2b* drive the development of autoimmune diseases and show how the study of such variants using a knock-in approach can provide insight into immune mechanisms not possible using conventional genetic manipulation, in this case demonstrating an unexpected critical role for the activation-induced up-regulation of FcgammaRIIb in controlling affinity maturation, autoantibody production and autoimmunity.

W3.14.05
Contribution of IL-10 competent Regulatory B cells (Bregs, CD19+CD24hiCD38hi) to cytotoxic T lymphocyte dysfunction after reactivation of HIV latent reservoirs

B. Siewe[1]*, S. Rygielski*[1]*, S. Deeks*[2]*, J. Martin*[2]*, A. Landay*[1]*;*
[1]*Rush University Medical Center, Chicago, IL, United States,*
[2]*University of California, San Francisco, San Francisco, CA, United States.*

HIV-infected "controllers" (HIV_{CON}) often exhibit robust anti-HIV cytotoxic T-lymphocyte (CTL) activity and control viral load without antiretroviral therapy (ART). In HIV-infected typical viremic non-controllers (HIV_{VIR}), CTL responses are impaired, persisting during ART, preventing clearance of the reservoir during curative interventions. During viral infections, Bregs attenuate CTL responses. We therefore investigated Breg-mediated CTL impairment during HIV infection. In HIV-peptides stimulated Breg-depleted or total PBMCs of ART-treated HIV^+ subjects (HIV_{ART}), Breg-depletion led to significant proliferation of cytotoxic $CD8^+$ T cells, total $CD4^+$ T cells and increased frequency of HIV-specific $CD8^+$ T cells. Breg-inhibition of $CD8^+$ T cell proliferation was partially IL-10-dependent. HIV_{CON} had higher Breg-frequencies than HIV_{ART} and HIV_{VIR} subjects. However, HIV_{VIR} Bregs expressed significantly more IL-10 than all other subjects; HIV_{ART} Bregs expressed more IL-10 than those of HIV_{CON} and HIV_{NEG} subjects. To evaluate if Bregs attenuate CTL activity after latent reservoirs reactivation, we assessed CTL-modulating factors in suberoylanilide hydroxamic acid (SAHA) supplemented Breg-depleted or total PBMCs of HIV_{CON} and HIV_{ART} subjects. Breg-depletion led to significant upregulation of MHC-II on B cells and MHC-II/I on dendritic cells ($LIN^-HLA\text{-}DR^+CD11c^+$). Finally, Breg-depletion was associated with significant clearance of infected cells $CD4^+$ T cells. In summary, we find that increased Breg function (IL-10 production) might contribute to CTL impairment and HIV control during untreated and treated infection. Further, Breg-depletion enhances anti-HIV CTL activity and increases *ex vivo* clearance of latently infected cells. Understanding Breg contributing to impairment of anti-HIV CTL effectiveness might be crucial in designing vaccines against HIV and immunotherapies towards viral eradication.

Human innate-like B cells with regulatory properties in response to viruses

X. Zhang[1]*,* ***D. Zhivaki***[1]*, S. Lemoine*[1]*, A. Lim*[2]*, C. Leclerc*[1]*, R. Lo-Man*[1]*;*
[1]*Unite de Regulation Immunitaire et Vaccinologie, INSERM 1041, Institut Pasteur, Paris, France,* [2]*Département d'Immunologie, Institut Pasteur, Paris, France.*

Newborns and very young infants are highly susceptible to infections and poorly responsive to vaccines with a Th2 bias. We identified in cord blood a population of innately responsive B lymphocytes with regulatory properties. This neonatal Breg population showed a biased immunoglobulin repertoire and an innate-like phenotype, and is not found in adult blood. Gene expression microarray analysis revealed an immunosuppressive signature for this Breg population. These innate-like Bregs can modulate neonatal CD4 Th1 development through the production of a high level of IL-10 upon TLR activation. This regulatory loop can be engaged following stimulation by viruses including mainly pediatric disease associated viruses. Plasmacytoid dendritic cells contributed to this regulatory mechanism through the production of type I IFNs that further enhance the production of antiinflammatory IL-10. Thus, we uncovered a novel mechanism by which innate and adaptive inflammatory responses to pathogens are controlled in early life through a population of innate B cells.

Regulation of human CD8+ T cell effector functions

R. A. Van Lier[1]*, K. Hertoghs*[2]*, F. Vieira Braga*[3]*, M. Brouwer*[3]*, L. Aarden*[3]*, I. Derks*[2]*, E. Eldering*[2]*, M. Nolte*[3]*, I. ten Berge*[4]*, K. van Gisbergen*[3]*;*
[1]*1 Division of Research, Sanquin Blood Supply Foundation, Amsterdam, Netherlands,* [2]*Dept of experimental Immunology, AMC, Amsterdam, Netherlands,* [3]*Division of Research, Sanquin Blood Supply Foundation, Amsterdam, Netherlands,* [4]*Renal Transplant Unit, Dept of Internal Medicine, AMC, Amsterdam, Netherlands.*

Our recent work has revealed the existence of a yet unrecognized transcription factor that is specifically expressed in human cytolytic CD8+ lymphocytes, a population that accumulates significantly in HCMV infected people (*J. Clin. Invest,* 2010). The factor, which we termed HOBIT, is highly related to BLIMP-1, a transcriptional repressor known to regulate terminal differentiation of B and T lymphocytes. An antibody that was raised against the unique N-Terminal part of HOBIT specifically stained cytolytic subsets of human lymphocytes. Knockdown of HOBIT in NK cell lines via siRNA reduced IFNγ production and increased cell survival but did not modulate Granzyme B expression. Interestingly, although structurally highly conserved, HOBIT expression in mice is very different from humans. Mouse HOBIT appear to be redundant for the formation and function of cytolytic T cells and NK cells, but is essential for the generation and function of NKT cells (*Nature Immunology,* 2012). Based on the combined human and mouse findings, we postulate that human HOBIT is essential for controlling formation, maintenance and function of resting cytolytic CD8+ T cells.

Disparate individual fates compose robust CD8+ T cell immunity

V. R. Buchholz[1], *M. Flossdorf*[2], *I. Hensel*[1], *L. Kretschmer*[1], *B. Weissbrich*[1], *P. Gräf*[1], *M. Schiemann*[1], *T. Höfer*[2], *D. H. Busch*[1,3,4]*;*
[1]Institute for Microbiology, Immunology and Hygiene, Technische Universität München (TUM), Munich, Germany, [2]Division of Theoretical Systems Biology, German Cancer Research Center (DKFZ), Heidelberg, Germany, [3]Focus Group "Clinical Cell Processing and Purification", Institute for Advanced Study, TUM, Munich, Germany, [4]National Centre for Infection Research (DZIF), Munich, Germany.

A core feature of protective T cell responses to infection is the robust expansion and diversification of naïve antigen-specific T cell populations into short-lived effector and long-lived memory subsets. We have developed a novel approach in which we combined high sensitivity flow cytometry and multiplexed single cell adoptive transfer to simultaneously map the fate of multiple individual T cells and their descendants in vivo during the course of bacterial and viral infection. Using this approach we find that in contrast to uniform expansion and diversification of CD8+ T cell populations single cell-derived responses are characterized by the expansion of very few effector-differentiated "giant" progenies dominating in overall size many memory phenotype "dwarfs". We identify the initial recruitment of multiple precursors as essential for robust acute and recall immunity and show that memory capacity of single cell-derived progenies is not predicted by their primary expansion size but - once established - robustly maintained during repetitive recall responses. The unique single cell origin or our data allowed us to implement novel unbiased mathematical modeling strategies. These identify the random integration of multiple differentiation and division events as the driving force behind single cell-derived variability. Reminiscent of recently described developmental processes in tissue stem cells, cell fate is specified within this probabilistic framework, along a linear developmental path that progresses from slowly proliferating long-lived to rapidly expanding short-lived subsets. Together, these data provide novel insights into how complex biological systems implement population-based developmental strategies to guarantee that stochastic processes generate robust results.

W3.15.02
Late IL-2 signals limit effector CD4 T cell contraction and serve as a checkpoint for transition to memory

K. K. McKinstry[1], *T. M. Strutt*[1], *A. M. Cooper*[2], *S. L. Swain*[1]*;*
[1]University of Massachusetts Medical School, Worcester, MA, United States, [2]Trudeau Institute, Saranac Lake, NY, United States.

Pathogen challenge causes the dramatic expansion of responding T cells resulting in large populations of activated effector cells at both secondary lymphoid sites where they originate, and at sites of infection and inflammation to which they migrate. Following the resolution of infection, most effector cells undergo apoptosis in the process known as 'contraction', while a cohort escapes death, transitions to a resting memory state, and persists for extended periods to provide long-term immunity. The factors and mechanisms determining the extent of T cell contraction and the efficiency of memory generation are unclear. We find that late, autocrine IL-2 during a narrow timeframe is required to limit the contraction of highly-differentiated CD4 T cell effectors generated by influenza A virus (IAV). We validate key findings by restoring IL-2 signals to IL-2-deficient CD4 T cells responding in wild type (WT) hosts, and by short-term neutralization of IL-2 in recipients of WT IAV-specific donor cells. Interestingly, late IL-2 is required to rescue effectors generated from both naïve and memory precursors from enhanced contraction. One of the few differences that distinguish WT and IL-2-deficient effectors at the peak of their response is higher expression of IL-7 receptor by WT cells. We find that late IL-2 is required for effectors to increase IL-7 receptor expression, allowing ambient IL-7 to limit excessive contraction and to sustain their long-term persistence in the lung and in secondary lymphoid organs. This establishes a late IL-2-dependent checkpoint for memory CD4 T cell generation, with important implications for vaccine design.

W3.15.03
Id2-mediated inhibition of E2A represses memory CD8 T cell differentiation*

F. Masson[1], *M. Minnich*[2], *M. Olshansky*[1], *A. Kallies*[1], *T. P. Speed*[1], *M. Busslinger*[2], *S. L. Nutt*[1], *G. T. Belz*[1]*;*
[1]The Walter and Eliza Hall Institute of Medical Research, Parkville, Australia, [2]Research Institute of Molecular Pathology, Vienna Biocenter, Vienna, Austria.

The transcription factor Inhibitor of DNA binding 2 (Id2) modulates T cell fate decisions but the molecular mechanism underpinning this regulation is unclear. Here we show that loss of Id2 cripples effector CD8 T cell differentiation and instead programs CD8 T cells to adopt a memory fate with increased expression of the transcriptional regulators Eomesodermin and Tcf7 expression. We demonstrate that Id2 restrains the differentiation of CD8 T cells into memory cells by inhibiting E2A-mediated direct activation of Tcf7 and that Id2 expression level correlates with T cell memory recall capacity. As a result of the defective effector differentiation, Id2-deficient CD8 T cells fail to induce sufficient level of Tbx21 expression to generate short-lived effector CD8 T cells. Indeed, enforced expression of Tbx21 in Id2-deficient CD8 T cells rescues the differentiation of short-lived effector CD8 T cells. Our findings reveal that the Id2-E2A axis orchestrates T cell differentiation through the induction or repression of downstream transcription factors essential for effector and memory T cell differentiation.

W3.15.04
The transcription factor Zeb2 plays a role in promoting terminal differentiation of CD8+ T-cells through repression of the miR-200 family

C. X. Dominguez, *S. M. Kaech;*
Yale University, New Haven, CT, United States.

CD8+ T-cells play an important role in the immune response against intracellular pathogens, preventing the spread of infection. Yet, the mechanisms involved in the development of a robust response and its resolution into a protective immune memory population remain to be fully elucidated. We are interested in how differentiation of the effector CD8+ T-cell response is regulated. Expression profiling revealed the transcription factor Zeb2 is highly enriched in short lived effector CD8+ T-cells (SLECs). To further investigate what role Zeb2 might play in promoting SLECs we knocked out Zeb2 in activated CD8+ T-cells. Upon infection with lymphocytic choriomeningitis virus, we found the Zeb2 KO CD8+ T-cells were phenotypically skewed towards a memory precursor effector CD8+ T-cell (MPEC) phenotype, with low expression of KLRG1, and the gain of IL-7R, CD27, CXCR3, and IL-2 production. The Zeb2 KO SLECs also had altered transcriptional profiles, with reduced levels of T-BET and Prdm-1 but elevated TCF-7, EOMES, and BCL-6, genes known to be critical for memory formation. In many cancer cell lines undergoing EMT Zeb2 functions in part through repression microRNAs. We found that miR-200a, miR-200b, and mir200c where all inversely expressed with Zeb2. Furthermore, overexpression of these microRNA's largely phenocopied the Zeb2 KO, and all 3 microRNAs are upregulated in the Zeb2 KO. Our work has revealed a role for the miR-200 family in inhibiting terminal differentiation in CD8+ T-cells and a role for Zeb2 in regulating the miR-200 family to promote differentiation.

W3.15.05
IL-12-mediated STAT4 signalling and T-cell receptor (TCR) signal strength cooperate in induction of CD40L in human and mouse CD8+ T cells

R. Stark[1], *A. Haese*[1], *S. Durlanik*[1], *K. Hoffmann*[1], *N. Matzmohr*[1], *D. Zehn*[2,3], *M. Frentsch*[1], *A. Thiel*[1]*;*
[1]Berlin-Brandenburg Center for Regenerative Therapies (BCRT), Charité, Berlin, Germany, [2]Swiss Vaccine Research Institute (SVRI), Epalinges, Switzerland, [3]Division of Immunology and Allergy, Department of Medicine, Lausanne University Hospital (CHUV), Lausanne, Switzerland.

CD40L is one of the key molecules bridging the activation of specific T cells and the maturation of professional and non-professional antigen-presenting cells (APCs) including B cells. Originally, CD4+ T

cells have been regarded as the major T-cell subset that expresses CD40L upon cognate activation. We could demonstrate that a putative CD8+ helper T-cell subset expressing CD40L is generated in human and mice. To analyse which conditions during priming of CD8+ T cells lead to the induction of CD40L on CD8+ T cells we cultured naïve human or mouse CD8+ T cells with a variety of cytokines produced by dendritic cells (DCs) early after activation. STAT4-mediated IL-12 signalling proved to be the major instructive cytokine signal to boost the ability of CD8+ T cells to express CD40L not only in vitro but also in vivo after immunisation with peptide loaded DCs. Furthermore, modulation of T-cell receptor (TCR) signalling strength using stimulation of OT1 CD8+ T cells with SIINFEKL or altered peptide ligand loaded APCs revealed a correlation of TCR signalling strength during priming with CD40L induction in CD8+ T cells in vitro as well as in vivo. The induction of CD40L in CD8+ T cells regulated by IL-12 and TCR signalling may enable CD8+ T cells to respond autonomously of CD4+ T cells. Thus, we propose that under proinflammatory conditions a self-sustaining positive feedback loop could facilitate the efficient priming of T cells stimulated by high affinity peptide-displaying APCs.

W3.15.06
Survival of CD8 memory T cell precursors depends on NKG2D mediated PI3K signaling and Mcl-1 induction

F. M. Wensveen[1], *M. Lenartić*[1], *V. Jelenčić*[1], *N. A. W. Lemmermann*[2], *A. ten Brinke*[3], *S. Jonjić*[1], *M. Colonna*[4], *B. Polić*[1];
[1]*Univ. of Rijeka, School of Medicine, Rijeka, Croatia,* [2]*Johannes Gutenburg Univ., Mainz, Germany,* [3]*Sanquin Research, Amsterdam, Netherlands,* [4]*Washington Univ. School of Medicine, St.Louis, MO, United States.*

Memory formation of activated CD8 T cells is the result of a specific combination of signals that promote long-term survival and inhibit differentiation into effector cells. Much is known about initial cues that drive memory formation. Which signals are essential during the intermediate stages before terminal differentiation, however, is poorly understood. We show that the activating co-receptor NKG2D controls formation of CD8 memory T cells by promoting survival of precursor cells. We demonstrate that NKG2D enhances PI3K signaling in a specific phase of memory cell commitment. This phase characterizes a transition stage from IL-2 to IL-7 dependency, during which activated cells highly rely on NKG2D-signaling for their survival. NKG2D-induced PI3K signaling is essential for the induction of pro-survival protein Mcl-1 and precursor cell survival. NKG2D-deficiency results in reduced memory cell formation and impaired protection against re-infection. Our findings show a new role for PI3K and NKG2D in an underappreciated stage of effector to memory transition that is essential for the generation of efficient long-term anti-viral protection.

It was recently reported by the present team that 3β-hydroxysterol Δ24-reductase (DHCR24) is induced by hepatitis C virus (HCV) infection. In addition, upregulation of DHCR24 impairs p53 activity. In human hepatoma HuH-7 cells, the degree of DHCR24 expression is higher than in normal hepatic cell lines (WRL68) at the transcriptional level. The genomic promoter sequence of DHCR24 was characterized and nucleotide substitutions were observed in HuH-7 cells at nucleotide numbers -1453 (G to A), -1420 (G to T), - 488 (A to C) and -200 (G to C). The mutations of these sequences from HuH-7 cell types to WRL68 cell types suppressed DHCR24 gene promoter activity. The sequences were further characterized in hepatocytes from patient tissues. Four tissues from HCV-positive patients with cirrhosis or hepatocellular carcinoma (#1, 2, 3, and 5) possessed HuH-7 cell type sequences. Interestingly, one patient with liver cirrhosis (#4) possessed WRL68 cell-type sequences; this patient had been infected with HCV and was HCV negative for 17 years after interferon therapy. Next, the effect of HCV infection on these polymorphisms was examined in humanized chimeric mouse liver and HuH-7 cells.
The human hepatocytes possess WRL68 cell type and did not show the nucleotide substitution after HCV infection. The HCV-replicon was removed by interferon treatment and established the cured K4 cells. These cells possess HuH-7 cell type sequences. Thus, this study showed the genomic polymorphism in DHCR24 promoter is not directly influenced by HCV infection.

W4.01.01
Suppressor of cytokine signalling (SOCS) 4 is a critical regulator of the anti-viral immune response

L. Kedzierski[1,2], *E. Linossi*[1,2], *N. Bird*[3], *B. Day*[3], *T. Kolesnik*[1,2], *G. Belz*[1,2], *B. Kile*[1,2], *N. Nicola*[1,2], *K. Kedzierska*[3], *S. Nicholson*[1,2];
[1]*Walter and Eliza Hall of Medical Research, Parkville, Australia,* [2]*Department of Medical Biology, University of Melbourne, Parkville, Australia,* [3]*Department of Microbiology and Immunology, University of Melbourne, Parkville, Australia.*

The suppressors of cytokine signalling (SOCS) proteins are negative regulators of cytokine signalling, immune cell development and function, and the inflammatory response. SOCS1-3, CIS and to some extent SOCS5-7 have defined roles in controlling the magnitude of response of various cytokines including interferons, IL-12, IL-10, gp130, G-CSF, prolactin, growth hormone, insulin, IL-4, and IL-2. SOCS4 is the last remaining SOCS protein for which there is no described biological role or intracellular target. Given the important role of other SOCS proteins in controlling the immune response and the expression of SOCS4 in the haematopoietic system, we have investigated its role during infection. Using a murine influenza model

we have demonstrated that mice lacking functional SOCS4 protein (*socs4*$^{108/108}$) show greater susceptibility to viral infection. *socs4*$^{108/108}$ mice have exacerbated symptoms of infection including substantially increased weight loss, linked to dysregulated cytokine and chemokine production in the lungs. SOCS4-deficeint mice also have delayed viral clearance associated with impaired trafficking of influenza specific CD8$^+$ T cells. *In vitro*, *socs4*$^{108/108}$ CD8$^+$ T cells display defective proliferation upon T cell receptor stimulation indicating defective TCR signalling. Investigation of candidate SOCS4 interacting partners by affinity purification and mass spectrometry identified an adapter protein involved in TCR signalling as a putative target, further implicating SOCS4 in regulating viral responses. This is the first demonstration of a functional phenotype for SOCS4-deficient mice and suggests that SOCS4 plays a role in immune regulation during infection. We postulate that SOCS4 is a critical regulator of the anti-viral response.

Viral infection triggers IFN-β gene induction upon recognition of viral RNA and subsequent activation of transcription factors IRF-3/7 and NF-κB. Secreted IFN-β stimulates antiviral gene expression via the IFN-α receptor. IFN-β expression is heterogeneous, however, the contribution of cellular signalling is unknown. Here, we visualize dynamics of IFN signalling at cellular and subcellular resolution with BAC-encoded reporter genes and chimeric transcription factor-fluorescent proteins. We find stochasticity on multiple layers of the IFN system. While viral dose impacts on IFN expression frequency, variation of expression timing appears stochastic and largely independent of viral influence. Sister cells reveal quick randomization of response timing to viral infection. To elucidate underlying mechanisms of stochastic IFN gene expression we quantitatively analyze signalling dynamics of IRF-3, NF-κB and the mitochondrial adaptor MAVS.
The IFN-stimulated response within a cell population exhibits bimodality at suboptimal concentrations as revealed by IRF-7 reporter gene expression and validated for other IFN-stimulated genes. We find the frequency of IFN-stimulated expression increasing in a dose-dependent manner. Consequently, upon viral infection the fraction of cells responding to IFN is protected whilst non-responders are not.
Our multi-scale mathematical model suggests that despite temporal variability of IFN-β production, the signal amplifies by paracrine stimulation into an all-or-nothing protective state of the population.
Thus, we hypothesize antiviral response control by tuning expression frequency of IFN-β and IFN-stimulated genes coupled with multiple stochastic signalling components controlling timing of IFN-β. These findings deepen our understanding how cell-to-cell variability can regulate innate immunity at the population level.

Serological diagnosis of Pepino mosaic virus with new generated monoclonal antibodies

A. Souiri[1,2,3], *M. M. Ennaji*[1], *H. Laatiris*[3], *S. Amzazi*[2], *M. Zemzami*[3];
[1]*Laboratory of virology and hygiene & Microbiology, Faculty of Science and Technology, University Hassan II, Mohammedia-Casablanca, Morocco,* [2]*Laboratory of Biochemistry and Immunology, Faculty of Science University of Mohammed V, Rabat, Morocco,* [3]*Laboratory of sanitary control, Agricultural Domain Group, Sale, Morocco.*

Pepino Mosaic Virus (PepMV), monopartite RNA virus, belonging to Flexiviridae and potexvirus group is highly infectious and easily transmissible. Its economic impact is major for the tomato producer's countries. Prevention, based on early virus detection is the only effective control measure. Monoclonal antibodies appeared to be very useful tools. We used hybridomas technique to generate monoclonal antibodies, by fusing B cells of immunized BALB/C mice to PepMV and myeloma cells.
The aim of this work is to produce in Morocco hybridomas producers of Mab that could be used for ELISA. In the same time, these efforts will serve to decrease expenses of producers concerning phytosanitory control. We obtained 16 hybridomas lines producers of Mab specific for PepMV. They were tested for efficiencies in ELISA and 2 lines were retained for production of Mab on large scale 1B11-G10 and 5A1- G5. Isotyping of these 2 lines was carried out using Ouchterlony double diffusion; both clones are of the IgG1 isotype. The conjugation of these two antibodies to alkaline phosphatase has been verified by DAS-ELISA.
These antibodies will enable to diagnose the disease from infected tomato plants, integrating several serological tests to control it in field and target the actions of struggles.

W4.01.04
An identical miRNA of the human JC and BK polyoma viruses targets the stress-induced ligand ULBP3 to escape immune elimination

Y. Bauman, *O. Mandelboim;*
Hebrew University, Jerusalem, Israel.

The human polyoma viruses JC virus and BK virus establish asymptomatic persistent infection in 65%-90% of humans but can cause severe illness under immunosuppressive conditions. The mechanisms by which these viruses evade immune recognition are unknown. Here we show that a viral miRNA identical in sequence between JCV and BKV targets the stress-induced ligand ULBP3, which is a protein recognized by the killer receptor NKG2D. Consequently, viral miRNA-mediated ULBP3 downregulation results in reduced NKG2D-mediated killing of virus-infected cells by natural killer (NK) cells. Importantly, when the activity of the viral miRNA was inhibited during infection, NK cells killed the infected cells more efficiently. Because NKG2D is also expressed by various T cell subsets, we propose that JCV and BKV use an identical miRNA that targets ULBP3 to escape detection by both the innate and adaptive immune systems, explaining how these viruses remain latent without being eliminated by the immune system.

W4.01.05
CD4+T cells modulate Epstein-Barr virus (EBV) latency types

N. Nagy, *F. Heuts, D. Salamon, M. Adori, A. E. Rasul, H. S. Madapura, M. Rottenberg, G. Klein, E. Klein;*
Department of Microbiology, Tumor and Cell Biology, Karolinska Institute, Stockholm, Sweden.

Following infection with EBV, the virus is carried for lifetime in the memory B cell compartment in a silent state (latency I/0). These cells do not resemble the proliferating lymphoblastoid cells (LCL, latency III) that are generated after infection.
It is of fundamental significance to identify how the different EBV latencies are established. In view of the prompt response of CD4+T cells in primary EBV infection and their role in B cell differentiation, we studied the involvement of CD4+T cells in the regulation of EBV latency.
Co-culture of LCLs with activated CD4+T cells led to changes in viral protein expression, indicating a shift from latency III to the less proliferating latency II. This effect was mediated by soluble factors. IL21 and soluble CD40L are two of the responsible cytokines.
To study the in vivo establishment of latency, we infected humanized mice (NOD/SCID/IL2R-/- mice engrafted with human CD34+ HSC) with EBV. Q-PCR analysis of viral promoters confirmed that besides latency III, other latencies were also present in the splenocytes of the infected mice. Depletion of CD8+T cells (leading to higher numbers of CD4+T cells) lead to about 4 times higher relative Q promoter activity (used in latency II and I) compared to mice with unmanipulated T cells. On the other hand, depletion of CD4+T cells was associated with the lack of Qp activity in the majority of mice. Thus, both our in vitro and in vivo experiments suggest that CD4+T cells contribute to the establishment of type II/I latency.

W4.01.06
HSV-2 regulates inflammatory response in the vaginal epithelium via the Fas/FasL pathway

***M. Krzyzowska**, P. Orlowski, W. Stankiewicz;*
Military Institute of Hygiene and Epidemiology, Warsaw, Poland.

Introduction. The role of Fas/FasL in the development of mucosal epithelium lesions and regulation of the early immune response during sexually transmitted diseases, such as HSV-2 infection has been poorly investigated. Here we define the role of Fas/FasL in maintaining the mucosal epithelium integrity and launching local immune response.
Materials and methods. Fas (lpr) and FasL (gld) knock-out mice with C57BL background were infected intravaginally with HSV-2. The vaginal tissues were used for detection of apoptosis, phenotyping of immune competent cells, determination of virus titers, and expression of selected cytokines and chemokines as well as anti- and proapoptotic proteins.
Results. Infection of Fas and FasL-deficient mice resulted in the increased accumulation of inflammatory cells, but also Tregs within the infected vaginal epithelium, followed by decreased recruitment of monocytes, NK and CD8+ T cells, in parallel with decreased production of CXCL9 and TNF-α. Fas (-) and FasL (-) mice showed delayed virus clearance from the infected vaginal tissue. Furthermore, lack of Fas or FasL increased the percentage of apoptotic, HSV-2 infected cells due to the activation of caspase-9 in comparison to HSV-2 infected C57BL6 wild type strain at early stage of infection. Additionally, Fas and FasL-deficient mice showed a significant decrease in the anti-apoptotic Bcl-2 protein expression.
Conclusion. Fas/FasL pathway in the HSV-2 infected vaginal epithelium participates in regulation of inflammatory response and further recruitment of immune competent cells by influencing production of chemokines and cytokines

W4.01.07
Evolution of neutralizing antibodies against HIV-1C gp160 molecular envelope clones from acute heterosexually acquired HIV-1C infections in Botswana

***T. Mduluza**[1], K. Bedi[2], S. Dzoro[2], W. Mpoloka[2], R. Musonda[3];*
[1]University of Zimbabwe, Harare, Zimbabwe, [2]University of Botswana, Gaborone, Botswana, [3]Botswana AIDS Partnership, Gaborone, Botswana.

Thirty years after the discovery of HIV, there is still no potent and efficacious vaccine against the infection. The recent discovery of potent and broad neutralizing antibodies against HIV-1 has revived the interest in the search for more of these antibodies and to investigate their possible role in preventing the infection. A cohort of eight HIV-1C acutely infected individuals were enrolled and followed for a period more than 24 months. Plasma samples were collected at different time points during the follow-up and stored at -80ºC. Viral RNA was extracted from the plasma of these individuals collected at or around baseline as well as 6 months post enrolment and envelope protein, glycoprotein 160, amplified. The HIV-1C envelope gene from these individuals was cloned into pcDNA3.1D/V5-His expression vector. The envelope clones were subsequently used to co-transfect 293 T cells along with a backbone vectors to produce pseudoviruses. A standardised neutralization assay based on TZM-bl cells was used to determine the autologous neutralizing capacity. All but one individual's envelope pseudotyped viruses were neutralised by some of the autologous plasma albeit very late. Viruses generated for individuals displayed varying neutralization sensitivities towards autologous plasma. Potency of the neutralization increased with time. Neutralizing antibody development lags behind as evidenced by the lack of neutralizing capacity of the contemporaneous plasma. HIV-1C neutralizing antibodies develop much later, around 5 months, with significant potency increasing at around 2 years post infection. This gives interesting pointers to HIV vaccine development and design for prevention.

W4.01.08
Dual deletion of type I and type II interferon-binding proteins in NYVAC-HIV-1 Env-Gag-Pol-Nef poxvirus vaccine vectors markedly improves vector immunogenicity

***J. Delaloye**[1], A. Filali-Mouhim[2], M. Cameron[2], E. Haddad[2], M. Esteban[3], G. Pantaleo[4], T. Roger[1], R. Sékaly[2], T. Calandra[1];*
[1]Infectious Diseases Service, Centre Hospitalier Universitaire Vaudois and University of Lausanne, Lausanne, Switzerland, [2]Vaccine and Gene Therapy Institute, Port St Lucie, FL, United States, [3]Centro Nacional de Biotecnología,CSIC, Madrid, Spain, [4]Division of Immunology and Allergy, Centre Hospitalier Universitaire Vaudois and University of Lausanne, Lausanne, Switzerland.

Background: NYVAC, a replication deficient derivative of the Copenhagen vaccinia virus used, is a safe and immunogenic HIV vaccine vector. Deletion of immune evasion genes is an attractive strategy for improving NYVAC immunogenicity. Our aim was to characterize the innate immunological profile of NYVAC expressing the HIV-1 clade C env-gag-pol-nef genes (NYVAC-C) with single or double deletion of genes encoding type I (ΔB19R) or type II (ΔB8R) IFN-binding proteins. Methods: Human monocytes were infected with NYVAC-C, ΔB19R or ΔB8RB19R. Gene arrays and biological pathways were analyzed using the Illumina BeadChips and Ingenuity Pathway Analysis. Cytokines were quantified by RT-PCR, Western blot and ELISA. Proliferation of allogenic CD4-T cells was measured by H3-incorporation. Results: Transcriptomic analyses of monocytes infected with NYVAC-C, ΔB19R and ΔB8RB19R revealed a concerted up-regulation of innate immune pathways (IFN-stimulated genes-ISGs) of increasing magnitude with ΔB19R and ΔB8RB19R relative to NYVAC-C. Deletion of *B8R* or *B19R* enhanced activation of IRF3, IRF7 and STAT-1 and production of IFNs whose expressions were inhibited by anti-type I IFN antibodies. ΔB8RB19R induced the production of much higher levels of pro-inflammatory cytokines than NYVAC-C or ΔB19R and a strong inflammasome response. Consistent with these findings, ΔB8RB19R-infected monocytes induced stronger type I IFN-dependent and IL-1b-dependent allogenic CD4-T cell responses than NYVAC-C or ΔB19R. Conclusions: Deletion of type I and II IFN evasion genes in NYVAC markedly enhanced its immunogenic properties via an increased expression of type I IFNs and IL-1b and make it an attractive candidate HIV vaccine vector.

W4.01.09
A novel mechanism of HTLV-1-associated mylopathy/tropical spastic paraparesis (HAM/TSP) pathogenesis

***A. Pishdadian**[1], J. Tavakkol Afshari[1], M. Foroughi Poor[2], A. Zamani[3];*
[1]Immunobiochemistry Lab, Bu-Ali research institute, Mashhad University of Medical Sciences, Mashhad, Iran, [2]Neurology Department, Ghaem Hospital, Mashhad University of Medical Sciences, Mashhad, Iran, [3]Immunology Department, School of Medicine, Hamedan University of Medical Science, Hamedan, Iran, Hamedan, Iran.

Human T cell leukemia virus type 1 (HTLV-1), is etiologic agent of HTLV-1 associated myelopathy/tropical spastic paraparesis (HAM/TSP), a slowly progressive neurologic disease. Soluble form of Fas (sFas) molecule implicate in Fas signaling, suggesting a role in some pathogenesis. We hypothesized that existence of sFas might cause partial resistance against Fas-mediated apoptotsis seen in HAM/TSP patients.
Twenty people of each HAM/TSP patient, asymptomatic HTLV-1 carrier (AC) and healthy volunteer groups, who were followed at HTLV-1-Clinic of Ghaem Hospital, were chosen. Gene expression (using semi-quantitative reverse transcriptase-polymerase chain reaction (RT-PCR)) and serum protein level (using a highly sensitive enzyme-linked immunosorbent assay (ELISA)) of sFas in each three subject groups were evaluated.
The Mean sFas serum level in patients (0.389 ng/ml) was significantly higher than healthy individuals (0.131 ng/ml) ($p<0.05$). There were no significant differences between HAM/TSP patients and ACs (0.253 ng/ml) ($p=0.17$) and also no significant differences between AC and healthy groups ($p=0.16$).
Although the mean sFas gene expression in patients (0.456) was higher than both carriers (0.304) ($p=0.35$) and control individuals (0.221) ($p=0.15$), and also in carriers was higher than controls ($p=0.6$), but these differences were not statistically significant. There

was no significant difference and correlation between sFas serum level and gene expression in each three subject groups.
These results suggest that sFas may play an important role in the pathogenesis of HAM/TSP and that serum sFas may be related to clinical activity in HAM/TSP patients, but the source of the elevated serum sFas in HTLV-1 infected patients remains unclear.

W4.01.10
Molecular characterization of immunoglobulin (Ig) genes reveals that plasmablasts generated during heterologous secondary dengue infections and circulating memory B cells after recovery are of distinct origin

R. Appanna[1], *M. H. Xu*[1], *V. Hadinoto*[1], *K. Joensson*[1], *Y. X. Toh*[1], *T. Balakrishnan*[1], *Y. S. Leo*[2], *C. Wang*[1], *K. Fink*[1];
[1]*Singapore Immunology Network (SIgN), Singapore, Singapore,* [2]*Department of Infectious Diseases, Communicable Disease Centre,Tan Tock Seng Hospital, Singapore, Singapore.*

Memory B cells generated after exposure to dengue viral (DENV) infection are a central component in shaping immune memory. However, re-exposure to dengue virus of a different serotype is often associated with an increased disease pathogenesis. During repeated infection, the rapid activation of memory B cells leads to the generation of massive amounts of cross-reactive antibodies. In the acute phase of a secondary infection, this B cell memory pool probably outcompetes the newly generated virus specific B cells. To characterize the specificity of plasmablasts and memory B cells generated during and after acute infection, we performed single cell RT-PCR for sequence analysis of Ig variable regions. Surprisingly, we found that memory B cells isolated one month after disease were of different genetic composition than acute phase plasmablasts. Our data reveal preferential usage of the Ig heavy chain variable region gene VH1 in DENV binding plasmablasts. In contrast, VH3 family repertoires were noted in specific long lasting circulating memory cells isolated over a month after infection. The antibodies isolated from these memory B cells had a broad reactivity, with only 30% being specific to DENV envelope (E) protein, whereas 70-80% plasmablasts were specific to E protein. Whether VH gene usage differs in primary and secondary infected patients and reflects a specific antigen/epitope selection is currently under investigation. This study can help to understand immune mechanism of protection for potential application in vaccination.

W4.01.11
Chronic viral infection alters subnuclear localization of PD-1 and L-selectin loci linked to transcriptional programming in LCMV-specific CD8 T-cells

C. Sacristan[1], *B. A. Youngblood*[2], *J. X. Xu*[2], *P. Lu*[2], *K. McGary*[1], *S. L. Hewitt*[1], *J. A. Skok*[1], *J. M. Boss*[2], *R. Ahmed*[2], *M. L. Dustin*[1];

Mechanisms that mediate changes in transcriptional regulation during differentiation of long-lived memory T-cells during infection remain poorly understood. During chronic viral infection, CD8 T-cell differentiation yields a unique transcriptional profile: T-cell exhaustion. The suboptimal effector function of exhausted cells is partly due to sustained expression of the inhibitory receptor PD-1. Using the lymphocytic choriomeningitis virus mouse model of infection, we examined pdcd1 (PD-1) and sell (L-selectin) gene regulation at different stages of T-cell differentiation. We hypothesized that epigenetic programming and nuclear localization of these genes were coupled to viral persistence and T-cell differentiation. Changes in gene expression are accompanied by patterns of locus conformation and positioning of genes relative to specific compartments such as nuclear lamina (silencing). Using DNA-FISH, we report a significant decrease in pdcd1 alleles associated to nuclear lamina in exhausted cells relative to other CD8 T-cell subsets (permissive). Dissociation from nuclear lamina was consistent with upregulated expression of PD-1 mRNA and protein, and with loss of PD-1 DNA methylation in exhausted cells. In contrast, we observed a significant increase in sell alleles associated to nuclear lamina with exhaustion (repressive), which mirrored changes in sell gene expression. CD8 T-cells from Blimp-1-deficient chronically infected mice exhibited an impaired ability to regulate pdcd1 and sell association to lamin, thus implicating Blimp-1 in modulating gene expression of both PD-1 and L-selectin during chronic infection. Our findings contribute to the understanding of the molecular pathways mediating T-cell memory and exhaustion, and may provide insight into implementing therapeutic strategies to resolve chronic infections.

The anti-apoptotic protein Mcl-1 is essential for the CD8 T cell response upon chronic viral LCMV infection

E. Ottina[1], *S. P. Preston*[2], *A. Strasser*[2], *M. Pellegrini*[2], *A. Villunger*[1];
[1]*Biocenter, Innsbruck Medical University, Innsbruck, Austria,* [2]*Walter & Eliza Hall Institute for Medical Research, Melbourne, Australia.*

Chronic infections with viruses such as hepatitis B virus, hepatitis C virus or HIV are in endemic steady state in the world population, constituting a major global public health problem. Studies of chronic viral infections in humans and mice show that persistent antigenic stimulation induces deregulation of T cell responses by a process called T cell exhaustion that culminates in deletion of virus-specific T cells. The ability to generate and retain sufficient numbers of functionally competent T cells relays on the balance between T cell proliferation and apoptosis. Apoptosis is regulated by the interplay of pro-survival and pro-apoptotic molecules of the Bcl-2 family. In particular a pro-apoptotic protein of the family, Bim, has been implicated in the deletion of virus-specific CD8 T. However is still unknown which of the pro-survival Bcl-2 family members is neutralized by Bim to mediate deletion of cytotoxic T cells.
The aim of this project is to determine the role of the anti-apoptotic protein Mcl-1 in promoting CD8+ T cell responses upon chronic viral infection. To address this question we infected Mcl-1 haploinsufficient mice with LCMV docile, which causes chronic infection in mice. Indeed infected Mcl-1+/- mice show a reduction of viral-specific CD8+ T cells and reduced viral elimination in Mcl-1+/- mice. These data indicate that Mcl-1 is essential for the CD8+ T cell response upon chronic viral infection.
We propose that pharmacological targeting of Mcl-1, e.g. during anti-cancer therapy, may cause enhanced susceptibility to viral infection as one possible side effect.

Pregnancy-induced deviation of chemokine/cytokine serological levels during influenza virus AH1N1 infection

L. A. Flores-Mejía[1,2], *I. Mancilla-Herrera*[2,1], *E. D. Cerezo*[2,1], *A. Cérbulo-Vázquez*[3], *E. Ferat-Osorio*[2], *C. R. López-Macías*[2], *A. Isibasi*[2], *L. A. Arriaga-Pizano*[2];
[1]*Instituto Politécnico Nacional, ENCB, México City, Mexico,* [2]*Unidad de Investigación Médica en Inmunoquímica, Hospital de Especialidades. Centro Médico Nacional Siglo XXI, IMSS, México City, Mexico,* [3]*Instituto Nacional de Perinatología "Dr. Isidro Espinosa de los Reyes, México City, Mexico.*

Introduction: For seasonal and pandemic influenza, pregnancy is one of the major risk factors for severe complications. It has been hypothesized this is related with the "tolerant" state needed for pregnancy maintenance, which include diminished inflammatory cytokine production. Interestingly, for high virulence influenza virus, fatal complications among young people seem to be related with hypercytokinemia, which may not occur in pregnant women. We decided to establish if there were differences in serological cytokine-chemokine levels from pregnant and non-pregnant women infected with influenza virus pdm2009.
Methods: Serum was obtained from pregnant (n=10) or non-pregnant women(n=14) infected with influenza virus AH1N1 pdm2009. None of the patients required hospitalization. As control, serum samples from clinically healthy women(n=7) were included. chemokines/cytokines (TNFa, IL-6, IL-8, MCP-1, MIG, IP-10)quantification was made using cytometric bead array system for flow cytometry.
Results: When pregnant and non-pregnant healthy women are compared with influenza infected pregnant and non-pregnant women, non-pregnant patients showed diminished TNFa and IL-10 serological levels (TNF: 54.1+/-13.6pg/mL vs 3.5+/-2.6pg/mL; IL-10: 37.5+/-

13.6pg/mL vs 7.4+/-7.3pg/mL). For chemokines, pregnant women showed diminished, MCP-1, MIG and IP-10 concentrations compared with non-pregnant infected women (MCP-1: 153.0+/-160.2pg/mL vs 974.7+/-1256.2pg/mL); (MIG: 243.5+/-208.9pg/ml vs. 2748.2+/-1665.8pg/mL) (IP-10: 308.4+/-223.0pg/mL vs. 4270.8+/-1371.8pg/mL).
Conclusion: Pregnancy deviates cytokines/chemokines responses induced by AH1N1 pdm2009 influenza infection, with exacerbated inflammatory responses but less leucocyte migration capabilities to infected tissues.

W4.01.14
Spred-2 deficiency exacebates Influenza A Virus (H1N1)-induced Pneumonia

T. Ito[1]*, A. Yoshimura*[2]*, A. Matsukawa*[1]*;*
[1]*Department of Pathology and Experimental Medicine, Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama University, Okayama, Japan,* [2]*Department of Microbiology and Immunology, Keio University School of Medicine, Tokyo, Japan.*

Influenza A (H1N1) viral infections have been identified as the etiologic agents for historic pandemics, and contribute to the annual mortality associated with acute viral pneumonia. Many studies have elucidated the functions of H1N1-viral proteins of this negative-strand RNA virus have been well elucidated. However, the virus-induced intracellular signaling events remain unknown. The Raf/MEK/ERK cascade is the prototype of mitogen-activated protein (MAP) kinase cascades and has an important role in cell growth, differentiation, and survival. The Sprouty-related Ena/VASP homology 1-domain-containing protein (Spreds) has recently been identified as a negative regulator of Raf-dependent ERK activation. Here, we demonstrated that Spred-2-knockout (KO) mice led to higher mortality compared with wild-type (WT) mice during influenza A (H1N1) viral infection. Spred-2 KO mice showed more severe pneumonia with increased number of neutrophils in bronchoalveolar lavage. Whole lungs from Spred-2 KO mice had significantly higher levels of Type-I interferon (IFN-α and IFN-β) and pro-inflammatory cytokine (IL-6) in comparison to WT mice. Moreover, the administration of U0126, MEK inhibitor, improved the survival with decreased virus titers and cytokines in mice during influenza A (H1N1) viral infection. Together, the results of this study show that Spred-2 negatively regulates the development of anti-viral immunity and has an effect on abrogated cytokine balance through Raf/MEK/ERK pathway. We propose these regulations of intracellular signaling through Spred-2 during influenza viral infection might provide mechanistic approaches for modifying and controlling the immune response against influenza H1N1 virus infection.

IL4.02.01
Innate Sensing A Virus Designed Not To Be Seen

F. V. Chisari*;*
The Scripps Research Institute, La Jolla, CA, United States.

Viral nucleic acids often trigger an innate immune response in infected cells. Many viruses, including hepatitis C virus (HCV), have evolved mechanisms to evade intracellular recognition. Despite this, HCV triggers a robust interferon-stimulated gene (ISG) response in the infected liver. In an attempt to reconcile these apparently contradictory observations, we discovered that HCV-infected cells and HCV subgenomic replicon cells can trigger a viral RNA-, TLR7- and cell contact-dependent interferon response in nonpermissive plasmacytoid dendritic cells (pDCs). Here we report that these events are mediated by transfer of HCV RNA-containing exosomes from infected cells and subgenomic replicon cells to pDCs. In contrast, pDCs are not stimulated by infectious virus particles, even after very high multiplicity inoculation. Exosomal viral RNA transfer is dependent on the endosomal sorting complex (ESCRT) machinery and on Annexin A2, an RNA-binding protein involved in membrane vesicle trafficking, and it is suppressed by exosome release inhibitors. Further, purified concentrated HCV RNA-containing exosomes are sufficient to activate pDCs. Thus, vesicular sequestration and exosomal export of viral RNA may serve both as a viral strategy to evade pathogen-sensing within infected cells and as a host strategy to induce an unopposed innate response in replication-nonpermissive by-stander cells.

IL4.02.02
NK cells and HCV: a complex and controversial relationship

M. U. Mondelli*, S. Varchetta, B. Oliviero, S. Mantovani, D. Mele;*
Research Laboratories, Department of Infectious Diseases, Fondazione IRCCS Policlinico San Matteo and Department of Internal Medicine, University of Pavia, Pavia, Italy.

NK cells are important antiviral effectors of innate immunity either via direct killing of infected cells or cytokine (namely IFN- and TNF-) release, and are controlled by a complex network of signals which interact with membrane-expressed, germline-encoded, inhibitory and activating receptors. NK cell responses are readily generated during acute HCV infection and persist through chronic infection. Despite the availability of standardized reagents, studies on NK cells in HCV infection have generated controversial findings in the past recent years. Current evidence suggests that peripheral NK cells are polarized towards cytotoxicity and that interferon-gamma secretion is deficient in chronic HCV infection, consistent with a functional dichotomy and a consequent inability to control the virus through non-cytolytic mechanisms. However, intrahepatic NK cells display an exhausted phenotype characterized by reduced TRAIL expression and degranulation ability which may also contribute to viral persistence. Consistent with this view, exposure of healthy donors' NK cells to culture-derived HCV resulted in significant TRAIL upregulation and degranulation, whereas this was not observed using NK cells from patients with chronic HCV infection. Recent findings also suggest that early NK cell activation following administration of IFN- based therapies is associated with sustained virological response and that the NK perforin content play a role in response to antiviral treatment. Collectively, this data underlines the importance of innate immune cells in controlling HCV infection and provides new translational applications in this setting.

W4.02.01
Dynamic changes in the liver upon persistent viral infection

A. Bhattacharya, J. Colinge, K. Bennett, ***A. Bergthaler****;*
Research Center for Molecular Medicine (CeMM) of the Austrian Academy of Sciences, Vienna, Austria.

Persistent viral infections such as hepatitis C and hepatitis B pose a great challenge for human health. Yet, the molecular mechanisms of viral pathogenesis remain poorly understood. This is in part due to the inherent complexity of the involved multi-layered host-pathogen interactions as well as due to experimental limitations. Here we adopted the lymphocytic choriomeningitis virus mouse model, which provides a pathophysiologically relevant and versatile experimental benchmark system, to study virus-induced changes and chronic inflammation in the liver upon persistent infection. Using RNAseq and iTRAQ protein mass spectrometry we identified extensive dynamic changes in the liver transcriptome and proteome over a period of more than 60 days after infection. We integrated these systems-wide data with virological readouts, immunohistopathology and bioinformatical network analysis in order to delineate key molecular events and pathways that govern and precede virus-induced liver immunopathology. This model approach shall contribute to the identification of novel general principles of host-virus interactions relevant to persistent viral hepatitis in man.

CD8+ T cells are of critical importance to prevent chronic viral infections because they not only promote virus elimination, but also induce virus mediated immunopathology. Elevated levels of reactive oxygen species (ROS) have been reported during virus infections. However, the role of ROS in T cell mediated immunopathology remains unclear. Here we used the murine lymphocytic choriomeningitis virus to explore the role of ROS during the processes of virus elimination and induction of immunopathology. We found that virus infection led to elevated levels of ROS producing granulocytes and macrophages in virus infected liver and spleen tissue that was triggered by the NADPH oxidase. Lack of the regulatory subunit p47phox of the NADPH oxidase diminished ROS production in these cells. While CD8+ T cells exhibited ROS production that was independent of NADPH oxidase expression, survival and T cell function was elevated in p47phox deficient (Ncf1-/-) mice. In the absence of p47phox, enhanced T cell immunity promoted virus elimination and blunted corresponding immunopathology. In conclusion, we find that NADPH-mediated production of ROS critically impairs the immune response, impacting elimination of virus and outcome of liver cell damage.

W4.02.03
Cellular inhibitors of apoptosis (IAPs) play a critical role in the host response to hepatitis B virus and their repression promotes viral clearance

G. Ebert*, S. Preston, C. Allison, J. Toe, J. Cooney, H. Scott, M. Pellegrini;*
The Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia.

Background: Pattern recognition receptors, TNF-alpha (and other death receptors), and IL-1 are involved in inflammation, apoptosis, necroptosis and pyroptosis signalling. These processes are critical regulators of innate and adaptive immune responses to infectious diseases. IAPs form the central hub that modulate inflammatory and death signalling and we hypothesised that they determine the host responses to hepatitis B infection (HBV). HBV uses several strategies to antagonise immunity and cell death allowing persistence of its transcriptional matrices called covalently closed circular (ccc) DNA within hepatocytes. The aim of our study was to investigate the role of IAPs in HBV infection.
Design: We used a combination of gene-targeted mice and compound mutant mice, small drug molecules that target IAPs, and a highly novel mouse model of HBV. The model recapitulated HBV chronicity with HBV viremia persisting beyond 8 weeks and innate and adaptive immunity were critically required to control infection.
Results: Modulation of IAP function, through gene-targeting or the use of small molecule drugs profoundly affected host control of HBV and its elimination. As early as three days post drug treatment, mice showed a substantial log reduction in viral loads.
Conclusion: Using a novel mouse model we show that IAPs are central regulators of host responses to HBV and they are critical determinants of infectious outcomes.

Imaging the innate immune response to viral infection: neutrophils, platelets, and NETs

C. N. Jenne[1], *C. H. Y. Wong*[1], *F. J. Zemp*[2], *B. McDonald*[1], *M. M. Rahman*[3], *P. A. Forsyth*[2], *G. McFadden*[3], *P. Kubes*[1];
[1]*Snyder Institute, Univeresity of Calgary, Calgary, AB, Canada,* [2]*Southern Alberta Cancer Research Institute, Univeresity of Calgary, Calgary, AB, Canada,* [3]*University of Florida, Gainesville, FL, United States.*

Through the use of intravital spinning-disk confocal microscopy, we have visualized the immune response to viral infection of the liver within live mice. Following intravenous injection of myxoma virus, we observe infection of host cells and a rapid accumulation of neutrophils in the mouse liver. These neutrophils adhere in the liver sinusoids, crawl within the vessels, and appear to probe the liver microvasculature. Neutrophils are not specifically recruited to virally infected cells, but rather, appear throughout the liver vasculature. We also observe recruitment of platelets to liver sinusoids, which associate with neutrophils, forming large aggregates. These platelet aggregates are dynamic structures, continually expanding and sloughing off, re-entering the circulation.
Using various blocking antibodies, and mice deficient for specific immune receptors and adhesion molecules we have characterized, in detail, many aspects of this early innate immune response to virus. Surprisingly, the observed platelet-neutrophil interactions led to the formation of neutrophil extracellular traps (NETs) within the liver. NETs are diffuse, web-like structures comprised of sticky, extracellular DNA decorated with histones and antimicrobial proteins. Importantly, we have demonstrated, for the first time using an *in vivo* model, the presence of NETs within the vasculature protects host cells from viral infection.
This work will provide a better understanding of the roles of, and interactions between, immune cells within the liver in response to virus and will allow for the better design of treatments to optimize the host response to viral infections.
This work is supported by the AHIS, CIHR and CFI.

W4.02.05
Tim-3/galecin-9 pathway modulates the cross talk between NK cells and CD8+ T cells in chronic hepatitis B

D. Zhao, L. Gao, X. Liang, ***C. Ma****;*
Institute of Immunology,Shandong University School of Medicine, Jinan, China.

T cell immunoglobulin and mucin domain-3 (Tim-3) has been widely known as immune regulator which plays important roles in various disease. We previously reported the repression of Tim-3 on NK cells in patients with chronic hepatitis B (CHB). In this study, we characterized the role of Tim-3 on NK-CD8+ T cells cross talk in HBV infection. We found that Tim-3 expression was significantly up-regulated on CD8+ T cells which significantly correlated with HBV viral load. Tim-3 expressing CD8+ T cells had a higher expression of activated maker CD69 but failed to produce IFN-gamma, Granzyme B, perforin or proliferate in response to HBs-antigen peptide or anti-CD3 and anti-CD28, indicating the negative role of Tim-3 on CD8+T cells. Consistently, blocking Tim-3 pathway in PBMCs enhanced HBV specific IFN-γ expression and proliferation in CD8+ T cells of CHB patients. However, blocking Tim-3 pathway didn't change HBs-stimulated IFN-γ expression of purified CD8 T cells from CHB patients. Depletion of NK cells destroyed the Tim-3 mediated suppression on HBV specific IFN-γ expression and proliferation in CD8+ T cells. Pretreatment of lactose which blocks galectins significantly increased the activity of CD8 T cells from CHB patients. In conclusion, the Tim-3-mediated suppression on CD8+T cells needs the presence of NK cells. All these findings have an implication that Tim-3 represents a new therapeutic target in chronic hepatitis B infection.
(* This study is supported in part by grants from the NSFC of China (No. 30972753 & 91129704), Programme for NCET-10-0524, and RFDP(20110131110034))

Breaking T-cell tolerance to viral antigens in a model of chronic HBV infection

M. Di Scala[1], *I. Gil-Fariña*[1], *L. Vanrell*[2], *M. Scarpino*[3], *C. Olagüe*[1], *A. Vales*[1], *M. Galarraga*[1], *L. Guembe*[1], *J. Prieto*[1], *G. González-Aseguinolaza*[1];
[1]*CIMA, Pamplona, Spain,* [2]*Universidad de la República, Montevideo, Uruguay,* [3]*Catania University, Catania, Italy.*

Chronic HBV infection is characterized by a weak and exhausted T cell response. To promote sustained viral clearance it is necessary to boost a viral specific immune response of the host. HBV transgenic mice are immunologically tolerant to HBV antigens, representing a good model to test strategies aiming at breaking T cell tolerance. Gene delivery of cytokines to the liver may represent an interesting strategy to maximize its antiviral efficacy and reduce side effects. We now provide a novel strategy to induce functional T cell in HBV transgenic mouse model based on the genetic transfer of immunostimulatory cytokines. Sustained liver specific IL-15 expression expands the population of HBV-specific CD8 T cells in spleen and the liver, as shown by pentamer lymphocyte staining. However, IL-15 expanded T cells failed to kill peptide loaded cells in an in vivo killing assay, indicating that they remained functionally silent. When IL-15 expression is combined with IFN-α, we observed an increase in the number of HBV specific T cell but more importantly those cells are functional, since they were able to kill antigen loaded cells. Furthermore a strong antiviral effect was observed. Thus, our study defines a potent new approach to brake the tolerance in a model of chronic viral infection by 1.- expanding virus-specific CD8 T cell with IL-15 and 2.- blocking negative signals with IFN-α. Such an approach may have broad applications in developing treatment strategies for chronic infections in general, and perhaps also for tumors.

W4.03 HIV pathogenesis and immunity

IL4.03.01
The Fight Between HIV Infection and Macrophage Polarization

G. Poli*;*
San Raffaele University and Scientific Institute, Milano, Italy.

HIV-1 infects CD4+ T lymphocytes and cells of the mononuclear phagocyte lineage, including dendritic cells, circulating monocytes and tissue macrophages. Unlike T cells, macrophages are resistant to the cytopathic effects of the virus and accumulate virions in intracellular compartments of debated origin. We have described already that functional polarization of human monocyte-derived macrophages (MDM) as either M1 or M2a cells (after 18 h stimulation with TNF-a and IFN-g or IL-4, respectively) results in a restricted replication of HIV-1 when compared to nonpolarized MDM. The underlying mechanisms of restriction appear to be different for M1- and M2a-MDM and involve the upregulation of factors either known or suspected to play a role in controlling virus replication and transmission to other cells. These factors include the upregulation of CCR5-binding chemokines and of the intracellular factor known as APOBEC3A in M1-MDM and of DC-SIGN expression on M2a cell surface. Overall, macrophage polarization is a transient process that likely aims at containing or eliminating HIV-1 infection either directly or by potentiating adaptive recognition of infected cells via upregulation of MHC Class II antigens on the cell surface.

Endoplasmic reticulum aminopeptidase 2 (ERAP2) haplotypes play a role in antigen presentation and resistance to HIV-1 infection

I. Saulle[1], *M. Biasin*[1], *F. La Rosa*[1], *M. De Luca*[1], *D. Trabattoni*[1], *M. Sironi*[2], *R. Cagliani*[2], *F. Mazzotta*[3], *S. Lo Caputo*[3], *M. Clerici*[1,4];
[1]*University of Milan, Milan, Italy,* [2]*Scientific Institute IRCCS E.MEDEA, Bosisio Parini, Italy,* [3]*Santa Maria Annunziata Hospital, Florence, Italy,* [4]*Fondazione Don Gnocchi, Milan, Italy.*

Background: Haplotype-specific alternative splicing of the endoplasmic reticulum aminopeptidase type 2 (*ERAP2*) gene results in either full-length (FL, haplotype A) or alternatively spliced (AS, haplotype B) mRNA. As this protein trims peptides loaded on MHC class I and CD8+ T lymphocytes play an important role in protection against viral infections, we analysed the role of this gene in resistance to HIV-infection. Methods: *ERAP2* was genotyped in a cohort of 104 Spanish HESN individuals exposed to HIV through injection drug use (IDU-HESN). PBMC isolated from 139 healthy controls (HC) grouped according to their *ERAP2* genotype were infected with HIV-1_{Ba-L} and analysed for: 1) mRNA specific for *ERAP2* and 96 genes involved in the antigen presentation pathway; 2) MHC class I MFI on CD45+ cells; 3) susceptibility to HIV infection; 4) ERAP2 protein expression. Finally, we analysed the co-segregation of *HLAB*57* with *ERAP2* haplotype in a cohort of Italian HESN. Results: Genotype analysis indicated that *ERAP2* haplotype A is associated with protection from HIV infection (meta-analysis *p* value of 7.6 x10^{-5}) and that *HLAB*57* allele is significantly more common among HESN homozygous for haplotype A (homoA). In vitro HIV-1 infection mRNA for ERAP2-FL and a number of genes involved in antigen presentation as well as of MHC class I on CD45+ cells were significantly increased in homoA cells from HC; notably, these same cells, but not isolated CD4+ cells, were less susceptible to HIV-1 infection.
Conclusions:*ERAP2* haplotype A confers resistance to HIV infection secondarily to its effect on antigen processing and presentation.

Molecular characterization of high avidity CD4+ T cells in HIV Controllers

D. Benati[1], *M. Galperin*[1], *O. Lambotte*[2], *A. Lim*[3], *B. Lemercier*[3], *S. Hendou*[4], *F. Boufassa*[4], *J. Delfraissy*[2], *F. Arenzana-Seisdedos*[1], *L. Chakrabarti*[1];
[1]*Institut Pasteur, Unite de Pathogenie Virale, Paris, France,* [2]*Hopital de Bicetre, AP-HP, Medicine Interne et Maladies Infectieuses, Le Kremlin-Bicetre, France,* [3]*Institut Pasteur, Departement d'Immunologie, Paris, France,* [4]*INSERM U822, Le Kremlin-Bicetre, France.*

Background: HIV Controllers spontaneously control HIV replication to levels undetectable by standard assays in the absence of antiretroviral treatment. We previously reported that HIV Controllers harbour a pool of memory CD4+ T cells able to respond to the immunodominant Gag293 peptide with particularly high TCR avidity. We set to functionally analyze high avidity CD4+ T cells and to characterize their TCRs at the molecular level.
Methods: HIV Controllers from the ANRS CODEX CO21 cohort (n=8) were compared to efficiently treated patients (HAART group, n=8). Primary CD4+ T cell lines were generated by stimulating PBMCs with decreasing doses of Gag293 peptide. Next, Gag293-specific CD4+ T cells were analyzed for cytokine production by IFNγ ELISPOT and for Gag293/MHC-classII tetramer binding ability. TCR diversity in sorted Gag293/Tetramer+ cells was evaluated by immunoscope analysis.
Results: Stimulation with low Gag293 peptide doses generated IFNγ-positive CD4+ T cell lines in HIV Controllers (response rate: 6/8 at 10-9M, 2/8 at 10-11M), but not in HAART patients, confirming the presence of high avidity Gag-293-specific cells in the HIV Controller group. The immunoscope analysis revealed major amplifications of certain TCR Vα and Vβ chains in the sorted tetramer+ Gag293-specific population, indicating the presence of dominant clonotypes.
Conclusion: We identified a number of TCR Vα and Vβ chains preferentially expressed by the high avidity population of Gag293-specific CD4+ T cells. Transfer of these TCRs to heterologous cells will help determine whether they are sufficient to confer the efficient Gag-specific responses characteristic of HIV Controllers.

HIV-1 infection is associated with a progressive decrease of CD4 T-cell count and an increase in viral load. However, Natural Controllers

(NC) maintain high level of CD4 and a low viral load for several years in the absence of therapy. Our study characterized the HIV-1 specific CD8 T-cells response, an important player in controlling virus replication, in three Italian cohorts with a different story of progression of HIV-1 infection. Immune-dominant Gag- and Nef-specific responses as well as Tat-response, important in the early phase of infection, have been investigated.
Chronic HIV-infected patients under therapy (CHIwT) show a significant reduction of Gag- and Nef-specific response ($p<0.05$). NCs (56.4%) show a higher frequency of Tat-responder than CHIwT (20%, $p<0.01$) and subjects naïve for therapy (Naïve, 16%, $p<0.01$), with a significant increase of Tat-specific IFN-γ producing T-cells (median 80, IQR 13-457, $p<0.05$), that correlate inversely with plasma viral load ($\rho=-0.3231$, $p=0.0346$). Fully differentiated Tat-specific CD8 T-cells (expressing CD45RA) are higher in NCs (median 0.29% of total CD8, IQR 0.2-0.54%) than Progressors (median 0.17%, IQR 0.11-0.38%, $p<0.01$), correlating inversely with viral load ($\rho=-0.4202$, $p=0.0208$). Interestingly, Tat-specific response shows a peculiar immune response patterns in NCs. CD45RA+ GzB+ IFN-γ+ MIP-1β+ CD8+ (present in 89% of NCs) and CD45RA+ GzB- IFN-γ+ MIP-1β+ CD8+ (present in 67% of NCs) subsets are absent in Progressors and cover the 10% of the total Tat-specific CD8 T-cell response ($p<0.01$).
In conclusion, Tat-specific response shows unique features in NCs: a higher magnitude and two polyfunctional CD8 subsets exclusively present in NCs.

Control of HIV replication in Elite Controllers (EC) and Long-Term Non-Progressor (LTNP) patients has been associated with features of efficient CD8+CTL function. However, innate immunity, in particular NK cells, may play a role in HIV control.
We studied the expression of Natural Cytotoxicity Receptors (NCR, NKp46,NKp30,NKp44) and their induction over a short time-frame (2-4 days) upon activation of purified NK cells in a cohort of 31 HIV-controller patients (15EC,16LTNP), 10 HIV-infected patients on ART and 10 Healthy Donors (HD).
In EC/LTNP, induction of NKp46 expression was normal but shortlasting (2days) and NKp30 was induced to lower levels vs. HD. In antiretroviral-treated aviremic progressor patients (TAPP) no induction of NKp46 or NKp30 expression occurred. EC/LTNP failed to induce expression of NKp44, a receptor efficiently induced in activated NK cells in TAPP. The specific lack of NKp44 expression resulted in sharply decreased capability of killing target cells via NKp44, while TAPP had conserved NKp44-mediated lysis. In addition, peripheral NK cells from EC/LTNP were activated as shown by significant HLA-DR expression and a mature effector phenotype (NKG2A-CD57+KIR+CD85j+), with conserved cytolytic function also against immature dendritic cells. Importantly, conserved NK cell responses, accompanied by a selective defect in the NKp44-activating pathway may result in lack of killing of uninfected CD4+NKp44Ligand+ cells that may be induced by an HIVgp41 peptide.Thus, NK cells in EC/LTNP can maintain substantially unchanged functional capabilities and actively control virus replication, while the lack of NKp44 induction may be related to CD4 maintenance, representing a hallmark of these patients.

W4.03.05
Inhibition of human immunodeficiency virus type-1 replication in CD4+ natural killer T cells by gamma-delta T lymphocytes

K. Omi*, M. Shimizu, E. Watanabe, A. Owaki, C. Takaku, E. Shinya, H. Takahashi;*
Department of Microbiology and Immunology, Nippon Medical School, Tokyo, Japan.

It has widely been accepted that human immunodeficiency virus type-1 (HIV-1) in the circulating blood in HIV-1-infected patients can be controlled by highly active anti-retroviral treatment (HAART). However, shortly after the termination of HAART, HIV-1 virions emerged in the circulating blood. The fact suggest the existence of reservoir even after the HAART. In addition, it has turned out that the majority of emerged HIV-1 is macrophage-tropic that will infect CD4+ CCR5-expressing cells. On the basis of these observations, we focused on R5-HIV-1-susceptible cells as the reservoirs during HAART. There are three distinct cell populations are known as R5-HIV-1 susceptible, such as CD4+ natural killer T (NKT) cells, dendritic cells (DC) and macrophages, and tissue-associated T cells mainly arranged at surface mucosal areas. After the extensive analysis, we found that CD4+ NKT, one of the main components of innate immunity, efficiently expanded HIV-1 in vitro and also confirmed the existence of HIV-1-infected CD4+NKT cells in the small intestine of persistently infected patients with HAART. These findings indicate that CD4+ NKT cells play an important role in HIV-1 persistency even during HAART. Here, we show that gamma-delta T lymphocytes, as innate effctors, may suppress R5-type HIV-1 replication in CD4+ NKT cells through secreting CC chemokines like macrophage inflammatory protein (MIP)-1α. These results suggest the importance of innate immunity to control HIV-1 persistency during HAART.

Immune exposure to a specific sequence of antibody escape variants could program long-term potential for neutralization breadth in subtype A HIV-1 infection

M. K. Murphy[1], *L. Yue*[1], *R. Pan*[2], *A. Sethi*[3], *E. Karita*[4], *S. A. Allen*[1], *J. E. Robinson*[5], *S. Gnanakaran*[3], *X. Kong*[2], *C. A. Derdeyn*[1];
[1]*Emory University, Atlanta, GA, United States,* [2]*NYU Langone Medical Center, New York, NY, United States,* [3]*Los Alamos National Laboratory, Los Alamos, NM, United States,* [4]*Projet San Francisco, Kigali, Rwanda,* [5]*Tulane University School of Medicine, New Orleans, LA, United States.*

Approximately one quarter of HIV-1 infected individuals will generate broadly neutralizing antibodies, but the exact mechanisms for triggering and maturation of these responses are presently undefined. We consequently investigated the roots of neutralization breadth. In a subtype A HIV-1 infected Rwandan seroconverter, we pinpointed the primary neutralizing antibody target and the successive routes of viral escape using envelope glycoproteins from the transmitted/founder virus and longitudinal escape variants along with autologous plasma and monoclonal antibodies. Initially, a single mutation at one of three clustered residues proximal to gp120's third hypervariable loop conferred viral escape. This putative epitope subsequently elicited at least two somatically related monoclonal antibodies, which bound and neutralized the established escape mutations. Resistance to this secondary wave of immune pressure then arose in later viral envelopes through introduction of two glycans that obscured this consistently targeted space. At 16-months post-infection, what had been a narrow, regional response evolved to force recognition and neutralization of distinct envelope portions, which resulted in moderate cross-clade humoral breadth. Our data suggest that unveiling a certain chain of envelope mutations could drive B cells toward the production of broadly neutralizing antibodies. Appreciating this knowledge during immunogen construction could positively impact HIV-1 vaccine design.

W4.03.07
Decrease of CD73 expressing CD8 T cells in the course of HIV infection correlates with immune activation and T cell exhaustion

I. Tóth[1], *A. Q. Le*[2], *P. Hartjen*[1], *A. Thomssen*[1], *C. Beisel*[1], *A. W. Lohse*[1], *J. Hauber*[3], *J. van Lunzen*[1], *J. C. R. Schulze zur Wiesch*[1]; [1]*University Medical Center Hamburg-Eppendorf, Hamburg, Germany,* [2]*Simon Fraser University, Vancouver, BC, Canada,* [3]*Heinrich Pette Institute Leibniz Institute for Experimental Virology, Hamburg, Germany.*

In murine models, the ectonucleotidases CD39 and CD73 play an important in-tandem role for T regulatory cell (Tregs) mediated T effector cell suppression by adenosine production. For human Tregs, an elevated expression of CD39 was shown in HIV infection. However, no studies concern the expression of CD73 on T cells in HIV infection so far.
In our study, we analyzed the expression of CD73 on peripheral and lymph nodal T effector cells and Tregs in a cohort of 101 HIV patients at different stages of disease, including long term nonprogressors (LTNP) and elite controllers (EC) and 27 healthy controls. In contrast to murine Tregs, CD73 was only expressed on a minority (ca 10%) of peripheral Tregs. In contrast, we see a high expression of CD73 on peripheral CD8+ T cells. In HIV infection CD73 is markedly reduced on all T effector and Treg cells regardless of their memory status. On CD8+ T cells, a positive correlation between CD73 expression and CD4 counts (p=0.0003) was detected. CD73 expression on CD8 T cells negatively correlated with HLA DR (<0.0001) and PD1 (p=0.0312) expression. The lower CD73 expression on CD8+ T cells was partially reversible after initiation of antiretroviral therapy (ART). Functionally, we observed that CD8+CD73+ T cells produce more IL-2 upon HIV-specific and unspecific stimulation than their CD73- counterparts and show a higher proliferative capacity. These data indicate that down regulation of CD73 on CD8+ T cells correlates with immune activation and leads to functional T cell deficits in HIV infection.

W4.03.08
Telomere length and CD38 expression on monocytes and CD8 T cells of HIV infected people

M. Tarkowski[1], *D. Misciagna*[1], *F. Strambio de Castillia*[2], *C. Gervasoni*[2], *C. Resnati*[2], *L. Ferraris*[2], *R. Piolini*[1], *M. Galli*[1], *A. Riva*[2]; [1]*University of Milan, Milan, Italy,* [2]*Ospedale L.Sacco, Milan, Italy.*

Background: Infection with HIV leads to persistent inflammation and premature immune senescence.Progression of the disease is predicted by expression of CD38 on CD8 T cells which are also known to undergo premature senescence. Evidence shows that these processes,characterized by shortening of telomeres also take place in monocytes. We sought to determine the relation between the expression of CD38 as a marker of the disease progression and the telomere length as an indicator of immunosenescence.Methods:We enrolled 38 HIV infected patients and 53 healthy patients in the study. Analyses of CD38 expression were performed on CD8+T cells and CD14+ monocytes by means of cytofluorimetry. Telomere lengths were assessed in PBMCs by RT-PCR. Results: Regardless of the clinical status of HIV infected patients,percentage of CD38+CD8+T cells and CD38+CD14+ monocytes was higher than in uninfected people(10,5 vs. 2,1%;p<0.001; 61,6 vs. 35,5%; p<0,001 respectively) and in the latter group telomere length was inversely corelated with age (R2=0,17; p=0.002). In HIV infected patients the correlation with age was not present. We show that telomere length is inversely correlated with the frequency of CD38+CD14+monocytes (R2=0,18; p=0,015),but such correlation was not found in CD8+T cells. Conclusions: We show that CD38 expression may differently mark monocytes and CD8+T cells in terms of senescence and that the percent of CD38+ monocytes is indicative of these cells undergoing senescence. We confirm recent data showing HIV induced monocyte senescence and its persistance despite antiretroviral therapy and suggest that events taking place in these cells can have different timing from those characteristic of CD8+ T cells.

W4.03.09
HIV-1 infection impairs CD34+ hematopoietic progenitor cells differentiation toward Dendritic Cells

V. Bordoni[1], *D. Viola*[1], *A. Sacchi*[1], *G. Castelli*[2], *M. Bibas*[1], *A. Ammassari*[1], *C. Agrati*[1], *A. Amendola*[1], *I. Abbate*[1], *F. Martini*[1]; [1]*INMI L.Spallanzani, Rome, Italy,* [2]*Istituto Superiore di Sanità, Rome, Italy.*

The impairment of dendritic cells (DCs) homeostasis during HIV-1 infection is central to both the spread of the infection and the progression of the immunodeficiency. Given previous indirect evidences that DCs maturation and function are impaired by HIV, we explored the possibility that HIV infection impairs CD34+ hematopoietic progenitor cells (HPC) differentiation toward DCs. In the present work, we used a culture model which allows CD34+ HPC differentiation toward monocytic lineage, and upon treatment with GM-CSF and IL-4, further switching to functional DCs. We showed that both CD34+ HPC infected in vitro by HIV, and CD34+ HPC from HIV patients undergoing cART, were found unable to generate DCs, suggesting that an HIV-1-induced impairment of CD34+ differentiation may play a key role in decreased DCs frequency observed in vivo. The absence of replicating HIV-1 in differentiation studies of CD34+ HPC from chronic patients underlies the need to further investigations, in order to clarify the direct or indirect mechanism through which HIV may block DC differentiation.

W4.03.10
Over-production of BAFF by dendritic cells and inflammatory monocytes during primary HIV-1 infection

G. Borhis[1], *N. Chaoul*[2], *C. Gilbert*[3], *C. Gras*[4], *C. Goujard*[5], *L. Meyer*[6], *S. Paul*[7], *H. Saoudin*[7], *J. Herbeuval*[4], *Y. Richard*[1]; [1]*INSERM U-1016, CNRS UMR8104, Institut Cochin, Université Paris Descartes,, Paris, France,* [2]*Division of Immuno-Virologie, CEA/DSV, iMETI, Fontenay aux Roses, France,* [3]*Université Laval, Centre de Recherche du CHU de Québec, Quebec, QC, Canada,* [4]*UMR-CNRS 8603, Université Paris Descartes, Faculté de Médecine, Paris, France,* [5]*INSERM U-802, AP-HP, Université Paris-Sud, Kremlin-Bicêtre, France,* [6]*INSERM U-1018, Centre de Recherche en Epidémiologie et Santé des Populations - Université Paris-Sud, Kremlin-Bicêtre, France,* [7]*GIMAP EA3064, Université de Lyon, Université Jean Monnet de St-Etienne, St-Etienne, France.*

Recent studies indicate that early activation of the immune system bears a major role in shaping B-cell repertoire and virus-specific antibody (Ab) response during primary HIV-1/SIV infection. The B cell–activating factor belonging to the TNF family (BAFF) is an inflammatory cytokine involved in Ab response and Ig class switching. However, BAFF excess also promotes the abnormal survival of self-reactive B-cell clones. We have thus evaluated the potential contribution of BAFF/APRIL impaired B-cell responses in 35 untreated primary HIV-1-infected patients (PHI) (PRIMO-ANRS Co06). Serum BAFF levels were strongly increased at enrolment, which occurs between 20 and 45 days post-infection (pi), and rapidly decreased after one month. At six months pi, the average BAFF level was similar to that of healthy donors in most patients. BAFF levels correlate directly with plasma viral load and inversely with $CD4^+$ T-cell counts. Moreover, human monocytes and myeloid dendritic cells released BAFF when exposed *in vitro* to R5 HIV-1, TLR3 agonist or type I IFN. Plasmacytoid dendritic cells were unable to secrete BAFF but exhibited its enhanced membrane expression in response to HIV-1 and CpG. However, preliminary data indicated that blood $CD16^+$ monocytes might be a major source of BAFF in PHI patients. Altogether, our data suggest that HIV-1 triggers BAFF over-production by dendritic cells and inflammatory monocytes, which likely contributes to local inflammation after their rapid relocation in various tissues, including gut mucosa. BAFF over-production might thus contribute to early inflammation and to the imbalance between polyclonal and virus-specific Ab responses.

W4.03.11
HIV-infected T cells are migratory vehicles for viral dissemination

T. T. Murooka[1]*, M. Deruaz*[1]*, F. Marangoni*[1]*, V. Vrbanac*[1]*, E. Seung*[1]*, U. von Andrian*[2]*, A. Tager*[1]*, A. Luster*[1]*, T. R. Mempel*[1]*;*
[1]Massachusetts General Hospital (MGH), Boston, MA, United States, [2]Immune Disease Institute and Department of Microbiology and Immunology, Harvard Medical School, Boston, MA, United States.

The mechanisms by which HIV spreads among permissive target cells locally during early stages of transmission, and systemically during subsequent dissemination are not known. In vitro studies suggest that formation of virological synapses (VSs) during stable contacts between infected and uninfected T cells greatly increases the efficiency of viral transfer. It is unclear, however, if T cell contacts are sufficiently stable in vivo to allow for functional synapse formation under the conditions of perpetual cell motility in epithelial and lymphoid tissues. Here, using multiphoton intravital microscopy (MP-IVM), we examined the dynamic behavior of HIV-infected T cells in lymph nodes (LNs) of humanized mice. Unexpectedly, we found that most productively infected T cells migrated robustly, resulting in their even distribution throughout the LN cortex. A subset of infected cells formed multinucleated syncytia through HIV envelope (Env)-dependent cell fusion. Both dyssynchronous motility of syncytia as well as adhesion to CD4+ LN cells led to the formation of long membrane tethers, increasing cell lengths to up to 10 times that of migrating uninfected T cells. Blocking the egress of migratory T cells from LNs into efferent lymph, and thus interrupting T cell recirculation, limited HIV dissemination and strongly reduced plasma viremia. Thus, we have found that HIV-infected T cells are motile, form syncytia, and establish tethering interactions that may facilitate cell-to-cell transmission through VS. While their migration in LNs spreads infection locally, T cell recirculation through tissues is important for efficient systemic viral spread, suggesting new molecular targets to antagonize HIV infection.

W4.03.12
TLR3 activation on dendritic cells causes complete suppression of HIV-1 infected dendritic cells by inducing up-regulation of miR-155 and APOBEC-3G

F. P. Rossi*, G. Swaminathan, J. Martin-Garcia;*
Drexel University College of Medicine, Philadelphia, PA, United States.

Human Immunodeficiency Virus type-1 (HIV-1) is transmitted predominantly through the vaginal or rectal mucosa where dendritic cells (DCs) are among the first cells to interact with the virus. In addition to supporting viral replication, DCs facilitate viral dissemination and contribute to HIV-1 pathogenesis by migrating to the lymph nodes and contributing to trans-infection of CD4+T cells. However, upon maturation, DCs show reduced susceptibility to HIV-1 infection, concurrently with the up-regulation of various cellular host factors such as microRNA-155 (miR-155) and Apolipoprotein B mRNA editing enzyme 3G (APOBEC-3G). Our goal was to investigate the mechanism(s) by which maturation of DCs causes suppression of HIV-1 infection in vitro. Immature DCs were activated with different Toll-like receptor ligands to obtain a mature phenotype and we then determined the expression levels of miR-155, APOBEC-3G, and their susceptibility to infection by a HIV-1 recombinant virus. We observed an up-regulation on the expression of both miR-155 and APOBEC-3G upon TLR3 stimulation in comparison to unstimulated cells ($p=0.003$) and those stimulated with other TLR ligands. This up-regulation correlated with increased expression of the maturation markers CD80, CD86, HLA-DR and CD83 ($p=0.03$), and with the extent of inhibition of HIV-1 infection ($p=0.031$). By using a miR-155 inhibitor and silencing APOBEC-3G, infectivity was restored to 60% of that observed in unstimulated cells. This suggests that other factors are also involved in suppressing infection upon TLR3 stimulation. Future studies will address other mechanism(s) involved in these processes.

W4.03.13
Trogocytosis between germinal center B cells and TFH cells during acute SIV infection of macaques

A. Chowdhury[1]*, P. M. Del Rio Estrada*[1]*, M. Reuter*[2]*, N. Patel*[1]*, T. Hayes*[1]*, S. E. Bosinger*[1]*, J. D. Estes*[3]*, M. Paiardini*[1]*, M. Betts*[2]*, G. Silvestri*[1]*;*
[1]Emory University, Atlanta, GA, United States, [2]University of Pennsylvania, Philadelphia, PA, United States, [3]SAIC- Frederick, Inc, Frederick, MD, United States.

$CD4^+$ T follicular helper cells (T_{FH}) play a critical role in the development of class-switched and affinity-matured antibodies by supporting germinal center (GC) B-cell responses. Studies of passive antibody transfer in macaques demonstrated that virus-specific neutralizing antibodies prevent Simian-Human Immunodeficiency Virus (SHIV) acquisition. However, these antibodies are only rarely produced during natural infection. Defining novel aspects of the interaction between T_{FH} and GC B-cells may improve our understanding of HIV immunology and pathogenesis.
This study describes a novel lymphocyte $CD3^+CD20^+$ "double positive" (DP) population in lymph nodes and spleen of healthy macaques. Image stream and immunohistochemistry experiments confirmed co-expression of these two molecules on the same cell, and flow cytometric and microarray analysis demonstrated that a significant subset of these "double positive" cells have a T_{FH} phenotype ($CD4^+PD1^{bright}CXCR5^+ICOS^+Bcl\text{-}6^+$), function ($IL\text{-}21^+IL\text{-}17^-IL\text{-}2^{+/-}IFN\text{-}g^-$) and profile of gene expression. In addition to CD20, DP cells also express B-cell markers such as CD79, CD21, and surface immunoglobulins. Importantly, expression of CD40L upon brief in vitro stimulation identifies DP cells that are T_{FH} in origin vs. those of B-cell lineage. Longitudinal analysis of lymphoid tissues has shown a marked increase in DP cells during acute SIV/SHIV infections of macaques. We propose that (i) DP cells arise as a result of membrane exchange in active germinal centers after high-affinity contact between T_{FH} and GC B-cells, through a process defined as trogocytosis, and (ii) the DP phenotype may identify T_{FH} and GC B-cells that have recently undergone high affinity interactions during acute HIV and SIV infections.

W4.03.14
Characterization of XCR1+ dendritic cells in healthy and SIV-infected Rhesus Macaques

C. Dutertre[1]*, J. Jourdain*[1]*, M. Rancez*[1]*, S. Amraoui*[1]*, Y. Richard*[1]*, M. Dalod*[2]*, V. Feuillet*[1]*, R. Cheynier*[1]*, A. Hosmalin*[1]*;*
[1]Institut Cochin, Paris, France, [2]CIML, Marseille, France.

In mice, the $CD8^+$ myeloid dendritic cells (mDC) optimally cross-present antigens to $CD8^+$ T cells and respond strongly to TLR3 ligands, which are often expressed by viruses. An equivalent DC subset has been identified by comparative genomic analysis and functional studies in human $CD141(BDCA\text{-}3)^+$ mDCs, and in sheep $SIPR^{neg}CD26^+$ mDCs. In all three species, the XCR1 chemokine receptor and the adhesion molecule CADM1 were found to be characteristic membrane markers for this DC subset as compared to other myeloid cells. Here we identified a new $XCR1^+$ mDC population in Rhesus Macaques, with a strong phenotypic and transcriptional homology to human $CD141^+$ mDC and murine $CD8^+$ mDC. Like their human and murine homologs, simian $XCR1^+$ mDC had much higher responses to TLR3 stimulation than other myeloid and dendritic cells. Taking this novel DC subset into account, the frequencies of all DC and monocyte subsets were monitored in 17 rhesus macaques after SIV_{mac251} infection in vivo, the most relevant animal model for pathogenic HIV-1 infection. $XCR1^+$ mDC increased sharply, transiently and in inverse correlation with viral loads during acute infection, and were reduced in blood and spleen during advanced disease. The identification and characterization of macaque $XCR1^+$ mDC opens new avenues for future preclinical vaccinal studies.

IL4.04.01
Lesson from Leishmania Infection to Combat Bacterial-Mediated Inflammatory Response

***M. Olivier**;*
The Research Institute of the McGill University Health Centre, Montréal, QC, Canada.

Bacterial infection often conducts to exacerbate inflammatory disorder such as septic shock leading to death if not properly controlled. However, parasites of Leishmania genus can infect and survive within macrophages by inhibiting several microbicidal molecules, such as NO and by taming down pro-inflammatory cytokines. For instance, Leishmania has been reported to inhibit or significantly reduced the production of IL-1β in vitro and in vivo. However, the mechanism whereby Leishmania parasite can influence IL-1β production by macrophages is still not fully understood. Recent reports have been proposed that IL-1β production is importantly regulated by the NLRP3 inflammasome complex. In the present work we investigated whether Leishmania parasites could modulate inflammasome activation. Using PMA-differentiated THP-1 cells we demonstrated that Leishmania infection effectively inhibit macrophage IL-1β production, and to involve the expression of the zinc metalloprotease GP63, a critical virulence factor produced by all infectious Leishmania sps. GP63 can be secreted, membrane bound, as well as to be released with Leishmania exosomes vesicles. Both L. mexicana purified GP63 and GP63-containing exosomes inhibited macrophage IL-1β production and caspase-1 cleavage, suggesting their effect upstream of caspase-1. Some known mechanisms to regulate the inflammasome activation involve ROS production, cathepsin B release and signaling pathway. Indeed ROS production is inhibited by Leishmania infection and could confer in part the explanation whereby Leishmania can interfere with NLRP3 complex. Collectively, we report herein the first observation that Leishmania surface metalloprotease can strongly affect NLRP3 inflammasome complex and therefore could be envisaged as a new therapy to abolish IL-1β-mediated inflammation.

IL4.04.02
Fooling phagocytes and delivering T cell vaccines: The 'yin and yang' of Bordetella adenylate cyclase toxin

***P. Sebo**;*
Institute of Microbiology of the ASCR, v.v.i., Academy of Sciences of the Czech Republic, Prague, Czech Republic.

Bordetella adenylate cyclase toxin (ACT) targets myeloid phagocytes bearing the $\alpha_M\beta_2$ integrin CD11b/CD18 (Mac-1 or CR3), such as neutrophil, macrophage or dendritic cells (DC, $CD11b^{high}$). ACT penetrates across cell membrane, promotes influx of calcium ions, binds cytosolic calmodulin and converts ATP to cAMP, thus causing phagocyte impotence. We showed that ACT mobilizes its receptor into membrane lipid rafts, where translocation of the AC domain across cell membrane is completed. AC next produces subversive phagocyte ruffling through cAMP signaling that inhibits complement-mediated opsonophagocytosis. In DCs, partial maturation is induced that compromises their capacity to stimulate T cells. Influx of calcium ions allows ACT to escape endocytic removal from cell surface and oligomerize into cation-selective pores, causing potassium efflux and NALP3 inflammasome activation.
The AC domain of detoxified ACT, having the enzyme activity ablated genetically (dACT), in turn exhibits an amazing capacity to accommodate foreign T cell antigens and entrain them into the cytosol of dendritic cells both *in vitro* and *in vivo*. This allowed development of dACT toxoids into a particularly efficient tool for antigen delivery for cytosolic processing and MHC class I-restricted presentation to cytotoxic $CD8^+$ T lymphocytes. Moreover, a fraction of dACT molecules is taken up by clathrin-dependent uptake, which enables endosomal antigen delivery for presentation on MHC II molecules. dACT thus promotes efficient induction of prophylactic, as well as therapeutic antigen-specific $CD4^+$ and $CD8^+$ T cell immune responses. I will, hence, conclude by reviewing the recent applications of ACT technology for antigen delivery and tumor immunotherapy.

W4.04.01
Orchestration of inflammation and adaptive immunity in Borrelia burgdorferi-induced arthritis by NapA

***G. Codolo**[1,2], F. Bossi[3], P. Durigutto[3], M. M. D'Elios[4], M. A. Cassatella[5], M. de Bernard[1,2];*
[1]Department of Biology, University of Padova, Padova, Italy, [2]Venetian Institute of Molecular Medicine, Padova, Italy, [3]Department of Life Sciences, University of Trieste, Trieste, Italy, [4]Department of Internal Medicine, University of Firenze, Firenze, Italy, [5]Department of Pathology and Diagnostics, Division of General Pathology, University of Verona, Verona, Italy.

Lyme arthritis (LA) is characterised by infiltration into the joints of inflammatory cells, mainly neutrophils (PMNs) and T cells. Traditionally, LA inflammation has been defined as a Th1-mediated response; however, the paradigm of the disease has been extended to include the Th17 cells: we demonstrated that T cells from synovial fluid of patients with LA produce IL-17 in response to NapA, a *Borrelia burgdorferi* major antigen.
Accordingly to the fact that two major types of T cells are involved in LA pathogenesis, there is a prominence of some chemokines crucial for their recruitment into the synovial fluids of patients: CXCL10 and CCL2. Moreover, although not evaluated yet in LA, CCL20-mediated recruitment of Th17 cells into the joints of rheumatoid arthritis patients has been described. Macrophages contribute in creating a T cells chemoattractants enriched milieu in the joint fluid of LA patients has been established; however, the possibility that PMNs are also involved exists.
In this study, we demonstrate that the protein NapA, which accumulates in the joint cavity of LA patients, recruits PMNs in the early stage of the disease and, subsequently, T lymphocytes. We show that NapA acts with the contribution of chemokines released by PMNs in recruiting T cells. The latter are Th1 or Th17 cells, but include also a subset producing both IFN-γ and IL-17. Our results show that NapA is crucial in driving the generation of a pro-inflammatory T cell response responsible for clinical onset and histopathological changes in LA.

W4.04.02
Imaging Bacillus anthracis edema toxin effects on normalized murine dendritic cells and macrophages

***Y. Trescos**, D. Fiole, M. Mulier, J. N. Tournier;*
Institut de Recherche Biomédicale des Armées (IRBA), La Tronche, France.

Virulence of *Bacillus anthracis*, the agent of anthrax is caused by two main factors, the capsule and two toxins. One of these toxins, edema toxin (ET) is an adenylate cyclase, producing a rise in intracellular cAMP concentrations. ET deregulates the immune system but little is known on its effects on immune cell cytoskeleton. Using adhesive micropattern array, initially designed for cells capable of stretching on micropatterns and forming stress fibers, we have developed a method of depositing immune cells to normalize their morphology. First, we present an innovative, robust and sensitive model to study murine bone-marrow-dendritic cells (BMDCs) and macrophages (BMDMs) *in vitro*, based on their adhesion to micro-patterns to standardize their morphology. This model reduces the variability of shape inherent in our cell cultures and gain sensitivity and reproducibility. Thus, the quantification of sub-cellular phenomena has become possible for studying many functions of immune cells. Second, our micro-patterning model has been used to identify and quantify the effects of ET on cytoskeleton of BMDCs and BMDMs. We observed that ET caused a time-dependent retraction of the actin cytoskeleton on both cells. This retraction begins with the formation of actin-rich cortical protrusions, appearing like membranes ruffles. This reorganization is accompanied by a perinuclear accumulation of actin, responsible of a deformation of the nucleus. We thus infer that our imaging model on immune cells opens new perspectives for high throughput analysis of morphology and functions of BMDCs and BMDMs *in vitro*.

Role for coagulation factor XI during pneumococcal pneumonia independent of factor XII activation

I. Stroo[1,2], *C. van 't Veer*[1], *J. J. T. H. Roelofs*[3], *J. C. M. Meijers*[4,5], *F. J. Castellino*[6], *S. Zeerleder*[7,2], *T. van der Poll*[1,8];
[1]*Center of Experimental and Molecular Medicine, Academic Medical Center, Amsterdam, Netherlands,* [2]*Department of Immunopathology, Sanquin Research at CLB and Landsteiner Laboratory of the AMC, Amsterdam, Netherlands,* [3]*Department of Pathology, Academic Medical Center, Amsterdam, Netherlands,* [4]*Department of Experimental Vascular Medicine, Academic Medical Center, Amsterdam, Netherlands,* [5]*Department of Vascular Medicine, Academic Medical Center, Amsterdam, Netherlands,* [6]*W.M. Keck Center for Transgene Research, University of Notre Dame, Notre Dame, IN, United States,* [7]*Department of Hematology, Academic Medical Center, Amsterdam, Netherlands,* [8]*Division of Infectious Diseases, Academic Medical Center, Amsterdam, Netherlands.*

Background: Pneumococcal pneumonia is associated with activation of coagulation.
Coagulation is initiated via the tissue factor (extrinsic) pathway or via the intrinsic pathway both converging in the formation of thrombin. Factor XI (FXI), the key component of the intrinsic pathway, can be activated either via factor XII (FXII) or via thrombin.
Aim: To determine whether intrinsic coagulation is involved in pneumococcal pneumonia and whether this is dependent on FXII activation.
Methods: Pneumonia was induced by intranasal inoculation with *S. pneumoniae* serotype 2 in male wildtype (WT), FXI-KO and FXII-KO mice. Mice were sacrificed 48 hours following infection, blood, organs and bronchoalveolar lavage fluid (BALF) were collected to determine bacterial loads, inflammatory markers and pathology.
Results: Bacterial loads in lung, blood and distant organs were significantly higher in FXI-KO mice. In line, increased lung cytokine and chemokine levels were detected in FXI-KO mice. Lung damage in FXI-KO mice was increased, mainly caused by presence of endothelialitis. Enhanced plasma and lung E-selectin levels confirmed endothelialitis. No differences in any of the examined parameters were observed between WT and FXII-KO mice. In a separate experiment BALF was collected. Although FXI-KO mice again showed higher bacterial counts in blood and distant organs, BALF bacterial loads and leukocyte influx were comparable between WT and FXI-KO or FXII-KO mice.
Conclusion: FXI deficiency increased bacterial dissemination during *S. pneumoniae* induced pulmonary infection, while FXII deficiency did not influence the host response. These results indicate that FXI protects against pneumococcal pneumonia via a mechanism independent of FXII activation.

W4.04.04
The macrophage serves as a gate-keeper for the induction of protective host immunity and bacterial dissemination during Chlamydia infection

E. Gracey[1], *Y. Baglaenko*[1], *A. Lin*[2], *A. Akram*[1], *R. D. Inman*[1];
[1]*University of Toronto, Toronto, ON, Canada,* [2]*University Health Network, Toronto, ON, Canada.*

The obligate intracellular pathogen, Chlamydia, is a common sexually transmitted bacterial infection and a leading cause of infectious blindness. Here we demonstrate the central importance of the macrophage in directing a protective immune response to Chlamydia.
To deplete host macrophages at the site of infection, clodronate-liposomes were injected intra-peritoneally with PBS-liposomes as the control. Subsequent to macrophage depletion mice were infected IP with Chlamydia muridarum and examined at days 2, 7 and 14 post-infection. Significant weight loss was associated with infection of control mice, but unexpectedly macrophage depletion was protective against this early weight loss. During early infection, robust IFN-γ production by peritoneal NK and NKT cells was observed using flow cytometry, with macrophages being indispensable for this host innate immune response. During the ontogeny of adaptive immunity, IFN-γ by CD4 and CD8 T cells also proved to be dependent on an intact macrophage population. Chlamydia growth was controlled in the presence of macrophages, yet in the absence of macrophages, persistent growth was observed using qPCR. Indeed, macrophage depleted mice had greater dissemination of Chlamydia beyond the portal of entry, as reflected by Chlamydia 16sRNA in circulating leukocytes. Adoptive transfers of infected macrophages confirmed that these cells are necessary and sufficient for the IFN-γ surge by lymphocytes at the site of infection.
These data identify the macrophage as the central orchestrator of innate and adaptive immunity to Chlamydia. These studies suggest that quantitative or qualitative alteration in macrophages may play a key role in the development of Chlamydia-associated diseases.

B cells participate on the early stages of immune response against intracellular bacterial pathogen *Francisella tularensis*

Z. Krocova, *K. Kubelkova, L. Plzakova, L. Zarybnicka, Z. Sinkorova, A. Macela;*
University of Defense, Faculty of Military Health Sciences, Hradec Kralove, Czech Republic.

Francisella tularensis, as an intracellular bacterial pathogen, adhere, interact, and enter the range of phagocytic and non-phagocytic cells. Recently, we have demonstrated, using *in vitro* model, that both, vaccine strain *F. tularensis* LVS and virulent *F. tularensis* strain FSC200 are able to adhere and even to enter the human (Ramos) and mouse (A20) B cells where survive in non-replicative state. The entrance of *F. tularensis* into B cells required active participation of bacterium and engagement of B cell receptor. The *in vivo* analysis of the cellular response during early stages of *F. tularensis* FSC200 i.p. infection on murine model demonstrated that the cells responding early are the B1b cells and macrophages expressing CD11c marker. In parallel the monocyte-derived CD123+ F4/80+ dendritic cells started to express CD11b and disappeared from the site of infection. During this stage of infection *F. tularensis* induces increased expression of MHC class II molecules on B1a and B1b cells in peritoneum and activates genes for IL-12, TNF alpha, TGF beta, IFN-gamma, and iNOS at splenic B cells. Twenty-four hours after infection murine splenic B cells produce the specific anti-*F. tularensis* antibodies. Moreover, the co-cultivation of A20 B cells with the *F. tularensis* virulent strain FSC200 rendered them to be potent antigen presenting cells presenting *F. tularensis* antigens. Thus, considering the protective efficacy of circulating antibodies, production of cytokines, and potent antigen-presenting function of B cells, B cell-mediated, as well as T cell-mediated immunity plays an equivalent role in control of *F. tularensis* infection in mice.

W4.04.06
Immune evasion in *Leptospira*: the secretion of proteases that cleave complement proteins

T. R. Fraga[1], *D. S. Courrol*[1], *M. M. Castiblanco-Valência*[1], *I. Y. Irata*[2], *L. Juliano*[2], *S. A. Vasconcellos*[3], *A. S. Barbosa*[4], *L. Isaac*[1];
[1]*University of São Paulo, Institute of Biomedical Sciences, São Paulo, Brazil,* [2]*Federal University of São Paulo, São Paulo, Brazil,* [3]*University of São Paulo, Faculty of Veterinary Medicine, São Paulo, Brazil,* [4]*Butantan Institute, Department of Bacteriology, São Paulo, Brazil.*

Leptospirosis is a neglected infectious disease of public health importance. The complement system is a major arm of innate immunity. However, pathogenic leptospires have evolved multiple strategies to escape complement attack. In this work we analyzed the ability of leptospires to secrete proteases that cleave and inactivate complement proteins, which could constitute an immune evasion strategy. We demonstrated that the culture supernatant of pathogenic, but not saprophytic leptospires, was able to inhibit the activation of the three complement pathways. Moreover, the supernatant of seven pathogenic strains presented proteolytic activity against C3, C3b and iC3b, proteins from the alternative (Factor B), classical and lectin pathways (C4b and C2). The cleavages were also observed when normal human serum was used. Interestingly, the proteases act together with the host regulators Factor I and Factor H, promoting an efficient inactivation of C3b. Proteolytic fragments of C3 had their N-terminal portion sequenced by Edman degradation. The α-chain cleavage produced 43 kDa (RSSKI-), 47 kDa (YGGGYG-) and 68 kDa bands and the β-chain degradation generates 28 kDa (HPSQKPL-) and 46 kDa fragments. Furthermore, the proteolytic

activity was inhibited by 1,10-phenanthroline, indicating the participation of metalloproteases. A recombinant leptospiral metalloprotease from the thermolysin family was produced and cleaved C3 in human serum, suggesting that this protein could be one of the proteases responsible for the effect observed with the whole supernatant. In conclusion, pathogenic leptospiral proteases can deactivate immune effector molecules, and represent potential targets for the development of new therapies and prophylactic approaches in leptospirosis.

Ex vivo chemokines and cytokines measrurements as biological markers in the immuno-diagnosis of active pulmonary tuberculosis

H. Mayanja-Kizza[1]*, A. Namuganga*[2]*, M. Nsereko*[3]*, G. Muzanye*[3]*, J. Baseke*[2]*, P. Peters*[2]*;*
[1]*Makerere University, Kampala, Uganda, Uganda,* [2]*Joint Clinical Research Centre, Kampala, Uganda, Uganda,* [3]*Uganda CWRU Research Collaboration, Kampala, Uganda, Uganda.*

Background: Early and accurate diagnosis of active tuberculosis (TB) is important for the effective management diagnosis, and control of active TB. Improved diagnostic methods are also crucial in clinical trials especially with innovative therapies and vaccine studies. In extrapulmonary tuberculosis, paucibacillary and smear negative disease, and pediatric TB, immunodiagnosis would improve outcomes. Newer research for TB biomarkers often employs technology which may be unfeasible in resource limited countries.
Methods: To determine the role of ex vivo biomarkers in diagnosis of active tuberculosis, patients with clinical features of TB, non TB controls with or without HIV positive had plasma collected. Patients had chest XRay and sputum microscopy and culture. Controls also had tuberculin test. Plasma was measured for selected cytokines and chemokines by either ELISA or LUMINEX.
Results: Ex vivo MIP-1-alpha and RANTES, TGFα, sCD40L, MMP2, sCD40L, MMP2, MMP9, IFNg, IP-10 and IP-10 and MMP9 exhibited higher ability to differentiate active TB from no infection or latent infection. Most had an area under the curve AUC 0.70 with sensitivity between 66% and 88%, and specificity 63% and 75%. Combinations of some cytokines/chemokines had higher sensitivity and specificity, and had potential for more accurate detection of active tuberculosis
Conclusions:
Ex vivo chemokine and cytokine levels have a potential for timely serodiagnosis of active tuberculosis , and would be especially beneficial in areas where advanced technology may not be available.

W4.05.01
Antigen transfer drives CD4 T cell activation in tuberculosis

S. Srivastava*, J. Ernst;*
NYU School Of Medicine, NY, NY, United States.

CD4 T cells are essential for immunity to tuberculosis in humans and mice, but the mechanisms underlying their initial activation and limited efficacy during chronic infection in tuberculosis are incompletely understood. Our previous finding that CD11bhiDC (the heavily infected cell-type) are poor at stimulating antigen-specific CD4+T cells even after addition of exogenous antigenic peptide, suggests that CD11bhiDC may not directly prime CD4+T cells during M. tuberculosis-infection.
In our studies, intra-tracheal transfer of M. tuberculosis-infected MHC-II-/- migratory DC into MHC-II+/+ mice resulted in activation of M. tuberculosis antigen (Ag85B)-specific naïve CD4+T cells in MLNs, indicating that migratory DC transfer bacterial antigen to other DC. The antigen transferred from infected to uninfected DC was full-length, in unprocessed form and involved a vesicular pathway independent of apoptosis or exosomes. Uninfected lung CD11b+CD11chiDC flow-sorted from mice infected with GFP-expressing M. tuberculosis, activated Ag85B-specific CD4+ effector T cells without addition of exogenous peptide at a better efficiency than the infected DC. However, studies with MHC-II-/- mixed bone-marrow chimeras showed that direct recognition of infected DC and macrophages by CD4 effector T cells lead to control of intracellular M. tuberculosis invivo.
Our results provide evidence that M. tuberculosis-infected DC transfer antigen to uninfected cells in lungs and lymph nodes. While antigen-loaded uninfected DC activate CD4 effector T cells efficiently, direct interaction between infected cells and CD4 effector T cells leads to intracellular bacterial control implying that in tuberculosis, activation of effector T cells by bystander antigen-loaded uninfected cells may not contribute to better control of infection.

W4.05.02
Accumulation of Gr-1^{dim} myeloid-derived suppressor cells during experimental TB infection in mice

E. N. Tsiganov*, A. M. Razinkova, I. V. Lyadova;*
Central Tuberculosis Research Institute, Moscow, Russian Federation.

Severe TB infection is characterized by excessive inflammation and impaired T-cell responses. How these two features are interrelated is poorly understood. Earlier we revealed, that experimental TB in mice is associated with the accumulation of unusual Gr-1^{dim} CD11b^{+} cells. The role of these cells during TB is unknown. However, in cancer researches it was established, that similar cell population can be induced under the influence of pro-inflammatory cytokines, suppress T-cell responses and is named myeloid-derived suppressor cells (MDSC). Considering the peculiarities of TB progression, we suggested that Gr-1^{dim} cells, accumulating during TB may represent MDSC and influence TB outcome.
To test this assumption we studied dynamics, characteristics and possible role of Gr-1^{dim} cells during TB. We found out that Gr-1^{dim} cells were rare in un-infected mice, but accumulated in lungs, bone marrow and blood of infected mice during TB progression reaching their maximum (30 - 40%) at the prelethal stage of infection. These cells co-expressed monocytic (F4/80^{+}) and granulocytic (Ly-6G^{dim}) markers and had mononuclear morphology, thus, displaying the phenotype of immature myeloid cells. Further we revealed that magnetically sorted Gr-1^{dim} cells suppressed proliferation of anti-CD3-stimulated T-cells and their IFN-γ production. The suppressive activity of Gr-1^{dim} cells was mediated by NO-dependent mechanism and required cell-to-cell interactions with target cells.
Thus, here we report the accumulation of MDSC during TB infection. This may represent the new mechanism of TB progression and may also be helpful in disease monitoring or therapy development in future.

W4.05.03
Annexin1 plays a critical role in dendritic cells cross-presentation and protection against *Mycobacterium tuberculosis*

M. Divangahi[1]*, F. Tzelepis*[1]*, J. Daoud*[1]*, J. Jaworska*[1]*, T. Nishimura*[2]*, M. Verway*[1]*, K. Hassani-Ardakani*[1]*, H. G. Remold*[2]*, H. Vali*[1]*, M. Tabrizian*[1]*;*
[1]*McGill University, Montreal, QC, Canada,* [2]*Harvard University, Boston, MA, United States.*

Annexin1 is a 37kDa protein with a wide spectrum of biological activity. Although there are emerging data emphasizing the anti-inflammatory role of Annexin1 in inflammatory diseases, little is known about its role in pathogenesis of tuberculosis. Recently, Annexin1 has been described to be involved in different stages of immune response including: (1) formation of apoptotic envelope; (2) generation of “eat me” signal that mediates recognition, tethering, and internalization of apoptotic cells/vesicles; and (3) activation of T cells. As phagocytosis of apoptotic vesicles from *Mycobacterium tuberculosis* (*Mtb*) infected macrophages is one of the main source of antigens for CD8 T cells via cross-presentation, we hypothesized that impaired capacity of Annexin1-deficient DC in cross-presentation will increase host susceptibility to pulmonary *Mtb* infection. We found that Annexin1$^{-/-}$ mice were highly susceptible to pulmonary *Mtb* infection. The high levels of pulmonary bacterial burden and mortality in Annexin1$^{-/-}$ mice were associated with reduced antigen-specific CD8+T cell response (H-2K^{b}-32c$_{309-318}$) in the lungs. This reduced

CD8+ T cell response was not due to an intrinsic role of Annexin1 in macrophages apoptosis or T cell activation as the generation of chimeric mice in which the T cells were only deficient in Annexin1 showed no sign of impairment in T cell mediated immunity or protection against *Mtb* infection. Interestingly, Annexin1-deficient DC demonstrated a significantly reduced capacity to cross-present antigens to CD8 T cells. Collectively, these data identify Annexin1 as a central player in protective immunity against *Mtb* infection by primarily regulating the power of DC in cross-presentation.

W4.05.04
Analysis of the global CD8 T cell response during *Mycobacterium tuberculosis* infection

D. Di Liberto[1]*, M. La Manna*[1]*, N. Caccamo*[1]*, G. Pietra*[2]*, C. Mingari*[2]*, L. C. Sullivan*[3]*, A. G. Brooks*[3]*, F. Dieli*[1]*;*
[1]Department of Biopathology, Palermo, Italy, [2]Department of Experimental Medicine, Genova, Italy, [3]Department of Microbiology and Immunology, University of Melbourne, Parkville,VIC, Melbourne, Australia.

Tuberculosis is a world-wide re-emerging infectious disease caused by *Mycobacterium tuberculosis* (Mtb) and both BCG vaccine and therapy are not fully effective in containing its spreading.
We investigated the frequency of Mtb epitope-specific HLA-E-restricted CD8 T cells in adult patients affected by tuberculosis (TB) before and after 6 months of anti-mycobacterial therapy and in healthy subjects. Using peptides/HLA-E tetramers, we found a high frequency of peptide-specific CD8 T cells in peripheral blood of patients with active TB, which consistently decrease after therapy. HLA-E-specific T cells produced *in vitro* high levels TNF, but very poor IFN- and/or IL-2 and exerted cytotoxic activities toward peptide-pulsed HLA-E transfected target cells. Monitoring of epitope-specific HLA-E-restricted CD8 T cells by the use of tetramers in PBMC of Mtb patients during chemotherapeutic treatment, showed their frequency decreased, a pattern opposite to HLA-A*0201-restricted CD8 T cells, whose frequency instead increased after therapy. Our results indicate that HLA-E-restricted CD8 T cells behave and function differently than HLA-A-restricted CD8 T cells and could be an useful parameter to check the efficacy of therapy.
Moreover, since HLA-E is an highly conserved molecule with a very limited polymorphism and it's not down-regulated by HIV infection, often associated to TB reactivation, the evaluation of *ex-vivo* frequencies of peptides-specific HLA-E CD8 T cells could be useful to predict subjects that are at high risk to develop the disease and these peptides could be suitable candidates for a more effective vaccine against Mtb in HIV subjects.

W4.05.05
Cytokine polymorphisms, their influence and levels in Brazilian patients with pulmonary tuberculosis during anti-tuberculosis treatment

E. Peresi[1]*, L. R. C. Oliveira*[1]*, W. L. da Silva*[2]*, E. A. P. N. da Costa*[1]*, J. P. Araujo Junior*[1]*, J. A. Ayres*[1]*, M. R. P. Fortes*[1]*, E. A. Graviss*[3]*, A. C. Pereira*[2]*, S. A. Calvi*[1]*;*
[1]UNESP, São Paulo State University, Botucatu, Brazil, [2]Lauro de Souza Lima Institute, Bauru, Brazil, [3]The Methodist Hospital Research Institute, Houston, TX, United States.

Cytokines play an essential role during active tuberculosis disease and cytokine genes have been described in association with altered cytokine levels. Therefore, the aim of this study was to verify if *IFNG, IL12B, TNF, IL17A, IL10 and TGFB1* gene polymorphisms (SNP) influence the immune response of Brazilian patients with pulmonary tuberculosis (PTB) at different time points of anti-tuberculosis treatment: T1: beginning; T2: three months; and T3: six months. Our results showed that the *IFNG*+874 T allele and the *IFNG*+2109 A allele were associated with higher IFN-gamma levels. The *IL12B*+1188 C allele was associated with higher IL-12 levels. A *TNF*-308 A allele was associated with higher TNF-alpha plasma levels in controls and mRNA levels in PTB patients at T1. The *IL17A* A allele at rs7747909 was associated with higher IL-17 levels. The *IL10*-819 T allele was associated with higher IL-10 levels. A *TGFB1*+29 CC genotype was associated with higher TGF-beta plasma levels in PTB patients at T2. The present study suggests that *IFNG*+874T/A, *IFNG*+2109A/G, *IL12*+1188A/C, *IL10*-819C/T and *TGFB1*+21C/T are associated with different cytokine levels in PTB patients and may play a role in the initiation and maintenance of acquired cellular immunity to TB and in the outcome of the active disease and anti-tuberculosis treatment. Cytokine profile determined by the respective functional SNPs could demonstrate the actual pattern of the cytokine response against the mycobacteria and may provide a better understanding of active TB disease progression and response to the anti-TB treatment and may serve as genetic risk markers of TB susceptibility.

W4.05.06
Mycobacterium Tuberculosis-specific lung innate and adaptive immunity in close contacts of TB index cases

J. G. Peter*, A. Binder, M. Davids, R. Meldau, R. van Zyl-Smit, K. Dheda;*
University of Cape Town, Cape Town, South Africa.

Background: Despite exposure, almost half of the close contacts of smear-positive tuberculosis (TB) patients remain TST/IGRA-negative. We hypothesised that a lack of TB sensitization is associated with a specific innate immune biomarker signature.
Methods: Phlebotomy and bronchoscopy were performed on 22 close contacts of smear-positive index cases with cavitatory TB. Pattern recognition receptors (TLRs, MMR) and innate (autophagy, cathelicidin, perforin, granulysin, granzyme A) immune profiles were investigated with flow cytometry on unstimulated and PPD-stimulated PBMCs and broncho-alveolar lavage (BAL) cells. TST- and IGRA-positive (converters) contacts were compared with TST- and IGRA-negative (non-converters) contacts.
Results: The biomarker-specific immune profiles are different in BAL and blood reflecting compartmentalisation of the infection. In the BAL compartment, both for unstimulated and PPD-stimulated macrophages, TLR-9 expression was significantly higher in non-converters versus converters (p=0.04). However, no differences were found between groups for other pattern recognition receptors including TLR-2, TLR-4, DC-SIGN and Mannose-receptor. In the blood and BAL compartment, both for unstimulated and PPD-stimulated CD4+ T-cells, LC3BII expression was significantly higher in non-converters versus converters (p=0.02). No differences in the numbers of NK, NKT or γδ T cells or the expression of granulysin (NK-T), granzyme A (INK) and perforin (NK-T) was found between groups.
Conclusion: A differential innate immune signature between converters and non-converters was found. These patterns and on-going work may reveal important insights into the mechanisms underlying protective pulmonary TB immunity and may have therapeutic and diagnostic implications.

W4.06 Immunity to fungal infection

IL4.06.01
The crucial role of indoleamine 2,3-dioxygenase (IDO) in the tolerogenic and immunogenic mechanisms against Paracoccidioides brasiliensis infection

V. L. G. Calich*, E. F. Araújo;*
Institute of Biomedical Sciences, University of São Paulo, São Paulo, Brazil.

IDO is an enzyme that catalyzes the oxidative degradation of tryptophan along the kynurenine pathway. IDO is mainly expressed by dendritic cells, is regulated IFN-gamma, and controls pathogen growth by inducing tryptophan starvation. However, this enzyme also plays a robust suppressive activity on the innate and adaptive mechanisms of immunity. Importantly, in fungal infections IDO was shown to control the tolerogenic function of DCs, the intensity of inflammatory reactions and pathogen persistence. We developed a murine model of paracoccidioidomycosis where susceptibility was associated to immunosuppression mediated by excessive proinflammatory responses and resistance with initial TGF-beta mediated tolerance followed by tightly regulated T cell responses. Using this model, we verified that P. brasiliensis infection induces an

increased expression of IDO that controls fungal growth but inhibits inflammation and T cell responses. In addition, IDO was involved in the tolerogenic activity of plasmacytoid DCs developed by resistant mice, and in the early control of fungal growth that, unexpectedly, characterizes the innate immunity of susceptible mice. Furthermore, the mutual regulation of Th17/Treg cells was also controlled by IDO expression. Interestingly, IDO inhibition by 1-methyl tryptophan had a detrimental effect to B10.A mice whose susceptibility is linked to excessive pro-inflammatory immunity, whereas a neglected effect was observed in resistant mice because the increased fungal burdens were compensated by impaired tolerance and precocious development of adaptive immunity. Interestingly, our data indicate that in susceptible mice IDO plays a dominant catalytic function whereas in resistant mice this enzyme appears to play both, enzymatic and signaling functions.

IL4.06.02
Dectin-2 and NLRP3 Are Involved in Inflammasome Activation in Dendritic Cell Response to *Histoplamsa* Stimulation

***B. Wu-Hsieh**, T. Chang;*
National Taiwan University, Taipei, Taiwan.

Histoplasma capsulatum is an opportunistic dimorphic fungal pathogen. Dendritic cells can take up *Histoplasma* yeasts and present antigens to activate both CD4 and CD8 T cells. Therefore, the interaction of dendritic cells with *Histoplasma* is critical to host defense against *Histoplasma* infection. Here, we investigated the receptors and signals that are involved in the activation of inflammasome in dendritic cells after stimulation by *Histoplasma*.
We found that bone-marrow-derived dendritic cells (BMDC) responded to *Histoplasma* stimulation by producing IL-1β. Flow cytometric analysis revealed that high percentages of BMDC expressed CR3, Dectin-1, Dectin-2 and TLR-2. However, only by blocking Dectin-2 and not other receptors reduced pro-IL-1β synthesis and caspase-1 activation. While blocking Dectin-2 inhibited the phosphorylation of JNK, ERK and p38, inhibiting the phosphorylation of ERK and JNK but not p38 suppressed pro-IL-1β synthesis and caspase-1 activation. NLRP3-deficient BMDC failed to activate caspase-1 and to process pro-IL-1β. Our results showed that both Dectin-2 and NLRP3 are important in the production of IL-1β in response to *Histoplasma* stimulation. Dectin-2 activation triggered both the first (transcription of pro-IL-1β) and the second (activation of caspase-1) signals and NLRP3 was involved in triggering the second signal.

W4.06.01
IL-17 regulates fungal immunity by controlling the functional competence of NK cells

***E. Bär**, S. LeibundGut-Landmann;*
Institute for Microbiology, Zürich, Switzerland.

IL-17-mediated immunity plays a key role in host protection from fungal infections, which is generally believed to be mediated by Th17 cells. Although IL-17RA-deficient mice are highly susceptible to acute systemic infection with Candida albicans, we found that blocking IL-17RA in wild type mice during the course of infection did not interfere with fungal control, suggesting that IL-17RA signaling may have unanticipated indirect effects on the immune system. Indeed, we could show that IL-17RA is essential for the development of functional NK cells and that these cells have a non-redundant role in protection from acute systemic candidiasis. Adoptive transfer of wild type NK cells was sufficient to restore normal fungal clearance in IL-17RA-deficient mice. Moreover, RAGγc-/- mice, which lack NK cells, could be rendered resistant to C. albicans by transferring wild-type (but not IL-17RA-deficient) NK cells prior to infection, confirming that NK cells act as novel key players in fungal immunity. They critically enhance the viability and fungicidal activity of neutrophils in infected mice in a GM-CSF-dependent, but completely IFN-γ-independent manner. Together, these data reveal a new role of IL-17 signaling: In addition to its well-known pro-inflammatory and protective functions during infection at mucocutaneous surfaces, IL-17 regulates NK development and thereby impacts critically on the control of systemic infections. These findings have implications for NK-mediated immunity not only against fungi, but also against bacteria, viruses and tumors.

W4.06.02
LAB/NTAL facilitates fungal/PAMP-induced IL-12 production and Th1 responses by repressing β-catenin activation in dendritic cells

***S. J. Orr**[1,2], A. R. Burg[2], L. Quigley[2], G. W. Jones[1], J. W. Ford[2], G. M. O'Connor[2], P. R. Taylor[1], G. Trinchieri[2], D. W. McVicar[2];*
[1]Institute of Infection and Immunity Cardiff University, Cardiff, United Kingdom, [2]CIP, NCI-Frederick, Frederick, MD, United States.

Fungal pathogens elicit cytokine responses downstream of immunoreceptor tyrosine-based activation motif (ITAM)-coupled or hemiITAM-containing receptors and TLRs. The Linker for Activation of B cells/Non-T cell Activating Linker (LAB/NTAL) encoded by *Lat2*, is a known regulator of ITAM-coupled receptors and TLR-associated cytokine responses. Here we demonstrate that LAB is involved in anti-fungal immunity. We show that *Lat2*$^{-/-}$ mice are more susceptible to *C. albicans* infection than WT mice. Dendritic cells (DCs) express LAB and we show that it is basally phosphorylated by the growth factor M-CSF or following engagement of Dectin-2, but not Dectin-1 or TLRs 2/4. Our data revealed a unique mechanism whereby LAB controls basal and fungal/PAMP-induced nuclear beta-catenin levels. This in turn is important for controlling fungal/PAMP-induced cytokine production in DCs. *C. albicans*- and LPS-induced IL-12 and IL-23 production was blunted in *Lat2*$^{-/-}$ DCs. Accordingly, *Lat2*$^{-/-}$ DCs directed reduced Th1 polarization *in vitro* and *Lat2*$^{-/-}$ mice displayed reduced Natural Killer cell (NK)/Th1-mediated IFN-gamma production *in vivo/ex vivo*. Thus our data define a novel link between LAB and beta-catenin nuclear accumulation in DCs that facilitates NK/Th1-mediated IFN-gamma responses during anti-fungal immunity. In addition, these findings are likely to be relevant to other infectious diseases that require IL-12 family cytokines and an NK/Th1 response for pathogen clearance.

W4.06.03
IL-33-dependent signaling regulates innate and adaptive immunity following pulmonary Cryptococcus neoformans infection

***A. Flaczyk**, C. U. Duerr, M. Shourian, E. I. Lafferty, J. H. Fritz, S. T. Qureshi;*
McGill University, Montreal, QC, Canada.

The opportunistic fungus *Cryptococcus neoformans* (*Cn*) is a major cause of death among immune compromised individuals. Susceptibility to *Cn* is associated with an allergic (Th2) pattern of lung inflammation while resistance is mediated by a Th1 pro-inflammatory response. The epithelial polarizing cytokine IL-33 has been implicated in Th2 mucosal inflammation caused by allergens and helminths; however, its role in defense to fungal infection is not well characterized.
To investigate the regulation of host immunity by IL-33, Balb/c mice were intratracheally infected with the virulent *Cn* strain H99 that is known to provoke a Th2 response. These mice had a significant time-dependent induction of lung *Il33* mRNA. Following *Cn* H99 infection, mice deficient for the IL-33-receptor subunit T1/ST2 had a prolonged survival time with decreased fungal burdens in the lung, spleen, and brain.
T1/ST2 signaling during *Cn* H99 infection was required for the early pulmonary accumulation of recently characterized CD25^{+}CD127^{+}Sca-1^{+}cKit^{low} type-2 innate lymphoid cells (ILC2) and for the concurrent production of the Th2 cytokines IL-5 and IL-13. T1/ST2$^{-/-}$ mouse lungs also exhibited an increased number of CD11b^{+}CD11c^{+}MHCII^{Int} fungicidal exudate macrophages that correlated with a decrease in lung mRNA expression of the alternative activation markers *retnla* and *chi3l3*. T1/ST2-deficiency also prevented Th2 lymphocyte polarization in lung-associated lymph nodes, airway eosinophilia, and serum immunoglobulin E production.

These observations establish a detrimental role for IL-33-dependent innate and adaptive immunity during invasive *Cn* infection and identify a novel pathway that may be amenable to future therapeutic intervention.

W4.06.04
Pathogen recognition by the long pentraxin PTX3: fine tuning by protein glycosylation

A. Inforzato[1], *M. Sironi*[1], *S. Valentino*[1], *B. Bottazzi*[1], *A. Mantovani*[1,2]; [1]*Istituto Clinico Humanitas IRCCS, Rozzano, Italy,* [2]*Department of Translational Medicine, University of Milan, Rozzano, Italy.*

Background. The long pentraxin PTX3 is a soluble Pattern Recognition Molecule (sPRM) with non-redundant protective roles against the opportunistic fungus *A. fumigatus* (AF). PTX3 is a functional ancestor of antibodies: it has opsonic activity towards AF, and enhances recognition, phagocytosis and killing of fungal conidia by immune cells, mainly polymorphonuclear neutrophils (PMNs) [1]. The human PTX3 protein contains a single N-glycosylation site that carries complex type sialylated oligosaccharides. Here we report on the role of this post translational modification in the PTX3-depedent opsono-phagocytosis of AF.
Results. Natural and recombinant PTX3 both contain complex type sugars, which however are heterogeneous with regard to content of terminal sialic acid (SA) and glycan branching, depending on cellular source. Enzymatic removal of SA causes ~50% reduction of PTX3 binding to AF, with no further change upon additional deglycosylation. Conversely, saccharide hydrolysis has no effect on PTX3 interaction with PMNs, both producer and binder of this long pentraxin. Desialylated PTX3 shows reduced potentiation of conidia phagocytosis by PMNs as compared to the unmodified protein.
Conclusions. Different pathogens express neuraminidases on their surface and innate immunity cells, such as PMNs, mobilize intracellular neuraminidases to the plasma membrane during infection. Here, we report that the glycosylation status of PTX3 changes, with respect to SA, depending on cellular source and inducing stimuli. We describe that SA modulates the PTX3-dependent recognition and phagocytosis of AF, which points to glycosylation as a strategy to tune PTX3 functions in innate immunity.

W4.06.05
Enhancement of innate immune response to *Penicillium marneffei* conidia by cooperative interaction of pattern recogntion receptors

S. C. Chaiyaroj[1], *N. Ngaosuwannakul*[2], *M. Thongpan*[1], *Y. Srinoulprasert*[3], *P. Chansrichavala*[2]; [1]*Faculty of Science, Mahidol University, Bangkok, Thailand,* [2]*Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand,* [3]*Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand.*

Toll-like receptors (TLRs) and C-type lectin receptors have been identified as a family of pattern recognition receptors (PRRs). They recognize conserved molecules called pathogen-associated molecular patterns (PAMPs) that presented by microbes, i.e., bacteria, fungi, parasites and viruses. Recent studies have demonstrated a crucial involvement of TLR members and the C-type lectin receptor, Dectin-1, in the recognition of several fungal pathogens such as *Candida albicans*, *Aspergillus fumigatus*, *Histoplasma capsulatum* and *Cryptococcus neoformans*. In this study, cytokine inhibition assay and cell transfection system were utilized to verify the interaction of the thermal dimorphic *Penicillium marneffei* conidia to TLR1, 2, 4, CD14 and Dectin-1 that leads to NF-B activation and subsequently TNF- secretion. Here, we demonstrated by blocking experiments that TLR2 and Dectin-1 play role in *P. marneffei* conidia recognition and TNF- production by human monocyte-derived macrophages. TLR4 also involves in sensing of *P. marneffei* conidia depicted by an increase in IL-8 mRNA expression in *P. marneffei* conidia-stimulated TLR4/MD2 transfected HEK293 cells. In cell co-transfected with both TLR4/MD4 and CD14 stimulated with *P. marneffei* conidia, an enhanced expression of IL-8 has been observed compared to the stimulated TLR4/MD2 transfected cells indicating the collaborative function between TLR4 and CD14 in *P. marneffei* conidia sensing. Furthermore, the cooperation between TLR4 and Dectin-1 in the recognition of conidia of *P. marneffei* has also been demonstrated in this study by luciferase reporter system. Recognition of the fungal conidia by a glycoreceptor and PRRs on skin cells will also be demonstrated.

W4.06.06
Are lipid rafts involved in the immune response to Candida albicans?

R. Teloni[1], *A. Torosantucci*[1], *S. Becattini*[2], *F. Sallusto*[2], *R. Nisini*[1], ***M. C. Gagliardi***[1]; [1]*Istituto Superiore di Sanità, Rome, Italy,* [2]*Institute for Research in Biomedicine, Bellinzona, Switzerland.*

Several pathogens have been described as entering host cells via cholesterol enriched lipid rafts. Here we show that the antifungal drug Amphotericin B (AmB), that binds and sequesters ergosterol and cholesterol of fungal and mammalian cell membranes respectively, strongly impairs *Candida albicans* uptake by human monocytes. The cholesterol-removing agent methyl-beta-cyclodextrin (beta-mD), that is known to cause disruption of lipid rafts, similarly inhibits fungus uptake, suggesting a role of these membrane microdomains in *Candida albicans* phagocytosis.
Dectin-1 is the C-type lectin receptor that recognizes beta-glucan in the cell wall of fungi. Here we show by video-lapse microscopy that Dectin-1 localizes to lipid rafts upon *C.albicans* uptake by monocytes, supporting the hypothesis that pathogen recognition receptors specific for Candida albicans may exploit lipid rafts as an entry and signaling platform.
Interestingly disruption of lipid raft integrity by AmB modulates proinflammatory cytokine production by monocytes in response to *Candida albicans* and preliminary data indicate also an impact on antigen specific T cell response.
In conclusion we raise the question regarding the role of host cell lipid rafts in the innate and adaptive T cell response to *C. albicans* and highlight a new and unexpected immunomodulatory function of the antifungal drug Amphotericin B.

Driving disease outcome in schistosomiasis: correlating antibody to disease severity

A. C. La Flamme[1], *B. Manivannan*[1], *J. Jaurigue*[1], *T. W. Jordan*[1], *W. E. Secor*[2], *B. Doughty*[3]; [1]*Victoria University of Wellington, Wellington, New Zealand,* [2]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [3]*Texas A & M University, College Station, TX, United States.*

Approximately 85 million people worldwide are infected with the parasitic helminth, Schistosoma mansoni, and of these, 10% will develop severe heptaosplenic disease. Hepatosplenic schistosomiasis is characterized by significant enlargement of the spleen and liver (heptosplenomegaly) and periportal fibrosis leading to portal hypertension and vascular shunting. Using an experimental model of this disease, we compared how the proteomic and immunomic signatures of male CBA/J mice changed over time and correlated these changes to liver and spleen pathology to identify early markers of the development of severe disease. Specific signature molecules including cytokeratin 18 were validated by determining their abundance in the serum of patients with moderate or hepatosplenic schistosomiasis. Additionally, we explored the recognition of unique parasite proteins by host antibodies and found specific parasite molecules that correlated closely with severe pathology. Together these studies reveal valuable biomarkers for the early detection of hepatosplenic schistosomiasis and shed light on the early events that dictate and drive disease outcome.

W4.07.01
CD209a expression on dendritic cells is critical for the development of pathogenic Th17 cell responses in murine schistosomiasis

H. E. Ponichtera[1], *R. Raychowdhury*[2], *M. G. Shainheit*[1], *J. M. Russo*[1], *B. M. Larkin*[1], *D. B. Salantes*[1], *S. C. Bunnell*[1], *N. Hacohen*[2], *M. J. Stadecker*[1];
[1]*Tufts University School of Medicine, Boston, MA, United States,* [2]*Broad Institute of MIT and Harvard, Cambridge, MA, United States.*

In murine schistosomiasis, immunopathology and cytokine production in response to schistosome eggs is uneven and strain dependent. Infected CBA mice develop severe hepatic egg-induced granulomatous inflammation associated with prominent Th17 and Th1 cytokine responses, whereas in BL/6 mice milder lesions develop in a Th2-dominant cytokine environment. The pathogenic Th17 response in CBA mice is largely dependent on IL-1β and IL-23 produced by schistosome egg-stimulated dendritic cells (DC); by comparison, this pro-inflammatory cytokine pathway fails to materialize in low-pathology BL/6 mice. The requirements for Th17 cell differentiation induced by CBA DC have been elucidated; however, the reason for strain-dependent difference in APC reactivity to live eggs is not known. Initial gene profiling disclosed a significant difference in C-type lectin receptor (CLR) expression between CBA and BL/6 bone marrow derived DC (BMDC). CLR are pattern recognition receptors capable of binding carbohydrates, including those secreted by schistosome eggs. A dramatic increase in CD209a, a murine homologue of human DC-specific ICAM-3-grabbing non-integrin (DC-SIGN), was documented by real-time PCR and flow cytometry on tissues from infected CBA mice, including liver, spleen and granuloma cells. Functional assays determined that CBA DC, but not macrophages, B cells, or granulocytes, elicit Th17 cell differentiation in response to schistosome eggs. Gene silencing in CBA DC, and over-expression in BL/6 DC, demonstrated CD209a to be essential for IL-1β and IL-23 production and subsequent Th17 cell differentiation. These findings reveal a novel role for CD209a in mediating pathogenic pro-inflammatory Th17 responses in helminthic disease.

W4.07.02
Immunological changes in epidermal keratinocytes following infection with schistosome cercariae

C. D. Bourke*, A. P. Mountford;*
University of York, York, United Kingdom.

The epidermis is the site of initial interaction of schistosome parasites with their mammalian host. Infective larval schistosomes (cercariae) actively penetrate the skin and release excretory/secretory (E/S) products containing proteolytic enzymes and glycans. Infection promotes angiogenesis and differentiation of 'wound healing' leukocytes but it is unclear how this process is orchestrated in the skin. Since epidermal keratinocytes play a prominent role in repairing cutaneous tissues, we hypothesised that these cells become activated early during schistosome infection leading to changes in the cutaneous immune responses.
The pinnae of C57BL/6 mice were infected with cercariae and populations of non-haematopoietic (CD45-) cells were isolated from the infection site and phenotyped at 6h, 24h and 96h post-infection via flow cytometry. Relative to un-infected skin, a population of epidermal keratinocytes (CD45- CD326- CD34+) were identified that increased in proportion following infection. The expansion of this population coincided with up-regulation of keratinocyte activation- and wound healing-associated molecular markers in skin explants. Exposure of primary keratinocyte cultures to cercariae E/S material also demonstrated that parasite antigens activate these cells in vitro. The functional relevance of changes in the activation state and proportions of epidermal keratinocytes was explored via analysis of parallel changes in skin-infiltrating antigen presenting cells and tissue inflammation.
These results suggest that cutaneous non-haematopoietic cells, particularly keratinocytes, may be important mediators of the early innate immune responses to schistosomiasis in situ.

W4.07.03
Basophils contribute to the Th2-type protective immunity against re-infection with intestinal helminths

K. Obata-Ninomiya[1], *H. Tsutsui*[1], *K. Ishiwata*[2], *N. Watanabe*[3], *H. Kanuka*[2], *H. Karasuyama*[1];
[1]*Department of Immune Regulation, Tokyo Medical and Dental University, Tokyo, Japan,* [2]*Department of Tropical Medicine, Jikei University School of Medicine, Tokyo, Japan,* [3]*Department of Allergology, Jikei University School of Medicine, Tokyo, Japan.*

Basophils had long been considered as minor relatives of tissue-resident mast cell owing to their paucity and phenotypic similarity to mast cells. However, recent studies using newly-developed analytical tools have illustrated critical and non-redundant roles for basophils in a variety of immune responses. We previously demonstrated that basophils are involved in the acquired protective immunity to tick infestation. In the present study, we explored the possible role for basophils in protection against intestinal helminth *Nippostrongylus brasiliensis* (Nb) in mice. Nb shows a complex, multi-stage life cycle: infected larvae enter mice through skin penetration, and migrate into the small intestine through the lung. We found that many larvae were retained in the skin, and therefore restrained from migrating toward the lung during the second but not first Nb infection. Many eosinophils and neutrophils as well as smaller numbers of basophils accumulated in the skin lesions during the second but not first infection. IL-4-deficient mice failed to inhibit the migration of Nb larvae to the lung during the second infection. We found that basophils were the major source of IL-4 in the skin lesions. Basophil ablation before the second infection significantly reduced the number of larvae trapped in the skin during the second infection. These results suggest that basophils contribute to the acquired protective immunity through trapping larvae in the skin of penetration sites in an IL-4 dependent manner.

W4.07.04
Innate and adaptive IL-9 orchestrate type 2 immunity

P. Licona-Limón[1], *J. Henao-Mejía*[1], *N. Gagliani*[1], *I. Licona-Limón*[2], *D. R. Herbert*[3], *R. A. Flavell*[1];
[1]*Yale University, New Haven, CT, United States,* [2]*UNAM, Mexico DF, Mexico,* [3]*UCSF, San Francisco, CA, United States.*

Type 2 responses induced during helminth infections and allergies are controlled by a variety of cytokines including IL-4, IL-5, IL-9 and IL-13. Previous studies, from our group, using transgenic mice that constitutively express IL-9 selectively in lung epithelial cells supported an important role for IL-9 in the pathogenesis of asthma, however its contribution in host protection during parasitic infections is still controversial. To definitively determine the role of IL-9, its cellular sources and targets in vivo, we generated two different genetic tools, an IL-9 fluorescent reporter knock-in mice and an IL-9 deficient mice. Using a hookworm infection model, we found that IL-9 expression is induced in T cells (Th9) and innate lymphoid cells (ILC2) in lung and mesenteric lymph nodes of infected mice; importantly, IL-9 expression preceded the expression of other Type 2 cytokines in all organs analyzed. Furthermore, our data suggest that IL-9 amplify Type 2 responses in vivo not only inducing activation of mast cells and goblet cells as previously reported, but also by promoting IL-5 and IL-13 expression as well as basophilia and eosinophilia in mice infected with Nippostrongylus brasiliensis. Interestingly, transfer of Th9 cells but not Th2 cells into Rag deficient mice, promoted basophil recruitment leading to increased worm clearance. In conclusion, innate and adaptive IL-9 orchestrate anti-helminth responses in vivo through activation of different cellular subsets and cytokine secretion that ultimately promote an effective helminth expulsion.

W4.07.05
Mechanisms of the lymphocyte hypo-responsiveness after repeated exposure of the skin to Schistosoma mansoni cercariae

***C. T. Prendergast**, P. Cook, A. Mountford;*
University of York, York, United Kingdom.

Schistosomiasis is a debilitating helminth disease currently infecting 200 million people. In areas endemic to Schistosomiasis people are likely to be repeatedly exposed to invasive cercariae. In order to investigate the innate and acquired immune response to repeated infection, we have developed a model in which mice are exposed to repeated doses of S. mansoni cercariae via the pinnae. This allows us to specifically investigate the early immune responses in the skin to larvae, prior to the onset of egg deposition, and to compare the innate immune responses generated by single (1x) versus repeated (4x) infections.
Previously we have shown that 4x exposures of the skin to S. mansoni cercariae results in the development of CD4+ T cell hypo-responsiveness within the skin draining lymph nodes. This project aims to determine how immune cells within the skin are conditioned by repeated exposure, leading to T cell hypo-responsiveness. Key constituent cells in the skin include eosinophils, macrophages and dendritic cells (DCs). A microarray has been performed to determine which key genes are up- or down-regulated in these populations. Relmα, Ym1 and Egr1 are significantly up-regulated in the 4x skin populations indicating a regulatory/alternative activation phenotype which could lead to downstream hypo-responsiveness. In addition IL-10, a known key regulatory cytokine, is produced by these innate populations of the skin. In the absence of IL-10, lymphocyte proliferation is restored, highlighting the importance of IL-10 in inducing the hypo-responsiveness.
The results shown give an insight into the mechanisms which give rise to the lymphocyte hypo-responsiveness.

W4.07.06
IL-10 secreting, type 1 regulatory T cells and naturally occurring regulatory T cells differently modulate IgG secretion by B cells in human hypo-responsive onchocerciasis

***T. Adjobimey**[1], C. von Horn[1], J. Satoguina[1], J. Oldenburg[2], L. Layland[3], A. Hoerauf[1];*
[1]Institute for Medical Microbiology, Immunology and Parasitology, Bonn, Germany, [2]Institute of Experimental Hematology and Transfusion Medicine, Bonn, Germany, [3]Institute of Medical Microbiology, Immunology and Hygiene, Munich, Germany.

Onchocerciasis is the second leading infectious cause of blindness after trachoma. The disease is caused by the nematode Onchocerca volvulus (O.v) and usually presents two pathological outcomes: the sowda or hyper-reactive form, associated with high levels of IgE and strong local immune reactions and the generalized or hypo-reactive form, characterized by tolerance and elevated amounts of the non cytolytic immunoglobulin IgG4. The molecular mechanisms associated with these polar forms are still not fully clarified. Here, we investigated the role of different regulatory T cell subsets in the human onchocerciasis. We could show that, IgG4 secretion correlated with hypo-responsiveness. We could also demonstrate that, both Tr1 and Treg cells are involved in this IgG4 secretion. However, direct co-cultures of Tr1 and Tregs with B cells reveal differences in the mechanisms of modulation of B cell responses by the two regulatory T cell types. While Tr1 are capable of inducing antibody secretion, purified Foxp3+CD4+CD25+ Tregs inhibit immunoglobulin secretion and only weakly induce IgG4. Remarkable differences were also observable depending on the methods used for Treg-isolation. While CD4+CD25+ Tregs moderately induced IgG4, CD4+CD25+CD127dim and CD4+CD25+CD49d- Tregs inhibited B cells activation and antibody secretion by reducing B cell proliferation, survival and maturation into plasma cells. These findings confirm the implication of both IL-10 secreting regulatory T cells and CD25+ Tregs in IgG4 induction during generalized onchocerciasis. Our results also suggest a direct role for Tr1 cells in IgG4 secretion by B cells, whereas Tregs inhibit IgG secretion and only indirectly promote IgG4 secretion.

W4.08 Immunity to protozoan parasite infection

W4.08.01
Deletion of IL-4 receptor alpha on dendritic cells renders BALB/c mice hypersusceptible to Leishmania major infection

***R. Hurdayal**[1], N. E. Nieuwenhuizen[2], M. Revaz-Breton[1], L. Smith[1], J. C. Hoving[1], S. P. Parihar[1], B. Reizis[3], F. Brombacher[1];*
[1]International Centre for Genetic Engineering & Biotechonology (ICGEB) & Institute of Infectious Diseases & Molecular Medicine (IIDMM), University of Cape Town, Cape Town, South Africa, [2]Max Planck Institute for Infection Biology, department: Immunologie, Berlin, Germany, [3]Columbia University Medical Center, Department of Microbiology, New York, NY, United States.

In BALB/c mice, susceptibility to *Leishmania major* infection is driven by the development of T helper 2 (Th2) responses and the production of interleukin (IL)-4 and IL-13, which share a common receptor subunit, the IL-4 receptor alpha chain (IL-4Rα). While IL-4 is the main inducer of Th2 responses, paradoxical evidence suggests that exogenously administered IL-4 can promote dendritic cell (DC) IL-12 production and enhance Th1 development if given early during infection. To investigate the relevance of this during *in vivo* infection, DC specific IL-4Rα deficient ($CD11c^{cre}IL\text{-}4R\alpha^{-/lox}$) BALB/c mice were generated by gene targeting using the cre/*lox*P system under control of the CD11c promoter. DNA, protein and functional characterization showed abrogated IL-4Rα expression on dendritic cells and alveolar macrophages in $CD11c^{cre}IL\text{-}4R\alpha^{-/lox}$ mice. Following infection with *L. major*, $CD11c^{cre}IL\text{-}4R\alpha^{-/lox}$ mice became hypersusceptible to disease, presenting earlier and increased footpad swelling, necrosis and parasite burdens, upregulated Th2 cytokine and type 2 antibody responses as well as impaired classical activation of macrophages. Hypersusceptibility in $CD11c^{cre}IL\text{-}4R\alpha^{-/lox}$ mice was accompanied by a striking increase in parasite burdens in peripheral organs such as the spleen, liver and even brain. $CD11b^{+}$ inflammatory DCs were the major infected cell population in infected $CD11c^{cre}IL\text{-}4R\alpha^{-/lox}$ mice and showed deficiencies in iNOS production and increased parasite loads. IL-4Rα-deficient DCs produced reduced IL-12 but increased IL-10 due to impaired DC instruction. Together, these data demonstrate that abrogation of IL-4Rα signaling on DCs is severely detrimental to the host, leading to rapid disease progression and increased survival of parasites in infected $CD11b^{+}$ DCs.

W4.08.02
Recognition of Leishmania parasites by the macrophage-inducible C-type lectin Mincle subverts adaptive immunity and promotes susceptibility to infection

***S. Iborra**[1], H. Izquierdo[1], N. Enamorado[1], R. Conde[1], R. Reguera[2], M. Soto[3], D. Sancho[1];*
[1]CNIC Centro Nacional de Investigaciones Cardiovasculares, Madrid, Spain, [2]Departamento de Ciencias Biomédicas, Universidad de León, Facultad de Veterinaria, León, Spain, [3]Centro de Biología Molecular Severo Ochoa (CSIC-UAM), Madrid, Spain.

Leishmania utilizes a variety of strategies to escape from an effective immune response. We describe that targeting of the C-type lectin receptor Mincle (Clec4e) by Leishmania results in the inhibition of the adaptive immunity against the parasite. We find that Leishmania parasites encode for a cytosolic ligand for Mincle that is exposed upon infection in vivo. The recognition of this ligand by Mincle promotes the infiltration of neutrophils and monocytes to the infected dermal site, correlating with an enhanced chemokine production early after infection. Mincle-deficient mice are more resistant to L. major intradermal infection in the ear, exhibiting a reduction in the dermal pathology and the parasite burden. Accordingly, Mincle deficiency enhances the adaptive immunity against the parasite, boosting the early priming of CD4+ T cells specific for L. major- derived antigen. This improved priming correlates with an increased activation and migration of the dermal dendritic cells to the draining lymph nodes. These findings suggest that L. major exploits their recognition by Mincle to modulate and subvert the development of acquired resistance.

W4.08.03
Marginal zone B-cells suppress antigen-specific T-cell responses during experimental L. donovani infection

*R. Bankoti[1], K. Gupta[1], **S. Stager**[2];*
[1]Johns Hopkins University, Baltimore, MD, United States, [2]INRS - Institut Armand-Frappier, Laval, QC, Canada.

Various studies have now demonstrated that B-cells play a negative role in several experimental models of leishmaniasis. However, the mechanism by which B-cells exacerbate Leishmania infections is yet unknown. In the present study, we investigate the role of B-cells, in particular marginal zone B-cells (MZB), in the development of adaptive CD8 and CD4 T-cell responses in L. donovani infected mice. Here we show that that marginal zone B-cells contribute to suppress protective T-cell responses during the very early stages of L. donovani infection. MZB were able to capture parasites, which was associated with upregulation of surface IgM and MyD88-dependent IL-10 production. Moreover, MZB presented parasite antigens to CD4 T-cells in vitro. Depletion of MZB also enhanced T-cell responses and led to a decrease in the parasite burden, but did not alter the generation of effector memory T-cells. Thus, MZB appear to suppress protective T-cell responses during the early stages of L. donovani infection.

W4.08.04
Cellular immune polarization to a cell phenotype Th-1 and T-Reg is induced after the treatment of human dendritic cells infected by Leishmania with the compound 11α,19β-dihydroxy-7-acetoxy-7-deoxoichangin

***G. Delgado**, D. Granados-Falla, C. Coy-Barrera, L. Cuca;*
Universidad Nacional de Colombia, Bogota, Colombia.

Several studies for the evaluation of the immune response generated against natural infection and the "required" for the appropriate resolution of the infection caused by Leishmania parasites have been developed in order to design therapies that promote a favorable response and which generate memory cells. It has been proposed that by using bioactive molecules with leishmanicidal and immunomodulatory activity can be achieve that "ideal" response. In the present study we evaluated the ability of 11a, 19b-dihydroxy-7-acetoxy-7-deoxoichangin compound for activate dendritic cells (DCs) and to polarize the effector response, using for this purpose DCs infected in vitro with L. panamensis as well their T cells, for evaluate the expression of surface markers, the production of nitric oxide (NO) and cytokines involved in inflammatory processes by flow cytometry. Here, was observed an increased in the HLA-DR expression as well on NO and proinflammatory cytokine production in DCs infected and treated with the compound. Also, we observed a polarization of effector cell response towards a Th-1 and T-Reg phenotype, which according to reports from literature these phenotypes promotes the development of an adequate response against this intracellular pathogen. These findings are consistent with previous evidence which show the compound's ability to induce the control of the Leishmania infection on in vitro and in vivo assays, showing an antileishmanial activity on antigen presenting cells (APCs) infected without any activity against extracellularly form of the pathogen, as well as the resolution of skin lesions or total cure at least 50% of the animals tested.

W4.08.05
Protective CD8$^+$ T effector memory cells elicited by heterologous prime-boost vaccination expand and re-circulate after an infectious challenge with *Trypanosoma Cruzi*

*J. R. Vasconcelos[1], M. R. Dominguez[1], R. Lemos[1], L. I. Santos[2], F. Virgilio[1], A. V. Machado[3], O. Bruna–Romero[2], R. T. Gazzinelli[3], **M. M. Rodrigues**[1];*
[1]UNIFESP-EPM, São Paulo, Brazil, [2]UFMG, Belo Horizonte, Brazil, [3]FIOCRUZ, Belo Horizonte, Brazil.

INTRODUCTION: Heterologous prime-boost strategy using recombinant plasmid DNA followed by replication-defective human recombinant adenovirus 5 is as a powerful strategy to elicit a stable pool of functional long-lived CD8$^+$ T cells with an effector (TE) or effector memory (TEM) phenotype (CD11a^{High} , CD44^{High} , CD127^{Low}/^{High} and CD62L^{Low}). After a challenge with the human protozoan parasite *Trypanosoma cruzi*, specific CD8$^+$ T cells mediate a strong protective immune response against experimental systemic infection. The present study aimed at characterizing the importance for the protective immunity of the recirculation and proliferation of these specific TE or TEM after an infectious challenge.
RESULTS: To confirm that specific CD8$^+$ T expanded after the infectious challenge were indeed TE(M) induced by vaccination, we used the gzmBCreERT2/ROSA26EYFP transgenic mouse line. After heterologous prime-boost vaccination, specific TE(M) CD8$^+$ T lymphocyte became indelible labeled with enhanced yellow fluorescent protein (EYFP). Following an infectious challenge, these EYFP-labeled TE cells expanded at similar rate as the non-labeled cells and had significantly higher frequency of KLRG1 expressing specific CD8$^+$ T-cells. We also observed that the specific CD8$^+$ T cells capable of producing the anti-parasitic mediators IFN-γ and/or TNF-α re-circulated. This re-circulation was critical for protective immunity as administration of the drug FTYS-720 led to a strong accumulation of these cells in the lymph node and reversed protective immunity induced by vaccination.
CONCLUSION: We concluded that antigen-experienced CD8$^+$ TE(M) cells expanded after experimental infection and that recirculation was critical for the protective immunity they exert.

Immunological mechanisms of co-infection of Schistosomiasis and malaria in a primate model

***R. K. Nyakundi**[1], J. Maamun[1], M. Akinyi[1], O. Nyamongo[1], I. Mulei[1], H. Ozwara[1], I. O. Farah[1], I. Malhotra[2], C. L. King[2], T. Kariuki[1];*
[1]Institute of Primate Research, Nairobi, Kenya, [2]Case Western Reserve University, Cleveland, OH, United States.

Co-infections are a common phenomenon in developing countries especially Africa. To determine the effect of co-infections on disease outcome, we conducted a controlled experiment in baboons (papio anubis), to investigate the effect of chronic schistosomiasis on severe malaria, and its influence in the development of acquired immunity to malaria infection. To study the effect of chronic schistosomiasis on severe malaria, we infected three groups of animals with 500 S. mansoni cercarie, and allowed the disease to progress to the chronic phase. To determine the effect of treatment on co-infection, we treated one group with Praziquantel at week 14 and 15 post infection. Four weeks later, the test groups were inoculated with 105 P. knowlesi parasites. In a second experiment designed to explore the development of acquired immunity to malaria, three new groups of animals were subjected to the same experimental procedure as before, except that after the 1st infection with P. knowlesi, animals were treated with anti-malarial drug Coartem® at 2% parasitaemia. Four weeks later, animals were infected two more times with plasmodium parasites, and treatment administered in between the infections. In both experiments animals were monitored daily after malaria infection. Sera and cells were collected at baseline, before and after treatment and at end-point to determine humoral and cellular responses. Results showed that animals infected with P. knowlesi had an early onset of parasitaemia and succumbed to severe malaria, unlike the majority of baboons with co-infection that survived. Comprehensive data on immunological profiles and clinical parameters will be presented.

IL4.09.01
Malaria and its delectable mammalian organ - the liver

***U. Krzych**, A. V. Pichugin, S. N. Zarling, O. Jobe;*
WRAIR, Silver Spring, MD, United States.

Malaria, caused by *Plasmodium* ssp., often leads to death, particularly amongst young children. It is initiated upon inoculation of sporozoites by a mosquito bite through the skin of a mammalian host.

Sporozoites travel via circulation and/or lymphatics to the liver, and after traversing different cell types, infect a small number of hepatocytes to continue their development, which culminates in blood stage merozoites that infect red blood cells. The morphologically and antigenically distinct phases of parasite development involve different organs: the skin, liver, spleen, lymph nodes and red blood cells. Merozoites can also infiltrate the brain and the lungs, where they cause severe pathologies. The Malaria/Pathogenesis and Vaccines Workshop will highlight immune responses and pathologies associated with the different phases of Plasmodium. Using radiation-attenuated *P.berghei* sporozoite model system of sterile and protracted protection, we demonstrated that induction of protective IFN-γ^+CD8 T cells is mediated by liver, but not splenic, CD8α^+DC in a MHCI- and IL-12-dependent manner; liver CD8 T cells recognize epitopes on Ags expressed by liver-stage parasites. Finally, lasting protection to malaria is achieved by a balance between effector and memory CD8 T cells and survival promoting cytokines, e.g., IL-15. Thus, the mammalian liver not only plays a pivotal role by supporting the life cycle of the *Plasmodium* parasite but also in the induction and maintenance of immune memory responses. Understanding the liver-stage of malaria and the associated liver-stage-specific protective immunity will enhance our knowledge and thus facilitate exploitation of these responses towards vaccine development against this serious infectious disease.

IL4.09.02
Pathogenetic role of hemozoin (malaria pigment) in severe *P. falciparum* malaria

*N. Basilico, Y. Corbett, S. Parapini, S. D'Alessandro, D. P. Ilboudo, D. Scaccabarozzi, **D. Taramelli**;*
Università di Milano, Milano, Italy.

Severe *P falciparum* malaria, is defined as the occurrence of cerebral symptoms (convulsions, coma), severe anemia or acute respiratory distress (ARDS) with excess inflammatory response in hyperparasitaemic patients. Cytoadherence of infected erythrocytes to the vascular endothelium of different organs, including brain, lungs and bone marrow, is the main pathological feature, and it is associated with elevated cytokine production.
Hemozoin (HZ, malaria pigment), an insoluble crystal made of hematin dimers and the detoxification product of haemoglobin's heme, is tought to contribute to the pathogenesis of severe malaria by interfering with monocytic and endothelial cell functions.
Our recent studies indicated that HZ may contribute to the blood-brain barrier (BBB) damage in cerebral malaria, by inducing *de novo* matrix metalloproteinases-9 (MMP-9) expression and release by human endothelial cells (Prato et al., 2011). Moreover, HZ stimulated the production of CXCL-8 and CCL-5, two chemokines involved in neutrophils/monocytes recruitment. The lipids attached to or generated by HZ, such as 15-HETE, but not 4-HNE, were able to induce both CXCL8 and CCL5, whereas de-lipidated HZ was ineffective. Endothelial cell growth was also impaired.
Monocyte/macrophages respond to the phagocytosis of HZ with the activation of the inflammasome, production of cytokines, oxygen and nitrogen radicals and lipid peroxidation products, which can then impair macrophage functions or cause tissue damage.
It is likely that parasite products and inflammatory mediators contribute to the pathogenesis in the anatomical sites where infected erythrocytes sequester, namely brain, bone marrow or lungs, leading to cerebral symptoms, diserythropoiesis and thus anaemia, or lung pathology.

Severe malaria are the major complications of *P. falciparum* infection, resulting from a complex cascade of events, possibly including insufficient qualitative and/or quantitative Ab responses against key targets of anti-parasite immunity such as mérozoïte antigens. Immunity against *P. falciparum* blood stage antigens is clearly associated with the type of protective antibodies.
We investigated IgG responses to several recombinant merozoite surface proteins [MSPs] in 110 hospitalised urban patients (13-70 yrs) with confirmed severe malaria (SM), recruited in an urban setting of Dakar. The cohorts included 28 fatal malaria [FM] cases. IgG responses to crude merozoite extracts and to several recombinant MSPs, including MSP1p19, MSP3, MSP4 and MSP5, were evaluated by ELISA and by an antibody dependent polynuclear cell mediated phagocytosis assay.
Collectively, >75% of the sera showed IgG responses to all antigens tested (OD ratios > 2), the levels of those responses were significantly correlated within the antigens (*P<0.01, Rho* from *0.4 to 0.9*) (except for MSP3 and MSP5) but unrelated to age. Interestingly, IgG levels against MSP1p19 were significantly correlated with phagocytic indexes (PI) (*P<0.01, Rho = 0.52*). The correlation was higher in IgG1 subclasses. Comparison between SM and FM showed a significant lower IgG response to MSP1p19 and to MSP4 (*P<0.01*).in FM, measurable for both antigens by the PI. These results are consistent with a role of IgG responses to certain merozoite surface Ags in conferring protection against fatal prognosis of urban SM. Nevertheless, these results suggest that this approach deserves further investigation with more patients.

W4.09.02
Hemozoin induces lung inflammation and correlates with malaria-associated acute respiratory distress syndrome

K. Deroost[1]*, A. Tyberghein*[1]*, N. Lays*[1]*, E. Schwarzer*[2]*, M. Komuta*[3]*, M. Prato*[2]*, P. Arese*[2]*, D. Daelemans*[1]*, G. Opdenakker*[1]*, P. E. Van den Steen*[1]*;*
[1]*Rega Institute, KU Leuven, Leuven, Belgium,* [2]*University of Torino, Torino, Italy,* [3]*KU Leuven, Leuven, Belgium.*

Malaria-associated acute respiratory distress syndrome (MA-ARDS) is a deadly complication of malaria infections and its pathophysiology is insufficiently understood. Both in humans and mouse models, MA-ARDS is associated with marked pulmonary inflammation. We investigated the role of hemozoin, a crystal with inflammatory properties produced during intraerythrocytic parasite replication, in MA-ARDS in different murine malaria models. By quantifying hemozoin in the lungs and measuring disease parameters of MA-ARDS, we demonstrate a highly significant correlation between pulmonary hemozoin levels, lung weight and alveolar edema. Histological analysis of the lungs demonstrated that hemozoin is localized in phagocytes and infected erythrocytes, and only occasionally in granulocytes. Species-specific differences in hemozoin production, as measured in individual schizonts, were associated with variations in pulmonary pathogenicity. Furthermore, we found that both pulmonary hemozoin and lung pathology correlated positively with the mRNA expression of IL-6, IL-10, TNF, MCP-1/CCL2, IP-10/CXCL10 and Hmox1, with VEGF protein levels in the bronchoalveolar lavage fluid, and with the number of monocytes/macrophages, inflammatory monocytes, neutrophils, CXCR3$^+$CD4$^+$ T cells and CXCR3$^+$CD8$^+$ T cells in the lungs. The causal relation between hemozoin and inflammation was demonstrated by injection of *P. falciparum*-derived hemozoin intravenously in malaria-free mice. Hemozoin potently induced the pulmonary expression of pro-inflammatory chemokines (IP-10/CXCL10, MCP-1/CCL2, and KC/CXCL1), cytokines (IL-1β, IL-6, IL-10, TNF, and TGF-β) and other inflammatory mediators (iNOS, Hmox1, NOX2, and ICAM-1). Thus, we identified hemozoin as an important parasitic factor in the induction of pulmonary inflammation during MA-ARDS.

W4.09.03
IL-27 receptor signalling restricts the formation of pathogenic, terminally differentiated Th1 cells during malaria infection by repressing IL-12 dependent signals

A. Villegas-Mendez[1,2]*, B. J. de Souza*[2,3]*, S. Lavelle*[2]*, E. G. Findlay*[2,4]*, T. N. Shaw*[5,2]*, N. van Rooijen*[6]*, C. J. Saris*[7]*, C. A. Hunter*[8]*, E. M. Riley*[2]*, K. N. Couper*[1,2]*;*
[1]Faculty of Life Sciences, University of Manchester, Manchester, United Kingdom, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]University College London Medical School, London, United Kingdom, [4]Queen's Medical Research Institute, University of Edinburgh, Edinburgh, United Kingdom, [5]Faculty of LIfe Sciences, University of Manchester, Manchester, United Kingdom, [6]VU Medical Center, Amsterdam, Netherlands, [7]Amgen, Inc., Thousand Oaks, CA, United States, [8]Department of Pathobiology, University of Pennsylvania, Philadelphia, PA, United States.

The IL-27R, WSX-1, is required to limit IFN-gamma production by effector $CD4^+$ T cells in a number of different inflammatory conditions but the molecular basis of WSX-1-mediated regulation of Th1 responses *in vivo* during infection has not been investigated in detail. In this study we demonstrate that WSX-1 signalling suppresses the development of pathogenic, terminally differentiated ($KLRG\text{-}1^+$) Th1 cells during malaria infection and establishes a restrictive threshold to constrain the emergent Th1 response. Importantly, we show that WSX-1 regulates cell-intrinsic responsiveness to IL-12 and IL-2, but the fate of the effector $CD4^+$ T cell pool during malaria infection is controlled primarily through IL-12 dependent signals. Finally we show that WSX-1 regulates Th1 cell terminal differentiation during malaria infection through IL-10 and Foxp3 independent mechanisms; the kinetics and magnitude of the Th1 response, and the degree of Th1 cell terminal differentiation, were comparable in WT, $IL\text{-}10R1^{-/-}$ and $IL\text{-}10^{-/-}$ mice and the numbers and phenotype of $Foxp3^+$ cells were largely unaltered in $WSX\text{-}1^{-/-}$ mice during infection. As expected, depletion of $Foxp3^+$ cells did not enhance Th1 cell polarisation or terminal differentiation during malaria infection. Our results significantly expand our understanding of how IL-27 regulates Th1 responses *in vivo* during inflammatory conditions and establishes WSX-1 as a critical and non-redundant regulator of the emergent Th1 effector response during malaria infection.

W4.09.04
Apolipoprotein E is critical for the development of cerebral malaria

F. A. Kassa*, M. Olivier;*
Department of Microbiology and Immunology, McGill University, Montreal, QC, Canada.

Cerebral malaria claims the life of millions of children each year. From our previous work, utilizing proteomic approach and sera from malaria-infected individuals, we have identified unique malaria biomarkers, including Apolipoprotein E (ApoE). Due to its implication in cerebral diseases and as the major apolipoprotein in the brain, we sought to investigate the role of ApoE in cerebral malaria. Herein, we report the first finding that the complete absence of ApoE protects mice from cerebral malaria. While B6 mice die of cerebral malaria within 7-9 days of infection with Plasmodium berghei ANKA, mice lacking ApoE significantly survived up to the third week of infection and then died of anemia due to high parasitemia. Whereas WT mice display the clinical manifestation of cerebral malaria, the surviving ApoE-/- were devoid of these symptoms. Mice lacking the major brain ApoE receptors were used to assess the role of the receptors and none showed a significant survival. Since ApoE-/- mice also exhibit alterations in lipid profile, we utilized the ApoA1-/- mice, which have similar lipid profile to ApoE-/- mice. Nevertheless, our results show that ApoA1-/- mice are susceptible to cerebral malaria. These experiments clearly showed that it is ApoE glycoprotein per se as opposed to the involvement of brain ApoE receptors or the alteration of lipid profiles responsible for the effect. Overall, here we report that absence of ApoE renders resistance to cerebral malaria infections in mice and this could be used as a potential therapeutic target in combating the deadly cerebral malaria disease.

W4.09.05
Validation of novel antigenic targets identified by whole-genome screening for next-generation malaria vaccines

S. Schussek[1,2]*, A. Trieu*[1]*, S. H. Apte*[1]*, D. L. Doolan*[1,2]*;*
[1]Queensland Institute of Medical Research, Brisbane, Australia, [2]University of Queensland, Brisbane, Australia.

The identification of protective antigens and development of vaccines against complex pathogens, in particular those for which cell mediated immunity is implicated in protection, has been problematic. For example, despite intense malaria research, only a handful of predicted Plasmodium spp. proteins (representing less than 0.5% of the genome) have been pursued as vaccine targets and there is still no licensed vaccine. Facilitated by the availability of genomic, proteomic and transcriptomic datasets, rational vaccine design strategies can now be employed for malaria and other complex pathogens. We hypothesize that proteins identified from genomic sequence data using biologically relevant criteria, including association with protection and IFN-γ induction, may be excellent vaccine targets. Accordingly, using malaria as a model, we have employed two different immunomics approaches to identify novel proteins targeted by protective immune responses and have evaluated the vaccine potential of the most promising ones. P. yoelii orthologues of these proteins have been characterised for their ability to induce Type I cytokine secreting T cells (especially IFN-γ) and protection against parasite challenge in mice. Most of our newly identified proteins induced partial protection against sporozoite challenge, while immunisation with a combination of the two most promising antigens resulted in sterile protection in 80% of mice. The cytokine profile induced by these protective antigens showed an increase in IL-2, TNF and multi-functional T cells secreting IFN-γ, IL-2 and TNF. These data demonstrate that novel proteins identified by immunomic-based approaches are targets of protective cell-mediated immunity and indicates the potential of multi-antigen malaria vaccines.

W4.09.06
Progress towards a broadly neutralizing vaccine against the asexual blood-stage of Plasmodium falciparum

A. D. Douglas*, A. R. Williams, J. J. Illingworth, K. Hjerrild, S. J. Draper;*
Jenner Institute, University of Oxford, Oxford, United Kingdom.

There is a need for a more effective vaccine against *P. falciparum* than the current leading candidate, RTS,S. Vaccines against the parasite's asexual blood-stage may reduce mortality, morbidity and transmission of malaria, but face problems of antigenic polymorphism and the apparent requirement for exceptionally high antibody levels to achieve protection.
We recently reported that vaccines based upon the blood-stage merozoite antigen PfRH5 induce antibodies capable of strain-transcending *in vitro* growth inhibition activity (GIA). Here we will describe cross-strain protection achieved by these vaccines in the stringent *Aotus nancymaae* non-human primate - *P. falciparum* challenge model, which correlates strongly with vaccine-induced pre-challenge GIA and total IgG anti-PfRH5 ELISA titres. This is the first example of clinically meaningful cross-strain protection of *Aotus* by a human-compatible blood-stage vaccine regime, and supports the strategy of vaccine selection using *in vitro* GIA.
We will also describe work to characterise the mechanism of parasite neutralisation by anti-PfRH5 antibodies. This includes generation of novel monoclonal antibodies with neutralisation potency among the highest described for any anti-merozoite antibody, and mapping of minimal linear epitopes for two of these. We will present data which suggest that fine epitope specificity and interaction kinetics are more important determinants of neutralisation potency than ability to block the interaction between PfRH5 and its receptor, basigin. These data shed important insight on the mechanism of blood-stage malaria parasite neutralisation, and support the continued clinical development of PfRH5-based vaccines. Phase Ia clinical trials of PfRH5 vaccine candidates are due to commence in Oxford in 2014.

IL4.12.01
Adenoma induced reshaping of the gut microbiome controls host dependent progression of colon cancer

V. R. Jala[1], P. Maturu[1], E. Krishnan[1], S. Mathis[1], S. R. Bodduluri[1], M. Wang[1], R. Knight[2], ***H. Bodduluri[1]****;*
[1]University of Louisville Health Sciences Center, Louisville, KY, United States, [2]University of Colorado, Boulder, CO, United States.

Inflammation and infection are key promoters of cancer but the molecular interplay between these events is largely unknown. Inflammation mediated by MyD88 dependent signaling promotes intestinal tumor development in mice with a heterozygous mutation in the adenomatous polyposis coli ($Apc^{Min/+}$) gene. Mice deficient in leukotrieneB_4 receptor BLT1 are protected in inflammatory disease models of arthritis, asthma and atherosclerosis. Here, we show that $BLT1^{-/-}$ mice when bred onto $Apc^{Min/+}$ background displayed an increase in the rate of spontaneous colon tumor development and mortality. A paradoxical increase in inflammation in the tumors from the $BLT1^{-/-}Apc^{Min/+}$ mice is coincidental with defective host response to infection. The defective host response in $BLT1^{-/-}$ mice became evident as lethal neonatal infections in the context of MyD88 deficiency**.** Treatment with a broad-spectrum antibiotic eliminated neonatal lethality in $BLT1^{-/-}MyD88^{-/-}$ mice and $BLT1^{-/-}MyD88^{-/-}Apc^{Min+}$ mice are highly protected from colon tumor development. Germ-free $BLT1^{-/-}Apc^{Min/+}$ mice are completely protected from colon tumor development and fecal transplantation led to reappearance of colon tumors in these mice. Analysis of fecal microbiome showed adenoma induced host dependent alterations in bacterial populations suggesting that defective host response in $BLT1^{-/-}$ mice in $Apc^{Min/+}$ background reshapes the gut microbiota to promote colon tumor development. These results identify a novel interplay between the Toll-like receptor mediated microbial sensing mechanisms and BLT1-mediated host response in the control of colon tumor development.

IL4.12.02
Control of mucosal immune responses by vitamin A

R. Mebius*[1,2], G. Goverse[2], B. Olivier[2], R. Molenaar[2], M. Knippenberg[2], M. Greuter[2], T. Konijn[2], T. O'Toole[2], G. Bouma[2];*
[1]Netherlands, [2]VU Medical Center, Amsterdam, Netherlands.

Dendritic cells within the intestine have the ability to drive the differentiation of T regulatory cells (Treg), to induce the production of protective secretory IgA immunoglobulins and to direct the migration of lymphocytes to the intestine, by inducing the expression of gut homing molecules. For these immune controlling functions, $CD103^+$ mucosal dendritic cells express vitamin A converting enzymes, which allows for the generation of retinoic acid. $CD103^+$dendritic cells were furthermore shown to protect against experimental colitis.
We and others have reported that this capacity of dendritic cells to express vitamin A converting enzymes and to act as tolerogenic dendritic cells is induced by intestinal epithelial cells and dependent on the synthesis of retinoic acid within the intestinal environment. $CD103^+$ dendritic cells in BALB/c mice had an increased expression level, when compared to C57BL/6 mice, of vitamin A converting enzymes. Concomitantly, intestinal epithelial cells of BALB/c had an increased ability to convert vitamin A, thus explaining the observed differences in $CD103^+$ dendritic cells. Consequently, BALB/c mice showed higher levels of IgA secretion into the intestinal lumen, as well as increased accumulation of T cells and B cells in the intestinal lamina propria. Furthermore, BALB/c mice were more resistant to Dextran Sulphate Sodium (DSS) induced colitis, while mice that consumed vitamin A deficient diet had a more severe form of DSS induced colitis compared to control mice. Therefore, the level of RA production and consequently the degree of RA-mediated signaling is crucial for the efficiency of the mucosal immune system.

W4.12.01
The molecular characterization of Helicobacter activated regulatory B cells and their role in gastric immunopathology

A. Sayi Yazgan*[1], M. Karayılan[1], N. Mansur[1], A. Müller[2];*
[1]ITU Department of Molecular Biology and Genetics, Istanbul, Turkey, [2]University of Zurich, Institute of Molecular Cancer Research, Zurich, Switzerland.

Helicobacter infections are acquired during childhood and, despite triggering strong local and systemic immune responses, typically persist for life. Although a majority of infected individuals remain asymptomatic, ~20% develop one or more *Helicobacter*-associated severe gastric and duodenal disease manifestations; these include chronic active gastritis, ulcers, gastric B cell lymphoma, and, rarely, gastric adenocarcinoma. The information about the protective mechanisms that operate in the majority of infected individuals not developing disease symptoms are limited. IL-10 producing regulatory B (Breg) cells can suppress inflammatory responses in autoimmune pathologies and chronic inflammatory conditions. Recently, we have shown that B cells have the ability to negatively regulate adaptive immune responses to bacterial pathogens. Using mouse models of infection with *Helicobacter felis*, a close relative of the human gastrointestinal pathogen *H. pylori*, we found that B cells activated by *Helicobacter* TLR-2 ligands produce IL-10 and induce IL-10–producing $CD4^+CD25^+$ T regulatory-1 (Tr-1)–like cells *in vitro* and *in vivo*. Tr-1 conversion depends on TCR signaling and a direct T-/B-interaction through CD40/CD40L and CD80/CD28. B cell-induced Tr-1 cells acquire suppressive activity *in vitro* and suppress excessive gastric *Helicobacter*-associated immunopathology *in vivo*. Additionally IL-10 producing regulatory B cells express CD1d, CD5, CD21 and CD23 in their surface. Also, $IL\text{-}10^+$ Breg cells do not secrete any antibodies. Our overall findings describe a novel regulatory B cell subset with an important immunomodulatory function during immune responses to persistent bacterial infections.

W4.12.02
Dietary fibers downregulate low-grade inflammation systemically in mice

S. B. Metzdorff*[1], C. H. F. Hansen[1], A. G. Christensen[1], A. Bergström[2], T. R. Licht[2], A. K. Hansen[1], H. Frøkiær[1];*
[1]Department of Veterinary Disease Biology, Copenhagen University, Frederiksberg C, Denmark, [2]National Food Institute, Technical University of Denmark, Mørkhøj, Denmark.

Dietary carbohydrates improve growth conditions for distinct populations of bacteria which may affect mucosal and systemic immunity. We have demonstrated that a 10% xylooligosaccharide (XOS) supplemented diet significantly increases *Bifidobacterium* throughout the intestine compared to control fed mice, with the highest proportions found in the ileum after XOS feeding. In the intestinal epithelium, most innate immune-related genes were unaffected by XOS feeding, while expression of *Il1β* and *Ifnγ* was significantly less in the blood from XOS fed mice than from controls. *In vitro* treatment of blood with propionate significantly decreased *Il1β*, *Ifnγ*, and *Il18* expression, supporting our hypothesis that increased production of short chain fatty acids (SCFA) in the gut that are transported across the intestine and into the systemic compartments results in a down-regulation of low-grade inflammatory cytokines. The defensin RegIIIγ was significantly higher expressed in the small intestine in XOS fed mice compared to controls, suggesting only minor contact between bifidobacteria and epithelial cells. A SCFA-induced sodium/hydrogen exchanger isoform 3 expression tended to be greater in the XOS group than in controls, indicating an indirect SCFA mediated anti-inflammatory effect of XOS. In conclusion, XOS feeding decreases systemic inflammation and this effect is most likely caused by higher SCFA concentrations as a result of an increased bifidobacterial saccharolytic fermentation in the entire gut and not only in the large intestine. With the aim of testing the systemic anti-inflammatory effect of dietary fibers in a challenged animal model, we are feeding prebiotics to already established low-grade inflammatory mice.

W4.12.03
Critical IL-23 based cross regulation of colonic DCs by macrophages protects mice from Citrobacter challenge

***T. Aychek**, A. Mildner, S. Yona, K. Kim, S. Jung;*
weizmann institute of science, Rehovot, Israel.

Strategically positioned intestinal lamina propria mononuclear phagocytes are considered crucial for maintaining gut homeostasis and immune defense. This includes: monocyte-derived CX3CR1+ CD11c+ cells displaying macrophage (MΦ) features and migratory CD103+ CD11c+ cells that are derived from dedicated dendritic cell (DC) precursors and display DC hallmarks. Understanding differential contributions of these two cell types and their intercellular communication should provide critical insights into the mechanisms that maintain the gut homeostasis or lead to IBD.
Here we focused on the cytokines IL-12 and IL-23 that are considered to play a key role in the development of Th1 and Th17 cell responses. To define the importance of cytokine production by the specific mononuclear phagocyte populations, we used a cell ablation strategy combined with a challenge by the murine Attaching & Effacing (A&E) pathogen Citrobacter rodentium. Chimeras generated with CD11c-DTR and IL-23(p19)-\- BM allowed us to show that DC/MΦ-derived IL-23 is required for the induction of IL-22 and anti-microbial peptides (AMPs). Moreover, also when the IL23 deficiency was restricted to CX3CR1+ cells using newly established CX3CR1Cre:iDTR mice AMP and IL22 production were impaired. Surprisingly, C. rodentium-challenged mice carrying IL23 deficiencies died from the challenge. Our results suggest that in an IL-23 deficient environment, IL-12 secreted by CD103+ DCs drives uncontrolled IFN-γ production by T cells leads causing severe immunopathology. In support of this notion, the immunopathology was prevented by neutralization of IFN-γ that rescued the mice.

W4.12.04
Fungal communities throughout the intestine and their role in intestinal inflammation

***I. D. Iliev**, V. Funari, D. Underhill;*
Cedar-Sinai Medical Center, Los Angeles, CA, United States.

Mucosal fungal infections are relatively common in IBD patients, and antibodies against fungal antigens (ASCA) have been used as a clinical marker for disease. We recently found that fungi are common inhabitants of mammalian intestine. However, how fungi are distributed throughout the gastrointestinal tract and whether immunity to fungi might play a role in inflammatory disease is currently unknown. Fungi are sensed by number of innate immune receptors among which Dectin-1 has emerged as a main innate immune receptor for recognition, phagocytosis, and killing of fungi. We found that mice lacking Dectin-1 are more susceptible to experimental colitis characterized by increased infiltration of Th17 and Th1 cells in the colon. Interestingly this pathology was driven by intestinal fungi, and antifungal therapy ameliorated colitis severity in knockout mice. Deep sequencing analysis of gut mycobiome revealed fungal genera that are overrepresented during experimental colitis. Using this technology we surveyed the mycobiomes of the entire murine gastrointestinal tract, as well as other mucosal sites throughout the body. Our results show specific distribution of certain fungal genera which might be associated with site specific immune responses to fungi and might promote inflammatory conditions at those sites as a result of aberrant immunity to fungi.

W4.12.05
Diet and Gut Microbiota play a key role in Autoimmune Diabetes

*E. Marino, **E. Marino**;*
Monash University, Melbourne, Australia.

Type 1 Diabetes (T1D) is an autoimmune disease resulting from the specific destruction of insulin-producing beta cells in the pancreas. The incidence of T1D has been growing and this is more pronounced in western countries, where changes in lifestyle and diet differ from developing countries that have relatively low occurrence in T1D. Diet affects the makeup of the gut microbiota and it is now clear that the gut microbiota regulates host immune responses, both locally and in the periphery. Children with T1D have an altered intestinal immune system and increased small intestinal permeability, which suggests T1D may stem from an altered gut homeostasis (leaking gut syndrome). Thus one simple hypothesis is that altered dietary habits in western countries (lack of fibre) modifies intestinal integrity and corrupts the normal processes of immune tolerance. The notion that diet and/or the gut microflora influences immunity and autoimmunity has not been taken that seriously, in part because precise molecular pathways had not been identified. Here we show that a high fiber diet protects NOD mice from diabetes in a process dependent in part on G-protein coupled receptor GPR43. NOD.Gpr43-/- mice developed accelerated diabetes and presented reduced numbers of iNKT cells. The composition of the gut microflora was markedly altered in NOD mice fed a diet deficient in fiber. These results establish the immunoregulatory role of diet and microbiota through the binding between SCFAs and GPR43 as an important pathway, but once disrupted, like with the western diet, may increase the incidence of autoimmune T1D.

W4.12.06
Probiotics as immune-regulators in the rat Experimental Autoimmune Encephalomyelitis and Myasthenia Gravis models

***C. Cordiglieri**[1], R. Marolda[1], M. Elli[2], R. Mantegazza[1], F. Baggi[1];*
[1]Istituto Neurologico Carlo Besta Fondazione IRCCS, Milano, Italy,
[2]Advanced Analytical Technologies, Piacenza, Italy.

Probiotics, including Bifidobacteria, mostly present among the human intestinal microbiota, and Lactobacilli, more predominant in the human gastric tract, are viable non-pathogenic bacteria able to modify metabolism and induce immunomodulatory activity. Probiotics can modulate dendritic cell maturation, modify T helper cell balance and induce regulatory response and immunological tolerance, thus representing an innovative therapeutic strategy for autoimmune diseases.
We have selected strains of Lactobacillus and Bifidobacterium based on their immunomodulatory effects on human DCs and leukocytes. In particular, the analysis of maturation (CD80, CD86, MHCII) and regulatory (TGFb, IL10) markers, evaluated by qPCR and FACS, following exposure to probiotics, identified Lactobacillus crispatus (LC) and Bifidobacterium Breve (BB) as candidate immunomodulatory agents. Moreover, biochemical analysis of BB, compared to other bifidi strains, showed its enhanced activity to convert Linoleic Acid in the anti-oxidant and anti-inflammatory fatty acid Conjugated Linoleic Acid (CLA).
Both LC and BB were tested for in vivo gut colonization capability, after three-weeks administration in healthy rats, showing stable persistence of BB leading to TGFb and CCR7 increment in mesenteric LNs and Peyer's Patches.
The selected probiotics BB and LC were tested, in comparison to commercially available lactobacilli and bifidi, in the Lewis rat models of Myasthenia Gravis (EAMG) and Multiple Sclerosis (EAE), showing interesting immunomodulatory effects both locally in GALT and Peyer's Patches and systemically.

W4.13 Immune regulation at barrier sites

W4.13.01
Intestinal epithelium-intrinsic Notch signaling maintains mucosal immune homeostasis by ensuring epithelial barrier functions

***Y. Obata**[1], D. Takahashi[2], Y. Furusawa[1], S. Hori[3], H. Ohno[3], K. Hase[1];*
[1]Laboratory for Mucosal Barriology, The Institute of Medical Science, The University Of Tokyo, Tokyo, Japan, [2]LIAI, San Diego, CA, United States, [3]RCAI, RIKEN, Yokohama, Japan.

Intestinal epithelial cells (IEC) play a critical role in the first line of defense against diverse microorganisms on the luminal surface. Impaired integrity of IEC has been implicated in increasing the risk of inflammatory bowel disease; however, the underlying pathological mechanism remains to be clarified. Notch signaling plays a critical

role in the maintenance of epithelial integrity by regulating the balance of secretory and absorptive cell lineages, and also by facilitating rapid epithelial turnover. We found that epithelium-intrinsic Notch signaling ensures mucosal barrier functions. Mice harboring IEC-specific deletion of *Rbpj* (RBP-JΔ^{IEC}), a transcription factor responsible for Notch signaling, spontaneously develop T_H17-dominant chronic colitis. Interestingly, regulatory T (Treg) cells accumulated in the inflamed colonic lamina propria (cLP), where nearly half of $CD4^+$ T cells were occupied by Treg cell. Microarray analysis demonstrated that functional molecules for immune regulation were remarkably downregulated in Treg cells of RBP-JΔ^{IEC} mice compared to normal mice. FACS analysis also confirmed the downregulation of functional molecules of Treg cells under inflammatory condition. Reciprocally, genes encoding effector molecules such as IL-2 and IFN-γ increased in these cells. These data suggest that persistent microbial stimulation due to impaired epithelial barrier may lead to the development of functionally defective Treg cells, resulting in T_H17-dominat chronic inflammation. Collectively, epithelial cell-intrinsic Notch signaling ensures the epithelial barrier function and this mechanism is required for the maintenance of appropriate function of colonic Treg cells.

Oral administration of poly-reactive high-affinity IgA monoclonal antibody against intestinal microbiota improved inflammatory colitis in mice

S. Okai[1]*, Y. Horii*[1]*, Y. Shiraki*[1]*, S. Matsumoto*[2]*, T. Naitoh*[2]*, M. Nanno*[2]*, K. Yamamoto*[3]*, K. Kurokawa*[3]*, S. Nomura*[1]*, R. Shinkura*[1,4]*;*
[1]Nagahama Institute of Bio-Science and Technology, Nagahama, Japan, [2]Yakult Central Institute, Tokyo, Japan, [3]Tokyo Institute of Technology, Yokohama, Japan, [4]PRESTO, Tokyo, Japan.

Immunoglobulin A (IgA) is the main antibody secreted into the intestinal lumen, and plays a critical role in defense against pathogens and in intestinal microbiota homeostasis. Activation-induced cytidine deaminase (AID) is essential to both class switch recombination and somatic hypermutation (SHM). We have generated SHM-specific deficient mutant mice, AID-G23S mice, which carry a knock-in point mutation (G23S) in AID. They secreted normal amount of IgA in gut but those IgA were less mutated. In these mice, due to low-affinity of IgA against intestinal microbiota, expanded gut microflora caused germinal center B cell hyperplasia as predisposition towards inflammatory colitis in older mice. It indicates SHM in IgA is critical to control intestinal microbiota and to prevent inflammatory colitis. Since microbiota community is huge and easily changed by food, the size of IgA repertoire must be enormous. However, it is unknown how each mutated IgA recognizes its specific bacterial target. We hypothesized that the intestinal IgA may be selected to be cross-reactive to multiple bacteria and to obtain high-affinity against them through SHM. To prove this hypothesis, we generated hybridomas from intestinal IgA-secreting cells and found that several monoclonal IgAs recognized more than ten different intestinal bacteria. Oral administration of the poly-reactive monoclonal IgA with highest affinity into AID-G23S mice normalized germinal center B cell hyperplasia. Oral monoclonal IgA treatment is thus a potential therapeutic approach for inflammatory colitis.

W4.13.03
Caspase-8 is essential to maintain intestinal barrier function in response to mucosal pathogens

C. Günther*, B. Buchen, H. Neumann, M. Neurath, C. Becker;*
Medical Department I, Universitätsklinikum Erlangen, Erlangen, Germany.

The intestinal epithelium is equipped with numerous Toll like receptors (TLR) that play a pivotal role in pathogen recognition, initiating of immune response and cell death activation of infected cells. Beside apoptosis, we have recently discovered necroptosis as a new form of epithelial cell death and a potential pathogenic mechanism driving the development of ileitis in Caspase-8ΔIEC mice and Crohn´s disease patients. However, the triggering factor for necroptosis is still unknown. Recently, we could identify that additional deletion of Tnf-R1 did not rescue the phenotype of Caspase-8ΔIECmice. To examine the impact of TLR on necroptosis, we injected Poly(I:C) and LPS into mice. TLR-ligands induced a dramatic villous atrophy and severe destruction of the intestine of Caspase-8ΔIECmice as compared to control littermates, leading to the death of the former mice within 6 hours. Immunohistochemistry revealed an excessive number of dying epithelial cells with necrotic morphology after TLR-stimulation in Caspase-8ΔIECmice, but not in Rip3-/-Caspase-8ΔIECmice, indicating that this form of cell death is due to Rip3-mediated necroptosis. Moreover we discovered that Poly(I:C) triggered necroptosis was directly mediated via the TLR3-TRIF pathway, whereas LPS-induced programmed necrosis was prevented in Tnf-R1-/-Caspase-8ΔIECmice, indicating the influence of TNF-α in this setting. Beyond we could demonstrate that TNF-α is produced by intestinal immune cells and not by epithelial cells themselves.
Taken together, our data for the first time demonstrate a host protective function of caspase-8 by maintaining intestinal barrier function in response to mucosal pathogens through controlled shedding of infected epithelial cells and inhibition of necroptosis.

W4.13.04
CD200 receptor signalling facilitates murine cytomegalovirus persistence in mucosal tissue

G. Stack[1]*, M. Marsden*[1]*, M. A. Stacey*[1]*, E. Jones*[1]*, R. J. Snelgrove*[2]*, S. M. Cuff*[1]*, A. M. Gallimore*[1]*, A. N. Barclay*[3]*, G. W. G. Wilkinson*[1]*, I. R. Humphreys*[1]*;*
[1]Cardiff University, CARDIFF, United Kingdom, [2]Imperial College London, London, United Kingdom, [3]University of Oxford, Oxford, United Kingdom.

Mucosal surfaces are critical ports of entry and/or exit for human cytomegalovirus (HCMV). The salivary glands also represent a significant site of persistent replication of murine cytomegalovirus (MCMV). CD200 receptor (CD200R) is a negative regulator of peripheral and mucosal immunity. Viruses, including certain herpesviruses, have targeted the CD200R signalling pathway through acquisition of functional CD200 homologues. However the role that CD200R signalling plays during persistent herpesvirus infection is unclear. We now report that the CD200-CD200R pathway suppresses innate and adaptive antiviral immunity during MCMV infection. CD200R-/- mice exhibited elevated NK cell accumulation during acute MCMV infection that corresponded with improved control of virus replication in the spleen. During MCMV persistence, CD200R-/- mice exhibited a dramatic increase in CD4 T cell and monocyte/macrophage accumulation, and enhanced NK cell cytotoxicity in the salivary glands that, critically, resulted in decreased virus replication. Concurrent depletion of NK cells and CD4 T cells abrogated improved control of virus replication by CD200R-/- mice. Moreover therapeutic blockade of CD200 during persistent infection of RAG-/- mice also improved control of virus replication. Thus, CD200R inhibits innate immune responses that afford protection from cytomegalovirus persistence independently of adaptive immunity. These results uncover CD200R as a critical regulator of antiviral immunity during cytomegalovirus persistence in mucosal tissue, and highlight the potential importance of promoting innate, as well as adaptive, immune responses during chronic cytomegalovirus infection.

W4.13.05
Endoplasmic reticulum stress aggravates CVB3-induced myocarditis by promoting NF-κB-mediated proinflammatory cytokine production

Y. Yue*, S. Xiong, X. Zha, W. Xu;*
Institutes of Biology and Medical Sciences, Soochow University, Suzhou, Jiangsu Province, China.

Coxsackieviruses B3 (CVB3) is a major pathogen for viral myocarditis with no effective control measures, and the main reason for the lack of effective treatments is the limited understanding of its pathogenic mechanisms. Recently, endoplasmic reticulum (ER) stress response has been proven to participate in CVB3-induced myocarditis by promoting myocardiocyte apoptosis, however its role in myocardial inflammation has not been elucidated. Here, we found that

expression of myocardial GRP78 and GRP94, hallmarks of ER stress, was robustly up-regulated following CVB3 infection and appeared in a time dependent pattern which was highly accordance with the pathogenic process of viral myocarditis. Augment of ER stress by tunicamycin significantly increased myocardial inflammatory cytokine production such as TNF-α, IL-6, IL-12 and MCP-1, and consequently led to aggravated myocardial inflammation and injury. On the contrary, blockade of ER stress by tauroursodeoxycholate substantially reduced the production of myocardial inflammatory cytokines and efficiently relieved viral myocarditis evidenced by the slighter body weight loss, limited inflammation foci and enhanced survival rate. To further explore the underlying mechanism, we found that ER stress response promoted the expression and activation of inflammatory transcriptional factor NF-kB in CVB3-infected heart tissues. Taken together, our results demonstrate that CVB3 infection activated myocardial ER stress, which was involved in the pathogenesis of myocarditis by promoting NF-κB-mediated proinflammatory cytokine production. In addition, ER stress may represent a potential therapeutic target for CVB3-induced myocarditis and other inflammatory heart diseases.

Impaired maintenance of gut homeostasis in mice lacking GGTase-I in intestinal epithelial cells

R. López Posadas[1], *M. O. Bergö*[2], *C. Becker*[1], *F. Sánchez de Medina*[3], *M. F. Neurath*[1], *I. Atreya*[1];
[1]*Medizinische Klinik 1, Universitätsklinikum Erlangen, Erlangen, Germany,* [2]*Molecular and Clinical Medicine, Institute of Medicine. University of Gothenburg. Sahlgrenska Academy, Gothenburg, Sweden,* [3]*Department of Pharmacology, University of Granada, Granada, Spain.*

Prenylation is one of the most important posttranslational processes. Although prenylation inhibitors show immunomodulatory and antineoplasic properties, the impact of prenylation on immune response remained undefined. Focusing on intestinal epithelium, main and primary immunological barrier in gastrointestinal immune response, we aim to establish the consequence of a genetic deletion of GGTase-I (geranylgeranyltransferase-I) in Intestinal Epithelial Cells (IEC) for gut homeostasis. Conditional GGTase-I KO mice were generated by crossbreeding Pggt-Iβ$^{flx/flx}$, and VillinCre as well as VillinCre-ERT2 mice. Spontaneous phenotype was reported and gut and IEC were analyzed in order to clarify the underlying mechanism.
Deletion of GGTase-I gene in IEC leads to embryonic lethality in mice. Tamoxifen-induced abrogation of geranylgeranylation in IEC of adult mice caused a lethal enteric disease, more prominent in small intestine (endoscopy), which could be mimicked *in vitro* (organoid culture). Microscopic analysis showed a complete disruption of epithelium architecture and increased cell shedding into the gut lumen (H&E staining). Our data ruled out apoptosis, necroptosis and intestinal microflora as main responsible for intestinal damage. However, GGTase-I deficient epithelium showed a disrupted disposition of actin fibers (confocal microscopy), which pointed out cytoskeleton function as key mediator. IEC lacking geranylageranylation exhibited decreased RhoA activation (pull-down assay), which correlated with its modified subcellular localization (Western blot, immuhistochemistry).Absence of geranylageranylation in IEC implies in the loss of intestinal homeostasis and death. The mechanism underlying this dramatic phenotype might be related to an impaired Rho A activation, which would lead to a defective cytoskeleton function and the breakdown of epithelial barrier.

Dengue infection triggers platelet-derived IL-1β: Mechanisms and roles to increased vascular permeability

E. D. Hottz[1], *J. Lopes*[1], *C. Freitas*[1], *F. A. Bozza*[2], ***P. T. Bozza***[1];
[1]*Instituto Oswaldo Cruz, Rio de Janeiro, Brazil,* [2]*Instituto de Pesquisas Clinicas Evandro Chagas, FIOCRUZ, Rio de Janeiro, Brazil.*

Dengue is the most frequent hemorrhagic viral disease and re-emergent infection in the world. The severe forms of the disease are characterized by thrombocytopenia and increased vascular permeability that may lead to bleeding and shock. Although thrombocytopenia is characteristically observed in dengue, the role of platelets in dengue pathogenesis has not been fully elucidated. Here we investigate platelet activation and its potential contribution to thrombocytopenia and endothelium activation in dengue. We found that platelets from dengue patients exhibited increased activation, mitochondrial dysfunction and apoptosis. Platelet activation and mitochondrial dysfunction could also be observed when plateles where directly exposed to dengue virus (DENV) in vitro through mechanisms dependent of DC-SIGN. Increased expression of IL-1β in platelets and platelet-derived microparticles (MPs) from patients with dengue or after platelet exposure to DENV in vitro was observed. The mechanisms involved in IL-1β synthesis and processing in platelets was investigated. We demonstrated that DENV infection lead to assembly of NLPR3 inflammasome and caspase-1-dependent IL-1β secretion by platelets. Our findings also indicate that platelet-derived IL-1β is chiefly secreted into MPs through mechanisms dependent of mitochondrial ROS triggered inflammasome. Inflammasome activation and platelet shedding of IL-1β-rich MPs correlate with signs of increased vascular permeability. Moreover, MPs from DENV exposed platelets triggered endothelial cell activation and increased permeability in vitro through IL-1R dependent mechanism. In conclusion, our findings provide new evidence that platelets may contribute to inflammatory response amplification and to the genesis of increased vascular permeability in dengue illness.

Nuclear DNA sensor IFI16 as circulating protein in autoimmune diseases is a signal of damage that impairs endothelial cells through high-affinity membrane binding

M. De Andrea[1,2], *M. Bawadekar*[2], *F. Gugliesi*[1], *V. Dell'Oste*[1], *V. Caneparo*[2], *A. Tincani*[3], *M. Gariglio*[2], *S. Landolfo*[1];
[1]*Department of Public Health and Paediatric Sciences, University of Turin, Medical School, Turin, Italy,* [2]*Department of Translational Medicine and Interdisciplinary Research Center of Autoimmune Diseases (IRCAD), University of Piemonte Orientale "A. Avogadro", Medical School, Novara, Italy,* [3]*Rheumatology and Clinical Immunology, Spedali Civili and University of Brescia, Brescia, Italy.*

IFI16, a nuclear pathogenic DNA sensor induced by several pro-inflammatory cytokines, is a multifaceted protein with various functions, including suppression of transcription, induction of inflammation, and restriction of virus replication. It is also a target for autoantibodies as specific antibodies have been demonstrated in the sera of patients affected by systemic autoimmune diseases. Various research groups, including ours, have shown that following transfection of virus-derived DNA, or treatment with UVB, IFI16 delocalizes from the nucleus to the cytoplasm and is then eventually released into the extracellular milieu. In this study, using an in-house capture ELISA we demonstrate that significant levels of IFI16 protein can also exist as circulating form in the sera of autoimmune patients. We also show that the recombinant IFI16 protein, when added in vitro to endothelial cells, does not affect cell viability, but severely limits their biological activities. It was further demonstrated that IFI16 released by apoptotic cells bind to neighbouring cells in a co-culture. Immunofluorescence assays revealed the existence of high-affinity binding sites on the plasma membrane of endothelial cells, and radiolabeling experiments allow us to estimate the presence of 250,000 to 450,000 specific binding sites per cell. Corroborating the results from the functional assays, this binding could be completely inhibited using the anti-IFI16 N-terminal antibody. Altogether, these data demonstrate that IFI16 may exist as circulating protein in the sera of autoimmune patients which binds endothelial cells causing damage, suggesting a new pathogenic and alarmin function through which this protein triggers the development of autoimmunity.

W5.01.01
The TNF family member TL1A: a key player in type 2 immunity in both adaptive and innate lymphocytes

*F. Meylan[1], E. Hawley[1], L. Barron[2], P. Penumetcha[1], J. Barlow[3], A. Richard[1], T. Wynn[2], A. Mckenzie[3], I. Gery[4], **R. M. Siegel**[1];*
[1]NIAMS, NIH, Bethesda, MD, United States, [2]NIAID, NIH, Bethesda, MD, United States, [3]LMB, Cambridge University, Cambridge, United Kingdom, [4]NEI, NIH, Bethesda, MD, United States.

The TNF-family cytokine TL1A costimulates T cells through its receptor DR3. TL1A polymorphisms and increased expression has been linked to Rheumatoid Arthritis and Inflammatory Bowel Disease. TL1A-DR3 interactions are required for diverse mouse models of autoimmune disease. The effects of TL1A on T cell differentiation and its role in innate lymphocyte biology has not been explored. During T cell activation, we have found that TL1A costimulation specifically promotes production of the allergy-promoting cytokine IL-9 through a mechanism dependent on IL-2 and STAT5 signaling, and TL1A promotes pathology in mouse models of asthma and ocular inflammation. Transgenic mice chronically expressing TL1A spontaneously develop small intestinal pathology characterized by high levels of IL-13, muscular and goblet cell hyperplasia, and infiltration with immune cells. Mucosal and goblet cell hyperplasia is dependent on IL-13 but not T cells or commensal flora. We find that the major IL-13 producing cells in TL1A transgenic mice lack T and B cell lineage markers and are phenotypically similar to 'type 2' innate lymphocytes (ILC2), which promote allergic and anti-parasitic responses in mice. ILC2 express surface DR3 and produce IL-13 in response to TL1A ex-vivo. However, DR3 deficient mice mount a vigorous response to the intestinal nematode Nippostrongylus brasiliensis, which depends on ILC2 derived IL-13. Thus, TL1A can directly induce IL-13 production by innate lymphocytes through mechanisms distinct from parasitic infection. TL1A thus coordinately enhances type 2 immunity in both adaptive and innate lymphocytes and may be a good target for therapy in allergic diseases.

W5.01.02
Oxazolone and ethanol induce colitis in NOD-scid IL2R γnull mice engrafted with human peripheral blood mononuclear cells

***R. Gropp**[1], T. Nolte[2], M. Zadeh-Khorasani[2], F. Rueff[2], A. Wollenberg[2], V. Gülberg[2], E. Wolf[3], M. Siebeck[2];*
[1]Technology Consulting, Munich, Germany, [2]Ludwigs-Maximilian-Universität, Munich, Germany, [3]Gene Centre, LMU Munich, Munich, Germany.

Oxazolone induced colitis in mice has become a recognized model to study the mechanism underlying the development of colitis and the efficacy of therapeutics targeting immunological responses. However, this model poorly reflects the pathophysiological mechanisms in the genetically heterogeneous patient population and cannot be used when therapeutics designed to address human targets do not interact with the respective murine counterpart.
In a new model oxazolone mediated colitis was induced in NOD-scid IL2Rγ null mice engrafted with human peripheral blood mononuclear cells (hPBMC) derived from patients suffering from ulcerative colitis (UC). Read outs were the clinical severity- and histological score, hIgG and hIgE levels and colon length. Human lymphocytes were analyzed by immunohistochemistry and FACS analysis.
Mice developed the same symptoms and phenotype as previously observed in immune-competent mice. Challenge with oxazolone resulted in a mixed inflammatory cell infiltrate into the lamina propria consisting of human T- and B-cells and neutrophils and NK T-cells. Colon architecture was characterized by the development of edema, fibrosis and crypt loss. Engraftment alone without further challenge was not sufficient to cause UC, however in contrast to the results obtained in immune-competent mice, ethanol vehicle alone induced UC like symptoms and phenotype. The phenotype was most pronounced in mice engrafted with PBMC derived from a patient suffering with UC. This model has the potential to elucidate molecular mechanisms underlying flares of the disease and to study the efficacy of therapeutics. Drug profiling in this model might deliver results with higher predictive quality for later clinical studies.

W5.01.03
Chronic infection with Toxoplasma gondii aggravates experimental sublethal sepsis induced by CLP and predisposes to septic shock

***M. C. Souza**[1], D. M. Fonseca[1], A. Kanashiro[1], L. Benevides[1], G. Bonfá[1], D. Golenbock[2], R. T. Gazzinelli[2], J. C. F. Alves-Filho[1], F. Q. Cunha[1], J. S. Silva[1];*
[1]University of São Paulo, Ribeirão Preto - São Paulo, Brazil, [2]University of Massachusetts Medical School, Worcester, MA, United States.

Most studies of parasite-host interaction have focused on a single pathogen interaction. However, in natural environment, the host is commonly exposed to multiple pathogens sequentially or simultaneously. Sepsis by Cecal Ligation and Puncture (CLP) is a well characterized model, but has not been correlated with co-infection model. In this context, we hypothesized that chronic infection by Toxoplasma gondii can modulate the host response against CLP. To test this hypothesis, C57BL/6 mice were orally infected with 5 cysts of T. gondii and 40 days post infection, they were subjected to sub lethal CLP (SL-CLP). In our study, when mice were chronically infected with T. gondii, they became more susceptible to SL-CLP, showing improvement of bacterial killing, increased cells recruitment to the site of infection, intestinal damage and increased inflammatory infiltrate in this organ. These mice had also increased pro-inflammatory cytokines (IFN-γ, TNF-α, IL-6 and IL-1β) which induced increased nitric oxide (NO) observed within 24 hours after SL-CLP. We showed that the TCD4+ and TCD8+ cells were responsible to produce IFN-γ and TNF-α. We suggest that early response against SL-CLP after infection with T. gondii happens due to the presence of Th1 memory cells, produced during T. gondii infection. In conclusion, we demonstrate that chronic infection with T. gondii aggravates SL-CLP by Th1 memory generation that induces increased pro-inflammatory cytokines which leads to hypotension and predisposes to septic shock.

W5.01.04
Foxo3 transcription factor controls susceptibility to central nervous system inflammation

***C. Stienne**, N. Carrié, A. Dejean;*
INSERM, Toulouse, France.

Foxo3 transcription factor regulates cell cycle progression, survival, and DNA repair pathways. Studies have established the crucial role of Foxo3 in the control of antiviral immune response and in the differentiation of induced-regulatory T cells. However, the role of Foxo3 in the physiopathology of autoimmune disease is still unknown. In this context, our goal was to determine the role of Foxo3 in autoimmunity using experimental autoimmune encephalomyelitis (EAE), a well-established animal model of multiple sclerosis.
Here, we show that Foxo3 deficiency is associated with a significant decrease in the severity of an active EAE induced by immunization with myelin-derived peptide MOG35-55. Foxo3-deficient mice display no defect in CD4 T cells migration to the central nervous system. However, the decreased severity of EAE in Foxo3-deficient mice is characterized by an inability of Foxo3-deficient CD4 T cells to differentiate into encephalitogenic T cells. Indeed, CD4 T cell deficient for Foxo3 failed to secrete IFN-γ, IL-17 and GM-CSF. By dissecting the cellular mechanism involved in this phenotype, we have shown that Foxo3 plays crucial roles in both dendritic cells and T cells.
Thus, our results reveal for the first time that Foxo3 plays a role in autoimmune diseases. Identification of Foxo3 as a target gene implicated in the differentiation of CD4 T cells in the context of autoimmunity could give crucial information in the molecular mechanism of autoimmune diseases.

W5.01.05
Factor Xa and thrombin stimulate an inflammatory and fibrotic response by retinal pigment epithelial cells: a role in vitreoretinal disorders?

J. Bastiaans[1], *J. C. van Meurs*[2], *C. van Holten*[1], *M. Smits - te Nijenhuis*[1], *M. J. Kolijn - Couwenberg*[1], *N. M. A. Nagtzaam*[1], *M. P. van Hagen*[1], *R. W. A. M. Kuijpers*[1], *H. Hooijkaas*[1], *W. A. Dik*[1];
[1]*Erasmus MC, Rotterdam, Netherlands,* [2]*Rotterdam Eye Hospital, Rotterdam, Netherlands.*

Vitreoretinal disorders, including proliferative vitreoretinopathy (PVR), proliferative diabetic retinopathy (PDR) and exudative age-related macular degeneration (AMD) are a major cause of visual impairment worldwide and can lead to blindness. Loss of blood-retinal barrier (BRB) integrity associated with vitreoretinal fibrin deposition, inflammation, fibrosis and neovascularization contribute to the pathophysiology of these disorders. Retinal pigment epithelial (RPE) cells are well recognized to contribute to vitreoretinal inflammation/fibrosis and are likely to encounter contact with coagulation factors upon loss of BRB integrity.
We examined the effect of factor Xa and thrombin on the production of cytokines and growth factors by RPE cells as well as there effects on α-SMA, ZO-1 and collagen type 1 expression. For this purpose we used cytokine arrays that allow simultaneous detection of 120 cytokines and growth factors, ELISA, RQ-PCR and fluorescence microscopy. The involved signaling cascades were examined using specific inhibitors for PAR-1, PAR-2, NF-κB and PDGF-R.
Factor Xa and thrombin regulated the production of many mediators (including GM-CSF, IL-6, IL-8, MCP-3, PDGF-AA, PDGF-BB, TIMP-1 and TGF-α) that fit well in the pathobiology of vitreoretinal disorders. Blocking studies revealed that these effects were mediated via PAR1 induced NF-κB activation. Thrombin enhanced α-SMA and collagen type 1 levels and reduced ZO-1 levels expressed by RPE. The effect of thrombin on α-SMA and collagen type 1 was mediated via PDGF signaling. Our findings suggest that factor Xa and thrombin can drive vitreoretinal inflammation and fibrosis and should be considered as treatment targets in vitreoretinal disorders such as PVR, PDR and AMD.

W5.01.06
Aberrant expression of IL-22RA1 on hematopoietic cells as immunologically signature of primary Sjogren's Syndrome and Sjogren-associated non-Hodgkin lymphomas

G. Guggino[1], *F. Ciccia*[1], *A. Rizzo*[2], *S. Raimondo*[1], *A. Giardina*[1], *G. Giardina*[1], *G. Sireci*[1], *R. Alessandro*[1], *F. Dieli*[1], *G. Triolo*[1];
[1]*University of Palermo, Pelermo, Italy,* [2]*Azienda Ospedaliera Ospedali riuniti Villa Sofia-Cervello, Pelermo, Italy.*

Aim of this study was to better characterize the role of IL-22 and the cognate receptor IL-22R1 in the pathogenesis of primary Sjogren Syndrome (p-SS) and p-SS-associated lymphomas.
Minor salivary gland biopsies were obtained from patients with p-SS and with non-specific chronic sialo-adenitis (n-SS). IL-22, IL-22R1 and IL-22BP were evaluated by RT-PCR, immunohistochemistry and confocal microscopy. IL-22R1 expression was also analyzed by flow cytometry on peripheral blood mononuclear cells (PBMCs). PBMCs were also cultured with recombinant IL-22 and the modulation of the transcripts for pro-inflammatory cytokines was assessed by RT-PCR. Paraffin embedded sections of non-Hodgkin lymphomas from p-SS patients were finally evaluated for the expression of IL-22R1.
Our result showed significantly up-regulated transcript levels for IL-22, STAT3 and IL-22BP but not for IL-22R1 in the inflamed salivary glands of p-SS respect to n-SS. Immunohistochemistry and confocal microscopy analysis confirmed the increased salivary glands expression of IL-22 and p-STAT3 and demonstrated a significant increased protein levels of IL-22R1 in p-SS.
Also $CD14^+$ monocytes aberrantly expressed IL-22R1 in p-SS patients but not controls. The stimulation with recombinant IL-22 of PBMCs from p-SS, significantly up-regulated the expression of IL-17 and IL-22. Non-Hodgkin lymphoma tissues from p-SS patients were also characterized by the aberrant expression of IL-22R1 on macrophages and neoplastic B cells.
The aberrant expression of IL-22R1 on cells of hematopoietic origin seems to be an immunological signature of p-SS and p-SS associated lymphomas. Targeting of IL-22 pathway may represent a successful therapeutic strategy in p-SS patients.

Regulation of wound healing and fibrosis by macrophages

T. A. Wynn[1,2], *L. Borthwick*[2], *L. Barron*[2], *R. W. Thompson*[2], *K. Vannella*[2], *K. Kindrachuk*[2], *K. Hart*[2], *A. W. Cheever*[2], *T. R. Ramalingam*[2], *P. J. Murray*[2];
[1]*MD, United States,* [2]*National Institutes of Health, Bethesda, MD, United States.*

Macrophages are found in close proximity with collagen-producing myofibroblasts and play key roles in the mechanisms of wound healing and fibrosis. They produce growth factors and pro-fibrotic mediators that directly activate fibroblasts, including transforming growth factor beta, insulin-like growth factor, vascular endothelial growth factor, and platelet-derived growth factor. They also regulate extracellular matrix turnover by influencing the balance of various matrix metalloproteinases and tissue inhibitors of matrix metalloproteinases. Macrophages also regulate fibrogenesis by secreting chemokines that recruit fibroblasts and other inflammatory cells and by producing various inflammatory and anti-inflammatory cytokines. With their potential to act in both a pro- and anti-fibrotic capacity at distinct stages of the wound healing response, macrophages and the factors they express are integrated into all stages of the fibrotic process. These various and sometimes opposing functions are performed by distinct macrophage subpopulations, the identification of which is a growing focus of fibrosis research. Although collagen-secreting myofibroblasts once were thought of as the master ''mediators" of fibrosis, in this presentation I will illustrate how macrophages function as the master ''regulators'' of fibrosis.

W5.02.01
Th-2 cytokine producing Tregs are present in the skin of patients with systemic sclerosis

R. Broady, *J. Huang, K. MacDonald, J. Dunne, M. K. Levings; University of British Columbia, Vancouver, BC, Canada.*

Systemic sclerosis (SSc) is a connective tissue disorder characterized by fibrosis of the skin and internal organs. Immune dysfunction is accepted to play a role in the pathogenesis of SSc, however the exact pathways involved are not understood. Since T regulatory cells (Tregs) are key for preventing the development of autoimmune diseases, a deficiency or dysfunction of this subset may be a key factor in SSc. Deficiencies in Tregs are implicated in several autoimmune disorders but their role in SSc remains controversial. Limitations of previous studies are that in humans, expression of FOXP3 alone is insufficient to define Tregs; Tregs may become unstable and change their cytokine phenotype and/or function and activated effector T cells can also be FOXP3+. Furthermore evaluation of Tregs in the blood may not reflect their status in target organs.
In this study we aimed to determine whether Tregs play a role in the pathogenesis of SSc. Peripheral blood and skin biopsies were from obtained from patients with SSc and healthy controls (HCs). We found no difference in the proportion of Tregs in the blood or skin of patients with SSc compared with HCs. In contrast we found significantly more Th2-cytokine producing Tregs in the skin of patients with SSc. Furthermore, analysis of the TSDR in SSc Tregs revealed a similar pattern of demethylation to that of non-cytokine secreting Tregs from HCs. These data are the first to reveal conversion of Tregs into Th2-cytokine producing cells. Studies are ongoing to elucidate the mechanism underlying the plasticity.

W5.02.02
IL-33 precursor and bleomycin synergize in inducing lymphocyte accumulation and fibrosis in the lungs

I. G. Luzina[1,2], *V. Lockatell*[1,2], *P. Kopach*[1], *N. W. Todd*[1,2], *S. P. Atamas*[1,2];
[1]*University of Maryland, Baltimore, MD, United States,* [2]*Baltimore VA Medical Center, Baltimore, MD, United States.*

We and others have previously found that precursor IL-33 (PRIL33) protein is biologically active without proteolytic activation. We reported that the levels of PRIL33 are substantially elevated in the lungs of patients with interstitial lung disease (ILD), which is associated with idiopathic pulmonary fibrosis and systemic sclerosis. PRIL33 remains intranuclear and promotes inflammation in a non-Th2 fashion by not engaging the mature IL-33 receptor T1/ST2. To further assess the biological role of the elevated expression of PRIL33 in ILD, intratracheal bleomycin injury to the lung, alone or in combination with recombinant adenovirus delivery of PRIL33, was used to model ILD in mice. Combined PRIL33 gene delivery and bleomycin challenge had a potentiating effect on pulmonary lymphocytosis; accumulation of collagen; expression of HSP70; and the levels of TGF-β, CCL6, MCP-1, and MIP-1α, with these combined effects significantly exceeding the sum of the effects of PRIL33 gene delivery or bleomycin challenge alone ($p < 0.05$). By contrast, the combined effects of PRIL33 expression and bleomycin on bronchoalveolar lavage counts of macrophages and neutrophils in these mice were additive of the effects of each of these factors alone. The Th2 cytokines IL-4, IL-5, and IL-13 were not part of this synergy, and gene deficiency of T1/ST2 did not affect the synergistic nature of the "double-hit" from PRIL33 expression and bleomycin injury. It was concluded that elevated PRIL33 expression in ILD is a likely contributor to inflammatory and fibrotic lung injury, and that this contribution is independent of the T1/ST2 receptor or Th2 cytokines.

A short-term model of COPD identifies a role for mast cell tryptase

P. M. Hansbro[1,2], *E. L. Beckett*[2], *R. L. Stevens*[3,4], *A. G. Jarnicki*[1,2], *R. L. Kim*[1,2], *S. Keely*[1,2], *J. C. Horvat*[1,2], *P. A. Wark*[5,1], *B. G. Oliver*[6], *P. S. Foster*[1,2];
[1]*Hunter Medical Research Institute, Newcastle, Australia,* [2]*The University of Newcastle, Newcastle, Australia,* [3]*Harvard Medical School, Boston, MA, United States,* [4]*Brigham and Women's Hospital, Boston, MA, United States,* [5]*John Hunter Hospital, Newcastle, Australia,* [6]*Woolcock Institute of Medical Research, Sydney, Australia.*

Chronic obstructive pulmonary disease (COPD) represents a spectrum of airways diseases, and represents a huge social burden. Therapies are largely ineffective with the development of treatments hampered by the lack of an animal model that mimics aspects of human disease in a practical time-frame. We have developed a mouse model of cigarette smoke-induced COPD that develops the major hallmark features of the human disease in a relatively short amount of time. This was achieved by treating mice with tightly controlled amounts of cigarette smoke to the airways of mice. We then assessed the development of the pathological features of COPD. Also, the role of macrophages in the pathogenesis was evaluated in depletion studies, and as tryptases play an important role in tissue homeostasis, we analysed the role of MC protease-6 in COPD by exposing protease-6 deficient mice to cigarette smoke. After 8 weeks of cigarette smoke exposure, wild-type mice developed chronic inflammation, mucus hypersecretion, airway remodeling, emphysema, and reduced lung function. These characteristic features of COPD were glucocorticoid-resistant and did not spontaneously resolve after cigarette smoke sessation. Systemic effects on skeletal muscle and the heart, and increased susceptibility to respiratory infections also were observed. MC tryptase-6 deficient mice had reduced lung pathology, indicating its requirement in COPD development. *In vitro* studies demonstrated that MC tryptase is able to induce TNFα and KC expression from macrophages, indicating a role in enhancing inflammatory responses in the lung. This model provides an opportunity to study the multiple components that result in COPD pathogenesis.

W5.02.04
Suppressive role of neuroimmune semaphorin 4A in allergen-induced and VEGF-regulated lung inflammatory responses

S. P. Chapoval[1], *E. Smith*[1], *E. Nkyimbeng-Takwi*[1], *K. Shanks*[1], *M. M. Lipsky*[1], *L. J. DeTolla*[1], *J. A. Elias*[2], *A. D. Keegan*[1];
[1]*University of Maryland, Baltimore, MD, United States,* [2]*Yale University, New Haven, CT, United States.*

Asthma-relevant responses can be induced by innate (VEGF, TSLP) as well as adaptive stimuli (allergens). Our studies of VEGF lung overexpressor transgenic (tg) mice highlighted the mechanisms by which innate immune stimuli can predispose the lung to Th2 sensitization (Lee CG et al., Nat Med, 2004, 10:1095-1103; Chapoval SP et al., Clin Immunol, 2009, 132:371-384). Our study on allergen administration to Sema4A$^{-/-}$ mice provided a new insight into the lung immune semaphorin biology and Th2 inflammatory response regulation (Nkyimbeng-Takwi EH et al., Mucosal Immunol, 2012, 5:409-419). We have shown that Sema4A$^{-/-}$ mice displayed a more robust allergic response as compared to WT mice. This included selective increases in eosinophilic airway infiltration, bronchial epithelial cell hyperplasia, AHR, and BAL IL-13 content but lower Treg numbers. We recently generated VEGF tg/Sema4A$^{-/-}$ mice and assessed the effect of Sema4A deficiency on VEGF tg lung tissue phenotype. As we have shown previously, lung bronchial epithelial expression of VEGF transgene lead to an asthma-like phenotype with inflammation, parenchymal remodeling, increased vascularization, edema formation, mucous cell and myocyte hyperplasia and airway hyperreactivity. The observed lung tissue inflammatory response and vascularization in VEGF tg/Sema4A$^{-/-}$ mice were more pronounced than those found in tg mice alone. In addition, similarly to allergen-treated Sema4A$^{-/-}$ mice, we observed higher local levels of IL-13 in VEGF tg mice with Sema4A deficiency. Thus, Sema4A downregulates both innate and adaptive lung allergic responses. The new knowledge obtained from this study will be used for the development of optimal strategies for asthma intervention.

W5.02.05
The condition of host CD4+CD25+ regulatory T cells determines the phenotype of autoimmune-like chronic Graft-versus-Host Disease

Y. Akieda[1], *T. Nakamura*[2], *E. Wakamatsu*[1], *Y. Obata*[1], *S. Ogawa*[1], *S. Watanabe*[1], *R. Abe*[1,2];
[1]*Division of Immunobiology, Research Institute for Biomedical Sciences, Tokyo University of Science, Noda City, Chiba, Japan,* [2]*Faculty of Pharmaceutical Sciences, Tokyo University of Science, Noda City, Chiba, Japan.*

Chronic graft-versus-host disease (cGVHD) is a frequent complication of allogeneic hematopoietic stem cell transplantation and has features similar to various autoimmune diseases such as SLE and scleroderma (SSc). Because cGVHD phenotype varies among patients, we considered that host factors might influence on the decision of cGVHD phenotype. Therefore, we focused on host factors, especially host T cells, and investigated the role of host T cells in the pathogenesis of cGVHD using CD28-deficient mice as a host whose T cells were dysfunctional, because CD28 costimulation is important for T cell activation. We found that the absence of CD28 signaling in host T cells converted cGVHD phenotype from SLE-like to SSc-like. The transfer of allogeneic donor cells into WT host resulted in SLE-like cGVHD with anti-dsDNA autoantibody and glomerulonephritis, whereas CD28-deficient host developed SSc-like cGVHD with fibrotic damage to skin and internal organs. Also, CD28-deficient host manifested no elevation of anti-dsDNA IgG. Furthermore, cytokine pattern of donor CD4$^+$T cells in WT versus CD28-deficient host were qualitatively distinct. Reconstitution experiments demonstrated that cGVHD phenotypic conversion was attributed to the defect of host CD4$^+$T cells, particularly CD25$^+$CD4$^+$T cells, but not CD8$^+$ and NK1.1$^+$T cells. Moreover, SSc-like phenotype of CD28-deficient host was dependent on the disruption of CD28-cytoplasmic C-terminal proline-rich motif, which is the critical motif for regulatory T cells (Treg) development, independently of other two motifs, which contribute to only conventional T cells functions. Therefore, we suggest that the state of host Treg is the determinant of cGVHD phenotype.

W5.02.06
Endogenous and immune cell derived BDNF supports regeneration in human skeletal muscle

E. Colombo[1], *F. Bedogni*[1], *I. Lorenzetti*[1], *N. Landsberger*[1,2], *S. C. Previtali*[1], *C. Farina*[1];
[1]*San Raffaele Scientific Institute, Milan, Italy,* [2]*University of Insubria, Busto Arsizio, Italy.*

Idiopathic inflammatory myopathies (IIM) are rare skeletal muscle disorders characterized by tissue damage and immune cell infiltration. Despite several evidences point to a pathogenic role of immunity in IIM, some studies provided insights into the cross-talk between inflammatory cells and skeletal muscle after acute damage and in chronic degenerative diseases, suggesting an involvement for immune cells in promoting muscle repair. Recent researches in animal models highlighted a role for the neurotrophin BDNF in muscle regeneration, however its expression, localization and function in human skeletal muscle are unknown. Here we show that BDNF was displayed by muscle satellite cells and mature myofibers in skeletal muscle. Interestingly, in IIM tissue newly-forming myofibers displayed enhanced BDNF immunoreactivity and expressed the neurotrophin receptor p75NTR, suggesting autocrine usage of the neurotrophin supporting in vivo regeneration. Consistently, BDNF and p75NTR were expressed in human myoblasts and myotubes in vitro. Functional experiments demonstrated the role of this neurotrophin in myogenesis, as BDNF gene silencing or protein blockade dampened myocyte differentiation. Importantly, infiltrating immune cells in IIM were not evenly distributed within the tissue, but were preferentially located near p75NTR-positive regenerating fibers and produced BDNF. Both T lymphocytes and macrophages contributed to BDNF synthesis. In conclusion, BDNF is a positive regulator of human myogenesis. Thus, the preferential localization of BDNF-producing immune cells near p75NTR-regenerating fibers supports the hypothesis of protective immune responses in inflamed skeletal muscle. This work was supported by the Association Française contre les Myopathies (AFM) and by the Italian Ministry for Health (Ricerca Corrente)

Effect of multiple genetic risk factors associated with rheumatoid arthritis on immune cell phenotypes

L. Chovanova[1,2], *M. Vlcek*[1,2], *K. Krskova*[1], *F. Spoutil*[3], *J. Rovensky*[4], *R. Brownlie*[5], *R. Zamoyska*[5], *R. Imrich*[1,2];
[1]*Institute of Experimental Endocrinology, Slovak Academy of Sciences, Bratislava, Slovakia,* [2]*Center for Molecular Medicine, Slovak Academy of Sciences, Bratislava, Slovakia,* [3]*Institute of Experimental Medicine, Academy of Sciences, Prague, Czech Republic,* [4]*National Institute of Rheumatic Diseases, Piestany, Slovakia,* [5]*Institute of Immunology and Infection Research, University of Edinburgh, Edinburgh, United Kingdom.*

The involvement of genetics, environment and autoimmunity in the pathogenesis of rheumatoid arthritis (RA) has been proposed recently. The most important genetic factor is the HLA-DRB gene, followed by more than 30 variants in potentially pathogenic non-MHC genes. The knowledge about their actual effect on immune cell function and related mechanisms is relatively poor. The aim of our study was to obtain a broader picture of relations between circulating immune cell phenotype, cytokine production after stimulation and the genetic background. PBMC were isolated from 35 healthy individuals and 36 RA patients with known RA-associated genotype in the genes: PTPN22, STAT4, CTLA4, PADI4, AFF3, IRF5, TRAF1/C5 and HLA-DRB1. The proportions of selected PBMC subsets were analysed by flow cytometry. TNF-α, IFN-γ and IL-17 production was assessed after stimulation with PMA/ionomycin. Redundancy analysis (RDA) was applied to analyse the data. Our preliminary results suggest an increase in pro-inflammatory cytokines and the proportion of CD14 monocytes in RA patients. Higher proportions of memory B cells were associated with the presence of one risk allele in PTPN22 and two risk alleles in AFF3, PADI4 and TRAF1/C5 genes. The presence of two risk alleles in IRF5, STAT4 and CTLA4 genes or 2 alleles coding the shared epitope sequence was associated with increased percentage of CD8 memory cells and production of TNF-α and IFN-γ by NKT cells regardless of the diagnose. Alterations in immune cell proportions and cytokine secretion are suggested as the possible mechanism behind risk allele association.

HLA-B27 micropolymorphisms correlate with differences in function and susceptibility to Ankylosing Spondylitis

M. T. Fiorillo[1], *V. Tedeschi*[1], *C. Vitulano*[1], *F. Paladini*[1], *G. Camilli*[1], *C. Rossetti*[1], *S. Tuncer*[1], ***R. Sorrentino***[1,2];
[1]*Department of Biology and Biotechnology, Sapienza University, Roma, Italy,* [2]*Fondazione Pasteur-Cenci Bolgnetti, Roma, Italy.*

More than 100 diseases, many of which with an autoimmune-mediated pathogenic mechanism, have been associated with HLA genes. Very often, HLA region accounts for the greater part of the genetic predisposition of these complex diseases. HLA genes are the most polymorphic in the human genome, and the extensive allelic variation together with the strong linkage disequilibrium among genes primary involved in the regulation of the immune response, have made difficult to identify the exact location of the causative variants. The study of functional differences dictated by micropolymorphisms distinguishing between associated and not associated alleles can help to give some insights. We focused our research on the HLA-B27 family of genes, strongly associated with Ankylosing Spondylitis. In particular, we have reported the existence of an allelic variant, HLA-B*2709, differing from the most frequent HLA-B*2705, for a single amino acid at position 116 (Asp to His substitution) in the pocket F of the groove hosting the C-terminus of the antigenic peptides. Interestingly, the B*2709 allele is virtually absent in patients. The Asp116-His116 variation correlates with differences in binding specificity and epitope presentation to CD8+ T cells. We show here, using theoretical (dynamics simulation and modeling) and experimental (antigen presentation) approaches, how this single substitution influences the structure not only of the F pocket but of the entire peptide-binding groove, thus dictating the binding specificity and TCR recognition.

W5.03.02
Variants in the IRF5-TNPO3 locus are associated with the development of lupus and its clinical presentation and shared with other autoimmune disorders

L. C. Kottyan*, E. E. Zoller, S. Hawtrey, K. M. Kaufman, J. B. Harley; Cincinnati Children's Hospital Medical Center, Cincinnati, OH, United States.*

Recent improvements in genetic methods allow for more complete identification of candidate causal variants. Exploiting genotyping, DNA sequencing, imputation, and trans-ancestral mapping, we modeled the IRF5-TNPO3 genetic association on chromosome 7, now implicated in two immunotherapies and seven autoimmune diseases. Specifically, in systemic lupus erythematosus (SLE) we resolve separate associations in the IRF5 promoter (all ancestries) and an extended European haplotype. We capture 7,650 IRF5-TNPO3 genetic variants across five ethnicities in 8,395 SLE cases and 7,367 controls. The six plausible causative IRF5 promoter variants are confined to 5.7 kb. The 22 potentially causal variants of an 85.5 kb haplotype of IRF5 and TNPO3. The possible models from this sample virtually eliminate the previously purported IRF5 functional variants as causal. Strikingly, this model also appears to operate in Sjögren's syndrome and systemic sclerosis (both components) and primary biliary cirrhosis (haplotype only), demonstrating the nuances of similarity and difference in autoimmune disease risk mechanisms at IRF5-TNPO3. Finally, we performed case-only subphenotypic analyses to identify variants in the IRF5-TNPO3 region useful in predicting the disease progression of patients with lupus and found strong association with age-of-onset (variants in the haplotype) and the antigen specificity of autoantibodies anti-Ro and anti-dsDNA (variants in the IRF5 promoter). In conclusion, genetic variants in the IRF5-TNPO3 region critically regulate the development of multiple autoimmune diseases and the clinical presentation of lupus. Given the importance of this locus to multiple immune disorders, future studies will be aimed at understanding the immunological mechanisms driving the genetic associations.

W5.03.03
The lupus-associated variant of the ITGAM allele (rs1143679) impairs phagocytosis, but not migration nor TLR7/8 induced cytokine release

L. Fossati-Jimack[1], *G. S. Ling*[1], *A. Cortini*[1], *M. Szajna*[1], *T. H. Malik*[1], *J. U. McDonald*[2], *M. C. Pickering*[1], *H. T. Cook*[1], *P. R. Taylor*[2], *M. Botto*[1];
[1]*Centre for Complement and Inflammation Research, Imperial College London, London, United Kingdom,* [2]*Cardiff Institute of Infection and Immunity, Cardiff University School of Medicine, Cardiff, United Kingdom.*

The minor allele of a non-synonymous ITGAM polymorphism (rs1143679, converting arginine to histidine at position 77: R77H) represents one of the strongest genetic risk factors in systemic lupus erythematosus, with heterozygosity (77R/H) being the most common disease associated genotype. ITGAM encodes for an integrin, CD11b, which associates with CD18 to form the complement receptor 3 (CR3) that plays a crucial role in several immunological processes including leukocyte extravasation and phagocytosis. In this study, we assessed the influence of R77H on different CR3-mediated functions in monocytes, neutrophils, macrophages and dendritic cells. The surface expression of CD11b was not altered by R77H in any of these cell types. Nevertheless, phagocytosis of iC3b-coated targets was significantly impaired in heterozygous 77R/H macrophages, monocytes and neutrophils compared to 77R/R cells. We confirmed this using immortalized macrophage cell lines expressing either allele. R77H polymorphism did not affect adhesion and transmigration of neutrophils assessed by *in vivo* and *in vitro* assays. Toll-like receptor 7/8-mediated cytokine release by monocytes or dendritic cells with or without CR3 pre-engagement by iC3b-coated targets was similar between the two alleles. Our findings demonstrate that the reduction in CR3-mediated phagocytosis associated with the 77H CD11b variant is not macrophage-restricted and that susceptibility to systemic lupus erythematosus most likely relates to impaired waste disposal, a key component of lupus pathogenesis.

W5.03.04
Genetic variants in PXK are associated with the development of lupus and critically regulate BCR internalization

S. E. Vaughn[1,2], *I. T. W. Harley*[1,2], *C. Foley*[3], *L. C. Kottyan*[1], *K. M. Kaufman*[1], *J. A. Kelly*[4,5], *J. B. Harley*[1,2,6];
[1]*Cincinnati Children's Hospital, Cincinnati, OH, United States,* [2]*University of Cincinnati College of Medicine, Cincinnati, OH, United States,* [3]*Spelman College, Atlanta, GA, United States,* [4]*University of Oklahoma, Oklahoma City, OK, United States,* [5]*US Department of Veterans Affairs, Oklahoma City, OK, United States,* [6]*US Department of Veterans Affairs, Cincinnati, OH, United States.*

Systemic Lupus Erythematous (SLE) is a systemic autoimmune disease with a strong genetic component. Over 50 genes have been associated with SLE, many with no immediate or obvious biological connection to disease. We previously identified one such gene, *PXK*, as being a candidate gene associated with SLE in women of European descent and these findings have since been replicated. *PXK* has additionally been identified as a risk gene for RA as well, suggesting a broad role in the pathobiology of autoimmune disease. In this work we undertake the fine mapping of the *PXK* genetic locus in an effort to refine the association signal. We identify one independent effect in the region occurring strictly in individuals of European ancestry. In tandem with refinement of the genetic signal, we also attempt to identify the SLE relevant biological import of *PXK* by examining the role it plays in B cells. While PXK has been shown to participate in receptor internalization, nothing is known about its function in the context of SLE. Using ImageStream technology, we find that PXK colocalizes with the B cell receptor (BCR) upon BCR internalization. Finally, we show that the BCR is more rapidly internalized in cells carrying the *PXK* risk allele. These results suggest that PXK may play an important role in the regulation of BCR signaling and B cell differentiation and survival. As B cell regulation is crucial to SLE pathogenesis, understanding the specific changes induced by SLE-associated variants in *PXK* will provide important insight into SLE pathogenesis.

Enhanced apoptosis by disruption of the STAT3-IκB-ζ signaling pathway in epithelial cells induces Sjögren's syndrome-like autoimmune disease

A. Okuma[1], *K. Hoshino*[2,3,4], *T. Kaisho*[2,3], ***T. Muta***[1];
[1]*Graduate School of Life Sciences, Tohoku University, Sendai, Japan,* [2]*RIKEN Research Center for Allergy and Immunology, Yokohama, Japan,* [3]*World Premier International Immunology Frontier Research Center, Osaka University, Suita, Japan,* [4]*Faculty of Medicine, Kagawa University, Miki, Japan.*

Sjögren's syndrome is an autoimmune disease characterized by exocrinopathy that leads to dry eye and dry mouth. Although lymphocyte infiltration into exocrine glands and the generation of autoantibodies have been reported in Sjögren's syndrome, its pathogenic mechanism remains elusive. Here, we show that mice lacking the transcriptional regulator, IκB-ζ, developed Sjögren's syndrome-like inflammation characterized by lymphocyte-infiltrated dacryoadenitis and Sjögren's syndrome-associated autoantibodies. In particular, epithelial cells, but not hematopoietic cells, lacking IκB-ζ were essential for the development of inflammation. IκB-ζ-deficient epithelial cells in the lacrimal glands exhibited enhanced apoptosis even in the absence of lymphocytes. Administration of caspase inhibitors ameliorated the inflammation, indicating the critical role of caspase-mediated apoptosis. Furthermore, epithelial cell-specific STAT3-deficient mice developed Sjögren's syndrome-like inflammation with impaired IκB-ζ expression in the lacrimal glands. Thus, this study reveals a pathogenic mechanism of Sjögren's syndrome in which dysfunction of epithelial cells caused by disruption of STAT3-mediated IκB-ζ induction elicits the activation of self-reactive lymphocytes.

Vav1 cooperate with Themis to modulate regulatory T cell suppressive functions

C. Pedros[1], *M. Chabod*[1], *A. Dejean*[1], *I. Bernard*[1], *O. Andreoletti*[2], *G. Fournié*[1], *A. Saoudi*[1];
[1]*INSERM U1043, Toulouse, France,* [2]*INRA ENVT 1225, Toulouse, France.*

Natural Foxp3+ regulatory T cells (Treg) are of paramount importance for establishing self-tolerance, controlling inflammatory responses and maintaining immune homeostasis. The identification of new molecules controlling Treg functions is nowadays an important challenge. We previously reported the implication of Themis, a new actor of TCR signaling, in Treg suppressive capacities. Indeed, Treg from Themis deficient BN rats were defective, leading to the development of an inflammatory bowel disease. In the present study, we show that Themis deficiency does not impair Treg suppressive functions and does not induce any pathological manifestations in LEW rats. These findings suggest that an interaction with other(s) gene(s) may contribute to the Treg defect and disease development in Themis deficient BN rats. To test this hypothesis and identify the involved gene(s), we performed a genetic dissection using different congenic lines. We show that the impact of Themis deficiency on Treg suppressive functions requires the expression of a constitutively active Vav1 variant. Together, these studies highlight the importance of Vav1 and Themis signaling hub in regulating the suppressive functions of Treg. Understanding the underlying molecular mechanisms may lead to advances in Treg biology and favor the identification of new pharmacogenetic markers and therapeutic targets in immune mediated diseases.

IL5.05.01
'ASIA' - Autoimmune (Auto-inflammatory) syndromes induced by adjuvants

Y. Shoenfeld[1,2];
[1]*Zabludowicz Center for Autoimmune Diseases, Sheba Medical Center, Tel Hashomer, Israel,* [2]*Sackler Faculty of Medicine, Tel-Aviv University, Tel Aviv, Israel.*

Four enigmatic medical conditions were described recently, all characterized by hyperactive immune response and similar clinical and laboratory manifestations. These conditions (siliconosis, Gulf War Syndrome, macrophagic myofasciitis syndrome and post-vaccination phenomena) imply that environmental factors may play a role in inducing or aggravating autoimmunity and auto-inflammation.
In rare occasions vaccines may induce autoimmune or auto-inflammatory conditions both in animals and in humans. These conditions - defined diseases (Gullian-Barre syndrome) or enigmatic ones - have been reported following vaccines and vaccination protocols. The susceptibility factors and the temporal association between vaccines and these immune mediated reactions remain to be defined; however, the similarities between vaccines and infections and the addition of adjuvants to almost every vaccine are considered major contributors to such adverse events. In MMF a cause was clearly delineated. MMF is a rare condition caused by deposition of alum, an adjuvant in different vaccines, which cause an immune mediated muscles disease. In genetically prone patients, alum may induce this syndrome.
Another similar phenomenon is exposure to silicones. In a study, a group of patients with silicone breast implants had a statistically significant increase in 16 of 28 investigated symptoms consistent with fibromyalgia and chronic fatigue syndrome criteria, compared to a group of women who underwent reduction mammoplasties, congruent with the FDA's establishment of a link between fibromyalgia and ruptured silicone implants.
A common denominator to these syndromes is the trigger entailing adjuvant activity.
We suggest including these four conditions in one syndrome, the "Autoimmune Syndrome Induced by adjuvants" (ASIA).

IL5.05.02
Early-life microbial exposures and allergy development - exploring the role of herpesviruses

E. Sverremark-Ekstrom;
Stockholm University/Dept of Molecular Biosciences, Stockholm, Sweden.

There is increasing evidence to support a role for early-life microbial exposures in influencing immune- and allergy development in children. Epstein-Barr virus (EBV), a human herpesvirus, is often acquired during childhood and persists latently in B cells. We have found that EBV sero-positivity connects to immune-modulatory effects in children such as altered T- and NK-cell functional responses in vitro as well as protection against early IgE-sensitization. This potential "allergy-protection" was further dependent on time-point for infection. Therefore we have continued to study whether age at infection and if co-infection with another common herpesvirus, cytomegalovirus (CMV), influence immune characteristics following EBV infection in vitro. This has been investigated in cells from a well-characterized cohort of children with known EBV and CMV serostatus. Upon in vitro EBV infection of peripheral blood cells from children of different ages we found that age, and the capacity to produce IFN-γ in particular, clearly had an impact on the degree of EBV-induced B-cell activation and expansion. Further CMV serostatus significantly influenced EBV-infection in vitro, as we observed a reduced enrichment of (switched memory) IgD-CD27+ B cells associated with high levels of IFN-γ and frequencies of highly mature CD8+CD57+ T cells in CMV+ children following EBV-infection. Our results demonstrate that both a child's age and serostatus to CMV will have an impact on EBV-induced B-cell activation and expansion, and points to the ability of persistent viruses with immune-modulatory functions to impact on immune responses within the host.

W5.05.01
Ectopic lymphoid structures support Epstein-Barr virus persistence and autoreactive plasma cell infection in Sjogren's Syndrome salivary glands

C. Croia[1], *B. Serafini*[2], *N. Sutcliffe*[1], *A. Tappuni*[1], *F. Aloisi*[2], *C. Pitzalis*[1], *M. Bombardieri*[1];
[1]*Queen Mary University of London, London, United Kingdom,* [2]*Istituto Superiore di Sanita', Rome, Italy.*

Background: Epstein-Barr virus (EBV) infects B-cells and modifies their differentiation programme leading to B-cell activation and immortalization. EBV has been suggested to rescue autoreactive B-cells and promote autoimmunity. Although different evidences support a link between EBV infection and Sjogren's syndrome (SS), the role of EBV in SS pathogenesis remains elusive.
Objectives: To investigate the role of EBV in SS by analysing EBV infection in the salivary glands and its relationship with ectopic lymphoid structures (ELS), in situ autoreactive plasma cell differentiation, autoantibody production and cytotoxic immune response.
Methods: Latent and lytic EBV infection was investigated in SS salivary glands characterised for the presence/absence of ELS by RT-PCR, in situ hybridization and immunohistochemistry/ immunofluorescence. Local production of anti-Ro52 antibodies and anti-EBV antibodies was investigated in situ and/or in vivo in the SCID/SS chimeric model.
Results: EBV dysregulation was observed exclusively in ELS+ SS salivary glands as revealed by EBER transcripts and EBER+ cells and immunoreactivity for EBV latent (LMP1/LMP2A) and lytic (BFRF1) antigens in B-cells and plasma cells, respectively. A subset of EBV+ plasma cells produced anti-Ro52 antibodies and ELS-containing SS salivary glands transplanted into SCID mice supported the production of anti-Ro52, anti-La and anti-EBV antibodies. Analysis of CD4/CD8 T-cell localization and granzyme-B expression suggested that EBV persistence is favoured by impaired cytotoxicity and exclusion of CD8+ T-cells from B-cell follicles.
Conclusions: We demonstrated latent and active EBV infection within ELS in SS salivary glands that appears to contribute to local growth and differentiation of autoreactive B cells producing SS-associated autoantibodies.

W5.05.02
A single non-synonymous polymorphism of TLR2 is sufficient to recapitulate the variability of Experimental Multiple Sclerosis

G. Migliara, *G. Di Sante, A. Piermattei, C. Nicolò, M. Valentini, A. Procoli, M. Geloso, M. Corbi, A. Sgambato, F. Ria;*
Università Cattolica del Sacro Cuore, Rome, Italy.

In the pathogenesis of Multiple Sclerosis a growing body of evidence is directing the attention also to bacteria. It is known that TLRs are involved in maintaining tolerance and inducing inflammation against the pathogens. We showed that M tb-derived motives play an essential role in the induction of the experimental model of Multiple Sclerosis (EAE). To examine TLR2 (the main receptor for M tb) in the development of EAE we crossed different strains of mice, SJL and B6, in both of which is possible to induce EAE after immunization with myelin derived proteins. These two strains display a non-synonymous SNP of TLR2 that condition mobility of encephalitogenic T cells, with the allele of B6 dominant over that of SJL. Using of a strain lacking for TLR2 expression ($B6^{tlr2-}$) we observed that a single NSP of TLR2 has a complex effect on clinical and histology of EAE. Although TLR2 haplotype does not influence incidence of disease, it is crucial for the course of EAE (more severe in F1 SJL x $B6^{tlr2-}$ than in F1 SJL x $B6^{wt}$ mice), significant for remission of EAE symptoms and involved in localization of infiltrates and demyelination in frontal lobes. The polymorphic site of TLR2 influences polarization of T cells by the expression of cytokines modifying the bias towards Th1/Th17, while no effect was seen in FoxP3 expression.

W5.05.03
High salt diet exacerbates autoimmune disease by induction of pathogenic Th17 cells

M. Kleinewietfeld[1,2], *A. Manzel*[3], *R. A. Linker*[3], *D. N. Muller*[4], *D. A. Hafler*[1,2];
[1]*Yale School of Medicine, New Haven, CT, United States,* [2]*Broad Institute of MIT and Harvard, Cambridge, MA, United States,* [3]*University of Erlangen-Nuremberg, Erlangen, Germany,* [4]*Experimental and Clinical Research Center, Berlin, Germany.*

Over the last half-century there has been a marked increase of autoimmune diseases in the Western world. This increase could not be explained by genetic predisposition but must be triggered by changes in the environment. It has been shown that pathogenic IL-23 dependent Th17 cells play a critical role for the development of autoimmune diseases. Genetic risk factors associated with multiple sclerosis (MS) are related to the IL23/Th17 axis and Th17 cell are crucial for the induction of experimental autoimmune encephalomyelitis (EAE), an animal model for MS. However, how changes in the environment could directly influence Th17 cells is not well established. With this study we show that high-salt (sodium chloride; NaCl) concentrations boost the induction of murine and human Th17 cells in vitro. High-salt concentrations activate the p38/MAPK pathway involving nuclear factor of activated T cells 5 (NFAT5) and serum/glucocorticoid-regulated kinase 1 (SGK1) during cytokine-induced Th17 polarization. In line with increased IL-17 secretion, high-salt induced Th17 cells up regulate the pro-inflammatory cytokines GM-CSF, TNFα and IL-2, characteristic for a highly pathogenic phenotype. Finally, mice fed a high-salt diet develop a severe form of EAE, in line with augmented central nervous system infiltrating and peripherally induced Th17 cells. Thus, increased dietary salt intake might represent an environmental risk factor for the development of autoimmune diseases through the induction of pathogenic Th17 cells.

W5.05.04
Impact of infectious agents on trafficking of effector T cells is mediated by a polymorphic site of TLR2 and CD44 isoforms expression

G. Di Sante[1], *E. De Paolis*[1], *A. Piermattei*[1], *M. Valentini*[1], *G. Migliara*[1], *C. Nicolò*[1], *G. Constantin*[2], *E. Giorda*[3], *G. Delogu*[1], *F. Ria*[1];
[1]*Università Cattolica del Sacro Cuore, Rome, Italy,* [2]*Università di Verona, Verona, Italy,* [3]*Ospedale Bambino Gesù, Rome, Italy.*

The nature of triggers activating auto-aggressive lymphocytes in Multiple Sclerosis is poorly understood, but both environmental and genetic factors are relevant. The role of infectious agents in the regulation of antigen-specific T cell trafficking is currently unknown. We showed that the amount of *M tuberculosis* in the adjuvant modulates rapid relocation of antigen-specific T cells from draining lymph nodes (LN) to spleen, in the SJL mouse. We observed that the modulation of T cell mobilization was strain dependent and linked to a NSP of TLR2 responsible for early/late relocation phenotype. To clarify the mechanisms controlling early and late mobilization of T cells we examined the expression of activation markers and adhesion molecules involved in T cell trafficking. We show that early relocation associated with intermediate expression of CD44, a molecule controlling T cell migration under inflammatory conditions. TLR2 directly regulates the distribution of CD44 and the expression of its isoforms. Our results show that pathogens engaging TLR2 on activated T cells through a polymorphic site modulate expression of CD44 and regulate effector T cells trafficking in vivo.

W5.05.05
Aryl hydrocarbon receptor modulates psoriatic skin inflammation

P. Di Meglio[1], *J. H. Duarte*[1], *H. Ahlfors*[1], *N. D. L. Owens*[1], *F. Villanova*[2], *K. Hirota*[1], *M. Gilchrist*[1], *F. O. Nestle*[2], *U. Mrowietz*[3], *B. Stockinger*[1];
[1]*NIMR, London, United Kingdom,* [2]*King's College London, London, United Kingdom,* [3]*University Medical Center Schleswig-Holstein, Kiel, Germany.*

Psoriasis is a chronic inflammatory skin disease resulting from the interaction of genetic and environmental factors. Cross-talk between innate, adaptive and epithelial/stromal cells, such as keratinocytes and fibroblasts, underpins the pathological response in this disease. More than 40 disease-associated loci have been identified to contribute to psoriasis. Environmental risk factors on the other hand remain less well-defined on a mechanistic basis.
The Aryl hydrocarbon receptor (AhR) is a ligand-activated transcription factor responsive to environmental stimuli and it is essential for the maintenance of intestinal barrier integrity. The wide expression of AhR in several skin cell types suggests a role for AhR signalling at this barrier organ. Here, we combine the imiquimod-induced mouse model of psoriasiform skin inflammation with the analysis of psoriasis patient skin biopsies, to investigate the role of AhR in psoriasis.
AhR deficiency in the skin resulted in a more severe psoriasiform skin inflammation with increased epidermal thickness, neutrophils infiltration and expression of pro-inflammatory mediators. Conversely, AhR ligation in wild-type mice ameliorated the skin phenotype. Finally, exposure of psoriasis skin biopsies to either AhR agonist or antagonist modulated psoriasis-related genes with AhR agonist reducing their expression in lesional skin, and AhR antagonist up-regulating these genes in non-lesional skin.Taken together, our results suggest that AhR has a critical role in dampening skin immune responses and that lack of AhR in the skin exacerbates dysregulated cross-talk between innate and adaptive cells in psoriasis.

W5.05.06
IL-33-mediated innate response and adaptive immune cells contribute to maximum responses of protease allergen-induced allergic airway inflammation

S. Kamijo[1], ***T. Takai***[1], *M. Hara*[1], *A. Matsuda*[1], *H. Saito*[1], *S. Nakae*[1], *K. Sudo*[2], *S. Ichikawa*[3], *H. Ogawa*[1], *K. Okumura*[1];
[1]*Atopy (Allergy) Research Center, Juntendo University School of Medicine, Tokyo, Japan,* [2]*Animal Research Center, Tokyo Medical University, Tokyo, Japan,* [3]*Department of Materials and Biological Sciences, Faculty of Science, Japan Women's University, Tokyo, Japan.*

How the innate and adaptive immune systems cooperate in the natural history of allergic diseases has been largely unknown. Plant-derived allergen, papain, and mite allergens, Der f 1 and Der p 1, belong to the same family of cysteine proteases. We examined the role of protease allergens in the induction of antibody production and airway inflammation after repeated intranasal administration without adjuvants and that in basophil/mast cell stimulation *in vitro*. Papain induced papain-specific IgE/IgG1 and lung eosinophilia. Der f 1 induced Der f 1-specific IgG1 and eosinophilia. Although papain-, Der f 1-, and Der p 1-stimulated basophils expressed allergy-inducing cytokines including IL-4 *in vitro*, basophil-depleting antibody and mast cell deficiency did not suppress the papain-induced *in vivo* responses. Protease inhibitor-treated allergens and a catalytic site-mutant did not induce the responses. These results indicate that the protease activity is essential to antibody production and eosinophilia *in vivo* and basophil activation *in vitro*. IL-33-deficient mice lacked eosinophilia and had reduced papain-specific IgE/IgG1. Coadministration of ovalbumin with papain induced ovalbumin-specific IgE/IgG1, which was reduced in IL-33-deficient mice. We demonstrated IL-33 release, subsequent IL-33-dependent IL-5/IL-13 release, and activation of T1/ST2-expressing lineage$^-$CD25$^+$CD44$^+$ innate lymphoid cells in the lung after the papain inhalation, suggesting the contribution of the IL-33_type 2 innate lymphoid cell_IL-5/IL-13 axis to the papain-induced airway eosinophilia. Rag2-deficient mice, which lack adaptive immune cells, showed significant, but less severe eosinophilia. Collectively, these results suggest cooperation of adaptive immune cells and IL-

33-responsive innate cells in protease-dependent allergic airway inflammation.

The CD28 superagonist TGN1412: After the storm

***T. Hünig**;*
Institute for Virology and Immunobiology, Würzburg, Germany.

During a first-in-human trial in 2006 in London, application of the CD28 superagonist TGN1412 resulted in a life-threatening cytokine release syndrome. This is in contrast to rodent models, where Treg cells are preferentially activated, allowing interference in multiple models of autoimmunity and inflammation. Using a novel cell culture system in which the response to soluble TGN1412 is readily detected, we have found that a) the dose of TGN1412 applied during the FIH study was in functional saturation, maximally activating both pro-inflammatory CD4EM T-cells as well as Treg cells; b) just as in rodents, reduction of CD28 SA concentration leads to a loss of the pro-inflammatory response while partially maintaining the regulatory T-cell response, and c) that using this protocol, effective Treg activation is readily observed in vitro with PBMC from patients with various autoimmune/inflammatory disorders such as RA, MS, SLE, and Psoriasis. Finally, results from a new, low-dose study with human volunteers will be reported.

IL5.06.02
Molecular Control of Treg Stability and Function

***D. Vignali**;*
St Jude Children's Research Hospital, Memphis, TN, United States.

Regulatory T cells (T_{reg}) represent a critical component of the immune system that prevents autoimmunity and inflammatory diseases, and maintains immune homeostasis, but also limits effective anti-tumor immunity. The signals that maintain T_{reg} stability and potentiate their function remain obscure. We have shown that the immune cell surface ligand semaphorin-4a (Sema4a) on conventional T cells and the T_{reg}-restricted receptor neuropilin-1 (Nrp1) interact to potentiate T_{reg} function. Mice with a T_{reg}-restricted deletion of Nrp1 exhibit limited tumor-induced tolerance and thus substantial resistance to certain tumors, yet do not develop any autoimmune manifestations. Nrp1-deficient T_{reg} are also unable to control colitis. Increased Nrp1 signaling represses Akt activity, facilitates Foxo nuclear translocation and induces a transcriptional program that promotes T_{reg} stability and function while repressing the induction of lineage-specific transcription factors. Nrp1 is also expressed on activated human T_{regs} and promotes their suppressive function. Thus, Nrp1 ligation maintains T_{reg} stability and function in highly inflammatory sites but is dispensable for the maintenance of immune homeostasis, highlighting Nrp1 as a potential immunotherapeutic target in cancer while induction of this pathway may present novel treatments for inflammatory and autoimmune diseases. The utilization of this pathway in autoimmune diseases will be discussed.

W5.06.01
TRAF6 is essential for maintenance of regulatory T cells and suppression of Th2 type inflammation

***G. Muto**, R. Morita, S. Niikura, H. Kotani, T. Kobayashi, A. Yoshimura;*
Keio University School of Medicine, Tokyo, Japan.

Regulatory T cells (Tregs) maintain immune homeostasis by limiting inflammatory responses.
Tumor necrosis factor (TNF) receptor-associated factor 6 (TRAF6) has a key role in the regulation of innate and adaptive immune responses by mediating signals from various receptors including T-cell receptor. Previously, T cell-specific deletion of TRAF6 has been shown to induce multiorgan inflammatory disease, however, the role of TRAF6 in Tregs remained to be investigated. Therefore, we generated Treg-specific TRAF6-deficient mice by using Foxp3-Cre and TRAF6-flox mice. Treg-specific TRAF6-deficeint mice developed fulminant multiorgan inflammatory diseases including dermatitis, multiple lymphadenopathy, arthritis, and hyper IgE phenotypes. Although TRAF6-deficeint Tregs possesses similar in vitro suppression activity compared to wild-type Tregs, TRAF6-deficeint Tregs could not suppress autoimmune colitis induced by naïve T cells in Rag2-deficeint mice due to low proliferation capacity under lymphopenic conditions. Consistently, the fraction of TRAF6-deficeint Tregs was reduced in number compared with wild-type Tregs in TRAF6 flox/flox, Foxp3YFP -Cre/+ mice, which suggests the in vivo instability of TRAF6-deficeint Tregs without inflammation. Moreover fate-mapping analysis of Tregs suggested the number of exFoxp3 cells increased, and IL-4 was mostly produced from exFoxp3 cells under Th2 type inflammation. These data indicate that TRAF6 play important roles in stable maintenance of Tregs against Th2 type inflammation.

W5.06.02
Breakdown of immune tolerance by quantitative and qualitative alterations of ZAP-70

***A. Tanaka**[1,2], S. Maeda[2,3], T. Nomura[2], S. Tanaka[2], L. Jin[1], S. Akizuki[2], N. Sakaguchi[1,2], R. Zamoyska[4], D. M. Standley[1], S. Sakaguchi[1,2];*
[1]Osaka University, Suita, Osaka, Japan, [2]Kyoto University, Kyoto, Japan, [3]Nagoya City University, Nagoya, Japan, [4]The University of Edinburgh, Edinburgh, United Kingdom.

ZAP-70 protein is an essential mediator of TCR signaling and its alteration can drastically change the course of thymic development and immune tolerance. Here, we show that a series of qualitative and quantitative alterations of ZAP-70 result in spontaneous developments of arthritis and other chronic autoimmune diseases. Qualitative alterations of ZAP-70 by knock-in mutagenesis resulting in 10- or 20-fold reduction in affinity to phosphorylated ITAMs of CD3ζ lead to developments of arthritis and other autoimmune diseases. Quantitative alterations in a tetracycline-inducible ZAP-70 reconstitution system in ZAP-70 KO mice showed that approximately 4-fold reduction resulted in chronic arthritis and a variety of autoimmune diseases. All the alterations of ZAP-70 that caused CD4+ T cell dependent arthritis showed selection of few CD4 SP cells with skewed TCR towards self-reactive repertoire and defective thymic development of natural regulatory T cells in the thymus. Furthermore, modulation of ZAP-70 levels distinctly in the thymus and the periphery demonstrated that those T cells developed in the thymus with a quantitatively low level of ZAP-70 lead to the development of autoimmune diseases irrespective of their ZAP-70 levels in the periphery. Our results suggest that a range of ZAP-70 reduction low enough to impair Treg selection and promote the selection of self-reactive TCR, but sufficiently high to maintain their TCR responsiveness confer spontaneous autoimmunity.

W5.06.03
KLRG1 expression in ICOS+Foxp3+ Treg cells delineates a functionally fatigued Treg subset during T1D progression in NOD mice

***M. Kornete**[1], C. Piccirillo[1,2];*
[1]McGill University, Montreal, QC, Canada, [2]Research Institute of McGill University Health Centre (MUHC), Montreal, QC, Canada.

A progressive waning in Treg cell function is thought to provoke autoimmunity in the non-obese diabetic (NOD) model of type 1 diabetes (T1D). We have shown that the abrogation of the inducible T cell co-stimulator (ICOS) pathway in NOD-BDC2.5 mice exacerbates T1D. More specifically, we demonstrated that the majority of islet-infiltrating Treg cells express ICOS in pre-diabetic mice, and that ICOS+ Treg cells display improved fitness and suppressive function. We also showed that T1D progression is associated with a decline in ICOS expression, in expansion and in suppression in these cells. Strikingly, as much as 50% of ICOS+ Treg cells express KLRG1, a

marker of terminal differentiation. We thus hypothesized that KLRG1 expression designates a subpopulation of dysfunctional ICOS+ Treg cells in islets and might therefore provoke T1D progression. We find that ICOS+ Treg cells expressing KLRG1 have decreased proliferative capacity and CD25 expression in vitro and in vivo. In addition, loss of fitness in KLRG1+ICOS+ Treg cells correlates with a poorer suppressive capacity, both in vitro and in vivo. We also observe an increased inflammatory cytokine production by KLRG1+ICOS+ Treg cells which correlates with a loss of Foxp3 expression in these cells. Overall, we demonstrate that KLRG1 expression delineates a subpopulation of dysfunctional ICOS+ Treg cells during the progression of T1D. Finally, the KLRG1 ligand E-cadherin is expressed by the beta cells of the pancreas, suggesting a crosstalk between these cells and the autoimmune target organ, and highlighting the potential relevance of KLRG1+ICOS+ Treg cells in T1D physiopathology.

W5.06.04
B cell derived IFN-γ contributes to the negative regulation of T-regulatory cell differentiation in arthritis

***S. A. Olalekan**, Y. Cao, T. Glant, A. Finnegan;*
Rush University, Chicago, IL, United States.

Depletion of mature B cells using Rituximab has proven efficacious in patients with rheumatoid arthritis (RA). We have previously shown in our mouse model of RA, proteoglycan induced arthritis (PGIA), that depletion of B cells leads to enhanced T regulatory cells (Tregs) numbers and activity essential in the suppression of arthritis. This increase in Treg numbers and function correlated with a decrease in T cell IFN-γ production. In this study, we investigate the effects of B cells on the generation of Tregs and how IFN-γ contributes to this process. We show that in vitro IFN-γ suppresses the differentiation of $CD4^+CD25^-CD62L^+$ T cells into $Foxp3^+$ Tregs. $CD4^+CD25^-CD62L^-$ T cells were resistant to Treg differentiation and this resistance correlates with copious IFN-γ production. Through an in vivo transfer model of transgenic T cells into immunized and B cell depleted mice, we find that $CD4^+CD62L^+Foxp3^-$ T cells are converted into Tregs more effectively than $CD4^+CD62L^-Foxp3^-$ T cells. To determine if IFN-γ is responsible for the suppression of Treg generation, we setup in vitro Treg differentiation using wild type and IFN-$\gamma^{-/-}$ $CD4^+CD25^-CD62L^+$ T cells in the presence of TGF-β and wild type or IFN-$\gamma^{-/-}$ B cells. We find that IFN-$\gamma^{-/-}$ B cells resulted in an increase in Treg differentiation in comparison to WT B cells. Chimeras with a specific deficiency in IFN-γ in B cells also show an increase in the percentage of Tregs. Our findings demonstrate that B cell derived IFN-γ can negatively regulate the generation of Tregs in arthritis.

W5.06.05
The *in vivo* impact of CD25 blockade on human regulatory T cells and evidence for compensatory maintenance by IL2Rβγ and IL7R signaling

*D. Huss, D. Mehta, A. Sharma, L. Amaravadi, J. Elkins, **J. D. Fontenot**;*
Biogen Idec, Cambridge, MA, United States.

The biology of IL-2 is pleiotropic and complex. As a growth factor for effector T cells and regulatory T cells (Treg), IL-2 can both potentiate and limit the adaptive immune response. In mouse models, the role of IL-2 in mediating immune tolerance through the support of Treg homeostasis appears dominant. Mice deficient in IL-2, IL2Rβ (CD122), and IL2Rα (CD25) all succumb to lymphoproliferative autoimmune pathology. Monoclonal antibodies against CD25 exacerbate EAE. In contrast, data from two recent Phase II clinical trials demonstrate that therapy using a humanized monoclonal antibody against CD25 (Daclizumab HYP) is efficacious in the treatment of relapsing-remitting multiple sclerosis (RRMS) despite reducing Treg numbers in the peripheral blood.
To better understand the role of CD25 in human Treg biology and to reconcile seemingly contradictory observations from mouse and human biology, we analyzed Treg subsets using refined immunophenotyping and epigenetic analysis of the *FOXP3* promoter of peripheral blood lymphocytes. Together this data provides the largest and most comprehensive analysis of human Tregs in a single study. A comparison of placebo- and Daclizumab-treated RRMS patients from the SELECT phase II clinical trial reveals differential effects of Daclizumab on specific Treg subsets. The observed changes in Treg subsets did not appear to be associated with treatment response or adverse events. Additionally, we find evidence that intermediate-affinity IL-2 receptor and IL-7 receptor signaling maintain the Treg compartment in the face of CD25 blockade.

W5.06.06
Restoration of normoglycemia in diabetic NOD mice by oral L.lactis secreting human pro-insulin plus IL-10 combined with short-term low-dose anti-CD3 is dependent on FOXP3+ Tregs

***T. Takiishi**[1], T. van Belle[1], S. Robert[1], H. Korf[1], P. Rottiers[2], C. Gysemans[1], C. Mathieu[1];*
[1]Katholieke Universiteit Leuven, Leuven, Belgium, [2]Actogenix, Ghent, Belgium.

INTRODUCTION/GOALS: In Type 1 Diabetes (T1D) re-establishing tolerance to beta-cell antigens is an ultimate goal. We have previously shown that combination therapy (CT) of L.lactis secreting human pro-insulin plus IL10 and short-term low-dose of anti-CD3 could stably revert diabetes in new-onset diabetic NOD mice and induce an increase in CD4+CD25+FOXP3+Tregs. The AIM of this study was to characterize and investigate dependence of the clinical effect on the presence of these induced Tregs. METHODS: New-onset diabetic NOD or transgenic NOD-FOXP3-DTR mice received anti-CD3 (145-2C11 clone) i.v for 5 consecutive days and were gavaged during 6 weeks with genetically-modified L.lactis. At 6 weeks, CD4+CD25+Tregs from spleen and pancreatic draining lymph nodes of CT-cured mice were tested in polyclonal suppression assays using transwell plates or blocking antibodies against TGFβ, CTLA-4 or IL10. In cured male NOD-FOXP3-DTR mice FOXP3+Tregs were specifically depleted by difteria toxin ((DT) injections i.p.) RESULTS: In vitro, we demonstrated that Treg suppression was cell contact-dependent as use of transwell abrogated suppression completely. Addition of anti-TGFβ or anti-CTLA4 decreased suppression by 74% and 75% respectively ($0.001<p<0.0001$), while blocking IL10 had no effect. In NOD-FOXP3-DTR mice, CT induced disease reversal in 66% of mice. In cured male NOD-FOXP3-DTR mice, DT injections eliminated >90% of FOXP3+Tregs followed by return to hyperglycemia, indicating break of tolerance in 3/3 mice. CONCLUSION: The combined therapy of low-dose anti-CD3 and L.lactis secreting pro-insulin plus IL-10 induces diabetes remission in newly diagnosed diabetic NOD mice and maintenance of tolerance is dependent on the presence of FOXP3+Tregs.

IL5.07.01
Experimental model of autoimmune prostatitis

***C. M. Riera**[1], M. Maccioni[2], R. Motrich[2], V. Rivero[2];*
[1]Argentina, [2]Facultad de Ciencias Quimicas.Univ.Nac.de Córdoba, Córdoba, Argentina.

Animal models have long been used to study human disease in order to identify etiologies, pathogenic mechanisms and development of therapies. Ideally, they must mimic, if not all, most of the features observed in human disease. Despite continuing debate about ethics on using animal models in biomedical research, the field has experienced considerable progress during last decades. Several animal models, particularly mouse models, have been developed. Diseases can be spontaneous (naturally occurring), or be induced by physical, chemical or biological means.
The prostate is the target of several diseases, such as infection, chronic inflammation, benign hyperplasia and cancer. Autoimmune prostatitis (AP) has become to be recognized as a disease occurring in patients, and animal models of Experimental Autoimmune Prostatitis (EAP) are available. Certainly, NOD mice develop AP spontaneously with age and immunization of young males with prostate antigens induces an exacerbated disease mimicking most features observed in human pathology. Florid infiltrates circumscribed

to dorsolateral prostatic lobes are observed, accompanied of humoral and T cell-mediated responses. Prostate-specific IFN-γ secreting cells are detected in periphery and Th1-related cytokines in the target organ. Increased IFN-γ and IL-12 levels are observed in prostate tissue from immunized animals, while IL-10 and IL-4 levels are decreased. Moreover, mice deficient in IFN-γ, IL-12, or in factors involved in IFN-γ signaling cascade (IRF-1 or STAT-1) are resistant to EAP induction. On the contrary, IL-4-deficient animals develop a more exacerbated disease.
After reviewing all the experimental evidence, we propose EAP models as valid for the study of human disease.

W5.07.01
Effector Memory Exhausted Tissue Resident CD8 T Cells Accumulate During Chronic Experimental Autoimmune Uveitis (EAU)

J. Boldison[1], *D. Copland*[2], *A. D. Dick*[2,1], *L. B. Nicholson*[2,1];
[1]*School of Cellular and Molecular Medicine, University of Bristol, Bristol, United Kingdom,* [2]*School of Clinical Sciences, University of Bristol, Bristol, United Kingdom.*

Using CD4 T cell mediated Experimental Autoimmune Uveitis (EAU) as a model for human intraocular inflammation we have demonstrated that different infiltrating leukocyte populations accumulate during disease. CD8 T cells increase in the secondary progressive phase of EAU and it remains unknown whether they contribute to the persistence of disease. Because CD8 T cells of an effector memory (EM) phenotype take up residence in the tissue following infection we determined whether the retinal CD8 T cell population fulfilled a similar function. C57BL/6J mice were immunised with RBP-3 (IRBP) 1-20 peptide to induce EAU. Disease progression was measured by Topical Endoscopic Fundal Imaging (TEFI) and CD8 T cell retinal infiltrate and phenotype assessed by flow cytometry. Cytokine production and cytotoxic potential was measured by intracellular cytokine staining. Treatment with FTY720 was used to interrogate the tissue half-life of retinal CD8 T cells. Retinal CD8 T cells expanded significantly late in disease. These cells lacked effector function and upregulated PD-1 and CD69 expression but not CD103. Treatment with FTY720 decreased circulating levels of CD4 and CD8 T cells in the blood; while analysis of retinal cell content revealed a significant decline in the numbers of CD4 T cells but not CD8 T cells. In conclusion, effector memory CD8 T cells migrate to the retina during peak inflammation and upregulate markers associated with recent antigen stimulation. Over time the CD8 T cells expand while chronic antigen stimulation leads to changes in phenotype associated with T cell exhaustion.

W5.07.02
Small intestine inflammation in roquin-mutant and roquin-deficient mice

J. S. Schaefer, D. Montufar-Solis, N. Vigneswaran, ***J. R. Klein****;*
The University of Texas Health Science Center at Houston, Houston, TX, United States.

Roquin is an E3 ubiquitin ligase that localizes to cytosolic RNA granules that is involved in regulating mRNA stability and translation. Mice that have a M199R mutation in the Roquin protein (sanroque, *Roquin*$^{san/san}$ mice) develop autoimmune pathologies, although the extent to which these occur in the intestine has not been assessed. *Roquin*$^{san/san}$ mice were found to reproducibly develop intestinal inflammation in the small intestine but not the colon. Similar findings were observed in mice generated in our laboratory in which the *Roquin* gene was disrupted by insertion of a gene trap cassette (*Roquin*$^{gt/gt}$ mice). MLN cells in *Roquin*$^{san/san}$ mice consisted of activated proliferating T cells that included CD44^{hi} CD62L^{lo} KLRG1^{+} short-lived effector cells (SLECs). More small intestinal intraepithelial lymphocytes in *Roquin*$^{san/san}$ mice expressed the ICOS T cell activation marker compared to normal mice. Importantly, small intestinal lamina propria lymphocytes in *Roquin*$^{san/san}$ mice consisted of a high proportion of Gr-1^{+} T cells that included IL-17A^{+} cells and CD8^{+} IFN-γ^{+} cells. There was extensive cytokine dysregulation resulting in both over-expression and under-expression of chemotactic cytokines in the ileum of *Roquin*$^{san/san}$ mice, the intestinal region most prone to inflammation. These findings demonstrate that chronic inflammation ensues in the intestine following Roquin protein mutation or gene disruption, and they have implications for understanding how chronic small intestinal inflammation is perpetuated. Because the primary gene/protein defects in these Roquin animal systems are known, it will be possible to elucidate the underlying genetic and molecular mechanisms that drive the disease process.

W5.07.03
Tolerance induction by hair-specific keratins in murine alopecia areata

U. Erb[1], *P. Freyschmidt-Paul*[2], *M. Zoeller*[1];
[1]*Universitätsklinikum Heidelberg, Heidelberg, Germany,* [2]*Universität Marburg, Marburg, Germany.*

Alopecia areata (AA) is a T cell-mediated autoimmune disease of the skin with non-scarring hair loss by destruction of anagen stage hair follicles. AA is characterized by perifollicular infiltrates of CD4+ and CD8+ T cells and aberrant MHC expression on hair follicle epithelium, the loss of immune privilege being suggested to allow for autoreactive T cell activation. The autoantigen(s) have not been defined. Hair- and nail-specific keratins are potential candidates, which we controlled in C3H/HeJ mice that develop AA spontaneously or after skin transplantation. From 9 keratins, K6irs and Ha1 peptides supported T cell activation when presented by dendritic cell (DC) to syngeneic naive T cells and young C3H/HeJ mice receiving subcutaneous injections of peptide-loaded DC developed AA. The frequency of K6irs- and Ha1-specific CD4+ and CD8+ T cells increased 4-5-fold by vaccination, which corresponds with the frequency seen in skin transplantation-induced AA mice. Also, accessory molecule expression, the cytokine profile with a dominance of IFNγ, the proliferative response against AA lysate or peptide-loaded DC as well as peptide-specific cytotoxic T cells were similar in keratin peptide- and skin transplantation-induced AA. Instead, vaccination with soluble K6irs or Ha1 peptides significantly retarded AA induction and prevented progression. Soluble peptide vaccination did not provoke immunosuppression, but induced long-lasting T cell anergy with unresponsiveness to DC-presented K6irs and Ha1 peptides.
Thus, keratins (K6irs and Ha1) are an AA autoantigen, our data suggesting a contribution of additional self antigens. Importantly, keratin peptide vaccination prevents AA induction and progression in about 50% of mice.

W5.07.04
Inducible tertiary lymphoid structures, autoimmunity, and exocrine dysfunction in a novel model of sialoadenitis in wild-type mice

D. Lucchesi[1], *M. Bombardieri*[1], *S. Nayar*[2], *G. Proctor*[3], *F. Barone*[2], *C. D. Buckley*[2], *C. Pitzalis*[1];
[1]*William Harvey Research Institute, London, United Kingdom,* [2]*University of Birmingham, Birmingham, United Kingdom,* [3]*King's College, London, United Kingdom.*

Salivary glands (SG) of patients with Sjögren's syndrome (SS) develop ectopic lymphoid structures (ELS) characterized by B/T cell compartmentalization, the formation of high endothelial venules (HEV), follicular dendritic cell networks (FDCs), functional B cell activation and local differentiation of autoreactive plasma cells. The mechanisms triggering these phenomena in SS are largely unknown. Here we present a novel model of inducible ELS formation, breach of self-tolerance and salivary hypofunction following delivery of a replication-deficient adenovirus-5 (AdV5) in SGs of C57BL/6 mice. Luciferase- or LacZ-encoding Ad5 were delivered in mice SGs through retrograde cannulation. SGs were collected at various time-points 1, 2 and 3 weeks post-cannulation (pc) and sections were graded for infiltration and stained for T/B cell segregation, FDCs and HEV markers. Submandibular salivary flow was induced by pilocarpine stimulation. Expression of ELS-related genes was investigated by TaqMan-PCR. Anti-viral antibodies and autoantibodies were detected by IF and western blot. In this model, inflammation rapidly and consistently evolves from diffuse infiltration towards the development of SS-like periductal lymphoid aggregates

within 2 weeks pc. These infiltrates progressively acquire ELS features and support functional GL7+/AID+ germinal centers. Formation of ELS is preceded by ectopic expression of lymphoid chemokines CXCL13, CCL21, CCL19 and lymphotoxin-β and is associated with development of anti-nuclear antibodies in 75% of the mice. Reduction in salivary flow was observed over 3 weeks pc. This novel model has the potential to unravel the cellular and molecular mechanisms regulating ELS formation and their role in exocrine dysfunction and autoimmunity in SS.

W5.07.05
Phenotype conversion from rheumatoid arthritis to systemic lupus erythematosus by introduction of Yaa mutation into FcγRIIB-deficient C57BL/6 mice

S. Hirose[1], *S. Kawano*[2], *Q. Lin*[1], *H. Amano*[2], *T. Kaneko*[2], *K. Nishikawa*[1], *H. Tsurui*[1], *N. Nishimura*[3], *T. Shirai*[1];
[1]*Department of Pathology, Juntendo University School of Medicine, Tokyo, Japan,* [2]*Department of Internal Medicine, Juntendo University School of Medicine, Tokyo, Japan,* [3]*Department of Biomedical Engineering, Toin University of Yokohama, Yokohama, Japan.*

We previously established an IgG Fc receptor IIB (FcγRIIB)-deficient C57BL/6 (B6)-congenic mouse strain (KO1), which spontaneously develops rheumatoid arthritis (RA), but not systemic lupus erythematosus (SLE). Here we show that when Y chromosome-linked autoimmune acceleration (Yaa) mutation was introduced in KO1 strain (KO1.Yaa), the majority of KO1.Yaa mice did not develop RA, but instead did develop SLE. This phenotype conversion did not depend on autoantibody specificity, since KO1.Yaa mice, compared with KO1, showed a marked increase in serum levels of both lupus-related and RA-related autoantibodies. The increase in frequencies of CD69+ activated B cells and T cells, and the spontaneous splenic GC formation with T follicular helper (TFH) cell generation were manifest early in life of KO1.Yaa, but not KO1 and B6.Yaa, mice. Activated CD4+ T cells from KO1.Yaa mice showed up-regulated production of IL-21 and IL-10, compared with the finding in KO1 mice, indicating the possibility that this aberrant cytokine milieu relates to the disease phenotype conversion. Thus, our model is useful to clarify the shared and the disease-specific mechanisms underlying the clinically distinct systemic autoimmune diseases RA and SLE.

W5.07.06
SPARC deficiency promotes lupus like autoimmunity by defective clearance of dead PMN

C. Vitali[1], *S. Sangaletti*[1], *C. Tripodo*[2], *C. Bassani*[1], *M. Parenza*[1], *M. P. Colombo*[1];
[1]*Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy,*
[2]*Department of Human Pathology, University of Palermo, Palermo, Italy.*

Increased apoptotic neutrophils and impaired clearance by macrophages have been associated to pathogenesis of systemic lupus erythematosus (SLE). Accumulation of apoptotic bodies leads to availability of autoantigens promoting autoimmunity.
SPARC (Secreted Protein, Acidic and Rich in Cysteine) is a matricellular protein with known functions in wound healing, inflammation and cancer. In such conditions, SPARC is upregulated to modulate cell survival, adhesion, migration and matrix deposition.
To test whether SPARC deficiency impact on the outcome of an autoimmune disease, we compared Sparc-/- and wt mice for the evolution of a lupus-like model induced by injection of Pristane which causes chronic peritonitis followed by SLE-like manifestations (auto-antibodies, arthritis, glomerulonephritis and lung vasculitis).
Sparc deficiency accelerated the onset of autoimmune symptoms. Sparc-/- produced detectable titers of autoantibodies against small nuclear ribonucleoproteins (snRNP), single- and double-stranded DNA (ssDNA, dsDNA) 120 days after treatment, while Sparc+/+ mice took 170-200 days to show similar titers. Also, Sparc-/- mice developed accelerated arthritis with augmented frequency of Th17 cells in popliteal lymph nodes.
We excluded that SPARC deficiency had a direct effect on B cell activation, since vaccination of wt and Sparc-/- mice with the T-dependent and -independent model antigens produced similar antibody titers.
Rather, accelerated autoimmunity depends on augmented availability of auto-antigens, according to the increased fraction of necrotic neutrophils found in the peritoneal cavity and circulation of Sparc-/- than wt mice.
Collectively, our data uncover a new activity for the matricellular protein SPARC in homeostasis and clearance of apoptotic PMN that, if lost, might promote autoimmunity.

W5.08 Atherosclerosis and cardiovascular diseases

T cells regulate lipid metabolism and vascular stability. Role in atherosclerosis

G. K. Hansson;
Karolinska Institute, Stockholm, Sweden.

Atherosclerosis is an inflammatory disease. When infiltrating the artery wall, cholesterol-laden plasma lipoproteins trigger activation of innate immune responses that lead to recruitment of professional immune cells to the forming lesion. By activating antigen-specific T cells, oligopeptides of plasma lipoproteins elicit adaptive immune responses, largely of the Th1 type, which aggravate vascular inflammation and promote atherosclerosis. Depending on signals provided by the dendritic cell during antigen presentation of lipoprotein components, CD4+ T cells develop into alternative Th pathways that have entirely different consequences for disease. We have characterized the role of Treg and Th17 cells in atherosclerosis by eradicating Foxp3+ regulatory T cells or targeting Smad7 in the TGF-beta signal transduction cascade in a mouse model of human disease. In the absence of Treg, disease development is accelerated, not only because of increased vascular inflammation but also since hyperlipidemia is aggravated in the absence of Treg. This is likely due loss of cytokine regulation of sortilin-1, a hepatocyte receptor for very low density lipoproteins. These findings highlight the interplay between the immune and metabolic systems and its importance in atherosclerosis.

IL5.08.02
Anti-VEGF therapy normalizes pulmonary vasculature in Endoglin and Alk1 heterozygous mice

M. Letarte[1,2], *D. S. Ardelean*[1,2], *M. Jerkic*[1,2], *M. Peter*[1,2];
[1]*Hospital for Sick Children, Toronto, ON, Canada,* [2]*Department of Immunology, University of Toronto, Toronto, ON, Canada.*

Mutations in endoglin (*ENG*) and *ALK1* genes lead to Hereditary Hemorrhagic Telangiectasia (HHT), a vascular dysplasia affecting 1 in 5000 people worldwide and associated with arteriovenous malformations in multiple organs. Haploinsufficiency is the underlying mechanism of disease and heterozygous (*Eng*$^{+/-}$ and *Alk1*$^{+/-}$) mice serve as experimental models. We characterized their phenotype and angiogenic profile and tested the effects of anti-VEGF therapy. As we demonstrated previously, these mice develop with age a rarefied peripheral pulmonary vasculature, leading to increased resistance and right ventricular hypertrophy (RVH). We now assessed peripheral microvascular density, RVH and several angiogenic factors in these mice after treatment with an antibody to mouse VEGF. Administering 4 weekly i.p. injections (5mg/kg, G6-31 monoclonal antibody) to 15 week-old mice led to high levels of circulating antibody-bound VEGF and to reduced VEGF levels in *Eng*$^{+/-}$ and *Alk1*$^{+/-}$ lungs. The treatment paradoxically increased the number of peripheral lung vessels and consequently attenuated RVH. Basal pulmonary levels of the angiostatic factor TSP-1 were higher in *Eng*$^{+/-}$ than control mice and were normalized by anti-VEGF treatment. In *Alk1*$^{+/-}$ mice, the vessel destabilizing factor, angiopoietin-2, was increased under basal conditions and normalized by treatment. Our findings suggest that the factors responsible for the rarefied pulmonary vasculature may differ between *Eng*$^{+/-}$ and *Alk1*$^{+/-}$ mice, possibly explaining some of the disease heterogeneity. Our data also indicate that anti-VEGF therapy can reverse the angiogenic/angiostatic imbalance in lungs of *Eng*$^{+/-}$

and *Alk1*$^{+/-}$ mice, and could account for its emerging beneficial effects in patients with HHT.

Circulating CD40$^+$ and CD80$^+$ B cell subsets are opposingly associated with risk of stroke

P. Mantani, I. Ljungcrantz, L. Andersson, R. Alm, B. Hedblad, H. Björkbacka, J. Nilsson, ***G. N. Fredrikson****;*
Clinical Sciences Malmö, Malmö, Sweden.

Background: Accumulating evidence show that immune cells play an important role in atherosclerosis. Most attention has focused on the role of different T cell subsets, while the possible involvement of B cells has been less studied. In this study we assessed the association of two different B cell subsets, CD19$^+$CD40$^+$ and CD19$^+$CD86$^+$ B cells, with risk for development of acute cardiovascular events.
Methods and Results: The prospective study included 700 subjects randomly selected from the cardiovascular cohort of the Malmö Diet and Cancer study. Mononuclear leukocytes, stored at -140°C at the baseline investigation in 1991-94, were thawed and B cell subsets analyzed by flow cytometry. Cytokine release from stimulated mononuclear leukocytes was measured with multiplex ELISA. Baseline carotid intima-media thickness and stenosis were assessed by ultrasonography and clinical events were monitored through validated national registers during a median/mean follow-up time of 15 years. The CD19$^+$CD40$^+$ B cell subset correlated with release of an anti-inflammatory cytokine profile and subjects in the highest tertile of CD19$^+$CD40$^+$ B cells had a significantly lower risk of incident stroke after adjustment for other risk factors. In contrast, CD19$^+$CD86$^+$ B cells correlated with increased release of pro-inflammatory cytokines and risk for development of a stroke event.
Conclusions: These observations provide evidence for an involvement of B cells in the incidence of stroke and suggest that both pathogenic and protective B cell subsets exist.

Genetically controlled myocardial expression of CXCL9 may be responsible for the selective migration of Th1 T cells and magnitude of myocarditis in Chagas disease cardiomyopathy

E. Cunha-Neto*[1,2], L. Nogueira[1], R. H. Santos[1], B. M. Ianni[1], A. Frade[1], L. Benvenuti[1], E. Donadi[3], B. Saba[4], A. Fragata[4], J. Kalil[1,2];*
[1]University of São Paulo, Sao Paulo, Brazil, [2]Institute for Investigation in Immunology-iii/INCT, Sao Paulo, Brazil, [3]FMRP-University of São Paulo, Ribeirao Preto, Brazil, [4]Dante Pazzanese Institute of Cardiology, Sao Paulo, Brazil.

Chronic Chagas cardiomyopathy (CCC) affects 30% of those infected by the protozoan *Trypanosoma cruzi*. Even though the Th1 T cell-rich myocarditis plays a pivotal role in CCC pathogenesis, little is known about migration and dynamics of T cell subsets in CCC myocardium. We first analyzed expression of hallmark transcription factors and cytokines of the Th1, Th2, and Treg populations, using Real time qPCR in myocardial samples from end-stage CCC patients and controls. CCC myocardial samples displayed robust mRNA expression of IFNγ and T-bet, with absent effector Th2 (IL-4, IL5, IL13) or limited expression of Th17 (IL17; no RorγT) or Treg-associated cytokines and molecules (CTLA4, FoxP3; no IL10 or TGFβ). We also assessed mRNA expression of chemokines chemotactic for different T cell subsets using qPCR and confocal microscopy. Expression of CXCL9 and CCL5, chemoattractants for Th1 cells, was robustly upregulated in CCC myocardium; other CCR5/CXCR3 ligands were also upregulated. CXCL9 expression positively correlated with the intensity of myocarditis. Analyzing single-nucleotide polymorphisms from the chemokines in a cohort of CCC patients with different degrees of severity, we found that the *CXCL9* rs10336CC genotype was associated with less severe CCC. Significantly, myocardial samples from end-stage CCC carrying this genotype displayed lower CXCL9 expression and intensity of myocarditis. Results suggest that the robust Th1 response in CCC myocardium is apparently unopposed by local Th2 and Treg cells. Genetically controlled myocardial expression of CXCL9 may be responsible for the selective migration of Th1 T cells to CCC myocardium, and thus modulate the magnitude of myocarditis.

W5.08.03
Transforming growth factor-beta signaling in T cells promotes stabilization of atherosclerotic plaques through an interleukin-17 dependent pathway

A. Gistera*[1], A. K. Robertson[1], J. Andersson[1], D. F. J. Ketelhuth[1], O. Ovchinnikova[1], S. K. Nilsson[2], A. M. Lundberg[1], M. O. Li[3], R. A. Flavell[3,4], G. K. Hansson[1];*
[1]Department of Medicine, Karolinska Institutet, Stockholm, Sweden, [2]Department of Medical Biosciences/Physiological Chemistry, Umeå University, Umeå, Sweden, [3]Department of Immunobiology, Yale University School of Medicine, New Haven, CT, United States, [4]Howard Hughes Medical Institute, Yale University School of Medicine, New Haven, CT, United States.

Adaptive immunity has a major impact on atherosclerosis, with pro- and anti-atherosclerotic effects exerted by different subpopulations of T cells. Transforming growth factor- β (TGF-β) may promote development either of regulatory T cells or Th17 cells, depending on factors in the local milieu. In the present study, we have addressed the effect on atherosclerosis of enhanced TGF-β signaling in T cells. Bone marrow from mice with a T-cell specific deletion of *Smad7*, a potent inhibitor of TGF-β signaling, was transplanted into hypercholesterolemic *Ldlr*$^{-/-}$ mice. *Smad7*-deficient mice had significantly larger lesions that contained a large collagen-rich smooth muscle cap, consistent with a more stable phenotype. The inflammatory cytokine interleukin-6 was expressed in the atherosclerotic aorta and increased mRNA for IL-17A and the Th17 specific transcription factor RORγt were detected in draining lymph nodes. Treating *Smad7*-deficient chimeras with neutralizing IL-17A antibodies reversed the stable cap formation. IL-17A stimulated collagen production by human vascular smooth muscle cells and RORγt mRNA correlated positively with collagen type-1 and alpha-smooth muscle actin mRNA in a biobank of human atherosclerotic plaques. These data demonstrate that TGF-β modulates atherosclerosis in a context dependent manner and links IL-17A to induction of a stable plaque phenotype.

W5.08.04
A Novel Role for Rip2 in T cell regulation; Rip2 Deficiency leads to increased Th17 Skewing

K. Shimada*, S. Chen, T. Crother, W. Zhang, M. Arditi;*
Cedars Sinai Medical Center, Los Angeles, CA, United States.

Background: Receptor-interacting serine/threonine protein kinase 2 (Rip2) is the critical adapter molecule for both Nod1 and Nod2 signaling complexes in the innate and adaptive immune pathways in myeloid, epithelial, and endothelial cells. However, the role of Rip2 in T cells is unknown.
Methods and Results: We observed that Rip2-/- CD4 T cells are skewed towards increased Th17 skewing. To investigate the mechanism of this observation, we adoptively transferred naïve CD4 T cells from Rip2-/- mice into Rag1-/- mice, and infected them with Chlamydia pneumoniae (CP). Rag1-/- mice receiving Rip2-/- CD4 T cells displayed significantly more IL-17A but less IFN-γ production during infection when compared to Rag1-/- mice receiving wt CD4 T cells despite similar bacterial burdens, indicating that T cell-derived Rip2 deficiency is that factor that leads to increased Th17 skewing. To investigate the functional impact of this observation, we used two different experimental models. We found that in Rip2-/- mice had a severe and chronic lung inflammation following CP infection, which was not observed in the Rip2-/-Il17a-/- mice. When irradiated Ldlr-/- mice (on high fat diet) received Rip2-/- bone marrow, we found a significant increase in atherosclerotic lesion development, which was not observed if recipient mice were given Rip2-/-Il17a-/- BM .
Conclusion: We demonstrate in multiple models that increased inflammation in Rip2-/- mice is due to increased Th17 skewing observed in Rip2-/- T-cells. Our study demonstrates a novel role for Rip2 in T cell regulation and suggests that Rip2 in CD4 T cells negatively regulates Th17 mediated chronic inflammation.

W5.08.05
TIPE2 prevents atherosclerosis by negatively regulating macrophage responses to oxLDL

*Y. Lou[1], **S. Liu**[1], G. Zhang[1], Y. Chen[2], Y. Zhang[3];*
[1]Immunology Institute, Shandong University School of Medicine, Ji'nan, China, [2]Department of Pathology and Laboratory Medicine, University of Pennsylvania, Philadelphia, PA, United States, [3]Key Laboratory of Cardiovascular Remodeling and Function Research, Chinese Ministry of Education and Chinese Ministry of Health, Ji'nan, China.

Atherosclerosis has been widely recognized as an inflammatory disease of the arterial wall in which macrophages play a major role. TIPE2, the tumor necrosis factor (TNF)-alpha-induced protein 8-like 2 (TNFAIP8L2), is highly expressed in resting macrophages and can negatively regulate inflammation through inhibiting immune receptor signaling. In this study, we first report that TIPE2-deficient macrophages treated with ox-LDL produced more oxidative stress and proinflammatory cytokines, were resistant to activation-induced cell death, and exhibited heightened activation of the JNK, NF-κB, and p38 signaling pathways. As a consequence, TIPE2 deficiency in bone marrow-derived cells exacerbated atherosclerosis development in *Ldlr*$^{-/-}$ mice fed a high-fat diet. Interestingly, TIPE2 deficiency doesn't affect lipoprotein metabolism or blood cell counts of *Ldlr*$^{-/-}$ recipients mice, while the sera levels of some cytokines were significant higher than WT controls. These results indicate that TIPE2 plays a crucial atheroprotective role by negatively regulating macrophage responses to ox-LDL and may be a potential new drug target for treating the disease.

Co-stimulatory signaling through lymphocyte CD40 limits adipose tissue inflammation and protects from de novo and pre-established metabolic disease in mice

D. Wolf[1], *F. Jehle[1], N. Bukosza[1], P. Aichele[2], N. Varo[3], C. Bode[1], P. Libby[4], K. Peter[5], A. Zirlik[1];*
[1]University Heart Center, University of Freiburg, Freiburg, Germany, [2]Department of Immunology, University of Freiburg, Freiburg, Germany, [3]University of Navarra, Pamplona, Spain, [4]Brigham and Women's Hospital, Cardiovascular Medicine, Harvard Medical School, Boston, MA, United States, [5]BakerIDI Heart and Diabetes Institute, Melbourne, Australia.

Background: Immune cell functioning drives adipose tissue inflammation during the metabolic syndrome. Co-stimulatory cascades such as the CD40L-CD40 dyad enhance immune cell activation during chronic inflammation. Here, we tested the hypothesis that CD40 modulates diet-induced obesity in vivo.
Methods and Results: To induce the metabolic syndrome, WT or CD40-/- mice consumed a high fat diet (HFD) for 20 weeks. CD40-/- mice exhibited an aggravated metabolic phenotype with increased weight gain, enhanced fat depositions, aggravated insulin resistance, and increased accumulation of inflammatory cells in adipose tissue. Accordingly, multiple pro-inflammatory gene sets were up-regulated in adipose tissue. This phenotype could be transplanted in lethally irradiated WT mice by reconstitution with bone marrow lacking CD40 on lymphocytes, indicating that lymphocyte CD40 accounts for its phenotype. In a gain-of-function approach, mice were fed HFD for 6 weeks and treated with the activating CD40 antibody FGK45 for 6 weeks. Activation of CD40 signaling with FGK45 abolished further weight gain, lowered glucose levels and improved insulin resistance. Correspondingly, immune cell accumulation in adipose tissue was substantially reduced. Mechanistically, expression of the TH1-cytokine IFN-γ in T-helper cells decreased after CD40 activation. In a cohort of 183 patients with a high prevalence of the metabolic syndrome levels of soluble CD40 were elevated in obese patients, indicating clinical relevance of our findings.
Conclusion: We present that CD40 deficiency aggravates, while activation of CD40 signaling improves adipose tissue inflammation and its metabolic complications in mice. Positive modulation of co-stimulatory pathways might describe a novel therapeutic concept against cardio-metabolic disease.

EBV specific CD8+ T cells in Multiple Sclerosis

***L. Battistini**;*
Neuroimmunology Unit, Santa Lucia Foundation Scientific Institute, Rome, Italy.

Epstein-Barr virus (EBV) has been associated with multiple sclerosis (MS).
We used a highly standardized flow cytometric analysis with EBV-specific pentamers, that unequivocally identifies antigen-specific CD8+ T cells, on freshly isolated PBMCs from HD and MS patients. We find that differences in the prevalence and magnitude of the CD8+ T cell response to EBV latent and lytic proteins between MS patients and HD and within the MS cohort emerge only when patients are stratified according to disease activity.
Fewer inactive MS patients have a detectable CD8+ T cell response against EBV lytic antigens compared with HD and active MS patients, while the frequency of lytic antigen-specific CD8+ T cells is higher in active MS patients. On the other hand, responses to the latent antigen EBNA-3A are higher in inactive MS patients. Thus, changes in the immune control of EBV replication are associated with MS disease activity.
PD-1 was upregulated only in EBV-specific CD8 T cells of inactive MS patients, whereas PD-1 expression levels in total CD8 were comparable to controls. We speculate that in inactive MS patients there is an attempt by CD8+ T cells to control abnormal expansion of a latently infected B-cell pool.
Based on the present findings, we propose that failure to fully control EBV latent infection in the CNS could lead to recrudescence of EBV reactivation. Exposure to newly synthesized viral antigens would promote expansion of lytic antigen-specific CD8+ T-cells targeting intracerebral viral deposits and hence induce the active phase of MS.

W5.09.01
Regulatory T cells together with resolving macrophages orchestrated by Th1 cells are non-redundant pivotal players in CNS repair

***C. Raposo**, M. Schwartz;*
Weizmann Institute of Science, Rehovot, Israel.

The perception of the central nervous system (CNS) as an immunologically inert tissue, where the presence of immune components was considered an imminent sign of pathology, is now obsolete. Over the last few years, the understanding of the role of monocyte-derived macrophages (mo-MΦ) in CNS repair has undergone a major revolution, and the beneficial contribution of these cells to repair is now well appreciated. In parallel, several studies highlighted the neuroprotective role of T cells, but as T cell activity in the CNS can be potentially hazardous, understanding the mechanisms that ensure their beneficial rather than destructive effect is of critical importance.
Using a paradigm of spinal cord injury, we found that T helper-1 (Th1) cells activated the remote blood-cerebrospinal fluid barrier, facilitating the recruitment of IL-10-expressing mo-MΦ to the injury site. Subsequently, the mo-MΦ controlled the local levels of Foxp3+ regulatory T cells (Tregs); with late ablation of the Tregs impairing the extent of myelination. The IL-10 mo-MΦ and Tregs were non-redundant in resolving the innate and adaptive inflammatory responses, respectively. As a corollary to the need for effector T cells at the acute stage, reducing Treg levels at the time of injury is beneficial, allowing a risk-free effector immune response, and highlighting the need for a delicate balance between Th1 and Tregs for proper repair.
Overall, recovery from CNS injury requires a spatially and temporally orchestrated response involving Th1 cells, mo-MΦ, and Foxp3+ Tregs; all of these cells are needed, none of them are only harmful or harmless.

W5.09.02
Triggers of anti-CNS autoimmunity in mouse model of Multiple sclerosis

***P. Palle**, T. Buch;*
Institute for Medical Microbiology, Immunology and Hygiene, Technische Universität München, Munich, Germany.

Multiple sclerosis (MS) is an inflammatory and demyelinating central nervous system disorder of unknown etiology. Recent data, from induced and spontaneous mouse models (experimental autoimmune encephalomyelitis, EAE) of the disease implicate a pivotal role for gut microbiota not only in disease progression but also in protection from it. Toll-like receptors (TLRs), key components of innate system are the prominent players in recognising microbial products. This recognition culminates in induction of inflammatory signalling cascades. Currently, confusion is reigning over the role of TLRs in EAE. We have performed EAE experiments in mice quintuple-deficient for TLRs 2, 3, 4, 7, and 9 to gain better understanding of the role of TLR activation in anti-CNS autoimmunity. Surprisingly, we could not observe a pronounced influence of simultaneous absence of these five TLRs on EAE disease course. We also observed that quintuple deficient mice displayed a delayed but rapidly progressing disease suggesting less prominent role for these TLRs in EAE. This observation was confirmed in histological analysis. Interestingly, the immunization against the myelin peptide resulted only in a delayed T cell response.

W5.09.03
IL-33/ST2 axis mediates resistance to EAE by promoting regulatory B and tolerogenic dendritic cells

***M. Z. Milovanovic**, A. N. Arsenijevic, J. Z. Milovanovic, B. Stojanovic, N. N. Arsenijevic, M. L. Lukic;*
Faculty of Medicine, Kragujevac, Serbia.

BALB/c mice are resistant to EAE induction with MOG35-55. ST2 molecule is expressed on immune cells and its signaling is accompanied by accentuated ST2 response. We recently published (Milovanovic et al. PlosOne 2012) that deletion of ST2 molecule abrogates resistance to EAE, as evaluated by clinical and histological findings. Adoptive transfer of ST2 KO lymphocytes restimulated with MOG35-55 induced clinical signs of the disease in ST2 KO and BALB/c mice. MOG35-55 specific CD4+ lymphocytes of ST KO mice had higher expression of transcriptional factor T-bet, inflammatory cytokines IFNγ, IL-17, GM-CSF, TNFα and chemokine receptors important for migration to CNS (CCR6, CXCR5 and CXCR3). ST2 KO mice had higher incidence of activated antigen presenting cells, myeloid/regulatory dendritic cells (DC) ratio and percentages of myeloid cells containing inflammatory cytokines, IL-1, IL-12 and IL-6. ST KO DC induced higher in vitro proliferation of CD4+ cells and stimulated in vitro with TLR1/2 agonist produced more cytokines involved in Th1 and Th17 differentiation compared with DC isolated from BALB/c mice. Interestingly we also observed the increase of regulatory CD11b+CD5+ B lymphocytes, IL-10 producing B1 lymphocytes and decrease of IL-6 producing B cells in BALB/c mice after immunization with MOG35-55 peptide. The opposite results were found in ST2 KO mice. Results indicate that ST2 signaling influences the activity of regulatory B1 cells and differentiation of proinflammatory antigen presenting cells, consecutively affecting the differentiation of encephalytogenic T cells in the periphery.

W5.09.04
N-methyl-D-aspartate receptor (NMDAR) Antibodies in Post Herpes Simplex Virus Encephalitis (HSVE) Neurological Relapse

***Y. Hacohen**[1], K. Deiva[2], P. Pettingill[1], P. Waters[1], P. Chretien[2], E. Menson[3], e. Lin[3], M. Tardieu[2], A. Vincent[1], M. Lim[3];*
[1]Oxford University, Oxford, United Kingdom, [2]Assistance Publique Hôpitaux de Paris, Hopitaux Universitaires Paris Sud, Paris, France, [3]Evelina Children's Hospital @ Guy's and St Thomas' NHS Foundation Trust, King's Health Partners Academic Health Science Centre, London, United Kingdom.

Background: Herpes Simplex Virus encephalitis (HSVE) is a devastating condition that relapses, often with a chorea in children, despite adequate antiviral treatment. At relapse, evidence of viral replication is frequently absent, suggesting that the relapse may be immune-mediated.
Methods: Seven children who had a neurological relapse following their initial encephalitis, identified from 20 cases of HSVE, were studied. Serum and/or CSF were tested for N-methyl-D-aspartate receptor (NMDAR) and other antibodies previously reported in central nervous system autoimmunity.
Results: The children initially presented with clinical, laboratory and radiological findings consistent with HSVE and had made a significant clinical improvement with intravenous acyclovir. Viral reactivation was identified only in one patient (14%). For the remaining 6 patients with no evidence of viral reactivation, a range of infective and alternative inflammatory causes were sought but not identified at the time. Three out of six (50%) children who had relapsed with choreoathetosis, seizures and/or cognitive regression following HSVE, had NMDAR antibodies. In two of the NMDAR antibody positive patients who were treated at relapse, a beneficial response was observed.
Conclusion: Neurological relapses after HSVE may frequently be immune-mediated, particularly (but not exclusively) in children with chorea. NMDAR antibodies are common, and immunotherapy should be considered.

W5.09.05
Neuroimmunological changes in the Cstb-/- mouse: a model for progressive myoclonus epilepsy

***O. Okuneva**[1,2], Z. Li[3], I. Körber[1], L. Tian[3], T. Joensuu[1], A. Lehesjoki[1], O. Kopra[1];*
[1]Folkhälsan Institute of Genetics, Haartman Institute, Department of Medical Genetics and Research Program's Unit, Molecular Medicine, Neuroscience Center, University of Helsinki, Helsinki, Finland, [2]Krasnoyarsk State Medical University, Krasnoyarsk, Russian Federation, [3]Neuroscience Center, University of Helsinki, Helsinki, Finland.

Loss-of-function mutations in the *cystatin B* gene encoding cystatin B (CSTB) an inhibitor of cysteine proteases cathepsins cause neurodegenerative disorder called progressive myoclonus epilepsy of Unverricht-Lundborg type (EPM1). Neuropathological change in *Cstb-/-* mouse include early microglial activation (P14) that precedes astrocytosis and neurodegeneration and, presumably, is central in initiating of the neuronal loss. Our aim is to characterize in detail cystatin B-deficient microglia.
Resting and activated (lipopolysaccharide) cultured *Cstb-/-* and control microglia were analysed for cytokine, NO production, chemotaxis and phagocytosis. Microglia extracted directly from the brains was studied for expression of MHC II and M1-M2 polarization using flow cytometry. Myeloid cell population in bone marrow and spleen, cytokines' level in blood serum were analysed in P14 animals. Our results show increased secretion of proinflammatory chemokines by *Cstb-/-* microglia, which is chemotactically more active whereas their phagocytic activity is decreased. *Cstb-/-* microglia show decreased expression of MHC II on the cell surface. Activated *Cstb-/-* microglia directly extracted from the brain has predominantly proinflammatory M1 phenotype. We have registered high concentrations of proinflammatory chemokines and cytokines in blood serum of *Cstb-/-* pups. Amount of granulocytes is enhanced in *Cstb-/-* bone marrow and spleen as well as level of GM-CSF in their blood serum and microglial conditioned medium.
Results suggest a role for cystatin B in regulation of immune response. CSTB-deficiency is associated with early inflammatory processes both in the brain and the peripheral tissues. We consider that EPM1 should be treated as a disorder combining neuropathological and immunological features.

W5.09.06
Elucidation of pathogenic mechanism of myasthenia gravis with MuSK antibodies using a novel murine model

*M. Shuuichi[1], S. Kubo[1], M. Kishi[2], T. Konishi[3], **K. Shigemoto**[1];*
[1]Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan, [2]Toho University Sakura Medical Center, Chiba, Japan, [3]National Hospital Organization Utano National Hospital, Kyoto, Japan.

Myasthenia gravis (MG) is caused by autoantibodies against postsynaptic membranes at neuromuscular junctions (NMJs). Antibodies against muscle-specific kinase (MuSK) are found in a

variable proportion of MG patients who lack antibodies against acetylcholine receptors. MuSK antibodies predominantly belong to the IgG4 subclass, which has distinct features compared with other human IgG subclasses. (1) IgG4 does not activate the classical complement pathway. (2) The production is promoted by T-helper 2 (Th2) cytokines. These unique properties are directly associated with the pathogenic mechanisms of MG with MuSK antibodies (MuSK-MG). Although several models of experimental autoimmune MG (EAMG) with MuSK antibodies have been produced, it has been doubt on the similarity in the pathogenic mechanism of MuSK-EAMG caused by complement-fixing antibodies. Here we generated a new EAMG model by injecting MuSK protein into complement-deficient mouse strains. Nearly all of the mice tested manifested MG with morphological and functional changes in NMJs observed in MuSK-MG patients, providing the evidence that complement activation is dispensable for the onset of MuSK-MG. In addition, MuSK antibodies produced by all strains were predominantly IgG1 subclass, which has functional similarities with human IgG4 in terms of Th2 dependency for production and complement-binding capacity, suggesting that these EAMG mice share a common immune regulatory pathway with MuSK-MG patients. Taken together, our novel EAMG model provides a platform for research of MuSK-MG in humans not only to develop appropriate medication, but also to reveal the immune mechanisms.

IL5.10.01
CNS tissue damage by T cells

R. Liblau[1,2];
[1]*Department of Immunology, CHU Toulouse, Toulouse, France,* [2]*2Inserm UMR 1043 - CNRS 5282, Toulouse, France.*

The CNS is confronted to a double challenge regarding its interactions with the immune system. On the one hand it should allow the immune system to fight invading pathogens and on the other it should prevent inflammatory damage given its vital functions and poorly regenerative capacity. A series of mechanisms, collectively referred to as 'immune privilege', ensures that immune reactions are kept minimal and are rapidly controlled within the CNS. However, accumulating evidence show that T cells readily penetrate the brain and spinal cord parenchyma in numerous inflammatory neurological diseases such as Multiple Sclerosis. The consequence for CNS resident cells, and more specifically for neurons, of their encounter with activated T cells is a question that we have addressed recently using experimental rodent models.
Shedding light on the mechanisms by which T cells promote CNS tissue damage may allow the design of more refined therapeutic strategies for immune-mediated neurological diseases, including multiple sclerosis.

IL5.10.02
Immunological knowledge integration in MS

M. Salvetti[1,2];
[1]*Università Sapienza, S. Andrea Hospital, Rome, Italy,* [2]*Center for Experimental Neurological Therapies (CENTERS), Università sapienza, S. Andrea Hospital, Rome, Italy.*

The immunology of multiple sclerosis is providing an ever growing picture of potential mechanisms whose expansion parallels the progress of our understanding of basic immunology. During the last two decades this knowledge has led to great advances in the therapy of this disease. The challenge ahead is now to exploit this pathogenetic information to infer an etiologic understanding that may lead to definitive cures. To do so we should ameliorate our ability to intepret these data across different knowledge domains. In particular, we should strive to constantly put immunological data into the context of what we are learning about heritable and nonheritable causative factors and their interactions. A constant process of "cross-validation" between these domains may lead to a better characterization of genome to phenome correlation and bring about substantial progress for the cure, diagnosis and prevention of this disease. Examples of how this could be done, in a pragmatic way, for existing knowledge will be provided.

Identification, isolation and characterization of brain-infiltrating, in situ clonally expanded T cell clones in multiple sclerosis

R. Planas[1], *N. Vilarrasa*[1], *B. Reinhart*[1], *S. Hoffmeister-Ullerich*[2], *I. Metz*[3], *W. Brück*[3], *B. Fehse*[2], *C. Pinilla*[4], *R. Martin*[1], *M. Sospedra*[1];
[1]*Zürich University, Zürich, Switzerland,* [2]*University Medical Center Hamburg-Eppendorf, Hamburg, Germany,* [3]*University of Göttingen, Göttingen, Germany,* [4]*Torrey Pines Institute for Molecular Studies, San Diego, CA, United States.*

Multiple sclerosis (MS) is a chronic inflammatory demyelinating disease of the central nervous system (CNS). MS is considered an autoimmune disease mediated by T cells. However, the spectrum of autoantigens targeted by pathogenic T cells in MS is until now poorly understood. Only few myelin antigens are considered well defined autoantigens. There is also limited knowledge about the possible environmental triggers that could activate the autoreactive T cells in the periphery. Our hypothesis is that the spectrum of autoantigens in MS is broader than previously assumed and that new autoantigens and molecular triggers will be identified by using unbiased methods to test the antigen specificity pathogenic T cell populations in MS.
Most T cell specificity studies in MS are based on peripheral blood T cells, and for these it is difficult to determine if they are related to the disease. Our purpose is to test the specificity of brain-infiltrating, in situ clonally expanded T cell clones (TCC) from a MS patient, who died due to aggressive MS. We have first identified by T cell receptor sequencing T cells that are clonally expanded in brain lesions (frozen tissue). Currently we are isolating the same TCC from the cerebrospinal fluid T cells of the patient, expand them *in vitro* and characterize them phenotypically. Our purpose is to test the antigen specificity of these disease-relevant brain-infiltrating clonally expanded CD4+ and CD8+ TCC combining synthethic combinatorial peptide libraries and a brain-derived cDNA library screening system with cDNAs from affected brain tissue from the patient.

W5.10.02
T cells specific for both a myelin and a neuronal antigen are frequent in C57BL6 mice and contribute to CNS inflammation during EAE

L. E. Lucca[1], *A. Ramadan*[1], *S. Desbois-Beaumel*[1], *P. Rufas*[1], *J. Guery*[1], *T. L. Geiger*[2], *R. S. Liblau*[1], *L. T. Mars*[1];
[1]*Center of Physiopathology of Toulouse Purpan, INSERM UMR 1043, Toulouse, France,* [2]*St. Jude Children's Research Hospital, Memphis, TN, United States.*

Pathogenic T cells in autoimmunity can recognise multiple self-antigens simultaneously. We have shown that in T cell receptor (TcR)-transgenic mice on a C57BL/6 background (H-2b), the 2D2 TcR co-recognises the myelin oligodendrocyte glycoprotein epitope MOG35-55 and an epitope within the axonal protein Neurofilament medium (NF-M15-35). Here we assessed whether this is a common feature of the pathogenic MOG35-55 specific T cell response. To this end, we analysed the CD4 T cell response of MOG35-55-immunised C57BL/6 mice for cross-reactivity with NF-M15-35. Using antigen recall responses and ELISpot assays we established that purified CD4+ T cells from all MOG35-55-immunised mice tested revealed cross-reactivity to NF-M15-35. To study the clonality of this response we analysed twenty-four MOG35-55-specific T-cell hybridomas expressing distinct T cell receptors. Eight hybridomas were found to cross-react to NF-M15-35, while sixteen responded only to MOG35-55. Using an alanine-scan of NF-M18-30, we established that the aminoacids E19 and R21 are I-Ab anchoring residues, while F24, R26 and V27 proved important TCR contact residues. Strikingly, the three identified TCR contact residues are conserved within the MOG38-50 epitope. Our data indicates that part of the MOG35-55-specific T cell repertoire of C57BL/6 mice co-recognises NF-M15-35 due to linear sequence homology. Using approaches to silence these bi-specific cells or trace their frequency over time in the central nervous system of C57BL/6 mice with experimental autoimmune encephalomyelitis (EAE), we subsequently defined the functional

contribution of these distinct T cell pools during MOG35-55-induced EAE. These observations provide insight into the mechanisms underlying chronic organ-specific autoimmune diseases.

W5.10.03
Cell-intrinsic estrogen receptor α activation in CD4+ T cells control Th1/Th17 differentiation in trans and protect from CNS autoimmunity

***S. Laffont**, L. Garnier, N. Rouquié, J. Guéry;*
INSERM U1043, CPTP, Toulouse, France.

Estrogens influence many physiological processes in mammals. In autoimmune diseases, estrogens can display either beneficial or deleterious effects. Clinical remissions in patients with multiple sclerosis (MS) during pregnancy have suggested that sex hormones, particularly estrogens, could modulate CNS-autoimmunity and inflammation. Indeed, 17ß-estradiol (E2) treatment has been shown to inhibit the development of experimental autoimmune encephalomyelitis (EAE), the animal model of (MS). Two molecular targets essentially mediate E2 actions: estrogen receptor alpha (ERα) and beta (ERβ). We and others have shown that the protective effect of E2 on EAE was strictly dependent on ERα. However, the underlying mechanisms responsible of anti-inflammatory effect of E2 in EAE protection are still ill defined. Using tissue-specific ERαKO mouse models, we demonstrated that ERα-signaling in T lymphocytes, but not myeloid cells (monocytes/macrophages or dendritic cells), was required for sustained EAE protection by E2 (Lélu et al., *J. Immunol.* 2011 187:2386). Using adoptive transfer model of MOG-specific 2D2 CD4 T cells, we now show that ERα-signaling in endogenous host CD4+ T lymphocytes rather than responding 2D2 CD4+ T cells orchestrates the inhibition of MOG-specific Th1/Th17 cell priming. Coadministration of naive 2D2 $ER\alpha^{-/-}$ T cells with E2-responsive $ER\alpha^{+/+}$, but not $ER\alpha^{-/-}$, CD4 T cells strongly delayed EAE development in $Rag2^{-/-}$ $ER\alpha^{-/-}$ hosts. Thus, these results identify a suppressive activity of E2-primed CD4+ T cells, by which they can restrict differentiation of Th17 cells in *trans* and protect from CNS autoimmunity.

A role for TNF signalling in cortical grey matter pathology in multiple sclerosis

***R. Magliozzi**[1,2], P. Durrenberger[1], O. Howell[3], F. Roncaroli[1], E. Aricò[2], F. Aloisi[2], R. Reynolds[1];*
[1]Imperial College London, London, United Kingdom, [2]Istituto Superiore di Sanità, Rome, Italy, [3]Swansea University, Swansea, United Kingdom.

Neuroimaging and neuropathology studies indicate that accumulating grey matter pathology is the main correlate of clinical progression in multiple sclerosis (MS). Recent studies of cortical pathology in secondary progressive MS (SPMS) have shown that a more severe clinical course and the presence of extended subpial grey matter lesions (GMLs) with significant neuronal/glia loss and microglia activation are associated with diffuse meningeal inflammation and presence of lymphoid-like structures in the subarachnoid space. We investigated the hypothesis that pro-inflammatory and cytotoxic molecules diffusing from the meninges are the main determinant of GM pathology.
We used 20 post-mortem MS brains with and without substantial meningeal inflammation and 10 non-neurological controls to determine differentially expressed genes and pathways in subpial GMLs and normal appearing GM (NAGM) of the motor cortex by using Illumina HumanRef8 Beadchip arrays.
Gene expression profiling of GMLs and NAGM not only confirmed the substantial GM pathological cell changes, but also demonstrated the upregulation of multiple genes/pathways associated with the inflammatory response. In particular, genes involved in TNF mediated apoptosis/survival signalling have been found significantly deregulated in MS cases compared to controls, and increased meningeal inflammation was found associated with a shift in the balance of TNF signalling from the TNFR2 and NFkB anti-apoptotic pathway towards TNFR1 and RIP3 pro-apoptotic signalling.
These results support the hypothesis that the inflammatory milieu in the subarachnoid space of the meninges has a fundamental role in subpial grey matter pathology in MS and that TNF is a key mediator of brain tissue damage.

Characterization of the impact of CD25 blockade on the NK and T cell populations of relapsing-remitting multiple sclerosis patients

***D. J. Huss**, D. S. Mehta, L. Amaravadi, J. S. Elkins, J. D. Fontenot;*
Biogen Idec, Cambridge, MA, United States.

Multiple sclerosis (MS) is an immune-mediated neuroinflammatory disorder believed to be mediated by autoreactive T cells. Therapies that target T cell activation and effector function have shown promise in patients with relapsing-remitting MS (RRMS). Daclizumab high yield process (DAC HYP), a humanized monoclonal antibody that binds the high-affinity IL-2R (IL-2Rα or CD25) and prevents its association with IL-2, has demonstrated efficacy in two phase II clinical trials. Despite evidence of changes to immune cell populations based on altered IL-2 signaling, including an increase in CD56bright NK cells and a decrease in regulatory T cells, the mechanisms by which DAC HYP mediates its therapeutic benefit are poorly understood.
The biology of IL-2 is complex. As a growth factor for natural killer (NK) cells, conventional T cells and regulatory T cells, IL-2 is able to both potentiate and limit innate and adaptive immune responses. Adding to this complexity, IL-2 can signal through both high-affinity (IL-2Rαβγ) and intermediate-affinity (IL-2Rβγ) receptors. Thus, the response to IL-2 at the single cell level is dependent on both receptor expression and local IL-2 concentration.
Here we present data characterizing the impact of Daclizumab therapy on NK and T cell populations of RRMS patients. Using multi-color flow cytometric analysis of PBMCs from DAC HYP- and placebo-treated patients at baseline and week 24, we provide evidence of dynamic changes to immune cell subsets based on requirements for IL-2 signaling and expression of IL-2R components.

Confirmation of Human Endogenous Retrovirus HERV-Fc1 role in multiple sclerosis risk

***B. de la Hera**[1], J. Varadé[1], I. Alloza[2,3], A. Alcina[4], R. Arroyo[5], R. Álvarez-Lafuente[5], K. Vandenbroeck[3,2], F. Matesanz[4], E. Urcelay[1];*
[1]Immunology Department, Hospital Clínico San Carlos. Instituto de Investigación Sanitaria del Hospital Clínico San Carlos (IdISSC), Madrid, Spain, [2]Neurogenomiks Laboratory, Dept. of Neuroscience, University of the Basque Country UPV/EHU, Leioa, Spain, [3]IKERBASQUE, Basque Foundation for Science, Bilbao, Spain, [4]Inst. Parasitología y Biomedicina "López Neyra", CSIC Instituto de Investigación Sanitaria del Hospital Clínico San Carlos (IdISSC), Granada, Spain, [5]Multiple Sclerosis Unit, Hospital Clínico San Carlos. Instituto de Investigación Sanitaria del Hospital Clínico San Carlos (IdISSC)., Madrid, Spain.

Background: Multiple sclerosis (MS) is a chronic demyelinating disease with an aetiology not completely ascertained, albeit the prevailing hypothesis contemplates the triggering effect of environmental factors in genetically susceptible individuals. The genetics of MS has undergone a spectacular advance propelled by the genome wide association studies (GWAS) recently performed. However, this robust approach accounts only for part of the estimated genetic load, and where the so called missing heritability lies is intriguing. Provided GWAS do not scrutinize repetitive regions of the genome, their role in MS predisposition gains interest. Part of these repetitive sequences corresponds to human endogenous retroviruses (HERVs), which are proviral loci inherited under a Mendelian pattern. We aimed to validate the previously reported association of HERV-Fc1 with MS susceptibility.
Methods: The rs391745 polymorphism located upstream of the HERV-Fc1 locus in chromosome X was genotyped by TaqMan assays in independent cohorts from Central (714 patients and 692 controls), South (880 patients and 1359 controls) and North (368 patients and 980 controls) Spain.

Results: North and Central Spanish cohorts including non primary progressive MS patients and showing association results without heterogeneity were combined to achieve a higher statistical power. A significant association with MS risk was evidenced [pM-H=0.02; OR (95% CI)=1.27 (1.03-1.55)], replicating previously reported Danish and Norwegian results. Meta-analysis of all available data yielded a strong effect [p=0.0003; OR (95% CI)=1.32 (1.32-1.53)].
Conclusion: Our work supports the association of HERV-Fc1 in MS pathogenesis, identifying a chromosome-X genetic marker that could lay behind genetic differences in MS clinical forms.

Necrotizing autoimmune myopathy: emergence of a new autoimmune disease

O. Boyer[1,2], *L. Drouot*[1], *F. Jouen*[1,2], *Y. Allenbach*[3], *J. Charuel*[4], *L. Musset*[4], *I. Marie*[1,5], *O. Benveniste*[3], *&. French Myositis Network*[6];
[1]*Inserm U905, Normandy University, Institute for Research and Innovation in Biomedicine (IRIB), Rouen, France,* [2]*Laboratory of Immunology, Rouen University Hospital, Rouen, France,* [3]*Department of Internal Medicine, Pitié-Salpêtrière University Hospital, Paris, France,* [4]*Laboratory of Immunochemistry, Pitié-Salpêtrière University Hospital, Paris, France,* [5]*Department of Internal Medicine, Rouen University Hospital, Rouen, France,* [6]*Institute of myology and other French collaborative centres, Paris and other French hospitals, France.*

Necrotizing autoimmune myopathy (NAM) is a new group of acquired myopathies. Patients present with severe progressive muscle weakness, high serum creatine kinase (CK) levels and prominent myofiber necrosis with little muscle inflammation. Hence, NAM patients may be misdiagnosed as having muscular dystrophy, which prevents the initiation of an appropriate therapy. NAM is commonly associated with deposit of C5b-9 in muscle and presence of autoantibodies (aAbs) against signal-recognition particle (SRP) or 3-hydroxy-3-methylglutaryl-coenzymeA reductase (HMGCR) in serum.
We developed Luminex assays to quantify these aAbs. Anti-SRP aAbs stained the endoplasmic reticulum (ER) on muscle sections (electronic microscopy) and their titers (Luminex) correlated to CK levels. Anti-SRP$^+$ plasma was toxic for myoblast and myotubes in culture. It induced muscle weakness (grip test) after injection to mice, with *in vivo* binding to myofibers and C5b-9 deposits. This suggests that anti-SRP aAbs are directly pathogenic.
NAM may also be a complication of treatment with statins, an anticholesterol drug targeting HMGCR. In a series of 150 patients with suspicion of NAM, 37 were anti-HMGCR$^+$. These patients presented with proximal and bilateral muscle weakness and had very elevated (mean > 6,000 IU/L) CK levels. Sixty percent had not taken statins. Histologically, muscle biopsies always showed regenerating and necrotic muscle fibers.Detection of anti-SRP/HMGCR aAbs allows to ascribe patients with necrotizing myopathy to an autoimmune form, rendering them eligible to immunosuppression. These aAbs are likely to be directly pathogenic. Yet, more than 20% of NAM patients are seronegative, suggesting that other aAbs remain to be discovered.

Role of soluble CD30/CD30L and of CD30/CD30L+ T cells in the modulation of inflammatory response in rheumatoid synovitis

A. Barbieri[1], *E. Tinazzi*[1], *A. Rigo*[1], *R. Gerli*[2], *G. Patuzzo*[1], *R. Beri*[1], *A. Puccetti*[3,4], ***C. Lunardi***[5,1];
[1]*Department of Medicine, University of Verona, Italy,* [2]*Department of Clinical and Experimental Medicine, University of Perugia, Italy,* [3]*Giannina Gaslini Institute, Genova, Italy,* [4]*Department of Experimental Medicine, University of Genova, Italy,* [5]*Italy.*

CD30 and CD30 ligand (CD30L) are members of TNF-Receptor and TNF superfamilies, respectively. CD30+ Tcells are increased in several human diseases and interaction of CD30L with CD30+ cells induces signals that cause cell proliferation or apoptosis. A percentage of Tcells from synovial fluid (SF) from patients affected by Rheumatoid Arthritis (RA) express surface CD30 and high levels of soluble CD30 (sCD30) have been reported in sera and SF of RA patients. The increase of sCD30 levels seems to reflect the recruitment of CD30+ T cells into the inflamed joints and is predictive of a positive response to immunosuppressive therapy. Recently a soluble form of CD30L has been described in RA patients' sera. Our aim was to investigate the role of sCD30L and CD30L+ Tcells in RA.
sCD30L was not detectable in PB of healthy controls whereas it was present in PB and SF of patients with RA showing a correlation with the disease activity and with response TNFα blockade therapy. sCD30L molecule is shedded upon interaction between CD30+ and CD30L+ cells, binds to surface CD30 and is functionally active, since it induces a decrease in CD30+ Tcell proliferation due to apoptosis. Therefore sCD30L may favour chronic inflammation by inducing apoptosis of CD30+ Tcells. Moreover a great number of Treg cells are CD30+. Finally, synovial CD30L+ Tcells stimulated with CD30-chimera produce high levels of the proinflammatory cyotkines IFN-g and IL-17.
In conclusion, sCD30L and CD30L+ Tcells may play a pivotal role in RA synovitis and are correlated with response to therapy.

DERAA directed T-cells: a link between HLA class II association and Rheumatoid Arthritis

J. van Heemst[1], *D. Jansen*[1], *M. Bax*[1], *A. Feitsma*[1], *M. Baarse*[1], *A. Moustakas*[2], *D. Bontrop-Elferink*[1], *G. Papadopoulos*[2], *T. Huizinga*[1], *R. Toes*[1];
[1]*Leiden University Medical Center, Leiden, Netherlands,*
[2]*Technological Educational Institute of Epirus, Arta, Greece.*

The HLA system represents the most prominent genetic risk factor for rheumatoid arthritis (RA), but the biological mechanism is poorly understood.
Recently, we showed that HLA-DRB1*13:01 protects against RA characterized by the presence of RA-specific anti-citrullinated protein antibodies (ACPA). These antibodies recognize citrullinated proteins, often found among structural proteins.
A dominant peptide source presented by HLA class II molecules are HLA derived peptides. Natural processing of the protective HLA-DRB1*13:01 yields a peptide containing the amino acid sequence DERAA that is found in few self-proteins but many pathogens. We hypothesized that cross-reactive DERAA-directed T-cells against "DERAA-containing" pathogens "help" B-cells recognizing the "DERAA-containing" structural protein vinculin which is recently identified as a citrullinated self-protein present in synovial fluid of RA-patients. Such T-cells would be tolerized in HLA-DRB1*13:01 donors.
Intriguingly, we detected autoreactive T-cells, restricted by RA predisposing HLA molecules HLA-DQ7 and HLA-DQ8, specifically directed to the DERAA containing epitope of vinculin. Moreover, T-cell responses to pathogen-derived DERAA epitopes were readily detectable. Importantly, these T-cell responses were absent in HLA-DRB1*13:01-carriers. Likewise, we showed cross-reactivity of a DERAA-directed T-cell receptor with both pathogen- and self-derived DERAA-sequences. Moreover, we showed that ACPA recognize citrullinated vinculin.
Together, our data indicate the presence of pathogen-induced "DERAA"-directed T-cells that cross-react to human vinculin. These T-cells are absent in HLA-DRB1*13:01 carriers and recognize DERAA-antigens presented by RA-predisposing HLA-molecules, possibly explaining the long known HLA-RA connection. These data point to a role for DERAA-directed T-cells in the pathogenesis of ACPA-positive RA by helping ACPA-producing B-cells recognizing citrullinated vinculin.

W5.12.02
Impaired TNFα production by dendritic cells from rheumatoid arthritis patients upon contact with Porphyromonas gingivalis

K. C. M. Santegoets[1,2], *M. H. Wenink*[1,2], *W. B. van den Berg*[2], *T. R. D. J. Radstake*[1,2];
[1]*Department of Rheumatology and Clinical Immunology & Laboratory of Translational Immunology, University Medical Center Utrecht, Utrecht, Netherlands,* [2]*Department of Rheumatology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.*

The prevalence of periodontitis is increased in patients with rheumatoid arthritis (RA) and the severity of periodontitis can affect the level of arthritis. Porphyromonas gingivalis is one of the main bacteria causing periodontitis and our aim was to determine if there are differences in the immune response against P. gingivalis between healthy controls and RA patients. Therefore we compared the response of dendritic cells (DCs) from RA patients with healthy donors for their response towards P. gingivalis. We isolated monocytes from healthy controls, RA patients and psoriatic arthritis (PsA) patients and cultured them into monocyte-derived dendritic cells. DCs were stimulated with a set of bacteria possibly involved in RA including the periodontal bacteria P. gingivalis and Prevotella intermedia. TNFα production was significantly decreased in RA patients as compared to healthy controls upon stimulation with P. gingivalis, but not with any of the other bacteria or single TLR agonists. PsA patients were included as a diseased control group and the cytokine production by PsA DCs was not different from healthy controls, suggesting a RA specific deregulated response to P. gingivalis. The decreased response towards P. gingivalis is present in all medication groups. The response to P. gingivalis was not correlated with the presence of auto-antibodies, disease activity or erosions. In conclusion, DCs from RA patients produce less pro-inflammatory cytokines upon P. gingivalis stimulation. This could result in prolonged survival of P. gingivalis resulting in an increased bacterial burden in RA patients.

Antibodies From Rheumatoid Arthritis Patients Target Citrullinated Histone 4 Contained in Neutrophils Extracellular Traps

F. Pratesi[1], *I. Dioni*[2], *M. Alcaro*[3], *I. Paolini*[3], *F. Panza*[1], *I. Puxeddu*[1], *P. Rovero*[4], ***P. Migliorini***[1];
[1]*Pisa University, Pisa, Italy,* [2]*Florence University, Firenze, Italy,* [3]*Toscana Biomarkers, Siena, Italy,* [4]*Florence University, Florence, Italy.*

Background: Histone deimination is a crucial event in cell biology, regulating gene function and contributing to antimicrobial response, through the formation of neutrophil extracellular traps (NETs). Deiminated proteins are target of disease-specific antibodies (ACPA) in rheumatoid arthritis (RA).
Objective: Aim of the present study is to investigate the presence in RA sera of a new subset of ACPA, antibodies reactive with deiminated histones.
Methods: Neutrophils from peripheral blood were stimulated with calcium ionophore; NETosis was induced by phorbol myristate acetate and NET proteins were isolated. Sera were tested by immunoblot on acid extracted proteins from neutrophils and from NETs and by ELISA on deiminated histone H4 or H4-derived peptides. Bands reactive with RA sera were digested with trypsin and subjected to MALDI-TOF analysis, before and after derivatization to detect citrullinated peptides.
Results: RA sera reacted with an antigen of 11 KDa expressed in nuclei of activated neutrophils, identified as H4. MALDI TOF analysis indicated that this antigen, present also in NETs, is citrullinated. By ELISA, RA sera bound in vitro citrullinated H4. Citrullinated H4 14-34 and 31-50 AA peptides detected antibodies in 67% and 63% of RA sera and in less than 5% of controls; preincubation with peptides inhibited binding to citrullinated H4.
Conclusion: Citrullinated H4 from activated neutrophils and NETs is a target of antibodies in RA. As NETosis can generate antigens for ACPA, these data suggest a novel connection between innate and adaptive immunity in RA.

W5.12.04
DNAse IgG activity in patients with early arthritis

M. Volkava[1], *A. Kundzer*[2], *I. Generalov*[1];
[1]*Vitebsk state medical university, Vitebsk, Belarus,* [2]*Belarusian Medical Academy of Post-graduate Education, Minsk, Belarus.*

The aim of our study was to study the levels of DNAse IgG activity in patients with early arthritis (EA).
We studied 190 persons: 64 patients with early rheumatoid arthritis (ERA), 55 patients with acute reactive arthritis (AReA), 36 patients with unclassified arthritis (UA) and 39 healthy controls.
The samples of purified from the sera by combined method polyclonal IgG isolated from patients and healthy persons were investigated. The experiments, confirming that DNAse activity is the essential quality of IgG were performed. DNAse IgG activity was determined by rivanol clot prevention test and agarose electrophoresis.
The levels of DNAse IgG activity in patients with ERA (Me 4.00, 95%DI 3.50-4.50), AReA (Me 2.50, 95%DI 2.00-3.00), UA (Me 3.50, 95%DI 2.50-4.00) were higher ($p<0.01$) than in controls (Me 0.00, 95%DI 0.00-0.50). The levels of DNAse activity in ERA were higher ($p<0.05$) than in AReA and UA.
There were correlation between DNAse IgG activity and ESR ($r=0.42$) in ERA, T-lymphocytes number ($r=0.40$), immune complexes number ($r=0.42$) in AReA, CRP ($r=0.37$), CD4+lymphocytes number ($r=-0.49$), CD8+lymphocytes number ($r=-0.50$) in UA, $p<0.05$ respectively.
The determination DNAse IgG activity elevated levels might be applied for discrimination of ERA from AReA and UA (sensitivity 82.81%, specificity 71.43%, PLR 2.90, NLR 0.24).
For the first time we confirmed the presence of elevated levels of DNAse IgG activity in EA in comparison with controls and prevalence of this activity in ERA. We proposed original test for differentiation of ERA from AReA and UA.

W5.12.05
Endogenous SLPI controls B cell survival factor expression in TLR3-stimulated rheumatoid synovial fibroblasts

N. W. Kam[1], *F. Brentano*[2], *D. Kyburz*[2], *S. Gay*[2], *A. Filer*[3], *C. Buckley*[3], *C. Pitzalis*[1], *M. Bombardieri*[1];
[1]*William Harvey Research Institute, QMUL, Barts and The School of Medicine and Dentistry, London, United Kingdom,* [2]*Department of Rheumatology, University Hospital Zürich, Zürich, Switzerland,* [3]*Division of Immunity and Infection, College of Medical and Dental Sciences, University of Birmingham, Birmingham, United Kingdom.*

Background and aims: Secretory leukocyte protease inhibitor (SLPI) is known as a serine protease inhibitor mainly synthesized by epithelial cells which also exerts anti-inflammatory and microbicidal activities. Rheumatoid arthritis (RA) is characterized by the presence of synovial niches of autoreactive B cells. Importantly, autocrine mechanisms such as production of B cell survival factors BAFF and APRIL by RA synovial fibroblasts, support ongoing B cell activation within the RA synovium. Here we investigated whether SLPI is produced by RASF and regulates BAFF expression in response to Toll-like receptors (TLRs).
Methods: mRNA and protein expression of SLPI in RASF/RADF stimulated with/without TLR2/TLR3/TLR4 ligands was assessed by QT-PCR and ELISA, respectively. We also study the effect on BAFF mRNA/protein expression by RASF in the presence/absence of recombinant SLPI and blocking anti-SLPI antibodies.
Results: In vitro stimulation of TLR3, but not TLR2/TLR4 on RASF led to an about 15-fold induction of SLPI mRNA expression. In response to TLR3, SLPI was time-dependently released in the supernatant of RASF but not RADF. SLPI restrained BAFF production released by TLR3-stimulated RASF. In turn, TLR3-induced BAFF production was upregulated by endogenous SLPI blockade.
Conclusion: We demonstrated that RASF are able to release high levels of SLPI constitutively and upon TLR3 stimulation. The release of SLPI can directly modulate BAFF released by TLR3-stimulated RASF, highlighting the existence of an endogenous negative feedback loop centred on SLPI which regulates the release of B cell survival factors by RASF.

W5.12.06
In-vivo rnai mediated silencing of HNRNP-A2 decreases chronic inflammation by inhibiting proliferative and secretory capacity of monocytic cells

S. Herman[1], *J. Presumey*[2], *M. Koenders*[3], *W. van den Berg*[3], *F. Apparailley*[2], *G. Steiner*[1];
[1]*Internal Medicine III, Vienna, Austria,* [2]*University Hospital Saint Eloi University, Montpellier, France,* [3]*Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.*

Background: HnRNP-A2 belongs to a heterogenous family of nuclear proteins, importantly involved in mRNA processes. Recent evidence let suggest that hnRNPs posttranscriptionally modulate inflammatory mediators such as COX-2, TNF-α, IL-1β and iNOS by affecting mRNA stability.
Upregulation of hnRNP-A2 at sites of inflammation, and the generation of autoreactive T-cells against hnRNP-A2 in different arthritis models points towards an involvement in arthritis pathogenesis.
Objective: To gain more insight in the role of hnRNP-A2 in inflammation we have investigated the impact of hnRNP-A2 silencing in-vivo in mice suffering from collagen-induced arthritis (CIA) and in the KRN serum transfer arthritis model.
Animals and methods: In both arthritis models hnRNP-A2 was targeted using siRNA containing lipoplexes injected intravenously once a week. Control animals were treated with unspecific siRNA/lipoplexes or PBS. Arthritis was measured by a clinical scoring system. Inflammation and bone erosions were analyzed by histomorphometry.
Results: HnRNP-A2 was exclusively expressed in lymphoid organs. Cells of the mononuclear phagocyte system (MPS) showed the strongest expression of hnRNP-A2. Incidence of arthritis in hnRNPA2 silenced mice was significantly lower. Arthritis scores and weight loss differed significantly from control animals. Histological analysis of paws confirmed that both inflammation and erosion was significantly diminished in animals treated with hnRNP-A2 specific siRNA. Cytokines typically produced by cells of the MPS such as TNF-α, IL-23 and IL-1 were strongly reduced.
Conclusion: In-vivo silencing of hnRNP-A2 in two inflammatory arthritis models largely prevents induction of disease presumably by affecting the mononuclear phagocyte system.

Innate immune activation promotes autoimmune response in generalized pustular psoriasis

A. Arakawa*, S. Vollmer, B. Summer, Y. Kawakami, B. Petra, P. Thomas, A. Wollenberg, J. Schauber, T. Ruzicka, J. C. Prinz;*
Department of Dermatology, Ludwig-Maximilians-University, Munich, Germany.

Generalized pustular psoriasis (GPP) is a rare, life-threatening disease characterized by recurrent episodes of systemic inflammation and pustulosis. It has been thought to belong to the spectrum of psoriasis, which is an HLA-class-I associated autoimmune disease. However, the recent identification of genetic defects in the IL-36 receptor antagonist (IL-36RN), a physiological antagonist of IL-36 signaling, suggests an autoinflammatory pathomechanism with excessive activation of the IL-1 pathway in GPP (Marrakchi *et al* 2011, Onoufriadis *et al* 2011). In this study, we investigated how autoinflammation and autoimmunity contribute to GPP pathogenesis. We identified two novel mutations of IL-36RN and particular HLA-molecules in GPP patients, which may correspond with a genetic predisposition for autoinflammation and autoimmunity, respectively. Real-time PCR for cytokine expressions and immunohistochemical studies confirmed local and systemic inflammation in GPP patients. Meanwhile, increased susceptibility to proinflammatory signals promoted auto-antigen driving T-cell activation in T-cell stimulation assays using lymphocytes from patients. T-cell receptor (TCR)-beta chain fragment length spectratyping and single cell TCR analysis were performed, and strong clonal T-cell expansions were detected in the skin and circulation of GPP patients. These results provide a comprehensive picture of GPP pathogenesis; whereby aberrant innate immune reactions enhance adaptive autoimmune responses, and have important therapeutic implications.

W5.14.02
PD-1 and other new molecules in the psoriatic infiltrate: an immunohistochemical and confocal laser microscopic study

D. Fanoni[1], *B. Vergani*[2], *S. Recalcati*[1], *S. Tavecchio*[1], *A. V. Marzano*[1], *A. Villa*[2], *E. Berti*[1];
[1]*Dept. of Dermatology - Fondazione IRCCS Cà Granda - Ospedale Maggiore Policlinico, Milan, Italy,* [2]*Consorzio MIA, Monza, Italy.*

Basic and translational research is recently focusing on immunopathogenesis of psoriasis for the development of new therapeutic strategies. Few studies have recently demonstrated the role of PD-1, PD1-L inhibitory molecules in the control of T-cell activation and in favouring T-reg proliferation. The aim of our study was to evaluate the psoriatic infiltrate of 10 patients at baseline conditions. An immunohistochemical method and confocal laser microscopy with a large panel of monoclonal antibodies was used to better characterize the different cell subtypes. Our results showed many CD11c+ cells, several BDCA2+ plasmacytoid dendritic cells in a perivascular distribution and isolated Langerin+, CD103+ DCs. Many macrophages were also present, particularly CD163+ (M2) cells. Few CTLA-4+ Tcells and T-reg (Fox-P3+) were demonstrated. Monoclonal antibodies against classic cytokines, such as IFN, TNFα and IL17 labelled macrophages, lymphocytes or endothelial cells. PD1 expression was clearly detected on CD8+, TIA1+ cytotoxic T cells in the epidermis, on CD4+, T-Bet+, TIA-1- (Th1) lymphocytes in the papillary and superficial dermis and on macrophages, but not on CD11c+ dendritic cells. High expression of PD1-L was observed on stromal cells and keratinocytes in lesional skin. PD-1:PD-L interactions exert a wide range of immunoregulatory actions in T cell activation, tolerance, and immune-mediated tissue damage. Thus, further studies are needed to better understand the role of PD-1:PD-L pathway in the regulation of the immune response, in both physiological and pathological conditions, paving the way to new drugs that act by regulating PD1 expression in immune-mediated disorders.

W5.14.03
Inhibition of keratinocyte differentiation by the synergistic effect of pro-inflammatory cytokines mimics psoriasis

H. Rabeony[1], *I. Paris*[1,2], *J. Garnier*[3], *C. Barrault*[3], *N. Pedretti*[3], *K. Guilloteau*[1], *V. Huguier*[1,2], *F. Bernard*[3,1], *J. Lecron*[1,2], ***F. Morel***[1];
[1]*LITEC EA4331, Poitiers University, France,* [2]*CHU, Poitiers, France,* [3]*BIOalternatives, Gençay, France.*

Epidermal integrity is based on tight regulation of the communication between keratinocytes and leucocytes, particularly provided by balanced cytokine production. An imbalance network leads to skin inflammatory diseases such as psoriasis. Our attempt to model skin inflammation showed that combination of IL1a-IL17A-IL22-OSM-TNFa synergistically increases expression of chemokines and antimicrobial-peptides, leading to neutrophil infiltration, recapitulating some features of psoriasis.
Our goal was to characterize in vitro and in vivo the activity of cytokine combinations on keratinocyte differentiation and to compare with psoriatic skin lesions.
If IL1a, IL17A, IL22, OSM or TNFa were able to decrease cytokeratin-10, loricrin, filaggrin and cadherin-1 expressions, IL22, OSM and TNFa were the most powerful. Combination of these 5 cytokines (M5) generated a synergistic effect on inhibition of differentiation markers expression. This was confirmed on reconstructed epidermis. IL22 and OSM significantly decreased expressions of cytokeratin-10, filaggrin and cadherin-1, and induced epidermal hyperplasia. Injection of M5 in vivo in mice caused a thickening of the epidermis associated with decreased expression of cytokeratin-10, filaggrin and cadherin-1. Similarly we demonstrated a decreased expression of these markers in psoriatic skin lesions, as obtained in vitro and in vivo.
Our results showed that synergistic effect of cytokines was responsible for the production of antimicrobial-peptides, chemokines and inhibition of keratinocyte differentiation. If IL1a, IL17A and TNFa

were important for the production of antimicrobial-peptides and chemokines, IL22, OSM and TNFa seemed essential to the differentiation inhibition. Establishment of these models should clarify the role of cytokines in the establishment of the inflammatory response.

W5.14.04
In vivo induction of cutaneous inflammation results in the accumulation extracellular trap forming neutrophils expressing RORγt and IL-17, while IL-17+RORγ+ T cells remain absent

*R. R. M. C. Keijsers[1], P. E. J. van Erp[2], P. C. M. van de Kerkhof[2], I. Joosten[3], **H. J. P. M. Koenen**[3];*
[1]Radboud University Medical Centre, Department of Laboratory Medicine, Laboratory of Medical Immunology and Dermatology, Nijmegen, Netherlands, [2]Radboud University Medical Centre, Dermatology, Nijmegen, Netherlands, [3]Radboud University Medical Centre, Department of Laboratory Medicine, Laboratory of Medical Immunology, Nijmegen, Netherlands.

Successful clinical trials using antibodies targeting IL-17 in psoriasis support the importance of IL-17 in the pathophysiology of psoriasis. However, there is debate concerning the cell source of IL-17 in the inflamed skin. In this study were to characterized IL-17-producing innate and adaptive cell populations in time by utilizing two established models for the induction of human skin inflammation *in vivo* that share many histological features with psoriasis: application of leukotriene B4 (LTB4) and tape stripping. Immunohistochemical studies showed that the application of LTB4 first led to an influx of neutrophils followed by an influx of T cells. Tape stripping caused an early influx of both neutrophils and T cells. Characterization of IL-17 associated cells, indicated that IL-17 was expressed by neutrophils and mast cells in both models. Only neutrophils co-expressed the IL-17 associated transcription factor RORyt. While the presence of mast cells remained steady during the skin inflammatory process, presence of neutrophils was clearly dynamic in time. Therefore, it is attractive to hypothesize that IL-17+/RORyt+ neutrophils contribute to the development of psoriasis. Surprisingly, none of the T cell subsets expressed RORγt or IL-17. These observations challenge the classical opinion that IL-17 is predominantly associated with T cells in psoriasis.

W5.14.05
Skin inflammation in Act1-deficient mice is T-cell intrinsic and due to exaggerated Th17 derived IL-22

***L. Wu**[1,2], C. Wang[2], V. K. Kuchroo[3], W. Ouyang[4], X. Li[2];*
[1]Department of Pathology, Case Western Reserve University School of Medicine, Cleveland, OH, United States, [2]Department of Immunology, Cleveland Clinic Foundation Lerner Research Institute, Cleveland, OH, United States, [3]Center for Neurologic Diseases, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, United States, [4]Department of Immunology, Genentech, Inc, San Francisco, CA, United States.

Psoriasis is a chronic inflammatory skin disease mediated in part by T helper 17 (Th17) cells and their cytokines (IL-17, IL-21, and IL-22). Act1 is the essential adaptor molecule for IL-17 receptor signaling. Here we report that Act1 is a 'client' protein of the molecular chaperone, Hsp90. Treatment of MEFs with Hsp90 inhibitors led to proteasomal-dependent Act1 degradation. We identified a highly conserved region in the N-terminus of Act1 that is required for the interaction with Hsp90. Recent genome-wide association studies linked a variant of Act1 (Act1(D10N)) to psoriasis susceptibility. As the variance occurred at the N-terminus, we found that Act1 (D10N) was indeed unable to interact with Hsp90, which resulted in an impaired interaction with all of the IL-17-signaling components (IL-17R, TRAF2, TRAF5, TRAF6, and IKKi) and thus failed to mediate IL-17-dependent gene induction. Given that IL-17 is linked to psoriasis pathogenesis, these findings are potential conundrums for the field. Using the Act1-deficient mice to model the mechanistic link between loss of Act1 function and susceptibility to psoriasis, we found that Act1-deficient mice had exaggerated Th17 cell generation and developed spontaneous skin inflammation that was resolved with anti-IL-22 treatment. Moreover, ex vivo Th17 polarization resulted in enhanced IL-17 and IL-22 production, indicating a T cell-intrinsic regulatory role for Act1. Taken together, in the absence of IL-17-signaling, IL-22 appeared to be the main contributor to skin inflammation, providing a molecular mechanism for the association of Act1(D10N) with psoriasis susceptibility.

W5.14.06
Autoreactive T cells in chronic idiopathic urticaria target the high-affinity IgE receptor Iα subunit (FcεRIα)

***P. Auyeung**[1], D. Mittag[2], P. Hodgkin[1], L. Harrison[1];*
[1]Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia, [2]Australian Red Cross Blood Service, Melbourne, Australia.

Background. Chronic idiopathic urticaria (CIU) is the recurrence of "hives" without an apparent trigger. 50% of CIU patients have IgG autoantibodies to the FcεRIα on dermal mast cells and basophils, which upon activation release mediators responsible for urticaria. T cells are present in the skin lesions but autoantigen-specific T cells have not been identified in CIU.
Aims. We aimed to identify autoreactive T cells to FcεRIα in CIU, to help elucidate the pathogenesis and to improve the diagnosis of this disease.
Methods. Peripheral blood T-cell responses to FcεRIα were assayed in 30 CIU and 18 control subjects. Cell proliferation was measured by CFSE dye dilution. IFN-γ, IL-5 and IL-13 secretion were measured by ELISpot. Serum autoantibodies to FcεRIα were measured by immunoprecipitation of ^{125}I-labelled FcεRIα.
Results. We detected significant $CD4^+$ T-cell proliferation to FcεRIα in 30% of CIU and 0% of control subjects. IFN-γ responses were detected in 58% of CIU subjects, while IL-5 and IL-13 responses were detected in 29% and 37% of CIU subjects respectively. We detected autoantibodies to FcεRIα in 45% of CIU and 0% of control subjects. Overall, at least one FcεRIα-specific response was detected in 97% of CIU and only 5% of control subjects.
Conclusion. Autoreactive $CD4^+$ T cells specific for FcεRIα were detected in a proportion of subjects with CIU and, in combination with the assay for autoantibodies to FcεRIα, may improve the diagnosis of CIU.

IL5.16.01
Progress in the genetics and epigenetics of primary biliary cirrhosis

***P. Invernizzi**, M. Correnti, C. Mascheroni, A. Lleo, F. Bernuzzi, I. Bianchi;*
Liver Unit and Center for Autoimmune Liver Diseases, Humanitas Clinical and Research Center, Rozzano (MI), Italy.

Primary biliary cirrhosis (PBC) is a chronic cholestatic liver disease that primarily affects middle-aged women. PBC has strong autoimmune features, including highly specific loss of tolerance to a ubiquitous mitochondrial antigen. Both environmental and genetic factors are considered important in the pathogenesis of disease. Prior to the advent of genome wide association studies, only HLA class II loci (HLA-DRB1*08, *11, and *13) had been reproducibly shown to be associated with disease. With application of genome wide technology HLA was confirmed as the strongest association and many other risk loci have been identified, including IL12A, IL12RB2, STAT4, IRF5-TNPO3, and CTLA-4. These collectively support an important role for innate and adaptive immunity in development of disease. A second wave of genome wide association studies is now in progress based on dense arrays, such as the immunochip assay, larger cohorts and different ethnicity. Disease sub-phenotypes such as response to therapy, clinical progression and symptoms remain additional areas for further dedicated studies, and in which different genetic risk factors may be relevant. In addition to genetics, also epigenetic factors seem to play a role in PBC; in particular epigenetic defects were found in immune-related genes located on the X chromosome, such as the CD40L gene. Finally, due to a loss of X and Y chromosomes in female and male patients respectively, a progressive aploinsufficiency of sex chromosome genes can be hypothesized.

Constitutive IKK Activation Promotes Hepatocellular Carcinoma via Formation of Inflammatory Micro-niches

E. Pikarsky[1], *S. Finkin*[1], *D. Yuan*[2], *I. Stein*[3], *K. Taniguchi*[4], *K. Rajewsky*[5], *M. Karin*[4], *Y. Ben-Neriah*[1], *M. Heikenwalder*[2];
[1]*Hebrew University, Jerusalem, Israel,* [2]*Technische Universität München, Helmholtz Zentrum München, Munich, Germany,* [3]*Hadassah-Hebrew University Medical Center, Jerusalem, Israel,* [4]*University of California, San Diego, CA, United States,* [5]*Max Delbruck Center for Molecular Medicine, Berlin, Germany.*

Hepatocellular carcinoma (HCC) is a common fatal malignancy developing in chronically inflamed livers. Chronic viral hepatitides commonly show NF-κB activation and are the most frequent underlying cause of HCC worldwide. Yet, the role of NF-κB signaling in the pathogenesis of HCC is controversial. We dissected the role of IKK activation in a new mouse model of HCC. Constitutive activation of IKKβ in mouse hepatocytes suffices to induce HCC in old age. Moreover, it dramatically accelerates carcinogen induced HCC. In both cases, HCC is preceded by discrete inflammatory follicles, forming micro-niches in which progenitor malignant hepatocytes are nursed until they are ready to exit micro-niches to form bona-fide HCCs. These follicles are characterized by a complex cellular and cytokine milieu, particularly lymphotoxins, and their downstream effectors. When outmigrating from micro-niches, the malignant hepatocytes acquire autocrine properties, previously provided non-autonomously in the niche. Hepatitis C infected human livers, previously shown to induce chronic NF-κB activation, harbor similar inflammatory follicles. Pharmacological blockade of all lymphotoxin family cytokines dramatically attenuates mouse HCC, despite persistent NF-κB activation. Our findings indicate that liver NF-κB promotes early carcinogenesis non-cell-autonomously, by stimulating distinctive focal inflammatory micro-niches that foster tumor progenitor cell growth.

W5.16.01
IL-17A Produced by γδT Cells Promotes Tumor Growth in Hepatocellular Carcinoma

S. Ma, Q. Cheng, Y. Cai, Y. Wu, X. Yu, ***H. Liu****;*
Soochow University, Suzhou, China.

IL-17A has been found in both mouse and human tumors, and shown to be critical involved in tumor development. However, the role of endogenous IL-17A in anti-tumor immunity remains controversial. Here we showed that IL-17A-deficient mice exhibited a significant reduction of tumor growth, while systemic administration of rmIL-17A promoted tumor growth in hepatocellular carcinoma (HCC), indicating a promoting role of IL-17A in HCC development. Further analysis showed that IL-17A promoted tumor growth through suppression of the antitumor responses, especially CTL responses. Furthermore, we demonstrated that, in the tumor microenvironment, IL-17A was predominantly produced by Vγ4 γδT cells. Moreover, depletion of Vγ4 γδ T cells reduced tumor growth while adoptive transfer of Vγ4 γδ T cells promoted tumor growth. Further studies showed that IL-17A inhibited antitumor immune responses though enhancing the migration and suppressive activity of MDSCs in tumor microenvironment. Thus, our results demonstrated that IL-17A produced by Vγ4 γδ T cells promoted tumor growth and suppressed anti-tumor immune responses in HCC through enhancing the migration and suppressive activity of the MDSCs in tumor microenvironment. These findings provided new insights into the role of IL-17A in tumor immunity and may have important implications in tumor immunotherapies.

A second generation therapeutic cellular vaccine for hepatitis C virus

B. Grubor-Bauk[1], *P. Latour*[2], *J. Torresi*[3], *W. Yu*[1], *S. Roberts*[4], *B. Loveland*[2], *E. Gowans*[1];
[1]*University of Adelaide, Adelaide, Australia,* [2]*Burnet Institute, Melbourne, Australia,* [3]*Austin Hospital, Heidelberg, Australia,* [4]*The Alfred, Mlebourne, Australia.*

We reported the results of a Phase I clinical trial using a cellular vaccine to treat HCV patients who had previously failed therapy. This trial fulfilled a major criterion of a Phase I trial viz. safety, the HCV-specific immune responses were transient. We have now designed a second generation vaccine based on preclinical data in mice and conducted a new Phase I trial.
A novel mouse dendritic cell line expressing the HCV NS3 was manipulated to ensure maximum immunogenicity, by inducing cell necrosis. Mice were vaccinated and ten days after the second dose, NS3 ELIspots were performed. Mice vaccinated with necrotic cells generated levels which were approximately 80-100 fold greater than viable cells. This protocol was used to vaccinate HCV patients.
Twelve chronically infected patients (HCV g1b) received interferon-alpha therapy for 4 weeks prior to vaccination. One week before the first vaccination, autologous monocyte derived dendritic cells (MoDc) were generated and transduced with a recombinant human adenovirus (rAd5), encoding HCV E1, E2 and NS3. Necrosis was induced in rAd5 transduced MoDc and patients received escalating dose of vaccine and vaccine boosts. Safety, viral load and responses to HCV peptides were assayed at various time points post final boost and compared to baseline levels for each patient. Here we report the preliminary data of this trial.
It will be expensive and time consuming to prove the efficacy of an HCV prophylactic vaccine. Consequently, we formed the hypothesis that an effective therapeutic vaccine will also represent an effective prophylactic vaccine.

W5.16.03
Gender predominance is mediated via testosterone in a mouse model of autoimmune cholangitis

D. Schwinge[1], *A. Carambia*[1], *A. Quaas*[2], *C. Wegscheid*[3], *G. Tiegs*[3], *A. W. Lohse*[1], *J. Herkel*[1], *C. Schramm*[1];
[1]*Department of Medicine I, University Medical Center Hamburg-Eppendorf, Hamburg, Germany,* [2]*Department of Pathology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany,* [3]*Experimental Immunology and Hepatology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany.*

Background and aims: Many autoimmune liver diseases, including autoimmune liver diseases predominantly affect women. A deeper understanding of gender effects exerts on disease pathogenesis was limited by the lack of suitable animal models. We investigated how gender affects the immune pathogenesis in a novel mouse model of autoimmune cholangitis.
Methods and results: Adoptive cell transfer of ovalbumin (OVA)-specific CD8+ T cells into mice, which express OVA on cholangiocytes (K14-OVAp) resulted in portal inflammation and cholangitis in female, but not in male recipient mice. Gender differences seemed to be mediated by significant increased recruitment of endogenous CD4+ T cells in female as compared to male livers. Furthermore the levels of IL-17, RORc and the chemokines CXCL-9 and -10 were markedly elevated in female cholangitis. In castration and hormone replacement studies we could demonstrate, that the male insusceptibility to liver inflammation could be attributed to the protective effects of testosterone; estrogen levels had no effect on the severity of inflammation
Conclusion: We here demonstrate that the protection from autoimmune cholangitis which was observed in male mice was mediated by testosterone. Indeed, testosterone supplementation induced resistance to disease in otherwise susceptible female mice. The increased inflammation observed in female mice was associated with increased IL-17 expression by endogenous CD4 positive T cells which seems to be recruited to the liver via an increased expression of chemokines that recruit T cells to the liver. These results may stimulate future investigations into the mechanisms involved in gender differences in autoimmune diseases.

W5.16.04
CD49a$^+$DX5$^-$ NK cells are liver-resident and confer adaptive immunity in skin-contact inflammation

Z. Tian[1], *H. Peng*[1], *X. Jiang*[1], *Y. Chen*[1], *D. Sojka*[2], *H. Wei*[1], *R. Sun*[1], *W. Yokoyama*[2];
[1]*University of Science & Technology of China, Hefei, China,* [2]*Washington University School of Medicine, St. Louis, MO, United States.*

Liver natural killer (NK) cells were recently reported to possess memory-like properties in contact hypersensitivity (CHS) models. However, the phenotype and origin of these “memory” NK cells cannot be distinguished from other NK cell subpopulations. Here, we defined the transcriptional, phenotypic and functional features of liver NK cell subsets and their roles in mediating CHS. Liver NK cells can be divided into two distinct subsets, CD49a$^+$DX5$^-$ and CD49a$^-$DX5$^+$. Substantial transcriptional and phenotypic differences existed between liver CD49a$^+$DX5$^-$ NK cells and other NK cell subsets; the former possessed memory potential and conferred hapten-specific CHS responses upon hapten challenge. Importantly, CD49a$^+$DX5$^-$ NK cells were liver-resident, present in the liver sinusoid blood but not the afferent and efferent blood of the liver. Moreover, they appeared to originate from hepatic hematopoietic progenitor/stem cells (HPC/HSC) but not from the bone marrow (BM), and maintained their phenotypes in the steady-state. Our findings of liver-resident NK cells shed new light on acquisition of memory-like properties of NK cells.

W5.16.05
Phenotypic evaluation of CD28 negative T cells in primary sclerosing cholangitis

E. Liaskou[1], *L. Jeffery*[2], *S. Suresh*[1], *P. Trivedi*[1], *T. Bruns*[1,3,4], *D. H. Adams*[1], *D. M. Sansom*[2], *G. M. Hirschfield*[1];
[1]*Centre for Liver Research and NIHR Biomedical Research Unit in Liver Disease, Institute of Biomedical Research, University of Birmingham, Birmingham, United Kingdom,* [2]*Medical Research Council Centre for Immune Regulation, School of Immunity & Infection, Institute of Biomedical Research, University of Birmingham, Birmingham, United Kingdom,* [3]*Department of Internal Medicine IV, Gastroenterology, Hepatology and Infectious Disease, Jena University Hospital, Friedrich Schiller University of Jena, Jena, Germany,* [4]*Centre for Sepsis Control and Care (CSCC), Jena University Hospital, Friedrich Schiller University of Jena, Jena, Germany.*

Background/Aims: Genetic, functional and epidemiologic studies implicate CD28 and vitamin D (vitD) as relevant to autoimmune diseases including primary sclerosing cholangitis (PSC). Here we studied the role of CD28-ve T cells in PSC and the effects of vitD on their phenotype. Methods: Liver-infiltrating (LIMCs) and peripheral blood mononuclear cells (PBMCs) were isolated from healthy donors or patients with PSC. The frequency and phenotype of CD28-ve cells [expression of activation (CD69, CD25) and exhaustion (PD-1) markers, perforin and granzyme B] were studied by flow cytometry. PSC LIMCs and PBMCs were activated and the release of IFNγ was examined. CD28-ve and CD28+ve cells from PSC PBMCs were stimulated with anti-CD3, autologous CD14+monocytes (5:1 ratio) with/without vitD for 4 days. Results: CD4+CD28-ve and CD8+CD28-ve T cells were highly expanded in PSC peripheral blood (3.9- and 2.1-fold increase respectively versus normal blood) and in PSC liver (17.8- and 2.45-fold increase respectively versus normal liver). The frequency of CD4+CD28-ve T cells in PSC liver was significantly higher than PSC peripheral blood (*p<0.01).* Liver-infiltrating CD4+CD28-ve T cells showed an activated CD25+CD69+PD-1- and cytotoxic phenotype granzymeB+perforin+. *In-vitro* stimulation of PSC liver-infiltrating CD4+CD28-ve cells induced the production of IFNγ (41%), which was much higher compared to their CD28+ve counterparts (12%). Stimulation of PSC peripheral blood CD28-ve and CD28+ve cells with vitD induced CD28 expression on CD28-ve (+52%) and CD28+ve (+65%) cells and suppressed IFNγ production (-43% and 67%, respectively). Conclusion: In PSC, CD28 negative T cells are pro-inflammatory, an effect that can be reduced by vitamin D supplementation.

W5.16.06
Tumor-infiltrating IL-10 producing T cells are potent suppressors of the local anti-tumor immunity in patients with liver cancer

A. Pedroza-Gonzalez[1], *J. Kwekkeboom*[1], *E. Vargas-Mendez*[1], *C. Verhoef*[1], *J. de Jonge*[1], *J. N. M. IJzermans*[1], *H. L. A. Janssen*[1], *D. Sprengers*[2];
[1]*Erasmus MC, Rotterdam, Netherlands,* [2]*Academic Medical Center, Amsterdam, Netherlands.*

Hepatocellular carcinoma (HCC) and liver metastases from colorectal cancer (LM-CRC) are the main malignancies affecting the liver and are among the most common cancers and leading causes of cancer mortality. Curative treatment options are limited to very early stages, and they cannot prevent the recurrence of the disease. Several attempts to design alternative immunotherapeutic strategies have only shown limited efficacy in clinical trials. The failure of immunotherapy may be related to suppressive mechanisms in the tumor environment. In support of this, we recently described the accumulation of highly activated FoxP3+ regulatory T cells (Tregs) that are potent suppressors of anti-tumor immunity at the tumor site of patients with liver cancer. Now, we observed that in addition to Treg, tumor-infiltrating lymphocytes (TILs) contain a subset of CD4+ T cells that produces IL-10, and does not express FoxP3. These cells do not produce the Th2-like cytokine IL-13, but the majority can produce IFNg. Tumor-derived IL-10 producing CD4+ T cells have a potent capacity to suppress proliferation and cytokine production by autologous and allogenic effector T cells in an IL-10-dependent manner. These results indicate for the first time to our knowledge that besides CD4+FoxP3+ Tregs, liver tumors contain another subset of CD4+ T cells that is able to suppress the local immune response. It's phenotype and function resemble that of type 1 regulatory T (Tr1) cells, and it may also interfere with immunotherapeutic efforts designed to treat patients with liver cancer.

Epigenetic regulation following AhR activation leads to suppression of inflammatory and autoimmune diseases

P. Nagarkatti[1,2], *M. Rouse*[2], *N. Singh*[2], *M. Nagarkatti*[2];
[1]*SC, United States,* [2]*University of South Carolina, Columbia, SC, United States.*

Aryl hydrocarbon receptor (AhR) plays a central role in mediating detoxification of xenobiotics. Interestingly, recent studies have demonstrated an exciting new role for AhR in the regulation of T cells leading to suppression of inflammation and autoimmune diseases. Chronic inflammation is considered to be the underlying cause of most clinical disorders including autoimmune, cardiovascular, neurodegenerative diseases, obesity, as well as certain types of cancer. Thus, identifying novel pathways to regulate inflammation could lead to new drug discovery with global impact. Numerous endogenous and plant derived products act as AhR ligands. In the current study, we investigated the effect of compounds such as Resveratrol (RES; 3,5,4’-trihydroxystilbene) and other dietary AhR ligands, on T cell differentiation and suppression of inflammation. We found that AhR ligands could suppress experimental autoimmune encephalomyelitis (EAE) as well as colitis, We noted that treatment of mice with AhR ligands resulted in a dramatic decrease in infiltrating T-cells at sites of inflammtion. Based on miRNA array screening, AhR ligands induced the expression of certain microRNA that targeted cytokine genes such as IL-17 and transcriptional regulator, FoxP3. Moreover, AhR ligands also altered the DNA methylation, specifically upregulating the methylation of IL-17 gene while down-regulating the methylation of FoxP3. Together, these studies demonstrated that dietary AhR ligands may promote Th17 to Treg switch through epigenetic pathways involving DNA methylation and micro-RNA regulation, to suppress inflammation and autoimmune diseases (Supported in part by NIH grants P01AT003961, R01AT006888, R01ES019313, R01MH094755, P20RR032684 and VA Merit Award BX001357).

IL5.17.02
Autoinflammatory diseases

A. Rubartelli*;*
IRCCS AOU San Martino IST, Genova, Italy.

"Autoinflammatory" diseases represent and expanding spectrum of genetic and non-genetic inflammatory diseases characterized by recurrent episodes of fever and systemic inflammation affecting the eyes, joints, skin, and serosal surfaces. Autoinflammatory differ from autoimmune diseases by several features, including the periodicity whereas autoimmune diseases are progressive, and the lack of signs of involvement of adaptive immunity such as association with HLA aplotypes, high-titer autoantibodies or antigen-specific T cells. Autoimmune diseases are responsive to biologic agents that targets T- and B-cell functions, including anti-TNFα, anti-IL-6 receptor, anti-IL-12/IL-23 antibodies etc. However, these therapeutics have no sustained effects in treating autoinflammatory diseases that, in contrast, are uniquely responsive to IL-1β blockade. Thus, autoinflammatory syndromes are recognized as disorders of innate immunity, where the monocyte-macrophage rather than the T-cell is the culprit and the defect is dysregulated secretion of active IL-1β. Although many autoinflammatory diseases have a genetic cause, increasing evidence indicates that the degree of cell stress concurs to the severity of the disease phenotype. In this workshop, we will discuss the recent advances on pathogenesis, pathophysiology and therapeutic approaches in autoinflammatory syndromes compared with autoimmune diseases.

W5.17.01
The molecular link between PSTPIP1 and S100A8/S100A9 in autoinflammatory diseases

S. Fassl*, D. Holzinger, J. Austermann, T. Vogl, J. Roth;*
Institue for Immunology, University Hospital Muenster, Muenster, Germany.

Hypercalprotectinaemia & hyperzincaemia is a rare autoinflammatory syndrome that is characterized by excessively high S100A8/A9 complex (calprotectin) serum concentrations. S100A8 and S100A9 are Damage Associated Molecular Pattern (DAMP) proteins that can be released by microtubuli (MT)-dependent alternative secretory pathways to promote inflammatory processes via TLR-4 dependent signalling pathways. By analyzing eleven patients we could identify a novel mutation in the proline serine threonine phosphatase-interacting protein 1 (PSTPIP1) gene. Ten patients were carrier of an E250K substitution encoded by the PSTPIP1 gene. Other PSTPIP1 mutations are responsible for the classical, clinically different Pyogenic sterile Arthritis, Pyoderma gangrenosum, and Acne (PAPA)-syndrome which presents with elevated, albeit significantly lower S100A8/A9 levels compared to patients with E250K mutation. Whether there is a molecular link between PSTPIP1 mutations and elevated S100A8/A9 concentrations is currently unknown. This project focuses therefore on the identification of molecular links between PSTPIP1 and S100A8/A9.
The double-staining immunofluorescence, proximity ligation assays (DuoLink II®), and immunoprecipitation results show an interaction between PSTPIP1 and S100A8/A9 after activation of monocytes by phorbolester. In biochemical assays we could specify a direct interaction of these proteins in a strictly calcium-dependent manner. Deletion constructs of PSTPIP1 indicate that the S100A8/A9 binding motif is located in the same region where the mutation of patients is located. MT co-sedimentation experiments indicate a mutual interference of PSTPIP1 and S100A8/A9 on their interaction with MT which is altered by E250K mutation. This in turn might be of important relevance for the uncontrolled, MT-dependent secretion of S100A8/A9 promoting inflammation in these patients.

W5.17.02
Increased Nlrp3-dependent Interleukin (IL) 1B secretion in patients with Familial Mediterranean Fever (FMF): correlation with Mefv genotype

A. Omenetti[1]*, S. Carta*[2]*, L. Delfino*[2]*, A. Martini*[1,3]*, M. Gattorno*[3]*, A. Rubartelli*[2]*;*
[1]*University of Genoa, Genoa, Italy,* [2]*IRCCS AOU San Martino - IST, Genoa, Italy,* [3]*IRCCS G Gaslini, Genoa, Italy.*

Objectives To define in patients affected by Familial Mediterranean Fever (FMF), whether or not interleukin (IL)-1β secretion (1) is enhanced, (2) correlates with the type of MEFV mutation and (3) is mediated by NLRP3. **Methods** Freshly isolated monocytes from 20 FMF patients (12 homozygous and 8 heterozygous), 14 MEFV healthy carriers (HC) and 30 healthy donors (HD), unstimulated or after LPS-induced activation, were analyzed for redox state (reactive oxygen species (ROS) production and antioxidant responses), and for IL-1β and IL-1Receptor antagonist (IL-1Ra) secretion. NLRP3 down-modulation was induced by NLRP3 *in vitro* silencing. **Results** LPS-stimulated monocytes from FMF patients displayed enhanced IL-1β secretion which correlated with the number and penetrance of MEFV mutations. Silencing of NLRP3 consistently inhibited IL-1β secretion. As in other autoinflammatory diseases, MEFV mutated monocytes produced more ROS than genetically negative controls. However, contrary to CAPS, they were featured by a conserved and sustained antioxidant response. Consistent with this finding, MEFV mutated monocytes did not exhibit the functional indicators of oxidative stress observed in CAPS, including accelerated IL-1β secretion and deficient IL-1Ra production. **Conclusion** MEFV mutated monocytes display enhanced IL-1β secretion which correlates with the number of high-penetrance mutations and level of endogenous ROS. Unlike NLRP3 mutated cells, monocytes carrying MEFV mutations withstand oxidative stress and preserve IL-1Ra production, thereby limiting inflammation. Finally, in contrast to what found in the animal model, the increased secretion of IL-1β by LPS-stimulated FMF monocytes is NLRP3-dependent.

W5.17.03
Defective IFN-γ-induced indoleamine 2,3-dioxygenase production in patients with macrophage activation syndrome

K. Put[1]*, F. Fallarino*[2]*, A. Avau*[1]*, S. Put*[1]*, B. Bader-Meunier*[3]*, B. Van den Eynde*[4]*, C. Orabona*[2]*, P. Quartier*[3]*, C. Wouters*[5]*, P. Matthys*[1]*;*
[1]*Laboratory of Immunobiology, Rega Institute for Medical Research, University of Leuven, Leuven, Belgium,* [2]*Department of Experimental Medicine and Biochemical Sciences, University of Perugia, Perugia, Italy,* [3]*Hôpital Necker-Enfants Malades, Université Paris-Descartes, Paris, France,* [4]*Ludwig Institute for Cancer Research and de Duve Institute, Université catholique de Louvain, Brussels, Belgium,* [5]*Pediatric Immunology, University Hospital Leuven, Leuven, Belgium.*

Macrophage activation syndrome (MAS) is a rare but severe immune-inflammatory condition seen in hemophagocytic syndromes, namely hemophagocytic lymphohistiocytosis (HLH), and as a complication of systemic juvenile idiopathic arthritis (sJIA). The syndrome is associated with increased production of inflammatory cytokines. Although increased IFN-γ serum levels have been reported in MAS and sJIA patients, gene expression studies on peripheral blood mononuclear cells (PBMCs) of these patients revealed a conspicuous absence of IFN-γ-upregulated genes, suggesting perturbed IFN-γ signaling. This study aimed to investigate IFN-γ responses and the regulatory role of IFN-γ in PBMCs of patients with MAS and sJIA. Hereto, freshly isolated PBMCs were stimulated with IFN-γ and induction of genes and proteins was measured by qPCR, ELISA, western blot, flow cytometry and HPLC. IFN-γ responses were studied in MAS (n=7), inactive and active sJIA (n=19) patients and healthy age-matched controls (n=18). In PBMCs of all patients and controls, IFN-γ equally induced IFN-γ-associated genes and proteins such as phosphorylated STAT-1 and interferon-inducible protein 10 (IP-10). In all study groups, IFN-γ also down-regulated autocrine induction of IL1β as well as IL-1β-induced IL-8. In contrast, upon analysis of IFN-γ-induced indoleamine 2,3-dioxygenase (IDO) protein, a >50% decrease in IDO production was observed in MAS patients compared to sJIA patients and healthy controls. In conclusion, MAS patients have no general defect in the IFN-γ response but display a

selective defect in IFN-γ-induced IDO production. Since IDO possesses potent immunosuppressive activity, this defect may contribute to uncontrolled immune activation and inflammation in MAS.

W5.17.04
Study MHC class II presentation of Multiple Sclerosis associated autoantigen using antibodies with T-cell receptor specificity

***E. Altman**, Y. Reiter;*
Technion - Israel Institute of Technology, Haifa, Israel.

Multiple sclerosis (MS) is an autoimmune disease characterized by demyelination, and axonal damage triggered by auto reactive T cells specific for myelin antigens, including Myelin Oligodendrocyte Glycoprotein (MOG). Antigen-presenting cells (APC) -associated MHC class-II molecules are key for activating these specific CD4+ auto-reactive T cells. Susceptibility to MS is strongly linked to the HLA-DR2 allele that confers the highest MS risk.
The main goal of this study was to generate MS-specific, recombinant antibody with MHC-restricted, peptide-specific reactivity, termed T-Cell Receptor-Like (TCRL). These antibodies will be used as antigen-specific immunotherapeutic approach. Such approaches could promote tolerance to MS antigens without generally weakening the immune system.
We have cloned and purified a soluble recombinant HLA-DR2 molecule and loaded it with the MOG35-55 peptide. Then, we isolated the desired antibodies by introducing the DR2/ MOG35-55 molecule to a large, naïve library using Phage Display approaches. The different antibody clones isolated from the library screening were characterized with some of them exhibiting TCR like specificity, thus, their binding was dependent on both DR2 and MOG peptide recognition. They were also able to bind naturally presented DR2/ MOG35-55 complexes. Most significant, the DR2/MOG-specific TCRL antibody was capable to block the recognition between MOG35-55 pulsed DR2 positive APCs and their cognate T cell hybridoma as measured by inhibition of IL-2 secretion.
In the future, the DR2/MOG-specific TCRL antibody will be used for two major research directions; to induce antigen-specific tolerance in vivo, in the EAE mouse model, and to analyze MS epitope presentation.

W5.17.05
Identification of commensal flora associated antigen,as a pathogenic factor of autoimmune pancreatitis

***Y. Abe**[1], N. Yanagisawa[1], I. Haruta[1], K. Shiratori[2], J. Yagi[1];*
[1]Department of Microbiology and Immunology,Tokyo Women's Medical University, Tokyo, Japan, [2]Department of Gastroenterology and Medicine,Tokyo Women's Medical University, Tokyo, Japan.

Background: Autoimmune pancreatitis (AIP) is a nosological entity of IgG4-related systemic sclerosing diseases. Although autoantibody and the MHC genotypes are suspected to have role in the etiology, pathogenic factors of AIP have not fully been elucidated. We previously reported a mouse model of AIP by repeatedly inoculating Escherichia coli in C57BL/6 mice. Methods: To determine pathogenic antigen of E. coli, 2D-DIGE was carried out followed by TOF/MS. Recombinant proteins of identified antigens were generated and inoculated into C57BL/6 mice as the same protocol as previously described (ref. Lab Invest 2010; 90(12):1757), to examine for the induction of AIP-like disorder in C57BL/6 mice. Results: (i) The immune-reactive spot against AIP-mice sera was determined as FliC of E. coli. (ii) Marked cellular infiltration, which was predominantly consistent with CD3-positive cell, was observed in the exocrine pancreas of rFliC-inoculated mice. (iii) Anti-lactoferrin and anti-carbonic anhydrase II titers were significantly higher in sera of rFliC-inoculated mice. Conclusions: FliC of E. coli could induce AIP-like pancreatitis in C57BL/6 mice. Bacterial protein itself would be directly pathogenic or molecularly mimic to unknown autoantigen to generate the status of AIP-like inflammation, perhaps, being influenced by additional factors such as MHC. To reconsider the importance of commensal bacteria as an environmental factor of the pathogenesis of autoimmune disease would give us many hints to overcome AIP. (Collaboration; Kyoko Shimizu[3], Toru Furukawa[4], [4]Integrated Medical Sciences, TWMU)

W5.17.06
Soluble CD91/LRP1 is elevated in the sera of a subset of children with different inflammatory diseases

***M. M. Newkirk**[1], R. Balhous[1], A. Cimino[1], Z. Li[1], S. Magalhaes[1], A. Bar-Or[1], A. Rosenberg[2];*
[1]McGill University, Montreal, QC, Canada, [2]University of Saskatchewan, Saskatoon, SK, Canada.

CD91 also known as LRP1 is a large 2-chain receptor that binds many ligands including heat shock proteins, lipoproteins, myelin basic protein, and alpha-2 macroglobulin. Proteolytic cleavage results in its shedding. Little is known about the half-life of soluble CD91 (sCD91) in circulation or other fluids or even its normal levels. Using an ELISA established in the laboratory, levels of sCD91 were measured in sera from children with juvenile idiopathic arthritis (JIA), children who had had a demyelinating event one year prior or in normal children. We also tested synovial fluid from 12 Rheumatoid Arthritis patients for sCD91. Elevated levels of sCD91 were detected in the sera of 14 and 27% of poly or oligo JIA patients respectively but were not detected in those with systemic disease. Numbers were too small to determine any correlations with disease activity. There was a trend for elevated levels of sCD91 in those diagnosed with JIA prior to 6-years of age compared to those with later onset. SCD91 was detected in 5 of 12 synovial fluid samples from RA patients. In patients who had experienced a demyelinating event, those with elevated levels of sCD91 appeared to have an increased risk of being diagnosed with multiple sclerosis. A 50 unit increase in sCD91 was associated with a 50% increased risk. These data suggest that CD91 can be shed as a component of different inflammatory responses, and that further characterization of sCD91 could reveal novel insight into disease pathogenesis.

Depletion of regulatory T cells improves anti-tumour immunity in colitis-associated colon cancer

*E. Pastille[1], K. Schumann[1], D. Fleissner[1], W. Hansen[1], T. Sparwasser[2], J. Buer[1], **A. M. Westendorf**[1];*
[1]University Hospital Essen; University Duisburg Essen, Essen, Germany, [2]Twincore, Hannover, Germany.

Chronic inflammation severely increases the risk for cancer development as seen in patients with inflammatory bowel diseases. Although the exact mechanism of inflammation-associated tumor development remains to be shown, a role for the adaptive immune system has been implicated in colitis-associated cancer (CAC). In this context, the role of regulatory T cells (Tregs) is controversial as they act as potent suppressor of inflammation and thus can have protective effects in CAC, but simultaneously can prevent antitumor immunity. Therefore, we investigated the role of $CD4^+Foxp3^+$ Tregs in a mouse model of CAC. Blood and tissue specific $CD4^+Foxp3^+$ Tregs from CAC mice were compared to Tregs from healthy mice and mice with chronic colitis. We found a strong increase of $CD4^+Foxp3^+$ Tregs in the colonic tumors and the mesenteric lymph nodes of mice suffering from CAC. Tumor-infiltrating $CD4^+Foxp3^+$ Tregs were highly activated, suggested by the increased expression of CD25, CTLA-4 and IL-10. Moreover, they exhibited an increased suppressive effect on $CD4^+CD25^-$ responder T cell proliferation and TH1-cytokine production *ex vivo*. Mice expressing a diphtheria toxin (DT) receptor-enhanced fluorescent fusion protein under the control of the foxp3 gene locus (DEREG mice) allow the depletion of $Foxp3^+$ Tregs by DT injection. *In vivo* depletion of $CD4^+Foxp3^+$ Tregs during carcinogenesis in DEREG mice suppressed the tumor progression accompanied by an increase of $CD8^+$ INF-γ producing effector cells. Our data suggest that selective, transient depletion of Tregs has the potential to evoke an efficient antitumor response and might have implications for therapeutic interventions in CAC patients.

W5.18.02
RIP3 promotes injury-induced cytokine expression and tissue repair

***K. Moriwaki**, F. K. Chan;*
University of Massachusetts Medical School, Worcester, MA, United States.

Receptor interacting protein kinase 3 (RIPK3/RIP3) is critical for programmed necrosis/necroptosis driven by tumor necrosis factor-like death cytokines, toll-like receptors, and antigen receptors. RIP3 was thought to promote inflammation through the release of danger-associated molecular patterns from necrotic cells when FADD or caspase-8 was inhibited. However, it is unclear if RIP3 can facilitate inflammation independent of necrosis when apoptosis pathway is intact. Here we present evidence that RIP3 has a unique role in promoting injury-induced inflammation and tissue repair that is independent of its pro-necrotic function. $RIP3^{-/-}$ mice were highly susceptible to colitis induced by dextran sodium sulfate (DSS). Bone marrow chimera experiments show that RIP3 expression in the hematopoietic compartment was critical for tissue repair upon DSS treatment. Induction of IL-22, a key cytokine for repair of intestinal epithelium, was significantly impaired in $RIP3^{-/-}$ mice. The blunted IL-22 expression was not due to intrinsic defects of innate lymphoid cells, the main cellular source of IL-22 in the gut. Rather, dendritic cells (DCs) expression of IL-23, a strong inducer of IL-22, was significantly suppressed in $RIP3^{-/-}$ mice. We found that LPS-induced activation of the NFκB pathway was severely dampened in $RIP3^{-/-}$ bone marrow derived DCs. These deficiencies led to sustained injury, inflammation, and higher incidence of colitis-associated colon adenomas in $RIP3^{-/-}$ mice. Our results reveal a previously unappreciated function of RIP3 in NFκB activation, innate inflammatory cytokine expression, intestinal tissue repair and inflammation-induced tumorigenesis.

W5.18.03
Induction of IL-33 is dependent on the gut microflora and is essential for EOS activation/migration and Th2 immune responses in the pathogenesis of experimental IBD

***C. De Salvo**[1], X. Wang[1], S. Chowdhry[1], D. Corridoni[1], F. Cominelli[1], J. J. Lee[2], W. Xin[1], T. T. Pizarro[1];*
[1]Case Western Reserve University, Cleveland, OH, United States, [2]Mayo Clinic, Scottsdale, AZ, United States.

IL-33 is a member of the IL-1 cytokine family known to promote Th2 immunity and has been linked to several inflammatory disorders, including inflammatory bowel disease (IBD). SAMP1/YitFc (SAMP) mice, a spontaneous model of IBD, raised under germ-free (GF) conditions develop a delayed onset of ileitis, with lower penetrance and severity, compared to age-matched specific pathogen free (SPF)-reared SAMP. Interestingly, mucosal-derived CD4+ T-cells from GF-SAMP display a vigorous Th1, but not Th2, immune response in the absence of bacterial flora that can be reversed upon fecal antigen exposure. The aim of this study was to determine the effects of the gut microflora on IL-33 expression and downstream mucosal Th2 immune responses, leading to chronic intestinal inflammation in SAMP mice. Our results showed that 20-26-wk-old GF-SAMP displayed a 5.2-fold decrease in ileal IL-33 mRNA levels compared to age-matched SPF-SAMP with comparable inflammatory scores (6.25±1.60 vs. 8.33±0.53, n.s.). In the absence of gut microflora, a dramatic decrease of infiltrating eosinophils (EOS) (44.10±7.15 vs. 22.67±4.65 EOS/HPF), and IL-4, IL-5, and IL-13 mRNA levels (12.7-, 2- and 3.5-fold, respectively) was observed in ilea of GF- vs. SPF-SAMP. Importantly, EOS depletion in SPF-SAMP did not affect IL-33 mRNA expression, suggesting that upregulation of IL-33 likely occurs before EOS activation and homing to the gut. Together, these data indicate that the gut microbiota induces IL-33 production that can promote EOS infiltration into the intestinal mucosa and confirm that the commensal flora is essential to mount potent Th2 immune responses, leading to chronic ileitis in SAMP mice.

W5.18.04
Targeting IL-23/T_H17 axis to suppress intestinal inflammation in murine spontaneous colitis induced by an epithelial defect

***R. Wang**[1], S. Hasnain[1], H. Tong[1], I. Das[1], A. Chen[1], T. Florin[1], R. Eri[2], M. McGuckin[1];*
[1]Mater Medical Research Institute, Brisbane, Australia, [2]University of Tasmania, Launceston, Australia.

Whilst the IL-23/T_H17 axis is activated in inflammatory bowel disease, its contribution to pathology and the best way to target it therapeutically remain unclear. Previously we found that genetic deficiency of IL-17A suppressed colitis in *Winnie* mice which carry a *Muc2* mutation, and develop goblet cell endoplasmic reticulum stress and progressive T_H17-dominant colitis. In an attempt to mimic biological therapy with antibodies, we assessed the efficacy of anti-IL-17A antibodies in *Winnie* with emerging and established colitis. Neutralizing IL-17A in young *Winnie* mice failed to alleviate colonic inflammation, while blocking IL-17A in older *Winnie* mice resulted in decreased histological colitis in the proximal colon, suggesting neutralizing IL-17A may have differential effects depending on the nature of colitis as it progresses. Neutralizing IL-17A together with IL-17F or blocking IL-17Ra did not further suppress intestinal inflammation suggesting that targeting T_H17 effector cytokines or IL-17 receptor signalling is not sufficient to alleviate *Winnie* colitis even in the context of strong T_H17 inflammation.
However, targeting IL-23 by monoclonal antibodies against the p19 subunit greatly reduced colon weight of *Winnie* mice with established colitis compared to a control group ($P < 0.01$). Anti-p19-treated *Winnie* mice had significantly decreased distal histological colitis scores ($P < 0.05$), with less neutrophil infiltration, limited crypt hyperplasia and reduced epithelial damage. Anti-p19 treatment was more efficacious than anti-p40, which is shared with IL-12, indicating that the IL-23/T_H17 axis, not IL-12/T_H1, is responsible for pathology in *Winnie* colitis. Clinical trials also suggest that targeting IL-23 is more efficacious than targeting IL-17.

W5.18.05
The p50 NF-κB subunit is a key orchestrator of cancer-related intestinal inflammation

***C. Porta**[1], L. Carraro[1], M. G. Totaro[2], M. Rimoldi[2], F. Pasqualini[2], M. Nebuloni[3], A. Sica[1,2];*
[1]Department of Pharmaceutical Sciences, Università del Piemonte Orientale, Novara, Italy, [2]Humanitas Clinical and Research Center, Rozzano (Milan), Italy, [3]Institute of Pathology, University of Milan, Milan, Italy.

Colorectal cancer (CRC) is one of the best example of pathological association between chronic inflammation and cancer development. Tumor Associated Macrophages (TAM) represent the major leukocyte population present in tumors. During tumor-development, TAM undergo to phenotypic switch promoting an M2 polarized phenotype with tumor promoting properties. We previously demonstrated that nuclear accumulation of p50 NF-κB promotes an M2-polarized pro-tumoral phenotype, a condition shared also by endotoxin tolerant macrophages. This may be relevant in the gut, where macrophages are central regulators of intestinal homeostasis and orchestrate the balance between immune response and tolerance to intestinal microflora. Hence, we investigated the role of p50-driven polarized inflammation in CRC development, by using two distinct models of genetic- (ApcMin mice) and colitis-associated cancer (CAC). In the CAC model, we observed that p50-/- mice exhibit a dramatic intestinal inflammation (addressed by weight loss, colon shortening and histological analysis of colon tissues), paralleled by reduced incidence of tumor development. In agreement, analysis of mice survival, tumor incidence, progression, in ApcMin versus ApcMin-p50-/- mice, demonstrated that p50 NF-κB is required to support cancer growth at different stages of the neoplastic process, including early and late stages of tumor development. Finally, biochemical studies identified the p50 NF-κB subunit as a key player tuning the balance between two differentially expressed clusters of inflammatory genes, respectively involved in tumor inhibition and development. Overall our results indicate that, irrespective of the etiological events triggering CRC development, the p50 NF-κB subunit is required to promote cancer-related inflammation supporting CRC development.

Novel HLA-DR transgenic mice that spontaneously develop colitis with serious defects in lymphoid organs

A. Irie[1], *J. Yatsuda*[1], *Y. Michibata*[1], *T. Kubo*[2], *T. Imamura*[2], *N. Takeda*[3], *I. Shibuya*[4], *S. Sogo*[4], *Y. Nishimura*[1];
[1]*Department of Immunogenetics, Graduate School of Medical Sciences, Kumamoto University, Kumamoto, Japan,* [2]*Department of Molecular Pathology, Graduate School of Medical Sciences, Kumamoto University, Kumamoto, Japan,* [3]*Center for Animal Resources and Development, Kumamoto University, Kumamoto, Japan,* [4]*Microbiological Research Institute, Otsuka Pharmaceutical Co. Ltd., Tokushima, Japan.*

HLA-DR4 (HLA-DRA*01:01/HLA-DRB1*04:05) is one of the frequent HLA-DR molecules found in 26% of the Japanese population. We have established C57BL/6-background HLA-DR4-transgenic mice (DR4-tgm) and the peptide-specific HLA-DR4-restricted Th-cell responses were successfully observed in the DR4-tgm immunized with the peptide. Unexpectedly, the mice with homozygous transgenic alleles (homo-DR4-tgm) spontaneously developed serious colitis similar to human ulcerative colitis without any further genetic modification, adoptive cell transfer, bacterial infection or chemical treatment reported in previous experimental colitis model mice. The majority of the homo-DR4-tgm showed severe wasting and rectal prolapse within 4-5 months and died within 5-6 months. The histological analyses revealed that many neutrophils infiltrated in the lamina propria of colon but not in small intestine. Interestingly, the thymus of homo-DR4-tgm shrank and morphologically collapsed up to one month of age and disappeared in adult (after 2-3 months of age). Moreover, other lymphoid organs such as white pulp in the spleen and Payer's patches in the colon were hardly observed. Flow-cytometry showed that in adult homo-DR4-tgm, lymphocytes in the peripheral blood and spleen were markedly reduced while Gr-1+CD11b+ granulocytes were accumulated. The genome-wide sequencing and FISH analyses revealed that the HLA-DR transgenes were inserted in the telomeric region of chromosome 3 with deletion of 39 kb genomic fragment, which is close to but definitely separated from the colitis-susceptible Cdcs1 region reported in PNAS, 98: 13820, 2001. Hence, this novel animal model may contribute to our understanding of the pathogenesis of the inflammatory bowel disease and the immune manipulation against autoimmunity.

Galectins in pregnancy: the bitter side of sweet

S. Blois*;*
Universitätsmedizin Berlin, Berlin, Germany.

Members of the galectin family are expressed within the female reproductive tract and have been shown to be involved in multiple biological functions that support the progression of mammalian gestation, a physiological process that sustains life in this universe. Specific expression of several galectins has been identified at the maternal and placental compartments, where in some cases dysregulated functions have been associated with adverse pregnancy outcomes. Recent studies on galectins have shown that some members of this lectin family seem to be important for pregnancy maintenance, emphasizing their role as major regulators of the maternal immune adaptation to pregnancy (e.g. induction of tolerogenic dendritic cells, IL-10 expressing regulatory T cells, IFN-γ expression by NK cells and apoptosis of maternal T cells) and placental development (such as immuno-modulatory function exhibited by trophoblast cells and regulation of trophoblast invasion and fusion properties). This lecture will summarize current knowledge on galectins as regulators of pregnancy and discuss their implication in preeclampsia, a life threatening pregnancy specific disorder.

Fetal loss induced by depletion of innate 33D1+DC subset in mice

Y. Negishi[1,2], *A. Wakabayashi*[1], *M. Shimizu*[1], *T. Matsuhashi*[1,2], *T. Ichikawa*[1,2], *T. Takeshita*[2], *H. Takahashi*[1];
[1]*Department of Microbiology and Immunology, Nippon Medical School, Tokyo, Japan,* [2]*Department of Obstetrics and Gynecology, Nippon Medical School, Tokyo, Japan.*

Dendritic cells (DCs) play a crucial role in providing an appropriate fetal/maternal balance between Th1 and Th2 during pregnancy. The Th1/Th2 balance is thought to be regulated mainly by two distinct DC subsets, DEC-205+ DCs having the capacity to establish Th1 polarization and 33D1+ DCs to induce Th2 dominance. In addition, maternal hormones, such as progesterone and estrogen, have been thought to be important for the maintenance of pregnancy. We found that the balance of DC subtypes was affected mainly by progesterone, which induced a dose-dependent reduction of the DEC-205/33D1 ratio together with/without a stable amount of estrogen (Negishi, et al., Immunobiol. 217:951, 2012). The DEC-205/33D1 ratio decreased gradually with the progress of pregnancy and rapid augmentation of this ratio was seen around delivery period in vivo. Here, we demonstrate that the fetal loss was induced by the depletion of 33D1+DCs during perinatal period mediated through Th1 up-regulation via transient IL-12 secretion, and pre-administration of progesterone could rescue this fetal loss. Similar miscarriages were also observed when pregnant mice were intraperitoneally (i.p.) injected twice with IL-12 on Gd 9.5 and 10.5. Moreover, prior inoculation of progesterone suppressed the enhanced serum IL-12 production in mice treated with 33D1 antibody, indicating that progesterone might inhibit temporal IL-12 secretion around Gd 10.5 and miscarriage was prevented. These findings suggest that the balance of DC subsets is crucial for maintaining pregnancy and we can prevent miscarriage by manipulating the activity of the DC subpopulation of pregnant individuals by progesterone administration.

During human pregnancy, HLA-G molecules specifically expressed in the trophoblast have a role in reprogramming the local maternal immune response towards tolerance. DC-10 are tolerogenic dendritic cells (DCs) that secrete high amounts of IL-10 and express membrane-bound HLA-G and the immunoglobulin like transcript (ILT)4. DC-10 are present in the peripheral blood and promote the induction of adaptive regulatory T cells (Tr1) *in vitro*.
We investigated the presence of DC-10 and of a subset of regulatory CD4$^+$ T cells constitutively expressing HLA-G in the human decidua during the first trimester of pregnancy. Results showed a significantly higher percentage of DC-10 in the decidua (dDC-10) as compared to those present in the peripheral blood. Interestingly, dDC-10 expressed similar levels of HLA-G but significantly lower levels of ILT4 compared to circulating DC-10. We also observed a significantly higher frequency of HLA-G-expressing CD4$^+$ T cells in the peripheral

blood and in the decidua of pregnant women compared to that observed in peripheral blood of healthy donors. Notably, no significant differences in the frequency of DC-10 and HLA-G-expressing $CD4^+$ T cells were observed when decidua from women with spontaneous abortions and with elective abortions were compared.
This is the first report describing the presence of DC-10 and $CD4^+HLA\text{-}G^+$ T cells in the human decidua, indicating that these regulatory cells may contribute to control tolerance at the fetal-maternal interface.

W5.19.03
Placental cells promote a tolerant fetal environment by inducing homeostatic macrophages and regulatory T cells

***J. Svensson Arvelund**, R. B. Mehta, E. Mirrasekhian, S. Freland, G. Berg, M. C. Jenmalm, J. Ernerudh;*
Department of Clinical and Experimental Medicine, Linköping, Sweden.

Proper adaptation of the maternal immune system is essential to avoid rejection of the semi-allogeneic fetus. Fetally derived trophoblast cells have immune modulatory properties and thus the placenta itself might promote a tolerant immune environment at the fetal-maternal interface. We investigated the ability of human placental tissue and trophoblast cells to induce macrophages and Th cells with regulatory properties. Peripheral blood $CD14^+$ monocytes and $CD4^+$ Th cells from non-pregnant women were obtained by MACS. Macrophages were differentiated from monocytes in the presence of M-CSF or GM-CSF. The effect of conditioned medium (CM) from first trimester placental explants or the trophoblast cell line HTR8 on macrophages and Th cells was analyzed with flow cytometry. CM induced high expression of the homeostatic scavenger receptor (CD163) and the M2 marker DC-SIGN (CD209) in macrophages, consistent with the phenotype of decidual (uterine) macrophages. M-CSF, which promotes regulatory decidual macrophages *in vitro*, was produced at high levels by both HTR8 trophoblasts and placental tissue. The expression of CD163 was reversed by anti-M-CSF blocking antibodies, confirming the involvement of trophoblast-derived M-CSF in the polarization of decidual macrophages. Placental explant CM also reduced the expression of HLA-DR on Th cells and induced $CD25^{bright}Foxp3^+$ Treg cells, while transcription factors for Th1, Th2 and Th17 cells (Tbet, GATA-3 and Rorc) were not consistently affected. Altogether, our data shows that placental cells promote the polarization of homeostatic macrophages, limit T cell activation and contribute to the induction of Treg cells, supporting the tolerant environment required for normal fetal development.

W5.19.04
Demonstration of the deleterious impact of foeto-maternal MHC identity on the success of pregnancy in a macaque model

*A. Aarnink[1], E. T. Mee[2], N. Savy[3], N. J. Rose[2], **A. Blancher**[1,4];*
[1]Faculté de Médecine Purpan, Universite Paul Sabatier, Toulouse 3, Toulouse, France, [2]National Institute for Biological Standards and Control, Division of Virology, Hertfordshire, United Kingdom, [3]Institut de Mathématiques, Université Paul Sabatier, Toulouse 3, Toulouse, France, [4]CHU de Toulouse, Toulouse, France.

The impact of foeto-maternal histocompatibility on reproduction has inspired long-lasting debates. However, after the review of numerous articles, the impact of HLA allele sharing within couples on fecundity remains questionable. We decided to explore the impact of MHC foeto-maternal compatibility on reproduction in a cynomolgus macaque breeding unit composed of animals originating from Mauritius Island. The Mauritian macaque population presents a very restricted MHC polymorphism (only seven founding haplotypes) due to a strong founding bottleneck. The MHC polymorphism was investigated in 237 trios (male, female and offspring) using 17 microsatellite markers distributed across the MHC. Haplotypes were confirmed by segregation analysis. We evaluated the relative frequencies of offspring MHC-compatible and MHC-semicompatible with the mothers. Among the 237 trios, 106 offsprings were semi-compatible and 47 offsprings were fully compatible with their mother for all MHC markers. This repartition is incompatible with a random distribution with an interval of confidence of 99,9 %. In a second step, we selected 42 trios for which the identity of the father is certain with a theoretical equal probabilities of full compatible and semi-compatible offspring. We found 11 offsprings fully compatible and 31 offsprings semi-compatible with their respective mother. Again, the observed repartition was clearly outside the interval of confidence of 99 %, and therefore most probably resulted from a selection of the semi-compatible foetuses during pregnancy. We concluded that MHC fully compatible cynomolgus macaque foetuses have a selective survival disadvantage in comparison with foetuses inheriting a paternal MHC haplotype differing from maternal haplotypes.

W5.19.05
The atypical chemokine receptor D6 is expressed by trophoblasts and plays roles in placental formation and chemokine scavenging

***F. M. Menzies**[1,2], P. J. Teoh[2], C. Waddell[2], S. M. Nelson[2], R. J. B. Nibbs[2];*
[1]University of the West of Scotland, Paisley, United Kingdom,
[2]University of Glasgow, Glasgow, United Kingdom.

Placental dysfunction contributes to many important obstetric problems, including preeclampsia and fetal growth restriction. The crosstalk between maternal and fetal cells is critically important for effective placental function. Chemokines have been implicated in both the regulation of trophoblast migration into the uterus, and the recruitment of maternal immune cells into gestational tissues. The focus of this study is the atypical chemokine receptor D6, which has been hypothesized to be involved in reducing inflammation at the fetomaternal interface. Chemokine receptor expression by primary human trophoblasts did not vary with length of time in culture, however D6 mRNA was more abundant than other receptors (CCR1, CCR2, CCR3, CCR5, CCRL1, CXCR4) examined. To confirm expression of D6 protein in these cells, Western blotting and immunofluorescent staining were performed. The ability of trophoblasts to internalise CCL2 from the culture medium was found to be D6-dependent, thus demonstrating the chemokine scavenging ability of D6. D6-deficient mice exhibit higher rates of stillbirth and neonatal death than their wild-type counterparts (stillbirth, KO 21.3%, WT 10.2%; neonatal death, KO 37.0%, WT 16.7%, both $p<0.0001$). Placental stereology revealed that at E14 of gestation, D6-deficient mice have a larger junctional zone than wild type mice, and a smaller labyrinthine zone. However, by E18 of gestation, these differences are diminished. This is the first study to examine D6 in primary human cells, demonstrating a role for this receptor in immune regulation at the fetomaternal interface. In addition, our animal studies also suggest a role for D6 in regulating placenta formation.

W5.19.06
Genital Chlamydia trachomatis Infection Induced MicroRNA Profiles May Contribute to Associated Inflammation and Reproductive Sequelae

***B. P. Arulanandam**, R. Gupta, T. Arkatkar, J. Yu, S. Wali, J. P. Chambers, M. Guentzel;*
University of Texas At San Antonio, San Antonio, TX, United States.

Chlamydia trachomatis (CT) is the leading cause of human bacterial sexually transmitted infections and reproductive pathological sequelae. Given the involvement of microRNAs (miRs) as immune regulators and that CD4+ and CD8+ T cells and cytokines IFN-γ and IL-17A are associated with anti-chlamydial immunity, we analyzed modulation of miRs in genital tracts (GT) following CT challenge of wild type (WT), CD4+ deficient (CD4-/-), CD8+ deficient (CD8-/-), IFNγR deficient (IFNγR-/-) and IL17A deficient (IL17A-/-) C57BL/6 mice. CT elementary bodies (5X104 IFU) were inoculated intravaginally for analysis of GTs at days 6 (early infection) and 12 (established infection). Within WT LGT (vagina & cervix) at day 6, miRs significantly down-regulated were miR-125b-5p (-17.34 fold change), miR-16(-8.87), miR-214(-4.30), miR-182(-19.29) and miR-30c (-19.15) while miR-135a (+13.89) was significantly upregulated, profiles not exhibited by day 12 in LGT. We found significant differences in regulation of miR-125b-5p (+4.9), miR-135a (+4.7), miR-183 (+7.8) and miR-182 (+3.23) in CD4-/- GT and miR-125-5p (+5.7), miR-183 (+5.6) and miR-214 (+3.3) in IL17A-/- GT compared to WT mice. Antigen specific CD8+ T cells or IFNγ did not contribute to changes in these miRs. Moreover, these miRs were differentially modulated upon increasing CT challenge doses and in vitro knockdown analyses with specific inhibitors of these miRs resulted in 30-45% increase in CT infectivity. Since antigen specific CD4+ T cells and IL17A have been associated with CT clearance and GT pathology, we are currently investigating the contribution of these down selected miRs in modulating immunity in cohorts of CT-infected women with inflammation and reproductive pathology.

IL-1β is a major inflammatory cytokine that mediates the angiogenic switch in tumor invasiveness

***R. N. Apte**[1], Y. Carmi[1], S, Dotan[1], I. Kaplanov[1], Z. Shavshkevitz[1], C. A. Dinarello[2], E. Voronov[1];*
[1]Ben Gurion University of the Negev, Faculty of Health Sciencies, The Shraga Segal Department of Microbiology, Immunology and Genetics, Beer Sheva, Israel, [2]Department of Medicine, University of Colorado, Aurora, CO, United States.

Previously, we have demonstrated the crucial involvement of IL-1β in tumor-mediated angiogenesis, through mechanisms not yet elucidated. Here, we have assessed the role IL-1β in the early angiogenic response of tumors using Matrigel plugs supplemented with B16 melanoma cells. We described a new cross-talk between bone marrow-derived $VEGFR1^+/IL\text{-}1R1^+$ immature myeloid cells and tissue-resident endothelial cells in the early angiogenic response of tumors. Myeloid cells produce IL-1β and other pro-inflammatory molecules, while endothelial cells, activated by myeloid cell-derived cytokines, produce in turn VEGF and other direct angiogenic factors. Thus, endothelial cells are initially activated by IL-1β and subsequently they support in an autocrine manner blood vessel formation. This mechanism was also observed in inflammation-induced angiogenesis in Matrigel plugs supplemented with recombinant IL-1β or VEGF, as well as in Matrigel plugs containing supernatants of hypoxic macrophages, representing non-tumor scenarios of inflammation-induced angiogenesis. Furthermore, IL-1β inhibition stably reduces tumor progression, through limiting the local inflammatory response, but also by induction of maturation of $VEGFR1^+/IL\text{-}1R1^+$ cells into M1 macrophages with anti-tumor features. In sharp contrast, VEGF neutralization induced only a transient reduction in progression of tumor, followed by rebound angiogenesis and recurrence. Rebound angiogenesis occurs via re-programming $VEGFR1^+/IL\text{-}1R1^+$ cells that start to express HIF-1α and subsequently secrete VEGF and other direct angiogenic factors, which support in a paracrine manner endothelial cells for blood vessel formation. We suggest IL-1β inhibition as an efficacious anti-tumor therapy and its further optimization may leads to its application in the clinic.

Notch regulates anti tumor functions of gamma delta T cells in oral cancer

***S. Chiplunkar**[1], D. Gogoi[1], D. Chaukar[2], A. D'Cruz[2];*
[1]Advanced Centre for Treatment, Research & Education in Cancer, Tata Memorial Centre, Kharghar, Navi Mumbai, India, [2]Tata Memorial Hospital, Tata Memorial Centre, Mumbai, India.

Gamma delta (γδ) T cells exhibit anti microbial and anti tumor functions and are activated by phosphoantigens produced as intermediates of the mevalonate pathway in eukaryotic cells. The aim of the present study was to investigate the role of Notch signaling in regulating anti tumor responses of γδ T cells isolated from patients with oral cancer. γδ T cells from oral cancer patients showed impaired proliferative responses and IFN-γ release in response to stimulation with phospho antigens. mRNA expression of Notch1 and Notch2 genes were predominantly observed in peripheral γδ T cells. The presence of active Notch intracellular domain in γδ T cells was confirmed by confocal microscopy and western blotting. Proliferation of γδ T cells and IFN-γ release in response to phosphoantigens was inhibited in the presence of gamma secretase inhibitor (GSI) confirming involvement of Notch signal. Delta like ligands 1 and 4 activated γδ T cells while Jagged1 inhibited the γδ T cell response. Decreased expression of CD107a, and diminished lysis of oral tumors in the presence of GSI confirmed that Notch was involved in cytotoxic effector functions of γδ T cells. mRNA and protein expression of Jagged1 was observed on oral tumors. Blocking of Jagged1 ligand on regulatory T cells rescued the Treg induced suppression of γδ T cells. Thus, our data demonstrates that Notch signal plays an indispensable role in anti tumor responses of γδ T cells. Future immunotherapeutic strategies can exploit Notch signaling in γδ T cells to achieve therapeutic benefits in oral cancer patients.

W5.20.01
CD70 reverse signaling on NK cells enhances anti-tumoral immune response

***M. Al Sayed**[1], C. Riether[1], C. Schürch[1,2], A. Ochsenbein[1,3];*
[1]Department of clinical research, University of Bern, Bern, Switzerland, [2]Institute of Pathology, University of Bern, Bern, Switzerland, [3]Department of Medical Oncology, Inselspital, Bern University Hospital and University of Bern, Bern, Switzerland.

CD70 is the unique ligand for the TNF-receptor superfamily member CD27. CD70 is not expressed in healthy individuals. Upon immune activation CD70 is transiently induced on B- and T lymphocytes, NK cells and subsets of dendritic cells. The CD27-CD70 interaction provides a positive costimulatory signal through various downstream pathways resulting in proliferation,differentiation and survival of lymphocytes. As for other TNF family members, CD70 reverse signaling has been reported on normal and malignant B cells, T cells and NK cells. However, the physiological relevance of CD70 reverse signaling in vivo is poorly understood. In the present study, we analysed the role of CD70 reverse signaling in the immunological control of solid tumors. Tumor fragments expressing a truncated CD27 receptor consisting of the extracellular domain were transplanted subcutanteously on both flanks of BL/6 mice and tumor growth was monitored. Growth of tumors expressing the truncated form of CD27 was significantly reduced when compared to growth of parental tumor cells. Furthermore, tumor growth of cells expressing truncated CD27 was restored to growth of non-transfected control cells in mice treated with a monoclonal antibody blocking the CD27-CD70 interaction. In contrast, tumor growth of cells expressing truncated CD27 was significantly slower in Rag2-/- mice, indicating that inhibition of tumor development was independent of adaptive immunity. In contrast, depletion of NK cells in Rag2-/- restored growth of tumors expressing truncated CD27 to growth kinetics of control cells. Taken together, CD70 reverse signaling on NK cells contributes to tumor growth control.

Braf inhibitor impacts on melanoma cell immunogenicity

E. Fourmentraux-Neves[1], *M. Messaoudene*[1], *C. Nicolaizeau*[1], *M. Avril*[2], *K. Belkhiria*[3], *A. Savina*[3], *A. Caignard*[1];
[1]*INSERM, Paris, France,* [2]*APHP, Paris, France,* [3]*Roche, Paris, France.*

Melanoma incidence is increasing for several decades. Malignant melanoma displays a high metastatic potential. Conventional therapies induce rare sustained clinical responses in metastatic patients. Recently, targeted therapies directed towards signaling pathways altered in melanoma are evaluated in clinical trials.
BRAF mutations (V600E/K) are present in 50% of melanoma metastases. When the tumor harbors one of these mutations, treatment with BRAF inhibitors induces clinical responses in high percentages of patients. However, patients often experience a relapse of the disease, after 6-9 months of treatment. Thereby a better understanding of the mechanisms responsible for the resistance is required to design more active molecules or combined treatments. Furthermore MAPK inhibitors can induce off-target effects and thus may affect the regulation of immune cells.
We have recently showed that melanoma cell lines express stress molecules and are efficiently lysed in vitro by Natural Killer (NK) cells. In that context, we investigate the interest of combining immunotherapy with targeted therapy.
Seven melanoma cell lines displaying different mutational status were phenotyped for the expression of NK ligands. NK mediated cytolysis of melanoma cell lines was assessed by dynamic measure of adherent target cell index (xCELLigence system). We have studied how BRAF inhibitor interferes with melanoma/NK cell interactions. We showed that treatment with BRAF inhibitor modulates the expression of NK ligands on metastatic melanoma cell lines with different BRAF mutated status. It also interferes with the lysis of target cell by NK cells. Our data support the therapeutic potential of combining BRAF inhibitors with immunotherapy.

Predictive clinical significance of tumor infiltrating neutrophils in patients with colorectal cancer

M. R. Galdiero[1], *F. Grizzi*[1], *G. Di Caro*[1], *L. Laghi*[1], *C. Garlanda*[1], *A. Mantovani*[1,2], *S. Jaillon*[1];
[1]*Humanitas Clinical and Research Center, Rozzano, Italy,*
[2]*Department of Medical Biotechnology and Translational Medicine, University of Milan, Milan, Italy.*

Background: Infiltrating myeloid cells, mainly macrophages, have been involved in tumor growth and progression. Neutrophils have emerged as candidate cells that may modulate the tumorigenic process and the antitumor immunity. Epidemiological studies and animal models suggest that tumor-infiltrating neutrophils may be associated with poor clinical outcome.
Objective: To investigate the clinical significance of tumor-infiltrating neutrophils in 128 primary Stage I-Stage IV colorectal cancer (CRC) patients.
Method: A previous comparative analysis showed that CD66b is a more specific neutrophil marker compared to myeloperoxidase (MPO), which is also expressed by monocytes/macrophages. CRC histological sections were immunohistochemically treated with monoclonal antibodies against CD66b. For each section, intratumoral and peritumoral neutrophils densities were expressed as immunoreactive area ($CD66b^+$ IRA) in three randomly selected and non-contiguous fields using a computer-aided image analysis system.
Results: None of the clinico-pathological aspects affected values of CD66b+IRA, assessed both at the invasive margin (IM) and in the intratumoral compartment. Higher percentage of $CD66b^+$ IRA (based on the median value) both at the intratumoral compartment and IM were associated with better Disease Specific Survival (DSS) (p=0.001 and p=0.01, respectively) and Disease Free Survival (DFS) (p=0.01 and p=0.03, respectively). Multivariate analysis demonstrated that high intratumoral $CD66b^+$ IRA is an independent risk factor for better patient DSS (HR 0.48; 95% CI: 0.25-0.92; p= 0.03) and DFS (HR 0.58; 95% CI: 0.33-1.02; p= 0.0579).
Conclusions: Our findings suggest that intratumoral neutrophils are associated with a positive clinical outcome and might be considered as a novel independent prognostic factor in CRC patients.

W5.20.04
MicroRNA-9 regulates maturation and function of myeloid-derived suppressor cells by modulating Runx1

J. Tian, *Y. Zhang, X. Tian, K. Rui, X. Tang, S. Wang*;*
Department of Immunology, Jiangsu University School of Medical Science and Laboratory Medicine, Zhenjiang, China.

Myeloid-derived suppressor cells (MDSCs) accumulate in tumor-bearing hosts and play a major role in tumor-induced immunosuppression, which hampers effective immunotherapeutic approaches. Our previous study showed that β-glucans could promote monocytic MDSCs (M-MDSCs) differentiate into more maturate myeloid cells and down-regulate the suppressive capacity of MDSCs. However, the molecular networks regulating maturation and function of MDSCs are largely unknown. MicroRNAs (miRNAs) are involved in the regulation of immunity, including the immune cell development and differentiation. In this study, we identified that microRNA-9 (miR-9), whose expression was dramatically reduced after β-glucan stimulation, was considered an essential player in regulating the maturation and function of MDSCs. Inhibition of miR-9 remarkably promoted the maturation of MDSCs and down-regulated the suppressive effect of the cells by targeting runt related transcription factor 1 (Runx1), whereas overexpression of miR-9 significantly enhanced the activity of MDSCs and reversed β-glucan induced maturation. In addition, down-regulation of Runx1 resulted in increased suppressive effect of MDSCs and inhibited the maturation process. Furthermore, knockdown of miR-9 significantly impaired the activity of MDSCs and inhibited the tumor growth of Lewis lung carcinoma in vivo. Collectively, our findings reveal that miR-9 expression in MDSCs plays a critical role in the molecular events governing the maturation and function of MDSCs and might be identified as a potential target in cancer therapy.

Neuropilin-1 guides regulatory T cells into tumor tissues resulting in impaired anti-tumor immunity

W. Hansen, *M. Hutzler, I. Helfrich, J. Buer;*
University Hospital Essen, Essen, Germany.

Based on their immunosuppressive activity CD4+CD25+Foxp3+ regulatory T cells (Tregs) interfere with different immune responses including anti-tumor immunity. Elevated numbers of Tregs are found in the peripheral blood and tumor mass of cancer patients and are proposed to correlate with a poor prognosis. However, by which mechanism Tregs infiltrate the tumor tissue to locally suppress an effective anti-tumor immune response remains elusive. Here, we demonstrate that Neuropilin-1 (Nrp-1) highly expressed by Foxp3+ Tregs, mediates Treg infiltration into melanoma in dependency on tumor-derived Vascular Endothelial Growth Factor (VEGF). Mice deficient for T cell-expressed Nrp-1 exhibited a tremendously reduced tumor growth in a tumor transplantation model as well as in a spontaneously-driven melanoma model accompanied by a more pronounced CD8+ T cell response and significantly decreased numbers of Foxp3+ Tregs within the tumor section. Importantly, this phenotype was reversed by application of Nrp-1+ Tregs from wildtype mice. Due to the known function of Nrp-1 as a co-receptor for VEGF, we propose that Nrp-1 driven Treg tumor infiltration is dependent on tumor-produced VEGF. Indeed, we detected less Treg numbers in VEGF deficient tumors associated with a more effective CD8+ T cell response and clearly reduced tumor growth. From this we conclude that Nrp-1 guides Tregs into VEGF-producing tumor sections to locally suppress anti-tumor immunity.

A novel self-lipid antigen targets human T cells against CD1c+ leukemias

C. de Lalla[1], *M. Lepore*[2,1], *G. Ramanjaneyulu*[2], *D. Montagna*[3], *F. Locatelli*[4], *F. Ciceri*[5], *L. Mori*[2,6], *P. Dellabona*[1], *G. De Libero*[2,6], *G. Casorati*[1];
[1]*Experimental Immunology Unit, Division of Immunology, Transplantation and Infectious Diseases, San Raffaele Scientific Institute, Milano, Italy,* [2]*Experimental Immunology, Department of Biomedicine, University Hospital of Basel, Basel, Switzerland,* [3]*Laboratory of Immunology, Department of Pediatrics, University of Pavia and Fondazione IRCCS Policlinico San Matteo, Pavia, Italy,* [4]*Department of Pediatric Hematology–Oncology, IRCCS Bambino Gesù Hospital, Roma, Italy,* [5]*Bone Marrow Transplantation Unit, San Raffaele Scientific Institute, Milano, Italy,* [6]*Singapore Immunology Network (SIgN), Agency for Science, Technology and Research, Biopolis, Singapore, Singapore.*

T cells that recognize self-lipid antigens presented by CD1c molecules are frequent in the peripheral blood of healthy individuals and are capable of killing transformed hematopoietic cells, but little is known about the antigen specificity and the potential anti-leukemia effects of this intriguing T cell population. We find that CD1 molecules are frequently present on primary acute myeloid leukemia and B-cell acute lymphoblastic leukemia cells and exhibit disease-specific patterns of expression, with CD1c being the most prevalent isoform. CD1c self-reactive T-cells recognize the novel class of self-lipid antigen methyl-lysophosphatidic acids (mLPAs), which are expressed in primary leukemia cell lines and blasts. CD1c self-reactive T-cells efficiently recognized CD1c+ leukemia cells and were poorly responsive to non-transformed CD1c-expressing cells. Methyl-lysophosphatidic acid-specific T-cells protected NOD/scid mice against grafted CD1c+ human leukemia cells in vivo. The identification of a novel self-lipid antigen expressed in leukemia cells and the observed control of malignant cell growth by lipid-specific T-cells in vivo provide a new conceptual framework for leukemia immune surveillance and immunotherapy.

W5.20.07
Complement dependent immunosurveillance in Her-2/neu autochtonous carcinomas arising in BALB-neuT transgenic mice

S. Bandini[1], *C. Curcio*[2], *M. Macagno*[1], *M. Iezzi*[2], *F. Cavallo*[1];
[1]*MBC, Torino, Italy,* [2]*CE.SI., Chieti, Italy.*

Complement is a plethora of plasma and membrane-bound proteins acting at the interface of innate and adaptive immunity. Beside its role against infections, complement is an important component of tumor microenvironment. To evade complement-mediated inhibition cancer cells express membrane-bound and fluid-phase complement regulators. However, the importance of complement as microenvironmental regulator of tumor growth is not yet elucidated.
With a 100% penetrance all inbred BALB/c female mice transgenic for the rat ErbB-2 (Her-2/neu) oncogene (BALB-neuT mice) develop a carcinoma in all their mammary glands. The step-wise progression of these autochthonous tumors recapitulates several molecular and genetic features of human cancer, among which a slow progression, the natural occurrence of invasion and metastasis, and the presence of a long-lasting interaction between the evolving lesion and its microenvironment. By crossing BALB-neuT with BALB/c mice deficient for C3, we observed that the onset of the first palpable tumor is accelerated with a dramatic increase both in the number of mammary glands with tumor and in the tumor growth rate. Whole mounts of the mammary gland show that at the same week of age a higher number of focal lesions is spread all over mammary glands in BALB-neuT/C3KO compared to BALB-neuT mice. These data show, probably for the first time, that complement proteins can hamper even the onset of a mammary cancer aggressively driven by the overexpression of the ErbB2 oncogene that results markedly accelerated by the absence C3 in the tumor microenvironment.

Active STAT5 imprints a T-Bet-dependent Tc-1 program in CD8 T cells inducing efficient regression of autochthonous melanoma

M. Grange, G. Verdeil, A. Schmitt-Verhulst, ***N. Auphan-Anezin****;
Centre d'Immunologie Marseille-Luminy, Marseille, France.*

We have developed a genetically engineered TiRP mouse model which recapitulates key aspects of human melanoma,through the association of a melanocyte-specific deletion of both p16 and p19/Arf with a gain-of-function mutation of Ras. Development of melanoma in the inducible TiRP mouse strain is associated with systemic chronic inflammation and non functional endogenous CD8 T cells (TCs). A main limitation of TCs-based immunotherapy is the poor ability of transferred TCs to infiltrate the tumor mass and to resist the suppressive microenvironment. This includes abrogation by TGFβ1 of effectors molecules in CD8 TCs and promotion of aberrant Tc-17 polarization in conjunction with IL-6.
We engineered expression of activated STAT5 transcription factors (STAT5CA) in CD8 effector TCs (eTCs). When adoptively transferred in melanoma bearing TiRP mice, STAT5CA-transduced eTCs produced superior anti-tumor effects compared to non-transduced eTCs (Grange, Cancer Research 2012-72:p76). STAT5CA expression highly increased Granzyme B expression in intra-tumor CD8 eTCs implying that it can render eTCs resistant to the immunosuppressive environment.
At the molecular level, STAT5CA induced sustained expression of genes controlling tissue homing, cytolytic granule composition, Tc-1-associated cytokines and the potential for secondary responses. ChIP-Seq analyses showed that genes encoding T-Bet and Eomes transcription factors are
direct STAT5 target genes. Additionally, STAT5CA-expressing CD8 eTCs demonstrated reduced IL-6R/TGFbRII expression and dampened IL-6 and TGFβ1 signaling. The absence of T-Bet restored IL-2 secretion and IL-6R/TGFbRII expression and signaling, as illustrated by IL-17 induction. Therefore concerted STAT5/T-Bet/Eomes regulation controls homing, recall responses and resistance to Tc-17 polarization in CD8 eTCs.

W5.20.09
T cells from DNAM-1 deficient mice display polarity defects that impair anti-tumour immunity

J. Oliaro[1], *K. Ramsbottom*[1], *S. Russell*[1,2], *M. Smyth*[3];
[1]*Peter MacCallum Cancer Centre, East Melbourne, Australia,* [2]*Swinburne University, Melbourne, Australia,* [3]*Queensland Institute of Medical Research, Brisbane, Australia.*

DNAX accessory molecule 1 (DNAM-1/CD226) is an adhesion molecule expressed on all CD8+ cytotoxic T cells (CTLs) that acts as an accessory molecule to promote CTL functions such as activation, differentiation, migration and effector function. DNAM-1 interacts with LFA-1, a critical molecule for immunological synapse formation between T cells and antigen presenting cells (APC), and for cytotoxic killing of target/tumour cells. Indeed, mice lacking DNAM-1 display abnormal T cell responses and anti-tumour activity; however, the mechanism involved is not well understood. Here, we investigate the immunological synapse between DNAM-1 deficient T cells and APC, and show that DNAM-1 deficiency results in reduced proliferation and expansion of T cells in response to antigen presentation, which correlates with a decrease in cytokine production. Furthermore, we demonstrate that activated DNAM-1 deficient T cells show reduced stable conjugations with tumour cells and decreased recruitment of LFA-1 and lipid rafts to the immunological synapse, which correlates with reduced killing in vitro. This polarity defect may explain why DNAM-1 deficient mice cannot clear tumours in vivo and highlights the importance of the immunological synapse in T cell mediated anti-tumour immunity.

Density of Tertiary lymphoid structures predicts T cell infiltration with coordinated Th1 polarization and cytotoxic effectors functions in human lung cancer

J. Goc[1,2,3], *L. de Chaisemartin*[1,4], *A. Lupo*[1,3,5], *D. Damotte*[1,3,5], *P. Validire*[1,6], *D. Vo-Bourgais*[1,2,3], *P. Devi*[1,2,3], *W. Fridman*[1,3,7], *C. Sautès-Fridman*[1,3,2], *M. Dieu-Nosjean*[1,2,3];
[1]UMRS872 INSERM, Cordeliers Research Center, Paris, France, [2]Université Pierre et Marie Curie, Paris, France, [3]Université Paris Descartes, Paris, France, [4]UF Immunologie Autoimmunité et Hypersensibilités, APHP Hopital Bichat-Claude Bernard, Paris, France, [5]Department of Pathology, Hotel Dieu Hospital, AP-HP, Paris, France, [6]Department of Pathology, Institut Mutualiste Montsouris, Paris, France, [7]Department of Immunology, European Georges Pompidou Hospital, AP-HP, Paris, France.

Purpose/Objective: Numerous studies have demonstrated a strong correlation between the density of tumor-infiltrating T cells (TIL) and clinical outcome in human solid cancers. Nevertheless, the mechanisms governing T cells recruitment and activation into tumors remain poorly characterized. In lung cancer patients, we demonstrated that density of tertiary lymphoid structures (TLS) is associated with a favorable clinical outcome. We hypothesized that TLS are implicated in the shaping of a protective anti-tumor immune response and investigated their impact on the infiltration, differentiation and functionality of TIL in lung tumors.
Materials and Methods: The expression of relevant molecules was assessed by multicolor flow cytometry on fresh tumor samples, by immunohistochemistry on tissue sections and by low density array analysis on frozen tumors.
Results: A specific chemoattractants gene expression signature associated with high endothelial venules and T cells presence was identified in TLS. Most TLS T cells had a naive and early-memory T cells phenotype, as observed in canonical secondary lymphoid organs, whereas T cells located outside TLS were mainly composed of experienced T cells. We demonstrated that TLS density predicts a strong infiltration of activated effector-memory T cells. Finally, T-helper 1, activation and cytotoxic-related genes were overexpressed and coordinated with TLS density in human lung tumors.
Conclusions: Altogether, these data suggest that TLS represent a privileged area for T cell recruitment and activation in the primary site of the tumor. These results provide strong evidence supporting a major role of these structures in the shaping of a local anti-tumor immune response.

W5.20.11
Galectin-3 is involved in the immunosuppressive activity of prostate cancer stem cells

C. Brambillasca*, E. Jachetti, M. Grioni, S. Mazzoleni, M. Freschi, R. Galli, M. Bellone;*
San Raffaele Scientific Institute, Milan, Italy.

As cancer stem/initiating cells (CSC) are the major culprits of tumor development, it's reasonable to believe that they can adopt mechanisms of immune evasion to maintain their niche. Here we provide evidence that prostate CSC (PCSC) obtained from autochthonous tumors developed in transgenic adenocarcinoma of the mouse prostate (TRAMP) mice exert immunosuppressive activities on T lymphocytes, by inhibiting their proliferation and activation in vitro. PCSC-conditioned T cells showed reduced activation of TCR and IL-2 pathways, characteristics of anergic T cells. Immune suppression is mediated by several molecules, including Galectin-3. Indeed, Galectin-3 was found overexpressed on PCSC and in TRAMP and human prostate cancer tissues. Furthermore, silencing of Galectin-3 in PCSC reduced their immunosuppressive activity on T cells. While an immunosuppressive role of PCSC in vivo still needs to be demonstrated, our data suggest that targeting Galectin-3 in vivo might render the PCSC more susceptible to the attack by T cells.

W5.20.12
The BCR regulates Burkitt lymphoma survival and proliferation through the modulation of GSK3β activity

G. Varano[1], *S. Raffel*[2], *F. Zanardi*[1], *K. Rajewsky*[3], *S. Casola*[1];
[1]IFOM Foundation, The FIRC Institute of Molecular Oncology Foundation, Milano, Italy, [2]Deutsches Krebsforschungszentrum (DKFZ), Heidelberg, Germany, [3]Program of Cellular and Molecular Medicine, Children's Hospital, and Immune Disease Institute, Harvard Medical School, Boston, MA, United States.

Mature B-lymphocytes rely on expression of a functional B-cell-antigen-receptor (BCR) for their survival(1,2,3). Non-Hodgkin B-cell lymphomas (NHL) originate from mature B cells recruited into the germinal center reaction during a T-cell-dependent immune response. Most NHL retains expression of a functional BCR, suggesting a role for the BCR in the proliferation and/or survival of lymphoma cells. Using a Burkitt's lymphoma (BL) mouse model, in which conditional ablation of the BCR can be induced in tumor B cells through the Cre/loxP recombination system, we provide genetic proof that the BCR plays an essential role in BL maintenance. In response to BCR loss, tumor cells succumbed to their BCR+ counterparts both in vitro and in vivo. In BL cells, the BCR regulated survival and cell-cycle progression. Pharmacological inhibition of GSK3β prevented the competitive loss of BCR- tumors, whereas interference with the mTOR pathway accelerated their disappearance. The BCR controlled over 400 genes in BL cells most of which through modulation of GSK3β activity. Experiments are underway to determine which gene(s) critically contributes to the competitive advantage provided by the BCR to BL cells. Taken together, our study shows that the BCR supports the growth and survival of c-Myc-transformed B cells through the modulation of the PI3K/GSK3β pathway. Importantly, our data provide the rationale for the combination of small molecule inhibitors targeting BCR signaling (through PI3K/GSK3β) and the mTOR pathway for the treatment of BL and possibly other NHL.

Inhibiting the development of immunosuppressive Gr-1+ Dendritic Cells in Tumors by blocking TLR2 enhances immunotherapy

M. Tang*;*
University of Toronto, Toronto, ON, Canada.

Cancer cells secrete tumor-derived factors that activate immune cells to modulate the tumor inflammatory microenvironment. Recently, we found that tumor-derived TLR2 ligands promote differentiation of DC precursors (pre-cDC) towards an immunosuppressive Gr-1+ subpopulation (Gr-1+ cDC). Here, we attempt to enhance adoptive transfer immunotherapy in B16 melanoma models by inhibiting Gr-1+ cDC development. Compared to wildtype mice, we found that tumors from TLR2-/- mice contained much lower frequency of Gr-1+cDC. In addition, wildtype mice treated with monoclonal TLR2 antibody also contained a lower frequency of Gr-1+ DC in tumors compared to mice treated with isotype control antibody. To assess the effects of blocking TLR2 in adoptive transfer immunotherapy, wildtype and TLR2-/- mice bearing B16 or B16-OVA tumors were treated with CTL derived from OT-I mice. OT-I CTL treatment of TLR2-/- mice bearing B16-OVA tumors showed delayed tumor growth and improved survival compared to their wildtype counterparts. Furthermore, adoptively transferred OT-I CTLs produced more IFNγ after OVA peptide stimulation in vitro. Using the same immunotherapy model, we showed that inhibition of Gr-1+cDC in TLR2-/- mice enhanced proliferation and expansion of cytotoxic CD8+ cells. Compared to wildtype mice bearing B16-OVA, adoptively transferred CD8+ T cells in TLR2-/- tumor bearing mice showed higher expression of T cell activation markers, CD25 and CD69. Together, these results demonstrate that inhibiting the development of intratumor Gr-1+cDC by blocking TLR2 improves antitumor CTL responses and suggest a possible target for tumor immunotherapy.

Evaluating parameters that influence T cell responses to tumor antigens: A role for B7-H4

R. Rahbar[1,2]*, A. Lin*[1,2]*, M. Ghazarian*[1,2]*, T. Mak*[1,2,3]*, P. Ohashi*[1,2,3]*;*
[1]Campbell Family Institute for Breast Cancer Research, Ontario Cancer Institute, University Health Network, Toronto, ON, Canada,
[2]Department of Immunology, University of Toronto, ON, Canada,
[3]Department of Medical Biophysics, University of Toronto, ON, Canada.

The B7 family plays a critical role in regulating immune responses by engaging a variety of receptors on lymphocytes. Importantly, monoclonal antibodies against co-inhibitory molecules CTLA-4 and PD-1 have been shown to have an impact on promoting tumor immunity in patients. It is critical to understand the role of different family members as potential therapeutic targets. B7-H4 is another member with inhibitory function that is expressed on antigen presenting cells and also up-regulated on a variety of tumors. Here we show that B7-H4 expression by the tumor inhibits tumor growth in mouse models as well as in breast cancer patients. Furthermore, using a mouse model of breast cancer, we show that B7-H4 is critical for anti-tumor immunity. Importantly, in both mice and human samples, B7-H4 has an impact on class I expression via the polycomb repressor complex 2, which dampens IFN-γ signals. Consequently, the reduced class I expression impairs vaccine induced CD8+ immunity to tumors. Significance: The data presented are novel and timely appropriate for a broad range of audience. Notably, innovative monoclonal antibody treatments (i.e. ipilumumab) have been proposed to block negative signals, which improve antitumor immunity. Our data suggests that targeting B7-H4 in a similar fashion may not be beneficial for immune therapy. These findings are significant in that they present a slight paradigm shift, alternative to previous results. Additionally, our data provide insight into understanding factors critical for the induction of anti-tumor immunity, which can potentially predict patient populations that may respond best to immune therapy.

Cytokines and B cell lymphoproliferative disorders

V. Pistoia*, I. Airoldi;*
Istituto G. Gaslini, Via Gaslini, 5, Italy.

We have studied for a long time the relationships between cytokines and malignant B cells. These cells produce cytokines which may act as autocrine/paracrine growth factors or modulate cells in the tumor microenvironment towards a cancer-promoting phenotype. Conversely, cytokines produced by the latter cells can bind receptors expressed by neoplastic B cells and interfere with their functions. IL-12 is a heterodimeric cytokine binding a heterodimeric receptor (R) composed of the beta 1 and beta 2 chains and belonging to a superfamily that includes IL-23, IL-27 and IL-35. In the last decade, we have investigated the expression and function of the IL-12R in human malignant B cells spanning all stages of B cell differentiation, i.e. from acute lymphoblastic leukaemia (B-ALL) to multiple myeloma (MM) and identified three different paradigms. In paradigm 1, referred to B-ALL, the IL-12R beta 2 chain is not expressed as happens also in progenitor/precursor B cells; in paradigm 2, referred to chronic B cell malignancies, the beta 2 chain is not expressed due to methylation of a CpG island in exon 1 of the gene; in paradigm 3, referred to MM, the beta 2 chain is expressed at lower levels than in normal plasma cells. In paradigm 2, the IL-12R beta 2 chain gene has been formally identified as tumor suppressor. Additional studies carried out by the Airoldi's group with IL-23 and IL-27 will be discussed. Taken together, these results have translational relevance and may lead to the development of novel therapeutic strategies.

The existence of stereotyped B cell receptors (BCR) in different CLL patients is interpreted as an indication for specific antigenic stimulation driving CLL pathogenesis. These stereotypic BCRs can be found in 30% of CLL patients, while the other 70% express a heterogeneous receptor. So far, it has not been fully clarified which antigens are recognized by the CLL BCRs. In a recent paper by Dühren-von Minden (Nature 2012), CLL was shown to be driven by (higher basal) autonomous signaling based on Ca^{2+} influx assays rather than antigen-dependent signals. This autonomous signal is induced by the heavy chain complementarity determining region (HCDR3) of the CLL BCRs, which recognize an internal epitope within framework 2 of the BCR. However, the observed autonomous signaling does not explain the selection for stereotypic BCRs. Therefore, we aimed to see if there is variation in autonomous BCR signaling between stereotypic versus heterogeneous BCRs in CLL. From our cohort of well-defined CLL samples consisting of cases belonging to specific stereotypic CLL subsets and heterogeneous CLL, we selected representative samples for all major stereotypic subsets. In these samples, we investigated BCR signaling by use of Ca^{2+} influx assays.
Our results show variation in BCR signaling between stereotypic and heterogeneous CLL cells, with frequently a higher basal Ca^{2+} influx in heterogeneous CLL cells compared with CLL cells belonging to stereotypic subsets. These results would imply that heterogeneous CLL cells generally show autonomous BCR signaling, while stereotypic CLL cells might need their specific antigen to effectively induce BCR signaling.

W5.21.02
The bone-targeting of IL-27 is mediated by the poly-glutamic acid motif of its p28 subunit

A. Tormo[1]*, L. Beaupré*[1]*, G. Elson*[2]*, S. Crabé*[1]*, J. Gauchat*[1]*;*
[1]Université de Montréal, Montreal, QC, Canada, [2]NovImmune, Genova, Switzerland.

Interleukin 27 (IL-27) is a cytokine known to play an important role in the regulation of T, B or NK cells functions. Its potent antitumoral properties have made it attractive for the treatment of certain types of cancer.
The heterodimeric cytokine IL-27 is composed of the p28 subunit associated to the soluble receptor EBI3 (EBV-induced gene 3). Like the other members of the IL-6/IL-12 family, the p28 subunit is composed of four α helixes (A, B, C, D). Unlike other cytokines, p28 comprises a unique, negatively charged motif, in the loop connecting helixes C and D. The high conservation of this poly glutamic acids (polyE) motif, suggests a physiological role. A homologous polyE motif in the bone sialoprotein mediate binding to hydroxyapatite, the main bone mineral component.
We analyzed whether the p28 polyE motif allows : 1) IL-27 binding to hydroxyapatite and bone matrix ; 2) can be used as a tag for protein targeting to bone. Using a mutated form of IL-27, we demonstrated that IL-27 binds to hydroxyapatite and bone matrix through the polyE domain *in vitro*. Furthermore, our results demonstrate that IL-27 immobilized on bone remains active. Finally, we observed that *in vivo*, the p28 polyE motif targets IL-27 to the bone and is important for the activation of bone marrow cells.
In conclusion, the acidic motif specific to p28 might confer to IL-27 benefical pharmacological properties for therapy targeting immune cells located in endosteal niches.

MIP-1α/CCL3-mediated maintenance of leukemia initiating cells in the initiation process of chronic myeloid leukemia

***N. Mukaida**, T. Baba;*
Kanazawa University, Cancer Research Institute, Kanazawa, Japan.

In the initiation process of chronic myeloid leukemia (CML), a small number of transformed leukemia initiating cells (LICs) co-exist with a large number of normal hematopoietic cells, gradually increasing thereafter and eventually predominate in the hematopoietic space. However, the interaction between LICs and normal hematopoietic cells at the early phase has not been clearly delineated due to the lack of a suitable experimental model. In this study, we succeeded in causing a marked leukocytosis resembling CML from restricted foci of LICs in the normal hematopoietic system by direct transplantation of *BCR-ABL* gene-transduced LICs into the BM cavity of non-irradiated mice. Herein, we observed that BCR-ABL^{+}lineage^{-}ckit^{-} immature leukemia cells produced high levels of an inflammatory chemokine, MIP-1α/CCL3, which promoted the development of CML. Conversely, the ablation of *CCL3* gene in LICs dramatically inhibited the development of CML. Furthermore, normal hematopoietic stem/progenitor cells (HSPCs) can directly impede the maintenance of LICs in BM in the absence of CCL3 signal.

Early growth response gene 2 and 3 are essential for the regulation of tumour suppressor genes, Ikaros, Aiolos and FOXO3

***P. K. Bhullar**[1], T. Miao[2], A. L. J. Symonds[2], E. Ghaffari[1], S. Li[1], P. Wang[2];*
[1]Brunel University, Uxbridge, United Kingdom, [2]Barts and London School of Medicine and Dentistry, London, United Kingdom.

Non-Hodgkin lymphoma is the fifth most common cancer in the UK, accounting for 4% of all new cases and is associated with inflammatory autoimmunity. The understanding of lymphomagenesis still remains a challenge. We have discovered that early growth response gene (Egr) -2 and -3 are essential for the control of inflammatory responses of lymphocytes and also involve in the regulation of antigen-mediated proliferation. In addition to the control of inflammatory responses, here we report a novel role of Egr- 2 and/or -3, in controlling the development of lymphoma. The deletion of Egr-2 and Egr-3 in lymphocytes results in spontaneous B or T lymphoma. Despite poor responses to antigen stimulation, Egr-2 and -3 deficient B and T cells are resistant to apoptosis and survival longer in vitro in the absence of overt stimulation. We have discovered that Egr-2 and/or -3 directly bind to the promoter regions on Ikaros, Aiolos and FOXO3. The deletion of Egr-2 and -3 down regulates Ikaros, Aiolos and FOXO3 in T and B cells. The impaired expression associates with proliferative disorder and the development of T and B cell lymphoma. Thus, Egr-2 and -3 are suppressors for lymphomagenesis through the regulation of tumour suppressor genes Ikaros, Aiolos and FOXO3.

Detection of *de novo IGHV* mutations by ultra-deep sequencing from *in vitro* activated B-cell chronic lymphocytic leukemia cells: Evidence for activation-induced deaminase function

***C. C. Chu**[1,2], P. E. M. Patten[3,1], T. MacCarthy[4], X. J. Yan[1], J. E. Kolitz[1,2], S. L. Allen[1,2], J. C. Barrientos[1,2], K. R. Rai[1,2], N. Chiorazzi[1,2];*
[1]The Feinstein Institute for Medical Research, Manhasset, NY, United States, [2]Hofstra North Shore-LIJ School of Medicine, Hempstead, NY, United States, [3]King's College London, London, United Kingdom, [4]State University of New York, Stony Brook, NY, United States.

Human B-cell chronic lymphocytic leukemia (CLL) is a clonal CD5^{+}CD19^{+} B-lymphocyte whose B-cell receptor may be classified as unmutated (U-CLL) or mutated (M-CLL) depending on the level of *IGHV* mutation. Aggressive CLL associates with acquisition of new gene mutations and cytogenetic aberrations, perhaps caused by activation-induced deaminase (AID). To test if CLL cells can produce functional AID, CLL cells were activated by *in vitro* culture with CD32-transfected murine L cells, anti-CD40 and interleukin-4 (7 and 14 days, U-CLL1278 0.0% mutated *IGHV3-30*)(14 days M-CLL1299, 4.9% mutated *IGHV3-23*), plus irradiated T lymphocytes (10 or 14 days M-CLL1299). CLL cells in these cultures produced detetable AID protein. To evaluate mutational activity, CLL *IGHV* cDNA was ultra-deep sequenced using the 454 FLX system (Roche) prior to (day 0) or after activation. The resulting 458,124 sequence reads were processed to generate fixed sequence length datasets. Individual subclone sequences occuring at least twice were extracted and unique *de novo* subclones not shared between day 0 and activation were analyzed for new mutations. All culture conditions showed increases in *IGHV* mutation frequency relative to the *IGHM* constant region. U-CLL1278 showed increased mutation at AID hotspots, but an overall increase in transversion frequency. M-CLL1299 showed an overall high frequency of transitions, but an increase in mutation at AID hotspots only in the 10 day culture. Thus, *de novo* mutations consistent with AID activity were found, with some differences between U-CLL and M-CLL. Mutational active AID in CLL could lead to adverse consequences.

CD27 signaling promotes the proliferation of human acute myeloid leukemia cells

***C. Riether**[1], C. Schürch[1,2], A. F. Ochsenbein[1,3];*
[1]Tumor Immunology, Department of Clinical Research, University of Bern, Switzerland, [2]Institute of Pathology, University of Bern, Switzerland, [3]Department of Medical Oncology, Inselspital, Bern University Hospital and University of Bern, Switzerland.

The TNF receptor superfamily member CD27 is a costimulatory molecule mainly expressed on lymphocytes. Interaction of CD27 with CD70, the unique CD27-ligand which is only expressed on activated immune cells, leads to lymphocyte expansion and differentiation towards effector cells. Recently, it was shown that CD27 is also expressed on hematopoietic stem cells. We now demonstrate that CD27 and CD70 are both expressed on cell lines of acute myeloid leukemia (AML). The CD70-CD27-interaction promoted proliferation of AML cells by enhancing the Wnt signaling pathway through nuclear translocation of β-catenin. Similarly, CD27 was expressed on immature myeloid blasts in the blood and bone marrow (BM) of AML patients. Blocking CD27 on primary AML blasts reduced myeloid colony formation in vitro. In addition, serum soluble CD27, a marker for the CD70-CD27-interaction in vivo, was increased in AML patients and correlated with BM infiltration by immature blasts. Our results show for the first time that CD27 signaling plays a role in the pathogenesis of AML, revealing CD27 as a potential new therapeutic target in leukemia.

Mucosal immune dysregulation in Omenn Syndrome

***B. Cassani**[1,2], V. Maina[2], V. Marrella[1,2], F. Grassi[3,4], J. R. Mora[5], A. Villa[1,2];*
[1]CNR-IRGB, MIlan, Italy, [2]Humanitas Clinical and Research Center, Rozzano (MI), Italy, [3]Dipartimento di Biologia e Genetica per le Scienze Mediche, Universitá degli Studi, MIlan, Italy, [4]Institute for Research in Biomedicine (IRB), Bellinzona, Switzerland, [5]Gastrointestinal Unit, Massachusetts General Hospital, Harvard Medical School,, Boston, MA, United States.

Omenn syndrome (OS) is a rare monogenic disorder associating immunodeficiency and autoimmune-like manifestations that can present in the form of inflammatory bowel disease (IBD)-illness. We studied the intestinal homeostasis of the Rag2R229Q/R229Q murine model, closely recapitulating the human disease. Constant signs of inflammation, in both small and large intestines of mutant mice, were associated to different degree of spontaneous colitis, wasting diarrhea, and rectal prolapse, leading sometimes to early death. Increased cellularity of CD4+T cells and, intriguingly, of Foxp3+ Treg cells in the Rag2R229Q/R229Q mice was a unique feature of the lamina propria compartment, sharply contrasting with the overall

lymphoid depletion observed in the other peripheral lymphoid organs. Abnormal leukocyte trafficking to the intestinal mucosa was confirmed by the significantly higher percentages of CCR9 and a4b7-expressing splenic memory T cells in the mutants compared to WT mice. Interestingly, intestinal inflammation was associated to a Th1/Th17 cytokine predominance, strongly associated to the development of IBD in humans. In contrast to T cells, B cells are poorly present in the gut of Rag2R229Q/R229Q mice, as shown by the lack of Peyer's Patches and markedly reduced mucosal IgA levels. Studies are underway to investigate whether gut-blood barrier defects and break of tolerance to commensal microbiota play a pathogenic role in the immune dysregulation associated with hypomorphic RAG defects.

A new form of global leucopenia associated with mutation in the moesin gene

C. Lagresle-Peyrou[1], *F. Ouchani*[2], *S. Luce*[2], *J. Stephan*[3], *C. Hivroz*[4], *G. De Saint Basile*[2], *A. Fischer*[2], *N. Jabado*[5], *M. Cavazzana-Calvo*[2], *I. André-Schmutz*[2];
[1]*INSERM-CIC BT. Hôpital Necker enfants malades, Paris, France,* [2]*INSERM-U768. Hôpital Necker enfants malades, Paris, France,* [3]*Centre Hospitalier-Universitaire, Saint-Etienne, France,* [4]*INSERM-U520.Institut Curie, Paris, France,* [5]*McGill University, Montreal, QC, Canada.*

In 5 young patients (1.3- 15 years) from 4 differents families, we observed a profound lymphopenia (181-660 CD3+/ul;7-14 CD19+/ul) and low neutrophils count (0.2-1.4. 10-3/ul). Among the T lymphocytes, the naive compartment was particularly low and T cell proliferation in vitro is decreased as compared to the controls. All patients have a hypogammglobulinemia and a poor response to vaccinal Ag. During childhood, most of them developed severe varicella, pneumopathies and recurrent pulmonary infections.
Using exome sequencing analysis, we have identified in all patients a unique missense mutation in the moesin gene (Xq11.1), introducing an amino acid change into the highly conserved FERM domain of the protein (p.R171W). Moesin is a member of the ERM protein family which link plasma membrane proteins with actin-based cytoskeletons and are implicated in various cellular functions such as survival, adhesion, migration and activation. This mutation is associated with a low protein expression especially in T cells. Upon in vitro activation, proliferation (as measured by CFSE analysis and cell cycle checkpoints analysis) and survival capacity of patient's T cells were impaired despite expression of activation markers like CD25 and CD69. In addition, we observed enlarged synapses in patient's blasts. We reported here, for the first time, the association of a defect in an ERM protein and a primary immune deficiency.

Critical role of DOCK8 in dendritic cell trafficking during T cell immune responses

A. Shiraishi[1], *Y. Tanaka*[1,2,3], *Y. Fukui*[1,2,3];
[1]*Medical Institute of Bioregulation, Kyushu University, Fukuoka, Japan,* [2]*Japan Science and Technology agency, CREST, Tokyo, Japan,* [3]*Research Center for Advanced Immunology, Kyushu University, Fukuoka, Japan.*

DOCK8 is a member of the evolutionarily conserved DOCK family proteins that function as guanine nucleotide exchange factors (GEFs) for the Rho family of GTPases. Mutations of DOCK8 cause combined immunodeficiency syndrome in humans, yet the mechanism underlying T-cell dysfunctions remains unknown. In this study, we show that in the absence of DOCK8, dendritic cells (DCs) fail to accumulate in the lymph node parenchyma for T-cell priming. We found that DOCK8 KO mice exhibited a severe defect in antigen-specific T cell proliferation when antigens were injected into mouse footpads. Adoptive transfer experiments revealed that antigen presenting cell functions are primarily affected in the absence of DOCK8. DOCK8 deficiency affected neither antigen uptake nor presentation by DCs. However, when mice were painted on the flank skin with 1% FITC solution, accumulation of FITC+ DCs was severely impaired in the case of DOCK8 KO mice. Indeed, the migration efficiency of DOCK8-deficient DCs was reduced to less than 25% of the wild-type level. Collectively, these results indicate that DOCK8 plays a key role in DC trafficking during T cell immune responses.

Investigating T cell subsets in DOCK8 immunodeficiency

K. L. Randall[1,2,3], *H. D. Law*[2,3], *C. C. Goodnow*[2];
[1]*Canberra Hospital, Woden, Australia,* [2]*John Curtin School of Medical Research, ANU, Canberra, Australia,* [3]*ANU Medical School, ANU, Canberra, Australia.*

DOCK8 immunodeficiency is a rare human immunodeficiency that gives rise to susceptibility to a limited range of viral infections (human papilloma virus, herpes virus and molluscum contagiosum) as well as frequent sino-pulmonary infections. The patients also have allergic disease, increased levels of IgE and a significant rate of hematological and non-hematological malignancy[1,2]. Patients have a complete resolution of their infections with PBSC transplant.
Previous work carried out in ENU-mutant mouse models of DOCK8 immune deficiency have shown abnormal immune synapse formation in both B and T cells[3,4] but no clear mechanism for the specificities of the infections, nor the presence of allergic disease, have been found. Mouse models show some but not all features of DOCK8 disease, in particular no increase in IgE has been found in the DOCK8$^{pri/pri}$ mouse model on a C57Bl/6 background.
To further investigate the T cell polarization of CD4 T cells isolated from the DOCK8$^{pri/pri}$ mouse model, we have analyzed the number of splenic TH1, TH2 and TH17 cells. Analysis has been carried out using both polarizing and non-polarizing conditions, and for total splenic cells and FACS-sorted naïve T cells. No increase in TH2 cells were seen with either TH2 polarizing or non-polarizing conditions. In addition, no defect in TH17 cells was noted.

Considerable progress has been made elucidating the cellular and genetic basis of congenital human primary antibody deficiency. More than 80% of cases are accounted for by mutations in BTK. Recently, additional autosomal recessive genetic defects have been identified by whole exome sequencing of affected offspring of consanguineous parents. In contrast, most cases of non-congenital primary antibody deficiency (including common variable immune deficiency) remain unexplained. This group is clinically and serologically heterogeneous, and slow progress in elucidating the genetic cause has been attributed to assumed genetic heterogeneity. We have assembled a large CVID cohort from centres across Australia and are investigating causal pathways by combining whole exome sequencing with deep phenotyping. The results of the first 50 whole exome sequences obtained from a subgroup within the cohort confirm the genetic heterogeneity of the disorder. Furthermore, recessive or biallelic damaging mutations appear to be uncommon. Consequently, illumination of causal pathways demands specific analysis of candidate damaging mutations guided by comprehensive analysis of both B and T cell phenotypes. Our results have revealed novel gene defects within known CVID-associated signaling pathways, as well as defects in new pathways that combine to help explain the complexity of the disorder.

Altered B and T lymphocyte homeostasis in the bone marrow and the periphery correlates with clinical findings in Common Variable Immunodeficiency (CVID)

***V. Lougaris**, M. Baronio, M. Vitali, S. Masneri, K. Cattivelli, G. Tampella, D. Moratto, A. Soresina, R. Badolato, A. Plebani;*
Pediatrics Clinic and Laboratory for Molecular Medicine "A.Nocivelli", Spedali Civili di Brescia, Un, Brescia, Italy.

Introduction. Common Variable Immunodeficiency (CVID) is characterized by hypogammaglobulinemia due to defective B cell maturation. In almost 10% of cases, affected patients may present a reduction in the number and/or percentage of peripheral B cells; T cell alterations may also be present.
Objective. Evaluate B cell maturation in the bone marrow of CVID patients and correlate the results with peripheral B and T lymphocyte homeostasis and clinical findings.
Methods. Lymphocyte homeostasis (bone marrow, periphery) was studied by means of four-color flow cytometry.
Results. One third of the patients presented a developmental defect in the early phases of B cell maturation (group A). This defect was associated with B cell lymphopenia in the periphery in the presence of normal T cell development. Peripheral B cell lymphopenia was observed in a second group of CVID patients (group B) where bone marrow development was undisturbed. In this group however, CD4+ T cells and RTE cells were severely reduced. Finally, 50% of CVID patients presented normal B cell development in the bone marrow, normal percentages/numbers of B and T cells in the periphery (group C). Group C presented only URTI, group B was characterized by URTI and LRTI, important splenomegaly and gastrointestinal infections (during 10 year follow-up). Finally, group A was characterized by URTI and LRTI, bronchiectasis (already at diagnosis), invasive infections (at diagnosis) and autoimmune phaenomena.
Conclusions. CVID patients may be subdivided in three groups based on B and T lymphocyte homeostasis with significant differences in the severity of clinical manifestations.

IL6.01.01
Stopping T cells in their tracks, vitamin D suppresses naïve CD8 T cell proliferation

***M. T. Cantorna**, J. Chen, D. Bruce;*
Pennsylvania State University, University Park, PA, United States.

Diseases where T cell derived IFN-γ and IL-17 is pathologic like inflammatory bowel disease are suppressed by active vitamin D (1,25(OH)2D3). Paradoxically, infectious diseases that require these same responses for protection are unaffected by 1,25(OH)2D3 treatments. Vitamin D receptor (VDR) knockout (KO) CD8+ T cells, but not wildtype (WT) CD8+ T cells, induced colitis in Rag KO recipients. In addition, co-transfer of VDR KO CD8+ T cells with naïve CD4+ T cells accelerated colitis development. The more severe colitis was associated with rapidly proliferating VDR KO CD8+ cells and increased IFN-γ and IL-17 in the gut. Naïve CD8+ VDR KO T cells proliferated more rapidly than WT CD8+ T cells in vivo and in vitro. The increased proliferation of VDR KO CD8+ cells was due in part to the higher production and response of the VDR KO cells to IL-2. Vitamin D is critical in the control of CD8+ T cell proliferation. T cells express low levels of the vitamin D receptor until 48h post-stimulation. In addition, CD8+ T cells produce the 1-alpha hydroxylase that converts 25(OH)D3 into 1,25(OH)2D3 but the enzyme is not induced before 48h of stimulation. T cell regulation by vitamin D is a late event. Therefore the data support a new model where vitamin D is required to shut off the T cell response. The inability to signal through the VDR results in the generation of pathogenic CD8+ T cells from rapidly proliferating cells that contribute to the development of inflammation in the gut.

IL6.01.02
Vitamin D regulates complement receptor immunoglobulin (CRIg) expression in human macrophages

***A. Ferrante**;*
Department of Immunology, SA Pathology at Women's and Children's Hospital Campus; Discipline of Paediatrics and Microbiology and Immunology, University of Adelaide; School of Pharmacy and Medical Science, University of South Australia, Adelaide, Australia.

An entirely new facet of vitamin D effects distinct from those on homeostasis and bone metabolism has been recognised, which includes the regulation of macrophage function in immunity to infection and in chronic inflammatory diseases. Macrophages have all the requirements to synthesise and respond to 1,25-dihydroxy vitamin D3 (1,25D). This active form of vitamin D stimulates innate immunity and the anti-bacterial activity of macrophages. Since CRIg, a complement receptor distinct structurally and functionally from the classical complement receptors CR3/4, is expressed only by a subpopulation of macrophages and is involved in the rapid phagocytosis of complement (C3b/iC3b)-opsonised bacteria and immunity to *Listeria monocytogenes* and *Staphylococcus aureus*, the relationship between CRIg expression and vitamin D metabolism was studied in human macrophages. Monocytes derived macrophages cultured in the presence of 1,25D showed a marked increase in CRIg mRNA and protein expression. This effect was reflected in increased phagocytosis of complement-opsonised particles and microbial killing by the macrophages. In contrast, 1,25D had no effect on the expression of CR3 and CR4. These results were conducive with the effects of the steroidal anti-inflammatory agent dexamethasone, which also selectively increased CRIg expression and increased the anti-microbial activity of macrophages. Interestingly, the pro-hormone 25 hydroxy vitamin D had no effect on CRIg expression on macrophages unless the cells were stimulated with a Toll-like receptor 2/1 agonist. The results suggest a role for an intracrine action of vitamin D in innate immunity and underscore the need to maintain adequate levels of vitamin D in the community.

W6.01.01
Immunomodulatory role of vitamin D in allergic airway inflammation and airway hyperresponsiveness in bronchial asthma

***D. K. Agrawal**, T. Agrawal, G. K. Gupta;*
Creighton University School of Medicine, Omaha, NE, United States.

Rationale: Allergic airway inflammation and airway hyperresponsiveness (AHR) are hallmarks of asthma. NF-κB is a potent transcriptional factor involved in the generation of many inflammatory cytokines and chemokines. Active subunits of NF-κB are transported from cytosol to the nucleus by importin-α3 and importin-α4. Vitamin D is a potent immunomodulator regulating immune response. However, role of vitamin D in allergic asthma is still unclear. Here, we examined the effect of vitamin D status on allergic immune response in a mouse model.
Methods: Female pups from vitamin D-deficient BALB/c parents were continued on vitamin D-deficient mice. In parallel, mice were fed with vitamin D-sufficient (2,000IU/kg) or vitamin D-supplemented (10,000IU/kg) diet for 13wks, then sensitized and challenged with ovalbumin (OVA). Effect of vitamin D status was examined on AHR, airway inflammation, and the expression of importin-α3 and NF-κB in the lungs.
Results: Three groups of mice had serum 25(OH)D levels (ng/ml) of 5.0+0.2, 31.0+0.7, and 67.1+0.5, respectively at 13wks following OVA challenge. Vitamin D deficiency exaggerated AHR, collagen deposition, mucus gland hyperplasia, BAL eosinophilia, levels of BALF pro-inflammatory cytokines, and reduced blood T-regulatory cells and BALF IL-10 levels. In the lungs of vitamin D-deficient mice, there was increased expression of importin-α3 and NF-κB and decreased expression of VDR. Vitamin D supplementation did not completely reverse the features of allergic airway inflammation and AHR, but increased circulating T-regulatory cells and reduced pro-inflammatory response.
Conclusion: Vitamin D could be beneficial as an adjunct therapy in the treatment of allergic asthma.

W6.01.02
Effects of w3 fatty acid in experimental model of mucositis induced by 5-FU

T. U. Maioli[1], *B. Melo*[1], *M. Nobre*[1], *M. C. Oliveira*[1], *N. C. N. Paiva*[2], *V. N. Cardoso*[1], *A. C. Faria*[1], *A. V. M. Ferreira*[1], *C. M. Carneiro*[2], *S. V. Generoso*[1];
[1]*Universidade Federal de Minas Gerais, Belo Horizonte, Brazil,* [2]*Universidade Federal de Ouro Preto, Ouro Preto, Brazil.*

Mucositis is caused by chemotherapy and radiotherapy cytotoxic in cancer patients and is important to investigate new strategies for control mucositis. The administration of immunomodulators such as ω3 fatty acid could be an alternative to this. So, the aim of this study was to evaluate the effects of ω3 fatty acids in an experimental model of mucositis.
Thirty two male BALB/c were divided into four groups: Control (CTL), Mucositis (M), Control+ω3 (CTL+ω3) and Mucositis+ω3 (M+ ω3). The animals of ω3 group received a diet prepared with ω3 (50% of total lipid content) during ten days. On day tenth, mice received an intraperitoneal injection containing 200mg/kg of 5-FU. Three days after, the small intestines were collected for histological, oxidative stress and cytokine analyzes.
Animals subjected to mucositis showed microscopic lesions in jejunum and ileum. There were increased amount of lamina propria cells, altered villus/crypt ratio, necrosis, hypersecretion of Paneth cells and inflammatory infiltration. However, ω3 pretreatment was able to reduce the intensity of those effects. There was also a decrease in the levels of GSH in M compared to CTL. In mice treated with ω3, there is a decrease in IL-6 in ileum. There was no difference between the levels of IFN, IL-4 and IL-10 with ω3 treatment, although 5-FU seems to reduce cytokine secretion in jejunum and ileum.
The 5-FU leads to alterations in intestinal mucosal architecture and decrease levels of GHS and cytokines in BALB/c mice. The pre-treatment with ω3 appears to alleviate the damage of small intestine mucosal.

W6.01.03
The *Agaricus blazed*-based mushroom extract, Andosan™, has immuno- suppressive and anti-inflammatory effects when used as supplement to multiple myeloma patients receiving high-dose chemotherapy and autologous bone marrow transplantation

G. Hetland[1], *J. Tangen*[1], *A. Tierens*[1], *G. Kvalheim*[1], *L. Osnes*[1], *G. Tjønnfjord*[1,2];
[1]*Oslo University Hospital, Oslo, Norway,* [2]*University of Oslo, Oslo, Norway.*

Agaricus blazei Murill (AbM) is an edible Brazilian *Basidiomycetes* mushroom used in traditional medicine against cancer that has antitumor effects against myeloma and other cancers in mouse models. Ahn et al 2004, reported increased NK cell activity and life quality in patients with gynecological cancer who received AbM extract as supplement to high-dose chemotherapy. We found anti-inflammatory effects in inflammatory bowel disease patients of the AbM-based extract, Andosan™, also containing related medicinal mushrooms; *Hericium erinaceus* (15%) and *Grifola frondosa* (3%). In vitro Andosan™ activated human MDDC and increased proliferation of normal CD56+ hematopoietic stem cells. A placebo-controlled, double-blinded study in 33 multiple myeloma patients who drank 60 ml/day of Andosan™ for 7 weeks as supplement to high dose chemotherapy with autologous stem cell support, showed these immunological findings:
In the Andosan™ relative to placebo group there were increased Treg cells (CD4+, CD127d + CD25+) in the apheresis product harvested for bone marrow transplantation after 2 weeks treatment, and increased plasma levels after 7 weeks in IL-1 receptor antagonist, IL-5 and IL-7 cytokines and up-regulation of immune function-related genes in the bone marrow. This shows that the AbM-based mushroom extract, Andosan™, may have clinically significant immuno-suppressive and anti-inflammatory effects in multiple myeloma patients when used as supplement to high-dose chemotherapy with autologous bone marrow transplantation. The T reg cell increase is probably influenced by enhanced IL-7, a modulator of T cell development. There was no difference in circulating lymphocytes between the patient groups. Clinical status and survival rates are being supervised.

W6.01.04
Hepatocyte nuclear factor 4 alpha regulates immune cell activation and autoimmunity

M. Di Dario, *E. Colombo, C. Farina;*
San Raffaele Scientic Institute, Milan, Italy.

Hepatocyte nuclear factor (HNF) 4α, a member of the nuclear receptor superfamily, plays an important role in regulating metabolic processes such as glucose and lipid homeostasis. Long chain fatty acyl-CoA (FA-CoA) thioesters are endogenous, high affinity ligands for HNF4α and, depending on their chain length and degree of saturation, differentially affect HNF4a transcriptional activity. In fact, saturated FA-CoA activate HNF4α while polyunsaturated FA-CoA decrease HNF4α function. HNF4a is essential for liver development and function, but it has been also implicated in a number of diseases, including diabetes, inflammatory bowel disease and cancer, so that specific antagonists of this nuclear receptor have been developed for therapeutic intervention. Here we provide evidences for a role of HNF4α in immunity. In fact, HNF4a is expressed in human immune cells and its blockade by the antagonist BIM5078 impairs activation of and cytokine release from human monocytes and T-cells. Similarly, in animal models BIM5078 inhibits splenic T cell responses to the self antigen MOG35-55. Finally, in vivo administration of BIM5078 after induction of experimental autoimmune encephalitis (EAE) ameliorates clinical expression of EAE. In conclusion, HNF4a-dependent gene transcription sustains immune cell activation and autoimmunity, and therapeutic targeting of this signaling pathway is beneficial in experimental neuroinflammation. W6.01.05
Mast cell protease expression is reduced in vitro and in vivo in response to cinnamon treatment

Y. Hagenlocher[1], *I. Bergheim*[1,2], *S. C. Bischoff*[1], *A. Lorentz*[1];
[1]*University of Hohenheim, Stuttgart, Germany,* [2]*Friedrich Schiller University, Jena, Germany.*

Mast cells (MC) contain large amounts of proteases like chymase, tryptase and carboxypeptidase A (MC-CPA) in their secretory granules. MC proteases being released play a critical role in inflammatory processes. Cinnamon extract is known to affect diverse immunological cells like macrophages and shows anti-inflammatory capacities. Here, we analyzed the effect of cinnamon extract on the expression of pro-inflammatory MC proteases in vitro and in vivo. Expression of tryptase and MC-CPA was analyzed in vivo in the intestine of wild type mice as well as of IL-10 knockout mice - as a model of inflammatory bowel disease - after oral treatment with cinnamon extract in comparison to controls. In addition, human MC isolated from intestinal tissue were incubated with cinnamon extract prior to IgE mediated stimulation. Expression of MC proteases was examined by real time RT-PCR and Western blotting. Following oral treatment with cinnamon extract, expression of MC-specific proteases tryptase and MC-CPA was significantly reduced in wild type and IL-10 knockout mice. Moreover, severity of disease (weight loss, consistency of stool, rectal inflammation) was reduced in IL-10 knockout mice. In human MC from intestinal mucosa, cinnamon extract also caused a significantly decreased expression of tryptase and chymase. In summary, cinnamon extract mediates anti-inflammatory activities by reducing expression of MC-specific proteases in vitro and in vivo, and thus is a new plant-originated candidate for diverse MC associated therapeutical applications.

Immunomodulatory effects and anti-tumor activities of conjugated linolenic acids on the murine macrophage-like leukemia cells

***K. Leung**, W. Liu;*
Biochemistry Programme, School of Life Sciences, The Chinese University of Hong Kong, Hong Kong, China.

Naturally-occurring conjugated linolenic acids (CLN) derived from various plant seed oils have shown to possess various biological and pharmacological activities, including antioxidative, hypolipidemic, chemopreventive and anti-tumor properties. Although CLN are known to inhibit the growth of several cancer cell lines *in vitro*, however, their modulatory effects on macrophages and their action mechanisms on macrophage-like leukemia have not been investigated. In the present study, various CLN isomers were found to exhibit potent anti-proliferative effect on the murine macrophage-like leukemia PU5-1.8 cells in a time- and dose-dependent manner. The most potent CLN isomer, jacaric acid, also exerted significant growth-inhibitory effects on other murine macrophage-like leukemia cell lines *in vitro*. Mechanistic studies indicated that jacaric acid could lead to cell cycle arrest of PU5-1.8 cells at the G0/G1 phase, and this was associated with a decrease in cyclin E and CDK2 proteins, and an increase in p21, p27 and p53 proteins. Moreover, jacaric acid could induce apoptosis in PU5-1.8 cells as revealed by DNA fragmentation, phosphatidylserine externalization, and down-regulation of anti-apoptotic Bcl-2 and Bcl-xL proteins expression. Furthermore, pre-treatment of PU5-1.8 cells with jacaric acid significantly reduced the *in vivo* tumorigenicity of the leukemia cells in syngeneic BALB/c mice. Interestingly, jacaric acid exhibited no significant cytotoxicity on the thioglycollate-induced peritoneal macrophages but stimulated their cytostatic activity towards tumor cells and production of nitric oxide *in vitro*. Collectively, our results indicate that CLN can stimulate macrophages and exert their anti-tumor effects on the macrophage-like leukemia cells through cell cycle arrest and apoptosis induction.

Polyphenols from red grape and modulation of the immune Response

***E. Jirillo**[1], Y. Kumazawa[2], V. Pugliese[3], S. Fontana[4], G. Marzulli[1], T. Magrone[1];*
[1]Department of Basic Medical Sciences, Neuroscience and Sensory Organs, University of Bari, Bari, Italy, [2]Vino Science Japan, Inc., Tokyo, Japan, [3]Geriatric Center "Mamma Rosa", Turi, Bari, Italy, [4]Farmalabor S.p.A., Canosa, Bari, Italy.

Polyphenols, largely present in the vegetal kingdom, are endowed with a plethora of biological activities. Over recent years, we have been working with different extractions of polyphenols derived from red grape. In our initial studies, polyphenols extracted from red wine Negroamaro (N) were shown to *in vitro* release nitric oxide from human circulating monocytes as well as an array of cytokines from lymphomonocytes. In this last regard, a balance between production of inflammatory and anti-inflammatory cytokines was demonstrated. In addition, N polyphenols were able to inhibit activation of NF-KB pathway by LPS. In a second model, using fermented grape marc (FGM) from Koshu (K) and N *Vitis Vinifera*, especially K-FGM was able to *in vivo* attenuate murine experimental colitis with a dramatic reduction of TNF-α and IL-1β in colon homogenates. Both, N-FGM and K-FGM when *in vitro* incubated with peripheral human granulocytes and lymphomonocytes, led to the following results:
1. Increased expression of FoxP3 in CD4 lymphocytes;
2. Increased production of IL-10;
3. Decreased release of granzyme B from CD8+ lymphocytes;
4. Decreased release of oxygen radicals from granulocytes and monocytes;
5. Reduction of basophil burst.
Finally, epigallocathechin gallate extracted from grape seeds and contained in the Leucoselect® Phytosome® preparation, was able, when administered to frail elderly subjects, to recover the depressed Th1 response in these subjects. Taken together, these results emphasize the immunological properties of polyphenols and their potential application in inflammatory conditions.

IL6.02.02
Intracellular metabolic pathways control immune tolerance

***G. Matarese**;*
Dipartimento di Medicina e Chirurgia, Università di Salerno, Baronissi, Salerno, Italy.

The field that links immunity and metabolism is rapidly expanding. Apparently non-immunological disorders such as obesity and type 2 diabetes have been linked to immune dysregulation suggesting that metabolic alterations can be induced by or be consequence of an altered self-immune tolerance. In this context, a key role is played by signalling systems acting as metabolic "sensors" linking energy/nutritional status to regulatory T (Treg) cell functions such s the adipose tissue derived hormone, leptin. We propose that a dynamic/oscillatory activity of intracellular metabolism, particularly through the mammalian target of rapamycin (mTOR) complex, might represent a shift in understanding the molecular mechanisms governing Treg cell tolerance. In particular, the decision between Treg cell proliferation and hyporesponsiveness arises from their ability to probe the extracellular milieu and, modulating the metabolic intracellular signalling, to determine different qualitative and quantitative functional outcomes. The possibility to interfere with these pathways should lead to novel approaches for treatment of chronic-inflammatory and autoimmune disorders.

W6.02.01
Insulin impairs regulatory T cell function: implications for obesity

***J. M. Han**, S. J. Patterson, J. A. Ehses, M. K. Levings;*
Child & Family Research Institute, Vancouver, BC, Canada.

Chronic inflammation is known to drive metabolic dysregulation in obesity and type 2 diabetes. Although the precise origin of the unchecked inflammatory responses in obesity is unclear, it is known that over-production of pro-inflammatory cytokines such as TNF-α by innate immune cells has a key role in the development of metabolic dysregulation. One key hallmark of obesity is high levels of the pancreatic hormone insulin, and we hypothesized that there may be an unknown link between hyperinsulinemia and chronic inflammation. Here we show that high levels of insulin impair the ability of regulatory T cells (Tregs) to suppress inflammatory responses via effects on the AKT/mTOR signaling pathway. Insulin strongly activates AKT/mTOR signalling in Tregs, leading to specific inhibition of the production of the anti-inflammatory cytokine IL-10. As a result, insulin hinders the ability of Tregs to suppress the production of TNF-α by macrophages. Tregs from the visceral adipose tissue of hyperinsulinemic, obese mice also have a decrease in IL-10 production and a parallel increase in production of IFN-γ. These data suggest that the hyperinsulinemia associated with obesity may contribute to the development of obesity-associated inflammation via a previously unknown effect on Treg function.

Investigating the anti-inflammatory effects of High Density Lipoprotein in macrophages

***D. De Nardo**[1], L. Labzin[1], H. Kono[2], R. Seki[2], S. Schmidt[3], M. Kneilling[4], D. Lütjohann[5], S. Wright[6], J. Schultze[3], E. Latz[1];*
[1]Institute of Innate Immunity, University of Bonn, Bonn, Germany, [2]Department of Internal Medicine, Teikyo University School of Medicine, Tokyo, Japan, [3]Life and Medical Sciences Institute (LIMES), University of Bonn, Bonn, Germany, [4]Department of Dermatology, University Medical Center, Eberhard Karls University Tuebingen, Tuebingen, Germany, [5]Instititute for Clinical Chemistry and Clinical Pharmacology, University of Bonn, Bonn, Germany, [6]Cardiovascular Therapeutics, CSL Limited, Parkville, Australia.

Elevated plasma levels of High Density Lipoprotein (HDL) are associated with decreased risk of cardiovascular disease (CVD). The protective role of HDL in atherosclerosis has been attributed primarily to its ability to remove excess cholesterol from lipid-laden macrophages (foam cells) within the arterial walls. Clinical trials that simply raise HDL cholesterol levels have failed to show a therapeutic

benefit, casting doubts on our basic understanding of HDL function. Atherosclerosis is a chronic inflammatory condition underlying CVD and driven in part by the recognition of metabolic danger signals by innate immune receptors on macrophages. A potential feature that could contribute to its protective effects in CVD could be HDL's anti-inflammatory nature, such as its ability to reduce endothelial cell activation. However, the molecular mechanisms by which HDL reduces inflammatory macrophage responses remain poorly understood. Here we show that HDL protects against Toll-like receptor (TLR)-induced inflammation both in vivo and in vitro under normocholesteremic conditions by suppressing the transcription of inflammatory cytokines. We identify Activating Transcription Factor 3 (ATF3), a transcriptional repressor of the CREB family of basic leucine zipper transcription factors, as a HDL-inducible regulator of macrophage activation. HDL's ability to down modulate TLR responses was severely compromised in ATF3-deficient cells demonstrating that ATF3 mediates HDL's anti-inflammatory effects in macrophages and may explain the broad anti-inflammatory functions of HDL.

W6.02.03
Obesity-associated autoantibody production requires AIM to retain IgM immune complex on follicular dendritic cells

S. Arai[1], *S. Honda*[2], *A. Shibuya*[2], *Q. Li*[3], *T. Miyazaki*[1];
[1]*Lab of Molecular Biomedicine for Pathogenesis, Center for Disease Biology and Integrative Medicin, Faculty of Medicine, The University of Tokyo, Tokyo, Japan,* [2]*Department of Immunology, Institute of Basic Medical Sciences, Graduate School of Comprehensive Human Sciences, University of Tsukuba, Tsukuba, Japan,* [3]*Department of Immunology and Internal Medicine, University of Texas Southwestern Medical Center, Dallas, TX, United States.*

Natural IgM is polyreactive not only to foreign antigens but also to autoantigens, and thus, believed to be important for progression of autoimmunity. In blood, pentameric IgM loaded with antigens forms a large immune-complex containing various elements including apoptosis inhibitor of macrophage (AIM). Here we demonstrate that this IgM-AIM association critically contributes to the development of autoantibody producing plasma cells under obese condition. In mice fed a high-fat diet (HFD), natural IgM increased through B cell toll-like receptor-4 stimulation. Blood AIM associated with IgM pentamer at the Fc region. This association protected AIM from renal excretion, increasing blood AIM levels along with the obesity-induced natural IgM augmentation. Meanwhile, the AIM association inhibited IgM binding to the Fcα/μ receptor on splenic follicular dendritic cells (FDCs), thereby protecting the IgM immune complex from Fcα/μ receptor-mediated internalization. This supported IgM-dependent autoantigen presentation to B cells, stimulating IgG autoantibody production. In obese AIM-deficient (*AIM*$^{-/-}$) mice, the increase of multiple IgG-autoantibodies, observed in obese wild-type mice, was abrogated. Accordingly, the increase in high-affinity IgG producing plasma cells in response to HFD was diminished in the *AIM*$^{-/-}$ bone marrow. Thus, the AIM-IgM association plays a critical role in the obesity-associated autoimmune process.

W6.02.04
Novel factors regulating chemerin synthesis and function in fat tissue

M. Kwitniewski[1], *M. Banaś*[1], *N. Harasymowicz*[1], *J. Marczyńska*[1], *K. Kwiecień*[1], *B. A. Zabel*[2], *J. Cichy*[1];
[1]*Jagiellonian University, Krakow, Poland,* [2]*Palo Alto Institute for Research and Education, Palo Alto, CA, United States.*

Chemerin is a chemoattractant protein with adipokine properties. First identified as tazarotene- (retinoic acid-analog) induced gene 2 (TIG2) in tazarotene treated psoriatic skin, it has gained more attention over the past few years due to its multilevel impact on metabolism and immune responses. Pleiotropic actions of chemerin include chemotaxis of dendritic cell, macrophage and NK subsets, bactericidal activity, regulation of adipogenesis and glucose metabolism. The mechanisms underlying systemic and/or local chemerin expression remain obscure. Given the high levels of chemerin message in the liver and adipocyte tissue, as well as nanomolar levels of circulating protein, we hypothesize that, like certain other plasma proteins, chemerin expression and secretion by liver and adipocytes might be regulated by factors released upon inflammation. In these studies we demonstrate that oncostatin M (OSM), a cytokine of the IL-6 family, regulates chemerin expression and/or synthesis in mouse visceral white adipose tissue (vWAT) as well as mouse adipocytes differentiated from vWAT derived preadipocytes. Moreover, we show that OSM acts synergistically with IL-1b, leading to strong up-regulation of chemerin levels in vWAT and adipocyte cultures. In contrast to adipocytes, OSM or OSM+IL1b exerted weak if any response in liver or primary cultures of mouse hepatocytes, suggesting that the effect of the cytokines on chemerin expression is specific to fat tissue. Up-regulation of chemerin expression in vWAT by OSM and IL-1b correlates with changes in differentitation of adipocytes and the influx of natural killer cells into vWAT, suggesting that increases in chemerin levels might contribute to fat tissue remodeling.

W6.02.05
Amino acid sensing by mTORC1 is the vital prerequisite for alternative activation of macrophages

T. Kimura[1,2], *S. Nada*[3], *M. Okada*[3], *A. Kumanogoh*[1,2];
[1]*Osaka Univ. Immunology Frontier Research Center, Suita, Japan,* [2]*Department of Respiratory Medicine, Allergy and Rheumatic Disease, Graduate School of Medicine, Osaka Univ., Suita, Japan,* [3]*Osaka Univ. Research Institute for Microbial Diseases, Suita, Japan.*

Mechanistic target of rapamycin complex 1 (mTORC1) is an integrative sensor for nutrition and growth signals. Although the role of mTORC1 in several organs and some immune cells, such as T lymphocytes and dendritic cells, have been elucidated, little is known about its implications for macrophages. Gene expression microarrays comparing classically activated macrophages (CAM) with alternatively activated macrophages (AAM) revealed that a molecule of amino acid sensing pathway, namely p18/LAMTOR1, was predominantly expressed in AAM. Macrophage-specific p18 conditional knockout mice (p18 cKO) showed massive accumulation of macrophages in peripheral organs, and 50 to 200 fold greater serum levels of pro-inflammatory cytokines after the challenge with endotoxin. Surprisingly, macrophages derived from p18 cKO mice showed defective polarization of AAM with little expression of its signature genes such as arginase-1, resistin-like molecule alpha, and IL-10. Consistently, this defective polarization was reproduced by interfering amino acid sensing pathways: amino acid starvation, v-ATPase inhibition, and mTOR inhibition. These data indicated that mTORC1 pathway is the vital prerequisite for the polarization of AAM. Collectively, our present study shows first evidence that the amino acid sensing by mTORC1 is essentially required for AAM polarization.

W6.02.06
Gene profile of myeloid-derived suppressive cells from the bone marrow of lysosomal acid lipase knock-out mice

C. Yan[1], *X. Ding*[1], *N. Dasgupta*[2], *L. Wu*[1], *H. Du*[1];
[1]*Indiana University School of Medicine, Indianapolis, IN, United States,* [2]*Cincinnati Childrens Hospital, Cincinnati, OH, United States.*

Lysosomal acid lipase (LAL) controls development and homeostasis of myeloid lineage cells. Loss of the lysosomal acid lipase (LAL) function leads to expansion of myeloid-derived suppressive cells (MDSCs) in LAL knock-out (lal-/-) mice. Ly6G^{+} positive MDSCs actively participate in inflammation-induced pathogenic processes in lal-/- mice by suppressing T lymphocytes. Affymetrix GeneChip microarray analysis identified detailed intrinsic defects in Ly6G^{+} myeloid lineage cells of *lal-/-* mice. Ingenuity Pathway Analysis revealed activation of the mammalian target of rapamycin (mTOR) signaling, which functions as a nutrient/energy/redox sensor, and controls cell growth, cell cycle entry, cell survival, and cell motility. Loss of the LAL function led to major alteration of large GTPase and small GTPase signal transduction pathways. *lal-/-* Ly6G^{+} myeloid cells in the bone marrow showed substantial increase of cell proliferation in association with up-regulation of cyclin and cyclin-dependent kinase (cdk) genes. The epigenetic microenvironment was significantly changed due to the increased expression of multiple

histone cluster genes, centromere protein genes and chromosome modification genes. Gene expression of bioenergetic pathways, including glycolysis, aerobic glycolysis, mitochondrial oxidative phosphorylation, and respiratory chain proteins, was also increased, while the mitochondrial function was impaired in *lal-/-* Ly6G^{+} myeloid cells. The concentration of reactive oxygen species (ROS) was significantly increased accompanied by up-regulation of nitric oxide/ROS production genes in these cells. This comprehensive gene profile study for the first time identifies and defines important gene pathways involved in the myeloid lineage cells towards MDSCs using *lal-/-* mouse model.

IL6.03.01
Soluble CD52 released by activated T cells interacts with Siglec-10 to suppress T cell activation and prevent autoimmune disease

E. Bandala-Sanchez, Y. Zhang, S. Reinwald, J. A. Dromey, B. Lee, J. Qian, R. M. Boehmer, ***L. C. Harrison****;*
Walter and Eliza Hall Institute of Medical Research, Parkville, Australia.

Functionally diverse T-cell populations interact to maintain immune homeostasis. In testing the hypothesis that paracrine mechanisms limit proliferation of T cells following their activation we found that a sub-population of antigen-activated T cells characterized by high expression of the GPI-anchored glycoprotein CD52 suppresses other T cells. CD52hi CD4+ T cells are distinct from CD4+CD25+FOXP3+ regulatory T cells by several criteria, including their methylation at the FOXP3 locus and their mode of action. Suppression by CD52hi CD4+ T cells is mediated by soluble CD52, released by the action of phospholipase C. Soluble CD52 then binds to the inhibitory Siglec-10 receptor on T cells, leading to impaired phosphorylation of the T-cell receptor-associated tyrosine kinases Lck and ZAP-70 and impaired T-cell activation. This homeostatic mechanism may be important for the prevention of autoimmune disease. Thus, humans with, and at risk for, type 1 diabetes displayed reduced frequency and function of CD52hi CD4+ T cells generated in response to the pancreatic islet autoantigen GAD65 but not tetanus toxoid. Furthermore, in an autoimmune mouse adoptive transfer model, CD52hi-depleted splenic T cells from young, pre-diabetic mice markedly accelerated the onset of diabetes in syngeneic recipients. Our studies identify a previously undiscovered ligand and receptor mechanism of T-cell regulation that protects against autoimmune disease.

W6.03.01
Detection of Chromogranin A-reactive CD4^{+} T cells in type 1 diabetes in the nonobese diabetic (NOD) mouse

N. Jin*, F. Crawford, J. White, M. Philippa, J. Kappler;*
Deaprtment of Immunology,National Jewish Health,Howard Hughes Medical Institute, Denver, CO, United States.

We have identified the peptide WE14 as chromogranin A (ChgA) antigen for highly diabetogenic CD4+ T cell clones. Peptide truncation and extension analysis shows that WE14 bound to major histocompatibility complex class II (MHCII) molecule I-A(g7) in an atypical manner, occupying only the carboxy-terminal half of the I-A(g7) peptide-binding groove. We constructed modified fluorescent WE14 peptide-MHCII tetramer, in which WE14 was only bind to p5-p9 position of the I-A(g7) peptide-binding grove. In the nonobese diabetic (NOD) mouse, an animal model of type 1 diabetes (T1D), we used this peptide-MHCII tetramer to detect ChgA reactive CD4+ T cell in the pancreas, pancreatic lymph node and spleen, both in prediabetic and diabetic NOD mice. The results showed that ChgA reactive CD4+ cells accumulated into the pancreas at prediabetic stage and were disappearing from pancreas upon the onset of the disease. Further study of ChgA reactive CD4+ T cell hybridmas from NOD mice showed those T cells express a variety of T cell repertoire.

W6.03.02
IL21 is a critical regulator of chronic/persistent but not acute/accelerated auto-immune and allo-immune responses

M. Khattar*[1], P. Schroder[1], C. Baum[1], R. Deng[1], W. Chen[2], S. Stepkowski[1];*
[1]University of Toledo, Toledo, OH, United States, [2]Baylor College of Medicine, Houston, TX, United States.

IL21 is critical for T1D development in NOD mice, but its role in sustaining T cell responses against islets during T1D progression remains unexplored. Our preliminary studies show that NOD mice produce high levels of serum IL21 during T1D onset. Thus, we hypothesize that IL21 produced by activated CD4 T cells in spontaneously diabetic NOD mice sustains T cell responses to islets. We show that IL21 is required for maintaining the function of auto-reactive immune cells during T1D progression as transient therapy with IL21 receptor fusion protein (IL21RFc) is effective in reversing T1D onset in NOD mice (n=11) and inducing long-term T1D remission for up to 30 weeks. Pancreatic infiltrates of IL21RFc-treated NOD mice contain mostly CD4 T cells, that have lost surface ICOS expression, and few CD8 T cells, suggesting that IL21RFc inhibits CD4 T cell help to CD8 T cells. In a parallel study, we also show that IL21 deficient mice are protected from chronic allograft vasculopathy in a MHC class-II mismatched cardiac allograft model. However, IL21 deficient mice acutely reject fully mismatched cardiac allografts, similar to wild type. Thus, we demonstrate a novel and critical role for IL21 signaling in driving chronic immune responses against auto and allo-antigens. Based on our findings, IL21 has the potential to act as a serum biomarker for early T1D detection and a therapeutic target to abrogate persistent T cell responses in T1D and chronic allograft rejection. We continue to investigate the molecular mechanisms governing IL21 mediated chronic immune responses.

W6.03.03
Postnatal events in intestinal gene expression and splenic cell composition is altered in NOD mice

D. S. M. Damlund*[1], S. Metzdorff[1], M. B. Kristensen[2], A. K. Hansen[1], K. Buschard[3], H. Frøkiær[1];*
[1]University of Copenhagen, Faculty of Health and Medical Sciences, Frederiksberg C, Denmark, [2]Department of Microbiology and Risk Assessment, The National Food Institute, Technical University of Denmark, Søborg, Denmark, [3]The Bartholin Institute, Laboratory of Molecular Pathology, Rigshospitalet, København Ø, Denmark.

Evidence suggests that colonisation pattern of the gut in the early postnatal period is highly correlated with the risk of developing type 1 diabetes (T1D). We have recently shown that colonization in SPF mice accelerates gut maturation and that at postnatal day (PND) 1, in comparison with germ free mice, certain chemokines, including *Cxcl2* encoding macrophage inflammatory protein (MIP)-2 and involved in attraction of neutrophils was downregulated in the gut epithelium. The non-obese diabetes (NOD) mouse is widely used as a model for studying the pathogenesis of T1D, as it spontaneously develops insulitis at three to five weeks of age. The neonatal gut microbiota seems to play an important role in the development and control of T1D. We hypothesized that NOD mice in the perinatal period respond differently than mice not prone to develop T1D (C57/Bl6), and we investigated the differences in postnatal expression of genes in gut, spleen, liver and pancreas, and in cellular composition in spleen.
At PND1 and 2, the number of Ly-6G and CD11b positive cells in NOD mice was significantly higher as compared to C57/bl6. Furthermore, gene expression analyses of liver, spleen and intestine showed difference between the two mouse strains in the early postnatal expression of *Cxcl2* and the antibacterial lectin encoding *RegIII* gene. Our findings suggest that very early postnatal microbiota dependent events contribute to the development of T1D in NOD mice.

W6.03.04
Antigen-specific protection against highly aggressive cytotoxic T cells in diabetes by intradermal injection of heme-oxygenase-1 inducer

T. Simon[1], *J. Pogu*[1], *S. Pogu*[2], *J. Bach*[2], *S. Remy*[1], *E. Piaggio*[3], *I. Anegon*[1], *P. Blancou*[1];
[1]*INSERM UMR_S 1064, Nantes, France,* [2]*UMR_A 707 IECM ONIRIS/INRA/University, Nantes, France,* [3]*UMR 7211 (UPMC/CNRS), U 959 INSERM, Paris, France.*

Diabetes is the result of chronic inflammation created by CD4 or CD8 autoreactive T-cells attack of beta-cells in the pancreas. Once autoreactive CD4 or CD8 T-cells are activated, hijacking these cells from their initial target is challenging.
Heme oxygenase-1 (HO-1) is a cellular induced enzyme in response to inflammation that degrades free heme and results in the production of carbon monoxide (CO). We have recently obtained experimental data showing that anti-inflammatory properties of HO-1/CO can be used to in vitro induce tolerogenic dendritic cells that can decrease diabetes (Simon et al.Eur. J. Immunol. 2013).
The main objective of this research is to efficiently induce tolerance by manipulating HO-1 pathway directly in vivo that can be applicable to clinical practice. Autoimmune diabetes can be induced in Rat Insulin Promotor-Ovalbumin (RIP-OVA) transgenic mice by transfer of highly aggressive in vitro activated anti-OVA OT-I cells. Once transferred, these cells are very difficult to stop. However if an HO-1 inducer is intradermally injected along with OVA antigen, insulitis is reduced and diabetes can be prevented by more than 65%. This protection necessitates both the injection of the antigen and of HO-1 inducer. Inhibition of HO-1 activity is sufficient to abrogate the protection. Interestingly, we have been able to identify a tolerogenic MHC-class II population expressing high level of HO-1 induced in protected animals that can abolish the pathogenic capabilities of cytotoxic T cells. We are currently investigating the mechanism underlying the tolerogenic effect of these cells on cytotoxic T-cells.

W6.03.05
Inhibiting Th17 Cells and Reducing Insulitis in Diabetic NOD Mice by GW9508, a GPR40 and GRP120 Dual Agonist

Z. Guo*, A. Ansarullah, Y. Lu, M. Holstein, B. Deruyter;*
Sanford Research/USD, Sioux Falls, SD, United States.

G-protein coupled receptor 40 (GPR40) and G-protein coupled receptor 120 (GPR120) are expressed on monocytes, macrophages, and intestinal L cells. We investigated the effect of GW9508 (GW), a GRP40 and GPR120 dual agonist, on modulating autoimmunity in NOD mice. New-onset diabetic NOD mice were treated with GW for up to 8 weeks. Nonfasting blood glucose was monitored. After the treatment, $CD4^+CD25^+FoxP3^+$ T (Treg) cells in thymus, spleen and pancreatic lymph nodes were measured. To detect $IL\text{-}17^+CD4^+$ T (Th17) cells, lymphocytes from these mice were cultured for 5 days. To determine in vitro effect of GW on Th17 cells, lymphocytes from NOD mice were cultured with or without GW. Cytokines and chemokines in supernatants were determined. Diabetes was reversed in 13% of vehicle (DMSO) treated mice, in 54% of mice treated with GW at 10mg/kg/day and in 69% of mice treated with GW at 20 mg/kg/day ($P<0.01$). The insulitis score was significantly lower in GW-treated mice ($P<0.05$). Although the percentage of Treg cells was not significant difference, the percentage of Th17 cells and the ratio of Th17 cells to Treg cells in GW-treated mice were significantly lower ($P<0.01$). Th17 cells in GW-treated lymphocytes in culture were significantly reduced ($P<0.05$). IL-17, IFN-γ, IP-10, RANTES, and MIP-1α in supernatants of GW-treated lymphocytes were also significantly reduced ($P<0.05$). The percentage of $insulin^+/Ki67^+$ β cells in islets was significantly higher in GW-treated mice than in prediabetic mice ($P<0.01$). Our data indicate that targeting GPR40 /GPR120 is a new therapeutic approach for treating type 1 diabetes.

W6.03.06
New insights into Type 1 diabetes development and therapy

C. R. Parish*, A. F. Ziolkowski, Z. Wu, S. K. Popp, C. Freeman, C. J. Simeonovic;*
John Curtin School of Medical Research, Canberra, Australia.

Type 1 diabetes (T1D) is an autoimmune disease in which the insulin-producing beta cells in the pancreas are destroyed by the immune system, although the molecular basis of this autoimmune destruction is unclear. We have recently reported that mouse islets express extraordinarily high levels of the glycosaminoglycan heparan sulfate (HS) intracellularly and are also surrounded by a basement membrane (BM) rich in HS. In fact, beta cells are exquisitely dependent on intracellular HS for their survival, with in vitro addition of HS or related molecules maintaining beta cell viability and rendering the cells highly resistant to damage by reactive oxygen species. Furthermore, we have found in vivo that destructive insulitis is associated with high level expression by leukocytes of enzymatically active heparanase, an endoglycosidase that degrades HS. In addition, in vivo treatment with several heparanase inhibitors significantly protected NOD mice from clinical diabetes. Based on these data we propose that initially leukocyte-derived heparanase degrades HS in the islet BM, allowing leukocyte entry into islets. Thereafter, heparanase-mediated degradation of beta cell-associated HS results in a novel mechanism of beta cell death. Recent studies using an acute T1D model in heparanase knock out mice has confirmed the importance of heparanase in T1D development, with heparanase expression by several different cell types being important. Thus heparanase inhibition, possibly combined with HS replacement in beta cells, has great therapeutic promise for treating T1D patients at an early stage of the disease and, potentially, for the prevention of T1D in “at risk” individuals.

Human cathelicidin-derived peptide IG-19 regulates cytokine IL-32-induced inflammation in human blood mononuclear cells, and provides protection in a murine model of arthritis

K. Choi*, L. N. Y. Chow, M. Bossert, T. Klonisch, J. Uzonna, N. Mookherjee;*
University of Manitoba, Winnipeg, MB, Canada.

Human cathelicidin host defence peptide LL-37 can suppress pathogen-induced inflammatory responses, while maintaining the ability to resolve infections. The objective of this study was to investigate the effects of LL-37 and its derivatives in immune-mediated ‘sterile’ inflammation. We demonstrated that LL-37 and its derivative peptide IG-19 significantly suppressed inflammatory cytokine IL-32γ-induced TNF-α and IL-1β production, induced anti-inflammatory cytokine IL-1RA, without neutralizing chemokine responses in human peripheral blood derived mononuclear cells. Mechanistic studies revealed that IL-32γ-induced phosphorylations of Akt-1 (T308) and MKP-1 (S359), and the activation of p44/42 MAPK was not suppressed by either LL-37 or IG-19. The peptides induced the phosphorylation of MKP-1 (S359), a known negative regulator of inflammation. In contrast, the peptides abrogated IL-32γ-induced phosphorylation of Fyn (Y420), an inducer of inflammation. The peptides exhibited an overall anti-inflammatory effect in the presence of IL-32, by abrogating the Fyn protein tyrosine kinase phosphorylation, and in contrast inducing the activity of the negative regulator MKP-1 dual phosphatase. As IL-32γ is directly linked to the severity of chronic inflammatory diseases including rheumatoid arthritis, we further investigated the effect of the peptide IG-19 *in-vivo* using a murine model of collagen-induced arthritis (CIA). We demonstrated that the administration of the peptide IG-19 decreased disease severity, infiltration of immune cells into the joints, and serum levels of anti-collagen antibodies and pro-inflammatory cytokines TNF-α and IFN-γ, in the CIA mice. This study demonstrates the potential of human cathelicidin-derived peptides to regulate immune-mediated inflammation and provide a rationale for examining their use for chronic inflammatory diseases.

W6.04.02
The pro-inflammatory activities of Interleukin-6 are mediated by the soluble Interleukin-6 receptor via trans-signaling

S. Rose-John*;*
University of Kiel, Department Biochemistry, Kiel, Germany.

Cytokines receptors exist in membrane bound and soluble form. The IL-6/soluble IL-6R complex stimulates target cells not stimulated by IL-6 alone, since they do not express the membrane bound IL-6R. We have named this process 'trans-signaling'. Soluble gp130 is the natural inhibitor of IL-6/soluble IL-6R complex responses. Recombinant soluble gp130 protein is a molecular tool to discriminate between gp130 responses via membrane bound and soluble IL-6R responses. We used neutralizing monoclonal antibodies for global blockade of IL-6 signaling and the sgp130Fc protein for selective blockade of IL-6 trans-signaling in several animal models of human diseases. Inhibition of IL-6 trans-signaling was beneficial in a sepsis model. Defense against bacterial infections rely on the membrane bound IL-6R. The extent of inflammation is controlled by trans-signaling via the soluble IL-6R. Using the sgp130Fc protein or sgp130Fc transgenic mice we demonstrate in animal models of inflammatory bowel disease, peritonitis, rheumatoid arthritis, atherosclerosis pancreatitis, colon cancer, ovarian cancer and pancreatic cancer, that IL-6 trans-signaling via the soluble IL-6R is the crucial step in the development and the progression of the disease. Therefore, sgp130Fc is a novel therapeutic agent for the treatment of chronic inflammatory diseases and cancer and it will undergo phase I clinical trials as an anti-inflammatory drug later in 2013.

Survivin as a target for therapeutic RNA interference in experimental arthritis

S. E. M. Andersson*, M. N. D. Svensson, M. C. Erlandsson, I. Jonsson, K. M. E. Andersson, M. I. Bokarewa;*
Dept of Rheumatology and inflammation research, Gothenburg, Sweden.

Survivin is a proto-oncogene with a major function in cell division and regulation of apoptosis. It has an emerging role in autoimmune diseases. In patients with rheumatoid arthritis, survivin is an independent predictor of joint damage and resistance to the conventional and biological anti-rheumatic treatment.
We study whether in vivo silencing of survivin is sufficient to reduce inflammation and joint damage in experimental arthritis.
Survivin targeting shRNA (shSurv) in a lentiviral delivery system was provided by a single injection (10^6-10^7 particles /mouse) on first immunization day 0 (mBSA arthritis) or at the onset of arthritis (collagenII arthritis, CIA). Control groups received non-targeting shRNA.
shSurv-treated mice had significant inhibition of survivin in spleen (12-51%) and bone marrow (7-29%). shSurv significantly alleviates clinical and histological signs of mBSA-arthritis and CIA, joint damage (microCT) and MMP13 expression in synovial tissue.
shSurv mice had low MHCII expression on dendritic and B cells, suggesting impaired antigen presentation. Additionally, shSurv increases Treg (Foxp3+CD4+) subset in spleen and lymph nodes, and increases Foxp3 mRNA and GATA3 mRNA and production of IL 10 and IL-4 in splenocytes. shSurv reduces serum levels of antigen-specific and autoantibodies (anti-Fc-gamma), both in CIA and mBSA-arthritis. Low antibody levels correlates to the reduction of survivin and to the severity of arthritis.
We show that in vivo silencing of survivin expression is sufficient to alleviate arthritis by promoting anti-inflammatory immune responses and by reduction of antigen- specific antibodies.

W6.04.04
Critical role of all-trans retinoic acid in stabilizing human nTregs under inflammatory conditions

S. Zheng*[1,2], Z. Liu[1];*
[1]Shanghai Tongji University, Shanghai, China, [2]University of Southern California, Temple City, CA, United States.

Objective Recent studies have demonstrated that thymus-derived naturally-occurring CD4+Foxp3+ regulatory T cells (nTregs) in both human and mouse are unstable and dysfunctional in the presence of pro-inflammatory cytokines. All-trans Retinoic Acid (atRA), the active derivative of vitamin A, has been shown to regulate Treg and T effector cell differentiation. We hypothesize atRA stabilizes human nTregs in the inflammation condition.
Methods Human nTregs pre-treated with atRA or control (DMSO) were expanded and re-stimulated with IL-1 and IL-6. Foxp3 expression and suppressive activities were analyzed in vitro and in vivo using a standard assay and a humanized animal model. The epigenetic regulation in the Foxp3 locus has been analyzed by DNA methylation and histone acetylation.
Results atRA prevents human nTregs from converting to Th1 and/or Th17 cells and sustains their Foxp3 expression and suppressive function in vitro or in vivo following encountering with IL-1 and IL-6. Interestingly, adoptive transfer of human nTregs pre-treated with atRA significantly enhanced their suppressive effect on xeno-graft versus host diseases (xGVHD) and only these cells after stimulating with IL-1/IL-6 sustained the functional activity against xGVHD in a humanized animal model. atRA suppresses IL-1R upregulation and accelerates IL-6R downregulation and diminishes their signaling events, as well as increases histone acetylation on FOXP3 gene promoter and CpG demethylation in the region of Foxp3 locus (TSDR).
Conclusions These results strongly implicate that nTregs primed with atRA may represent a novel treatment strategy to control established chronic immune-mediated autoimmune and inflammatory diseases.

W6.04.05
Blockade of CCR6 and CCL20 interaction ameliorates arthritis and contact hypersensitivity reaction in mice

K. Muramoto*[1], A. Bender[2], T. Horizoe[3], M. Nishimura[1], T. Imai[1];*
[1]KAN Research Institute, Inc., Chuo-ku, Kobe, Hyogo, Japan, [2]Eisai Research Institute of Boston. Inc., 4 Corporate Drive, Andover, MA, United States, [3]Tsukuba Research Laboratories, Eisai Co., LTD., Tokodai, Tsukuba-shi, Ibaraki, Japan.

The immune response depends on the migration of leukocyte subsets, which track secreted chemokines via the activation of surface GPCRs. CCR6 is expressed to varying extents on effector memory T cells, mature B cells and immature dendritic cells and Th17 cells. It was reported that Th17 play an important role in arthritis models. So, to clarify the role of the CCR6-CCL20 pathway in experimental arthritis, the effects of an anti-CCL20 monoclonal antibody (mAb) on the collagen-induced arthritis model was investigated in mice. Anti-CCL20 mAb significantly inhibited the development of arthritis symptoms. We observed same result with CCR6 knockout mice. In this study, the infiltration of CD3+ T cells and F4/80+ macrophages was evaluated by immunohistochemical analysis. These infiltrating cells were decreased in CCR6 KO mice compared with WT mice. We also observed the suppressive effect of anti-CCL20 mAb in a contact hypersensitivity model, type IV allergic reaction. To evaluate migration of leukocytes, fluorescently labeled T cells from WT and CCR6 KO mice were injected into WT mice and then infiltrated cells were evaluated by imaging technology. There was no difference in edema formation between WT and KO mice, but infiltrating cells were decreased in the mice which CCR6 KO mice derived cells were injected. CCR6 KO mouse and application of anti-CCL20 antibody showed retardation of mouse arthritis development, suggesting that anti-CCL20 antibody could be a benefit to RA patients.

W6.04.06
The effect of CXCL10 blockade in C protein-induced myositis

Y. Song[1], *J. Kim*[2], *J. Choi*[1], *S. Chang*[1], *K. Shin*[1], *S. Park*[1], *E. Lee*[1], *E. Lee*[1], *H. Kawachi*[3], *H. Kohsaka*[4];
[1]*Seoul National University College of Medicine, Seoul, Republic of Korea,* [2]*Chungnam National University Hospital, Daejeon, Republic of Korea,* [3]*Institute of Nephrology, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan,* [4]*Graduate School, Tokyo Medical and Dental University, Tokyo, Japan.*

Background: CXCL10 (also called interferon-γ-inducible protein 10 [IP-10]) is a chemokine that plays a critical role in the infiltration of T cell in autoimmune diseases. CXCL10 is reported to be expressed in muscle tissue of polymyositis, thus we investigated the role of CXCL10 and the effect of CXCL10 blockade in C protein-induced myositis, an animal model of polymyositis.
Methods: C protein-induced myositis model was induced with human skeletal C protein fragment in 8-week-old female C57BL/6 mice. Immunohistochemistry was performed to detect CXCL10 and CXCR3, its receptor. CXCR3 in mouse splenocyte was investigated by flow cytometry. Migration assay of mouse splenocyte was performed with 5 μm pore transwell system. Mice with C protein-induced myositis were treated with anti-CXCL10 antibody or control IgG 8 days after the induction of myositis and the muscle inflammation was assessed 3 week after the induction.
Results: Immunohistochemistry showed the expression of CXCL10 and CXCR3 in the muscle of C protein-induced myositis. Flow cytometry demonstrated IFN-γ+ cells were increased among CXCR3+CD8+ T cells compared to CXCR3-CD8+ T cells (CXCR3+CD8+ T cell, 28.0 ± 4.2% vs. CXCR3-CD8+ T cell, 9.5 ± 1.5%, p = 0.016). Migration of splenocyte was increased in response to CXCL10 (chemotactic index=1.91±0.45). Treatment with anti-CXCL10 antibody (n=10) showed less inflammation score in muscles than treatment with control IgG (n=10; median [range], anti IP-10, 0.75 [0.25-2.00] vs. control IgG, 1.43 [1.125-4.25], p=0.045).
Conclusion: CXCL10 was expressed in the inflammation of C protein-induced myositis model and its blockade suppressed inflammation in muscle.

W6.05.01
Application of HLA classII peptide tetramers vs. allergen-induced proliferation for identification of allergen-specific CD4 T cells in the model of mugwort pollen allergy

B. Jahn-Schmid[1], *D. Van Hemelen*[1], *V. Mahler*[2], *I. Fae*[3], *G. Fischer*[3], *B. Bohle*[4];
[1]*Institute of Pathophysiology and Allergy Research, Vienna, Austria,* [2]*University of Erlangen, Erlangen, Germany,* [3]*Bloodgroup Serology, Medical University of Vienna, Vienna, Austria,* [4]*Institute of Pathophysiology and Allergy Research, Christian-Doppler Laboratory of Immunomodulation, Vienna, Austria.*

MHC-classII/peptide tetramer complexes are praised as tool to monitor antigen-specific CD4 T cells. The downsides of this costly technique are HLA-classII-polymorphism, the knowledge of immunodominant epitopes and scarcity of cells. Therefore, we investigated whether allergen-reactive T cells would identify a T cell subset comparable to tetramer-stained cells.
We used the HLA-DRB1*01:01/Artv1$_{19-36}$ tetramer, as Artv1, the major mugwort pollen-allergen, has only one single HLA-DR1-restricted epitope (Artv1$_{25-36}$). PBMC were obtained from mugwort-allergic patients. Artv1-reactive, dividing (CFSElo) T cells were studied at day 8 and compared to Artv1$_{25-36}$-specific T cell lines (TCL) established by Artv1-stimulation and expansion for 3-4 weeks.
Ex vivo characterization of tetramer$^+$ T cells was not possible due to low frequencies. The phenotype of tetramer+ and CFSElo CD4+ T cells was analyzed for cytokines and differentiation markers. Both, tetramer$^+$ cells in TCL and CFSElo T cells showed higher levels of Th2 cells duringallergen-specific treatment. The levels of Th1 cells tended to be higher in CFSElo compared to tetramer+T cells. Tetramer$^+$ cells in TCL showed an intermediate to highly differentiated phenotype compared to CFSElow T cells.
In summary, *ex vivo* analysis of allergen-specific CD4$^+$ T cells with MHC-classII tetramers for was hampered by their low frequency. Tetramer$^+$ T cells in long-term TCL maintained the original cytokine responses, but exhibited an altered, late differentiation phenotype. Although the CFSE-dilution method may also detect by-stander Th1 cells, earlier differentiation stages can be analysed. Therefore, it may be a more cost-/time-effective method to study allergen specific T cells when tetramer-staining *ex vivo* is not possible.

Allergy in the CIS-countries

R. Sepiashvili, *T. Slavyanskaya;*
People's Friendship University of Russia, Moscow, Russian Federation.

To summarize the results of the CIS-countries (CIS-C) research on the prevalence, structure and peculiarities of the course of allergic diseases (AD) for the last 5-10 years. in children(Ch), teenagers(Tg) and adults(Ad) living in industrial cities and rural areas. It was found out that the structure of AD of CIS-C is dominated by: bronchial asthma (BA), allergic rhinitis (AR), atopic dermatitis (AD), pollinosis (P). The average incidence of AD ranges from 15% to 40%. It was stated that 7% of 48.3% of the Ad and from 4% to 21% of Ch+Tg suffer from BA. The highest incidence of BA is reported in Tajikistan and Armenia. AR is diagnosed in 8%-34% of Ad and 4%-9% of Ch+Tg. Prevalence of symptoms of AR is particularly high in Armenia and Azerbaijan. The average incidence of AD in Ad is 5%-19%, in Ch+Tg- 5.3%. The high prevalence of AD is characteristic of Ukraine, Tajikistan and Kyrgyzstan. In Armenia and Tajikistan the level of AD diseases among Ch+Tg noted within 2.7%-4.7%. In Tajikistan and Armenia a significant number of patients is revealed with P, more often Ad are ill (15.7%-29.3%), Ch-4.3%-5.2%.In Armenia a significant incidence of allergic conjunctivitis is established among Ch+Tg (39.1%-62.2%), Ad-13.6%-32.9%. The structure of AD recorded by uptake, dominated the disease with medium-severe course. Monitoring of the true prevalence of AD shows hypodiagnostics of all forms of AD in the CIS-C, related to the underestimation of mild forms of the disease.

W6.05.02
Antibodies specific for the junction of CH4 domain and CεmX in membrane-bound IgE are potentially useful for down-regulating mIgE-B lymphocytes

C. Lin, *N. Chen, J. Chen, Y. Shiung, C. Lu, A. F. Hung, P. C. Wu, T. Chang;*
Genomics Research Center, Academia Sinica, Taipei, Taiwan.

It has been shown that membrane-bound IgE (mIgE) on B lymphocytes is essential for generating isotype-specific IgE response. The successful development of omalizumab, which neutralizes free IgE and binds to mIgE on B cells, as a treatment for allergic asthma has validated the IgE-mediated pathway as an effective therapeutic target for allergic diseases. The two mAbs, 4B12 and 47H4, which recognize their respective epitopes in the 52 a. a. CεmX, a discrete domain located between the CH4 and the C-terminal membrane-anchor peptide of the heavy chain of mIgE, are now in active development for the treatment of allergic diseases. Herein, we employed virus-like particles formed by hepatitis B virus core antigen that harbors a peptide segment encompassing a C-terminal segment of CH4 and an N-terminal segment of CεmX as an immunogen and generated mouse mAbs that are specific for linear epitopes representing the junction of CH4 and CεmX. One such mAb, 5A8, binds to SVNPGLAGGSAQSQRAP, of which SVNP is from the CH4 and GLAGGSAQSQRAP from CεmX. The mAb 5A8 cannot bind to secreted IgE and hence does not activate and degranulate IgE-pulsed human FcεRI-expressing rat basophilic leukemic cell line RBL SX-38 cells. Furthermore, 5A8 can mediate apoptosis and antibody-dependent cellular cytotoxicity of human mIgE-expressing B cell transfectoma Ramos and A20 cells. These results suggest that mAbs specific for the CH4-CεmX junction of mIgE can provide additional therapeutic candidates for the down-regulation of mIgE-B cells in allergic patients.

Mast cell-derived prostaglandin D_2 suppresses intestinal mastocytosis in food allergy

T. Nakamura[1], *S. Matsumoto*[1], *K. Aritake*[2], *M. Hori*[1], *H. Ozaki*[1], *Y. Urade*[2], *T. Murata*[1];
[1]*Department of Veterinary Pharmacology, Graduate School of Agriculture and Life Sciences, The University of Tokyo, Tokyo, Japan,* [2]*Department of Molecular Behavioral Biology, Osaka Bioscience Institute, Osaka, Japan.*

Objective:
Prostaglandin D_2 (PGD_2) is a major prostanoid secreted by mast cells. There have been controversial reports showing a pro- or anti-inflammatory role of PGD_2 in diverse allergy models. Its precise contribution in allergic inflammation remains unclear. We here investigated the role of PGD_2 in ovalbumin (OVA)-induced intestinal allergy using hematopoietic PGD synthase deficient (H-$PGDS^{-/-}$) mice.
Results: Oral administration of OVA induced allergic responses characterized by diarrhea, scratching, immovability, eye puffiness and piloerection in OVA-sensitized Wild-type (WT) mice. H-PGDS deficiency exacerbated all the OVA-induced allergic responses without changing in serum OVA-specific IgE level. Quantitative RT-PCR showed that H-PGDS deficiency did not influence the Th2-cytokine expressions, but it elevated TNF-α expression in the inflamed intestine. Morphological studies showed that c-kit/FcεRI-positive mast cells strongly expressed both H-PGDS and TNF-α in WT intestine. Of interest, H-PGDS deficiency greatly increased the mast cell-infiltration into intestine especially colonic mucosa. Administration of neutralizing antibody against TNF-α prevented the mastocytosis and exacerbation of allergic responses seen in H-$PGDS^{-/-}$.
Conclusion: We identified mast cell-derived PGD_2 as a negative regulator of mastocytosis and allergic responses in OVA-induced food allergy model. The PGD_2-mediated inhibition of TNF-α may be responsible for these phenomena.
Footnote: This work is supported by Programme for Promotion of Basic and Applied Researches for Innovations in Bio-oriented Industry.

W6.05.04
Robust long-term tolerance in IgE-mediated allergy through transfer of allergen-expressing bone marrow cells

U. Baranyi[1], *B. Linhart*[1], *A. M. Farkas*[1], *K. Hock*[1], *T. Rülicke*[2], *R. Valenta*[1], *T. Wekerle*[1];
[1]*Medical University of Vienna, Vienna, Austria,* [2]*University of Veterinary Medicine Vienna, Vienna, Austria.*

Objective: Robust and durable tolerance was established in IgE-mediated allergy towards the major grass pollen allergen Phlp5 by molecular chimerism. This strategy requires myelosuppressive conditioning of the recipient (i.e. irradiation). Here we investigated, if a tolerance protocol can be developed obviating the need for recipient conditioning.
Material and Methods: To this end we generated a novel transgenic mouse (on the Balb/c background) expressing Phlp5 ubiquitously on the surface. This transgenic mouse served as cell donor. Balb/c recipients were treated with a short-course of rapamycin (d-1,0,2) and costimulation blockade (CTLA4-Ig, d2) and transplanted with $15x10^6$ bone marrow (BM) cells isolated from Phlp5-transgenic mice. Subsequently, mice were challenged several times with splenocytes (+AlOH3) of transgenic mice and control allergen (Betv1, weeks 4,7,10 after BM transplantation [BMT]). Tolerance was analyzed by ELISA for allergen-specific isotypes and T-cell proliferation assays. Airway-hyperresponsiveness was determined by whole-body-plethysmography.
Results: Phlp5-specific IgE remained absent inrecipients of the full treatment protocol (e.g. w20 post BMT, 7/10), whereas controls transplanted with Phlp5-positive BM only developed high levels of anti-Phlp5 IgE. High levels of Betv1-specific IgE developed in both groups. Furthermore Phl p 5-specific T-cell proliferation was not detectable at the end of follow up (w35 post BMT). Additionally preliminary data reveal no airway hyperresponsiveness in BMT recipients in response to Phlp5 (6/6) compared to untreated sensitized controls (n=3).Conclusions: Transfer of allergen-bearing BM cells with costimulation blockade and short course rapamycin leads to robust tolerance without recipient conditioning. These data suggest that preventive cell-therapy is feasible with clinically acceptable toxicity.

W6.05.05
Sublingual immunotherapy induces regulatory T cells in cervical lymph node of murine allergic rhinitis model

H. Kawauchi[1], *T. Yamada*[1], *M. Tongu*[2], *Q. Infei*[1], *N. Aoi*[1], *I. Morikura*[1], *T. Fuchiwaki*[1], *F. Takaiwa*[3];
[1]*Department of Otorhinolaryngology, Shimane University, Faculty of Medicine, Izumo city, Japan,* [2]*Department of Experimental Animals, Center for Integrated Research in Science, Shimane University, Izumo city, Japan,* [3]**Plant Biotechnology Department, National Institute of Agrobiological Sciences, Tsukuba, Japan.*

Sublingual immunotherapy has been considered to be a painless and efficacious therapeutic treatment of allergic rhinitis which is known as type-I allergy of nasal mucosa. Nevertheless, its mechanisms need to be further investigated. In this study, we constructed an effective murine model of sublingual immunotherapy (SLIT) in allergic rhinitis, in which mice were sublingually administered with ovalbumin (OVA) followed by an intraperitoneal sensitization and nasal challenge of OVA. Sublingually treated mice showed significantly decreased allergic responses as well as suppressed Th2 immune responses. Sublingual administration of OVA did not alter the frequency of $CD4^+CD25^+$ regulatory T cells (Tregs), but led to up-regulation of Foxp3- and IL-10-specific mRNAs in the Tregs of cervical lymph nodes (CLN), which strongly suppressed Th2 cytokine production from $CD4^+CD25^-$ effector T cells *in vitro*. Furthermore, sublingual administration of plasmids encoding the lymphoid chemokines CCL19 and CCL21-Ser DNA together with OVA suppressed allergic responses. These results suggest that IL-10 expressing $CD4^+CD25^+Foxp3^+$ Tregs in CLN are involved in the suppression of allergic responses and that CCL19/CCL21 may contribute to it in mice received SLIT.

W6.05.06
Effective suppression of grass-pollen induced asthma manifestations by subcutaneous and sublingual immunotherapy in a mouse model

L. Hesse[1,2], *M. Nawijn*[1,2], *R. Gras*[1], *H. Oude Elberink*[2,3], *J. Brimnes*[4], *A. van Oosterhout*[1,2];
[1]*University Medical Centre Groningen, Groningen, Netherlands,* [2]*University of Groningen, GRIAC Research Institute, Groningen, Netherlands,* [3]*University Medical Center Groningen, Department Allergology, Groningen, Netherlands,* [4]*ALK-Abelló A/S, Department of Experimental Immunology, Hørsholm, Denmark.*

Allergic asthma is characterized by high levels of IgE, eosinophilic airway inflammation and airway hyperresponsiveness (AHR). Although specific immunotherapy is the only treatment providing long-term protection against allergic diseases, it needs further improvement to increase its efficacy. Previously, we developed a preclinical grasspollen (GP) model of asthma. Here, we aim to perform dose-finding experiments for subcutaneous- (SCIT) and for sublingual (SLIT) immunotherapy.
All Balb/c mice were sensitized with a crude extract of GP, after which we performed a dose-finding experiment (30, 100, and 300kSQ or placebo) for SCIT and SLIT. SCIT was given by three subcutaneous injections and SLIT by 40 sublingual administrations. Subsequently, mice were challenged intranasal three times on alternate days. Two days after the last challenge, we measured AHR to methacholine using FlexiVent, GP-specific IgE, IgG1, and IgG2a in serum, ear-swelling responses (ESR), eosinophils in broncho-alveolar lavage fluid (BALF) and T-cell cytokine release after re-stimulation of lung cells (IL-5, -10, and -13). In asthmatic mice, GP-challenge induced AHR, BALF eosinophilia, up-regulation of serum IgE levels and increased levels of Th2-type cytokines upon lung T-cell restimulation as compared to control mice. The highest dose of SCIT significantly decreased AHR and eosinophils in BALF, whereas ESR showed a trend for suppression. High dose-SLIT significantly suppressed AHR and ERS, and there was a trend for the suppression of BALF eosinophils. Interestingly, SCIT and SLIT have differential effects on

Th2-type cytokine production by lung cells. In conclusion, high dose-SLIT and SCIT effectively suppress asthma manifestations in an asthma mouse model.

Cell therapy of cancer with alloreactive intentionally mismatched IL-2 activated donor lymphocytes targeting anti-cancer killer NK & T cells using monoclonal and bispecific antibodies

S. Slavin[1,1]*, C. Brodie*[2]*;*
[1]*International Center for Cell Therapy & Cancer Immunotherapy (CTCI), Tel Aviv, Israel,* [2]*Faculty of Life Sciences, Bar Ilan University, Ramat Gan, Israel.*

Graft-vs.-leukemia or solid tumors effects following allogeneic stem cell transplantation (SCT) are well established, however, use of SCT may be hazardous and associated with unavoidble graft-vs-host disease (GVHD). We investigated whether short-term immunotherapy could be induced by intentionally mismatched alloreactive killer NK and T cells (IMAK), maximally activated with interleukin 2 with no SCT. Monoclonal and trifunctional bispecific antibodies (BSA) were used for targeting IMAK against antigens over-expressed on malignant cells confirmed efficacy of eradication of otherwise lethal inoculum of B16 melanoma while avoiding GVHD in mice. Successfully treated mice could also resist fresh tumor challenge, suggesting development of anti-cancer immunity by Fc binding of malignant cells to host dendritic cells and presentation to T cells cells. Commercially available monoclonal and BSA against target antigens (EGFR, VEGF, Her-2/neu, CD20, EpCAM) using Erbitux, Avastin, Herceptin, MabThera & Catumaxomab, respectively were used in a pilot clinical trial. We have confirmed that treatment of patients with hematologic malignancies and solid tumors with IMAK with (n=16) or without (n=40) targetting antibody is safe and potentially effective with no GVHD in patients with hematological malignancies and metastatic solid tumors. We are now investigating whether targeting of IMAK may be further improved using low energy acoustic shockwave therapy (AST) that may increase the perfusion of malignant tissue as well as increase binding of killer lymphocytes to cancer cells. Based on our cumulative experience we conclude that treatment with short-lived targeted IMAK may represent an effective future approach for personalized targeted cancer immunotherapy.

Examination of cancer testis antibodies and Th1/Th2 cytokines as prognosis markers in glioma patients treated with Delta-24-RGD oncolytic adenovirus

J. Fueyo*, F. Lang, C. Gomez-Manzano, A. Yung, R. Sawaya, C. Conrad;*
MD Anderson Cancer Center, Houston, TX, United States.

In a Phase I clinical trial of patients with recurrent gliomas treated with the intratumoral injection of Delta-24-RGD oncolytic adenovirus, we showed that a subset of patients had partial or complete responses as assessed by decrease of tumor volume or complete regression of the tumor mass in MRI images. These findings correlated with extended survival. Tissue samples and sera were examined to discover prognosis markers. Examination of the tumor tissue after the treatment showed that Delta-24-RGD replicates in gliomas. Importantly, spread of the virus caused tumor necrosis and recruitment of CD8 lymphocytes. We speculate that the trigger of an immune response after the injection of Delta-24-RGD, could be the cause for the tumor regression in some patients. Supporting this hypothesis, we showed a skew to Th1 response in patients with positive outcome. Thus, examination of cancer autoantibodies and Th1/Th2 cytokines in the serum of the patients enrolled in the clinical trial, showed that predominance of a humoral response (high titer of autoantibodies against cancer testis antigens) and lack of cytokine immune response, were associated with suboptimum outcome. On the contrary, high levels of Th1-related cytokines and lack of autoantibodies, seemed to potentially correlate with positive clinical outcome. This is the first study of the expression of anti-cancer related antibodies and Th1 cytokines in glioma patients treated with oncolytic viruses and suggest that it is possible to elucidate molecular markers to predict the clinical response to Delta-24-RGD. Our data could be relevant for any form of immunotherapy for solid tumors.

W6.06.02

Synergistic 4-1BB and CD28 costimulation enables CD19-targeted T cells to eliminate aggressive leukemia, in an IRF7-dependent manner

M. Condomines*, Z. Zhao, C. Kloss, M. Sadelain;*
Memorial Sloan-Ketterinig Cancer Center, New York, NY, United States.

Adoptive T-cell therapy using chimeric antigen receptor (CAR) engineered T cells is a promising cancer treatment. CARs include an scFv targeting a surface antigen and the CD3ζ chain to direct tumor cell killing. CAR- transduced T cells however need appropriate costimulation to proliferate and persist.
Here we assessed in a B-cell leukemia xenograft model the anti-tumor activities of human T cells transduced with an anti-CD19 CAR harboring either the zeta chain alone (19z1+) or CD3z fused to the CD28 or 4-1BB cytoplasmic domain (19-28z+, 19-BBz+), or co-expressed with 4-1BBL (19z1+4-1BBL+), or with 19-28z co-expressed with 4-1BBL (19-28z+4-1BBL+). At low T cell doses, we observed complete NALM-6 tumor regression in mice treated with 19-28z+4-1BBL+ T cells and no or partial regression in the other T-cell groups, as measured by bioluminescence imaging.19-28z+4-1BBL+ T cells showed the highest and longest bone marrow accumulation. Gene expression signatures of CD28 and/or 4-1BB costimulated T cells notably contained the transcription factors KLF2 and IRF7, solely overexpressed in T cells receiving dual costimulation. CD62L, described as directly regulated by KLF2, was overexpressed in 19-28z+4-1BBL+ T cells compared to 19-28z+ T cells. IRF7 and associated type I interferon-stimulated genes (ISG) were strongly expressed in 19-28z+4-1BBL+ CD4 and CD8 T cells. Using RNA interference, IRF7 down-regulation in 19-28z+4-1BBL+ T cells abolished their therapeutic activity due to decreased long-term survival.
Thus, concomitant CD28 and 4-1BB costimulation in human T cells induces the IRF7 pathway which is associated with the generation of long-lived tumor-reactive T cells capable of eradicating aggressive leukemia.

W6.06.03

Development of a tumor stem cell specific T-cell engaging antibody for the treatment of Glioblastoma multiforme

S. Prasad[1]*, S. Gaedicke*[1]*, M. Hettich*[1]*, E. Firat*[1]*, X. Zhu*[1]*, K. Klingner*[2]*, J. Schüler*[2]*,* ***G. Niedermann***[1]*;*
[1]*University Clinics Freiburg, Freiburg, Germany,* [2]*Oncotest GmbH, Freiburg, Germany.*

Glioblastoma multiforme is the most malignant form of primary brain tumor and is resistant to chemo- and radiotherapy. CD133 is a marker for glioblastoma stem cells which are thought to be responsible for tumor propagation and treatment resistance. We therefore developed a novel bispecific T-cell engaging antibody targeting CD133+ tumor stem cells in the format of a bispecific single chain variable fragment (bs-scFv). The recombinant antibody shows high binding to both CD133+ tumor cells and CD3+ human T cells. It also shows high cytotoxicity against CD133-overexpressing U251 glioma cells and primary patient-derived tumor stem cells *in vitro*. In immunodeficient mice, the bs-scFv antibody efficiently prevented the outgrowth of both subcutaneously implanted CD133-overexpressing glioma cells and primary CD133+ tumor stem cells, when co-implanted with human T cells. Tumor growth could also be efficiently prevented when CD133+ glioma cells were orthotopically co-implanted with human T cells into the brain of immunodeficient mice. In these experiments, the bs-scFv antibody was applied by continuous pressure-backed local infusion. In conclusion, tumor stem cell-directed T-cell recruiting antibodies might enlarge the armamentarium of therapeutics against highly aggressive, tumor stem cell-driven malignancies.

W6.06.04
Regeneration of Human Melanoma Antigen-Specific T cells from iPSCs Derived from Mature CD8+ T cells

***R. Vizcardo**, K. Masuda, D. Yamada, T. Ikawa, K. Shimizu, S. Fujii, H. Koseki, H. Kawamoto;*
RIKEN Yokohama, RCAI, Yokohama, Japan.

Antigen-specific T cells represent a potential therapeutic avenue for a variety of conditions, but current approaches for generating such cells for therapeutic purposes are limited. In this study, we established human induced pluripotent stem cells (hiPSCs) from mature cytotoxic T cells specific for the melanoma epitope MART-1. When cocultured with OP9/DLL1 cells, these hiPSCs efficiently generated TCRb+CD4+CD8+ double positive (DP) cells expressing a T cell receptor (TCR) specific for the MART-1 epitope. Stimulation of these DP cells with anti-CD3 antibody generated a large number of CD8+ T cells, and more than 90% of the resulting cells were specific for the original MART-1 epitope. Stimulation of the CD8+ T cells with MART-1 antigen-presenting cells led to the secretion of considerable ammount of IFNg, demonstrating their specific reactivity. The present study therefore illustrates an approach for cloning and expanding functional antigen-specific CD8+ T cells that might be applicable in cell-based therapy of cancer.

W6.06.05
Isolation of antigen-specific T cell receptor (TCR) genes and analysis of disease-associated TCR repertoires by TCR gene capture.

***C. Linnemann**[1], B. Heemskerk[1], P. Kvistborg[1], R. J. C. Kluin[1], D. A. Bolotin[2], R. M. Kerkhoven[1], M. Nieuwland[1], D. M. Chudakov[2], G. M. Bendle[1], T. N. M. Schumacher[1];*
[1]The Netherlands Cancer Institute, Amsterdam, Netherlands, [2]Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry RAS, Moscow, Russian Federation.

The transfer of T-cell receptor (TCR) genes into patient T-cells is a promising approach for the treatment of both viral infections and cancer. However, efficient strategies for TCRs gene isolation have thus far been lacking. Likewise, the study of TCR-repertoires related to different disease states has been limited to description of TCR Variable-gene usage and did not include assessing the properties of disease-associated TCRαβ pairs. To address these issues we have developed a high-throughput DNA-based TCR gene capture approach for the identification of TCR gene sequences of interest.
The approach involves the capture and sequencing of genomic DNA fragments encoding the TCRαβ gene-loci. The quantitative nature of the resulting next-generation-sequencing data reveals relative frequencies of all TCRα- and β-sequences and, because of this, TCRαβ pairs can be directly determined within oligoclonal T-cell populations, through 'frequency-based matching'.
We have exemplified the potential of TCR gene capture in two different applications. First, we demonstrate the possibility to rapidly assemble TCRαβ gene libraries against antigens of interest, in our case the Cancer/Germline (C/G) antigens that are frequently expressed in human tumors. Second, we demonstrate the ability to analyze TCR-repertoires of intratumoral T-cell subsets without knowledge of their antigen-specificity, and show that TCR gene capture can be used to identify dominant tumor-reactive TCRαβ pairs within such populations.
Taken together, our data shows that TCR gene capture can be used to describe the TCR-repertoire in diverse types of biological samples and to create large collections of TCR genes for genetic engineering of T-cell immunity.

W6.06.06
Glycoengineered defucosylated anti-CD20 antibodies activate neutrophils mediated phagocytosis more efficiently than rituximab

***J. Golay**[1], F. Da Roit[1], L. Bologna[1], C. Ferrara[2], J. H. Leusen[3], A. Rambaldi[1], C. Klein[2], M. Introna[1];*
[1]Laboratory of Cellular Therapy "G. Lanzani", Division of Haematology, Ospedale Papa Giovanni XXIII, Bergamo, Italy, [2]Roche Glycart, Schlieren, Switzerland, [3]Immunotherapy Laboratory, Department of Immunology, University Medical Center, Utrecht, Netherlands.

GA101 (obinutuzumab) is a glycoengineered, defucosylated anti-CD20 antibody with higher affinity for CD16A (FcγRIIIa) and stronger NK mediated antibody dependent cellular cytotoxicity activity (ADCC) than fully glycosylated rituximab (RTX) antibody. Polymorphonuclear leukocytes (PMN) express the homologous GPI-anchored CD16B (FcγRIIIb) molecule, which also shows enhanced affinity for glycoengineered antibodies, in addition to the activating CD32A (FcγRIIa) receptor. We have investigated the functional activity of human PMN in response to GA101 or defucosylated rituximab (G2), compared to the parent RTX antibody. We show that GA101 activated purified PMN more efficiently than RTX, leading to 50% increased CD11b expression and 70% down modulation of CD62L. This activation was not accompanied by generation of reactive oxygen species or by ADCC. In contrast, it was accompanied by up to 45% phagocytosis of opsonised targets and then followed by PMN death. Furthermore, significant phagocytosis (15% above background) could be observed in whole blood assays only in presence of defucosylated antibodies but not with unmodified antibodies, similarly to what was previously described for NK cell activation and ADCC. Finally, we demonstrated using blocking $F(ab)_2$ antibodies that the CD16B and CD32A FcγRs cooperate in PMN activation and phagocytosis of opsonised targets.
We conclude that phagocytosis of targets by PMN is an additional mechanism of action for anti-CD20 antibodies, which is more efficient with defucosylated compared to fully glycosylated parent molecules. Furthermore, these data may offer an explanation for the increased neutropenia observed in patients treated with GA101, therefore an effect likely to be related to its anti-lymphoma activity.

W6.06.07
FOXO3 regulates tumor-associated DC tolerogenicity by binding and sequestering NF-κB

***S. K. Watkins**[1], A. A. Hurwitz[2];*
[1]Loyola University Chicago, Maywood, IL, United States, [2]National Cancer Institute, Frederick, MD, United States.

Tumor-associated dendritic cells (TADC) are a major contributor of immune tolerance in the tumor microenvironment. We previously reported that the transcription factor FOXO3 is a critical mediator of TADC tolerogenicity and that silencing *Foxo3* expression promoted anti-tumor immunity. In the current study, we sought to identify the mechanism by which FOXO3 regulates TADC function. It was previously reported that FOXO3 to inhibits NF-kB activity in T cells through the transcriptional regulation of IkB proteins. In contrast, our data demonstrate that unlike in non-DC populations, FOXO3 was principally detected in the cytoplasm of TADC. Further analysis revealed that despite extensive phosphorylation, cytoplasmic FOXO3 was stable. These findings suggested that FOXO3 may not solely function as a transcriptional regulator. Instead, our findings show for the first time that FOXO3 binds both the RelA and p50 NF-kB subunits and sequesters them to the cytoplasm. The formation of this protein complex prevents nuclear translocation and downstream pro-inflammatory signaling by NF-kB. In the absence of FOXO3, NF-kB re-localizes to the nucleus and turns on expression of pro-inflammatory genes. We further demonstrate that NF-kB enhances cytoplasmic FOXO3 stability. These new insights into the regulation of DC tolerogenicity provide new potential targets for the enhancement of immune-based therapies for cancer, where FOXO3 may reduce pro-inflammatory activities of TADC.

W6.06.08
Host immunity contributes to the anti-melanoma activity of BRAF inhibitors

S. Ngiow[1,2,3], *D. A. Knight*[1,2], *M. Li*[1,2], *T. Parmenter*[2,4], *N. M. Haynes*[2,4], *K. Kinross*[2,4], *H. Yagita*[5], *A. Ribas*[6,7,8], *G. A. McArthur*[3,2,4], *M. J. Smyth*[1,2,3];
[1]*Cancer Immunology Program, Trescowthick Laboratories, Peter MacCallum Cancer Centre, Melbourne, Australia,* [2]*Sir Peter MacCallum Department of Oncology, University of Melbourne, Parkville, Melbourne, Australia,* [3]*Department of Pathology, University of Melbourne, Parkville, Melbourne, Australia,* [4]*Cancer Therapeutics Program, Trescowthick Laboratories, Peter MacCallum Cancer Centre, St. Andrews Place, Victoria, Melbourne, Australia,* [5]*Department of Immunology, Juntendo University School of Medicine, Tokyo, Japan,* [6]*Crump Institute for Molecular Imaging, UCLA, Los Angeles, CA, United States,* [7]*Department of Surgery, Division of Surgical Oncology, UCLA, Los Angeles, CA, United States,* [8]*Jonsson Comprehensive Cancer Center, UCLA, Los Angeles, CA, United States.*

The BRAF mutant, $BRAF^{V600E}$, is expressed in nearly half of melanomas, and oral BRAF inhibitors induce substantial tumor regression in patients with *$BRAF^{V600E}$* metastatic melanoma. The inhibitors are believed to work primarily by inhibiting $BRAF^{V600E}$-induced oncogenic MAPK signaling; however, some patients treated with BRAF inhibitors exhibit increased tumor immune infiltration, suggesting that a combination of BRAF inhibitors and immunotherapy may be beneficial. We used two relatively resistant variants of *BrafV600E* driven mouse melanoma (SM1 and SM1WT1) and melanoma-prone mice to determine the role of host immunity in type I BRAF inhibitor PLX4720 antitumor activity. We found that PLX4720 treatment downregulated tumor *Ccl2* gene expression and decreased tumor CCL2 expression in both transplanted *BrafV600E* mouse melanomas and in *de novo* melanomas, coincident with reduced tumor growth. While PLX4720 did not directly increase tumor immunogenicity, analysis of SM1 tumor-infiltrating leukocytes in PLX4720-treated mice demonstrated a robust increase in $CD8^+$ $T/Foxp3^+CD4^+$ T cell ratio and NK cells. Combination therapy with PLX4720 and anti-CCL2 or agonistic anti-CD137 antibodies demonstrated significant antitumor activity in mouse transplant and *de novo* tumorigenesis models. These data elucidate a role for host CCR2 in the mechanism of action of type I BRAF inhibitors and support the therapeutic potential of combining BRAF inhibitors with immunotherapy.

W6.06.09
Exploiting the good and blocking the bad: new strategies to convert the tumor into an in situ personalized vaccine

C. Vanpouille-Box, K. A. Pilones, M. L. Dustin, M. H. Barcellos-Hoff, S. C. Formenti, ***S. Demaria****;*
New York University School of Medicine, New York, NY, United States.

Ionizing radiation therapy (RT) has the potential to convert the tumor into an in situ, personalized vaccine, however this potential is rarely realized by RT alone. We have previously shown in mice models of poorly immunogenic tumors that the pro-immunogenic effects of RT can be exploited to improve the response to targeted immunotherapy strategies. For instance, effector T cell recruitment to the tumor by RT-induced CXCL16 chemokine and stabilization of interactions between CD8 T cells and tumor cells by RT-induced NKG2D ligands were critical for the therapeutic synergy of RT with anti-CTLA-4 antibody treatment (J Clin Invest 2012).
To determine if TGFβ, an immunosuppressive cytokine that is activated by RT, hinders the ability of RT to promote anti-tumor immunity we employed a mouse model of established metastatic carcinoma. Antibody-mediated neutralization of TGFβ did not have any effect by itself but improved significantly control of the irradiated tumor. CD8 T cells producing IFNγ in response to a tumor-specific antigen and inhibition of non-irradiated lung metastases were seen only in mice treated with RT+TGFβ blockade, but not each modality used alone. Depletion of $CD4^+$ or $CD8^+$ T cells abrogated the therapeutic benefit of the combination treatment. Notably, whole genome transcriptional analysis demonstrated the selective upregulation of genes associated with immune-mediated rejection only in tumors of mice treated with RT+TGFβ blockade. Data identify TGFβ as a master regulator of RT ability to generate an in situ tumor vaccine, and support testing inhibition of TGFβ during radiotherapy to promote therapeutically effective anti-tumor immunity.

A new class of iNKT cell agonist to harness tumor immunity

M. Terabe[1], *J. J. O'Konek*[1], *S. Kato*[1], *S. Takao*[1], *L. Izhak*[1], *Z. Xia*[1], *P. Illarinov*[2], *G. Besra*[2], *J. A. Berzofsky*[1];
[1]*NCI/NIH, Bethesda, MD, United States,* [2]*University of Birmingham, Birmingham, United Kingdom.*

Invariant (or type I) NKT (iNKT) cells are CD1d restricted T cells recognizing lipid antigens. iNKT cells enhance tumor immunity in mouse tumor models, especially when activated with the agonistic antigen α-GalCer. It also has been shown that IFN-γ is necessary for protection induced by α-GalCer. It was believed that that alpha-linked sugar moiety in α-GalCer's structure is essential for its anti-tumor activity. Here, we report a new class of iNKT cell tumor-protective agonistic antigen with a beta-linked sugar moiety, exemplified by β-ManCer. In both CT26 colon carcinoma and B16F10 melanoma lung metastasis models, we observed significant reduction of tumor burden in the lungs of β-ManCer treated mice compared to vehicle treated controls. In contrast to α-GalCer, β-ManCer still induced significant protection in IFN-γ-/- mice, whereas its protection was abrogated by blockade of TNF-α or NOS. Further, suboptimal doses of β-ManCer and α-GalCer synergized to induce protection. We conclude that β-ManCer protects against tumors through a pathway different from that induced by α-GalCer, defining β-ManCer as a new class of NKT cell agonist. We further observed that β-ManCer does not induce long lasting unresponsiveness or anergy of activated iNKT cells, which is known to be induced by α-GalCer. While prior treatment with α-GalCer completely abrogated the protective effect of either α-GalCer or β-ManCer against the CT26 lung metastasis, β-ManCer pretreatment did not affect the protection. Since β-ManCer can activate human NKT cells, this new NKT cell agonist may provide a novel opportunity for NKT cell-targeted immunotherapy in cancer.

W6.06.11
Naive-derived memory stem T cells: a novel promising platform for cancer immune-gene therapy

N. Cieri[1], *B. Camisa*[1], *F. Cocchiarella*[2], *M. Forcato*[3], *G. Oliveira*[1], *E. Provasi*[1], *A. Bondanza*[1], *F. Mavilio*[2], *A. Mondino*[1], *C. Bonini*[1];
[1]*San Raffaele Scientific Institute, Milano, Italy,* [2]*Center for Regenerative Medicine, Modena, Italy,* [3]*Center for Genome Research, Modena, Italy.*

Memory stem T cells (TSCM) with ability to self renew and plasticity to differentiate into potent effector cells represent ideal weapons to treat cancer. Nonetheless, clinical-grade procedures to target this T-cell population remain elusive. Here we report that it is possible and feasible to differentiate in vitro, vigorously expand and genetically engineer TSCM lymphocytes starting from naïve precursors. Requirements for the generation of this T-cell subset, defined as CD62L+CCR7+CD45RA+CD45R0+IL-7Rα+CD95+, are CD3/CD28 engagement and culture with low-dose IL-7/IL-15. The gene expression profile and functional phenotype validate this population as a distinct memory T lymphocyte subset, hierarchically superior to central memory (TCM) and effector memory (TEM) lymphocytes. To define naive-derived TSCM function and potential in a clinically relevant context, we evaluated their ability to mediate xenogeneic GvHD in vivo. Naïve-derived TSCM prove superior in vivo expansion and persistence than TCM counterparts, and are able to differentiate into effector cells, mediating a lethal xenogeneic GvHD with the same kinetics and intensity of unmanipulated lymphocytes. TSCM are the only T-cell subset able to engraft and mediate GvHD upon serial transplantation, thus demonstrating self-renewal abilities. Furthermore, TSCM lymphocytes are less sensitive to CD95-mediated apoptosis compared to memory counterparts, and do not express the inhibitory molecule PD-1. Finally, we identified and functionally validated the natural counterpart of our gene-modified TSCM population in healthy donors as a rare fraction of naive T cells, recapitulating the CD62L+CCR7+CD45RA+CD45R0+IL-7Rα+CD95+ phenotype. Our findings pave the way for a rapid clinical translation of

cancer immunotherapy approaches based on ex-vivo generated TSCM lymphocytes.

W6.06.12
Conditioning tumor microenvironments for effective entry and function of effector T cells

P. Kalinski[1], *R. Muthuswamy*[1], *N. Obermajer*[1], *H. J. Zeh*[1], *A. Zureikat*[1], *K. Odunsi*[2], *R. Edwards*[1], *D. Bartlett*[1];
[1]*University of Pittsburgh Cancer Institute, Pittsburgh, PA, United States,* [2]*Roswell-Park Cancer Institute, Buffalo, NY, United States.*

The desirable effector cells of antitumor immunity (CTLs, Th1 and NK cells) express high levels of "type-1" chemokine receptors CXCR3 and CCR5 and depend on their chemokine ligands (CXCL9, CXCL10 and CCL5) for effective entry into tumors. We observed that prostaglandin E_2 (PGE_2), a ubiquitous mediator of cancer-associated inflammation, suppresses the induction of immune effector cells and enhances local development and function of myeloid-derived suppressor cells (MDSCs). In addition, PGE_2 selectively inhibits the production of the effector cell-attracting chemokines within ovarian and colorectal cancers and promotes the MDC/CCL22- and SDF1/CXCL12-mediated accumulation of Tregs and myeloid-derived suppressor cells (MDSCs) in tumor tissues, orchestrating local inhibition of CTL function.
Blockers COX2 activity and selective antagonists of PGE_2 receptors (EP2 and EP4) antagonized the migration and immunosuppressive function of MDSCs and were necessary (although not sufficient) to restore local immune surveillance. While TLR-ligands used as stand-alone adjuvants were effective only in selected tumor samples and, in some cases, amplified the PGE_2-driven suppressive events, their combination with COX2 inhibitors and IFNα allowed to selectively induce effector cell-attracting chemokines within tumors (rather than marginal tissues) and suppressed the local production of the MDSC- and Treg-attracting CXCL12 and CCL22. Tumor-selectivity of the chemokine modulation by the combination of TLR3 ligands, IFNα and Celecoxib resulted from the preferential activation of NF-κB in tumor-associated fibroblasts and myeloid cells, the main chemokine sources in tumor tissues.
The safety and effectiveness of tumor-selective conditioning of tumor microenvironments is being currently tested in our phase I/II clinical trials.

W6.06.13
A bi-institutional pilot study of peptide-based vaccines in combination with poly ICLC in patients with WHO grade 2 low-grade glioma

H. Okada[1], *L. H. Butterfield*[1], *R. L. Hamilton*[1], *M. O. Lively*[2], *M. D. Chan*[2], *A. M. Salazar*[3], *D. M. Potter*[1], *E. G. Shaw*[2], *F. S. Lieberman*[1];
[1]*University of Pittsburgh, Pittsburgh, PA, United States,* [2]*Wake Forest University, Winston-Salem, NC, United States,* [3]*Oncovir, Inc., Washington, DC, United States.*

Adults with WHO grade 2 low-grade glioma (LGG) have a significant risk of tumor progression, especially via transformation to high-grade glioma (HGG), and most patients eventually die of the disease. We conducted a pilot study of subcutaneous vaccinations with synthetic peptides for glioma-associated antigen (GAA) epitopes emulsified in Montanide-ISA-51 and intramuscular administration of poly-ICLC in HLA-$A2^+$ patients with: newly diagnosed high-risk LGG without prior radiation therapy (RT) (Cohort 1); newly diagnosed high-risk LGG with prior RT (Cohort 2); or recurrent LGG (Cohort 3). Primary endpoints were safety and $CD8^+$ T-cell responses against vaccine-targeted GAAs: IL-13Rα2, EphA2, WT1, and Survivin. Cohorts 1, 2, and 3 have enrolled 12, 1, and 10 patients, respectively. No regimen-limiting toxicity has been encountered except for one case with Grade 3 fever (Cohort 1). ELISPOT assays, completed in 7, 1 and 7 patients in Cohorts 1, 2 and 3 respectively, demonstrated robust and sustained IFN-γ responses against at least 3 of the 4 GAAs in 6 and 3 cases of Cohorts 1 and 3, respectively. Cohort 1 patients demonstrated significantly higher magnitude of IFN-γ responses than Cohort 3 patients for all 4 GAA epitopes, suggesting that newly diagnosed patients may have better vaccine-responsiveness than recurrent patients. Median progression-free survival periods are 21 months (Cohort 1; since diagnosis; range 10-38) and 12 months (Cohort 3; since the 1st vaccine; range 3-14). The only patient in Cohort 2 with large astrocytoma has been progression-free for over 48 months since diagnosis. These data warrant further evaluation of the regimen.

Entire requirement of endogenous type I Interferon for the efficacious cancer treatment with viral vector-encoded IL-12

S. Hervas-Stubbs[1], *J. I. Quetglas*[1], *U. Mancheño*[1], *E. Casales*[1], *J. I. Riezu-Boj*[1], *M. C. Ochoa*[1], *M. F. Sanmamed*[1], *N. Thieblemont*[2], *C. Smerdou*[1], *I. Melero*[1];
[1]*Fundacion para la Investigacion Medica Aplicada, Pamplona, Spain,* [2]*Centre National de la Recherche Scientifique (CNRS-UMR 8147), Université René Descartes Paris V, Hôpital Necker, Paris, France.*

To date little is known about how the innate Interferon (IFN)-α/β response affects the efficacy of cancer treatments based in viral vector delivery of therapeutic genes. Using Semliki Forest virus encoding IL-12 (SFV/IL-12) we have explored this. Intratumoral injection of SFV/IL-12 induces production of IFNα/β that is readily detected in serum. Such production is abolished in interferon-beta promoter stimulator 1 (IPS1)ko mice and to some extent in TIR-domain-containing adapter-inducing IFN-β (TRIF)ko mice. Using bone-marrow chimeric mice we show that both hematopoietic and stromal cells are involved in the IFNα/β response. Macrophages, plasmacytoid and conventional dendritic cells are all implicated in the IFNα/β production, as was revealed by depleting experiments. The therapeutic activity of SFV/IL-12 against MC38 tumor is absolutely lost in mice deficient for the IFNα/β receptor (IFNAR) and when IFNAR signaling is blocked in vivo with anti-IFNAR mAb. This is also true for TC1 tumor. The lack of efficacy is not related to an impaired expression of IL-12 because IFNARko mice even express higher levels of the transgene. IFNAR absolute requirement is mainly operational at hematopoietic-derived cells. Interestingly, tumor-specific CTLs are outstandingly expanded upon SFV/IL-12 intratumoral injection to WT mice, but this does not happen when tumor-bearing mice are IFNARko, or have been treated with anti-IFNAR mAb. All in all, our data show that the efficacy of tumor immunotherapy with SFV/IL-12 is totally dependent on IFNs-I and unravels an unexpected mechanism of action of a therapy that is being translated to patients.

W6.07 Cell-based therapy

IL6.07.01
Cell therapy to induce tolerance: which cell type should we use?

G. Lombardi[1], *R. Lechler*[2];
[1]*Medical Research Council (MRC) Centre for Transplantation, King's College London, King's Health Partners, Guy's Hospital, London, United Kingdom,* [2]*Medical Research Council (MRC) Centre for Transplantation, King's College London, King's Health Partners, Guy's Hospital, London, Italy.*

Different mechanisms are active in the periphery to guarantee that tolerance to self-antigens is maintained. The most important mechanism is regulation in which specialized T cells, called regulatory T cells (Tregs), control the immune responses to autoantigens.
Tregs can be divided into two groups: naturally occurring (thymus-derived Tregs-nTregs) and induced or adaptive (iTregs) each with different functions.
In recent years many laboratories worldwide have started to develop strategies to tilt the balance between effector T cells and Tregs in favor of the latter to achieve tolerance. Two different approaches have been used to increase the number of Tregs. The first is the injection of different agents or cells that are able to induce/expand Tregs *in vivo*. Among these, dendritic cells (DCs) manipulated *in vitro* to become "tolerogenic" and mesenchymal stem cells (MSC).
The second approach involves the injection of either freshly isolated or *in vitro* expanded nTregs or iTregs. Three clinical trials have been already completed with nTregs to prevent GvHD showing that Treg

therapy is safe. Our laboratory has been involved in the polyclonal expansion of clinical grade nTregs and we are ready for the first clinical trials with nTregs in kidney and liver transplant patients. In the last few years other populations of cells with regulatory properties have emerged with the potential to be used in cell therapy (e.g. B cells and macrophages). Whether any of these cell types will dominate the scenes of cell therapy in the future is still an open question.

W6.07.01
Human CD8+ regulatory T cells inhibit GVHD and preserve general immunity in humanized mice

J. Zheng[1], *Y. Liu*[1], *Y. Liu*[1], *M. Liu*[2], *Z. Xiang*[1], *K. Lam*[1], *D. B. Lewis*[3], *Y. Lau*[1], *W. Tu*[1];
[1]*Dept. of Paediatrics & Adolescent Medicine, The University of Hong Kong, Hong Kong, Hong Kong,* [2]*Guangzhou Institute of Respiratory Diseases, Guangzhou Medical College, Guangzhou, China,* [3]*Division of Immunology and Allergy, Department of Pediatrics, Stanford University School of Medicine, Stanford, CA, United States.*

Graft-versus-host disease (GVHD) is a lethal complication of allogeneic bone marrow transplantation (BMT). Immunosuppressive agents are currently used to control GVHD but may cause general immune suppression and limit the effectiveness of BMT. Adoptive transfer of regulatory T cells (Tregs) can prevent GVHD in rodents, suggesting a therapeutic potential of Tregs for GVHD in humans. However, the clinical application of Treg-based therapy is hampered by the low frequency of human Tregs and the lack of a reliable model to test their therapeutic effects in vivo. Recently, we successfully generated human alloantigen-specific $CD8^{hi}$ Tregs in a large scale from antigenically naïve precursors ex vivo using allogeneic CD40-activated B cells as stimulators. We report a human allogeneic GVHD model established in humanized mice to mimic GVHD after BMT in humans. We demonstrate that ex vivo-induced $CD8^{hi}$ Tregs controlled GVHD in an allospecific manner by reducing alloreactive T cell proliferation as well as decreasing inflammatory cytokine and chemokine secretion within target organs through a CTLA-4-dependent mechanism in humanized mice. These $CD8^{hi}$ Tregs induced long-term tolerance effectively without compromising general immunity and graft-versus-tumor activity. Our results support testing of human $CD8^{hi}$ Tregs in GVHD in clinical trials.

W6.07.02
Therapeutic efficacy of human Mesenchymal Stromal Cells in a humanised mouse model of acute Graft versus Host Disease

K. English*, L. Tobin, M. Healy, B. P. Mahon;*
National University of Ireland Maynooth, Co Kildare, Ireland.

Mesenchymal stromal cells (MSC) are a heterogenous population of cells first identified in the bone marrow. MSC have the capacity to modulate the immune response both in vitro and in vivo. Based on a large body of data, autologous and allogeneic *ex vivo* expanded human MSC have been used to treat a number of inflammatory diseases including acute graft versus host disease (aGvHD) with promising results. However, the exact mechanisms of therapeutic action are unclear. Acute graft versus host disease (aGvHD) is a life threatening complication following allogeneic haematopoietic stem cell transplantation (HSCT), occurring in up to 50% of patients receiving HLA-matched sibling transplants. Current therapies focus on corticosteroids, however in cases of steroid refractory aGvHD, there are limited therapeutic options leading to poor patient prognosis. This study utilised a robust humanised mouse model of aGvHD based on delivery of human peripheral blood mononuclear cells (PBMC) to NOD-scid IL-2rγ^{null} (NSG) mice. This novel model allowed the investigation of the role of MSC in cell therapy. MSC therapy significantly increased survival and reduced liver and gut pathology associated with aGvHD. MSC therapeutic efficacy was dependent on the timing of MSC administration with un-stimulated MSC proving effective only after delayed administration. In contrast, IFNγ stimulated MSC were effective when delivered with PBMC on day 0. Interestingly, MSC did not inhibit donor PBMC chimerism, as $CD45^{+}$ and T cells successfully engrafted in this model. However, in this model MSC inhibited donor $CD4^{+}$ T cell proliferation and reduced human TNFα in the serum.

W6.07.03
Induction of donor-specific tolerance in organ transplantation using in vitro-generated immunosuppressive myeloid blood cells

C. Kleist[1], *F. Sandra-Petrescu*[1,2], *L. Jiga*[3], *L. Dittmar*[1], *E. Mohr*[1], *J. Greil*[4], *G. Opelz*[1], *P. Terness*[1];
[1]*University of Heidelberg, Institute for Immunology, Department of Transplantation Immunology, Heidelberg, Germany,* [2]*University of Heidelberg, University Medical Center Mannheim, Department of Surgery, Mannheim, Germany,* [3]*Victor Babes University of Medicine and Pharmacy, Department of Vascular Surgery, Division of Reconstructive Microsurgery, Timisoara, Romania,* [4]*University of Heidelberg, Center for Child and Adolescent Medicine, Department of Hematology and Oncology, Heidelberg, Germany.*

Immunosuppressive treatment in organ transplantation improves graft survival but causes serious side effects. Cell therapeutic approaches for induction of antigen-specific tolerance are on the rise.
Monocytes are one source of dendritic cells (DCs). We observed that when DCs are generated from monocytes preincubated with the chemotherapeutic drug Mitomycin C, myeloid cells (M-MCs), which suppress allogeneic T cell responses, are resulting. T lymphocytes which had encountered M-MCs could not be restimulated. Interestingly, M-MCs resemble morphologically and phenotypically myeloid-derived suppressor cells which occur in cancer patients. Analyses of M-MCs revealed downregulation of immunostimulatory cell surface molecules and upregulated transcription of immunosuppressive and pro-apoptotic genes.
We further analyzed the immunosuppressive property of M-MCs *in vivo*. For practical reasons MMC-treated peripheral blood mononuclear cells (PBMCs), containing a substantial proportion of monocytes, were used. In a rat heart transplant model a single treatment of recipients with MMC-treated donor PBMCs one week before transplantation resulted in a significant prolongation of allograft survival, 50% of recipients becoming tolerant. Importantly, rejection of third-party allografts revealed donor-specific tolerance. Depletion of monocytes from PBMCs abrogated the immunosuppressive effect, proving the essential role of these cells. Similar results were obtained in a kidney transplant model in pigs. Furthermore, in a compassionate treatment, a 6-year-old girl with acute lymphatic leukemia and therapy-resistant rejection of a haploidentical stem cell transplant received MMC-treated donor monocytes, after which the signs of rejection disappeared.
In conclusion, we have developed a therapeutic approach to specifically inhibit organ rejection episodes. A transfer into the clinic is possible.

Gene Therapy mediated by lentiviral vector transduced CD34+ cells for the treatment of Wiskott-Aldrich Syndrome

S. Scaramuzza[1], *F. Ferrua*[2], *M. C. Castiello*[1,3], *S. Giannelli*[1], *L. Biasco*[1], *F. Ciceri*[4], *M. G. Roncarolo*[1,2,3], *A. Villa*[1,5], *L. Naldini*[1,3], *A. Aiuti*[1,2,6];
[1]*San Raffaele Telethon Institute for Gene Therapy (HSR-TIGET), Milan, Italy,* [2]*Pediatric Immunology, Scientific Institute HS Raffaele, Milan, Italy,* [3]*Università Vita-Salute San Raffaele, Milan, Italy,* [4]*Division of Hematology, Scientific Institute HS Raffaele, Milan, Italy,* [5]*IRGB-CNR, Milan, Italy,* [6]*University of Rome Tor Vergata, Rome, Italy.*

Wiskott-Aldrich Syndrome (WAS) is an X-linked immunodeficiency characterized by thrombocytopenia, infections, autoimmunity and lymphomas. Gene therapy with ex vivo transduced hematopoietic stem cells could represent a valid therapeutic option to transplantation. We developed an approach based on a lentiviral vector (LV) encoding for WAS under the control of the homologous 1.6 kb WAS promoter. We designed a phase I/II clinical trial based on infusion of autologous transduced CD34+ cells derived from bone marrow (BM) or mobilized peripheral blood (PB) and reduced intensity conditioning. Transduction of clonogenic progenitors was

highly efficient (94.4 ± 4.2%), with a mean vector copy number (VCN)/genome in bulk CD34+ cells of 2.7 ± 0.98. In the first 3 treated patients, at the latest follow up, robust multilineage engraftment was observed in BM (VCN in myeloid lineages: 0.36-0.78) including clonogenic progenitors (25.8-48.2%), and in PB cells (VCN range of 0.30-1.30 in myeloid cells). As expected, a selective advantage was observed in lymphoid lineages (VCN: 0.93-2.04 and WASP+ cells: 70.9 ± 4.8%). TCR repertoire, proliferative responses to anti-CD3, and NK cytotoxic ability were improved. WASP expression was also observed in the majority of platelets. All patients are currently clinically well and independent from platelet transfusions.
In conclusion, the unprecedented level of gene transfer obtained with LV-WAS resulted in robust engraftment of transduced HSC even when combined to reduced intensity conditioning. The ongoing follow up will allow to establish the long-term safety and clinical efficacy of LV gene therapy for WAS.

W6.07.05
Multifunctional CD26hi Th17 cells eradicate large human tumors

M. H. Nelson[1]*, L. Huff*[1]*, S. Kundimi*[1]*, M. Goodyear*[2]*, S. R. Bailey*[1]*, C. M. Paulos*[1]*;*
[1]*Medical University of South Carolina, Charleston, SC, United States,* [2]*College of Charleston, Charleston, SC, United States.*

Human $CD4^+$ T cells differentiate into multiple effector subsets, but their distinct roles in anti-tumor immunity remain elusive. $CD4^+$ T cell subsets enriched from bulk human $CD4^+$ T cells [Th1 ($CXCR3^+$), Th2 ($CCR4^+$), and Th17 ($CCR6^+$ or $CD26^{hi}$)] were stimulated with anti-CD3 beads bearing agonists to either CD28 or ICOS and were then engineered with a chimeric antigen receptor that recognizes human mesothelioma. *In vitro*, ICOS costimulation proved superior to CD28 for augmenting the function of human Th1, Th2, $CCR6^+$ Th17 and $CD26^{hi}$ Th17 cells, as indicated by elevated production of IFN-γ, IL-4 and IL-17A, respectively. Moreover, $CD26^{hi}$ Th17 cells possessed strikingly enhanced polyfunctionality compared to Th1, Th2 or $CCR6^+$ Th17 cells, as demonstrated by their heightened capacity to co-secrete IL-17A, IFN-γ, IL-22, IL-2, and TNF-α simultaneously. Compared to other enriched T cell subsets, a greater percentage of $CD26^{hi}$ Th17 cells exhibit an effector memory phenotype. Additionally, $CD26^{hi}$ Th17 cells expressed higher levels of ICOS, but lower levels of the regulatory-associated molecule CD39 on their cell surface than the other subsets. *In vivo,* $CD26^{hi}$ Th17 cells more efficiently reconstituted immunodeficient hosts and persisted long-term. Furthermore, $CD26^{hi}$ Th17 cells possessed a superior ability to kill large human tumors (>150mm^2) when infused into mice compared to Th1, Th2 or $CCR6^+$ Th17 cells. These results suggest that the generation of multifunctional, long-lived human Th17 populations could be instrumental to the design of novel, effective T cell-based cancer therapies.

Identification of an alternative specificity for engineered T cells expressing an enhanced affinity MAGE-A3 TCR

B. K. Jakobsen[1]*, B. J. Cameron*[2]*, A. B. Gerry*[1]*, J. Dukes*[2]*, J. V. Harper*[2]*, E. A. Stadtmauer*[3]*, A. P. Rapoport*[4]*, C. H. June*[3]*, N. J. Hassan*[2]*, M. Kalos*[5]*;*
[1]*Adaptimmune Ltd., Abingdon, United Kingdom,* [2]*Immunocore Ltd., Abingdon, United Kingdom,* [3]*Abramson Cancer Center and Department of Pathology and Laboratory Medicine, University of Pennsylvania, Philadelphia, PA, United States,* [4]*The Greenebaum Cancer Center, University of Maryland, Baltimore, MD, United States,* [5]*Translational and Correlative Studies Laboratory, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA, United States.*

MAGE-A3 belongs to the family of cancer testis antigens and is considered an ideal target for adoptive therapy given its re-activation in various tumours and limited normal tissue expression. We developed an affinity optimised T cell receptor (TCR) specific for the HLA-A1 MAGE-A3 antigen for use in adoptive therapy. Pre-clinical studies indicated no off-target concerns and a clinical study in melanoma and multiple myeloma was initiated. Four days following administration the first patient died. The resulting autopsy revealed ASCVD with two prior silent MIs. Death was attributed to hemorrhagic MI precipitated by demand ischemia and review by the FDA allowed the study to be reopened. Infusion of the second patient resulted in cardiogenic shock and death at day 5. Immunohistochemical evaluation of the heart revealed T cell infiltrates; however, MAGE-A3 was not detected in cardiomyocytes or heart autopsy tissue. Post-mortem investigations did not reveal cross-reactivity against an array of cardiac cells. However, beating cardiomyocytes derived from induced pluripotent stem (iPS) cells triggered T cell killing. Using amino acid scanning, a peptide from the protein Titin was identified as an alternative target for the MAGE A3 TCR. Titin expression in iPs derived cardiomyocytes was confirmed and the displayed peptide was identified by mass spectrometry indicating targeting to Titin as the likely cause of *in vivo* toxicity. The results indicate recognition of similar but unrelated peptides by TCRs presents a safety risk for T cell-based therapies and highlights the requirement for preclinical studies to mitigate these risks in future clinical studies.

W6.08 Stem cells in immunity

IL6.08.01
Harnessing stem-cell like memory T cells for adoptive cell transfer therapy of cancer

L. Gattinoni*;*
National Cancer institute, Bethesda, MD, United States.

Stem cells are defined by the ability to self-renew and to generate differentiated progeny, qualities that are maintained by evolutionarily conserved pathways that can lead to cancer when deregulated. There is now evidence that these stem cell-like attributes and signaling pathways are also active in subsets of antigen experienced memory T lymphocytes, especially in T memory stem cells and IL-17-producing CD4+ and CD8+ T cells. Here, we will discuss how using stem cell-like T cells can overcome the limitations of current adoptive T cell therapies, including inefficient T cell engraftment, persistence and ability to mediate prolonged immune attack. Conferring stemness to naturally occurring or genetically engineered antitumor T cells by activation of pathways governing stem cell behavior or reprogramming terminally differentiated T cells with stem cell-associated transcription factors and microRNAs could unleash the full potential of cellular therapies and enable cancer immunotherapists to fight 'fire with fire' with ever increasing effectiveness.

W6.08.01
Potential roles for adipose-derived mesenchymal stem cells in the regulation of the mucosal immune system in aging

K. Aso[1]*, K. Kimura*[2]*, K. Takagaki*[3]*, T. Kobayashi*[2]*, K. Oki*[3]*, S. Sugimoto*[3]*, H. Tanemura*[3]*, N. Urushihata*[3]*, J. R. McGhee*[1]*,* ***K. Fujihashi***[1]*;*
[1]*University of Alabama at Birmingham, Birmingham, AL, United States,* [2]*Nihon University, School of Dentistry at Matsudo, Matsudo, Japan,* [3]*Seems Inc., Tokyo, Japan.*

Various clinical trials have shown the regenerative capacity of adipose-derived stem cells to differentiate into blood cells, epithelial cells, adipocytes, chondrocytes, and osteoblasts. Age-associated dysregulation of the gastrointestinal (GI) immune system has also been well documented. It has been shown that antigen (Ag)-specific secretory IgA (SIgA) antibody (Ab) responses in the GI tract are impaired in aged mice. In this study, we have examined the potential of adipose-derived mesenchymal stem cells (AMSCs) to restore the GI mucosal immune system in aged mice. One year-old mice were adoptively transferred with AMSCs (2 x 10^6 /mouse). Eight to ten months later, mice were orally immunized with ovalbumin (OVA, 1 mg) plus cholera toxin (10 μg) as mucosal adjuvant three times at weekly intervals. When fecal extracts and plasma were subjected to OVA-specific ELISA, elevated levels of mucosal SIgA and plasma IgG Ab responses were noted in aged recipients. When OVA-stimulated $CD4^+$ T cell cytokine production was examined, Peyer's patch $CD4^+$ T cells produced increased levels of IL-4. Further, $CD4^+$ T cells from GI tract lamina propria revealed elevated levels of IFN-γ and IL-4 production. In contrast, aged mice without AMSC transfer

showed essentially no OVA-specific Ab or $CD4^+$ T cell cytokine responses. Interestingly, total numbers of thymocytes and the frequency of double negative cells were increased in aged mice with AMSC transfer when compared with aged mice without AMSC transfer. These results show major roles for AMSCs in restoring impaired mucosal immunity and the thymus in aged mice.

W6.08.02
Clinical effects of intraperitoneal Mesenchymal stem cells and Mesenchmal stem cells - derived Neural Progenitor Cells in a chronic experimental model of multiple sclerosis

F. Nasri[1], *T. kalantari*[1], *M. S. Mohtasebi*[1], *F. Taki*[1], *E. kamali sarvestani*[2];
[1]*Shiraz University of Medical Sciences, Shiraz, Iran,* [2]*Shiraz University of Medical Science, Autoimmune Disease Research Center, Shiraz, Iran.*

Mesenchymal stem cells (MSCs) and neural stem cells have been shown to have immunoregulatory and regenerative potential. In this study we investigated the therapeutic effects of injection of mice Bone Marrow-derived MSCs and MSCs-derived neural progenitor cells (NPCs) in chronic experimental autoimmune encephalomyelitis (EAE), a well known animal model for multiple sclerosis. In this study, 1x106 MSCs or NPCs or a combination of MSCs and NPCs were injected intraperitoneally at the peak of disease (on day 22) into three EAE groups of mice and clinical scores, antigen-specific ex vivo proliferation of T cells as well as IFN-g, IL-10 and IL-17 secretion by splenocytes were assessed to evaluate the in vivo immunomodulatory effects of MSCs and NPCs. Clinical scores were significantly decreased in MSCs (1.6±0.17), NPCs (1.1±0.29) and MSCs+NPCs (1.1±0.36) treated groups compared to those of EAE control group (2.4±0.26) received PBS injection (p=0.001). Interestingly, in NPCs and MSCs+NPCs-treated groups continued clinical score improvement were observed without relapsing and worsening of EAE. In addition, in comparison to EAE control mice, injection of NPCs has resulted a significant decrease in proliferation of MOG-specific CD4+ T cells (p=0.001), reduced splenocytes-derived IFN-γ (1600 ±31 pg/mL and 200± 15 pg/mL, respectively; p=0.009) and IL-17 (108±506 for EAE control mice and 27±5.6 for NPCs, respectively; p=0.01) production as well as augmentation of IL-10 production (p=0.03). In conclusion, our study demonstrated that MSCs-derived NPCs are therapeutically more efficient than MSCs in the treatment of chronic EAE and their immunomodulatory potentials might be involved in this phenomenon.

W6.08.03
Interferon-gamma impairs the self-renewal of hematopoietic stem cells during viral infection

A. M. de Bruin[1], *B. Hooibrink*[1], ***M. A. Nolte***[2];
[1]*AMC, Amsterdam, Netherlands,* [2]*Sanquin, Amsterdam, Netherlands.*

Balancing the processes of hematopoietic stem cell (HSC) differentiation and self-renewal is critical in maintaining life-long supply of blood cells. The bone marrow (BM) produces a stable output of newly generated cells, but immunological stress conditions inducing leukopenia increase the demand for peripheral blood cell supply. An important mediator in this respect is the pro-inflammatory cytokine Interferon-gamma (IFN-γ), which is produced in the bone marrow by activated T cells during the course of a viral infection. Here we demonstrate that IFN-γ impairs the maintenance of HSCs by directly reducing their proliferative capacity both in vitro and in vivo, and that IFN-γ impairs restoration of HSC numbers upon viral infection. We show that IFN-γ reduces thrombopoietin (TPO)-mediated phosphorylation of STAT5, which is an important positive regulator of HSC self-renewal. Furthermore, IFN-γ deregulates the expression of the STAT5-mediated cell cycle genes CyclinD1 and p57. Interestingly, on more committed progenitors IFN-γ rather induced rapid differentiation towards the myeloid lineage. Based on these experiments we conclude that IFN-γ reduces HSC self renewal by modifying cytokine responses and expression of genes involved in HSC proliferation, whereas it boosts myelopoiesis in downstream hematopoietic progenitor cells. Our findings thereby provide challenging new insight regarding the impact of immune activation on hematopoiesis, in particular during viral infection. We postulate that the occurrence of BM failure in chronic inflammatory conditions, such as HIV, aplastic anemia and graft-versus-host disease is related to a sustained impairment of HSC self-renewal caused by chronic IFN-γ-signaling in these disorders.

W6.08.04
Mouse Compact Bone Derived Mesenchymal Stem Cells Supress Airway Inflammation in Both Chronic and Acute Murine Asthma Model

I. Ogulur[1], *G. Gurhan*[1], *A. Aksoy*[2], *G. Duruksu*[2], *D. Filinte*[1], *I. Barlan*[1], *E. Karaöz*[2], ***T. Akkoç***[1];
[1]*Marmara University, Istanbul, Turkey,* [2]*Kocaeli University, Kocaeli, Turkey.*

Aim: The aim of the present study was to investigate the efficacy of mouse compact bone (mCB) derived MSCs on lung histopathology and lymphocyte proliferation.
Methods: mCB-MCS were isolated from BALB/c mice, characterized and marked by GFP. To generate murine models of chronic and acute asthma, mice were i.p. sensitized with OVA and exposed to aerolized OVA. mCB-MSCs (2.5x105 cells) were administrated i.v. after last nebulization. Mice were sacrified, and splenocytes and lung lymphocytes were isolated and marked with CFSE. Cells stimulated with OVA (40µg/ml) were cultured under suitable conditions for 5 days. Flow cytometric analysis and histopathological examination of lungs were evaluated. In histopathological analysis, the measurements were performed from minimum 5 points of each airway and mean values were calculated. Goblet cells stained with PAS enumarated in 2500 cells.
Results: In sections stained with H&E, the distal [without MCS chronic:29,9µm acute:32,03µm; with MSC chronic:13,3µm acute:12,25µm] and proximal [without MCS chronic:42,6µm acute:28,97µm; with MSC chronic:17,4µm acute:18,9µm] airway epithelial thicknesses were observed to decrease in both mouse models. Likewise, in sections stained with PAS, a significant reduction in number of hyperplasic goblet cells in the proximal [without MSC chronic:140 acute:1200; with MSC chronic:4 acute:211] and distal [without MSC chronic:55 acute:118; with MSC chronic:0 acute:0] airways was observed. Morever, in the CFSE staining experiment, CB-MSCs inhibited lymphocyte proliferation in both asthma model.
Conclusion: The results reported here provide that mCB-MSCs may provide powerful alternative therapeutic for the treatment of chronic and acute asthma.

W6.08.05
Allogenicity of human cardiac stem/progenitor cells orchestrated by programmed death ligand 1 (PD-L1)

L. Lauden[1], *W. Boukouaci*[1], *L. R. Borlado*[2], *I. P. López*[2], *P. Sepúlveda*[3], *R. Tamouza*[1,4], *D. Charron*[1,4], ***R. Al-Daccak***[1];
[1]*INSERM UMRS940, Paris, France,* [2]*Coretherapix S.L., Madrid, Spain,* [3]*Fundación para la Investigación Hospital Universitario La Fe, Valencia, Spain,* [4]*AP-HP, Paris, France.*

Rationale: Transplantation of allogeneic cardiac stem/progenitor cells (CPC) in experimental myocardial infarction promoted cardiac regeneration and improved heart function. While this has enhanced prospects of using allogeneic CPC for cardiac repair, the mechanisms regulating the behavior of these allogeneic cells, which are central to clinical applications, remain poorly understood.
Objective: T cells orchestrate the allogeneic adaptive immune response. Therefore, to provide insight into the mechanisms regulating the immunologic behavior of human CPC (hCPC), we investigated the allogeneic T-cell response elicited by cryopreserved c-kit-selected hCPC.
Methods and Results: By using an experimental model of allogeneic stimulation, we demonstrate that, whether under inflammatory conditions or not, hCPC do not trigger conventional allogeneic Th1 or Th2 type responses but instead induce proliferation and selective expansion of suppressive CD25highCD127lowHLA-DR+FoxP3high effector regulatory T cells (Treg). The Treg proliferation and amplification was dependent on the interaction with the B7 family

member programmed death-ligand 1 (PD-L1) which is substantially expressed on hCPC and increased under inflammatory conditions. Thus, hCPC in allogeneic settings acquire the capacity to down-regulate an ongoing immune response, which was dependent on PD-L1. Conclusions: Collectively these data reveal that hCPC in allogeneic settings have a "tolerogenic" immune behavior, promoting a contact-PD-L1-dependent regulatory response and a PD-L1-dependent allogeneic-driven immunomodulation. Our study attributes an important role for PD-L1 in the immune behavior of allogeneic hCPC and raises the possibility of using PD-L1 expression as a marker to identify and select low-risk high-benefit allogeneic cardiac repair cells.

W6.08.06
The acquisition of immunomodulating properties by mouse mesenchymal stem cells in presence of interferon-gamma is associated with a reduced expression of Nanog and alteration of their differentiation potential

T. Vigo[1]*, C. Procaccini*[2]*, G. Matarese*[2]*, S. Baranzini*[3]*, N. Kerlero de Rosbo*[1]*, A. Uccelli*[1]*;*
[1]*University of Genoa, Genoa, Italy,* [2]*University of Naples, Naples, Italy,* [3]*UCSF, San Francisco, CA, United States.*

Bone marrow-derived adult stromal stem cells, referred to as mesenchymal stem cells (MSC), display a therapeutic plasticity, which has been exploited for the treatment of diseases where both immune and degenerative components are present. Indeed, MSC have the ability to modulate immunity and foster tissue repair, and to differentiate into cells of mesodermal lineage. The role of interferon-gamma (IFN-g) in the physiology of MSC has been demonstrated: IFN-g is necessary for the immunomodulatory activity of MSC and affects their differentiation potential. Here, we investigated the changes in gene expression profile of MSC following exposure to IFN-g. We observed a reduced expression of genes involved in WNT and TGF-beta pathway and of the transcription factor Nanog, which is essential for the maintenance of pluripotency, together with an increased expression of genes involved in MSC immunomodulatory function; the increased immunomodulatory effect of IFN-g-treated MSC was associated with a concomitant reversible alteration of pluripotency and differentiation potential. We have analyzed the dynamics of molecular pathways targeted by IFN-g in MSC. We show that IFN-g induces a time-dependent switch of mTOR activation. Incubation of MSC with the mTOR inhibitor Rapamycin increased the IFN-g-dependent induction of genes involved in the immunomodulatory effect of MSC and impaired differentiation towards adipocytes and osteocytes. In contrast, inhibition of STAT3 and ERK1/2 affected self-renewal and promoted differentiation, respectively. These data support the pivotal role of inflammation in inducing an immunomodulatory trait in MSC and suggest a relationship between the acquisition of strong immunomodulating activity and pluripotency in MSC.

W6.09 Vaccine adjuvants

IL6.09.01
Vaccine adjuvants for mucosal immunity: recent progress and future challenges

A. Harandi*;*
University of Gothenburg, Gothenburg, Sweden.

Most human pathogens take their portal of entry or establish infection in the mucosal tissues. There is an urgent need to develop new vaccines or improve the existing human vaccines to counter mucosally transmitted pathogens. Development of safe and potent vaccine adjuvants able to mount broad, long-lasting protective immune responses in the mucosal tissues represents a top priority. By employment of transcriptomics and metabolomics combined with systems biology, we could identify immunological and metabolical biomarkers predicting adjuvanticity in mice. A number of genes involved in immunological and metabolism process and pathways were found to be correlating with adjuvanticity in mice. Recent developments in the field of vaccine adjuvants as pertain to understanding the mode of action of the existing human vaccine adjuvants along with recent data from our lab on discovery of novel biomarkers of experimental mucosal adjuvants will be presented. The underlying premise is that understanding the mode of action of potent and safe immunomodulatory agents/adjuvants could inform rational development of novel adjuvants able to engender protective immune responses in the mucosal tissues.

IL6.09.02
Perspectives in vaccine adjuvants

P. Parronchi[1,2]*, L. Fili*[2]*, E. Cardilicchia*[2]*;*
[1]*Italy,* [2]*Denothe Center, University of Florence, Dept. of Experimental and Clinical Medicine, Florence, Italy.*

The design of more powerful adjuvants is a tool of crucial interest to ameliorate vaccination strategies to reduce injections and/or dose of antigen, induce local immunity and obtain better protection. Effective vaccines against pathogens should elicit protective T_H1 responses, cytotoxic CD8+ cells and antibody-forming cells. Type and persistence of the antigen, nature and differentiation state of antigen-presenting cells, cytokine microenvironment are equally key points for the development of appropriate adaptive immune responses in naive recipients and prophylactic or therapeutic vaccinations. There is a general consensus about the optimal cytokine milieu for protective immunization as IL-12 and type I IFN are necessary for adequateT_H1-polarization. Efficient adjuvants and delivery to appropriate DC subsets would be highly appreciated in order to properly boost innate immune cells especially in targeted therapeutic vaccinations when interference with an already-existing inappropriate immunity is required. Aluminium hydroxide used since almost one century, although safe, has been classically associated with the induction of a TH2 response to co-formulated antigens, at least in the mouse. Therefore, the use of appropriately conditioning as safe as alum, and potentially orally available, adjuvants, would be highly hopeful. In this perspective, MF-59 and detoxified LPS (MPL-A) actually represent improvements in vaccine strategies. However, large experiences both from in vivo as well as from in vitro cultured human cells come from several low molecular weight synthetic compounds, such as CpG-ODNs, imidazoquinolines and adenine derivatives, which could provide the optimal cytokine milieu to induce T_H1 differentiation and interfere with pathogenic T cells via innate sensors.

W6.09.01
Novel adjuvants for DNA vaccines

T. Gargett[1]*, T. Garrod*[1]*,* ***B. Grubor-Bauk***[1]*, W. Yu*[1]*, D. Miller*[2]*, L. Major*[3]*, S. Wesselingh*[4]*, A. Suhrbier*[3]*, E. Gowans*[1]*;*
[1]*University of Adelaide, Adelaide, Australia,* [2]*University of South Australia, Adelaide, Australia,* [3]*Queensland Institute of Medical Research, Brisbane, Australia,* [4]*South Australian Health and Medical Research Institute, Adelaide, Australia.*

The failure of protein-based vaccines to prevent HIV/HCV infection highlights the need for novel vaccine strategies. We provide evidence that induction of necrosis or co-expression of antigen with heat shock protein 70 (Hsp70) in DNA vaccine-targeted cells provides a potent adjuvant effect. Necrotic, antigen-positive cells release a range of intracellular factors that signal via receptors on dendritic cells (DC) and lead to enhanced cross-presentation of antigen. We report that a DNA vaccine that induces cytolytic, rather than apoptotic, cell death enhances CD11c+ CD8α+ DC activation, broad and multifunctional CD8 T cell responses and increases protection in mice challenged with a chimeric virus, EcoHIV. This was dependent on both the mechanism and timing of cell death after antigen expression.
Hsp70, as damage associated molecular pattern, can bind to dendritic cells and up-regulate the expression of co-stimulatory molecules, making Hsp70 a potential DNA vaccine adjuvant. A DNA vaccine encoding HIV gag and Hsp70 with antigen expression controlled by separate promoters was constructed. Genetic modifications resulted in cytoplasmic, secreted and membrane-bound forms of Hsp70. Membrane bound and secreted Hsp70 significantly increased the numbers of IFN-γ secreting T cells, $CD4^+$ and $CD8^+$ triple cytokine-producing T cells and T cell proliferation. Thus, indicating that modifying HSP70 to translocate to the plasma

membrane or to the extracellular milieu may greatly improve the potency of DNA vaccines.
These novel strategies have the potential to increase the efficacy of DNA vaccines, either as a DNA vaccine *per se* or as a prime in a DNA prime/virus boost regimen.

W6.09.02
Using immunopotentiating capacity of flagellin for sublingual immunotherapy

N. Muñoz-Wolf[1], *A. Rial*[1], *J. M. Saavedra*[1], *J. Tabareau*[2], *D. Fougeron*[2], *J. M. Marqués*[1], *J. Sirard*[2], *J. A. Chabalgoity*[1];
[1]*Laboratory for Vaccine Research, Department of Biotechnology. Institute of Hygine-School of Medicine, University of La República, Montevideo, Uruguay,* [2]*Team 8 - Lung Infection and Innate Immunity, CIIL - Center for Infection and Immunity of Lille. INSERM U1019 - CNRS UMR 8204, Institut Pasteur de Lille, Lille, France.*

Mucosal vaccination is an attractive strategy for preventing infectious diseases. Intranasal vaccination is particularly effective for prophylaxis of respiratory infections, but poses safety issues associated with brain toxicity. Instead, sublingual (s.l.) immunotherapy may offer a safer alternative, although due to the pro-tolerogenic environment of the s.l. mucosa strong adjuvants are often required to potentiate immunogenicity of non-living antigens.
We evaluated adjuvanticity of flagellin (FliC) from Salmonella enterica serovar Typhimurium, via s.l. route. Furthermore, we tested FliC as s.l. immunostimulant by assessing its therapeutic value against invasive pneumococcal pneumonia.To address FliC adjuvanticity by s.l. route, we used OVA as model antigen, and evaluated the response in mice vaccinated with OVA alone or OVA+FliC. Sublingual vaccination with OVA+FliC augmented serum levels of OVA-specific antibodies and induced isotype-switching. Using flagellin mutants deficient in TLR5 or NLRC4 activation, we confirmed that engagement of a single pattern-recognition receptor is sufficient for adjuvant effect. Adoptive transfer of OT-II lymphocytes to wild-type counterparts, demonstrated that OVA+FliC vaccination promotes priming of naïve CD4+-T cells in submaxilar lymph nodes. Subsets of dendritic cells involved in antigen processing were determined using self-quenched OVA, emitting fluorescence after lisosomal degradation.
S.l. FliC administration was also effective as a therapeutic agent to prevent mortality in a mouse model of pneumococcal pneumonia. FliC-treated animals had increased levels of Il6 and Cxcl1/2 mRNA in lungs compared to infected controls and protection depended on neutrophil recruitment into the airways.
Our results highlight flagellin as a candidate immunopotentiator for new therapeutic and prophylactic sublingual vaccines.

W6.09.03
A Dectin-1-assisted APC-targeting TLR9-agonist as an adjuvant

K. Kobiyama[1,2], *K. J. Ishii*[1,2];
[1]*National Institute of Biomedical Innovation, Ibaraki, Japan,* [2]*Immunology Frontier Research Center, Osaka University, Suita, Japan.*

Innate immune stimulators including TLR ligands have been shown to work as good vaccine adjuvant. One of these stimulators, CpG ODN is a potent innate immune activator through TLR9, and a promising vaccine adjuvant and anti-cancer drug candidate. β-glucans has been known to induce innate immune signaling through a C-type lectin receptor (CLR), Dectin-1. Recently, some studies showed CLR signaling inhibits TLR and IFNAR signaling. However, these studied did not fully elucidated correlation between TLR and CLR, especially type I IFN production and adjuvanticity.
In this study, we examined weather CLR signaling influences TLR-induced type I IFN production. Our data demonstrated that Zymosan Depleted, which acts as pure Dectin-1 ligand suppressed IFN-α production after CpG ODN stimulation. However, soluble Dectin-1 ligand (SPG) did not.
We have previously shown that SPG forms of triple helix structure with single stranded DNA using specific sequence. We examined bioactivity and adjuvanticity of CpG-SPG complex, in vitro and in vivo, respectively. Accordingly, our data demonstrated that stimulation of immune cells with CpG-SPG complex induced more IL-12 and IFN-α production than naked CpG ODN. In mice, CpG-SPG strongly induced both humoral and cellular immune responses in a TLR9 dependent manner, but partially dependent on Dectin-1. Furthermore, CpG-SPG complex showed a potent adjuvanticity against influenza vaccine. Finally, we demonstrated that humanized CpG-SPG complex enhanced IFN-α production from human PBMCs. Our results suggested that CLR signaling inhibits TLR signaling via Dectin-1 signaling and CpG-SPG complex is a superior vaccine adjuvant than naked CpG ODN to use in clinical.

W6.09.04
Adjuvants are the future of Vaccine Formulation. The case of Finlay Adjuvants

O. Pérez[1], *M. Lastre*[1], *B. Romeu*[1], *O. Cabrera*[1], *M. Cuello*[1], *E. González*[1], *A. Batista-Duharte*[2], *A. Labrada*[3], *W. Ramírez*[3], *R. Nicado*[1];
[1]*Finlay Institute, Havana, Cuba,* [2]*TOXIMED, Medical Science University, Santiago de Cuba, Cuba,* [3]*BioCen, Mayabeque, Cuba.*

Background. After Jenner/Pasteur most vaccinologists have been looking for specific antigens. Nevertheless, for unsolved-vaccine diseases adjuvants are determinant, and certainly, the future of these vaccine formulations. Current development of Immunology and related disciplines permits its rational design and characterization. **Aim.** To show resent advances using Proteoliposomes (PL) and its derivate Cochleate (Co) adjuvants for prophylactic and therapeutic vaccines. **Results.** AF (Adjuvant Finlay) namely AFPL and AFCo were design for parenteral and mucosal application, respectively. AFPL1 is derived from PL of *Neisseria meningitidis* serogroup B and adsorbed onto $Al(OH)_3$ in order to increase stability and safety. It has been widely used in humans in a prophylactic meningococcal vaccine where AFPL1 was an essential adjuvant. A comparable PL is also one of the components of 4CMenB Novartis vaccine. AFPL1 has been also evaluated as an adjuvant for a therapeutic/prophylactic allergen vaccine shifting the allergen-specific Th2 pattern to Th1/Tr1 in mice and a Phase I trial is ongoing. AFPL1 was used at preclinical stage with several other antigens. AFCo1, a Co derived from AFPL1, is a mucosal adjuvant. AFCo3 non-derived from AFPL1, has been tested as immunopotentiator in fish decreasing their mortality. AF are able to function in simultaneous primes by parenteral and mucosal routes, inducing also mucosal immune response. Lastly, AF overcomes the thymus-independence of plain bacterial polysaccharides inducing a Th1 polarization and memory immune response at least in mice. **Conclusion**. AF are very promising adjuvants for unsolved-vaccine diseases including mucosal approaches and therapeutic vaccines.

Antigen trafficking within lymphoid organs and humoral immune response: the effect of MF59 adjuvant

R. Cantisani[1], *A. Pezzicoli*[1], *C. Malzone*[1], *A. Seubert*[1], *F. Giusti*[2], *U. D'Oro*[1], *E. De Gregorio*[1], *M. Carroll*[3], *D. Piccioli*[1];
[1]*Novartis Vaccines and Diagnostics, Siena, Italy,* [2]*University of Siena, Siena, Italy,* [3]*Harvard Medical School, Boston, MA, United States.*

Antigen retention within lymphoid organs facilitates the encounter with cognate B cells. Subcapsular sinus (SCS) macrophages and follicular dendritic cells (FDCs) of lymphoid organs are described to have key role in the humoral immune response because of their ability to deliver antigen trapped in immune complexes (ICs) onto cognate B cells. Adjuvants are substances that enhance immune response by a variety of mechanisms that are still partially understood. Here we show that during an endogenous response to an injected antigen, MF59 enhances antigen retention by either SCS or medullary macrophages and afterwards by FDCs. In addition, we observed that MF59 reaches the SCS and medullary compartments of the draining lymph node and can be detected here for prolonged period of time, such as one or two weeks. Moreover, MF59 is engulfed by macrophages in the form of big vesicles. The antigen capture by macrophages is independent from the antigen-specific IgG titer and its enhancement correlates with the ability of MF59 to induce a strong early antigen-specific antibody production and generation of germinal

centers (GCs). We also demonstrated that the activation of FDCs is necessary but not sufficient to detect GC formation and that both antigen trapping by FDCs and generation of GCs requires IC formation and cell activation. Taken together all these findings strongly suggest that the antigen retention within lymphoid organs affects the quality of the humoral immune response. The elucidation of the way MF59 enhances antigen retention will help to improve the efficacy of emulsions as vaccine adjuvants.

W6.09.06
SBA-15 nanostructured silica adjuvant enhances immune responsiveness and modulates sensibility to bacterial toxins

K. Scaramuzzi[1,2], *G. D. Tanaka*[1,2], *M. Tino De Franco*[1,3], *A. G. Trezena*[1,4], *O. A. Sant´Anna*[1,2];
[1]*Butantan Institute, Sao Paulo, Brazil,* [2]*Immunochemistry Laboratory, Butantan Institute, Sao Paulo, Brazil,* [3]*Immunogenetics Laboratory, Butantan Institute, Brazil, Sao Paulo, Brazil,* [4]*Immunogenetics Laboratory, Butantan Institute, Sao Paulo, Brazil.*

Silicon oxide particles formed of ordered nanopores (SBA-15) are promising adjuvant vectors. Here we explored how silica might act in the enhancement of phagocytosis, the recruitment of inflammatory cells and also in the modulation of toxicity after administration of exo or endotoxins encapsulated in SBA-15. Confocal microscopy and flow cytometry tests confirmed that the pre-incubation of FITC labelled ovalbumin with SBA-15 improved the phagocytosis of the protein by bone marrow derived DC from C57BL/6 mice. The recruitment of cells evaluated by flow cytometry after 24 and 72 hours of subcutaneous injection of SBA-15 showed the presence of inflammatory cells at the site of injection, especially mature DC. BALB/c mice intraperitoneally immunised (ip) with diphtheria toxin (1 µg/mL): SBA-15 (25 µg/mL) presented 100% of survival rate whereas all mice that received diphtheria toxin (1 µg/mL): Alum (25 µg/mL) died. However, BALB/c mice inoculated ip with LPS from Salmonella typhimurium (100 µg/mL) in SBA-15 (1000 µg/mL) showed a higher death percentage (55%) compared to the LPS (100 µg/mL):Alum (1000 µg/mL) group (36%). Though, both experimental groups were able to produce similar specific antibody titres indicating that SBA-15 worked well as immunological adjuvant, reducing the toxicity of the diphtheria toxin in immunisations but increasing the death of mice injected with LPS. These data confirm that SBA-15 acts as adjuvant for antibody responses and suggest that its effects may reflect enhanced availability of antigen without modifying its properties.

W6.10 Mucosal vaccines

IL6.10.01
Acute epithelial death plays a role in intrinsic defense against enteric bacteria

M. Kweon*;*
Mucosal Immunology Section, International Vaccine Institute, Seoul, Republic of Korea.

The interactions of host and microbes, including those commensal and pathogenic, in the mucosal compartments are currently one of the hot topics in immunology field. Further, host cell death is critical to the fate
of bacterial infection, to host innate immune responses, and to disease outcome. “The demise of infected cells” plays a pivotal role in sacrificing damaged cells, eliminating pathogens, limiting microbial replication, and emitting alarm signals. Previous studies demonstrated that *Shigella* invasion induces both necrosis-like death in the epithelial cells and apoptosis-like death in the macrophages via a caspase-1-independent manner. In contrast, bacterial pathogens deploy multiple mechanisms to postpone host cell death and favor infection. Here we found that *Shigellae* can invade the terminal ileum of murine small intestine at 1 hour of the early phase but are rapidly cleared within 24 hours. At early phase, we found several histological changes without inflammation including epithelial shedding and cell death in the lamina propria and crypt. Dead products, including DNA and intracellular organelles, trapped *Shigellae* and then damaged tissue was mostly recovered within a day. These acute responses were general events against human-specific pathogens such as *E. coli* as well as murine-specific pathogens such as *Citrobacter rodentium*. Interestingly, the human intestine also shares this intrinsic defense. Therefore, we propose the concept of a general intrinsic mechanism that repels the initial introduction of enteropathogenic bacteria by sacrificing hazardous host cells. To overcome this defense mechanism and successfully disseminate, some pathogens may have evasion strategies

IL6.10.02
Novel HIV-1 IL-13Rα2 adjuvanted vaccines: High avidity mucosal and systemic CD8 T cells with greater protective immunity

C. Ranasinghe*, S. Trivedi, D. K. Wijesundara, R. J. Jackson;*
The John Curtin School of Medical Research, The Australian National University, Canberra, Australia.

Our studies have demonstrated that compared to a purely systemic (intramuscular - i.m.) HIV-1 prime-boost immunisation, mucosal (intranasal - i.n.) immunisation can induce cytotoxic CD8 T cells (CTL) of higher avidity with lower IL-4/IL-13 activity and better protective immunity. Our recent studies, indicate that co-expression of IL-13Rα2 soluble or membrane bound receptors together with HIV-1 vaccine antigens in an i.n./i.m pox viral prime-boost vaccination modality can i) dramatically enhance HIV-specific systemic and mucosal CTL avidity and multi-functionality. ii) Also following a surrogate mucosal HIV-1 challenge induce excellent protective immunity similar to an IL-13 gene knockout animal. When how the transient inhibition of IL-13 could induce high avidity CTL were investigated, data revealed that i) CD8 T cell avidity is defined at the vaccination site the lung mucosae at very early stages of priming and ii) according to the antigen presenting cell subsets these vaccines induce or recruit. Moreover at the T cell level, the down-regulation of IL-4Rα densities on effector CD8 T cells and up-regulation of CD8α/β co-receptors play a critical role in modulating CD8 T cell avidity. Our findings not only offer exciting prospects for a future HIV-1 vaccine development but also many other chronic mucosal infections where high avidity CD8 T cells are required for protection.

W6.10.01
Microbe-dependent proliferating IgA-producing plasma cells mediate early-phase robust intestinal IgA responses in mice

J. Kunisawa[1,2], *E. Hashimoto*[1], *I. Ishikawa*[1], *Y. Suzuki*[1], *R. Sumiya*[1], *S. Shikata*[1], *H. Kiyono*[1];
[1]*The University of Tokyo, Tokyo, Japan,* [2]*National Institute of Biomedical Innovation, Osaka, Japan.*

Intestinal plasma cells (PCs) predominantly produce IgA, but their immunological complexity remains obscure. Here, we show that murine intestinal IgA PCs can be newly classified into two populations on the basis of CD11b expression, which cannot be discriminated by currently known criteria such as general PC markers, B-cell origin (e.g., B1 and B2 cells), and T-cell dependence/independence. $CD11b^+$ IgA^+ PCs require the lymphoid structure of Peyer’s patches, produce more IgA than $CD11b^-$ IgA^+ PCs, proliferate vigorously, and require microbial stimulation and IL-10 for their development and maintenance. The proliferating IgA^+ cells dominantly present in the $CD11b^+$ IgA^+ PCs mediate early-phase antigen-specific intestinal IgA responses induced by oral immunization with protein antigen. Indeed, preferential depletion of $CD11b^+$ IgA^+ PCs results in the significant impairment of intestinal IgA production against orally immunized antigens. These findings reveal the functional diversity of IgA^+ PCs in the murine intestine and possible target in the development of oral vaccine.

Development a novel mucosal vaccine targeted to GP2 on Peyer's patch M cells

H. Shima[1,2]*, T. Watanabe*[2]*, O. Ohara*[2]*, H. Ohno*[1,2]*;*
[1]Division of Immunobiology, Graduate School of Nanobioscience, Yokohama City University, Yokohama, Japan, [2]RIKEN Yokohama institute IMS, Yokohama, Japan.

Mucosal vaccines can induce systemic immunity and mucosal immunity, such as antigen-specific SIgA, on mucosal surface. By contrast, vaccines injected by syringe and needle induce only systemic immunity, not mucosal immunity. Accordingly, mucosal vaccines can protect from pathogens before their invasion across mucosal barrier. However, mucosal vaccines have some disadvantage; for example, oral vaccines need to resist gastric acid and digestive enzymes to reach mucosal immune tissues such as Peyer's patches (PPs). To overcome the problem, live attenuated pathogens are often used as oral vaccines since they can propagate to produce enough immunogenicity even if a small portion of the administered amount could reach the immune tissue. However, attenuated pathogens could give rise to virulent revertants causing adverse side effects. To circumvent the problem, we developed a novel mucosal vaccine targeted to GP2. GP2 is an uptake receptor on PP M cells for $FimH^+$ bacteria to induce subsequent mucosal and systemic immune responses. We constructed a fusion protein of the Fab fragment from anti-GP2 monoclonal antibody and streptavidin core (anti-GP2-SA). In this report, we show that anti-GP2-SA is able to bind to GP2 on M cells and is taken up into PPs. Concurrently, biotinylated antigen proteins are delivered to PPs with anti-GP2-SA. These results suggest that anti-GP2-SA may induce mucosal immunity and obviate the risk of infectious diseases as a mucosal vaccine.

Molecular Uniformed Rice-based Oral Cholera Toxin B Subunit Vaccine without Plant-associated Sugar Modification Induces Toxin-specific Neutralizing Immunity in Mice and Macaques

Y. Yuki[1]*, M. Mejima*[1]*, S. Kurokawa*[1]*, T. Hiroiwa*[1]*, Y. Takahashi*[1]*, Y. Katakai*[2]*, M. Kuroda*[3]*, N. Takeyama*[1]*, K. Kashima*[1]*, H. Kiyono*[1]*;*
[1]The Institute of Medical Science, The University of Tokyo, Tokyo, Japan, [2]Corporation for Production and Research of Laboratory Primate, Ibaraki, Japan, [3]Rice Physiology Research Team, National Agriculture Research Cente, Niigata, Japan.

Plants have been used as expression systems for a number of vaccines. However, the expression of vaccines in plants sometimes results in unexpected modification of the vaccines by N-terminal blocking and sugar-chain attachment. Although MucoRice-CTB was thought to be the first cold-chain-free and unpurified oral vaccine, the molecular heterogeneity of MucoRice-CTB, together with plant-based sugar modifications of the CTB protein, has made it difficult to assess immunological activity of vaccine and yield from rice seed. By using a T-DNA vector driven by a prolamin promoter and a signal peptide added to an overexpression vaccine cassette, we established MucoRice-CTB/Q as a new generation oral cholera vaccine for humans use. We confirmed that MucoRice-CTB/Q produces a single CTB monomer with an Asn to Gln substitution at the 4th glycosylation position. The complete amino acid sequence of MucoRice-CTB/Q was determined by MS/MS analysis and the exact amount of expressed CTB was determined by SDS-PAGE densitometric analysis to be an average of 2.35 mg of CTB/g of seed. To compare the immunogenicity of MucoRice-CTB/Q, which has no plant-based glycosylation modifications, with that of the original MucoRice-CTB/N, which is modified with a plant N-glycan, we orally immunized mice and macaques with the two preparations. Similar levels of CTB-specific systemic IgG and mucosal IgA antibodies with toxin-neutralizing activity were induced in mice and macaques orally immunized with MucoRice-CTB/Q or MucoRice-CTB/N. These results show that the molecular uniformed MucoRice-CTB/Q vaccine without plant N-glycan has potential as a safe and efficacious oral vaccine candidate for human use.

Advantage of a new intra-cheek immunization route for therapeutic vaccines of human papillomavirus-associated head and neck cancers

R. Macedo[1]*, G. Lescaille*[1,2]*, V. Mateo*[1]*, C. Baillou*[1]*, B. Bellier*[1]*, F. M. Lemoine*[1]*;*
[1]UPMC Paris 06, CNRS 7211/INSERM 959, Groupe hospitalier Pitié-Salpêtrière, Paris, France, [2]Université Denis Diderot Paris 07, Paris, France.

Papillomavirus (HPV)-16 infection has been recently associated with oropharyngeal head and neck cancers (HNCs) that express the viral E6 and E7 oncoproteins. The licensed vaccines are efficient for the prevention of HPV infection, but not for established tumors. Therefore innovative therapeutic vaccines targeting HPV oncogenes are required. Recently, we have described the efficiency of therapeutic intra-dermic DNA vaccinations using plasmo-virus like particles carrying the E7 oncoprotein (pVLPs-E7) associated with electroporation to control the growth of TC1 tumors subcutaneously injected in the flank of C57Bl6 mice. The present study aims at comparing immune and anti-tumoral efficacy of different routes of vaccination with pVLPs-E7.
Here, we have used an orthotopic model of HPV-induced HNCs where TC1 cells were injected into the cheek of C57BL6 mice. Tumor growth and anti-E7 immune response were compared after intra-cheek (i.c.) or intra-dermal (i.d.) pVLP-E7 vaccinations. While i.d. route gave rise to better systemic anti-E7 cellular immune response than i.c. route, both routes elicited superposable local anti-E7 immune responses. Interestingly, only i.c. route elicited an anti-E7 humoral response. When vaccinations were performed in mice bearing well-established tumors, a better therapeutic effect was observed using i.c immunizations. Furthermore, anti-tumoral responses were optimized by combining vaccinations with TLR agonists (Imiquimod and CpG) as adjuvants.
Our data show that i.c. mucosal vaccinations with pVLP-E7 combined with adjuvants, evaluated in an orthotopic tumor model, appear to be a valuable therapeutic strategy for HPV-induced HNCs.

Cross-strain protective immunity elicited by a live attenuated nasal spray influenza vaccine after prime-boost immunization

J. Li, M. T. Arévalo, Y. Chen, ***M. Zeng****;*
Texas Tech University Health Sciences Center, El Paso, TX, United States.

Antigen drift and shift of influenza viruses requires frequent reformulation of influenza vaccines. This stresses the need for a universal influenza vaccine. In this study, mice were vaccinated with the trivalent live attenuated (LAIV, nasal spray FluMist) and inactivated (TIV, intramuscular injection FluZone) influenza vaccines using 1-3 dose prime-boost vaccination regimens. While vaccination with both LAIV and TIV elicited strong humoral responses, only LAIV induced significant protection against challenge with a non-vaccine strain: H1N1 PR8 influenza virus. Furthermore, protective immunity against PR8 was dose-dependent. Of note, IL-2 and IFN-γ cytokine secretion in lung alveolar fluids were significantly elevated in mice immunized with LAIV. Moreover, T cell depletion of LAIV-immunized mice compromised protection, indicating that T cell-mediated immunities were required. In contrast, passive transfer of sera from mice immunized with LAIV into naïve mice failed to protect against PR8 challenge. To verify these results, we performed virus neutralization assays in vitro and confirmed that LAIV did not induce cross-strain neutralizing antibodies against PR8 virus. Finally, we showed that 3 doses of LAIV also provided protection against challenge with two additional heterologous viruses: FM/47 (H1N1) and HK/68 (H3N2). These results support the potential use of the LAIV as a universal influenza vaccine under a prime-boost vaccination regimen.

Safety evaluation of Neuraminidase as a targeting substance of allergen-loaded microparticles for oral food allergy treatment

C. Schultz[1], *S. C. Diesner*[1,2], *X. Wang*[3], *F. Roth-Walter*[1,4], *T. Eiwegger*[2], *Z. Szépfalusi*[2], *I. Pali-Schöll*[1,4], *E. Jensen-Jarolim*[1,4], *F. Gabor*[3], *E. Untersmayr*[1];
[1]*Department of Pathophysiology and Allergy Research, Medical University of Vienna, Vienna, Austria,* [2]*Department of Paediatrics and Adolescent Medicine, Medical University of Vienna, Vienna, Austria,* [3]*Department of Pharmaceutical Technology and Biopharmaceutics, University of Vienna, Vienna, Austria,* [4]*Messerli Research Institute of the University of Veterinary Medicine Vienna, Medical University Vienna and University Vienna, Vienna, Austria.*

Background: We have reported that Neuraminidase (NA) from Vibrio cholera represents a promising novel functionalization substance of allergen-loaded Poly(D,L-lactide-co-glycolide) (PLGA) microparticles (MPs) due to specific binding to intestinal epithelial cells and enhanced uptake via M-cells. As NA is of bacterial origin, we aimed to assess the safety of orally applied NA-coated MPs in an ongoing Th2 biased immune response.
Methods and results: The enhanced binding of NA-coated, OVA-loaded MPs to CaCo2 cells was associated with a concentration dependent decrease of cell proliferation. In naïve animals no induction of mast cell mediator release was observed by oral gavages of NA-coated, allergen-loaded MPs suggesting biocompatibility. When splenocytes from naïve mice were stimulated with NA or NA-coated MPs, a release of IL-10 and IFN-γ was observed. To investigate the immunomodulatory capacity of NA-MPs, BALB/c mice were first intraperitoneally injected with ovalbumin (OVA) followed by two oral OVA challenges to induce a profound IgE-mediated, OVA-specific response. After 6 oral administration cycles with NA-coated MPs, the immune response of animals was re-evaluated. Whereas no significant changes in serum antibody levels were observed, we found significantly lower total and OVA-specific IgA levels in intestinal lavages in treated allergic mice than in control groups. When splenocytes from OVA allergic animals receiving NA-coated, OVA-loaded MPs were stimulated with OVA, significantly elevated levels of IL-10 and IFN-γ were measured.
Conclusion: Our data suggest that allergen entrapped in NA-functionalized MPs act immunomodulatory in this type I allergic BALB/c mouse model.

Novel Immune-modifying Nanoparticles for the Treatment of Inflammatory monocyte-mediated Disease

D. R. Getts[1,2], *R. L. Terry*[1,2], *M. T. Getts*[1], *C. van Vreden*[1], *T. M. Ashhurst*[1], *S. J. Cordwell*[1], *E. B. Thorp*[2], *S. Bao*[1], *S. D. Miller*[2], ***N. J. C. King***[1];
[1]*University of Sydney, Sydney, Australia,* [2]*Northwestern University, Chicago, IL, United States.*

Infiltrating inflammatory monocyte-derived macrophages and dendritic cells play key roles in initiating and exacerbating widely disparate disorders, including viral encephalitis, multiple sclerosis, myocardial infarction, reperfusion injury and inflammatory bowel disease. However, no effective therapy specifically targeting these cells exists.
We investigated the novel use of nanoparticles as tools to modulate the behaviour of circulating inflammatory monocytes during myeloid lineage-mediated disease in vivo. Intravenously infused, negatively charged, polystyrene, nanodiamond, or biodegradable poly (lactic-co-glycolic) acid immune-modifying-nanoparticles (IMP) were cleared from the blood within 30 minutes and taken up in an opsonin-independent fashion by inflammatory monocytes, which were then sequestrated by the spleen, undergoing phosphatidylserine flipping, and caspase 3-mediated apoptosis.
In lethal flavivirus encephalitis, this intervention resulted in substantially reduced monocyte migration to the brain, abrogated by splenectomy, with up to 80% long-term survival and sterilizing immunity. Parallel studies in other macrophage-mediated disease models, e.g., PLP139-151-induced experimental autoimmune encephalomyelitis (EAE) and thioglycollate-induced peritonitis, confirmed this therapeutic effect, evidently mediated through the class-A scavenger receptor, MARCO, expressed by both circulating inflammatory monocytes and marginal zone macrophages in the spleen, since IMP co-localize with MZM and this effect is not seen in MARCO-deficient mice.
IMP infusion in rodent models of myocardial infarction and inflammatory bowel disease (dextran sodium sulphate-induced colitis) also markedly reduced acute monocyte accumulation at inflammatory foci, attenuated disease symptoms and was associated with tissue repair. Our data highlight the interplay between scavenger receptor, inflammatory monocyte and spleen functions, and support the translation of IMP for therapeutic use in inflammatory monocyte-mediated diseases.

W6.11.01
HIV CD4 based vaccine pre-immunization increases CD8 T cell responses and confers protection against challenge with a recombinant vaccinia virus encoding HIV Gag-Pol proteins

S. P. Ribeiro[1,2], *A. D. Faria*[1,2], *R. R. Almeida*[1,2], *V. C. Santana*[1,2], *D. S. Rosa*[3], *E. G. Kallas*[1,2], *J. Kalil*[1,2,4], *E. Cunha-Neto*[1,5,2];
[1]*University of São Paulo School of Medicine (FMUSP), São Paulo, Brazil,* [2]*INCT, São Paulo, Brazil,* [3]*Federal University of São Paulo (UNIFESP), São Paulo, Brazil,* [4]*Butantan Institute, São Paulo, Brazil,* [5]*Heart Institute, São Paulo, Brazil.*

A vaccine able to provide cognate help may efficiently prime CD8+ T cell responses establishing an appropriate immune control of HIV. Furthermore CD4 T cells responses also have been correlated with HIV infection control. Our group has identified a set of 27 conserved and promiscuous CD4 epitopes from 8 HIV-1 proteins. HIVBr27 encoding such epitopes was highly immunogenic in BALB/c mice inducing strong CD4+ T cell responses. Here we tested whether pre-immunization with HIVBr27 could provide cognate help and improve CD4 and CD8 T cell responses against other HIV proteins (Gag, Pol and Vif) correlated with HIV protection/disease control.In relation to the CD8 T cells, we observed an overall increase in 57% and 40% of the breadth and magnitude of the responses, respectively, when comparing the CD4 based vaccine pre-immunized group to the control (empty vector pre-immunization). Into the CD4 T cell compartment we noticed an increase of 3 and 2 times in the breadth and magnitude of the responses, respectively, comparing CD4 versus control primed group. We also observed a 10 times reduction on the PFUs after recombinant Gag-Pol vaccinia virus challenge as well as a 32 fold increase in the anti-p24 antibody levels in the HIVBr27 pre-immunized group when compared to the control one. These results highlight the importance of having a CD4 inducer based component as a primer for the global responses, impacting in both cellular and humoral immune response.

W6.11.02
Enhanced and accelerated memory CD8 T cell formation by immunization with MVA-CD40L

H. Lauterbach[1], *J. Pätzold*[1], *R. Kassub*[1], *B. Bathke*[1], *K. Brinkmann*[1], *P. Chaplin*[1], *M. Suter*[2], *H. Hochrein*[1];
[1]*Bavarian Nordic GmbH, Martinsried, Germany,* [2]*University of Zurich, Zurich, Switzerland.*

Modified vaccinia Ankara (MVA) is a safe and promising viral vaccine vector that is currently investigated in several clinical and pre-clinical trials. In contrast to inactivated or sub-unit vaccines, MVA is able to induce strong humoral as well cellular immune responses. In order to further improve its CD8 T cell inducing capacity, we genetically adjuvanted MVA-BN® with the coding sequence of murine CD40L, a member of the tumor necrosis factor (TNF) superfamily. Immunization of mice with this new vector led to strongly enhanced primary and memory CD8 T cell responses. Concordant with the enhanced CD8 T cell response, we could detect stronger activation of dendritic cells and higher systemic levels of innate cytokines (including IL-12p70) early after immunization. Interestingly, acquisition of memory characteristics (i.e., IL-7R expression) was accelerated after immunization with MVA-CD40L in comparison to non-adjuvanted MVA. Furthermore, the generated CTLs also showed improved functionality as demonstrated by intracellular cytokine staining and *in*

vivo killing activity. Importantly, the superior CTL responses were able to protect B cell deficient mice against a fatal infection with ectromelia virus. Taken together, we show that genetic adjuvantation of MVA can change strength, quality and functionality of innate and adaptive immune responses.

W6.11.03
IL-4 and IL-13 regulates CD8 co-receptor expression to dampen the quality of anti-viral CD8+ T cell immunity following HIV-1 prime-boost vaccination

D. K. Wijesundara[1]*, R. J. Jackson*[1]*, D. C. Tscharke*[2]*, C. Ranasinghe*[1]*;*
[1]*The John Curtin School of Medical Research, Canberra, Australia,* [2]*The Research School of Biology, Canberra, Australia.*

$CD8^+$ T cells are important in controlling viral infections including HIV-1. We have previously shown that interleukin (IL)-4 and IL-13 can dampen the quality (i.e. avidity and polyfunctionality) of anti-viral $CD8^+$ T cells following pox virus infection and prime-boost vaccination. Therefore, we investigated how these cytokines act to regulate anti-viral $CD8^+$ T cell quality. We initially monitored the expression of T cell quality markers (i.e. CD2, CD11a, CD8, T cell receptor and lck) on anti-viral (HIV-specific) $CD8^+$ T cells using flow cytometry following pox viral prime-boost vaccination of BALB/c wild-type (WT), IL-4 $^{-/-}$, IL-13 $^{-/-}$ or signal transducer and activator of transcription 6 (STAT6) $^{-/-}$ mice against HIV-1. In these studies, only CD8 co-receptor expression was enhanced on HIV-specific $CD8^+$ T cells that developed in gene knockout mice compared to WT mice. Using *in vitro* CD8 blocking assays to limit CD8 co-receptor availability for $CD8^+$ T cells, we established that increasing CD8 co-receptor expression could indeed enhance the avidity and polyfunctionality of HIV-specific $CD8^+$ T cells following vaccination. Based on these findings, we have developed novel IL-13 inhibitor pox virus vaccines that can enhance the quality of HIV-specific $CD8^+$ T cells most likely via up-regulation of CD8 co-receptor following vaccination. Our findings suggest that IL-4 and IL-13 can reduce CD8 co-receptor expression to dampen anti-viral $CD8^+$ T cell quality. These findings have important implications for designing efficacious vaccines against not only HIV-1, but also other virus infections.

W6.11.04
Type 2 diabetes patients, both young and elderly, have optimal B cell responses to the seasonal influenza vaccine

D. Frasca[1]*, A. Diaz*[1,2]*, M. Romero*[1]*, A. Landin*[1]*, B. B. Blomberg*[1]*;*
[1]*University of Miami Miller School of Medicine, Miami, FL, United States,* [2]*University G. D'Annunzio, School of Advanced Studies, Chieti, Italy.*

The humoral immune response to the seasonal influenza vaccine in young and elderly patients with type 2 diabetes (T2D) was measured. Immune measures included the in vivo serum response to the vaccine by hemagglutination inhibition (HAI) and ELISA in 22 patients (14 young, 8 elderly) and 65 healthy age-matched controls (37 young, 28 elderly). B cell-specific biomarkers of optimal vaccine response were measured ex vivo by switched memory B cells and plasmablasts and in vitro by activation-induced cytidine deaminase (AID) in stimulated cells. Markers of systemic and B cell-intrinsic inflammation were also measured. Results show that in vivo responses, as well as B cell-specific markers identified above, decrease with age in healthy individuals but not in T2D patients. This occurred despite high levels of B cell-intrinsic inflammation (TNF-α) in T2D patients, which was surprising as we had previously demonstrated this negatively impacts B cell function. We have preliminary data to indicate that the innate immune system of T2D patients is beneficially hyperactivated and we suggest that this may induce a direct stimulation of B cells. These results altogether suggest that valid protection against influenza can be achieved in T2D patients and proposed mechanisms are discussed. Work supported by NIH grants AG032576 (BBB) and AI096446-01A1 (BBB+DF).

W6.11.05
Fusion of HCV non-structural antigen to MHC Class II associated invariant chain enhances T cell responses induced by vectored vaccines in non-human primates

A. Folgori[1]*, S. Capone*[1]*, M. Naddeo*[1]*, A. Abbate*[1]*, M. Del Sorbo*[1]*, M. Esposito*[1]*, V. Ammendola*[1]*, S. Colloca*[1]*, A. Nicosia*[1,2,3]*, R. Cortese*[1,2]*;*
[1]*Okairos Srl, Rome, Italy,* [2]*CEINGE, Naples, Italy,* [3]*University of Naples Federico II, Naples, Italy.*

Developing a vaccine against hepatitis C virus (HCV) infection is an important medical priority. Induction of robust T cell responses could provide effective immune control.
We have previously shown that adenovirus-vaccine encoding non-structural (NS) HCV proteins induces potent T-cell responses and efficacy studies in chimpanzees demonstrate that these responses can be protective against challenge. Our phase I trial based on prime/boost with a simian Adenoviral (ChAd3) and MVA expressing the HCV-NS antigen has demonstrated that this vaccine strategy is safe and highly immunogenic. However, even higher T cell responses might be required to achieve efficacy in at risk populations and to exert a therapeutic effect in chronically infected HCV patients.
In this study we assessed fusion of the HCV NS antigen to murine and human MHC Class II associated invariant chain (Ii) expressed by viral vaccine vectors for its ability to increase the induced T cell response in mice and non-human primates (NHP). A dramatic increase was observed in CD1 outbred mice where vaccination with ChAd3 expressing the fusion antigen resulted in a 10-fold increase in IFN- producing $CD8^+$ T cells. In NHP $CD8^+$ T cell responses were enhanced and accelerated with vectors encoding the antigen fused to the human or murine Ii. Further experiments are underway to elucidate the adjuvant mechanism of Ii.
These data showed for the first time that the enhancement induced by vector vaccines encoding antigen fused to Ii was not species-specific and translated from mice to non-human primates opening the way for testing in humans.

W6.11.06
Antigenization of bovine immunoglobulin variable regions for development of novel vaccines

Y. Pasman*, A. K. Kaushik;*
University of Guelph, Guelph, ON, Canada.

Immunoglobulin specificity and affinity is a function of the complementarity determining regions (CDRs) of the heavy and light chain variable regions. The CDRs interact with the antigen as they stick out of the beta-sheets formed by the framework regions. The CDRs as such are stable conformational structures of an Immunoglobulin. The molecular modeling of bovine heavy (V_H) and light (V_L) chain domains predicted that the V_L might only have a supportive role in antigen recognition in antibodies with exceptionally long CDR3H (>48 amino acids). It was hypothesized that bovine CDR3H could form the site for presentation of conformational B-cell epitopes in order to develop a vaccine. We have now expressed bovine V_H with a CDR3H of 61 amino-acids and V_L, as single chain variable fragment (scFv) with an 18 amino acid linker in *Pichia pastoris*. This scFv retained the (poly)specificity of the parent antibody in ELISA. This confirmed the conformational stability of the CDR3H region in this format. Previously a protein fragment containing a bovine herpesvirus-1 (BoHV-1) neutralizing epitope was identified in our laboratoy. The sequence encoding this fragment will be grafted into the CDR3H encoding sequence and expressed as scFv in *Pichia pastoris.* Confirmation of the epitope structure will be done in ELISA with recombinant scFv3-18L against BoHV-1, previously engineered in our laboratory and *in vivo* testing in a BoHV-1 susceptible host. Antigenization of recombinant bovine antibody fragments could provide a novel approach to develop safe targeted vaccines. [Supported by NSERC Canada]

Identification of novel *Streptococcus pneumoniae* candidate vaccine antigen

Y. Mizrachi Nebenzahl[1,2], *M. Pornoi*[1,2], *D. Kafka*[1,2], *M. Shagan*[1,2], *A. Adawi*[1,2], *A. Ohayon*[1,2], *S. Dotan*[3], *M. Tal*[3], *R. Ellis*[3], *R. Dagan*[1,2];
[1]*Ben Gurion University of the Negev, Beer Sheva, Israel,* [2]*Soroka University Medical center, Beer Sheva, Israel,* [3]*Protea Vaccine Technologies and NasVax Ltd, Ness Ziona, Israel.*

Mortality due to pneumococcal infections remains high worldwide, augmented by widespread antibiotic resistance in many pneumococcal strains. To identify protein antigens that may be involved in the development of natural immunity to *S. pneumoniae*, a pneumococcal cell wall protein-enriched extract was screened using 2-D gel electrophoresis and immunoblotting with sera obtained longitudinally from children attending day-care centers, frequently exposed to *S. pneumoniae*. We concentrated on proteins for which antigenicity increases with age, coinciding with decreased morbidity. The proteins from this group that do not share homology to human proteins and that are conserved among different *S. pneumoniae* strains were tested for their ability to elicit protection against *S. pneumoniae* challenge in animal models. *S. pneumoniae* proteins for which antigenicity increases with age (PPP, GtS, Nox, PsipB, FBA, TF and FtsZ) were amplified from TIGR4 strain, cloned, expressed in *E. coli*, and purified. Mice were immunized three times intranasally or subcutaneously with these proteins in the presence of adjuvant and challenged two weeks later. Nasopharyngeal and lung colonization levels were quantified 48hrs following bacterial challenge, and survival was monitored daily for seven days.
All seven proteins elicited protective immune responses in mice as determined by reduced nasopharyngeal and lung colonization, prolonged survival, and the ability of antibodies obtained from immunized mice to ex-vivo neutralize bacterial virulence in the intraperitoneal challenge model. Immunization with proteins that demonstrate age-dependent antigenicity recapitulates the development of natural immunity in children and elicits protective immune responses in mouse challenge systems.

W6.11.08
Diminished levels of pneumococcal polysaccharide (PPS) responding 'B1 like' cells and it's corelation with poor anti PPS response post PPV-23 in long term HAART cohorts

A. S. Iyer*, D. J. Leggat, N. M. Khaskhely, M. Westerink;
University of Toledo, Toledo, OH, United States.*

Despite HAART's success in reducing the incidence of opportunistic infections, invasive pneumococcal disease burden continues to be 35 to 100 fold higher in HIV infected population as compared to HIV negative individuals. PPV-23, a capsular polysaccharide vaccine is recommended as a prophylactic measure in HIV positive individuals; however its serological benefit in this group is currently unclear. In humans, B cells that respond to pneumococcal challenge are poorly characterized unlike in mice where B1 and MZ B cells are known to play an effective role in pneumococcal clearance. We designed a novel method for identifying pneumococcal polysaccharide (PPS) responding B cells by conjugating vaccine serotypes to fluorescent molecules. Using this method, we investigated serotype 14 and 23F responding B cells in HIV cohorts on long term HAART. On day 7 post PPV-23 vaccine, we saw a surge of 14 and 23F specific CD20+IgM+CD27+CD43+CD5+/- 'B1 like' cells in the peripheral blood of immunized volunteers as compared to pre-vaccination day levels. The percentage of 14 and 23F responding B1 like cells in HAART cohorts were comparable to HAART naïve group; but significantly less compared to young healthy HIV negative PPV-23 immunized volunteers. This correlates with the diminished anti PPS antibody response observed in the HAART treated group as opposed to healthy adults who exhibit appreciable serological response to PPV-23.Based on preliminary results, HAART does not appear to fully reconstitute the functional B cell subset required for protection against S.pneumoniae.

Chimeric flagellin as the selfadjuvanting antigen for antibody response against Helicobacter pylori

J. Mori[1], ***T. Vranac***[2], *B. Smrekar*[2], *M. Černilec*[2], *V. Čurin erbec*[2], *S. Horvat*[3,1], *A. Ihan*[4], *M. Benčina*[1], *R. Jerala*[1,5,6];
[1]*Department of Biotechnology, National Institute of Chemistry, Ljubljana, Slovenia,* [2]*Blood Transfusion Centre of Slovenia, Ljubljana, Slovenia,* [3]*Biotechnical Faculty, University of Ljubljana, Ljubljana, Slovenia,* [4]*Medical Faculty, Universiy of Ljubljana, Ljubljana, Slovenia,* [5]*EN-FIST Centre of Excellence, Ljubljana, Slovenia,* [6]*Faculty of Chemistry and Chemical Technology, University of Ljubljana, Ljubljana, Slovenia.*

Almost half of the world population is infected with Helicobacter pylori. In most hosts the infection is asymptomatic, however, a subset of patients develops gastritis, peptic ulcer, and even gastric cancer. These flagellated Gram-negative bacteria have evolved to escape immune clearance by avoiding detection of their flagellin by the Toll-like receptor 5 (TLR5). TLR5 recognizes amino- (N) and carboxy- (C) terminal conserved segment of flagellin of bacteria such as Escherichia coli. The central hypervariable region of flagellin is known to be antigenic, but it is not mandatory for TLR5 signaling.
With the aim to engineer an antigen which would retain the H. pylori-specific antigenicity, but would also gain the ability to activate TLR5 signaling pathway, we constructed a chimeric flagellin by replacing the N- and C-terminal segment of H. pylori flagellin with segments from TLR5 activating E. coli flagellin.
Chimeric flagellin folded correctly and activated TLR5 in cell cultures. The vaccination of mice with the chimeric flagellin resulted in increased serum IgG and IgA antibody response. We found that antibodies against chimeric flagellin recognized native flagellin from H. pylori lysate. Vaccination with chimeric flagellin provided mice with significant protection against H. pylori.
Our approach can be used for the development of functional vaccines against human pathogen H. pylori as well as against other flagellated bacteria that evade TLR5 recognition.
Flagellin could also be used as an adjuvant for development of other types of vaccines (e.g. against tumours) where synergistic effect of activation of innate immune response is desired.

Improved assay for quantification of immunoreactive hemagglutinin for potency determination and stability analysis in trivalent influenza vaccines using isotope dilution mass spectrometry

C. L. Pierce[1], *T. L. Williams*[1], *W. Wang*[2], *J. L. Bundy*[1], *J. R. Barr*[1];
[1]*US Centers for Disease Control and Prevention, Atlanta, GA, United States,* [2]*Battelle - Technical On-Site Professional Services; US Centers for Disease Control and Prevention, Atlanta, GA, United States.*

Vaccination is the primary strategy to reduce the morbidity and mortality associated with influenza virus. There is an important public health need to develop methods to improve vaccine quality and to decrease the time required to get a protective vaccine to the public. Currently, regulatory potency requirements for trivalent influenza vaccine (TIV) require hemagglutinin (HA) quantification based on the single radial immunodiffusion (SRID) assay, which is laborious, time-consuming and difficult to obtain reproducible results. We have developed a potency assay, immunocapture-isotope dilution mass spectrometry (IC-IDMS), to quantify immunoreactive HA.
IC-IDMS has been validated utilizing polyclonal antisera to strain-specific HA, provided by regulatory agencies as reagent standards for SRID. These antibodies coated on magnetic beads capture conformationally correct HA in purified bulk materials and final TIVs. The captured proteins are enzymatically digested, and evolutionarily conserved tryptic peptides are quantified for each HA subtype. IC-IDMS is also being adapted for use with monoclonal antibodies. Panels of mAbs have been generated, purified, and characterized for evaluation as capture antibodies. These reagents could alleviate the current requirement of annual production of strain-specific antisera.
IC-IDMS provides accurate and specific quantification of immunoreactive H1, H3, and B in TIV samples. IC-IDMS is valuable for evaluating binding specificity and efficiency of antibodies, can be used to determine sub-potent TIVs and to monitor the stability of final vaccine products. IC-IDMS has several advantages over SRID,

including higher throughput as well as improved precision, accuracy, selectivity, and sensitivity. IC-IDMS has the potential to significantly impact influenza vaccine testing.

Necrotic cell vaccine against Hepatitis C

B. Grubor-Bauk[1], *P. Latour*[2], *W. Yu*[1], *B. Loveland*[2], *E. Gowans*[1];
[1]*University of Adelaide, Adelaide, Australia,* [2]*Burnet Institute, Melbourne, Australia.*

Potent, broad and sustained cell-mediated immune response, resulting in effective memory has the potential to restrict HCV infection and eliminate virus-infected cells after challenge. Among the HCV non-structural (NS) proteins, NS3 is more conserved across the genotypes and early, multi-specific CD4+ helper and CD8+ cytotoxic T cell responses against NS3 have been associated with viral clearance and protection.
We developed a novel mouse dendritic cell (DC) line, stably expressing HCV g1b NS3. Overexpression of NS3 had no effect on the maturation of this DC cell line. NS3 DCs were then manipulated to induce cell necrosis and C57BL6 mice were vaccinated with live or necrotic NS3 DCs in a prime boost regimen. We report that a single vaccination with necrotic cells expressing NS3 resulted in a greater influx of necrosis-sensing, cross-presenting CD11+ CD8+ Clec9A+ DCs in lymph nodes draining the site of injection at early time points post-vaccination and greater levels of T cell activation. This in turn, resulted in broad and greater responses to NS3, induction of multifunctional NS3-specific T cells, increased cytokine production and proliferation by NS3-specific T cells after prime-boost vaccination. On the basis of these promising results, we suggest that necrotic cell vaccination provides an innovative new strategy for immune modulation and enhancement of vaccine effectiveness.

Langerin negative dendritic cells promote potent CD8+ T-cell priming after skin delivery of a recombinant adenovirus-based vaccine using microneedle arrays

V. Bachy[1], *C. Hervouet*[1], *P. Becker*[1], *L. Chorro*[2], *L. M. Carlin*[2], *S. Herath*[1], *S. Oh*[3], *S. Y. Kwon*[3], *F. Geissmann*[2], ***L. S. Klavinskis***[1];
[1]*Peter Gorer Department of Immunobiology, Kings College London, London, United Kingdom,* [2]*Centre for Molecular and Cellular Biology, Kings College London, London, United Kingdom,* [3]*TheraJect Inc,, Fremont, CA, United States.*

Improving antigen immunogenicity and reducing dependence on the cold chain are key goals in vaccine development. To achieve this we have developed a simple dissolvable microneedle array (MA) delivery system, fabricated to confer properties that maintain the transduction competence of a live adenoviral vaccine vector within the microneedle matrix and provide tensile strength to enable skin penetration with subsequent vaccine delivery to DCs. Using recombinant Adenovirus (Ad5) vectors encoding either HIV-1 CN54 gag or ovalbumin in a biodegradable polymer matrix containing a disaccharide as preservative, we addressed both the utility of this approach in eliciting $CD8^+$ T cell immunity and the DC populations critical to programming this response.
Dried AdHu5 M.A. immunization in B6 mice induced $CD8^+$ T cell expansion and multifunctional cytokine responses equipotent with conventional injectable routes of immunization. Intravital imaging of langerin-eGFP and CD11c-eGFP reporter mice, using flurochrome-linked dextran included with Ad5 in the needle matrix, demonstrated fluorescent M.A. cargo distributed both in the epidermis and dermis, with acquisition by dermal CD11c+ DC. Analysis of skin draining LNs after Ad5 vectored MA immunization, found no evidence for significant accumulation of $CD11c^+MHCII^{hi}Lang^+CD8^{neg}CD103^{neg}$ Langerhans cells or presentation of Kb/SIINFEKL complexes by $Lang^+$ DCs. Strikingly, we found a critical role for $CD11c^+$ MHC II^{hi} $CD8a^{neg}$ $EpCAM^{neg}$ $CD11b^+$ $Lang^{neg}$ DCs in priming the CD8+ T cell response, while $Lang^+$ DCs were dispensable.
These data shed new light on the early events following dermal vaccine delivery and have important implications for the development of viral vectored vaccines.

W6.11.13
Targeting of antigen via XCR1, the lineage marker for cross-presenting dendritic cells, elicits potent CD8 cytotoxicity in vivo

E. Hartung, *M. Becker, A. Bachem, N. Reeg, Y. Yang, A. Jäkel, H. Weber, V. Henn, H. Mages, R. A. Kroczek;*
Robert Koch-Institut, Berlin, Germany.

Current vaccines essentially elicit protective neutralizing antibodies. However, some pathogens like mycobacteria, hepatitis C virus, Plasmodium, or HIV can only be cleared by cytotoxic T cells. We have recently shown that the chemokine receptor XCR1 is selectively expressed on cross-presenting dendritic cells (DCs), the key players in the induction of CD8+ T cell cytotoxicity. Based on this finding we have now established model systems for antigen targeting into cross-presenting DCs via XCR1. To this end, a mAb to murine XCR1 (MARX10) or XCL1, the natural chemokine ligand for XCR1, were fused to ovalbumin using recombinant techniques. Neither targeting reagent activated DCs when injected without adjuvant. A single i.v. injection of small amounts (1-2.5 µg) of either targeting reagent, applied together with LPS, efficiently induced proliferation and expansion of antigen-specific CD4+ and CD8+ T cells. Both targeting systems generated potent CD8+ T cell killing capacity in naïve C57BL/6 mice, when tested using an in vivo kill assay and an aggressive tumor model system. Both targeting strategies were highly specific as neither proliferation nor cytotoxicity was detected in XCR1-deficient mice. In clear contrast, injection of soluble ovalbumin was ineffective in all assay systems used. We thus could demonstrate that targeting of antigen into murine cross-presenting DCs via XCR1 induces a potent antigen-specific cytotoxic CD8+ T cell response in vivo. Since XCR1 is also selectively expressed on human cross-presenting CD141+ DCs, these targeting strategies will be transferable to the human, enabling the development of novel preventive and therapeutic vaccines.

miR-21 confers resistance against CVB3-induced myocarditis by inhibiting PDCD4-mediated myocyte apoptosis

W. XU, *J. He, Y. Yue, S. Xiong;*
Institutes of Biology and Medical Sciences, Soochow University, Suzhou, China.

The participation of microRNAs (miRNA) in physiopathologic processes of cardiovascular diseases endows them with the feasibility as potential targets for clinical intervention. Herein, key myocardial miRNA involved in the murine myocarditis following Coxsackievirus B3 (CVB3) infection was screened and its contribution to the disease development was investigated. It was found that myocardial miR-21 level was significantly reduced during the process of viral myocarditis and was negatively related to the extent of CVB3-induced myocardial inflammation and injury. When retrieving miR-21 expression by injecting pMDH-miR-21 via hydrodynamic injection on day 1 post infection, viral myocarditis was significantly alleviated as evidenced by less body weight loss, less myocardial injury and elevated survival rate. Further study revealed that miR-21 conducted its protective role by reducing myocyte apoptosis via inhibiting the expression of its target gene-programmed cell death 4 (PDCD4). In conclusion, in vivo up-regulating miR-21 expression could protect CVB3-induced myocarditis by repressing PDCD4-mediated myocyte apoptosis .It indicates that miR-21 intensively regulates the pathogenesis of viral myocarditis, and might be used as a novel therapeutic target for the future treatment of CVB3-induced myocarditis.

Monitoring indirect allorecognition in renal transplant recipients

E. Breman, *P. P. van Miert, M. H. Heemskerk, D. Roelen, F. H. Claas, C. van Kooten;*
LUMC, Leiden, Netherlands.

After allogeneic transplantation, T-cells can ,recognize the donor HLA molecules in two different manners: intact donor HLA-on donor antigen presenting cells (APC, direct pathway) and donor-derived

HLA peptides restricted by self-HLA on recipient APC (indirect pathway). Most strategies to monitor alloreactive T-cells are restricted to cells with direct specificity.
We have set up an experimental model to measure indirect reactivity, using HLA-typed dendritic cells or PBMC as antigen presenting cells. For antigen loading we used cell lines expressing a single HLA antigen or HLA monomers. As a readout CD8 T cell clones recognizing HLA-A2 (direct) or CD4 T cell clones recognizing HLA-A2-derived peptides restricted by HLA-DR1 (indirect) were used.
HLA-A2 molecules from cells/fragments did not results in indirect presentation but were able to activate the CD8 T cells (semi-direct presentation). However, using HLA monomers, a specific and dose dependent induction of IFN-γ production and proliferation was observed with the indirect CD4 T cell clone. This method was applied to renal transplant recipients 1-2 years post transplantation receiving kidneys with multiple HLA-I mismatches. PBMC from recipients were incubated with mismatched monomers for up to 72h. A specific IFN-γ response was observed with one of the monomers, confirming presence of T cells with indirect alloreactivity.
In conclusion we have developed a system to monitor indirect T-cell alloreactivity which should be further exploited in a larger cohort of transplant recipients and allows a more detailed analysis of qualitative aspects of this T cell response.

W6.12.02
In vitro and in vivo characterization of IL-9 producing alloreactive T cells

***K. Stanko**, J. Schumann, U. Schliesser, C. Appelt, K. Vogt, B. Sawitzki;*
Charité - Universitätsmedizin Berlin, Institute for Medical Immunology, Berlin, Germany.

Alternative mechanisms of acute allograft rejection are related to T helper type 2 (Th2) alloimmune responses and are often associated with eosinophil infiltration and interleukin (IL)-9 production. In this regard, the existence of a recently described type of helper T cells, which is characterized by the secretion of IL-9, might be relevant. Therefore, the differentiation of alloreactive IL-9 producing cells was investigated.
Stimulation of CD4+ T cells from BALB/c mice with allogeneic bone marrow derived dendritic cells (DCs) from C57BL/6 mice in the presence of IL-4 and TGF-b induced IL-9 production in up to 8% of the T cells with 50% of the cells co-expressing IL-4, although it hast been reported that 'Th9' cells do not express cytokines attributed to other T helper cells. The differentiation strongly depended on the presence of TGF-b, as generation of IL-9 producing T cells showed a concentration dependency and was inhibited by neutralizing TGF-b. LPS stimulated DCs did induce more IL-9 producing alloreactive T cells compared to TNF-a stimulated DCs. Experiments concerning the expression of characteristic surface molecules revealed that IL-9 secreting cells neither express T1/ST2, a previously described Th2-associated marker, nor the IL-4 receptor. In vivo, IL-9 producing T cells are rather of CD44-low phenotype and can be found in the spleen following allogeneic skin transplantation. The contribution of IL-9 producing alloreactive T cells to graft rejection as well as the functional differences between IL-9 single and IL-4/IL-9 single producing cells need to be further investigated.

W6.12.03
Experimental chronic lung allograft damage

*S. Atanasova[1], A. Evers[1], D. Jonigk[2], K. Petri[1], A. Zakrzewicz[1], M. Obert[3], J. Schmitz[1], M. Hirschburger[1], W. Padberg[1], **V. Grau**[1];*
[1]Laboratory of Experimental Surgery, Giessen, Germany, [2]Institute of Pathology, Hannover Medical School, Hannover, Germany,
[3]Department of Neuroradiology, Giessen, Germany.

The success of human lung transplantation is limited by chronic lung allograft damage resulting in bronchiolitis obliterans syndrome (BOS). Acute rejection episodes and infections are important risk factors and seem to play major pathogenic roles. The aim of this study is to characterize a relevant experimental model for human BOS.
The Fischer 344 to Lewis rat strain combination was used for orthotopic left lung transplantation. Isografts were performed in Lewis rats. Recipients were treated with ciclosporin for 10 days. Lipopolysaccharide or vehicle was instilled into the airways 28 days after transplantation to mimic bacterial infection. Grafts were monitored using computed tomography and recipients were sacrificed on days 28-90. Graft histopathology was compared to lungs from patients, which were re-transplanted due to end-stage allograft dysfunction.
Three months after transplantation, the overall histopathology of rat lung allografts treated with lipopolysaccharide closely resembled human grafts with end-stage chronic pulmonary allograft damage, characterized by vasculopathies, fibrosis, leukocytic infiltrates, and a spectrum of mild to severe bronchial remodeling. By real-time RT-PCR, we demonstrated an induction of the TLR signaling system in allografts compared to isografts. Furthermore, chemokines CXCL9 and CXCL10 were induced in rat lung allografts before and after application of lipopolysaccharide. These chemokines are of prognostic value for human BOS.
In conclusion, we established an experimental model, which includes the most important risk factors, pivotal aspects of the pathogenesis and histopathological hallmarks of human BOS. This model will be helpful to elucidate the pathogenesis of BOS and to develop new therapeutic approaches.

W6.12.04
Soluble FGL2 induces tubular epithelial cells apoptosis in renal allograft rejection

***Z. Zhao**[1,2], C. Yang[1,2], L. Wang[3], L. Li[1,2], T. Zhao[1,2], L. Hu[4], R. Rong[1,2], M. Xu[1,2], T. Zhu[1,2];*
[1]Department of Urology, Zhongshan Hospital, Fudan University, Shanghai, China, [2]Shanghai Key Laboratory of Organ Transplantation, Shanghai, China, [3]Biomedical Research Center, Zhongshan Hospital, Fudan University, Shanghai, China, [4]4. Department of Urology, First Affiliated Hospital, Suzhou University, Suzhou, Jiangsu, China.

Background. Acute rejection (AR) hinders renal allograft survival. Tubular epithelial cells (TECs) apoptosis contributes to premature graft loss in AR, while the mechanism remains unclear. Soluble fibrinogen-like protein 2 (sFGL2), a novel effector of regulatory T cells (Tregs), induces apoptosis to mediate tissue injury. In this study, the role of sFGL2 in AR was investigated both *in vivo* and *in vitro*.
Materials and Methods. Serum level of sFGL2 and the peripheral percentage of $CD4^+CD25^+Foxp3^+$ Tregs were measured in renal allograft recipients with AR or stable renal function (n = 30). Human TECs were stimulated with sFGL2, TNF-α or PBS *in vitro*, and investigated for apoptosis by flow cytometry with Annexin V/PI staining. Apoptosis-associated genes expression in TECs were further assessed. Approval for this study was obtained from the Ethics Committee of Fudan University.
Results. Serum level of sFGL2 was significantly increased in the AR patients in correlation with peripheral Tregs. *In vitro*, sFGL2 remarkably induced TECs apoptosis, with a significant up-regulation of pro-apoptotic genes, including *CASP-3*, *CASP-8*, *CASP-9*, *CASP-10*, *TRADD*, *TNFSF10*, *FADD*, *FAS*, *FASLG*, *BAK1*, *BAD*, *BAX* and *NF-KB1*, without significant changes in anti-apoptotic genes, including *CARD-18*, *NAIP*, *BCL2*, *IKBKB* and *TBK1*.
Conclusion. sFGL2, an effector of Tregs, induces TECs apoptosis in renal allograft rejection through a comprehensive facilitation of both extrinsic and intrinsic apoptotic pathways and a modulation of regulatory signalings towards the pro-apoptosis profile. Our study suggests sFGL2 a crucial mediator in the pathogenesis of allograft rejection and provides novel insights into the role of Tregs in AR.

W6.12.05
Association of splenic $CD11c^+$ B-cell population with long-term graft tolerance in mouse cardiac transplantation model

*T. Wang, **T. Wang**, J. Guo, J. Tao, J. Yang, J. Zhu, W. Yang;*
Department of General Surgery, Division II, The First People's Hospital of Yunnan Province, Kunming, China.

Organ transplantation is currently the effective method to treat end-stage organ failure. Strong immuno-suppressive drugs significantly improve graft survival. However, their toxic complications prevent long-term patient survival. Therefore, induction, maintenance, and

forecast of transplantation tolerance have been the hot topics of the field. In clinic liver and kidney transplantations, γδ-T cells and B-cell-associated proteins are found to be associated with long-term graft acceptance. In animal models, there have been no objective cellular/molecular patterns to indicate graft tolerance or rejection yet. Anti-CD154/DST treatment is used in our BALB/c-to-C57BL/6 mouse cardiac transplantation model to induce graft tolerance, which can last for at least 180 days. We found that the presence of splenic $CD11c^+$ B cells in long-term tolerant recipients is associated with graft tolerance. The $CD11c^+$ B-cell population emerges from day90 post tolerance induction and peaks around day150, suggesting different tolerance maintenance mechanisms at different tolerant stages. Graft rejection leads to decrease of the $CD11c^+$ B-cell population. The $CD11c^+$ B cells express more CD19 molecules. The $CD11c^+$ B-cell population shows several signatures of B-cell tolerance, such as immature $IgM^{high}IgD^{low}$ B-cell profile and higher expression of PDL-1 and PDL-2, compared to the $CD11c^-$ B-cell population. However, we do not observe high expression of CD5 and IL-10 expression in the $CD11c^+$ B-cell population. Our observations suggest the existence of cellular/molecular patterns of long-term graft tolerance in animal models. These studies may result in a sensitive, easy, and objective criterion for tolerance prediction in animal models and clinical transplantations.

W6.12.06
Tolerance induction to immunogenic grafts via antigen-specific Tregs without the need for chronic immunosuppression

***M. Hardtke-Wolenski**, N. Seltrecht, N. Mpofu, R. Taubert, F. Noyan, M. P. Manns, E. Jaeckel;*
Hannover Medical School, Hannover, Germany.

Regulatory T cells (Tregs) play an important role in the induction of allospecific tolerance. However tolerance in solid organ transplantation by mere transfer of Tregs has been difficult. Besides this the stability of the differentiation phenotype of Tregs has recently been questioned.
We therefore aimed in generating large numbers of stable allospecific Tregs from naive T cells by retroviral transduction with Foxp3. These were tested in an immunogenic skin transplantation model.
We established a system of transduction of mouse T cells with ecotropic retroviruses expressing Foxp3 and Thy1.1 as a surface marker to follow up transduced T cells. Alloantigen-specific T cells were isolated and transduced with Foxp3. Alloantigen-specific Foxp3 T cells showed high expression for Treg markers. They could suppress a MLR and could be expanded in vitro while maintaining their Treg phenotype. These Tregs prevented skin graft rejection without the need for chronic immunosuppression and recipients showed allospecific tolerance. Alloantigen-specific Tregs were far more potent than polyspecific Tregs. Mechanisms of tolerance were graft specific homing, expansion and long-term persistence of Tregs within the graft. In fact, tolerance could be transferred with re-transplantation of the tolerant graft onto secondary recipients.
The results prove that large numbers of stable alloantigen-specific Tregs can be generated from a polyclonal repertoire of naive T cells. This is the first time that allotolerance was achieved in a non-lymphopenic transplant model using skin grafts in an immunogenic strain combination. Therefore, antigen-specific Tregs might have a huge therapeutic potential after solid organ transplantation.

W6.13 Bone marrow transplantation and graft versus host disease

W6.13.01
PI3K-independent signal contributes to ICOS-mediated T-cell costimulation in acute graft-versus-host disease in mice

***J. Li**[1,2], X. Yu[1,2];*
[1]Central South University, Changsha, China, [2]Moffitt Cancer Center, Tampa, FL, United States.

We and others have previously shown that ICOS plays an important role in inducing acute GVHD in murine models of allogeneic bone marrow transplantation (BMT). ICOS potentiates TCR-mediated phosphoinositide 3-kinase (PI3K) activation and intracellular calcium mobilization. However, ICOS signal transduction pathways involved in GVHD remain unknown. Here we examined the contribution of ICOS-PI3K signaling in the pathogenic potential of T cells using a knock-in mouse strain, ICOS-YF, which selectively lost the ability to activate PI3K. We found that when total T cells were used as alloreactive T cells, ICOS-YF T cells caused less severe GVHD compared to ICOS-WT T cells but they induced much more aggressive disease than ICOS-KO T cells. This intermediate level of pathogenic capacity of ICOS-YF T cells was correlated with similar levels of IFN-γ producing CD8 T cells that developed in the recipients of ICOS-WT or ICOS-YF T cells. We further evaluated the role of ICOS-PI3K signaling in CD4 vs. CD8 T cell compartment using GVHD models that are exclusively driven by CD4 or CD8 T cells. Remarkably, ICOS-YF CD8 T cells caused disease similar to ICOS-WT CD8 T cells whereas ICOS-YF CD4 T cells behaved very similarly to their ICOS-KO counterparts. Consistent with their *in vivo* pathogenic potential, CD8 T cells responded to ICOS ligation *in vitro* by PI3K-independent calcium flux, T-cell activation, and proliferation. Thus, in acute GVHD in mice, CD4 T cells heavily rely on ICOS-PI3K signaling pathways; in contrast, CD8 T cells can utilize PI3K-independent ICOS signaling pathways, possibly through calcium.

W6.13.02
$CD11b^+$ NK cells are the main effector NK cell subpopulation that impairs GVHD

*K. Meinhardt[1], I. Kroeger[1], R. Bauer[1], D. Dudziak[1], M. Rehli[2], A. Mackensen[1], **E. Ullrich**[3,1];*
[1]University Hospital Erlangen-Nuremberg, Erlangen, Germany, [2]University Hospital Regensburg, Regensburg, Germany, [3]Children's Hospital, Frankfurt, Germany.

Clinical studies exploiting the impact of Natural killer (NK) cells during bone marrow transplantation (BMT) have provided promising results. Murine NK cells can be separated along their expression of CD27 and CD11b and CD117 (c-kit). However, the functional relevance of the distinct NK subsets in graft-versus-host-disease (GVHD) has not been investigated so far. We have established different protocols for expansion of murine NK subpopulations. The four different NK cell subsets provide differences in their genomic, phenotypic and functional properties. Our data clearly demonstrate that CD11b+ NK cells express multiple genes of cytotoxic pathways and develop the highest tumorlytic capacity. We observed up to 60% tumor lysis by CD27- CD11b+ NK cells compared to 40-45% by CD27+ CD11b+, about 25% by CD27+ CD11b- and 10% by c-kit+ CD11b- NK cells. Interestingly, CD27+ NK cells provided the highest IFN-γ production upon incubation with tumor cells and/or IL-2. We further analyzed the migratory capacity and tissue homing of these NK subsets. CD11b+ NK cells migrate to the GVHD target organs, whereas CD27+ NK cells preferentially home to the bone marrow. Finally, we investigated the role of distinct NK subpopulations in the development of GVHD in a MHC mismatched BMT mouse model.
In summary, our study outlines that only the CD11b+ NK cells provide GVHD protection. These new insights are highly relevant for the selection of the optimal NK cell preparation in the field of cellular therapy.

W6.13.03
In vitro-generated myeloid-derived suppressor cells (MDSCs) inhibit graft-versus-host disease (GVHD) while preserving the graft-versus-tumor (GVT) effect

***J. J. Messmann**[1], M. B. Lutz[2], F. Leithäuser[3], K. M. Debatin[1], G. Strauss[1];*
[1]Department of Pediatrics and Adolescent Medicine, University Medical Center Ulm, Ulm, Germany, [2]Institute of Virology and Immunobiology, University Würzburg, Würzburg, Germany, [3]Institute of Pathology, University Ulm, Ulm, Germany.

Allogeneic bone marrow transplantation (BMT) is a curative treatment modality for hematologic malignancies, since alloantigen-specific donor T cells eliminate residual tumor cells (graft-versus-tumor (GVT) effect). However, these T cells are also responsible for the induction of graft-versus-host disease (GVHD) by attacking alloantigen expressing recipient tissue. Therapeutic goal in BMT is the inhibition

of GVHD while maintaining the GVT-effect. Myeloid-derived suppressor cells (MDSCs), a heterogenic population of myeloid precursors, suppress T cell activation and might therefore be a putative therapy in GVHD prophylaxis.
MDSCs were generated by culturing BM cells in the presence of GM-CSF and G-CSF. These in vitro-generated CD11b+Gr-1+ MDSCs suppressed allogeneic T cell proliferation in vitro. To test, whether MDSCs inhibit GVHD, B6-derived MDSCs were co-transplanted with B6-derived allogeneic BM and spleen cells (SC) into lethally irradiated B6.bm1 or B6D2F1 mice. In a dose dependent manner, MDSCs significantly suppressed clinical and histological GVHD and improved survival up to 70 % - 100 %, depending on the BMT-model used. Transplanted MDSCs homed into lymphoid and GVHD target organs. However, they did not interfere with phenotype and cytotoxicity of allogeneic T cells. Importantly, co-transplantation of MDSCs did not interfere with the GVT-effect, since syngeneic tumor cells were still efficiently eradicated after MDSC co-transplantation.
In summary, transplantation of in vitro-generated MDSCs efficiently prevented clinical and histological GVHD while preserving T cell-mediated tumor cytotoxicity, suggesting that MDSC co-transplantation represent a useful cellular GVHD-therapy.

W6.13.04
Fetal membrane cells for treatment of steroid-refractory acute graft-versus-host disease

***H. Kaipe**, T. Erkers, S. Nava, M. Uzunel, E. Iwarsson, R. Conrad, M. Westgren, J. Mattsson, O. Ringdén;*
Karolinska Institutet, Stockholm, Sweden.

The placenta protects the developing fetus from the mother's immune system. Fetal membranes have previously been used to treat severe burn injuries, indicating that these tissues can promote wound healing. We have previously found that fetal membrane cells (FMCs) isolated from term placenta prevent alloreactivity *in vitro*. FMCs share many features with bone marrow-derived mesenchymal stromal cells (MSCs), which we previously introduced to treat severe acute graft-versus-host disease (GVHD). Here, we tested FMCs for treatment of steroid-refractory acute GVHD. After two passages in culture, approximately 10^9 FMCs were obtained from one single placenta. The FMCs were positive for CD29, CD44, CD73, CD90, CD105, CD49d, PD-L1 and PD-L2, but were negative for hematopoietic and epithelial markers. Microsatellite polymorphism analysis showed that FMCs were of maternal origin. All FMCs used showed normal karyotype. Nine patients who had undergone hematopoietic stem cell transplantation and who had developed steroid-refractory grade III-IV acute GVHD were given 0.9-2.8 x 10^6 FMCs/kg at 15 infusions. Median age was 57 years. Two of eight evaluable patients had a complete response and four had a partial response, giving an overall response rate of 75%. Two patients showed no response at all. Three patients are alive from 11 to 26 months after HSCT. One patient is well and two have chronic GVHD. To conclude, we have developed a protocol for generation of large quantities of stromal cells with immunosuppressive capacities that are accessible without any invasive procedures. FMCs may be successfully used for immune modulation and tissue repair.

W6.13.05
CMV reactivation and kinetics of Natural Killer (NK) cell reconstitution in 439 patients after allogeneic hematopoietic stem cell transplantation (allo-HSCT)

***H. Moins-Teisserenc**[1], V. Kheav[1], R. Peffault de Latour[2], M. Busson[1], C. Scieux[3], G. Maki[4], A. Xhaard[5], G. Socié[5], A. Toubert[1], H. Moins-Teisserenc[1];*
[1]INSERM 940, IUH, Hopital Saint-Louis, AP-HP, Paris, France, [2]Service d'Hématologie Greffe, Hopital Saint-Louis AP-HP, Paris, France, [3]Laboratoire de Virologie, Hopital Saint-Louis, AP-HP, Paris, France, [4]Laboratoire d'Immunologie Histocompatibilité, Hopital Saint-Louis, AP-HP, Paris, France, [5]Service d'Hématologie Greffe, Hopital Saint-Louis, AP-HP, Paris, France.

NK-cells are the first subset to recover after allo-HSCT, and play a major role in early immunity. Relatively small cohort studies suggest that the kinetics of NK-cell reconstitution and cytomegalovirus (CMV) reactivations are closely intertwined. NK-cells that express the activating receptor NKG2C seem crucial in the resolution of CMV episodes, even in the absence of T-cells. Nevertheless, the alleged ability of NK-cells to control CMV infection still remains to be corroborated on larger cohorts.
We aimed at prospectively investigating the kinetics and profiles of NK cell reconstitution after allo-HSCT together with CMV reactivation patterns.
Freshly collected samples from 439 consecutive recipients were analyzed at months M3, M6, M12 and M24 post-transplantation in order to characterize NK-cell subsets.
Data were analyzed with respect to conditioning regimen, source of stem-cell, underlying disease, occurrence of GvHD, and profiles of CMV reactivation.
We showed, from multivariate analysis, that the cell-source was the major factor influencing the reconstitution of immature CD56bright NK subset (P=.03 at M3). Higher numbers of infused CD34+ cells were associated with higher CD56dim NK-cell counts from M3 to M12. The cumulative incidence of chronic GvHD was strongly associated to CD56dimNK-cell counts above 70/mm3 at M3. CD56bright NK-cell counts below 12/mm3 at M3 were associated with higher incidence of CMV reactivation between M0 and M3. Moreover, the numbers of CMV reactivations and CD56bright NK-cell counts were inversely correlated between M3 and M6.
These date highlight the interest to evaluate immune reconstitution at the subset rather than at the global level of NK-cells.

W6.13.06
CD8+ T-cells expressing the homing receptors CCR7 and CD62L mediate the pathogenesis of graft-versus-host disease

***A. Kreutzman**[1], I. Portero[1], M. Royg[2], V. Gómez García Soria[2], A. Ramirez[1], C. Muñoz Calleja[1];*
[1]Instituto de Investigación Sanitaria Princesa, Servicio de Inmunología, Hospital Universitario de la Princesa, Madrid, Spain, [2]Instituto de Investigación Sanitaria Princesa, Servicio de Hematología, Hospital Universitario de la Princesa, Madrid, Spain.

Graft-versus-host disease (GVHD) represents one of the major complications associated with allogeneic stem cell transplantation. The pathogenesis involves migration of the transplanted donor naïve T-cells into the secondary lymphoid organs in the recipient, which is mainly steered by CD62L and CCR7. Therefore, we aimed to study whether the expression of CD62L and CCR7 in cytotoxic CD8+ T-cells is associated with GVHD.
This single center study included 27 donor-recipient pairs. All patients had reached at least 100 days after SCT. Samples from the apheresis product (donor) were phenotyped by flow cytometry (CD45, CD3, CD4, CD8, CD62L, CCR7). CD62L and CCR7 expression in CD4+ and CD8+ T-cells were compared between patients who developed GVHD (n=12) and those who did not (n=15).
The patients who developed GVHD were transplanted with a slightly higher number of T cells (mean 241 vs. 201*106/kg; p=0.17) and CD8+ T cells (92 vs. 71*106/kg; p=0.10) compared to patients without GVHD. Interestingly, the GVHD group received a significantly higher number of CCR7+CD8+ T-cells (52*106/kg, p=0.010) and CD62L+CD8+ T-cells (39*106/kg, p=0.041) compared to the no GVHD group (29 and 25*106/kg, respectively). The GVHD group received also a higher number of CD62L+CCR7+CD8+ T-cells compared to no GVHD (30 vs. 17*106/kg, p=0.033). In contrast, no differences were seen in the absolute number of transplanted CD4+ (p=0.51), CD4+CCR7+ (p=0.31), CD4+CD62L (p=0.99), or CD4+CCR7+CD62L+ (p=0.81) T-cells.
Our results indicate that CCR7+ and CD62L+ expressing CD8+ T-cells mediate pathogenesis of GVHD and are potential therapeutical targets for the disease.

W6.14 Immunosuppressive and tolerogenic treatments

W6.14.01
Immunological outcomes during 1 year of treatment with the anti-interleukin-12/23 p40 monoclonal antibody ustekinumab for psoriasis

A. Rozieres[1], *C. Lambert*[2], *C. Paul*[3], *K. Reich*[4], *M. Brunori*[5], *P. Bergmans*[6], *E. Martens*[6], *E. Rizova*[5], *J. Nicolas*[1];
[1]*University of Lyon, Lyon, France,* [2]*Laboratory of Immunology, CHU-Saint-Etienne, France,* [3]*Larrey Hospital, Paul Sabatier University, Toulouse, France,* [4]*Dermatologikum Hamburg, Hamburg, Germany,* [5]*Janssen, Issy Les Moulineaux, France,* [6]*Janssen-Cilag BV, Tilburg, Netherlands.*

Psoriasis is a chronic inflammatory disease mediated by cytokine-producing T helper (Th) 1 and Th17 cells. Ustekinumab, a biotherapy targeting the IL-12/23 p40 subunit is highly efficient in patients with moderate-to-severe plaque psoriasis.
The TRANSIT study (NCT01059773), a 52-week, randomised, open-label trial in patients with moderate-to-severe plaque psoriasis and inadequate response to methotrexate, assessed the safety and efficacy of two methotrexate-to-ustekinumab transition strategies.
At week 52, 77% of patients achieved clinical benefit (75% reduction in psoriasis area severity index compared with baseline [PASI 75]) and 83% had only minimal residual lesions (PASI≤5). The systemic immunological effects of ustekinumab during 1 year of treatment were analysed in a subgroup of patients (n=117) by monitoring the immune phenotype and function of circulating leukocytes at baseline, week 12 and week 52. The results show that ustekinumab induced only mild changes in circulating leukocytes at week 52 compared with baseline: i) slight increases in the numbers of T and B cells (both $p<0.001$); ii) increases in the numbers of regulatory T cells ($p=0.004$); iii) decreases in the numbers of natural killer (NK) cells ($p<0.001$). More importantly, the immune functions tested were not substantially altered, including: i) NK cell cytotoxicity; ii) mitogen- and recall antigen-induced T cell proliferation; iii) IL-17, interferon-γ, tumour necrosis factor (TNF)-α, and IL-22 secretion; iv) frequency of Th1 and Th17 cell precursors.
Collectively these data show that, for the patients studied, ustekinumab treatment did not impair systemic immune functions.

W6.14.02
Induction of immune tolerance by antigen loaded erythrocytes: Innovative therapy for therapeutic protein allergy

M. cremel*, N. Guerin, W. Berlier, F. Horand, Y. Godfrin;*
Erytech Pharma, Lyon, France.

Introduction:
Pompe disease is a rare inherited metabolic disorder caused by deficiency of the enzyme acid alpha-glucosidase. Currently, the unique approved therapy is the intravenous administration of a recombinant enzyme called alglucosidase-alpha (AGA). However, due to its immunogenicity, the life-long treatment and the frequency of injections, the use of AGA leads to severe adverse reactions and/or reduced therapy efficacy. In this context, our aim is to reduce / abolish the specific humoral response to antigen (Ag) using the properties of erythrocytes to deliver specifically the Ag to antigen-presenting cells and to induce antigen-specific immune tolerance.
Methods:
AGA was entrapped by a hypotonic dialysis process in erythrocytes treated with [bis(sulphosuccinimidyl)] suberate (BS3) to stimulate erythrocyte phagocytosis and favor organ targeting. To demonstrate that our technology can prevent the immunization to AGA, mice were intravenously injected three times with AGA entrapped in RBCs before being sensitized to AGA using Cholera Toxin (CT) as adjuvant. Control animal received injections of unentrapped AGA.
Results:
We demonstrated that AGA delivered by BS3-treated erythrocytes is able to induce immune tolerance. A strong decrease in specific humoral response was observed despite three humoral stimulations with AGA and CT (more than 80% of IgG decreased). Furthermore, this tolerance induction is maintained at least for 2 months and the mice remain fully responsive to CT stimulation.
Conclusion:
We have developed a promising strategy to inhibit protein-specific humoral responses. This therapeutic approach of tolerance induction could offer multiple applications in patients developing hypersensitivity to therapeutic proteins.

W6.14.03
Therapeutic role of the novel negative checkpoint regulator VISTA in murine autoimmune disease models

S. Ceeraz[1], *I. Le Mercier*[1], *P. Sergent*[1], *A. Schned*[1], *C. Burns*[1], *R. Noelle*[1,2];
[1]*Geisel School of Medicine at Dartmouth, Lebanon, NH, United States,* [2]*MRC Centre for Transplantation , King's College London , Guys' Hospital, London, United Kingdom.*

Therapeutics targeting negative checkpoint regulators such as CTLA-4 and PD-L1 has been effective in treating human cancer and to a lesser extent autoimmune diseases. We have recently discovered the novel checkpoint regulator designated V-region Immunglobulin-containing Suppressor of T cell Activation (VISTA) bearing homology to the extracellular domain of PD-L1.
This is the first study focused on the therapeutic efficacy of VISTA-Ig, a fusion protein in murine autoimmune models of Multiple Sclerosis (Experimental Autoimmune Encephalomyelitis (EAE)) and Systemic Lupus Erythematosus (SLE).
In EAE mice, prophylactic and therapeutic treatment with VISTA-Ig significantly reduced disease severity compared with control-Ig treated mice in vivo. In the lupus prone mouse strains NWBW-F1 and NZM2410, therapeutic treatment with VISTA-Ig prevented the onset of proteinuria, dramatic weight loss and increased regulatory T cells in contrast with control-Ig treated mice. Clinical analysis of kidneys from the VISTA-Ig treated group showed minimal to mild glomerulonephritis compared with mice treated with control-Ig. Collectively these studies demonstrate that VISTA-Ig is a novel effective therapeutic in murine autoimmune diseases.

W6.14.04
Interleukin-7 receptor blockade by monoclonal antibody to IL-7Rα induces islet allograft tolerance and long-term skin allograft survival through inhibition of T cell reconstitution

H. L. Mai[1], *F. Boeffard*[1], *J. Lepourry*[1], *R. Danger*[1], *B. Martinet*[1], *B. Vanhove*[1,2], *S. Brouard*[1], *J. P. Soulillou*[1];
[1]*INSERM UMR 1064 - Institut de Transplantation-Urologie-Nephrologie (ITUN), Nantes, France,* [2]*Effimune, Nantes, France.*

Using a pancreatic islet allograft model, we show that anti-IL-7Rα mAb given every other day from 3 weeks before graft to 4 weeks post-graft induced graft tolerance (graft survival >180d compared to 21d in untreated mice, $p<0.001$) and maintained an abrogation of both cellular and humoral alloimmune responses long time after the cessation of treatment. In a stringent skin allograft model, IL-7R blockade given after T cell depletion by anti-CD4 and anti-CD8 mAbs doubled graft survival to 58d versus 30d with depletion alone ($p<0.0001$), and when low-dose tacrolimus was added, two-third of mice accepted skin graft for at least 90d. IL-7R blockade following T cell depletion inhibited T cell reconstitution and resulted in: (1) 4 to 10-fold reduction in the absolute number of total T cells, CD4+, CD8+ T cells, and CD44hiCD62Llo memory T cells, (2) moderate increase in CD4+FoxP3+ Treg frequency, (3) abrogation of both cellular and humoral alloimmune responses as shown by IFNγ Elispot, MLR-3H thymidine and DSA measurement, (4) inhibition of skin graft leukocyte infiltrate, (5) diminution of intragraft expression of TH1, TH2, and TH17 cytokines, chemokines, and chemokine receptors (all $p<0.05$). Interestingly, a 5-week treatment with anti-IL-7Rα mAb did not decrease cellular and humoral anti-viral immune response in mice previously infected with an adenovirus vector. Taken together, we demonstrate for the first time that IL-7R blockade has strong tolerizing effect and synergizes with other immunosuppressants to induce long-tem graft survival even in a stringent allograft model and therefore might be a clinically relevant therapy in transplantation.

W6.14.05
Control of autoimmunity by Treg-inducing liver sinusoidal endothelial cells

A. Carambia[1], *B. Freund*[2], *D. Schwinge*[1], *O. T. Bruns*[3], *S. C. Salmen*[4], *H. Ittrich*[5], *R. Reimer*[6], *M. Heine*[7], *J. Heeren*[8], *J. Herkel*[1]; [1]*University Medical Centre Hamburg-Eppendorf, Department of Medicine I, Hamburg, Germany,* [2]*Department of Biochemistry and Molecular Cell Biology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, Hamburg, Germany,* [3]*Department of Chemistry, Massachusetts Institute of Technology, Cambridge, MA, United States,* [4]*Institute of Physical Chemistry, University of Hamburg, Hamburg, Germany,* [5]*Department of Diagnostic and Interventional Radiology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany,* [6]*Department of Electron Microscopy and Micro Technology, Hamburg, Germany,* [7]*Department of Anatomy and Experimental Morphology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany,* [8]*Department of Biochemistry and Molecular Cell Biology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany.*

Background & Aims: The lack of treatments that specifically suppress the immune response to disease-relevant self-antigens is a major obstacle for the efficient therapy of autoimmune diseases such as multiple sclerosis. Previously, we have shown that the liver favors the generation of autoantigen-specific CD4+ Foxp3+ regulatory T cells (Tregs) that could suppress autoimmune disease (Lüth S et al., J Clin Invest. 2008 Oct;118(10):3403-10). Here we aimed to identify the Treg-inducing cells in the liver, and explore whether Treg-induction by liver cells could be harnessed for the treatment of autoimmune disease.
Methods: Antigen-specific Treg-induction by various liver cell types was analyzed in vitro and Treg functionality was assessed in vivo in mouse models of multiple sclerosis. For the treatment of autoimmune disease, we developed a carrier system for delivery of autoantigen peptides to Treg-inducing liver cells in vivo.
Results: We show that liver sinusoidal endothelial cells (LSECs) efficiently induce the TGF-β -dependent conversion of CD4+ Foxp3- non-Tregs into CD4+ Foxp3+ Tregs. To harness LSECs for Treg-based treatment of autoimmune disease, we engineered a nanoparticle carrier that facilitates selective and efficient delivery of autoantigen peptides to LSECs in vivo. In two independent mouse models of multiple sclerosis, only a single administration of nanoparticles loaded with autoantigen peptides provided complete disease protection and effective therapy of established disease.
Conclusions: LSECs are potent inducers of antigen-specific Tregs. The selective delivery of autoantigen peptides to LSECs by nanoparticles enables effective treatment of autoimmune disease.

W6.14.06
Induction of immunosuppression by mesenchymal stem cells

Y. Shi*;*
Institute of Health Sciences, Shanghai Institutes for Biological Sciences, Chinese Academy of Sciences, Shanghai, China.

Mesenchymal stem cells (MSCs), also called multipotent mesenchymal stromal cells, are believed to exist in almost all tissues as a key cell source for tissue repair and regeneration. Our recent studies showed that MSCs are strongly immunosuppressive *in vivo* and *in vitro* in both animals and humans. This immune modulatory property of MSCs is not innate, rather induced by by IFNγ and the concomitant presence of any of three other proinflammatory cytokines, TNFα, IL-1α or IL-1β. These cytokine combinations provoke the expression of high levels of several chemokines and inducible nitric oxide synthase (iNOS) by MSCs. These chemokines drive T cell migration into proximity with MSCs, where T cell responsiveness is suppressed by local high concentrations of nitric oxide (NO). This cytokine-induced immunosuppression was absent in MSCs derived from $iNOS^{-/-}$ or $IFN\gamma R1^{-/-}$ mice. Blockade of chemokine receptors also abolished the immunosuppressive effect of wild type MSCs. In vivo administration of wild-type MSCs, but not $IFN\gamma R1^{-/-}$ or $iNOS^{-/-}$ MSCs, prevented GVHD, liver cirrhosis and Parkinson's disease, Human MSCs demonstrated dramatic therapeutic effect in patients suffering from end-stage liver disease. Since mesenchymal stem cells (MSCs) have extensive proliferative capacity in vitro, and could be expanded to sufficient quantity for in vitro and in vivo investigations, we believe that further studies on their immune modulatory properties will provide critical information for proper clinical applications of these valuable cells.

Modelling human inflammation *in vitro* with human blood monocytes

D. Boraschi*, P. Giungato, Y. Li, P. Italiani;*
Istitute of Biomedical Technologies (ITB), National Research Council (CNR), Pisa, Italy.

The use of human primary cells *in vitro* is becoming the preferred choice for obtaining valid and meaningful immunopharmacological data, in particular when addressing inflammation, as animal models have proved largely unreliable and transformed cell lines do not reliably reproduce the response of primary cells.
The human innate/inflammatory response in a tissue can be modelled *in vitro* by culturing human normal monocytes isolated from blood in conditions that resemble the recruitment from blood into the inflamed site, then the encounter with the inflammatory agents, and eventually the conditions promoting tissue repair and homeostatic regulation upon resolution. The interindividual variability of the monocyte response proved very low, underlining the robustness of the model. Changing the culture conditions could also allow us to reproduce the conditions of persistent inflammation characteristic of chronic inflammatory diseases, for instance in rheumatoid arthritis, or those of elderly individuals. Since reacting/adapting to the changing microenvironment is typical of immune responses, the full development of the reaction should be examined in the *in vitro* models, in order to indentify possible anomalous reactivity.
These kinds of models can be used for different scopes, including
1. identification of subtle kinetic or dynamic changes or markers that distinguish a normal inflammatory response from a persistent pathological reaction;
2. evaluation of the immunomodulatory effects of microorganisms and other agents, alone or in combination;
3. screening of anti-inflammatory compounds;
4. assaying the immunosafety of drugs, contaminants, or engineered nanoparticles.
This study was supported by MIUR (PRIN2007Y84HTJ), EU Commission (PRD College, GA-223581; NanoTOES, PITN-GA-2010-264506), and Fondazione Cariplo (Inter-cellular delivery, trafficking, and toxicity of engineered magnetic nanoparticles in macrophages and CNS cells, 2011-2014).

IL6.15.02
Molecular mechanisms associated to a new combined therapy for multiple sclerosis

G. Penton Rol[1], *N. Lagumersindez-Denis*[2], *M. Cervantes-Llanos*[1], *V. Falcón-Cama*[1], *L. Muzio*[3], *M. Nazabal-Gálvez*[1], *T. Veliz*[4], *R. Furlan*[3], *A. Mantovani*[4], *E. Pentón-Arias*[1];
[1]*Center for Genetic Engineering and Biotechnology (CIGB)., Havana, Cuba,* [2]*Center for Research and Biological Evaluations (CEIEB), Institute of Pharmacy and Food, University of Havana., Havana, Cuba,* [3]*San Raffaele Scientific Institute, Milan, Italy, Milan, Italy,* [4]*Clinic Institute Humanitas, Milan, Italy, Milan, Italy.*

Multiple sclerosis (MS) is the most common demyelinating disease of the central nervous system. While there have been significant advances in therapies targeting immune system dysfunction, there is an urgent need for developing drugs aimed at protecting demyelination and axonal loss as part of the pathogenic mechanism of MS. In our study, we used the experimental autoimmune encephalomyelitis (EAE) model induced in C57BL6 mice, by immunization with MOG35-55 peptide. We studied the molecular mechanisms involved in the effect of C-Phycocyanin (C-Pc), a natural antioxidant derived from *Spirulina platensis* (a blue - green algae) and beta IFN, on EAE. The study involved clinical evaluations, measurements of regulatory T cells in the spleen, effector and regulatory cytokines by qPCR in the brain and serum by Bioplex, and analyses using Transmission Electron Microscopy. Results showed a reduction of clinical signs, the induction of CD4 + Foxp3 + in the spleen and the reduction of effector cytokines, such as IL-17 in the

brain and serum. Also, ultra-structural analyses demonstrated that C-Pc was able to remyelinate axons, and the gene expression profile of Microarray studies identified common and specific processes modulated by C-Pc and beta IFN. This suggests the need of a combined Multiple Sclerosis therapy with two components targeting the main steps of the MS pathogenic mechanism, one related to immune dysfunction and the other directed towards neurodegenerative changes. Our study, consistent with current approaches on the use of combined therapies, constitutes an attractive and potentially effective strategy for future clinical trials in MS.

W6.15.01
L-GILZ forms a complex vith p53 and mdm2 and suppresses tumor growth through p53 activation

E. M. Ayroldi[1], *M. Petrillo*[2], *A. Bastianelli*[1], *S. Ronchetti*[1], *C. Marchetti*[1], *G. Nocentini*[1], *L. Cannarile*[1], *C. Riccardi*[1];
[1]*Department of Clinical and Experimental Medicine, Section of Pharmacology, University of Perugia, Perugia, Italy,* [2]*Department of Clinical and Experimental Medicine, Section of Pharmacology, University of Perugia, Perugia, Italy.*

Long Glucocorticoid-Induced Leucine Zipper (L-GILZ) is a newly identified isoform of the better characterized GILZ, a glucocorticoid (GC)-induced gene, which plays an important role in GC-induced immunomodulation. GILZ interacts with many signaling proteins, such as NF-kB, Ras and Raf, inhibiting downstream signaling pathways and affecting cell cycle, apoptosis, and differentiation. L-GILZ interacts with Ras and contributes to cell differentiation control. The p53 transcription factor regulates the expression of genes crucial for biological processes such as apoptosis, cell proliferation, metabolism, senescence and cell repair. Activation of p53 can suppress neoplastic transformation, inhibiting the growth of mutated or damaged cells. Notably, p53 binding proteins, such as MDM2, limit p53 activity thus regulating p53 stress response. We here demonstrate that L-GILZ activates p53 and induces inhibition of cell proliferation and tumor cell growth. In particular, over-expression of L-GILZ in (*p53*+/+) HCT116 human colorectal carcinoma cells, results in inhibition of cell proliferation, induction of apoptosis and suppression of growth of xenograft in mice. Moreover, expression of p21 and PUMA is increased in L-GILZ-transfected (*p53*+/+) but not in (*p53*-/-) HCT116 cell line. A direct interaction of L-GILZ with both p53 and MDM2 appears to regulate p53 activation. In fact, we demonstrate that the binding affinity of L-GILZ for MDM2 is higher than that for p53 and that L-GILZ disturbs p53/MDM2 complex formation thus making p53 available for downstream gene activation. These findings reveal L-GILZ as a novel p53 regulator and as a candidate for new therapeutic anticancer strategies targeting p53.

RITA (Reactivation of p53 and Induction of Tumour cell Apoptosis) is a compound activating p53, a key tumor suppressor gene defective in 90% of tumors. RITA treatment induces ULBP2 expression on tumors leading to a higher NK cells susceptibility (Li et al. Cell Cycle 2011).
To enhance the pharmacological effect of RITA on tumour cells a novel drug delivery strategy will be developed, by functionalizing the shell of RITA-loaded nanoparticles with immunogenic peptides thus enabling combinatorial effects consisting of RITA as well as NK cell mediated antitumor responses in vivo.

PEG-PLA copolymer micelles with a hydrophilic, non-immunogenic corona made of poly (ethylene glycol) (PEG) and a hydrophobic biodegradable poly(lactide) (PLA) core have enormous potential as long-circulating drug carrier systems. “Tree shaped” copolymers made of a PEG trunk and two or four arms of PLA have been synthesized. The interactions of the copolymers, previously functionalized with fluorescent agent, at single cells and population levels by using confocal analysis have been evaluated. PEG-PLA linear (AB), A(B)2 and A(B)4 enter inside the cells between 2 and 24 hours.
Our data indicate that the copolymer PEG-PLA A(B)2 is get efficiently internalized by HEK 293T since its nanoparticles can be found inside the cytoplasm. In the time course experiments, increased number of cells displays signs of copolymer internalization with substantial accumulation of foci present at 24 hrs; no staining was observed on the cell membranes and nuclei. Effects of PEG-PLA linear on lymphocyte cell subsets and their cytotoxicity towards tumour targets will be discussed.

W6.15.03
Sub-visible particles in protein therapeutics - are they responsible for the induction of unwanted immune responses?

C. Lubich*, M. Malisauskas, T. Prenninger, C. Lenk, E. Hopfner, F. Scheiflinger, B. M. Reipert;*
Baxter Innovations GmbH, Vienna, Austria.

Sub-visible particles in protein therapeutics have received increasing attention in recent years because they are believed to play a major role in the induction of unwanted immune responses. In particular amyloid-like protein particles could be associated with an activation of the innate immune system as was demonstrated for Amyloid beta peptides. Currently available technologies such as Micro-Flow Imaging and Nanoparticle Tracking Analysis are suitable for quantification of sub-visible particles but have limited capability for more in-depth characterization of the nature of these particles.
We developed a novel flow-cytometry-based technology that combines quantification and in-depth characterization of sub-visible particles over a size range of 0.75µm- 75µm. This technology allows assessment of the amount, size and nature of sub-visible particles. The inclusion of the fluorescent dye 4-(dicyanovinyl)-julolidine (DCVJ) which binds to cross-beta-sheet structures in amyloid-like protein particles, provides important information on the nature of the particles.
We used the new technology to assess amount, size and nature of sub-visible particles in a variety of *in vitro* generated sub-visible particle preparations originating from different therapeutic proteins. We also included non-protein particles in the analysis. Concomitant to particle analysis we used cellular *in vitro* assays to assess the potential of different protein particles to trigger the innate immune system. We believe that the combination of sub-visible particle characterization with the assessment of potential immune stimulatory activities can provide new insight into important mechanisms regulating the induction of unwanted immune responses by protein therapeutics.

W6.15.04
Assessing immune toxicity of engineered nanoparticles: modulation of inflammation in a novel in vitro model based on human primary monocytes

Y. Li[1,2], *P. Italiani*[1], *E. Caslas*[3], *V. F. Puntes*[3], *D. Boraschi*[1];
[1]*Institute for Biomedical Technologies (ITB)-National Research Council (CNR), Pisa, Italy,* [2]*Department of Molecular Biology-University of Salzburg, Salzburg, Austria,* [3]*Institut Català de Nanotecnologia (ICN), Barcelona, Spain.*

The potential effects of engineered nanomaterials on innate/inflammatory responses need to be considered when assessing nanosafety issues, since the alteration of the normal progress of inflammatory defence response may cause pathological derangement even in the absence of overt toxicity.
To investigate the interference of nanomaterials with the normal development of the inflammatory response, a human monocyte-based *in vitro* model has been developed and proved to realistically

reproduce the human inflammatory reaction. $CD14^+$ human blood monocytes were sequentially stimulated with different combinations of agents and conditions (CCL2, LPS, TNFα, IFN-γ, 37°C *vs*. 39°C), so as to mimic the entire course of a physiological inflammatory reaction (initiation, development, eventual resolution). A model of persistent inflammation has been also designed to investigate the possible modulation of with pathological inflammation by nanoparticles.
Monocytes were exposed to Au nanoparticles (diameter 10 nm, 1.28 µg/ml, 0.16 $cm^2/10^6$ cells, endotoxin-free) during the course of the *in vitro* inflammatory reaction. Gene expression and protein production of inflammatory and anti-inflammatory cytokines were analysed at different times during the course of the inflammatory response.
Preliminary results show that Au nanoparticles do not significantly affect the course of either the physiological or the persistent inflammatory response in the *in vitro* monocyte-based models, indicating that these particles do not pose a significant risk for human health.
This study thus proposes the use of a valid and representative model for human inflammation, for realistically investigating the effects of nanoparticles on inflammatory/innate immune responses, predictive on immuno-nanorisk for human health.
Supported by NanoTOES (PITN-GA-2010-264506).

Protein kinase Cδ regulates inducible nitric oxide synthase expression through IRF1

T. Leppänen[1], *R. Korhonen*[1], *M. Laavola*[1], *R. Nieminen*[1], *R. K. Tuominen*[2], *E. Moilanen*[1];
[1]*The Immunopharmacology Reseach Group, University of Tampere School of Medicine and Tampere University Hospital, Tampere, Finland,* [2]*The Division of Pharmacology and Toxicology, University of Helsinki Faculty of Pharmacy, Helsinki, Finland.*

In inflammation, pro-inflammatory cytokines and bacterial products induce the production of high amounts of NO by inducible nitric oxide synthase (iNOS) in inflammatory and tissue cells. NO is an effector molecule in innate immunity, and it also has regulatory and pro-inflammatory/destructive effects in the inflammatory process. Protein kinase Cδ (PKCδ) is an important signaling protein regulating B lymphocyte functions, but less is known about its role in innate immunity and in the regulation of expression of inflammatory genes in activated macrophages and tissue cells. In the present study we investigated the role of PKCδ in the regulation of iNOS expression in inflammatory conditions.
Down-regulation of PKCδ by siRNA and inhibition of PKCδ by rottlerin suppressed NO production and iNOS expression in activated macrophages and fibroblasts. PKCδ targeted siRNA and inhibition of PKCδ by rottlerin suppressed also the expression of transcription factor IRF1. Accordingly, down-regulation of IRF1 by siRNA reduced iNOS expression in activated macrophages. In addition, inhibition of PKCδ showed anti-inflammatory effects in carrageenan induced paw inflammation in mice as did iNOS inhibitor L-NIL.
These results show, that PKCδ up-regulates transcription factor IRF1, possibly through activation of transcription factor STAT1, and by that mechanism enhances the expression of iNOS in cells exposed to inflammatory stimuli. In addition, inhibition of PKCδ was found to have anti-inflammatory properties also in vivo. Taken together, these results suggest that PKCδ inhibitors hold anti-inflammatory properties in vitro and in vivo, making PKCδ a potential target for anti-inflammatory drug development.

Multiple sclerosis (MS) is the most common demyelinating disease of the central nervous system. While there have been significant advances in therapies targeting immune system dysfunction, there is an urgent need for developing drugs aimed at protecting demyelination and axonal loss as part of the pathogenic mechanism of MS. In our study, we used the experimental autoimmune encephalomyelitis (EAE) model induced in C57BL6 mice, by immunization with MOG35-55 peptide. We studied the molecular mechanisms involved in the effect of C-Phycocyanin (C-Pc), a natural antioxidant derived from Spirulina platensis (a blue - green algae) and beta IFN, on EAE. The study involved clinical evaluations, measurements of regulatory T cells in the spleen, effector and regulatory cytokines by qPCR in the brain and serum by Bioplex, and analyses using Transmission Electron Microscopy. Results showed a reduction of clinical signs, the induction of CD4 + Foxp3 + in the spleen and the reduction of effector cytokines, such as IL-17 in the brain and serum. Also, ultra-structural analyses demonstrated that C-Pc was able to remyelinate axons, and the gene expression profile of Microarray studies identified common and specific processes modulated by C-Pc and beta IFN. This suggests the need of a combined Multiple Sclerosis therapy with two components targeting the main steps of the MS pathogenic mechanism, one related to immune dysfunction and the other directed towards neurodegenerative changes. Our study, consistent with current approaches on the use of combined therapies, constitutes an attractive and potentially effective strategy for future clinical trials in MS.

W6.16.01
An autoantibody profile for SLE diagnosis using the ImmunArray iCHIP™

I. R. Cohen[1,2], *V. Daniel Carmi*[2], *L. Belanis-Meirovich*[2], *R. Sorek*[2], *O. Cohen-Gindi*[2], *N. Dromi*[2], *M. Lerner*[2], *E. Sahar*[2], *I. Tamir*[2], *C. Putterman*[3];
[1]*Weizmann Institute of Science, Rehovot, Israel,* [2]*ImmunArray, Rehovot, Israel,* [3]*Albert Einstein Collage of Medicine, Bronx New York, NY, United States.*

Systemic lupus erythematosus (SLE) is a chronic, recurrent, potentially fatal multisystem inflammatory disorder mainly affecting women. SLE patients produce antibodies to many different self-antigens. Nevertheless, currently used serological markers for SLE are lacking in specificity and/or sensitivity. SLE is diagnosed through a combination of clinical and laboratory criteria with four out of 11 criteria developed by the American College of Rheumatology. Accurate and timely diagnosis of SLE is important because treatment can reduce morbidity and mortality. The aim of this study was to develop an improved diagnostic test by measuring and multiplexing specific autoantibody reactivities in SLE patients. Autoantibody reactivity profiles in serum samples collected from 97 SLE patients within three years of the diagnosis were compared with those of 56 healthy controls. Autoantibody profiles were determined using the ImmunArray iCHIP™ - a proprietary protein microarray technology that allows the display of antigens representing a wide range of SLE-associated biochemical pathways on a single chip. Using this novel platform, SLE patients could be differentiated from healthy subjects by a relatively small subset of auto-antigens and Epstein Barr Virus (EBV) antigens. The autoantibody reactivity profile that allowed SLE diagnosis with high sensitivity and specificity displayed differential response to known SLE-specific antigens, such as single-stranded DNA and EBV, and to several novel ones. Validation of this profile in additional patient samples showed good performance. An antibody profile for SLE diagnosis using a single multiplexed chip was successfully developed. This profile may differentiate between SLE patients and healthy individuals.

W6.16.02
Identification of potential biomarkers and therapeutic targets for Multiple Sclerosis by M2 proteomics.

***I. Raphael**, W. E. Haskins, T. G. Forsthuber;*
University of Texas at San Antonio, San Antonio, TX, United States.

Despite extensive research, multiple sclerosis (MS) remains a disease that lacks a definitive diagnostic test. Even after a diagnosis of MS has been established, currently it cannot be reliably predicted whether and when disease relapses will occur, thus patients may undergo years of unnecessary treatments. Additionally, because the current treatments for MS can produce dramatically different outcomes in individual patients, there is a critical need to develop biomarkers for treatment efficacy and resistance. We have recently developed a novel quantitative Microwave & Magnetic (M^2) proteomics method to quantitatively measure changes in proteome expression during experimental autoimmune encephalomyelitis (EAE), the standard murine animal model of MS. Our data revealed significant consistent changes in the proteome over the disease course. Changes in the expression of protein isoforms correlated either with time (days after EAE induction) or disease severity (clinical score). Interestingly, we have identified unique changes in the proteome prior to the clinical symptoms onset. Those pre-onset changes may allow us to predict the subsequent severity of the disease. Last, we have identified that glucocorticoid-drugs (GCs) have an effect on these changes with a strong statistical correlation to EAE severity and more importantly, these changes closely mirror disease progression independent of any cytokine response to the GCs. Thus, homologous human biomarkers may be useful to accurately and reliably predict disease initiation, clinical severity and GCs drug efficacy. Importantly, these biomarkers illuminate some of the key mechanisms that contribute to the disease and may be useful to develop new therapeutic targets for MS.

W6.16.03
The alarmins S100A8 and S100A9 as promising targets for non-invasive molecular imaging of phagocyte activation during inflammation

***T. Völler**, M. Eisenblätter, J. Roth, T. Vogl;*
Institute of Immunology, Münster, Germany.

The proinflammatory alarmins S100A8 and S100A9 are released by activated phagocytes at sites of inflammation. Due to their favorable kinetics S100A8/S100A9 (calprotectin) could be characterized as a very early and sensitive biomarker in a broad spectrum of acute and chronic inflammatory disorders like rheumatoid arthritis, allergies, inflammatory bowel or lung diseases. The purpose of our study was to avail these findings for *in vivo* imaging of inflammation with the perspective of monitoring disease activity in clinically relevant disorders.
S100A9-antibody was coupled to the fluorescence dye Cy5.5 for optical imaging studies by Fluorescence Reflectance Imaging (FRI). We investigated various mouse models of inflammatory and infectious diseases using anti-S100A9-Cy5.5 antibodies. S100A9 knock-out-mice served as additional controls to prove specificity. In the contact dermatitis model injection of anti-S100A9-Cy5.5 resulted in contrast to noise ratios (CNR) which were more than ten-fold higher compared to those of knock-out-mice and also significantly higher after injection of IgG-Cy5.5 without relevant specificity. With this specificity-proven marker we monitored inflammatory models of different immunological etiology, e.g. collagen-induced arthritis (CIA) or experimental leishmaniasis. In both models molecular imaging of S100A9 provides a sensitive and specific method of non-invasive monitoring even in subclinical disease stages. In addition, S100A9 is the first biomarker with a prognostic value for the Th1/Th2-driven inflammatory process in experimental leishmaniasis even weeks prior to the clinical outcome. In conclusion S100A9 has the potential to monitor disease activities *in vivo* for many other inflammatory diseases associated with a high phagocyte activity.

Fractalkine ligand-receptor axis dictates prognostic outcome in human colorectal cancer

***M. Erreni**[1], I. Siddiqui[1], F. Marchesi[1], S. Pesce[1], D. Morone[1], A. Doni[1], C. Rumio[1], L. Laghi[2], A. Mantovani[1,3], P. Allavena[1];*
[1]Humanitas Clinical and Cancer center, Rozzano, Italy, [2]Lab of Gastroenterology, IRCCS Istituto Clinico Humanitas, Rozzano, Italy, [3]Biotechnology and Translational Medicine, University of Milan, Milan, Italy.

In the tumor microenvironment chemokines affect cancer progression, influencing the composition of the tumor milieu and regulating metastatic processes. In this study we investigated the expression and role of the CX3CL1-CX3CR1 axis in 170 specimens of human colorectal cancer (CRC). We found that CX3CL1 and CX3CR1 were expressed by neoplastic cells at primary tumor sites, while - in marked contrast- expression at metastatic sites (lymph nodes and liver) was significantly reduced. High expression of both ligand and receptor by primary tumor cells (positive-axis tumors) was associated with better patient prognosis, compared to negative-axis tumors and with a reduced risk of developing metachronous metastasis. At inflammatory/tumor sites CX3CL1 has been associated with increased recruitment of immune cells; in our study, tumor expression of CX3CL1 did not correlate either with the density of CD3+ nor with CD68+ cells at the tumor invasive front. Since CX3CL1 is a trans-membrane molecule and affects cell-cell interaction, we hypothesized that double expression of the two molecules increased the adherence among cancer cells, preventing tumor dissemination. By using mixed populations of CX3CL1- or CX3CR1-transduced tumor cells, we observed that ligand-induced engagement of receptor-positive tumor cells resulted in enhanced adhesive activity and lower migratory ability in vitro. Furthermore, in a mouse spleen-liver model of metastasis, double expression of CX3CL1 and CX3CR1 significantly reduced the number of liver metastasis. In conclusion, tumor CX3CL1-CX3CR1 expression is associated with lower degree of disease recurrence and distant metastasis; thus, this chemokine axis is a potential biomarker with prognostic utility in human CRC.

W6.16.05
Tumor-specific adaptive immune responses to primary and metastatic ovarian tumors

***C. L. Desmarais**[1], R. Emerson[1], A. Sherwood[1], C. Sanders[1], M. Tewari[2], J. Guenthoer[2], C. Carlson[2,1], C. Drescher[2], H. Robins[2,1];*
[1]Adaptive Biotechnologies, Seattle, WA, United States, [2]Fred Hutchinson Cancer Research Center, Seattle, WA, United States.

The presence, abundance, population, and diversity of Tumor Infiltrating Lymphocytes (TILs) have been identified as prognostic indicators in several cancers. Emerging cancer therapeutics including immunomodulators and adoptive T-cell therapy highlight the need to better understand and track this population of T cells, especially the need to understand if the adaptive immune response is tumor specific or general. We have developed a method to amplify, using a multiplex PCR approach, and deeply sequence rearranged T-cell receptor Beta (TCRB) chains. We use this assay to characterize TIL populations of primary and metastatic tumors and matched blood. We sequenced 10 primary and metastatic ovarian tumors collected from 5 patients. Each tumor was divided into a grid pattern with 8-22 sections (tumor size dependent). For each tumor section we collected data on the number, diversity, and the unique CDR3 sequences carried by the TILs, to characterize the intra-tumor heterogeneity of TIL count, diversity, and T cell clone overlap. In addition, we sequenced the immune repertoire from a paired peripheral blood sample to identify if the immune response was tumor specific. We found that the immune response within peripheral blood was significant and quantifiably different than the tumor repertoire. TIL repertoire within sections of a tumor showed high similarity to each other. These data indicate that the TCR repertoire of the ovarian tumor environment is tumor specific and homogeneous.

W6.16.06
Unique TCR signature of a novel cross-reactive CMV-specific T cell receptor: potential clinical implications

N. A. Mifsud[1], *T. H. O. Nguyen*[1], *L. Rowntree*[1], *N. Bird*[2], *D. Pellicci*[2], *K. Kedzierska*[2], *T. Kotsimbos*[1,3];
[1]*Monash University, Melbourne, Australia,* [2]*The University of Melbourne, Melbourne, Australia,* [3]*The Alfred Hospital, Melbourne, Australia.*

Human cytomegalovirus (CMV) reactivation contributes to significant post-transplant clinical complications. Cross-reactive virus-specific T cells that co-recognise specific HLA alloantigens expressed by the donor allograft may evoke clinically relevant immune reactivity. We identified a novel HLA-A*02:01-restricted cytotoxic T-cell lymphocyte (CTL) with dual specificity towards the CMV-specific epitope (NLVPMVATV) and HLA-B27 subtypes. We examined the T cell receptor (TCR) repertoire encompassing conventional and cross-reactive virus-specific CTLs in a healthy individual and following an episode of post-transplant CMV reactivation in a lung transplant recipient (LTR; HLA-B27 allograft). Autologous peptide-pulsed A*02:01/NLV-specific CTLs were *in vitro* expanded, specificity confirmed by tetramer. Cross-reactive NLV-specific CTLs were identified as IFN-g-secreting following stimulation with HLA-B27 allele-expressing cell lines. Paired TCR variable alpha and beta chains from CDR3 were characterised using novel single-cell multiplex nested RT-PCR. In healthy individual, conventional NLV-specific TCR repertoire was dominated by a single TCR clone (81%; TRAV35TRAJ42_TRBV12-4TRBJ1-2). However, upon stimulation with HLA-B*27:09, cross-reactive NLV-specific TCR repertoire significantly skewed to a different clonotype (70%; TRAV3TRAJ31_TRBV12-4TRBJ1-1). This cross-reactive TCR clonotype was also identified in a LTR, increasing dramatically from pre-transplant (62%) to becoming the sole TCR (100%) prior to a clinically relevant episode of CMV reactivation. Functional activation by HLA-B27 molecules and NLV-specificity was confirmed by expressing LTRs cross-reactive TCR genes in a SKW3 T cell line. The public nature of the unique cross-reactive TCR signature can be used to monitor T cell dynamics during active viral infection in allogeneic transplant recipients and determine their ability to cause destructive immunopathology.

W7.01 Imaging of the immune system

IL7.01.01
In vivo imaging of intrahepatic effector CD8 T cell dynamics

M. Iannacone*;*
San Raffaele Scientific Institute, Milan, Italy.

Effector CD8 T cells play a critical role in viral clearance and liver disease during HBV infection. Accordingly, understanding the signals that modulate how these cells home to the liver, recognize antigen and exert effector functions within this organ is of paramount importance.
Through the use of intravital imaging and unique mouse models of HBV pathogenesis, we found that, in contrast to most microvascular beds in which leukocyte adhesion is restricted to postcapillary venules, >90% of intrahepatic effector CD8 T cells arrest occurs within liver sinusoids. This early intrahepatic accumulation is independent of selectins, integrins, chemokines and MHC/TCR interaction but involves platelets and CD44-hyaluronic acid interaction. Indeed, blocking CD44 on platelets (but not on CD8 T cells) prevented early intrahepatic CD8 T cell accumulation. Our results suggests a model whereby platelets - after adhering to liver sinusoidal endothelial cells and becoming activated - provide a preferential surface onto which CD8 T cells arrest their run within the hepatic microcirculation.
After their initial arrest, effector CD8 T cells exhibit an intrasinusoidal crawling behavior that is inhibited by antigen recognition. Indeed, by setting up an immunofluorescence staining that allows us to identify IFN-γ-producing cells relative to their position within liver sinusoids, we found that effector CD8 T cells become IFN-γ positive while still intravascular, suggesting that recognition of hepatocellular antigens occurs in a diapedesis-independent manner. Specifically, effector CD8 T cells were found to recognize hepatocellular antigens by extending protrusion through sinusoidal fenestrae and this process is required to allow T cell extravasation.

IL7.01.02
Intracellular control of central versus effector memory T cell migration and activation

J. V. Stein*;*
University of Bern, Bern, Switzerland.

New imaging techniques including twophoton microscopy (2PM) and mesoscopic imaging have uncovered the dynamic interactions between lymphocytes and antigen-presenting cells and the large-scale rearrangements of lymphoid tissue during inflammation. Here, we will discuss factors orchestrating central versus effector T cell migration in vivo, with a focus on G-protein-coupled receptors and their intracellular effectors. To this end, we use 2PM to follow the dynamic behavior of antigen-specific T cells in lymph nodes (“central memory T cells”) and salivary glands (“effector memory T cells”) during the memory phase of an antiviral immune response. In both tissues, central and effector memory T cells show robust migration, albeit at slower speeds and more complex cellular shape in salivary glands. Furthermore, both effector and central memory T cells maintain their ability to rapidly engage with CD11c+ antigen-presenting cells. The absence of the Cdc42 guanine exchange factor DOCK8 and pharmacological inhibition of the Rho effector ROCK resulted in impaired effector memory T cell migration in salivary glands, presumably owing in part to its greater stromal tissue complexity as compared to lymph nodes. Taken together, these findings suggest tissue-specific roles for intracellular signaling modules, which control tissue-specific T cell function.

W7.01.01
Lateral distribution of the T cell receptor and membrane lipid detected by high-resolution secondary ion mass spectrometry

F. Wang[1], *M. M. Lozano*[1], *B. F. Lillemeier*[2], *S. G. Boxer*[1], *M. M. Davis*[1];
[1]*Stanford University, Stanford, CA, United States,* [2]*Salk Institute for Biological Studies, La Jolla, CA, United States.*

The engagement of the T cell antigen receptor (TCR) by a specific peptide-MHC ligand initiates a trans-membrane signaling that activates the T cell. An important event in T cell signaling is the recruitment of signaling proteins to the cell membrane and the assembly of a multi-protein (and lipid) signaling complex. Although it has been suggested that lipid/cholesterol composition plays an important role in the regulation of surface signaling complexes, direct visual evidence on lipid/cholesterol participation in the formation of these complexes is still lacking. Here, we characterize the clustering of TCR within T cell and model membranes by secondary ion mass spectrometry (NanoSIMS) with a spatial resolution of 50 nanometers or better. Quantitative information about the chemical composition of membrane complexes can be obtained through the use of orthogonal isotopic labeling of each signaling molecule. Analysis of nanoSIMS images shows the accumulation of TCRs into 60-150 nm clusters/islands within the membrane of an activating T cell and we further attempt to reveal the composition and lateral distribution of TCR and other membrane components, including cholesterol, within model membranes. Because these membrane structures may be shared with many other cell types, we believe the insights we gain in this system will be generalizable to other examples of cell surface receptor signaling.

W7.01.02

Role of colonic lymphoid patch dendritic cells in patrolling the colonic lumen, transporting antigen, and imprinting homing of T cells to the colon

J. A. Berzofsky[1], *A. Dzutsev*[1], *A. Hogg*[1], *L. Koo*[2], *H. Yu*[1], *R. Goldszmid*[1], *J. Kabat*[3], *Y. Sui*[1], *O. Schwartz*[2], *G. Trinchieri*[1];
[1]*National Cancer Institute, National Institutes of Health, Bethesda, MD, United States,* [2]*National Institute of Allergy & Infectious Diseases, National Institutes of Health, Bethesda, MD, United States,* [3]*National Institute of Allergy & Infectious Diseases, National Institutes of Health, Bethesda, MD, United States.*

Viral transmission occurs largely through mucosal surfaces, but neither mechanisms of mucosal immune surveillance nor mechanisms of imprinting of T cell homing to the colon are well understood. Because CX3CR1$^+$ dendritic cells (DCs) that extend processes into the gut lumen are not mobile and cannot transport antigen, an explanation for antigen surveillance was sought. Here, we show that migratory CD103$^+$CD11b$^+$ DCs actively patrol the colonic lumen, phagocytose microorganisms, and transport them to colonic lamina propria. Recruitment of DCs to the colonic lumen depends on CCL20. These results resolve a paradox that DCs that could acquire antigen could not transport it, and explain pathogen sampling from the gut lumen. We also examined the ability of colonic DCs to imprint T cell homing to the colon. In contrast to small intestinal DCs that induce T cell homing to the small intestine, we find large intestinal DCs induce homing preferentially to the colon. They express lower levels of RALDH, responsible for RA production, than small intestinal DCs and thus induce only alpha4beta7 but not CCR9. Further, whereas beta7-deficient CD8$^+$ T cells were unable to home to the colon or small intestine, as expected, CCR9-deficient T cells still homed well to the colon but not to the small intestine. Thus, the signals for homing to the two compartments are different and homing to the large intestine is imprinted by the specialized DCs residing there. Understanding these functions may allow more rational design of mucosal vaccines targeted to the relevant compartment.

Comprehensive confocal imaging and 3D computer analysis of blood and lymphatic vascular channels across entire lymph nodes

I. Kelch[1,2], *G. Bogle*[1,3], *A. Phillips*[1,2,4], *I. J. LeGrice*[3,5], *G. B. Sands*[3], *D. A. Gerneke*[3], *C. J. Mansell*[1,2], *P. R. Dunbar*[1,2];
[1]*Maurice Wilkins Centre for Molecular Biodiscovery, Auckland, New Zealand,* [2]*School of Biological Sciences, University of Auckland, Auckland, New Zealand,* [3]*Auckland Bioengineering Institute, University of Auckland, Auckland, New Zealand,* [4]*Department of Surgery, University of Auckland, Auckland, New Zealand,* [5]*Department of Physiology, University of Auckland, Auckland, New Zealand.*

Lymph nodes (LNs) are highly organized organs of the adaptive immune system. An intricate network of blood and lymphatic vascular channels serves as entry and exit routes for lymphocytes but their overall structure and dynamism during LN activation remain poorly understood. By using a new automated imaging system which enables extended tissue imaging of whole lymph nodes at confocal resolution, we aim to gain new spatial information on the LN topology and make structural changes measurable through computer analysis. Fluorescently labeled vascular systems of murine LNs were imaged at 2 µm pixel resolution in their entirety of up to 8 mm^3 and analyzed using in-house designed software tools. High-resolution volume images of the blood and lymphatic networks alone provided new insights into their labyrinthine arrangement in LN subcompartments, while additional computer reconstruction allowed sophisticated measurements in 3D. As a first step, we calculated the blood vessel network volume, individual segment diameters, and the distribution of distance to the nearest blood vessel. Current experimentation is employing measurements of the vessel diameters to revisualize the blood vessel network, allowing functional elements such as the feed arteriole and putative high endothelial venules to be extracted and analyzed in detail. Subsequently, we plan to investigate LNs at different stages of the immune response to gather more information on the remodeling processes of vascular networks in response to increased lymphocyte traffic. Ultimately, we wish to elucidate the topological relationship and dynamism of structural elements in LNs and draw a comprehensive map of LN anatomy.

W7.01.04

Skin patrol by tissue-resident CD8+ T cells

S. Ariotti[1], *J. B. Beltman*[1], *G. Chodaczek*[2], *M. Hoekstra*[1], *A. E. van Beek*[1], *R. Gomez-Eerland*[1], *L. Ritsma*[3], *J. van Rheenen*[3], *A. Maree*[4], *T. Zal*[2];
[1]*NKI, Amsterdam, Netherlands,* [2]*MD Anderson Cancer Center, Houston, TX, United States,* [3]*Hubrecht Institute, Utrecht, Netherlands,* [4]*John Innes Centre, Norwich, United Kingdom.*

Recent work has demonstrated that following the clearance of infection, a stable population of memory T cells remains present in peripheral organs and contributes to the control of secondary infections. However, little is known about how tissue-resident memory T cells behave in situ and how they encounter newly infected target cells.
Here we demonstrate that antigen-specific CD8$^+$ T cells that remain in skin following Herpes Simplex Virus infection show a steady state crawling behavior in between keratinocytes. Spatially explicit simulations of the migration of these tissue-resident memory T cells indicate that the migratory dendritic behaviour of these cells allows the detection of antigen expressing target cells in physiologically relevant time frames of minutes to hours. Furthermore, we provide direct evidence for the identification of rare antigen-expressing epithelial cells by skin-patrolling memory T cells in vivo. These data demonstrate the existence of skin patrol by memory T cells and reveal the value of this patrol in the rapid detection of renewed infections at a previously infected site.

W7.01.05

Single cell analysis of molecular networks involved in T-cell activation and signalling

R. Brignall, *J. Bagnall, L. Schmidt, D. Spiller, D. A. Jackson, M. Travis, M. R. H. White, P. Paszek;*
University of Manchester, Manchester, United Kingdom.

Our immune system must be able to rapidly fight against pathogens, but at the same time be tightly regulated to prevent harmful responses. This intricate balance is controlled in part by T lymphocytes. Targeting T cells has the potential to revolutionize therapeutics, however a better quantitative understanding of molecular processes controlling the functions of these cells is still required.
T cell signaling is tightly regulated by a set of molecular networks that involve families of transcription factors called Nuclear Factor kappaB (NF-kappaB) and Nuclear Factor of Activated T-cells (NFAT). Using live-cell imaging we previously showed that in response to cytokine stimulation the NF-kappaB system undergoes nuclear-to-cytoplasmic oscillations, which might control downstream gene expression (Science, 324:242, 2009, PNAS 107:11644, 2010). However, the precise role of this dynamic behaviour in T cell signalling remains unresolved.
Here we use systems biology approaches involving cutting-edge live-cell-imaging to investigate activation and signaling of Jurkat and primary CD4+ T cells in response to cytokine and T-cell receptor stimulation. Single-cell NF-kappaB and NFAT dynamics are correlated with patterns of downstream gene expression, including Interleukin-2, which is indicative of complex dynamical control of T lymphocyte function. This new single-cell picture of T cell biology will move us towards better therapeutic strategies for inflammatory disease.

W7.01.06
Dynamic expression of co-stimulatory and co-inhibitory receptors regulates termination of T cell-DC interaction during CD8 T cell activation

M. Perro[1]*, J. Godec*[1]*, S. Loughhead*[1]*, I. Mazo*[1]*, S. Henrickson*[2]*, W. N. Haining*[3]*, A. H. Sharpe*[1]*, U. H. von Andrian*[1]*;*
[1]Harvard Medical School, Boston, MA, United States, [2]Children's Hospital Boston, Boston, MA, United States, [3]Dana-Farber Cancer Institute and Children's Hospital Boston, Boston, MA, United States.

Multiphoton intravital microscopy (MP-IVM) of the lymph-node (LN) has revealed that activation of naïve CD8 T cells by interaction with antigen (Ag)-laden dendritic cells (DCs) occurs in three distinct phases. The first phase of short-transient T cell-DC interactions is followed by a second phase of intense communication between T cells and DCs, characterize by long-stable interactions and reduced motility. After phase 2 termination, T cells re-acquire motility, shorten their interaction with DCs, start proliferating and exit the LNs. Whilst transition from phase 1 to phase 2 has been well characterized, the mechanisms responsible for termination of phase 2 are unknown. Systematic analysis of T cell expression profiles suggested that phase 2-3 transition is actively controlled by molecular mechanisms which involved a timed regulation of co-stimulatory and co-inhibitory molecules, such as CD28 and PD-1. Using MP-IVM of the LN, we studied the interstitial motility of PD-1-/- T cells. When compared with wild type T cells, PD-1-/- T cells have extended phase 2 defined as longer T cell-DC interaction and reduced motility. Whether and how PD-1/PD-L1 axis synergizes with other co-stimulatory and co-inhibitory receptors is under evaluation. Altogether these data provide evidences of a new molecular mechanism based on dynamic regulation of co-stimulatory and co-inhibitory receptors, which control T cell activation and may fundamentally shape the ensuing T cells response.

Methodological applications of host-pathogen data profiles conserved in Evolution

A. L. Rivas[1]*, M. D. Jankowski*[2]*, G. Leitner*[3]*, D. Schwarz*[4]*, J. M. Fair*[5]*, A. L. Hoogesteijn*[6]*, J. B. Hittner*[7]*, J. M. Hyman*[8]*, D. J. Perkins*[1]*;*
[1]University of New Mexico, Albuquerque, NM, United States, [2]University of Wisconsin-Madison, Madison, WI, United States, [3]Kimron Veterinary Institute, Bet Dagan, Israel, [4]Georg-August-University, Göttingen, Germany, [5]Los Alamos National Laboratory, Los Alamos, NM, United States, [6]Centro de Investigación y de Estudios Avanzados, Merida, Mexico, [7]College of Charleston, Charleston, SC, United States, [8]Tulane University, New Orleans, LA, United States.

The hypothesis that properties well conserved in Evolution may provide informative methods was evaluated in avian and mammalian species infected by viral, parasite, and bacterial agents. Three data levels were investigated: (i) non-structured data (percentages of lymphocytes, neutrophils, and macrophages), (ii) 'basic' data structures (interactions between two or more cell types, expressed as ratios), and (iii) 'high-level' structures (three-dimensional [3D] relationships).
In all studies, non-structured data did not differentiate disease-positive (D+, or observations in which a microbe was isolated) from disease-negative (D-, or microbial-negative) groups: D+ and D- data distributions overlapped. In contrast, when 'high-level' data structures were investigated in 3D space, all studies displayed a single and circular line of observations, which distinguished D- from D+ observations and also provided temporal information. However, when 'basic' data structures (the components of 'high-level' structures) were tested individually, they failed to discriminate D- from D+ observations.
Findings were consistent with Systems Biology/Evolutionary Biology theory: 'emergence' (the quintessential property of biological systems) does not depend on any one elemental factor, but may be revealed when such factors are assembled into and integrated with structures of higher level. Because 'emergence' revealed its robustness, infectious disease research may be facilitated by methods that, by focusing on data structure, may reveal properties well conserved in Evolution. Such methods may possess higher predictability than methods that, regardless of the number of individuals tested or factors investigated, do not and cannot capture phenomena conserved over millions of years.

W7.02.02
Higher expression of genes related to B cell activation in female spleen cells

R. Godínez-Aguilar[1]*, E. Aguirre-von-Webesser*[2]*, V. Bermúdez*[3]*, E. Lamoyi*[2]*, J. Berumen*[4]*,* ***J. Moreno***[3]*;*
[1]Autonomous University of Mexico City, Mexico City, Mexico, [2]National University of Mexico, Mexico City, Mexico, [3]National Institute of Public Health, Cuernavaca, Mexico, [4]General Hospital of Mexico, SSA, Mexico City, Mexico.

Vertebrate immune responses in males and females are dimorphic, where female immunity to infectious agents is usually more efficient but carry an increased incidence of autoimmune diseases. Although it has been suggested that such bias could be due to the positive effect of oestrogens on immune responses, the molecular basis for these changes are, as yet, unclear. We compared gene expression of healthy young adult male (baseline) and female (study subject) C57BL/6 mouse splenocytes, which had comparable cell ratios of T cells, B cells (B-1, B-2 and Bmz), and macrophages. Total spleen RNA (purity >1.9 260/280 OD) were used to produce cDNA and cRNA that was hybridised to Affymetrix 430 2 Complete Genome Mouse chips. Only data with twofold differences (increase or decrease) after normalisation (Qspline) were considered and were fit by means of the R package. False positives (False Discovery Rate) was 5% (adjusted $p<0.05$). Overexpressed genes grouped by gene ontology belonged to several categories, several of them immunologically relevant, including B cell activation (GO:0042113), among others. Overexpressed B cell activation genes included signalling proteins and receptors (**Bank1**, **Swap70**, **Cr2**, Prkcb, Pik3ap1, **CARMA1**, PTPN6, CD79a, CD22, CD40, Fcrla, Fcer2a, Ly6d), transcription factors (**Bcl11a**, Ebf1, FoxP1), etc. (Ighv14-2). Underlined gene names were confirmed and validated in B57BL/6 and Balb/c mice by quantitative RT-PCR and are being functionally examined. Polymorphisms of Bank1 and Cr2 have been linked to autoimmune diseases in humans.

W7.02.03
Functional proteomic interrogation of immune cell crosstalk and the effects of cytokine-targeted inhibitors using Single Cell Network Profiling (SCNP)

D. Hotson, A. Conroy, A. Cesano, ***R. Hawtin****;*
Nodality, Inc., South San Francisco, CA, United States.

Single cell network profiling (SCNP) is a multiparametric flow cytometry-based assay that measures simultaneous changes in multiple intracellular signaling proteins in response to modulators, providing a functional measure of pathway signaling in single cells without cell subset isolation. SCNP was applied to interrogate immune cell crosstalk and effects of targeted cytokine inhibitors upon crosstalk.
Healthy donor peripheral blood mononuclear cells (PBMCs) were modulated with Super Antigen (SAg) to drive immune cell cross talk via cytokine release and direct cell contact. Signaling kinetics in JAK-STAT, NFkB, MAPK and PI3K pathways were measured in monocytes, B cells and CD3+ CD4+/- T cells.
Within 45 minutes of SAg modulation multiple signaling pathways were selectively activated in monocytes. By 6 and 24 hours monocyte signaling resolved while lymphocyte signaling emerged. IL-2, TNFa and IL-6 inhibitors were used to deconstruct pathway specific contributions to cellular activation, identifying functional consequences of targeted cytokine blockade across cell subsets. IL-2 neutralization reduced PI3K pathway activation and p-STAT5 induction in T cells, while IL-6 blockade abrogated p-STAT3 induction in CD4+T cells, and TNFa neutralization reduced NFkB signaling in CD4- T cells.
Collectively these data demonstrate the ability of SCNP to better define disease pathophysiology and its abrogation, via interrogation

of immune cell crosstalk, dissection of pathway specific activity of targeted cytokine inhibitors, and holistic evaluation of the effects of targeted therapeutics on immune cell signaling. Expansion of this analysis to additional autoimmune and oncology-relevant modulators, signaling pathways, cell subsets and targeted therapeutics is in progress.

W7.02.04
Comparison of functional immune signaling profiles in peripheral blood mononuclear cells (PBMC) from rheumatoid arthritis (RA) patients versus healthy donors (HD) using Single Cell Network Profiling (SCNP)

J. Ptacek[1], **R. Hawtin***[1], *E. Evensen*[2], *J. Cordeiro*[2], *M. Atallah*[2], *C. Marimpietri*[2], *A. Cesano*[2], *.. TETRAD Investigators*[3], *P. K. Gregersen*[4], *S. L. Bridges*[5];
[1]**Co-first authors, Nodality, Inc., South San Francisco, CA, United States, [2]Nodality, Inc., South San Francisco, CA, United States, [3]TETRAD Clinical Sites/UAB Coordinating Center, Birmingham, AL, United States, [4]The Feinstein Institute for Medical Research, Manhasset, NY, United States, [5]University of Alabama at Birmingham, Birmingham, AL, United States.*

Prognostic and predictive biomarkers are lacking in RA. SCNP is a multiparametric flow cytometry-based assay that simultaneously measures changes in multiple intracellular signaling proteins in response to modulators providing a functional measure of pathway activity in single cells.
SCNP of 42 nodes (modulation/intracellular readout) within 21 immune cell subsets was performed on PBMCs from 181 RA patients collected before initiating new treatment, either MTX or biologic agent, within the national Treatment Efficacy and Toxicity in Rheumatoid Arthritis Database and Repository (TETRAD), and 10 age- and gender-matched healthy donors. TETRAD participants were 86% female and 76.5% Caucasian. All met ACR classification criteria for RA and mean Disease Activity Score on 28 joints (DAS28) was 4.77±1.40 [SD]. Using half the donors as a training set, multiple variations in signaling responses in discrete cell subsets associated with donor characteristics (e.g. healthy vs. RA, disease activity) were identified, and will be subsequently confirmed in the remaining donors (test set).
Specifically, TNFα signaling was lower in monocytes in most RA samples while analysis of T cell subsets identified significant differences with opposing directionality in IL-6 signaling as compared to healthy: RA helper T cell subsets had decreased IL-6→p-STAT1/3; cytotoxic T cell subsets showed increasing responsiveness to IL-6; central memory cytotoxic T cells had a significant increase in IL-6→p-STAT1. The clinical significance of these observations will be investigated with relation to RA pathophysiology and treatment response. These data reveal the functional biology associated with RA pathophysiology and enable the identification of potential prognostic and predictive biomarkers.

W7.02.05
The role of microRNAs in regulatory T cell function

C. Y. Brown[1], *T. Sadlon*[1], *S. Pederson*[1], *G. T. Goodall*[2], *M. Beyer*[3], *J. Schultze*[4], ***S. C. Barry***[1];
[1]*University of Adelaide, Adelaide, Australia, [2]SA Pathology, Adelaide, Australia, [3]University of Bonn, Bonn, Germany, [4]University of Bonn, Bon, Germany.*

The transcription factor FOXP3 is essential for the formation and function of regulatory T cells (Tregs) as demonstrated by the autoimmune disease in scurfy mouse and IPEX patients. However, little is known about the molecular basis of human FOXP3 function or the relationship between direct and indirect target genes in human Treg. We have performed a genome wide analysis of human FOXP3 target genes in natural Treg using chromatin immunoprecipitation array (ChIP-on-chip) combined with gene expression profiling and micro RNA profiling. These experiments identified 63 micro RNAs that are potential human FOXP3 target genes. We first analysed these miRs for differential expression, and a subset are up regulated in Treg. When we used lentivirus shRNAi to knock down FOXP3 expression in human Treg we observed that the miRs expression levels were reduced, suggesting regulation by FOXP3. We next identified putative miR target genes in our human Treg gene signature that are themselves down regulated, and analysed their expression in FOXP3 ablated Treg vs FOXP3 sufficient Treg. These experiments identified a number of genes that are direct targets of the miRs that are dependent on FOXP3, and suggest that these target genes may be tightly regulated as part of the human Treg gene network. The chromatin remodelling gene SATB1 is tightly repressed to maintiant Treg function. We are now investigating other miR and FOXP3 target genes in human natural vs induced reguatory T cells.These results provide new insights into the mechanism of action of FOXP3 in human Treg.

W7.02.06
A bioinformatics pipeline to uncover regulatory modules and their condition-specific regulators in human monocyte-to-macrophages differentiation and polarization

E. M. C. Mazza[1], *P. Italiani*[2], *S. Valsoni*[1], *I. Cifola*[3], *D. Boraschi*[2], *C. Battaglia*[3,4], *S. Bicciato*[1];
[1]*Center for Genome Research, Dept. of Life Sciences, University of Modena and Reggio Emilia, Modena, Italy, [2]Laboratory of Cytokines, Institute of Biomedical Technologies (ITB), National Research Council (CNR), Pisa, Italy, [3]Institute of Biomedical Technologies (ITB), National Research Council (CNR), Milano, Italy, [4]Department of Medical Biotechnology and Translational Medicine, University of Milano, Milano, Italy.*

In healthy organisms, inflammation is the first line of defense against infections and other damage. Monocytes and macrophages are key players of this process. Since a deregulation of the activity of these cells is at the basis of several pathological conditions, elucidating the molecular mechanisms of monocyte/macrophage activation represents a major step to study inflammatory disorders and, eventually, develop new therapeutic strategies. However, these mechanisms and their interplay during monocyte/macrophage activation and M1/M2 polarization remain poorly characterized. Here we report the application of computational methods to reconstruct gene regulatory networks and decipher transcriptional modules in an in vitro model of physiological inflammation. Specifically, gene expression profiles of human blood monocytes, from normal healthy donors and exposed to combinations of factors reproducing normal inflammatory conditions, have been monitored during a time course of 48 hours and transcriptional data analyzed using an ad-hoc bioinformatics pipeline aimed at reconstructing gene regulatory modules. The computational process starts with the identification of clusters of co-regulated genes whose expression changes during the time course. Through enrichment analysis and scanning analysis of transcription factor (TF) binding site motifs, we identified subsets of inflammation related genes and TFs that can be considered as process controllers and, thus, further used as candidates to reconstruct regulatory modules. The bioinformatics analysis identified several member of the interleukin-1 family as master regulators of specific regulatory modules linked to the inflammation process.

IL7.03.01
Structural basis of viral escape in Influenza

S. Gras[1], *S. Valkenburg*[2], *C. Guillonneau*[2], *L. Hatton*[2], *K. Twist*[1], *A. Purcell*[1], *P. Doherty*[2], *J. Rossjohn*[1], *S. Turner*[2], *K. Kedzierska*[2];
[1]*Monash University, Clayton, Australia, [2]University of Melbourne, Parkville, Australia.*

A high mutation rate in RNA viruses facilitates viral replication and escape from immune system surveillance. We used a reverse genetics approach to probe the mechanism underlying immune escape for influenza virus-specific CD8+ T cells responding to the immunodominant NP366 epitope restricted to the H2Db MHC molecule. All engineered mutants with a substitution at a critical residue (methionine at position 6, P6M) evaded recognition by wild-type DbNP366-specific CD8+ T cells. The mutants NP-M6I and NP-M6T were associated with a substantial “hole” in the naïve TCR

repertoire against these endogenous epitopes, and thus minimal primary responses. We solved the structures of the NP-M6I, NP-M6T and compare them with the NP-wt as well as the NP-M6W peptides. The structures revealed that the "hole" in the repertoire against those mutants could be due to altered conformation of a key residue (His155) in the MHC-I binding cleft, offering us a molecular mechanism for viral escape.

W7.03.01
Crystal structure of adenovirus E3-19K protein bound to HLA-A2 reveals mechanism for immunomodulation

L. Li, Y. Muzahim, ***M. Bouvier****;*
University of Illinois at Chicago, Chicago, IL, United States.

The cell-surface presentation of viral antigens by MHC class I molecules is critical for eliminating host infected cells. In turn, viruses have evolved various strategies to interfere with antigen processing and presentation. The adenovirus (Ad) E3-19K protein binds to and retains MHC class I molecules in the endoplasmic reticulum (ER), thereby suppressing anti-Ad activities of CD8+ T-cells. E3-19K is a type I transmembrane glycoprotein that comprises a N-terminus ER-lumenal domain, a transmembrane domain, and a C-terminus cytosolic tail. The ER-lumenal domain of E3-19K associates with the ER-lumenal domain of MHC I, while the dilysine motif in the cytosolic tail of E3-19K provides the signal for localization of the E3-19K/MHC I complex in the ER. We will describe a novel rescue refolding strategy that allowed formation of the Ad serotype 2 (Ad2) E3-19K/HLA-A2 complex, from which we recently grew crystals diffracting to 1.95 Å resolution. Ad2 E3-19K binds to the N-terminus of the HLA-A2 groove, contacting the α1-, α2-, and α3-domains and β2m. Ad2 E3-19K has a unique structure comprised of a large N-terminal domain, formed by two partially overlapping β-sheets arranged in a V-shape, a C-terminal α-helix and tail. The structure reveals determinants in E3-19K and HLA-A2 that are important for complex formation; conservation of some of these determinants in E3-19K of different Ad species and MHC I of different HLA loci suggests a universal binding mode for all E3-19K proteins. Our structure offers explanations for the mechanism by which E3-19K modulates antiviral cellular immunity.

W7.03.02
Structural insight into HLA DQ8 restricted TCR selection in celiac disease

J. Petersen*[1], S. E. Broughton[1], A. Theodossis[1], A. Thompson[2], J. van Bergen[2], Y. Kooy-Winkelaar[2], R. P. Anderson[3], F. Koning[2], H. H. Reid[1], J. Rossjohn[1];*
[1]Biochemistry and Molecular Biology, Monash University, Clayton, VIC, Australia, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Walter and Eliza Hall Institute of Medical Research, Parkville, VIC, Australia.

Celiac disease (CD) is almost exclusively associated with the HLA alleles DQ2 and DQ8, either alone or in combination. CD is characterized by an inflammatory T-cell response to dietary gluten that leads to a progressive degradation of the gastrointestinal lining. Gluten specific CD4+ T-cells present in the lamina propria of the small intestine respond to a number of DQ2 and/or DQ8 resticted, glutamine and proline rich epitopes and preferentially recognize deamidated peptides. Sequence analysis of T-cell receptors (TCRs) isolated from such gluten reactive T cells from different HLA-DQ8+ CD patients revealed an antigen dependent bias in Vα- and Vβ-chain usage (TRAV26-2 and TRVB9-1 for DQ8-glia-a1), as well as a high prevalence of non-germline encoded arginine residues within either the CDR3α or the CDR3β region of the TCRs. We solved five high-resolution crystal structures of TCRs recognizing the deamidated DQ8-glia-a1 epitope. The structural comparison of the ternary complexes revealed a striking degree of similarity in the overall docking modes of the TCRs on DQ8-glia-a1, as well as in the positioning of the characteristic CDR3 arginine residues. Using alanine substitution mutants of a TRAV26-2/TRVB9-1 TCR we demonstrated the importance of arginine in CDR3α and of two TRVB9-1 germline encoded residues for DQ8-glia-a1 recognition. In summary, our data points towards the presence of common structural drivers for TCR selection in CD.

W7.03.03
Divergent T cell recognition of a lengthy epitope bound to Major Histocompatibility Complex class I molecule

Y. Liu*;*
Monash University, Clayton, Australia.

The surface expression of T cell receptors on CD8+ T cells allows them to recognise short peptide antigens between 8 to 10 amino acids in length, presented by class I major histocompatibility complex molecules (MHC-I). Interestingly, longer epitopes (>10 amino acids) have also been shown to play essential role in the cellular immunity, yet how these antigens are recognised by T cell receptors remains under-explored. Our present study investigated two distinct T cell clones (CA5 and SB47) recognising a 13mer viral peptide (named LPEP) presented by the MHC class I molecule; HLA B*3508. Using biophysical (surface plasmon resonance), cellular and crystallographic approaches, we investigated the interaction between the CA5 and SB47 TCRs against the HLA-B*3508-LPEP complex. The crystal structure of the TCR-pMHC complex revealed that, whilst the CA5 TCR focused centrally to the super-bulged peptide antigen and struggled to contact the MHC surface, the SB47 TCR was able to avoid the bulged peptide landscape and engaged the extreme N-terminal part of the MHC-I surface. These structural differences between the CA5 and SB27 TCR-pMHC complexes have provided novel insights into the lengthy antigen detection by CD8+ T cells as well as shaping our understanding towards the fine-specificity of MHC restriction.

W7.03.04
The constant region affects antigen binding of antibodies to DNA by altering secondary structure

Y. Xia, A. Janda, E. Eryilmaz, A. Casadevall, ***C. Putterman****;*
Albert Einstein College of Medicine, Bronx, NY, United States.

We previously demonstrated an important role of the constant region in the pathogenicity of anti-DNA antibodies through modulation of immunoglobulin affinity and specificity. To determine the mechanisms by which the constant region affects autoantibody binding, a panel of isotype-switch variants (gG1, IgG2b, IgG2a) was generated from the PL9-11 IgG3 anti-nuclear antibody, which differed only in their constant region. The affinity of the PL9-11 antibody panel for histone antigens was measured by surface plasmon resonance (SPR). Tryptophan fluorescence was used to determine the wavelength shift of the antibody panel upon the addition of DNA and histone (2A and 2B) antigens. Finally, circular dichroism spectroscopy was used to measure changes in secondary structure corresponding to antibody/antigen interactions. SPR analysis revealed significant differences of histone 2A/2B binding affinity between members of the PL9-11 panel. The wavelength shifts of tryptophan fluorescence emission were found to be dependent on the antibody isotype, while increasing salt concentrations lowered K_D values. Circular dichroism analysis determined that changes in antibody secondary structure content differed between the PL9-11 IgG isotypes upon antigen binding. Thus, the antigen binding affinity of anti-nuclear antibodies is dependent on the particular constant region expressed. Moreover, the effects of antibody binding to antigen on tryptophan fluorescence, as well as secondary structure shifts, were also constant region dependent. Alteration of secondary structures influenced by constant regions may explain differences in fine specificity of anti-DNA antibodies between antibodies with similar variable regions, as well as cross-reactivity of anti-DNA antibodies with non-DNA antigens.

W7.03.05
Structural insight on the recognition of surface-bound opsonins by the integrin αI-domain of complement receptor 3

G. Bajic*, L. Yatime, T. Vorup-Jensen, G. R. Andersen;*
Aarhus University, Aarhus, Denmark.

Complement is the first line of defense against invading pathogens and bridges the innate and the adaptive immunity. Complement activation leads to proteolysis of the central complement component, C3, yielding an anaphylatoxin C3a and an opsonin C3b. The latter

becomes covalently bound to the target surface via its reactive thioester. C3b is further processed into iC3b and C3dg by factors I and H and finally to C3d by other plasma proteases. These fragments are ligands for complement receptors expressed on immune cells. Amongst these, integrin receptors CR3 (CD11b/CD18, αMβ2, Mac-1) and CR4 (CD11c/CD18, αXβ2) are essential for the recognition and phagocytosis of immune complexes. Until now, a systematic comparison of the binding selectivity amongst C3 fragments for these receptors has been lacking. Furthermore the CR3 binding-site on the C3 molecule has not been identified so far.
By using cell-adhesion and SPR assays, we have identified the minimal binding domain of C3 for CR3. Surprisingly, these results reveal a difference in selectivity towards C3 fragments for CR3 and CR4, since CR3 preferentially binds to C3d. Furthermore, we report the crystal structure of the CR3 I-domain in complex with C3d at 2.8 Å resolution. This structure provides the first atomic model for CR3 binding to iC3b, C3dg or C3d and explains the lack of binding to C3b. In addition, our structure suggests a simultaneous binding of CR3 and another receptor, CR2, to C3 fragments, which might be important for trafficking of opsonized antigen in lymph nodes between B-cells and follicular dendritic cells.

W7.03.06
Structural insights into S100 proteins recognition and signal transduction by the Receptor for Advanced Glycation End-products (RAGE)

L. Yatime[1,2]*, G. R. Andersen*[1,2]*;*
[1]Department of Molecular Biology and Genetics, Aarhus University, Aarhus, Denmark, [2]The Lundbeck Foundation Nanomedicine Centre for Individualized Management of Tissue Damage and Regeneration (LUNA), iNANO Centre, Aarhus University, Aarhus, Denmark.

RAGE is a pattern recognition receptor from the immunoglobulin superfamily that recognizes endogenous, danger-associated patterns. All these extracellular ligands accumulate in diseased tissues. Their binding to RAGE ectodomain triggers downstream signaling events that activate NFκB and other transcription factors, promoting pro-inflammatory molecules release. This maintains a high inflammatory state and imposes a massive stress on the cells, ultimately leading to tissue damage rather than healing and recovery. RAGE blockade has therefore been considered as a promising therapeutical strategy in various pathological settings. However, after a decade of efforts put in that direction, the results are still unclear, due to the fact that RAGE-mediated signaling has also a protective effect in tissue homeostasis and resolution of inflammation.
To determine the structural basis for RAGE signaling and to be able to design specific, efficient modulators of the receptor, we have pursued the structure determination of several RAGE:ligand complexes. We have obtained the crystal structure of the complex between human RAGE ectodomain and murine S100A6 at 2.3 Å resolution. This structure shows how ligand binding induces a novel dimeric conformation of RAGE, that appears to be suited for signal transduction and effector binding to the receptor intracellular domain. Surprisingly, the structure reveals a new, unexpected conformation for the dimeric S100A6. Modeling and bioinformatics suggest that this might be a common feature for other S100 proteins upon RAGE binding. This S100 conformation might therefore constitute a promising target for drug design of specific inhibitors with therapeutical potential for treating e.g. cancer and neurodegenerative diseases.

Antigen Mediated Positive and Negative Selection of Developing Chicken B Cells

M. J. H. Ratcliffe*, D. Davani;*
University of Toronto, Toronto, ON, Canada.

Cell surface immunoglobulin (sIg) expression is required for the productive colonization of follicles in the avian bursa of Fabricius. We have used retroviral gene transfer to introduce chimeric sIg receptors where the specificity determining region of lamprey variable lymphocyte receptors (VLRs) is fused to the chicken sIgM constant region (VLR:Tm). While expression of phycoerythrin (PE) specific VLR^{PE}Tm supported B cell development in the absence of endogenous sIgM, expression of VLR^{HEL}Tm with specificity for the self-antigen Hen Egg Lysozyme (HEL) leads to B cell deletion. Similarly i.v. injection of PE into VLR^{PE}Tm transduced embryos resulted in deletion of VLR^{PE}Tm expressing B cells.
Expression of mCD8alpha:chIgalpha receptors also supports bursal colonization by B cell precursors. Co-expression of TL, a natural ligand of mCD8alpha, however resulted in deletion of CD8alpha:Igalpha expressing B cells. Deletion required signaling through the mCD8alpha:Igalpha receptor as mutations in the Igalpha ITAM abrogated TL induced deletion. Thus negative selection requires signaling downstream of sIg.
In chicks transduced with VLR^{PE}Tm, VLR^{PE}Tm expressing bursal B cells disappeared within the first 10 days after hatch. In contrast, intrabursal introduction of PE into bursal follicles through the gut maintained the presence of VLR^{PE}Tm expressing B cells. Intrabursal PE further enhanced the emigration of bursal VLR^{PE}Tm expressing B cells to the periphery, including both short lived and longer lived VLR^{PE}Tm expressing B cells. This demonstrates that gut derived antigen can mediate positive selection of antigen specific chicken B cells and supports a role for antigen in gut associated B cell development.

IL7.05.02
Phenoloxidases and cytotoxicity in ascidians: an overview

L. Ballarin[1]*, N. Franchi*[2]*, F. Schiavon*[1]*, S. C. E. Tosatto*[1]*;*
[1]Department of Biology, University of Padova, Padova, Italy, [2]Department Biological, Chemical and Pharmaceutical Science and Technology, University of Palermo, Palermo, Italy.

Phenoloxidases (POs) belong to a family of copper-containing proteins (including also hemocyanins) widely distributed among invertebrates. They are able to convert polyphenols to quinones and induce cytotoxicity through the production of reactive oxygen species, a fundamental event in many immune responses. In ascidians, PO activity has been described and studied in both solitary and colonial species and the enzyme is involved in inflammatory and cytotoxic reactions against foreign cells or molecules, and in the formation of the cytotoxic foci which characterize the nonfusion reaction of botryllid ascidians. Expressed genes for putative POs have been recently identified in the solitary ascidian *C. intestinalis* (CiPO1 and CiPO2) and the compound ascidian *Botryllus schlosseri*.
Multiple sequence alignments evidenced the similarity between the sequences of ascidian POs and crustacean proPOs whereas the analysis of the three-dimensional structure reveals high similarity with arthropod haemocyanins, which share common precursors with arthropod proPOs. *Botryllus* and *Ciona* POs grouped in the same cluster, and all of them share the full conservation of the six histidines at the two copper-binding sites as well as of other motifs, also found in arthropod haemocyanin subunits, involved in the regulation of enzyme activity. *In situ* hybridisation indicated that the *Botryllus* PO is transcribed inside morula cells, a characteristic cytotoxic haemocyte type.
This research was supported by the Italian MIUR (PRIN 2010-2011).

W7.05.01
Generation of B lymphocytes and immunoglobulin diversity in Bos taurus

J. Liljavirta, A. Ekman, ***M. Niku****, T. Pessa-Morikawa, A. Iivanainen;*
University of Helsinki, Department of Veterinary Biosciences, Helsinki, Finland.

We have characterized B lymphopoiesis, germline IGLV, IGKV and IGHV repertoires and the mechanisms of the generation of the primary immunoglobulin repertoire in cattle.
B lymphopoiesis is active in fetal bovine bone marrow and lymph nodes, proceeding through CD79α+IgM- pre-B cells expressing RAGs and surrogate light chain. TdT is selectively expressed in fetal

bone marrow B cells, indicating diversification of the recombining Ig genes by junctional mechanisms.
During the last trimester of fetal development the immature B cells populate the ileal Peyer's patch, generating oligoclonal lymphoid follicles with extremely rapid B cell turnover. AID is strongly expressed in the follicles, associated with hypermutation of the IGHV genes before exposure to external antigens. AID is also expressed in the spleen, but the ileal Peyer's patch is likely quantitatively more significant to the generation of the diversified B cell pool due to the higher proliferation rate.
B lymphopoiesis is practically absent in the adult, possibly due to changes inherent to the hematopoietic lineage. Thus, cattle rely on the peripheral B cell pool generated in fetal and early postnatal period for the rest of the life.
The germline repertoire of Ig gene segments is very limited in cattle. There are a maximum of 33 functional paralogous light chain V genes dominated by a single subgroup, and a maximum of 20 functional paralogous heavy chain V genes belonging to a single clan II subgroup. Thus, junctional diversity and hypermutation are essential in the generation of sufficient primary immunoglobulin repertoire.

W7.05.02
Atlantic cod displays an unusual TLR repertoire - a Gadidae-specific feature?

***M. H. Solbakken**, M. Malmstroem, O. Toerresen, K. S. Jakobsen, S. Jentoft;*
Department of Biosciences, Centre for Ecological and Evolutionary Synthesis, University of Oslo, Oslo, Norway.

Atlantic cod has an unusual immune system compared to other vertebrates. A loss of major histocompatibility complex class II (MHC-II) is accompanied by a large expansion of MHC-I and an unusual repertoire of Toll-like receptors (TLR). Further, Atlantic cod lacks homologs of the mammalian surface TLRs 1, 2, 6 (and 10) in addition to having large gene expansions in TLR7, 8, 9 and 22. These features indicate an evolutionary adaption.
We have performed a complete characterization of TLR genes in Atlantic cod. Here we present a novel TLR, TLR25, previously reported only in Channel catfish and demonstrate that Atlantic cod has teleost derived surface TLRs: TLR14, 22 and 25. Within the individual gene expansions we find sites of diversifying selection that could account for the differential expression patterns for individual gene copies.
By examining several members of the gadidae family we found that the lack of mammalian surface TLR homologs is consistent with the findings in Atlantic cod. We further found that the gene expansion patterns are conserved except for TLR25 that seems to be specific for Atlantic cod and are currently investigating species belonging to the phylogenetically more distant gadiformes order.

W7.05.03
Evolution of antigen recognition by Vγ9Vδ2 T cells

***M. Karunakaran**[1], L. Starick[1], L. Walter[2], T. Goebel[3], T. Herrmann[1];*
[1]Institute for Virology and Immunobiology, University of Wuerzburg., Wuerzburg, Germany, [2]Dept. Of Primate Genetics, German Primate Center, Goettingen, Germany, [3]Institute for Animal Physiology, Dept. Of Veterinary Sciences, University of Munich, Munich, Germany.

Vγ9Vδ2 T cells carry TCR with eponymous V gene products and Vγ9Jγ1.2 rearrangements, which recognize pyrophosphate containing metabolites of host and microbial isoprenoid synthesis (phosphoantigens) such as IPP and HMBPP. It is generally perceived that these T cells are restricted to higher primates including humans. The aim of this study is to test for existence of such cells in other mammalian taxa and to use this knowledge to understand the molecular basis of their TCR-mediated activation. Analysis of public databases revealed fragments of Vγ9 and Vδ2 like genes in at least one clade of the Eutheria subgroups (Euarchontoglires, Laurasiatheria, Xenarthra, Afrotheria) suggesting the common emergence of Vγ9 and Vδ2 genes and placental mammals. In six species full length Vγ9 and Vδ2 like sequences including RSS were found: 1. Horse 2. Cow 3. Alpaca 4. Sloth 5. Bottlenose dolphin 6. Grey mouse lemur. The first three were further analyzed by (RT) - PCR and sequencing. Horse and cow showed Ig domain disrupting mutations or stop codons, respectively, but alpaca (Vicugna pacos) blood mononuclear cells revealed the presence of Vγ9 & Vδ2 containing TCR chains. Further cloning indicated absence of somatic hyper mutation (SHM) in these V genes and indicated a dominance of functional Vγ9Jγ1.2 rearrangements. Full length Vγ9 & Vδ2 containing TCR chains have been amplified. Attempts to clone, express and analyze the function of the presumed alpaca Vγ9Vδ2 TCRs are in progress along with analysis of those Vγ & Vδ genes which were recently reported to posses SHM in Camelus dromedaries.

W7.05.04
***Drosophila* Helical factor (Hf) and helical cytokine evolution: from *in silico* approaches to functional evidence**

***D. Malagoli**;*
Department of Life Sciences, University of Modena and Reggio Emilia, Modena, Italy.

Cytokines have been first discovered in human and their existence in invertebrates was only confirmed in the recent past, when molecular biology and functional studies lead to the discovery of cytokines in insects, crustaceans and tunicates. Nonetheless, fundamental conundrums pertaining the evolution of cytokines, *e.g.*, which is their origin and how their differentiation have proceeded, remain unanswered principally because of their primary sequence variability.
Drosophila helical factor (Hf) is the first soluble factor predicted to be an helical cytokine in invertebrates by an on-purpose developed algorithm. I*n vitro* and *in vivo* experiments have demonstrated that Hf expression increases after an immune challenge and the activation of the kinase dTAK1, homologue of the vertebrate MAP kinase MAP3K7. Confocal microscopy demonstrated that Hf has a cytoplasmic localization in *Drosophila* cultured hemocytes, and in accordance with early *in silico* predictions Hf is released after a bacterial challenge. The recombinant peptide rHf stimulates the expression of the antimicrobial gene *defensin* in absence of any further immune challenge, suggesting the involvement of Hf in the induction of *Drosophila* antimicrobial peptides.
By starting with *in silico* analyses and then experimentally verifying the computational predictions we have tackled the difficult task of the evolution of helical cytokines, demonstrating the importance of molecular fold recognition algorithms to find structurally conserved molecules when sequence variability hampers the application of sequence similarity-based investigations.

W7.05.05
Phenoloxidases and cytotoxicity in ascidians: an overview

***B. Loriano**[1], N. Franchi[2], F. Schiavon[3], S. C. E. Tosatto[3];*
[1]Department of Biology, University of Padova, Padova, Italy, [2]University of Palermo, Palermo, Italy, [3]University of Padova, Padova, Italy.

Phenoloxidases (POs) belong to a family of copper-containing proteins (including also hemocyanins) widely distributed among invertebrates. They are able to convert polyphenols to quinones and induce cytotoxicity through the production of reactive oxygen species, a fundamental event in many immune responses. In ascidians, PO activity has been described and studied in both solitary and colonial species and the enzyme is involved in inflammatory and cytotoxic reactions against foreign cells or molecules, and in the formation of the cytotoxic foci which characterize the nonfusion reaction of botryllid ascidians. Expressed genes for putative POs have been recently identified in the solitary ascidian *C. intestinalis* (CiPO1 and CiPO2) and the compound ascidian *Botryllus schlosseri*.
Multiple sequence alignments evidenced the similarity between the sequences of ascidian POs and crustacean proPOs whereas the analysis of the three-dimensional structure reveals high similarity with arthropod haemocyanins, which share common precursors with arthropod proPOs. *Botryllus* and *Ciona* POs grouped in the same cluster, and all of them share the full conservation of the six histidines at the two copper-binding sites as well as of other motifs, also found in arthropod haemocyanin subunits, involved in the regulation of enzyme activity. *In situ* hybridisation indicated that the *Botryllus* PO is

transcribed inside morula cells, a characteristic cytotoxic haemocyte type.
This research was supported by the Italian MIUR (PRIN 2010-2011).

The secondary structure of the pre-mRNA encoding the Antarctic fish Igμ chain drives its atypical splicing pattern

S. Giacomelli, *S. Varriale, U. Oreste, M. Coscia;*
Institute of Protein Biochemistry, CNR, Napoli, Italy.

Teleosts inhabiting the cold seawater of the Antarctic continental shelf (-1.87 °C constant throughout the year) underwent major modifications of their morphology, ecology and biology to adapt to the cooling of the environment. Our study was aimed at investigating Antarctic teleost Immunoglobulin μ heavy chain since, due to the plasticity of its gene locus, it is appropriate to identify the modifications occurred during the adaptive evolution. For this purpose, we sequenced both the membrane and the secreted form of IgM from 14 Antarctic and non-Antarctic species belonging to the suborder Notothenioidei. The primary mRNA splicing for the membrane form was found to be atypical in the majority of Antarctic species, because it led to exclusion of the entire CH2 and CH3 constant exons, and to inclusion of 39-nucleotide exons encoding an unusually long extracellular membrane-proximal domain. Genomic DNA analysis revealed that each 39-nucleotide exon fall within a long sequence that is antiparallel to an upstream region. By combining computational, molecular biology and physicochemical approaches, we demonstrated that the antiparallel regions of Igμ chain are responsible for the secondary structure of pre-mRNA, and, in turn, for the splicing mechanism. In fact, the presence of a long double-stranded structure was predicted by computational tools and confirmed by the physical analysis of a synthetic RNA fragment reproducing part of the primary transcript. By Atomic Force Microscopy the length, the thickness and the persistence length of RNA were determined. The double-stranded structure was demonstrated to be temperature dependent by Circular Dicroism spectroscopy analysis.

***In vitro* evaluation of the anti-inflammatory control actions of interferon-alpha in swine**

E. Razzuoli, R. Villa, ***M. Amadori****;*
IZSLER, Brescia, Italy.

Interferon-alpha (IFN-α) shows potent immunomodulatory properties, which underlies its use for successful low-dose oral treatments of diverse viral infections and immunopathological conditions. The studies on oral administration have been hampered by the lack of recognized *in vitro* models, reproducing the *in vivo* control action of IFN-alpha over inflammatory cytokine responses. Owing to the above, the aim of our study was to validate IPEC-J2 (a continuous cell line of porcine intestinal epithelial cells) as reporter system of the above properties of IFN-alpha. Three different experimental conditions (oxidative stress, inflammatory response and amplification of lymphoid cell signals) were selected to evaluate the effects of porcine recombinant IFN-alpha$_1$ (rIFN-alpha), two natural porcine IFN-alpha preparations (nIFN-alpha) and human lymphoblastoid IFNs. The IFNs under study showed significantly different control actions in IPEC-J2 cells at either low or moderate concentrations (1 and 100 U/ml, respectively). In particular, rIFN-alpha was shown to down-regulate interleukin (IL)-8, IL-1beta, TNF-alpha and beta-defensin 1 genes either directly, or indirectly through second messengers released by IFN alpha-treated lymphoid cells. Concerning IL-6, only second messengers from IFN alpha-treated lymphoid cells could regulate the expression of this cytokine in IPEC-J2 cells. Also, the supernatant of IFN alpha-treated tonsil cells (100 U/ml) caused a significant decrease of IL-8 gene expression and protein secretion ($P < 0.05$). The release of second messengers from IFN alpha-treated tonsil cells went along with a positive regulation of IgA and antibacterial peptides. Our findings confirm an important role of type I IFNs in the regulation of the inflammatory response.

W7.07.01
A novel multi-stage subunit vaccine against paratuberculosis induces significant immunity and reduces bacterial burden in tissues

A. Thakur[1], *C. Aagaard*[2], *U. Riber*[1], *K. Skovgaard*[1], *P. Andersen*[2], *G. Jungersen*[1];
[1]*Technical University of Denmark, Copenhagen, Denmark,* [2]*Statens Serum Institute, Copenhagen, Denmark.*

Effective control of paratuberculosis is hindered by lack of a vaccine preventing infection, transmission and without diagnostic interference with tuberculosis. We have developed a novel multi-stage recombinant subunit vaccine in which a fusion of four early expressed MAP antigens is combined with a MAP protein expressed in latent infection (FET11 vaccine). FET11 vaccine proteins were formulated with CAF01 adjuvant and injected to MAP challenged calves at two different ages. 28 calves divided into two FET11 vaccine groups, a commercial vaccine and a control group were used in the study and followed for a year. The FET11 vaccine induced a significant T cell response against constituent vaccine proteins characterized by a high percentage of CD4+ T cells and participation of polyfunctional CD4+ T cells. Of the two different age groups, late FET11 vaccination conferred protective immunity characterized by a significant containment of bacterial burden in gut tissues compared to non-vaccinated animals. There was no cross-reaction with bovine tuberculosis in vaccinated animals. This novel multi-stage vaccine has the potential to become a marker vaccine for paratuberculosis.

W7.07.02
Bovine viral diarrhea virus actively replicate in bovine monocyte-derived dendritic cells and use them as viral reservoirs

A. V. Capozzo[1,2], *O. L. Franco-Mahecha*[1,2], *W. Czepluch*[1], *D. A. Malacari*[1], *N. Cardoso*[1], *P. R. Grigera*[3];
[1]*Institute of Virology. CICVyA. INTA, Hurlingham. Buenos Aires., Argentina,* [2]*CONICET, Buenos Aires, Argentina,* [3]*ICT-MILSTEIN. CONICET, Buenos Aires., Argentina.*

Bovine viral diarrhea virus (BVDB) causes immune-suppression and persists in the host for long periods of time. The mechanisms underlying these behaviors have not been completely elucidated. The aim of this work was to study the interaction between BVDV (Type 1, cp) and bovine DC. Bovine DC-CD11b+ were differentiated in culture from purified CD14+ peripheral-blood monocytes and treated with infectious or inactivated virus for one hour, in the presence or absence of specific antibodies. Pre-incubation with anti E2 antibodies complete block DC infection. In the absence of anti E2 antibodies, the virus infected and rapidly replicated in DC. Negative strand RNA and viral non-structural protein NS3 were detected as soon as 3 hours post-infection. Extracellular virus increased 2 logs/IDTC50 titers in 6 hours. Infection down-regulated the expression of MHC-I, II and co-stimulatory molecules, that were not recovered by treating with mitogens. Synthesis of pro-inflammatory cytokines was not impaired. Infected DC were also unable to present FMDV antigens to T-cells. Infected DC remained inactivated and did not undergo apoptosis. The ability of BVDV to actively replicate in DC, keeping them alive and arrested in an immature state could be an evidence of a mechanism of the virus to evade the immune system while mantaining persistent infections. It may also explain the complete lack of adaptive responses observed in cattle up to three weeks post infection.

W7.07.03
Novel peptide-MHC tetramers to characterize the specificity of the CD8+ T cell response against Theileria parva

N. Svitek[1], *R. Saya*[1], *L. Steinaa*[1], *E. Awino*[1], *A. M. Hansen*[2], *M. Nielsen*[3], *S. Buus*[2], *V. Nene*[1];
[1]*International Livestock Research Institute, Nairobi, Kenya,* [2]*Department of International Health, Immunology and Microbiology, University of Copenhagen, Copenhagen, Denmark,* [3]*Centre for Biological Sequence Analysis, Technical University of Denmark, Copenhagen, Denmark.*

The *Theileria parva* parasite is able to transform bovine T lymphocytes resulting in a lethal lymphoproliferative disorder in cattle. A better understanding of the cytotoxic T lymphocytes (CTL) response elicited during the "infection and treatment method" vaccination will shed light on the mechanism of protective immunity against *T. parva* and help develop a better recombinant vaccine. Peptide-MHC tetramers have been extensively used in human and mouse studies to decipher T cell responses but remains a novel approach in bovine immunology. In the present study, we describe the creation of "one-pot, mix and read" peptide-MHC tetramers for the enumeration and phenotypic characterization of bovine T cells specific towards *T. parva* CTL epitopes. A set of eight bovine MHC class I heavy chains and corresponding known *T. parva* CTL epitopes have been used to generate peptide-MHC tetramers. These reagents were first validated using a bank of bovine CTL lines which are specific towards *T. parva* CTL-epitopes. Each of the tetramers was successful in binding to their respective CTL as observed by flow cytometry. Recent experiments demonstrated the capacity of these tetramers to stain *ex vivo* cells isolated from *T. parva*-infected cattle. The data show that these reagents can be used to generate, "on-demand", any peptide-MHC class I tetramers to evaluate cellular immune responses in cattle to any infectious diseases where CTL play a role. In the future, these tetramers will be used in a reverse immunology strategy to identify new *T. parva* CTL epitopes that can be used as novel vaccine candidates.

Dendritic cell tracking in pigs

E. Crisci[1], *L. Fraile*[2], *R. Novellas*[3], *Y. Espada*[3], *R. Cabezon*[4], *J. Martínez*[5], *D. Benitez*[4], *M. Montoya*[1,6];
[1]*CRESA (Centre de Recerca en Sanitat Animal), Bellaterra (Cerdanyola del Valles), Spain,* [2]*Universitat de Lleida, Lleida, Spain,* [3]*Fundació Hospital Clínic Veterinari Departament de Medicina i Cirurgia Animals, Universitat Autònoma de Barcelona, Cerdanyola del Valles, Spain,* [4]*Fundació Clínic per la Recerca Biomèdica, Centre Esther Koplowitz, Barcelona, Spain,* [5]*Departament de Sanitat i Anatomia Animals, Universitat Autònoma de Barcelona, Barcelona, Spain,* [6]*Institut de Recerca i Tecnologia Agroalimentàries (IRTA), Barcelona, Spain.*

Cellular therapies using immune cells are being increasingly applied in clinical trials. The success of cellular therapies depends in part on accurate delivery of cells to target organs. In dendritic cell (DC) therapy, in particular, delivery and subsequent migration of cells to regional lymph nodes is essential for effective stimulation of the immune system. Thus, the design of an optimal DC therapy would be facilitated by technologies for monitoring DC trafficking by different methods. Domestic pigs are closely related to humans and represent an excellent animal model for immunological studies. The aim of this study was to investigate the possibility to use the pig as a model for DC tracking *in vivo*.
Porcine monocyte derived DC (moDC) culture with superparamagnetic iron oxide (SPIO) particles was standardized considering SPIO concentration and culture mortality. Phenotyping (upregulation of SLA-II, CD80/86), cytokine production (TNF-α, IL-6 ELISA) and mixed lymphocyte reaction assay (moDCs:PBLs) confirmed that SPIO-moDC culture were similar as mock moDCs and fully functional for the *in vivo* tracking. After subcutaneous inoculation, SPIO-moDC migration was confirmed by magnetic resonance imaging (MR 0,2 T) at 24, 48 hours and by Perls staining of draining lymph nodes. Moreover, after one dose of different RHDV-VLPs-pulsed moDCs specific local responses in the draining lymph node cells were confirmed using ELISPOT IFN-γ. Additionally, systemic PBMCs were able to elicit specific responses to RHDV-VLP antigen.
This study has shown the possibility to use pigs as a suitable animal model to test DC trafficking with the aim of improving cellular therapies.

W7.07.05
Development of an ELISA method to diagnose infected poultries

T. Emami, *R. Madani, F. Golchinfar;*
Razi Vaccine and Serum Research Institute, Alborz , Karaj, Iran.

Influenza A viruses are enveloped viruses within the family Orthomyxoviridae and are further classified into subtypes depending upon their surface glycoproteins. Vaccination programs for the control of avian influenza (AI) in poultries have limitations due to the problem of differentiating between vaccinated and virus-infected birds. We have used NS1, the conserved nonstructural protein of influenza A virus, as a differential diagnostic marker for influenza virus infection. Experimentally infected poultry were evaluated for the ability to induce antibodies reactive to NS1 recombinant protein. The NS1 protein of influenza A is a nonstructural protein expressed in large amounts in virus-infected cells, but it has not been detected in virions. In this project two conserved amino acid sequences of NS1 protein were selected on the basis of their high degrees of antigenicity, as antigen to develop an ELISA method. ELISA could be used to screen the infected and vaccinated sera due to their titer of antibody.

W7.07.06
A role of myeloid precursor cells (MDSCs), p-STAT 3 and lymphocyte Treg in development of immunosuppression in dogs with skin and mammary cancer

J. M. Mucha, *T. Motyl, K. Majchrzak, M. Król;*
Warsaw University of Life Sciences, Warsaw, Poland.

Recent studies have indicated an important role of myeloid precursor cells (progenitor cells that express the Gr1 antigen also called MDSCs) in tumor progression and metastasis.
Thus, the aim of our study was to assess the number of MDSCs (CD11b+/Gr1+), T_{reg} (CD4+/CD25+/FoxP3+) as well as white blood cells panel (CD3/CD4/CD8) in dogs at various clinical stage of skin and mammary cancer (n=50) in comparison to healthy patients (n=20). Moreover, we have assessed the number of MDSCs, T_{reg}, as well as p-STAT3 and VEGF-C expression in canine skin and mammary tumour tissues (benign, malignant and metastatic; n=150).
We have shown that in dogs at the late stadium of disease (advanced tumour with present metastases) the number of circulating MDSCs was significantly higher whereas the number of circulating T_{reg} was significantly lower. The number of other lymphocytes (CD3+, CD4+ and CD4/CD8) was also significantly lower.
On the other hand, the numbers of MDSCs and T_{reg} in metastasizing tumour tissues as well as p-STAT3 and VEGF-C expression were significantly higher.
Our results indicated a significant immunosuppression in patients at advanced clinical stage of cancer disease. Moreover, our results indicated that MDSCs may play an important role in immunosuppression by influence on T_{reg} (their number in blood decreases due to their accumulation in cancer tissue where they cause local immunosuppression) and in promotion of angiogenesis due to phosphorylation of STAT3 (via VEGF-C).
This study was supported by the grant no. IP2011027171 from the Ministry of Science and Higher Education.

A defect in granulopoiesis in perforin-deficient mice

C. C. Almeida[1], *M. I. C. Gaspar-Elsas*[2], *T. Queto*[1], *B. Vieira*[2], *T. Vieira*[1], *D. M. Brito*[1], *P. P. Xavier-Elsas*[1];
[1]*Universidade federal do Rio de Janeiro, Rio de Janeiro, Brazil,*
[2]*FIOCRUZ, Rio de Janeiro, Brazil.*

Perforin is a major component in granules of cytotoxic T and Natural Killer lymphocytes, which are active against tumor cells and intracellular pathogens. We previously reported dexamethasone-induced upregulation of eosinophilopoiesis in bone-marrow cultures from different mouse strains, and observed that perforin-deficient bone-marrow lacked this response to dexamethasone. To explore the possible role of perforin in granulopoiesis modulation, we evaluated baseline and glucocorticoid-stimulated counts of total nucleated cells, neutrophils and/or eosinophils in: a) freshly harvested bone-marrow; b) bone-marrow cultured with IL-5 or GM-CSF, with or without dexamethasone. Steady-state bone-marrow cell counts were significantly reduced in perforin-deficient animals compared to wild-type controls. Dexamethasone upregulated IL-5-stimulated eosinophilopoiesis in a dose-dependent-manner in wild-type, but not perforin-deficient mice. In semi-solid cultures, dexamethasone upregulated GM-CSF-stimulated colony formation in wild-type (but not in perforin-deficient) bone-marrow. Intraperitoneal (i.p.) administration of dexamethasone upregulated eosinophilopoiesis and neutrophilopoiesis in wild-type (but not in perforin-deficient) bone-marrow. Dexamethasone induced thymic involution in both mouse strains, confirming that dexamethasone absorption led to similarly active systemic levels. To reconstitute the dexamethasone response in perforin-deficient mice, wild-type T lymphocytes (and their subsets) were transferred from naïve donors into perforin-deficient recipients intravenously, and the latter were subsequently injected with dexamethasone i.p., 24h before bone-marrow harvest and total/differential counts. Total T lymphocytes from wild-type (but not from perforin-deficient) donors reconstituted the response to dexamethasone for both eosinophils and neutrophils in perforin-deficient recipients. Furthermore, neutrophilopoiesis was upregulated when CD4-depleted T lymphocytes were transferred. Together, these data suggest a novel function of perforin in baseline and glucocorticoid-stimulated granulopoiesis. **support:** CNPq-FAPERJ-CAPES.

Different anti-HSP70 antibodies detect different dynamics of intracellular HSP70 content in heat shocked human neutrophils

A. Boyko*, O. Shustova, A. Klinkova, A. Sapozhnikov, E. Kovalenko;*
Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry, Moscow, Russian Federation.

The dynamics of stress-induced changes of intracellular HSP70 content and the mechanisms of stress-induced HSP70 release are still poorly described. We analyzed the dynamics of HSP70 content in human neutrophils in response to heat shock. The cells were stained intracellularly by a panel of six anti-HSP70 mAbs elaborated in our laboratory. Flow cytometry analysis demonstrated a substantial dependence of registered pattern of stress-induced HSP70 dynamics on mAbs used. In particular, in the cell samples stained by antibodies recognizing C-domain of HSP70 molecule, the hyperthermia-induced dynamics was characterized by an increase of HSP70 intracellular level immediately after the treatment and by considerable decrease of the cell HSP70 content in 15-30 min after heat shock followed by growth of intracellular level of HSP70 for next several hours. In contrast, we did not observe the initial phase with intracellular HSP70 level growth when we used for the protein staining the antibodies recognizing N-domain of HSP70. We also did not detect this stage with HSP70 increase by using Western blot analysis. We suggest that the registered distinction between patterns of dynamics obtained with different mAbs can reflect the involvement of HSP70 in the processes of hyperthermia-induced intracellular protein aggregation. Registered in our experiments the decrease of intracellular HSP70 content can be connected with HSP70 extracellular release. The short-term decrease of intracellular level of HSP70 at the initial phase of cell response to stress was confirmed by Western blotting normalized to β-actin.

P1.01.03
Role of CD63, CD11b and CD14 as potential markers of granule release induced by propionate in bovine neutrophils

R. A. Burgos*, M. D. Carretta, M. A. Hidalgo;*
Institute of Pharmacology and Morphophysiology, Faculty of Veterinary Science. Universidad Austral de Chile, Valdivia, Chile.

Short-chain fatty acids (SCFA) are produced in the rumen of cattle by bacteria, being the major energy source in ruminants. Propionate is one of the main SCFA and additional to the nutritional function can induce several neutrophil functions via calcium (Ca2+) release, such as reactive oxygen species production and intracellular pH changes. Recently, we demonstrated that propionate induces granule release. In the present work we assess the role of putative granule markers such as CD63, CD11b and CD14 on azurophil, gelatinase granules release and secretory vesicles.
Neutrophils isolated from blood samples of healthy heifers were used. Degranulation induced by propionate was recorded through the release of the neutrophil enzymes myeloperoxidase (MPO) by absorbance, lactoferrin by ELISA, matrix metalloprotease-9 (MMP-9) by zymography and alkaline phosphatase by absorbance. The changes of CD63, CD11b and CD14 expression induced by propionate were analyzed by flow cytometry. The stimulation of neutrophils with 0.3 mM propionate induced the release of lactoferrin and MMP-9 as revealed by ELISA and gelatin zymography, respectively. Propionate at 30 mM induced the release of MPO and alkaline phosphatase as demonstrated using an enzymatic assay. 30 mM of propionate induced an increase in forward scatter parameter and increased CD63, CD11b and CD14 expression. We proposed that CD63, CD11b and CD14 are associated with the release of azurophil and secretory vesicles in bovine neutrophils.

P1.01.04
Photoconversion and in vivo imaging reveal a role for neutrophils in regulating adaptive immune responses

H. R. Hampton[1], *J. Bailey*[1], *M. Tomura*[2], *R. Brink*[1], ***T. Chtanova***[1];
[1]*Garvan Institute Of Medical Research, Darlinghurst (Sydney), Australia,* [2]*Kyoto University Graduate School of Medicine, Kyoto, Japan.*

Rapid cellular communication between the site of injury and the secondary lymphoid organs, where adaptive immune responses are initiated, is essential for successful defense against pathogens. We used photoconversion to identify the cells that first leave the site of bacterial infection in the skin and migrate to secondary lymphoid organs to initiate immune responses. Unexpectedly we found that at the early stages of the response neutrophils were the main immune cells to egress from the site of inflammation.
Analysis of the phenotype and function of skin-egressing neutrophils in the draining lymph nodes showed that these neutrophils are activated and primed for interacting with other immune cells. Surprisingly however, neutrophils suppressed rather than activated adaptive immune cells.
Lastly we used two-photon microscopy in live mice to analyze the mechanisms of neutrophil migration from the skin to the lymph nodes and found that this migration most likely occurs via the lymphatic vessels.
In conclusion our data highlight a role for neutrophils in orchestrating early immune responses. These findings have potential implications in management of many inflammatory conditions.

P1.01.05
Different role of nitric oxide on adhesiveness and apoptosis of inflammatory granulocytes after burn injury

B. Draskovic-Pavlovic[1,2], *D. Vucevic*[1,2], *I. Majstorovic*[1], *B. Bozic*[3], *G. Zunic*[1,2], *M. Colic*[2];
[1]*Institute for Medical Research, Military Medical Academy, Belgrade, Serbia,* [2]*Medical Faculty of the Military Medical Academy, University of Defense in Belgrade, Belgrade, Serbia,* [3]*Institute for Physiology and Biochemistry, Faculty of Biology, University of Belgrade, Belgrade, Serbia.*

Nitric oxide (NO) is an important mediator of inflammatory reaction. Our previous studies showed increased production of NO at the wound site after burn injury. At the same time we found decreased adhesiveness and apoptosis rate of inflammatory granulocytes (Gr) ex vivo and in cultures. The aim of this study was to investigate the influence of locally originated NO on adhesion and apoptosis of inflammatory Gr at the wound site after burn injury. Inbred Albino Oxford rats were subjected to non-lethal, full-thickness burn injury. Immediately after injuring, sterile polyvinyl sponges were implanted subcutaneously on the borderline of the burned skin in order to obtain inflammatory Gr. Control group were animals implanted with sterile sponges only. In vivo application of aminoguanidin (AG), a specific inhibitor of inducible nitric oxide synthase (iNOS), resulted in increased apoptosis rate of inflammatory Gr from control animals, while this treatment was ineffective in burn injured animals. In regard to Gr adhesiveness, in vivo AG treatment had an opposite effect manifested by stimulation of inflammatory Gr adhesion from burn injured rats, while adhesiveness of Gr from control animals was unchanged. Cumulatively, these results indicate that locally produced NO contribute to the inhibition of Gr adhesiveness without significant influence on apoptosis rate of these cells at the wound site after burn injury.

P1.01.06
Glucocorticoid-induced leucine zipper (GILZ) promotes apoptosis in vitro in neutrophil-like cells

M. Espinasse[1], *P. Piednoir*[2], *G. Dufour*[2], *P. Montravers*[2], *S. Chollet-Martin*[1,2], *M. Pallardy*[1], *A. Biola-Vidamment*[1];
[1]*INSERM UMR 996, Chatenay Malabry, France,* [2]*APHP Bichat Hospital, Paris, France.*

Glucocorticoid-induced leucine zipper (GILZ) is an ubiquitous potent anti-inflammatory protein whose expression is induced by glucocorticoids, TGF-β or IL-10 in haematopoietic cells. We and others have evidenced that GILZ regulates inflammation -involved signal transduction pathways, such as AP-1, NF-kappaB or FOXO. Moreover, we recently detected GILZ expression in blood neutrophils of patients suffering from acute respiratory distress syndrome (ARDS).
The objective of this study was to evaluate the role of GILZ in human neutrophils apoptosis. For this purpose, we used neutrophil-like PLB-985 differentiated cells. We generated GILZ overexpressing cells stably transfected with the human gilz gene. These cells were then differentiated in neutrophil-like cells using all trans-retinoic acid (ATRA) and dimethylformamid (DMF). We measured CD11b expression, oxidative burst, phagocytosis capacity and verified the presence of multi-lobed nuclei. Differentiated PLB-985 cells were then characterized for their spontaneous and activation-induced apoptosis using PMA through SubG1 analysis and AnnexinV/7AAD staining. We found that GILZ overexpression led to an exacerbated apoptosis, characterized by caspase 3, 9 and 8 activation and loss of mitochondrial potential. These results suggested that GILZ-induced apoptosis involved the mitochondrial pathway. Interestingly, apoptosis of PLB-985 GILZ clones was associated with a downregulation of Mcl-1, whereas BID or BIM were not involved.
This model suggests that in neutrophils, GILZ could participate in the control of apoptosis, essential to the resolution of inflammation in vivo. Further investigations of GILZ functions in neutrophils are ongoing both in vitro and ex vivo during ARDS.

P1.01.07
In vivo induction of Neutrophil Extracellular Traps by Mycobacterium tuberculosis

G. Filio-Rodriguez, *I. Estrada, P. Arce-Paredes, S. Islas-Trujillo, B. Moreno-Altamirano, O. Rojas-Espinosa;*
Natl. School of Biol. Sci., Mexico City, Mexico.

Background.- A novel mechanism of cellular death, NETosis, was described in neutrophils, it is characterized by the expulsion of chromatin nets admixed with microbicidal granular proteins in which microorganisms, including bacteria, protozoa and fungi, get trapped and killed in vitro. A variety of microorganisms, are able to induce NETs in vitro. Neutrophils infected in vitro with M. tuberculosis H37Rv (Mtb) also produce NETs.
Aim of the study.- To investigate if Mtb is also able to induce NETs in vivo. Materials and methods.- Guinea pigs were intradermally inoculated with Mtb and the production of NETs was investigated. NETs were looked for in cryostat sections of the skin stained for DNA, histones, elastase, myeloperoxidase and acid-fast bacilli. Heat-killed Mtb (HK-Mtb), as well as M. lepraemurium and BCG were also investigated as possible NET-inducers.
Results. - Mtb resulted in an excellent NET-inducer; NETs were identified from 30 min after inoculation and reached maximal development 4 to 6 h thereafter. NETs were positive for DNA, histone, elastase, and myeloperoxidase, just as it has been described for NETs in vitro and they were linked to ROIs as deduced from the in situ reduction of NBT. Viable and HK-Mtb, M.lepraemurium and BCG, were all equally efficient as NET-inducers. Conclusion. - NETs production does not seem to be a particular response to infection with certain microorganisms; it is rather a general response of neutrophils to infection and occurs at the latest stages of phagocytosis; nevertheless NETs may have some beneficial effect in the control of tuberculosis.

P1.01.08
Activation of phagocytosis by a low molecular fraction (below 5 kDa) from cord blood in leukocytes after hypothermic storage or cryopreservation

A. K. Gulevsky, N. N. Moiseyeva, O. L. Gorina, J. S. Akhatova, ***A. N. Goltsev****;*
Problems of cryobiology and cryomedicine, Kharkov, Ukraine.

It is known that after hypothermic storage (+4^{o}C) and cryopreservation (-196^{o}C) the phagocytic activity of human donor blood leukocytes and the NBT test indices significantly decrease, which is primarily attributed to disturbances in cell energy metabolism. This study indicated that the cord blood low molecular fraction (CBF) in the concentration of 0.15 mg/ml stimulated the engulfing and digesting activities of phagocytes, while the comparator agent Actovegin had a similar effect in the concentration of 1.50 mg/ml. The investigation of neutrophil capacity for producing reactive oxygen species by NBT test showed that CBF led to a significant rise in the number of NBT-positive cells both after hypothermic storage and after cryopreservation. Actovegin significantly increased this index after cryopreservation of leukocytes, but did not affect the number of NBT-positive cells after hypothermia. CBF and Actovegin were proved to promote restitution of the functional activity of neutrophils in the presence of a glycolysis inhibitor - sodium iodoacetate (1mM). It was discovered that neither CBF nor Actovegin influenced the phagocytic activity of neutrophils during co-incubation with a microtubule polymerization inhibitor -colchicine (100 μM). There is evidence on CBF-induced alkaline phosphatase activation in native and frozen-thawed leukocytes. CBF was found to stimulate glucose transport from incubation medium into leukocytes, which appears to be one of the major mechanisms of its action.

P1.01.09
Chemerin aggravates DSS-induced colitis associated with defective protective innate responses

R. He[1]*, Y. Lin*[1]*, X. Yang*[1]*, W. Yue*[2]*, L. Zou*[1]*, B. Li*[1]*;*
[1]*Shanghai Medical College, Fudan University, Shanghai, China,* [2]*Huashan Hospital, Fudan University, Shanghai, China.*

Chemerin is characterized by a chemoattractant protein present in various inflammatory sites. Elevated circulating chemerin was recently found in patients with inflammatory bowel disease (IBD), however, the role of chemerin in IBD remains unknown. In this study, we examined a role for chemerin in the development of a mouse model of IBD induced by DSS. We found that administration of exogenous chemerin aggravated the severity of DSS-induced colitis, which was characterized by higher clinical disease scores, extensive mucosal damage and significantly increased expression of pro-inflammatory cytokines in the colons. The exacerbated colitis was associated with impaired early colonic infiltration of neutrophils and decreased colonic expression of IL-4 and M2 macrophage-associated genes. In vitro study further demonstrated that chemerin directly inhibited IL-4-induced M2 macrophage polarization. Significant up-regulation of chemerin levels were found in the colons from DSS-exposed mice and UC patients. Moreover, the chemerin levels appeared to correlate significantly with UC disease severity. Our results suggest that chemerin promotes DSS-induced colitis by impairing the protective innate responses and may contribute to the pathogenesis of IBD.

P1.01.10
Neutrophils as potential biomarkers in the differentiation of multiple sclerosis and neuromyelitis optica

L. Hertwig[1]*, N. Borisow*[2]*, K. Stürner*[3]*, B. Seeger*[1]*, C. Infante Duarte*[4]*, F. Paul*[2]*;*
[1]*Universitätsklinikum Charité Berlin, NeuroCure Clinical Research Center, Institute for Medical Immunology, Berlin, Germany,* [2]*Universitätsklinikum Charité Berlin, NeuroCure Clinical Research Center, Berlin, Germany,* [3]*Institute for Neuroimmunology and Clinical MS Research (inims), Center for Molecular Neurobiology Hamburg (ZMNH), University Medical Center-Eppendorf, Hamburg, Germany,* [4]*Universitätsklinikum Charité Berlin, Institute for Medical Immunology, Berlin, Germany.*

Neutrophils are the most abundant leukocytes in human peripheral blood, and provide a first line of defence against bacterial and fungal pathogens. They are known to play a critical role in acute inflammation, but their involvement in chronic inflammatory and autoimmune diseases is just about to emerge. The presence of neutrophils is a characteristic feature of lesions in neuromyelitis optica (NMO), but not multiple sclerosis (MS), although both conditions are chronic inflammatory demyelinating diseases of the central nervous system (CNS). In this study we aimed to examine the phenotype and functionality of neutrophils in peripheral blood of NMO and MS patients in order to examine the potential for these immune cells to be used in the differentiation and diagnosis of NMO and MS. Preliminary results indicate that neutrophils in both NMO and MS patients show a more primed phenotype compared to healthy controls (HC), based on a higher expression of the surface markers TLR2, CXCR1 and the fMLP receptor. Additionally, MS and NMO patients appear to differ with respect to neutrophil adhesion and migratory capacity, as well as in effector mechanisms such as degranulation and oxidative burst: relative to HC these features are increased in MS patients, but down-regulated in NMO patients. These data highlight the importance of neutrophils as potential cellular markers to discriminate between NMO and MS. Moreover, our results suggest a neutrophilic involvement in the pathogenesis of these two inflammatory conditions.

Background:
Sepsis is a complex clinical condition that arises from multiple interacting tissues and cell-specific host response mechanisms. Kinases play an integral role in the transduction of intracellular signalling cascades and regulate a diverse array of biological processes essential to immune cells. Polymorphonuclear cells (PMNs) play an important role in host defense against infection, but also contribute to collateral tissue damage during sepsis.
Aim and Methods:
The current study explored signal transduction events in PMNs purified from peripheral blood (>90% pure) of patients with sepsis admitted to the Intensive Care Unit (ICU). Sepsis patients were compared with critically ill patients admitted to the ICU for non-infectious disease and age and gender matched healthy controls. PMN kinase activities were determined in cell lysates using kinase activity arrays enabling the analysis of 1024 consensus sequences of protein kinase substrates.
Results:
Based on the profiling data MAPK pathways (including ERK1/2) shared common activities between SIRS and sepsis patient, however these pathways did differentiate from the controls. SIRS samples exhibited more differences (e.g. in DNA damage and AKT signalling) compared to control samples than samples from sepsis patients.
Conclusion:
As expected, according to our profiling data there is a difference in kinome activity between healthy and diseased states. SIRS exhibited more differences in kinome profile compared to control than sepsis. Both profiles exhibited inflammatory and stress MAPK signalling.

P1.01.12
The role of neutrophils upon infection with the protozoan parasite Leishmania mexicana in C57BL/6 mice

B. Hurrell[1]*, S. Schuster*[1]*, J. Alexander*[2]*, M. Malissen*[3]*, F. Tacchini-Cottier*[1]*;*
[1]*WHO Immunology Research and Training Center, Department of Biochemistry, University of Lausanne, Epalinges, Switzerland,* [2]*Strathclyde Institute of Pharmacy and Biomedical Sciences, University of Strathclyde, Glasgow, United Kingdom,* [3]*Centre d'Immunologie de Marseille-Luminy, Université de la Méditerrannée, Marseille, France.*

Neutrophils are massively and rapidly recruited to sites of Leishmania infection, and growing evidence suggests that these innate immune cells play a role in the development of the adaptive immune response. In response to infection with the protozoan parasite L. mexicana, C57BL/6 mice develop small chronic unhealing cutaneous lesions with persistent parasites. Only a weak L. mexicana-specific immune response develops, as revealed by low dendritic cell activation and poor differentiation of CD4+ Th1 cells. Following parasite inoculation, a first wave of neutrophil activity peaks at one hour, and they return 10 days later at the site of infection, as followed by live in vivo imaging. Here we investigated the early role of neutrophils upon infection with L. mexicana. To this end, we either transiently depleted neutrophils for the first days of infection with one single injection of the 1A8 mAb prior parasite inoculation, or we infected the recently generated neutropenic Genista mice. The development of an increased inflammatory lesion was observed in the neutrophil depleted mice compared to control mice, and the early

absence of neutrophils was associated with an increased CD4+ Th1 cell immune response in the draining lymph nodes, characterized by increased levels of IFNγ and TNFα. Altogether, these results demonstrate that during the first days of infection, neutrophils contribute to the immune hyporesponsiveness observed following L. mexicana infection, and indirectly contribute to the control of excessive inflammation

P1.01.13
Intercellular ROS signaling in granulocyte-mediated tumor cell destruction

M. Jaganjac[1,2], *T. Matijevic*[2], *G. Bauer*[3], *R. J. Schaur*[4], *A. A. Latiff*[1], *N. Zarkovic*[2];
[1]*Anti Doping Lab Qatar, Doha, Qatar,* [2]*Rudjer Boskovic Institute, Zagreb, Croatia,* [3]*University of Freiburg, Freiburg, Germany,* [4]*University of Graz, Graz, Austria.*

The involvement of granulocytes in the immune response against cancer is not well understood. Depending on the oxidative burst of granulocytes and cytokine milieu in which they act, granulocytes may play either an inhibitory or stimulatory role in tumor growth. Reactive oxygen species (ROS) released during oxidative burst of granulocytes can induce lipid peroxidation (LPO) resulting in the destruction of biomembranes. However, the intercellular ROS signaling in granulocyte mediated tumor cell destruction is unclear. Therefore, in the present work we have studied the relationship between plasma inflammatory mediators and oxidative burst of granulocytes in tumor growth. The involvement of LPO-derived aldehydes (i.e. 4-hydroxy-2-nonenal (HNE) and acrolein) in granulocyte-tumor response was further evaluated. Finally inhibitory studies were used to study the importance of certain ROS in redox signaling pathways on tumor cell destruction. The results obtained, revealed a significant differences in inflammatory mediators in animals with tumor regression/progression (e.g. IL-17 and TGFβ). Also we have found that coordinated action of HNE/acrolein and granulocytes stimulates intracellular tumor cell ROS formation and have effect on TLR4 expression. Moreover, inhibitory studies revealed possible main intercellular signaling pathway in granulocyte mediated tumor cell destruction. Still, further research is required to clarify the relationships between inflammation and cancer and to define new potential targets for granulocyte mediated malignant destruction.

P1.01.14
Cyclophilin A stimulates recovery of the hematopoietic and the immune system of the organism after radiotherapy

A. Kalinina[1], *N. Kulikova*[2], *D. Kazansky*[1], *Y. Silaeva*[1], *L. Khromykh*[1];
[1]*Federal State Budgetary Institution"N.N.Blokhin Cancer Research Center", Russian Academy of Medical, Moscow, Russian Federation,* [2]*Institute of Engineering Immunology, Lyubuchany, Russian Federation.*

Radiotherapy is accompanied with severe side effects: damage and death of hematopoietic cells and decrease of leukocytes in blood. Preparations, commonly used for restoration of the hemogram after such treatment, are colony stimulating factors, but their application is limited. Search of new factors, promoting neutralization of side effects after radiotherapy, is of great practical interest.
Previously in our laboratory it was shown, that Cyclophilin A (Cyp A) (a 18 kD protein) is a chemoattractant for stem cells and progenitors of different lineages, localized in bone marrow (Khromykh L., 2007). It was also shown that Cyp A induces differentiation of stem cells in granulocytes and thrombocytes (unpublished data). These findings suggest that the studied protein can promote recovery of the hematopoietic and the immune systems of the organism after radiotherapy.
We have shown that Cyp A stimulates restoration of bone marrow in mice post sublethal irradiation, promoting reconstitution of stem cells and granulocytopoiesis. Post irradiation Cyp A stimulates migration of bone marrow stem cells, committed toward granulocytes, in blood. On the third week post sublethaly irradiation Cyp A promotes full restoration of T lymphocytes in mice spleens that exceed 2-fold the percent of these cells in control irradiated animals. The level of humoral response in mice on the third week post irradiation was restored to the level of non-irradiated mice under Cyp A treatment. Thus, our data suggest that Cyp A is a factor taking part in recovery of the hematopoietic and the immune systems of the organism after radiotherapy.

P1.01.15
Effect of colchicine on expression of inflammation-related genes in neutrophils from healthy subjects and patients with familial Mediterranean fever

G. Manukyan[1,2], *M. Petrek*[2], *A. Martirosyan*[1], *Z. Navratilova*[2], *E. Kriegova*[2];
[1]*Institute of Molecular Biology NAS RA, Yerevan, Armenia,* [2]*Laboratory of Immunogenomics and Immunoproteomics, Faculty of Medicine and Dentistry, Palacky University, Olomouc, Czech Republic.*

Despite the long-standing use of antimitotic drug colchicine in the treatment of familial Mediterranean fever (FMF) the precise mechanisms of its action in polymorphonuclear neutrophils (PMNs) remain largely unknown. Colchicine is a microtubule depolymerizing agent which arrests microtubule assembly and inhibits many cellular functions. FMF is a hereditary autoinflammatory disorder characterized by abnormal activation of PMNs and their unprovoked influx into the affected sites. This study aimed to analyze transcriptional events elicited by colchicine in PMNs isolated from the peripheral blood of 16 FMF patients in the remission period and 11 healthy control subjects by determining mRNAs expression of 8 selected genes using quantitative real-time RT-PCR. Colchicine exposure (1μg/ml) elicited up-regulated expression of IL-8 and IL-1β genes in FMF (13-fold and 2.7-fold, $p<0.05$, respectively) and healthy (3-fold and 6.5-fold, $p<0.05$, respectively) PMNs, and at the same time in down-regulated caspase-1 in FMF PMNs (3-fold, $p<0.05$). In FMF PMNs treated with colchicine, mRNAs of IL-8 (51-fold, $p<0.01$) and c-FOS (7-fold, $p<0.05$) were elevated compared to cells from control subjects. By contrast, caspase-1 mRNA was decreased in FMF PMNs compared control cells (1.6-fold, $p<0.05$). Thus, we provide in vitro evidence of colchicine modulatory role on expression of inflammation-related genes at the transcriptional level. The up-regulation of IL-1β and IL-8 suggests that colchicine can, besides its well-known anti-inflammatory properties, exhibit pro-inflammatory features. Finally, suppressed caspase-1 expression by colchicine could represent a therapeutic target and may be implicated in effective therapy of FMF.

Cross-talk between neutrophils and Pseudomonas aeruginosa biofilm. Role of MPO-halide system products.

J. Marcinkiewicz[1], *M. Strus*[2], *M. Walczewska*[1], *E. Pasich*[1], *M. Ciszek-Lenda*[1], *A. Machul*[2], *D. Mikołajczyk*[2];
[1]*Department of Immunology Jagiellonian University Medical College, Kraków, Poland,* [2]*Department of Microbiology Jagiellonian University Medical College, Kraków, Poland.*

Formation of biofilm is observed in a majority of chronic bacterial infections such as chronic sinusitis, periodontal diseases and chronic wounds. These infections are persistent as they show increased resistance to antibiotics and host defence system. Interestingly, it has been shown *in vitro* that interaction between biofilm and neutrophils may result either in destruction of bacterial biofilms or in facilitation of biofilm formation. Contribution of MPO-halide system products to these opposite neutrophil-biofilm interactions is not clear. Taurine chloramine (TauCl) and taurine bromamine (TauBr) are the physiological products of activated neutrophils, resulting from the reaction between taurine with hypochlorous acid (HOCl) and hypobromous acid (HOBr), respectively. It has been shown *in vitro* that taurine haloamines exert anti-microbial properties against planktonic form of various bacteria. Moreover, clinical studies have shown that both haloamines are effective in the local treatment of skin and mucosa chronic infections. Nevertheless, it has not been tested yet whether they can kill bacteria hidden in biofilm or disrupt biofilm structure. In this study we have investigated the capacity of TauCl

and TauBr to inhibit *in vitro* the formation of *P.aeruginosa* biofilm. Our results suggest that TauBr is able to inhibit *in vitro* the formation of *P.aeruginosa* biofilm but it cannot destroy the preformed biofilm and effectively kill hidden bacteria. However, TauBr anti-biofilm properties are enhanced in the presence of DNase. In contrast to beneficial effect of MPO-halide system products, the addition of dead neutrophils to preformed biofilm enhanced *P. aeruginosa* development.

P1.01.17
Role of 5-lypoxygenase in the regulation of eosinophilopoiesis

D. Masid-de-Brito[1], *P. P. Xavier-Elsas*[1], *R. A. Luz*[1,2], *R. Lopes*[2], *C. Almeida-Da Silva*[1], *K. Pinnola*[2], *R. Ferreira*[2], *M. C. Gaspar-Elsas*[2];
[1]*Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil,* [2]*FIOCRUZ, Rio de Janeiro, Brazil.*

Leukotriene D_4, a product of 5-lipoxygenase, is a potent stimulator of eosinophilopoiesis in bone-marrow cell culture with IL-5 in BALB/c naïve mice. In sensitized and challenged (S/C) BALB/c mice, a similar upregulation of eosinophilopoiesis is observed in bone-marrow cells cultured with IL-5 alone, raising the issue of 5-LO contribution to this upregulation. Diethylcarbamazine is known as an effective inhibitor of leukotriene synthesis, although its mechanism of action is unclear. We showed that diethylcarbamazine suppresses eosinophilopoiesis in S/C animals, both *in vivo* and *in vitro*. We here evaluated the effect of leukotriene synthesis blockade on hematopoiesis in allergic mice, and compared it with diethylcarbamazine effects by analyzing: a) 5-lipoxygenase-deficient mice (ALOX) and wild-type controls (PAS) S/C; b) BALB/c mice S/C pretreated with MK886 (5-lipoxygenase activating protein inhibitor) and controls; c) ALOX and PAS mice S/C pretreated with diethylcarbamazine. We analyzed eosinophil numbers in bone-marrow (freshly collected or cultured with IL-5) and in peritoneal fluid of these mice. Blockade of 5-LO in OVA-challenged BALB/c mice by MK886: a) abolishes the challenge-induced increase in bone-marrow eosinophil numbers; b) inhibits challenge-induced eosinophil migration to the peritoneal cavity. In OVA-challenge ALOX mice: a) challenge-induced eosinophil migration into the peritoneal cavity is reduced; b) the challenge-induced increase in bone-marrow eosinophil numbers is abolished. Furthermore, diethylcarbamazine treatment suppressed eosinophilopoiesis in OVA-challenged PAS mice, but not in ALOX mice. These results suggest an important role for 5-LO in challenge-induces hematological changes and in the mechanism of action of diethylcarbamazine on the bone-marrow.

P1.01.18
The p38-MSK1 signaling cascade influences cytokine production through bZIP transcription factors in human neutrophils

P. P. McDonald*, T. Z. Mayer, F. A. Simard, A. Cloutier;*
Université de Sherbrooke, Sherbrooke, QC, Canada.

Neutrophils influence innate and adaptative immunity by generating numerous cytokines and chemokines whose regulation depends on transcription factors NF-κB and C/EBP. Here, we describe the critical involvement of CREB factors (CREB1, ATF-1) in this functional response, as well as the upstream signaling components. Neutrophil stimulation with physiological agonists (LPS, TNF) led to a rapid increase in the phosphorylation, DNA binding activity, and chemokine promoter association of CREB1 and ATF-1. These responses occurred downstream of the TAK1-p38-MSK1 signaling axis, as did the phosphorylation and promoter association of another bZIP factor, C/EBPβ. Accordingly, inhibition of TAK1, p38 MAPK, or MSK1 interfered with cytokine generation in neutrophils. Likewise, overexpression of a dominant negative CREB1 mutant (K-CREB) or of a point mutant (S133A) resulted in a decreased ability of human neutrophil-like PLB-985 cells to generate inflammatory cytokines (CXCL8, CCL3, CCL4, TNFα). These studies unveil several potential molecular targets that could be exploited in the context of several chronic inflammatory diseases that prominently feature neutrophils and their products.

P1.01.19
Down-modulation of activated human neutrophil by LMW-fucoidan: role of microparticles

J. A. Moraes[1], *A. C. Frony*[1], *P. Barcellos-de-Souza*[1], *C. Boisson-Vidal*[2], *C. Barja-Fidalgo*[1];
[1]*UERJ, Rio de Janeiro, Brazil,* [2]*INSERM U765, Paris, France.*

Background
During migration, neutrophils (PMN) interact with several mediators, which can lead to their activation, interfering with cell survival and inflammation resolution. Fucoidans are sulfated polysaccharides which are able to inhibit selectin-mediated events, inhibiting PMN rolling, a crucial step to inflammation resolution. A low-molecular-weight-Fucoidan (LMW-Fuc) fraction extracted from the brown algae *Ascophyllum nodosum* exhibits potent antithrombotic and proangiogenic properties, although its effects on inflammatory cells are still unknown. So we aimed to evaluate LMW-Fuc effect on activated PMN.
Results
LMW-Fuc inhibited PMN migration induced by LPS, fMLP or migration of PMN primed with LPS and further challenged to fMLP. Corroborating this data, in LPS/fMLP-activated PMN, LMW-Fuc attenuated the induced alterations on actin cytoskeleton dynamics and inhibited AKT phosphorylation. We also observed that LMW-Fuc was able to accelerate apoptosis of activated PMN and, corroborating this result, LMW-Fuc prevented Bad degradation (an AKT target) induced by LPS/fMLP treatment. Then we showed that LMW-Fuc was able to inhibit extracellular, but not the intracellular ROS production induced by LPS/fMLP treatment. Furthermore, in stimulated PMN LMW-Fuc inhibited microparticle (MP) release, which are the key actors of extracellular ROS production in these cells, mainly, as we observed, by its property to carry p47. Finally, we demonstrated that PMN MP was also able to induce extracellular ROS in macrophage, also in a p47-dependent mechanism, demonstrating a paracrine role for MP.
Conclusion
Thus LMW-Fuc presents a potent ability to attenuate PMN activation that might be potentiated by its ability inhibiting MP release.

P1.01.20
IL-4 derived from basophil play a pivotal role in cysteine protease-induced natural helper cell-mediated lung inflammation

Y. Motomura[1,2], *H. Morita*[3], *K. Moro*[4], *S. Nakae*[5], *S. Koyasu*[4], *M. Kubo*[1,2];
[1]*RIBS, Dept. Molecular Pathology, Tokyo University of Science, Noda, Japan,* [2]*Laboratory for cytokine regulation, RCAI, RIKEN Yokohama Institute, Yokohama, Japan,* [3]*National Research Institute for Child Health and Development, Tokyo, Japan,* [4]*Laboratory for immune systems, RCAI, RIKEN Yokohama Institute, Yokohama, Japan,* [5]*The Institute of Medical Science, The University of Tokyo, Tokyo, Japan.*

Cysteine proteases including plant derived papain and mite derived protease, Derp1 are known to be a potential trigger for allergic inflammation by barrier disruption leading to elevation of IL-33 mediated TH2 cytokine circuit in the absence of acquired immune cells. IL-33 released from the disrupted lung epithelial cells induced IL-5 and IL-13 production from lung natural helper (LNH) cells, resulting in eosinophilic airway inflammation. However, in present study, we found that papain stimulated basophils has a crucial role in the LNH cell mediated eosinophilic inflammation as a source of TH2 cytokine that controls activation and expansion of LNH cells. Conditional deletion of basophils in Bas-TRECK system, caused a resolution of the papain-induced eosinophilia and mucus formation in lungs. Similar recovery from eosinophilic airway inflammation was found in the mice lacking the IL-4 production specifically in basophils, 3'UTR KO mice, indicating basophil derived IL-4 had a critical role to induce LNH function. IL-4 not only enhanced the expression of eotaxin, IL-9 and IL-13 in LNH cells which is required for eosinophil attraction, but also extended a cell growth. These results demonstrated that papain-induced IL-4 production from basophils play a pivotal role to control the expression of eotaxin, IL-9 and IL-13 in LNH cells, subsequently leading to eosinophil mediated airway inflammation in lungs.

P1.01.22
The Dectin-1 ligand Beta-glucan triggers neutrophil extracellular trap (NET) formation via a signaling pathway requiring Src-family kinases and Syk

S. Nanì, ***G. Berton****;*
Department of Pathology and Diagnostics, University of Verona, Verona, Italy.

Neutrophil extracellular traps (NETs) are formed by fibers of chromatin and granule constituents that are released upon neutrophil stimulation. Strong evidence supports a role for NETs in host defenses against different pathogens. However, a role for NETs in inflammation-based pathologies has been also reported. We investigated formation of NETs in response to beta-glucan, a yeast surface component recognized by the C-type lectin receptor Dectin-1. We found that beta-glucan was as potent as phorbol myristate acetate (PMA) in stimulating NET formation in human neutrophils. PP2, a Src-family kinase (SFK) selective inhibitor, inhibited NET formation in response to beta-glucan, but not PMA. Consistently with the view that reactive oxygen species (ROS) play an essential role in NET formation, PP2 suppressed ROS formation in response to beta-glucan, but not PMA. Additionally, a new generation Syk inhibitor PRT-060318 markedly inhibited NET formation and ROS generation in response to beta-glucan in human neutrophils. Neutrophils from mice with the genetic deficiency of the SFK members Hck and Fgr or Hck, Fgr and Lyn formed NETs and generated ROS in response to beta-glucan. However both the SFK inhibitor PP2 and the Syk inhibitor, PRT-060318, inhibited NET and ROS formation in SFK-deficient neutrophils. This is the first evidence that the beta-glucan receptor Dectin-1 triggers NET formation. The evidence that targeting SFK and Syk inhibits NET formation highlights a possible new strategy to control NET formation in inflammation-based and autoimmune diseases.

P1.01.23
Effects of proton pump inhibitors and H2-antagonists on neutrophil oxidative metabolism in patients with gastric and duodenal ulcer bleeding

N. S. Obraztsova*, O. N. Sulaieva, V. Y. Delii, S. O. Zarikov;*
M. Gorky Donetsk national medical university, Donetsk, Ukraine.

Background. Despite the progress in pharmacotherapy and endoscopic management of bleeding 20-30% of patients demonstrate the recurrent bleeding. One of the reasons of it may be inflammation propagation related with dysfunction of neutrophils (Nph).
The goal of this research was to estimate the effects of the most common antisecretory drugs as proton pumps inhibitors (PPI) and H2 antagonists (H2A) on Nph oxidative metabolism.
Material and methods: Characteristics of bleeding were defined in 124 patients by clinical, laboratory and endoscopic criteria according to Forrest class. In total, 63 patients were treated with PPI, and 61 with H2A. To assess Nph oxidative metabolism, superoxide production was measured using the nitroblue tetrazolium reduction test (NBT) in isolated neutrophils at 1st, 3d and 7th day of therapy.
Results. NBT reduction rate was significantly higher in patients with active bleeding (F1a) than that in patients with sustained haemostasis ($p<0.05$). It has been shown that intensity of superoxide radicals' production by Nph was higher in patients who were admitted at 12-24 hours than at 3-6 hours after first clinical manifestation of hemorrhage ($p<0.05$). Administration of PPI was associated with decrease the NBT reduction rate ($p<0.01$), whereas H2A administration was associated with stimulation of NADPH-oxidase activity ($p<0.05$) in neutrophils.
Conclusion. Administration of PPI and H2A not only affect gastric acid production but also change innate immunity mechanisms since NADPH-oxidase activity of Nph is related with pagocytosis and lifespan. So antisecretory drugs can modulate the acute inflammatory reaction by cells kinetics in ulcer region.

P1.01.24
IgE-armed basophils and their skin-infiltration are essential for acquired tick resistance

T. Ohta*[1], S. Yoshikawa[1], K. Ishiwata[2], K. Horiguchi[1], L. LI[1], Y. Kawano[1], H. Kanuka[2], N. Watanabe[2], Y. Minegishi[3], H. Karasuyama[1];*
[1]Department of Immune Regulation, Tokyo Medical and Dental University, Tokyo, Japan, [2]Department of Tropical Medicine, The Jikei University School of Medicine, Tokyo, Japan, [3]Department of Molecular Medicine, Tokushima University, Tokushima, Japan.

Ticks transmit various pathogens to humans and animals, causing serious infectious diseases such as Lyme disease. Many animal species manifest resistance against tick feeding in re-infestation, and this resistance contributes to the prevention of pathogen transmission to the host. We previously demonstrated that basophils infiltrate the tick-feeding sites during the 2nd infestation, and that basophil depletion abolishes the acquired tick resistance. Adoptive transfer experiments revealed the importance of Ig-Fc receptors on basophils for the acquired protective immunity against tick-feeding. However, it remains elusive which class of antibodies is involved in the protection. Both FcγRIII and FcεRIα are highly expressed on basophils. We found that mice deficient for FcεRIα but not FcγRIII failed to manifest the acquired tick resistance, indicating the pivotal role of IgE but not IgG. Intriguingly, adoptive transfer of serum isolated previously-infestation mice, failed to confer the resistance naïve wild type mice, suggesting that anti-tick IgE alone is not sufficient for the manifestation of acquired tick resistance. We found little or no infiltration of basophil to tick feeding sites of recipient mice, and the pretreatment of naïve mice with both immunized serum and IL-3 lead to the acquisition of tick resistance, concomitantly with the basophil infiltrate the tick-feeding sites. These findings suggest that IgE-armed basophils and their skin-infiltration are essential for acquired tick resistance.

P1.01.25
IL-17A differential effects in murine bone marrow granulopoiesis in presence of GM-CSF or IL-5 in vitro

L. Pinto*[1], T. Queto[2], D. M. Brito[1], C. L. Coutinho[1], B. Luca[2], B. M. Vieira[1,2], J. C. Alves Filho[3], F. Q. Cunha[3], M. I. C. Gaspar-Elsas[2], P. P. Xavier-Elsas[1];*
[1]Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil, [2]FIOCRUZ, Rio de Janeiro, Brazil, [3]FMRP-USP, Sao Paulo, Brazil.

Interleukin (IL)-17A plays diverse roles in autoimmunity and allergy. Its best known functions are stimulatory and selective for the neutrophil lineage. However, IL-17A effects on granulopoiesis remain in completely understood. We examined IL-17A effects on eosinophil and neutrophil production from cultured murine bone-marrow (BM). In IL-5-stimulated liquid cultures, IL-17A suppressed eosinophilopoiesis. by contrast, IL-17A enhanced GM-CSF-stimulated eosinophilopoiesis. Downregulation of IL-5-stimulated eosinophilopoiesis by IL-17A was prevented by addition of zVAD-fmk (a terminal caspase inhibitor) and by aminoguanidine (a selective iNOS inhibitor). In cultured BM from iNOS- or IL-17AR-deficient mice, suppression of IL-5-stimulation eosinophilopoiesis was undetectable, contrasting with wild type controls. In wild-type BM (C57BL/6 or BALB/c), synergism was detectable when IL-17A and sodium nitroprusside (a NO donor) were present together, whereas either agent, added separately to the culture, had no effect on BM from both iNOS-deficient and wild-type donors. By contrast, the upregulation of eosinophilopoiesis in wild-type GM-CSF-stimulated BM cultures by IL-17A was iNOS-independent. In progenitor (clonal) semi-solid cultures seeded with GM-CSF, colony formation was decreased by 2 ng/ml (but not by 0.2 ng/ml) IL-17 A. Together, these results suggest divergent mechanisms of action for IL-17A as a regulator of BM granulopoiesis, depending on the cytokine environment, which may reflect the involvement of different subsets of target cells in hemopoietic tissue, which are broader for GM-CSF (multilineage stimulus) than for IL-5 (eosinophil-selective stimulus), at different steps. Funding-CNPq-FAPERJ-FIOCRUZ

P1.01.26
Effect of testosterone on the activity of inflammatory cells

***A. Quintar**, C. Leimgruber, N. Peinetti, C. Maldonado;*
Universidad Nacional de Córdoba-INICSA-CONICET, Cordoba, Argentina.

Immunomodulation by sex hormones have both physiological and pathological implications in several processes. However, the role of androgens in controlling the inflammatory response is just begun to be dissected. Our initial goal was to analyze the influence of testosterone on prostatic inflammation. Wistar rats were castrated and treated with vehicle(C) or testosterone at 0.75mg/rat/day(C+T) or 2.5mg/rat/day(C+TT) and then infected with 106CFU E. coli. At 2d postinfection, C+TT exhibited greater neutrophil invasion and lower levels of TLR4 and β–defensin1 in the prostate compared to C (ANOVAp<0.01) by western blot. An intense E.coli immunolabeling occurred, with numerous bacteria undergoing partial digestion by neutrophils, demonstrated by electron microscopy. All these changes were remarkable at 5th day in C+TT and C+T correlating with a greater bacterial growth (p<0.01vs.C). Conversely, C group exhibited a lower amount of neutrophils.
The effects of castration(C) on the recruitment and ex vivo activation of peritoneal neutrophils were subsequently analyzed. The amount of neutrophils, 4h post-injection of thioglycollate, and the production of ROS were lower in C(p<0,05vs.C+T), determined by cytometry and fluorescence of H2DCFDA after 20nM PMA activation. Coincidentally, the coincubation of peritoneal neutrophils with E.coli (1:1) resulted in a lower production of ROS by C (p<0.01). However, this group showed a better bactericidal activity after 30min(p<0.01vs.C+T). In agreement, the antiandrogen Flutamide reduced the synthesis of IL-10 by peritoneal granulocytes in response to LPS.
These results indicate a complex regulation of the early stages of the infectious/inflammatory process by androgens suggesting a better outcome in the absence of testosterone.

P1.01.27
Reveiling the death pathway leading to eosinophil cytolysis

***S. Radonjic-Hoesli**[1], C. Stoeckle[1], D. Simon[2,1], B. Styp-Rekowska[3], R. Hlushchuk[3], S. Yousefi[1], H. Simon[1];*
[1]Institute of Pharmacology, Bern, Switzerland, [2]Clinic of Dermatology, University Hospital Bern, Bern, Switzerland, [3]Institute of Anatomy, Bern, Switzerland.

Eosinophil cytolysis could be considered as a mode of degranulation, leading to the release of intact granules, so-called clusters of free eosinophil granules (cfegs). It has been referred to as “state of utmost activation”, however, leads to eosinophil death. The appearance of cfegs has been demonstrated in eosinophilic tissues in different diseases.
The mechanisms underlying this activation-induced form of cell death in eosinophils remain unclear. Here, we propose a cascade of events, involving adhesion, granule fusion processes, reactive oxygen species (ROS) production, and earlier degranulation steps, leading to a distinct morphology characterized by cytosolic vacuolization. This cascade of events involves amplification steps and leads to cell death, which is characterized by loss of granule, vacuole, plasma, and nuclear membrane integrity. On a molecular level, we demonstrate a signalling cascade, involving the β2-integrin Mac1, phosphatidylinositol 3-kinases (PI3K), p38 mitogen-activated kinase (MAPK), receptor-interacting serine/threonine-protein kinase 1 (RIPK1). Major effectors in the progression of cytosolic vacuolization to cytolysis are furthermore ROS, which are mitochondrial as well as NADPH oxidase derived. Taken together, we report an adhesion-triggered programmed cell death pathway in eosinophils associated with the release of cfegs that represents at least one signalling cascade leadingto the well known morphological phenomenon of eosinophil cytolysis.

P1.01.28
Basophils control T cell responses and limit disease activity in Experimental Murine Colitis

***M. Rodriguez Gomez**[1], F. Hermann[1], K. Claudia[2], Y. Talke[1], I. Ketelsen[1], B. Reich[1], K. Renner[1], S. Syed[3], H. Bruehl[2], M. Mack[1];*
[1]Department of Internal Medicine II, University Hospital Regensburg, Regensburg, Germany, [2]Department of Internal Medicine I, University Hospital Regensburg, Regensburg, Germany, [3]Department of Pathology and Molecular Medicine, McMaster University, Hamilton, ON, Canada.

Basophilic granulocytes have been recognized as important inducers of T helper cell 2 (Th2) responses. Using the colitis model of adoptive transfer of CD4+ CD62L+ T cells into lymphopenic hosts we analyzed how basophils regulate T helper cell responses and modulate disease activity. Transferred T helper cells rapidly proliferate, produce large amounts of interleukin 3 (IL-3) and expand the number of basophils in an IL-3 dependent manner. Depletion of basophils with two different antibodies substantially upregulated intracellular Th1 cytokine expression in transferred T cells at day 8. This increased Th1 cytokine expression persisted until the end of the experiment. Basophil depleted mice showed exacerbation of colitis with more severe loss of weight, stronger histological damage and colonic leukocyte infiltration combined with an increased production of proinflammatory cytokines. We show that basophil derived IL-4 and IL-6 downregulates prdouction of interferon gamma, IL-2 and tumor necrosis factor alpha in T helper cells. These data show a beneficial role of basophils in a T cell driven model of autoimmunity.

P1.01.29
Sympathoadrenergic modulation of human neutrophils

***A. Scanzano**, L. Schembri, E. Rasini, R. Bombelli, M. Legnaro, A. Luini, M. Cosentino, F. Marino;*
University of Insubria, Varese, Italy.

Background: Catecholamines (CA) are mediators of the central nervous system and of the sympathetic branch of the autonomic nervous system involved in the genesis of the stress response. The chronic stress seems to have a negative effect on the cardiovascular system. The cells of the immune system (IS) express adrenergic receptors (AR) and are sensitive to stimulation with adrenergic agents. Among the cells of IS involved in cardiovascular diseases, the PMNs has a key role. We will investigate the presence in PMNs of a catecholaminergic system and the role played by CA to influence the functions involved in cardiovascular diseases.
Materials and Methods: PMNs were obtained from healthy subjects and ARs expression were assayed by real-time PCR. ROS levels were detected by spectrofluorimeter and the β_2 integrin expression by flow cytometry. The migration was evaluated by Boyden chamber and CA by HPLC.
Results: PMNs expressed detectable levels of mRNA for tyrosine hydroxylase as well as for several subtypes of ARs. Stimulation with fMLP increased α_{1A}-, α_{2A}-, β_1-, β_2- and β_3-ARs. Adrenaline alone was unable to affect ROS, migration and β_2 expression, while coincubation with fMLP revert the fMLP- induced increase of these parameters.
Conclusions: Adrenaline seems to modify some functions of activated PMNs, suggesting that the sympathetic branch of ANS is able to influence PMN functions.

P1.01.30
Role of neutrophils in neovessel formation in atherosclerotic lesions: preliminary evidence in patients with carotid plaque

***L. Schembri**, A. Scanzano, M. Tozzi, E. Rasini, M. Legnaro, A. Luini, M. Cosentino, F. Marino;*
University of Insubria, Varese, Italy.

Background: Atherosclerosis is a chronic inflammatory process of the arterial wall. Angiogenesis plays a pivotal role in the development of atherosclerotic plaque instability. Polymorphonuclear cells (PMN) are present in atherosclerotic lesions and recent evidence suggests their involvement in plaque formation and destabilization.

Materials and Methods: PMN from venous blood of healthy subjects (HS) and patients with carotid plaque (Pt) were isolated by density-gradient centrifugation, while PMN from plaque were obtained by immunomagnetic sorting. Phenotypic assay of PMN is performed by means of real time PCR and ELISA.
In order to perform the neovessel formation assays we use human umbilical vein endothelial cells (HUVEC).
Results: 30 Pt and 10 HS were enrolled. PMN in carotid plaques were preferentially located in close proximity to neovessels. No differences was observed in IL-8 and elastase mRNA expression between HS and Pt, while VEGF mRNA levels was higher in Pt with respect to HS. No differences was measured in elastase production from PMN both in HS and in Pt; while for the VEGF production, we observed a major production in HS with respect to Pt . Preliminary data about neovessel formation assay show an effect of PMN-activated supernatant to stimulate capability of HUVEC cells to form neovessel.
Conclusions: Clarifying the role of PMN in the development and progression of the atherosclerotic plaque will likely provide novel insights into the cellular and molecular mechanisms contributing to the pathogenesis of ATH.

P1.01.31
Blockage of histamine receptor 2 ameliorates the progression of sepsis in NOD diabetic mice

G. T. Scortegagna*, P. H. Melo, D. Nascimento, V. Borges, F. O. Souto, D. Carlos, F. Q. Cunha;*
School of Medicine Ribeirao Preto, University of Sao Paulo, Ribeirão Preto, Brazil.

Infections are a common and serious complication of diabetes and a well-recognized cause of mortality of diabetic individuals. Neutrophils act as first-line-of-defense cells and a significantly lower chemotaxis has been found in PMNs of diabetic patients. The failure of neutrophil migration to the infection sites is associated with poor outcome in sepsis. Some studies have shown that mast cells (MCs) play a deleterious role in severe sepsis by inducing systemic release of pro-inflammatory mediator, contributing to the impairment of neutrophil migration and ultimately mortality. In this study, we examined whether blockage of histamine receptor 2 (H2R) interfere with the progression of sepsis induced by cecal ligation and puncture (CLP) in NOD diabetic mice. Diabetic mice undergoing mild sepsis (MS) exhibited 100% mortality within 24 hours, whereas around 40% of the treated diabetic mice survived upon 7 days. Correlated with decrease the mortality rate, H2R blockade also prevented the failure of neutrophil migration and systemic bacterial dissemination after MS. Furthermore, organ damage markers are elevated in diabetic mice serum and treatment normalizes this levels. These results suggest that histamine released by MCs plays a detrimental role in sepsis control during diabetes and that H2R blockade could be a novel potential therapeutic option to reduce lethality from sepsis in diabetic host.

P1.01.32
Entry of Staphylococcal Superantigen-Like Protein 11 into neutrophils attenuating their recruitment

R. P. Sequeira*, R. J. Langley, T. Proft, J. D. Fraser;*
University of Auckland, Auckland, New Zealand.

Immune evasion is an important part of *Staphylococcus aureus* pathology. Normally the host eradicates the bacteria through innate defences primarily mediated by neutrophil phagocytosis. However, *S. aureus* evades these important immune defences by inhibiting components involved in chemotaxis, opsonisation, phagocytosis and bacterial damage. One family of 14 virulence factors, known as the Staphylococcal Superantigen-Like (SSL) proteins, are involved in innate immune evasion. The conserved exotoxin SSL11 targets cells by binding to cell surface glycoproteins expressing trisaccharide sialyllactosamine and is rapidly internalised. As sialylation is an important glycosylation for many crucial immune molecules, it is likely that SSL11 is essential in aiding *S. aureus* immune evasion mechanisms. For this reason, the interaction of SSL11 with myeloid cells is being investigated. Using microscopic techniques, it has been identified that SSL11 disrupts the motility of neutrophils to opsonised bacteria but does not inhibit the ability of the neutrophil to phagocytose them. Internalisation of SSL11 into the cell is active and dependent on clathrin receptor-mediated endocytosis. SSL11 also causes potent neutrophil aggregation as a consequence of SSL11 dimerisation. This is likely to be central in aiding the survival of the bacterium by preventing neutrophil recruitment.

P1.01.33
Effect of exercise on cytokine production by neutrophils

I. Shvydchenko*[1], E. Bykovskaya[1], V. Romenskaya[1], G. Rozhkova[1], A. Simbirtsev[2];*
[1]Kuban State University of Physical Education, Sport and Tourism, Krasnodar, Russian Federation, [2]State Research Institute of Highly Pure Biopreparations, Saint-Petersburg, Russian Federation.

Purpose/Objective. It is known that neutrophils are important source of cytokines. Neutrophils take direct part in reaction of whole body on physical activity. We aimed to study a cytokine production by neutrophils in sportsmen.
Material and Methods. The capacity of neutrophils to produce cytokines IL-1b, IL-1RA,IL-6, IL-8, IL-10, TNF-α, MIF-1β and VEGF A was studied in 20 sportsmen with low level of training loads, and 22 highly qualified sportsmen of various specialization (12 bicyclists and 10 runners) with high level of training loads on different stages of a year training cycle. The untrained volunteers served as the control. ELISAs were used to measure cytokines.
Results. Neutrophils of sportsmen with low level of training loads produced the increased amount IL-1β, IL-1RA, IL-6, IL-8. Cytokine-secreted activity of neutrophils of highly qualified sportsmen did not differ from control, except for IL-8, but depended from specialisation and intensity training loads at various stages of a year training cycle. Spontaneous secretion VEGF A by neutrophils of bicyclists in the competitive season has been increased ($p<0,05$). It is found positive correlation of spontaneous production IL-1RA and IL-8 by neutrophils with cortisol in control ($r=0,59$ and $r=0,82$, respectively). Regular exercises reduce dependence of cytokine secretion by neutrophils from stressor factors.
Conclusion. Collectively, our data show different effects of exercise on capacity of neutrophils to produce cytokines. These differences, probably, reflect various degree of manifestation of adaptive processes in sportsmen.

P1.01.34
Role of nanoparticles in apoptosis and cytoskeleton rearrangement in human leukemia eosinophil like AML 14.3D10 cells

J. Simard*, F. Vallières, D. Girard;*
Institut Armand Frappier- INRS, Laval, QC, Canada.

Although inflammation is a toxic effect frequently reported following nanoparticle (NP) exposure, the direct interaction of NPs with human granulocytes, key players cells in inflammation, is not well documented. Recently, we demonstrated that several NPs, including TiO_2, ZnO, CeO_2, AgNPs of 20 nm ($AgNP_{20}$) and of 70 nm ($AgNP_{70}$) can alter the biology of human neutrophils. In the present study, we decided to determine whether or not these NPs can possess potential cytotoxic effects and alter the biology of eosinophils using the human leukemia eosinophil like AML 14.3D10 cell line. Low cytotoxicity was associated with the tested NPs as assessed by trypan blue exclusion and LDH liberation assays at 100 µg/ml. We also show that NP induce apoptosis at different potencies as determined by cytology, by flow cytometry using FITC-annexin-V and by DNA degradation. In addition, we show that NPs induce the processing of caspases-3, -4 and -9, as well as the degradation of some cytoskeletal proteins. Finally, using an ELIS-Array assay, we report here that NPs induce cytokine and chemokine secretion in AML 14.3D10 cells. Taken together, our results indicate that human eosinophils are important target to NPs that can alter their cell physiology, including, at least, apoptosis, caspase processing, degradation of cytoskeletal proteins, and cytokine/chemokine production.

P1.01.35
Orai1-mediated Ca2+ influx independent of SOCE is essential for LPS and C5a-induced neutrophil migration in acute inflammation

G. Sogkas[1], *T. Vögtle*[2], *B. Nieswandt*[2], *R. Schmidt*[1], *E. Gessner*[1];
[1]*Hannover Medical University, Clinic for Immunology and Rheumatology, Hannover, Germany,* [2]*Chair of Experimental Biomedicine, University Hospital and Rudolf Virchow Center, DFG Research Center for Experimental Biomedicine, University of Würzburg, Würzburg, Germany.*

The pattern of Ca^{2+} mobilization serving neutrophil migration is distinct in case of different chemoattractants. Migration, elicited by chemoattractants such as C5a and fMLP, depends on extracellular Ca^{2+}. However, this is not the case with MIP2-elicited migration. In vitro, Orai1 is required for C5a and fMLP-elicited migration but not for the Ca^{2+} influx independent MIP2-elicited migration. Elevation of the cytosolic levels of calcium post stimulation with C5a, which is due to Ca^{2+} influx, was substantially reduced in Orai1 deficient neutrophils. These data suggest the involvement of Orai1 in Ca^{2+} influx, serving neutrophil chemotaxis. These findings were recapitulated in vivo, in *Orai1*$^{-/-}$ bone marrow chimeric mice, in the context of agonist-induced peritoneal recruitment of neutrophils. Moreover, in case of LPS-induced peritonitis, where neutrophil recruitment largely depends on C5a, reduced numbers of neutrophils were thrived from the peritoneal cavity of *Orai1*$^{-/-}$ bone marrow chimeric mice as compared to wild type transplanted mice. Dispelling the strongly entrenched perception of Orai1 as a store-operated Ca^{2+} entry (SOCE) mediator, we provide several lines of evidence demonstrating that Orai1 requirement comes in a non-SOCE manner. We show that Orai1 is not involved in neutrophil SOCE. Although STIM1 is the master mediator of neutrophil SOCE, STIM1 deficient neutrophils exhibited efficient migration in vitro and in vivo. Finally, application of YM58483, with a regiment abrogating SOCE, was of no consequence in neutrophil migration.

P1.01.36
Soluble molecules from Trypanosoma cruzi are able to induce NETosis from human neutrophils in the absence of classical apoptosis and necrosis signals

L. F. A. Diniz, P. S. S. Souza, M. Thomaz-Tobias, D. Sousa-Rocha, M. F. Costa, ***K. A. Toledo****;*
Univ Estadual Paulista, UNESP, Assis, Brazil.

NETs (Neutrophil Extracellular Traps) have been described as a new mechanism of the microbicide neutrophils to quickly capture and kill many pathogens, including bacteria, fungi and parasites. NETs are formed during active cell death, named NETosis. New data indicate that this novel mechanism of cell death differs from previously known types of cell death, including apoptosis and necrosis. Here, our aim was to investigate if NETosis process induced by soluble molecules from Trypanosoma cryzi (T.cruzi) parasite occurs in the absence of apoptosis and necrosis signals. In order to answer our question, human neutrophils were isolated from blood by using sedimentation gelatin method and co-cultivated with different doses of soluble extract from T.cruzi parasite. The end of incubation we evaluated the cellular permeability, phosphatidylserine externalization and DNA degradation by flow cytometry. Images acquired and analyzed have been demonstrated that soluble molecules from T.cruzi induced NETosis on human neutrophils in dose-dependent manner. This release was similar to positive control (fMLP 10-6M) and opposite to negative control (RPMI only). However, any tested dose (0.1-50 µg/mL) was able to induce significantly cellular permeability, phosphatidylserine externalization or DNA degradation in those neutrophils after 1-4 hours of incubation. Together, our preliminary results suggest soluble molecules from T.cruzi are able to induce NETosis process from human neutrophils in the absence of classical apoptosis and necrosis signals. Extend this study will assist in to further understand this novel antimicrobial mechanisms of neutrophils, mast cells and eosinophils more recently.

P1.01.37
Role of PI3K, PKC and ERK on neutrophil extracellular trap release induced by Leishmania amazonensis

T. S. S. Vieira*, A. Guimarães-Costa, M. T. C. Nascimento, R. Mariante, E. M. Saraiva;*
Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil.

Neutrophils discharge to the extracellular medium web-like structures comprised of chromatin and proteins (NETs), which bind and kill microbes. Reactive oxygen species (ROS) and ERK phosphorylation are required for NETs induction by some stimuli, but the full process is still unclear for many others. We reported that Leishmania amazonensis (La) induces NETs release and that these fibers ensnare and kill this parasite. Here our aim is to further identify signaling pathways behind La-induced NETosis. Hence, neutrophils isolated from healthy donors were treated with selective inhibitors prior to the interaction with La, and NET-DNA measured in the culture supernatant. Our results show that PI3K, PKC and ERK selective inhibitors induced significant inhibition over NETs release. These results were confirmed by decondensed chromatin observed by DNA staining pattern under fluorescence microscopy. ERK phosphorylation after La-neutrophil interaction was abolished by the selective inhibitors. ROS generation, measured with specific probes, was abolished by PKC and reduced over 60% by ERK inhibitors. Both PI3Kδ and PI3Kγ inhibitors, reduced over 50% La-induced NETs release and we detected a 97% reduction of ROS generation only with the PI3Kγ inhibitor. Also, PI3Kγ inhibition diminished ERK phosphorylation. Depletion of intracellular calcium decreased 40% La-induced NETosis, but not ROS generation. Therefore, we suggest that PI3Kγ together with PKC controls ROS generation and that PI3Kγ is upstream of ERK phosphorylation on NETs signaling pathway induced by La. PI3Kδ and Ca2+i did not affected ROS generation but reduced NET generation, which might indicate activation by a different pathway. Supported by:FAPERJ, CNPq, CAPES.

P1.01.38
Modulation of human neutrophil functions with antioxidants in vitro

N. V. Vorobjeva*;*
Immunology Department, Biology Faculty, Lomonosov Moscow State University, Moscow, Russian Federation.

Background and aims. Signalling in neutrophils from soluble stimules resulting in degranulation and a respiratory burst has not been understood yet. A number of signal transmitters such as tyrosine and serine/threonine kinases (Abe et al, 2009) are sensitive to the redox status of granulocytes. The role of an antioxidant, cationic plastoquinone derivative containing charged phosphonium, was investigated in the model of degranulation of human neutrophils. Well-known antioxidants such as N-acetylcystein (NAC) and Trolox, ROS-scavengers, Tiron and TEMPOL, were used as controls.
Methods. Human neutrophils were purified from the blood of healthy donors using a standard protocol. The respiratory burst induced by fMLP was measured using luminol-dependent chemiluminescence. Hydrogen peroxide was quantified by flow cytometry using DCFH-DA. The exocytosis of specific and azurophil granules was determined from the expression of CD66b and CD63, respectively, in a flow cytometric assay.
Results. It was shown earlier that cationic plastoquinone derivatives possess strong antioxidant activity at a nanomolar concentrations and show pronounced prooxidant activity at higher concentrations. In this study it was demonstrated that at concentrations of 1-100 nM, it reduced degranulation of fMLP-activated neutrophils in a dose-dependent manner and inhibited intracellular hydrogen peroxide and luminol-enhanced chemiluminescence. NAC and Trolox decreased ROS generation and the exocytosis of neutrophils in a concentration-dependent manner.
Conclusions. Our results indicate that antioxidants of different origins can modulate neutrophil activity. Their use in the treatment of inflammatory diseases is discussed.

P1.01.39
Critical roles of DOCK2 and DOCK5 in neutrophil chemotaxis, ROS production, and NETs formation

M. Watanabe[1,2]*, A. Nishikimi*[1,2]*, M. Terasawa*[1,2]*, J. Côté*[3]*, Y. Fukui*[1,2]*;*
[1]Devision of Immunogenetics, Department of Immunobiology and Neuroscience, Medical Institute of Bioregulation, Kyushu University, Fukuoka, Japan, [2]CREST, Japan Science and Technology Agency, Tokyo, Japan, [3]Institut de Recherches Cliniques de Montréal, Montréal, QC, Canada.

Neutrophils are highly motile leukocytes and play important roles in the innate immune response to invading pathogens. Upon infection, neutrophils rapidly migrate to the site of infection, phagocytose bacteria, and kill them by producing reactive oxygen species (ROS). All these neutrophil functions are critically dependent on Rac, a member of the small GTPases that cycle between GDP-bound inactive and GTP-bound active states. However, the upstream regulators controlling Rac activation in response to chemotactic cues and other stimuli are not fully understood.
DOCK2 and DOCK5 are mammalian homologues of Caenorhabditis elegans CED-5 and Drosophila melanogaster Myoblast City. Although DOCK2 and DOCK5 do not contain the Dbl-homology domain and the pleckstrin homology domain typically found in guanine nucleotide exchange factors (GEFs), these molecules bind to nucleotide-free Rac and catalyze GTP-GDP exchange reaction through their DHR-2 domain. In this study, we show that DOCK2 and DOCK5 coordinately regulate various neutrophil functions. We found that fMLP- and PMA-induced Rac activation are almost completely lost in neutrophils lacking both DOCK2 and DOCK5, resulting in severe defects in neutrophil chemotaxis, phagocytosis, and ROS production. In addition, double KO mice exhibited a defect in formation of neutrophil extracellular traps (NETs), the extracellular structures composed of chromatin and granule proteins that bind and kill microorganisms. Although NETs play an important role in protective immunity, NETs are also involved in inflammatory response and autoimmunity. Therefore, DOCK2/DOCK5-mediated Rac activation would be a therapeutic target controlling NETs-mediated immune-related disorders.

P1.01.40
Untouched isolation of functionally unaffected neutrophils from whole blood within 20 minutes

C. Zyntek, J. Schmitz, ***G. Winkels****;*
Miltenyi Biotec GmbH, Bergisch Gladbach, Germany.

Human neutrophils are commonly obtained by density gradient centrifugation. Commonly used methods such as Ficoll-Paque gradients in combination with dextran sedimentation, discontinuous Percoll or Polymorphprep gradients are exceedingly time-consuming and frequently result in impure neutrophils which are contaminated by other leukocytes, mainly eosinophils.
With the new MACSxpress technology, untouched human leukocyte subsets can be isolated from up to 30 ml of anticoagulated whole blood. Erythrocyctes are aggregated and sedimented, while non-target cells are removed by immunomagnetic depletion with MACSxpress Beads, yielding untouched target cells of high purity.
MACSxpress-enriched neutrophils had average purities of 93% with yields of ~97% (n=14). ROS (reactive oxygen species) generation and expression levels of the surface markers CD11b, CD62L and CD181 (CXCR1) of MACSxpress-isolated neutrophils were comparable to cells isolated with density gradient centrifugation. In addition, separated neutrophils maintained efficient phagocytic capacity, which was assessed by uptake of opsonized bacteria and showed typical migration behavior toward fMLP. Cell viability was unaffected, as demonstrated by flow cytometric analysis of AnnexinV staining.

Role of mast cells and histamine in local reaction induced by *Potamotrygon motoro* stingray venom in mice

L. F. Kimura[1]*, J. P. Prezotto-Neto*[1]*, M. M. Antoniazzi*[2]*, S. Jared*[2]*, C. F. Teixeira*[3]*, M. L. Santoro*[4]*,* ***K. C. Barbaro***[1]*;*
[1]Laboratory of Immunopathology-Butantan Institute, São Paulo, Brazil, [2]Laboratory of Cell Biology-Butantan Institute, São Paulo, Brazil, [3]Laboratory of Pharmacology-Butantan Institute, São Paulo, Brazil, [4]Laboratory of Pathophysiology-Butantan Institute, São Paulo, Brazil.

Stingray accidents cause an intense pain followed by edema, erythema and necrosis formation. The therapy is based on administration of analgesic, antipyretic and anti-inflammatory drugs. The aim of this work was to verify the participation of mast cells and histamine on the inflammatory reaction induced by injection of *Potamotrygon motoro* venom (PmV). Mice were pre-treated with either cromoglycate, a mast cell inhibitor, or the histamine antagonists promethazine, cimetidine and thioperamide at selected time intervals before venom injection. PBS pre-treatment was used as control. PmV (8 µg/ 30 µL) or PBS were injected into mouse footpad to evaluate edema formation (0.25, 0.5, 1, 4, 24 and 48 h) and cell recruitment (4 h). Presence of mast cells was confirmed by histological analysis. Pre-treatment with cromoglycate diminished edematogenic activity in all time periods analyzed, reaching 62 % of reduction at 30 min. A decrease of edema formation was also noticed in animals treated with promethazine or thioperamide after PmV injection. Moreover, treatment with cromoglycate, promethazine, or thioperamide diminished local PmV-induced leukocyte infiltration, mainly of neutrophils (15, 20 and 30 % respectively). Cimetidine neither affects edema nor cell influx induced by PmV. Besides, thioperamide also reduced lymphocyte numbers. This is the first report demonstrating participation of mast cells and histamine in the local inflammatory response induced by freshwater stingray venom. The use of antihistaminic may be a new strategy for ameliorate the treatment for stingray envenomation. Supported by FAPESP, CAPES and INCTTox.

P1.02.02
Cross reactivity of IL-3 between mouse and rat in the induction of mouse bone marrow derived mast cells

J. Lee[1,2]*, K. Shin*[1]*, C. Kim*[3]*, K. Joo*[1]*,* ***S. Cho***[1,2]*;*
[1]Department of Parasitology, Korea University College of Medicine, Seoul, Republic of Korea, [2]Department of Microbiology and Immunology, Korea University Graduate School, Seoul, Republic of Korea, [3]Department of Pathology, Korea University College of Medicine, Seoul, Republic of Korea.

Both mouse and rat are classified as rodent and amino acid sequence homology (AASH) between mouse and rat shows more than 90% in most protein constituents of equivalents, with some except. The AASH is 96% in stem cell factor (SCF), however, that is 54% in IL-3 between both species. IL-3 is one of the important stimulators of hematopoietic stem cell. The addition of mouse IL-3 (mIL-3) alone or with mouse SCF (mSCF) to bone marrow cell culture (BMCC) induces mouse bone marrow derived mast cells (mBMMC). Mast cells are the important immune cells found even in shark that is the species regarded as an evolutionarily early stage animal. Rat IL-3 (rIL-3) induced proliferation of mBMMC at 7 week BMCC prepared with both mIL-3 and mSCF, not at 3 week. The BMMC proliferation induced by rIL-3 was enhanced by mSCF, but decreased by rat SCF. These results suggested both that rIL-3 deliver certain signal through mIL-3 receptor to allow mBMMC activation and that the change of rIL-3 from mIL-3 was not established simultaneously with SCF modification in evolution from mouse to rat.

P1.02.03
OX40L-STIMulated inhibition of mast cell calcium influx

F. D'Incà[1], *J. Almering*[2], *B. Frossi*[1], *H. Sandig*[3], *M. Freichel*[2], *S. Bulfone-Paus*[3,4], *C. Pucillo*[1];
[1]*Laboratory of Immunology, Department of Medical and Biological Science, University of Udine, Udine, Italy,* [2]*Pharmakologisches Institut, Universität Heidelberg, Heidelberg, Germany,* [3]*Faculty of Human and Medical Sciences, University of Manchester, Manchester, United Kingdom,* [4]*Department of Immunology and Cell Biology, Research Centre Borstel, Borstel, Germany.*

In the complex network of immune interactions, the amount of information available on the functional interplay between mast cells (MCs) and T regulatory cell (Tregs) is going to keep increasing.
Among the mysteries in this field is the nature of the inhibitory mechanism exerted by Treg on MC FcεRI-dependent extracellular Ca2+ flux. This process occurs on a single cell level through the OX40-OX40L axis without modifying Ca2+ mobilization from intracellular stores. To gain more insight into this mechanism we explored the relocation at lipid raft domains of STIM1, a transmembrane protein that mediates Ca2+ influx after depletion of intracellular Ca2+ stores by gating of store-operated Ca2+ influx channels (SOCs).
As visualized by confocal microscopy, the physical interaction with a single Treg leads to the inhibition of STIM1 relocation into lipid rafts. Additional findings suggest OX40L triggering as an underlying mechanism for the STIM1 defect observed, by a marked modification of lipid rafts organization.
In addition, both confocal and raft analysis showed aberrant STIM1 distribution upon antigenic stimulation in OX40L-deficient MCs.
Although their role in MC biology is not well understood, TRPC channels have been reported to contribute to Ca2+ influx. Here, preliminary results show their coupling to STIM1 dynamics and to OX40L engagement.
Taken together, these findings identify STIM1 as a critical mediator of OX40L "tuning" action on MC Ca2+ influx, but further investigations are required in order to have a more complete understanding of this inhibitory mechanism.

P1.02.04
Augmenting the effects of vaccine adjuvants by targeting mast cells

Y. Fang[1,2], *N. Lycke*[2], *Z. Xiang*[2];
[1]*Affliated Hospital of Guiyang Medical college, Guiyang, China,* [2]*Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden.*

Replacement vaccine adjuvants with better potency are desired especially in the face of a global resurgence of infectious diseases. Mast cells can be exploited for developing novel adjuvants by virtue of their potential in secreting cytokines that favour adaptive immunity.
Our research has focused on a detoxified cholera toxin (CT)-derived adjuvant, CTA1-DD which is a fusion protein consisting of the Al subunit of CT linked to a synthetic dimer of fragment-D of *Staphylococcus aureus* protein A (DD). CTA1-DD itself has been demonstrated to be a potent mucosal adjuvant in various immunization models. As the DD domain can unspecifically bind immunoglobulins, we proposed that IgG and CTA1-DD can form complexes that may activate mast cells through FcγRIIIA, an activating Fc receptor expressed on connective tissue mast cells (CTMC). In deed, CTA1-DD in combination with normal mouse IgG induced TNF-α production from mouse CTMC, resulting in greater antigen-specific immune responses than when CTA1-DD was used alone as an adjuvant in nasal immunization. Furthermore, FcγRIIIA-expressing CTMC were observed to reside in mouse nasal submucosa. Mice deficient in mast cells or FcγRIIIA, or treated with a CTMC inhibitor consistently expressed compromised antigen-specific immune responses to intranasal immunization adjuvanted with CTA1-DD/IgG complexes. Replacement of amino acid 7, arginine, by lysine (CTA1-R7K-DD) abolishes the adjuvant effect completely. Yet, CTA1-R7K-DD complexed with IgG could activate CTMC thus partially restoring the adjuvant function.
In conclusion, the effects of mucosal adjuvants can be further enhanced by engaging mast cells through adequately manipulating the adjuvant formulation.

P1.02.05
Generation of mast cells from murine fetus liver and transcriptome analysis using next generation sequencer; a comparison of the profiles between bone marrow derived mast cells with fetus liver derived mast cells

N. Fukuishi, *Y. Igawa, T. Kunimi, N. Matsui, M. Akagi;*
Faculty of Pharmaceutical Sciences, Tokushima Bunri University, Tokushima, Japan.

Embryonic lethal due to a gene manipulation provoke severe difficulty in the analysis of protein function, although conventional or conditional knockout techniques are widely used for exploring the roles of proteins in various cells. We generated mast cell-like cells from mouse early fetus liver (FLMCs), and compared the mRNA expression pattern of FLMCs with that of bone marrow-derived mouse mast cells (BMMCs).
The FLMC was generated from liver of C57BL/6 mouse embryos at embryonic age 12-13, and the RNA was purified by commercial kit. Messenger RNA expression pattern was analyzed using Illumina Genome Analyzer IIx. Transcripts were classified according to whether the mRNA in both BMMC and FLMC increased or not.
The coefficient of correlation between both transcripts revels in BMMCs and FLMCs was about 0.96. Approximately 95% of all mRNA we analyzed was expressed at similar levels on both types of non-stimulated cells. On both IgE cross-linked BMMC and FLMC, the changed expression was observed in about 0.7% mRNA of above-mentioned 95% mRNA. The changed mRNA belonged to the category of angiogenesis, cell cycle control, hormones, immune responses, and signal transduction. Meanwhile, approximately 5% of all mRNA we analyzed was expressed at significantly different levels between non-stimulated BMMC and FLMC; they involved mRNAs for chemokines, interleukins and their receptors.
FLMCs can be used as a powerful tool for the elucidation of proteins function in mast cells, even if the fetal lethal caused by a gene deletion has occurred.

P1.02.06
Mast cells induce invariant Natural Killer T cells to cytokine secretion and proliferation via CD1d: Another path to asthma?

N. Gonzalez Roldan, *S. Bulfone-Paus;*
Research Center Borstel, Borstel, Germany.

Increasing evidences show that beyond their role as effectors during allergic reactions, mast cells (MCs) can function as antigen presenting cells that activate diverse T cell populations. Recently, the role of invariant Natural Killer T cells (iNKT) in allergic asthma has become more evident, where they contribute to the development of Th2 responses. During allergic asthma, MCs-released mediators induce the recruitment and regulation of diverse innate lymphocytes, such as iNKT. Therefore it appears very likely that MCs interact with iNKT cells in the lung during the course of allergic asthmatic reactions.
In our study we analyzed the MCs and iNKT interaction. We found that mouse peritoneal MCs (PMC) express surface CD1d, which is upregulated *in vivo* after a single intraperitoneal administration of the prototypical glycolipid alpha-Galactosylceramide (aGalCer). In contrast to primary cells, in cultured peritoneal (CPMC) and bone marrow-derived MCs (BMMC) CD1d was located mostly intracellularly. However, after the induction of IgE-mediated degranulation, CD1d relocated to the cell surface at similar levels to those found *in vivo*. Moreover, when cultured in the presence of aGalCer and upon degranulation, the CD1d-aGalCer complex was detectable on the surface of BMMC, thus enabling the activation of iNKT by MCs. When co-cultured *in vitro*, mast cells loaded with aGalCer indeed induced the release of Il-4, IL-13 and IFN-gamma and proliferation of iNKT cells.
Our data provide the first evidence of the involvement of MCs in responses to glycolipids. And notably, reveal a yet unidentified scenario where MCs likely modulate iNKT cell activation and homeostasis.

P1.02.07
Mast cell CYP27B1 hydroxylase activity is required for 25OH vitamin D_3-induced suppression of IgE-mediated activation

M. A. Grimbaldeston[1,2], *K. Yip*[1], *C. Yu*[1], *N. Kolesnikoff*[1], *H. Taing*[1], *D. Goltzman*[3], *P. H. Anderson*[2], *M. Samuel*[1], *A. Lopez*[1];
[1]*Centre for Cancer Biology, Adelaide, South Australia, Australia,* [2]*University of South Australia, Adelaide, Australia,* [3]*McGill University, Montreal, QC, Canada.*

Mast cells (MCs) have gained notoriety based on their detrimental pro-inflammatory contributions to IgE-mediated allergic disorders, such as asthma and life-threatening anaphylaxis. We have determined that the pro-inflammatory properties of MCs can be reduced by application of 1α,25-dihydroxyvitamin D_3 (1α,25$(OH)_2D_3$), the biologically active form of vitamin D_3 (VitD_3). A number of immune cell types have the ability to produce endogenous 1α,25$(OH)_2D_3$ from the predominant inactive VitD_3 metabolite in circulation, 25-hydroxyvitamin D_3 (25OHD_3), due to expression and activity of the hydroxylase enzyme CYP27B1. In this study, we explored if 25OHD_3 can modulate IgE-dependent MC activation. Our data show, for the first time, that MCs express intracellular CYP27B1 and that 25OHD_3 can be converted to significant levels of 1α,25$(OH)_2D_3$ by MCs. In addition, MC-CYP27B1 activity is required for 25OHD_3 -induced inhibition of IgE-mediated MC-TNF and IL-6 production *in vitro*. By employing a mouse IgE-mediated MC-dependent passive cutaneous anaphylaxis (PCA) model, as well as four mouse groups with different cutaneous MC profiles in the ears, including WT mice, MC-deficient C57BL/6-*Kit*$^{W\text{-}sh/W\text{-}sh}$ mice and C57BL/6-*Kit*$^{W\text{-}sh/W\text{-}sh}$ mice engrafted with either WT or *CYP27B1*$^{-/-}$ MCs, we found that topical 25OHD_3 application significantly reduced the magnitude of PCA-associated ear swelling in the WT MC engrafted group but not in mice that received *CYP27B1*$^{-/-}$ MCs. Taken together, these findings provide evidence that MCs are capable of utilising 25OHD_3 to generate biologically active 1α,25$(OH)_2D_3$, and thereby extends the modus operandi of VitD_3 (via both 25OHD_3 and 1α,25$(OH)_2D_3$ metabolites) to efficiently negatively regulate IgE-mediated MC activation.

P1.02.08
IgE-mediated allergic responses in human mast cells in humanized NOG mice expressing human IL-3 and GM-CSF

R. Ito[1,2], *T. Takahashi*[1], *I. Katano*[1], *K. Kawai*[1], *S. Nunomura*[3], *C. Ra*[3], *A. Mori*[4], *S. Aiso*[2], *M. Ito*[1];
[1]*Central Institute for Experimental Animals, Kawasaki, Japan,* [2]*Keio University School of Medicine, Tokyo, Japan,* [3]*Nihon University Graduate School of Medical Sciences, Tokyo, Japan,* [4]*National Hospital Organization, Sagamihara National Hospital, Clinical Research Center, Kanagawa, Japan.*

Humanized mice reconstituted with human immune systems are essential to study human immune reactions in vivo and are expected to be useful for studying human allergies. However, application of this technology in the study of human allergies has been limited, largely due to the poor development of human myeloid cells, especially granulocytes and mast cells, which are responsible for mediating allergic diseases, in conventional humanized mice. In this study, we developed a novel transgenic strain, NOD/Shi-scid-IL2rγnull (NOG), bearing human interleukin (IL)-3 and granulocyte-macrophage colony-stimulating factor (GM-CSF) genes (NOG IL-3/GM-Tg). In this strain, a large number of human myeloid cells of various lineages developed after transplantation of human CD34+ hematopoietic stem cells. Notably, mature basophils and mast cells were markedly increased in peripheral blood (PB), bone marrow (BM), spleen and bronchoalveolar lavage (BAL) of Tg mice, and these cells expressed a significant amount of high affinity IgE receptor. These humanized NOG IL-3/GM-Tg mice developed human mast cell-mediated passive cutaneous anaphylaxis (PCA) reactions when administered anti-4-hydroxy-3-nitrophenylacetyl (NP) IgE antibodies (Abs) and NP. More importantly, combination of the serum from Japanese cedar pollinosis patients and the cedar pollen extract also elicited strong PCA responses in the mice. Thus, our IL-3/GM-Tg mice are the first humanized mouse model to enable the study of human allergic responses in vivo and are excellent tools for preclinical studies of allergic diseases.

P1.02.09
Roles of basophils and mast cells infiltrating the lung in murine asthmatic responses induced by multiple antigen challenges

H. Kida[1], *A. Takiguchi*[1], *H. Wakamori*[1], *K. Ishihara*[2], *S. Akiba*[2], *N. Mizutani*[3], *S. Yoshino*[3], *D. D. Chaplin*[4], *S. Ohya*[1], *T. Nabe*[1];
[1]*Department of Pharmacology, Kyoto Pharmaceutical University, Kyoto, Japan,* [2]*Department of Pathological Biochemistry, Kyoto Pharmaceutical University, Kyoto, Japan,* [3]*Department of Pharmacology, Kobe Pharmaceutical University, Kobe, Japan,* [4]*Department of Microbiology, University of Alabama at Birmingham, Birmingham, AL, United States.*

Mast cell hyperplasia has been observed in the lungs of mice with experimental asthma, but few reports have studied basophils. Here, we discriminated and quantified mast cells and basophils in the lungs in a murine asthma model, determining if both cells were increased by multiple antigen challenges, and assessing the roles of these cells in asthmatic responses. Sensitized Balb/c mice were challenged intratracheally with ovalbumin 4 times. Mast cells and basophils in enzymatically digested lung tissue were detected by flow cytometry. An anti-FcεRI monoclonal antibody, MAR-1, was administered i.p. during the multiple challenges. The numbers of both mast cells (IgE+ C-kit+) and basophils (IgE+ C-kit− CD49b+) increased in the lungs after three challenges. Treatment with MAR-1 completely abolished the increases; however, a late-phase increase in specific airway resistance (sRaw), and airway eosinophilia and neutrophilia were not affected by the treatment, although the early-phase increase in sRaw was suppressed. MAR-1 reduced antigen-induced airway interleukin (IL)-4 production. Basophils infiltrating the lungs clearly produced IL-4 after antigen stimulation in vitro; however, histamine and murine mast cell protease 1 were not increased in the serum after the challenge, indicating that mast cell activation was not evoked. In conclusion, both mast cells and basophils infiltrated the lungs by multiple intratracheal antigen challenges in sensitized mice. Neither mast cells nor basophils were involved in late-phase airway obstruction in this model, although early-phase airway obstruction was mediated by basophils. Targeting basophils in asthma therapy may be useful for an early asthmatic response.

P1.02.10
Immune suppression following exposure to UV-radiation is associated with increases in mast cell densities in primary and secondary lymphoid tissues

L. Kok[1,2,3], *C. Beuagie*[1,2], *C. Chan*[1,2], *S. Sarchio*[1,2], *G. Halliday*[2,3], *S. Byrne*[1,2];
[1]*Cellular Photoimmunology Group, Discipline of Infectious Diseases and Immunology, Sydney Medical School, The University of Sydney, Sydney, Australia,* [2]*Dermatology Research Laboratories, Bosch Institute, Sydney Medical School, The University of Sydney, Sydney, Australia,* [3]*Discipline of Dermatology, Royal Prince Alfred Hospital, NSW, Sydney, Australia.*

Ultraviolet (UV) radiation causes skin cancer, in part, by suppressing adaptive immune responses. One way UV achieves this is by altering the traffic of mast cells around the body. Exposing C57BL/6 mice to UV 4 times per week for 20 weeks resulted in significant increases in mast cell densities in the skin, lymph nodes and spleen. The density of mature mast cells was also higher in the bone marrow (but not thymus) of UV exposed mice as assessed by flow cytometry. In contrast, the frequency and number of T cells, B cells and DC were unaltered by UV in these primary lymphoid tissues. Mast cell accumulation in peripheral sites such as the skin and lymph nodes is associated with a UV-induced increase in CXCL12. Therefore, to determine whether the increase in bone marrow mast cells was due to changes in CXCL12, we isolated mRNA from bone marrow cells after 6, 12 and 16 weeks of irradiation. However, chronic UV did not significantly increase CXCL12 levels in the bone marrow suggesting another mechanism is involved in UV-induced mast cell increases in the bone marrow. To that end, we have discovered that exposure to chronic doses of UV results in an increase in mast cell progenitors in both the bone marrow as well as peripheral blood. These findings explain not only the increase in mast cells within bone marrow, but also those observed at peripheral sites.

P1.02.11
Intravenous injection of particulate antigens larger than the intracellular gap of endothelial cells can induce mast cell-mediated systemic anaphylaxis

***L. Li**, S. Yoshikawa, K. Horiguchi, T. Ohta, H. Deki, Y. Kawano, H. Karasuyama;*
Department of Immune regulation,Tokyo Medical and Dental University, Tokyo, Japan.

IgE-dependent systemic anaphylaxis is the most severe manifestation among mast cell-mediated hypersensitivity reactions. Mast cells are found throughout the body, particularly in a perivascular area and beneath epithelia. In blood vessels, endothelial cells are continuously connected by tight junctions, and the size of intercellular gaps is approximately 3.0 nm, limiting the passage of large molecules, for example, albumin (7 nm) and ovalbumin (5 nm). In spite of this fact, we unexpectedly found that allergen-conjugated microspheres with a 3,000 nm diameter could induce systemic anaphylaxis with drastic reduction in the body temperature when intravenously injected into mice that had been sensitized intravenously with allergen-specific IgE. The intravenous injection of allergen-conjugated microspheres also elicited a passive cutaneous anaphylactic reaction in mice sensitized subcutaneously with allergen-specific IgE. Of note, mast cell-deficient mice failed to induce both systemic and subcutaneous anaphylaxes, indicating the critical role for mast cells in the reactions. These results are consistent with the idea that perivascular mast cells can capture blood-circulating particulate antigens through the vessel wall and are activated to induce anaphylaxis.

P1.02.12
The development of oral tolerance is inhibited by TLR2 agonists but not by IgE-mediated mast cell activation

*M. Tunis, I. Haidl, **J. S. Marshall**;*
Dalhousie University, Halifax, NS, Canada.

Food allergy is linked to defective oral tolerance. Many factors have been implicated in this process. TLR2 activators are found in many foods, including processed meats, cheese and chocolate. In our study, we have investigated the role of mast cells and TLR2 in the development of oral tolerance. Mice were provided ovalbumin (OVA) in drinking water for one week and the extent of oral tolerance assessed following systemic immunisation (day 8) and boost (day 22) with alum precipitated OVA. Antigen specific IgE, IgA and IgG subclass responses were assessed by ELISA. In some experiments, TLR2 (Pam 3CSK4, FSL-1) or TLR4 (LPS) agonists were provided, three times by gavage, during the initial week of tolerance induction.
Neither two strains of mast cell deficient mice, nor TLR2 deficient mice, showed defective oral tolerance responses, compared with matched, wild type controls. Oral tolerance induction was associated increased antigen specific regulatory T cells in the mesenteric lymph node and spleen ($P<0.01$). IgE mediated mast cell activation also had little impact on oral tolerance development . In contrast, oral TLR2 agonist treatment significantly impaired suppression of humoral responses to foods upon systemic challenge ($P<0.05$ for anti-OVA IgE and IgA). Similar oral treatment with LPS did not modify oral tolerance responses.
In conclusion, neither TLR2 nor mast cells are necessary for oral tolerance induction. However, oral TLR2 activation, but not TLR4 activation, reduces the development of tolerance, these findings could have important implications for the mechanisms of development of food allergy.

P1.02.13
Notch1 signaling confers antigen-presenting functions on mast cells

***N. Nakano**, C. Nishiyama, H. Yagita, K. Okumura, H. Ogawa;*
Juntendo University School of Medicine, Tokyo, Japan.

Notch proteins (Notch1-4) are a family of transmembrane receptors that play important roles in the determination of cell fate. We have found that Notch1 and Notch2 are constitutively expressed on mouse mast cell surface. However, little is known about the roles of Notch-mediated signaling in mast cells. Here, we show that mast cells acquire antigen-presenting functions by Notch1-mediated signaling. Bone marrow-derived mast cells (BMMCs), which were generated *in vitro* by culturing bone marrow cells isolated from BALB/c mice with IL-3 and stem cell factor, were cocultured with Notch ligand-expressing CHO cell lines for 5 days. Flow cytometric analysis showed that the cell surface expression of MHC class II and a costimulatory molecule OX40 ligand was induced in BMMCs by stimulation with Notch ligand. The inducible expression of MHC class II depends critically on the expression of the class II transactivator (CIITA)-type III mediated by Notch1 signaling. Furthermore, Notch ligand-stimulated BMMCs directly activate antigen-specific $CD4^+$ T cells by antigen presentation *in vitro*. The ability to activate T cells was markedly elevated by sensitizing BMMCs with antigen-specific IgE. These findings suggest that mast cells acquire antigen-presenting cell functions by Notch1-mediated signaling and may contribute to the maintenance and/or augmentation of antigen-specific immune responses.

P1.02.14
Candida albicans activates mast cells in vitro

***A. U. Nieto-Patlán**[1], S. Estrada-Parra[1], I. Estrada-Garcia[1], O. Rodríguez-Cortes[2], S. Muñoz-Cruz[3], J. Serafín-López[1], R. Chacón-Salinas[1];*
[1]ENCB, Distrito Federal, Mexico, [2]Escuela Superior de Medicina, Distrito Federal, Mexico, [3]CMN Siglo XXI, Distrito Federal, Mexico.

Mast cells are long-lived cells that mature and reside in peripheral tissues such as skin and mucosae. They are equipped with several receptors that can recognize many microorganisms and can produce a great diversity of mediators. Recently, mast cells have been considered as sentinels of the immune system and they contribute to the elimination of pathogens. Candida albicans is a dimorphic fungus that usually behaves like a commensal but in cases like immunodeficiencies it can turn into a pathogen. The immune response against C. albicans is already described and many cell types that are important for the elimination of C. albicans have been described. However, the role of mast cells in this infection is still unclear.
We demonstrated that both hyphae and yeast induce mast cell degranulation. Moreover, mast cell activation was also reflected with cytokines production like TNFα IL-1β, RANTES, MIP-1α and MIP-1β. Finally, we observed that mast cells also produced ROS after stimulation with both phases of C albicans.
Our data suggest the importance of mast cell in the infection with C. albicans. It seems that the function of these cells is to initiate the inflammation, to recruit cells like neutrophils and monocytes with its mediators, and to induce maturation of T lymphocyte trough the production of RANTES. In conclusion these results support the hypothesis that mast cells are key cells to initiate the immune response against C. albicans.

P1.02.15
Involvement of transcription factors PU.1, GATA1 and GATA2 in the expression and function of human FcepsilonRI on mast cells

***C. Nishiyama**[1], E. Inage[1], K. Kasakura[1], T. Yashiro[1], M. Hara[1], H. Saito[2], T. Shimizu[1], H. Ogawa[1], K. Okumura[1];*
[1]Juntendo University School of Medicine, Tokyo, Japan, [2]National Research Institute for Child Health and Development, Tokyo, Japan.

The high affinity IgE receptor, FcepsilonRI, which is composed of three subunits, alpha-, beta- and gamma-chains, plays an important role in IgE-mediated allergic responses. We have previously identified several transcription factors including GATA-1, GATA-2 and PU.1 as transcriptional regulator of mast cell-specific gene expression. In the present study, we analyzed the involvement of PU.1, GATA1, and GATA2 in FcepsilonRI expression in the human mast cell line LAD2 and primary human mast cells using siRNA and chromatin immunoprecipitation (ChIP) assay to verify our previous findings. Transfection of siRNAs against PU.1, GATA1, and GATA2 into LAD2 cells caused significant downregulation of cell surface expression of FcepsilonRI. Quantification of the mRNA levels of alpha, beta and gamma revealed that PU.1, GATA1 and GATA2 siRNAs suppressed

the alpha transcript, whereas the amount of beta mRNA was reduced in only GATA2 siRNA transfectants. In contrast, gamma mRNA levels were not affected by any of the knockdowns. ChIP assay showed that significant amounts of PU.1, GATA1 and GATA2 bind to the promoter region of *FCER1A* (encoding FcepsilonRIalpha), and that GATA2 binds to the promoter of *MS4A2* (encoding FcepsilonRIbeta). These knockdowns of transcription factors also suppressed the IgE-mediated degranulation activity of LAD2. Similarly, all of three knockdowns suppressed FcepsilonRI expression in primary mast cells, especially PU.1 siRNA and GATA2 siRNA that target FcepsilonRIalpha and FcepsilonRIbeta, respectively.
This work was supported by the Funding Program for Next Generation World-Leading Researchers from the Ministry of Education, Culture, Sports, Science and Technology of Japan (LS111 to C. N.).

P1.02.16
Identification of a molecule critical for degranulation of mast cells and anaphylactic reaction

K. Ogawa[1,2], *Y. Tanaka*[1,2,3], *Y. Fukui*[1,2,3];
[1]*Medical Institute of Bioregulation,Kyushu University, Fukuoka, Japan,* [2]*Japan Science and Technology agency, CREST, Tokyo, Japan,* [3]*Research Center for Advanced Immunology, Kyushu University, Fukuoka, Japan.*

Anaphylaxis is a life-threatening allergic reaction. IgE-associated anaphylaxis is mainly mediated by mast cells that express FcεRI, the high-affinity receptor for IgE, on their surface. Crosslinking of FcεRI-bound IgE with multivalent antigens induces degranulation of mast cells, with concomitant secretion of chemical mediators.This process involves dynamic rearrangement of microtubules, yet the signaling cascade linking FcεRI to microtubule dynamics is not fully understood. In this study, we show that a member of DOCK family proteins plays a key role in degranulation of mast cells and anaphylactic reaction. By generating knockout (KO) mice, we found that FcεRI-mediated degranulation of mast cells was severely impaired in the absence of this molecule. While the KO mice exhibited a resistance to systemic and cutaneous anaphylaxis, transfer of wild-type mast cells restored the susceptibility, indicating that mast cells are primarily involved in these anaphylactic reactions. Imaging analysis using GFP-tagged C-terminal fragment of adenomatous polyposis coli (APC) also revealed that microtubule dynamic are impaired in the KO mouse-derived mast cells. Since DOCK family proteins act as guanine nucleotide exchange factors (GEFs) through the DHR-2 domain, we expected that the GEF activity would be important for this regulation. Interestingly, however, the expression of the mutant lacking DHR-2 domain completely restored degranulation response in the KO mouse-derived mast cells. Thus, we have identified a novel signaling molecule that links FcεRI to microtubule dynamics during mast cell activation.

P1.02.17
C. albicans phagocytosis by mast cells via Toll like receptor-2: protection or immune escape?

K. H. Pinke[1], *H. G. Lima*[1], *F. Q. Cunha*[2], *V. S. Lara*[1];
[1]*Bauru School of Dentistry. University of São Paulo., Bauru, Brazil,* [2]*School of Medicine of Ribeirão Preto. University of São Paulo., Ribeirão Preto, Brazil.*

Candida albicans (C. albicans) is a fungus commonly found in the mucosa of the gastrointestinal tract, including the mouth, and may cause candidiasis, especially in immunosuppression. Mast cells reside in the subepithelial region and actively participate in innate immunity, like one of the first lines of defense against *C. albicans.* The recognition of this fungus can occur via different receptors, *e.g.* Toll-like receptor 2 (TLR2), present on the surface of mast cells. Thus, this study evaluated in vitro the relationship of the phagocytosis, intracellular oxide nitric production by mast cells challenged with *C. albicans* and the involvement of TLR2 in these mechanisms. For this, Murine bone marrow cells (BMMC) wild type (TLR2+/+) or knockout (TLR2-/-) were cultured in presence of stem cell factor and interleukin-3. After, BMMCs were challenged with FITC-labeled *C. albicans* by 60 minutes and the phagocytosis analyzed by confocal laser scanning microscopy. Furthermore, intracellular oxide nitric production was measured used the DAF-FM diacetate and spectrophotometer. Our results showed that BMMC TLR2+ /+ phagocytose *C. albicans* but did not showed overproduction of the oxide nitric after stimulation with fungus, in relation with the basal production. However, in the absence of the TLR2, the oxide nitric production is increased, while the phagocytosis is reduced, in comparison with wild mouse. Therefore, we conclude that the *C. albicans* recognition by TLR2 results in the increased phagocytosis, but without oxide nitric stimulus. This can represent an escape way of the fungus of the defense mechanisms developed by mast cells via TLR2.

P1.02.18
Deciphering the molecular immunobiology of anaphylactic shock - and the de novo paradigm shift

P. N. Pushparaj[1], *L. A. Damiati*[2], *S. D. Kumar*[3], *J. Manikandan*[1], *M. H. Al-Qahtani*[1];
[1]*Center of Excellence in Genomic Medicine Research, King Abdulaziz University, Jeddah, Saudi Arabia,* [2]*Biology Department, King Abdulaziz University, Jeddah, Saudi Arabia,* [3]*Lee Kong Chian School of Medicine, Nanyang Technological University, Singapore, Singapore.*

Anaphylactic shock (AS) is a cardiovascular collapse caused by an acute, potentially lethal immune reaction primarily induced by the elevated immunoglobulin-E (IgE) antibodies that signal through the high affinity FcεRI receptor to release inflammatory mediators from immune cells such as mast cells. The AS is potently mediated through various intracellular signalling molecules such as Phospholipase Cγ (PLCγ), Phosphoinositide-3-Kinase (PI3K), Mitogen Activated Protein Kinases (MAPKs), Sphingosine Kinases (SPHKs), etc., These molecules induce calcium mobilization, nuclear factor kappa B (NFkB) activation, cytokine and eicosanoid secretion, and degranulation. These processes are essential for the initiation of peripheral vasodilatation, vascular permeability, leakage of plasma, and intravascular volume depletion eventually leading to cardiovascular collapse. various research groups around the globe has made a huge effort to better identify and understand the mechanisms responsible for the induction of anaphylaxis and AS to develop potential novel therapeutic modalities to effectively tackle sudden onset of AS. Much of this effort has been channelized toward the development and investigation of animal models since the development and availability of genetically modified mice have been very much economical and reliable to deduce the function of a gene in a particular molecular pathway necessary, either to enhance or attenuate the AS. In this poster presentation, we discuss various molecular immunological processes with an additional emphasis on the role of nitric oxide and a de novo paradigm shift in the immunobiology and molecular therapeutics of AS.

P1.02.19
Mast cell derived-histamine promotes the recruitment and immunoregulatory activity of myeloid derived suppressor cells

S. J. Saleem*, R. Martin, H. Zellner, G. Nguyen, L. Dean, D. Conrad; Virginia Commonwealth University, Richmond, VA, United States.*

Unresolved inflammation increases myelopoiesis, resulting in bone marrow release of a heterogeneous group of mononuclear (CD11b+Ly6Chigh) and polymorphonuclear (CD11b+Ly6Ghigh) cells, known as myeloid derived suppressor cells (MDSCs). We demonstrate that while each population of MDSCs deferentially regulates the immune response, both require mast cells (MCs). In the absence of MCs, MDSCs failed to promote B16 melanoma metastasis. This tumor-promoting property was limited to Ly6C+ MDSCs. In our parasitic model, mice infected with Nippostrogylus brasiliensis (Nb) and adoptively transferred (AT) with Ly6G+ MDSCs had enhanced parasite clearance. Upon AT, MDSCs preferentially migrated to the liver, which is the site of interaction with MCs, proliferation, and activation of MDSCs. This differential activity of Ly6C+ and Ly6G+ MDSCs as well as trafficking to the liver was abrogated in MC deficient mice. We next elucidated the contribution of MC-released histamine to this interaction. MDSCs expressed

histamine receptor 1 (HR1) and histamine enhanced MDSC survival and expansion. Additionally, histamine upregulated Arg1 and iNOS enzyme expression, both of which are utilized by MDSCs to inhibit T cell activity. To confirm this in our parasitic model, we utilized cetirizine, an HR1 antagonist. HR1 blockade decreased MDSC activity, migration to the liver, and parasite clearance. Lastly, we analyzed the mechanism by which histamine promotes MDSC activity. Our data thus far suggests that histamine induces Stat3 signaling in Ly6C+ MDSCs and Stat5 Ly6G+ MDSCs. Taken together, our studies indicate that in the absence of MCs as well as inhibition of histamine signaling, MDSCs are unable to exert their effects.

P1.02.20
The potential role of mast cells in the C-protein induced myositis model

K. Shin[1], *J. Choi*[2], *S. Jang*[2], *Y. Song*[2];
[1]*SMG-SNU Boramae Medical Center, Seoul, Republic of Korea,*
[2]*Seoul National University Hospital, Seoul, Republic of Korea.*

Background: Mast cells (MCs) function as immune sentinel cells in the tissue. The well-known cellular infiltrate in inflammatory myositis mainly consists of macrophages and lymphocytes that produce numerous inflammatory cytokines and chemokines augmenting inflammatory cell infiltration and damage of myofibers. The role of tissue-resident MCs has not been well studied in inflammatory myositis.
Objective: To study the phenotype and role of MCs in a murine myositis model.
Methods: C-protein induced myositis (CIM) was induced with human skeletal C-protein fragment in 8 week-old female MC-deficient SASH mice and C57BL/6 controls. Quadriceps muscles of both legs were harvested at day 21. Toluidine blue stain was used to identify degranulating MCs in the muscle tissue. Immunohistochemistry was performed to detect mouse mast cell protease (mMCP)-1, -4, -5, -6 positive MCs.
Results: MCs were mainly located in the connective tissue between fascicles showing a connective tissue MC phenotype. The density of MCs and percentage of degranulating MCs per 5 high power field (HPF) were increased in CIM tissues. MC deficient mice had lower histology score of muscle inflammation compared with controls. The difference mainly attributed to abrogated invasiveness of inflammatory infiltrates into fascicles in MC deficient mice.
Conclusion: Connective tissue-type MCs in skeletal muscles are activated upon CIM induction. MCs facilitate tissue invasion of inflammatory infiltrates into muscles in the CIM model.
AcknowledgementWe would like to thank Dr. Hitoshi Kohsaka for providing the C-protein construct and helpful discussions regarding this study. We also thank Dr. Michael Gurish for the antibodies.

IgE by itself affects, directly and indirectly, mast cell effector functions

A. Słodka*, E. Bąbolewska, P. Witczak, E. Brzezińska-Błaszczyk;*
Department of Experimental Immunology, Medical University of Łódź, Łódź, Poland.

Recent findings have implied that IgE by itself may modulate mast cell (MC) response, however detailed data are limited. Therefore, the aim of this study was to evaluate the influence of IgE alone on various aspects of mast cell biology. The study was conducted *in vitro* on mature rat peritoneal MCs. We examined effect of IgE alone on FcεRI expression (flow cytometry) and MC migratory response (Boyden microchamber assay). IgE-induced MC-derived mediator release, such as histamine (spectrofluorometric method), cysteinyl leukotrienes (cysLTs) and TNF (ELISA) was also assessed. We stated that IgE alone transiently up-regulated FcεRI expression. Spontaneous as well as TNF- and CCL5-induced migratory response of IgE-primed MCs was highly increased, as compared with native MC migration. Moreover, IgE alone triggered MCs to preformed mediator release, cysLTs generation and *de novo* TNF synthesis; in synergy with TLR2, but not TLR4 ligands, IgE was found to amplified cysLTs generation. Importantly, IgE was effective only at concentrations ≥ 3 μg/mL. Molecular basis investigation using an array of specific inhibitors showed that Src kinases, PLC/A2, MAP kinases (ERK and p38) and PI3 kinase were entirely or partially involved in IgE-induced MC response. In conclusion, we documented that IgE alone not only enhances surface FcεRI level and mediates/influences preformed and *de novo*-synthesized MC mediator release but also strongly affects MC migratory response. These observations may provide new insight into MCs activity in conditions where elevated IgE level is observed, including allergic diseases. This study was supported by the Medical University of Łódź (Grant 502-03/6-164-01/502-64-037).

Mast cells play a crucial role in non-IgE mediated experimental allergic enteropathy

M. Toda[1], *M. Burggraf*[1], *H. Nakajima-Adachi*[2], *S. Hachimura*[2], *D. Dombrowicz*[3], *J. Kirberg*[1], *H. Kiyono*[4], *G. Hermann-Josef*[5], *S. Vieths*[1];

Allergic enteropathy (AE) is a clinical phenotype of food allergies. Detailed pathomechanisms for AE are still not known. To investigate cellular and molecular mechanisms for AE, we established a murine model. BALB/c mice were sensitised with ovalbumin (a major egg white allergen) plus ALUM and fed egg-white diet (EW-diet). The mice developed acute inflammation in the jejunum accompanied by a strong induction of OVA-specific IgE antibodies by short-term feeding of the allergenic diet for 7 days, and presented chronic inflammation by further long-term feeding of the diet totally for 28 days. To assess the involvement of IgE antibodies in the jejunamal inflammation, we used mice deficient of FcεRI, the high affinity IgE receptor. In the FcεRI deficiency, acute inflammation was still induced by the short-term EW diet, while resolution of inflammation was observed after the long-term EW diet. Interestingly, high levels of mouse mast cell protease 1 (mMCP-1) were detected in the jejunum of both WT and FcεRI-deficient mice on the short-term EW diet. A treatment using an anti-c-kit monoclonal antibody to abolish mast cell function attenuated the induction of intestinal inflammation in WT and FcεRI-deficient mice. The results suggested that (i) mast cells play a crucial role in both IgE- and non-IgE mediated AE, and that (ii) IgE antibodies are involved in the induction of chronic AE. Our findings could contribute to establish a therapeutic strategy for AE.

P1.02.23
Mast cells support in vitro differentiation of Th17 cells

A. Walczak-Drzewiecka*, M. Ratajewski, J. Dastych;*
Institute of Medical Biology, Polish Academy of Sciences, Poland, Lodz, Poland.

Th17 differentiate from CD4+ naive cells following activation within specific cytokine milieu. Some of the cytokines are expressed by mast cells. It also known that T cells are capable to activate mast cells by cell to cell contact. Taking into consideration that in certain pathological conditions such as rheumatoid inflammatory immune response is characterized by activation of both Th17 and mast cells we decided to investigate interaction of mast cells and Th17 cells. Naïve CD4+ cells isolated from peripheral blood were cocultured with mast cell lines HMC-1 and LAD2. Cells were activated with anti-CD2;CD3;CD28 Ab in medium alone or in the presence of cytokines and production of cytokines was analyzed by ELISA. We observed that in the presence of mast cells activation of CD4+ lymphocytes with anti-CD2,CD3,CD28 Ab alone was sufficient to obtain in 5 days long culture significantly higher IL-17 production than that observed in cultures of CD4+ stimulated with Ab in the presence of cytokines. Presence of mast cells has also resulted in enhancement of IL-17 production in cultures stimulated with Ab and cytokine cocktail. Separation of mast cells from T cells by microporous membrane significantly decreased but not abolished the mast cell mediated

effect on IL-17. In conclusion mast cells support differentiation of CD4+ cells toward IL-17 producing Th17 cells in a process that in part requires direct cell to cell contact. Activation of Th17 cells in the presence of mast cells may generate different pattern of cytokine production than activation of each these cell types separately.

P1.02.24
Maturation of mast cells by Wnt family proteins

T. Yamaguchi[1], *K. Tashiro*[1], *H. Mizuguchi*[1,2], *K. Kawabata*[1,2];
[1]*National Institute of Biomedical Innovation, Osaka, Japan,* [2]*Graduate School of Pharmaceutical Sciences, Osaka University, Osaka, Japan.*

Mast cells play an important role in the pathogenesis of allergic diseases. Immature mast cells migrate into peripheral tissues from the bone marrow and undergo complete maturation in the peripheral tissues. The tissue microenvironment affects the process of the maturation of mast cells. However, maturation mechanism of mast cells is poorly understood. Previous studies showed that co-culture of bone marrow-derived mast cells (BMMCs) with feeder cells, such as Swiss 3T3 fibroblasts and OP9 cells, in the presence of stem cell factor facilitated morphological and functional maturation toward a connective tissue-type mast cells (CTMCs)-like phenotype. To investigate whether maturation of mast cells requires physical contact between mast cells and feeder cells, BMMCs were co-cultured with feeder cells in the Transwell apparatus. Our results indicated that both soluble factors and cell-adhesion molecules, which are derived from feeder cells, might play an important role in mast cell maturation. Quantitative RT-PCR analysis revealed that several Wnt genes expressed in both Swiss 3T3 fibroblasts and OP9 cells. To determine whether Wnt signal play a role in the maturation of mast cells, we compared the degree of mast cell maturation of the BMMCs that were treated with or without Wnt protein. The expression levels of CD81 protein and histidine decarboxylase (HDC) mRNA, and activity of mast cell-specific protease, were elevated in BMMCs treated with Wnt protein. These results suggest that Wnt signals can promote the maturation of BMMCs into CTMCs. This study provides important insights into molecular mechanisms of the maturation of mast cells.

P1.03 NK cells and NK receptors

P1.03.01
Sp1 transcription factor is involved in the regulation of NKG2D ligands in tumor cells and during tumor Progression

A. Acebes Huerta[1], *L. Huergo Zapico*[2], *A. Lopez Soto*[2], *A. Fernandez Guizán*[2], *M. Villa Álvarez*[2], *S. González Rodríguez*[1];
[1]*Instituto Universitario de Oncología del Principado de Asturias, Gijón, Spain,* [2]*Instituto Universitario de Oncología del Principado de Asturias, Oviedo, Spain.*

MICA/B and ULBPs are tumor-induced ligands for NKG2D, an activating receptor expressed by NK and T cells, which is crucially involved in the recognition and elimination of cancer cells. MICA and ULBP1 are overexpressed in tumor cells; however the mechanisms involved in their expressions are poorly defined. Herein we study the regulation of NKG2D ligands expression in tumor cells and during tumor progression. We characterized that Sp1 and Sp3 transcription factors are the main regulators of NKG2D ligands expression in tumor cells. The induction of tumor progression by TGF-β stimulation, by GSK-3β inhibition and by Snail1 over-expression in several tumor cell lines was associated with strong up-regulation of MICA/B and ULBP1-3 expressions. Transcriptional studies showed that the overexpression of Snail and the inhibition of GSK-3B increased Sp1 transcription factor activity. Moreover, pharmacological and RNA interference experiments demonstrated that the induction of NKG2D ligands expression during tumor progression was dependent on the induction of Sp1 transcription factor activity. Accordingly with an increase of NKG2D ligands expression in tumors cells, these cancer cells were more susceptible to NKG2D-mediated killing by NK cells. In conclusion, our experiments demonstrate that Sp1 is the main regulator of NKG2D ligands expression in cancer cells. We also show that tumor progression activates NKG2D-dependent immune response against carcinoma cells and this induction of NKG2D-mediated response was mainly mediated by the increase of Sp1 transcription factor activity in the tumor cells.

P1.03.02
A novel immunological approach to prevent HCV recurrence in liver transplantation

E. Badami, *P. Pizzillo, D. Galvagno, M. Spada, B. Gridelli, P. Conaldi;*
Mediterranean Institute for transplantation and Advanced Specialized Therapies - ISMETT, Palermo, Italy.

HCV chronic infection accounts for over 180 million of patients worldwide and represents the leading indication for liver transplantation. HCV liver reinfection universally occurs upon transplantation driven by the remnant virus still circulating in the peripheral blood and sustained by the immunosuppressive regimen associated to the anti-rejection therapy. Following an initial dramatic decrease, HCV-RNA viremia rapidly increases early after transplantation, peaking already at day 3-4 post-operation.
In the acute phase of infection NK cells strongly respond to HCV by killing infected hepatocytes in a cell-cell contact manner or via release of soluble factors such as IFN-gamma. However, HCV escapes innate immunity and establishes chronic infection by inhibiting/outnumbering NK cells. Here we describe an innovative immunological approach for the prevention of HCV recurrence based on the infusion of activated NK cells in recipients promptly after liver transplant. High doses of NK cells will be injected in recipients within the first 16-48 hours post transplant to exploit the viremia reduction that follows the anhepatic phase. Patients will receive multiple infusions of NK cells to outnumber HCV virions before its rapid expansion. NK cells will be manipulated in vitro to preferentially direct towards the expression of IFN-gamma. Homing to the liver IFN-gamma+ NK cells should clear HCV infection without being aggressive on target cells. IFN-gamma+ NK cells might represent an appealing tool to cleanse HCV infection without destroying liver tissue suggesting a role for this cells as efficient therapeutic to adjuvant liver transplantation to prevent HCV relapse.

P1.03.03
CD56+ cells in demyelinating polyneuropathies

I. P. Balmasova[1,2], *O. L. Timchenko*[1], *R. I. Sepiashvili*[2], *N. D. Yushchuk*[1];
[1]*Moscow State University of Medicine and Dentistry named after A.I.Evdokimov, Moscow, Russian Federation,* [2]*2Peoples' Frendship University of Russia, Moscow, Russia, Moscow, Russian Federation.*

Acquired autoimmune demyelinating polyneuropathies include Guillain-Barré Syndrome (GBS) and Chronic Inflammatory Demyelinating Polyneuropathy (CIDP), which differ in the etiology (GBS usually develops as a complication of infectious processes, immunopathogenesis, course duration, methods of treatment and therefore call for differential diagnosis. Were observed 68 patients with demyelinating polyneuropathies by flow cytometry who were divided into two groups: 42 GBS patients and 26 - with CIDP. Expression of cell-surface markers such as CD3+/CD56+/CD4+, CD3+/CD56+/CD8+, CD3+/CD56+/DN, CD3-/CD16-/CD56+, CD16+/CD56+/CD158a,h+, CD16+/CD56+/CD94+, CD16+/CD56+/NKG2D+, CD16+/CD56+/NKp46+ were assessed by multiparametric FACS. It was found that in GBS unlike in the CIDP the fall of NKT number was not present but reliably reduced the NK cell number. In all patients CD4+ NKT increased 10 and more times, subpopulation CD8+ NKT significantly decreased. The changes in NK cell in GBS patients were accompanied by a decline in their expression of KIR (CD158a,h), NKG2D, NKp46. The fall of natural cytotoxicity of receptor content (NKp46) in 1,8 fold on NK membrane is observed only in GBS while negative shift in receptor expression of antibody dependent cytotoxicity is observed in all manifestations of demyelinating polyneuropathies. It is expected that the observed immunopathogenetic features with NKT and NK cells participation can help in differentiation of GBS from CIDP.

P1.03.04
Assessment of natural killer receptors and activity in severe and moderate Chronic Fatigue Syndrome

*S. L. Hardcastle[1], **E. W. Brenu**[1], D. Staines[2], S. Marshall-Gradisnik[1]; [1]National Centre for Neuroimmunology and Emerging Diseases, Griffith Health Institute, Griffith University, Gold Coast, Australia, [2]Queensland Health, Gold Coast Public Health Unit, Gold Coast, Australia.*

Abnormalities in the immune system are a common finding within sufferers of Chronic Fatigue Syndrome (CFS). Research has consistently found compromised Natural Killer (NK) cell function in CFS subjects. The mechanism of the reduced NK function is unknown and however this may potentially be related to the presence of NK receptors. It is also unknown whether reduced NK function is further compromised within CFS subjects who are very severely affected by the disease. The purpose of this study was to examine NK activity and Killer Immunoglobulin-like Receptors (KIRs) in moderate (MFS) and severely affected CFS (SFS) subjects in comparison to controls. CFS subjects were characterised as either moderate or severely affected based on health and quality of life questionnaires. Severe subjects were housebound. Blood samples were collected s from controls (n=9; 50.9 $\pm$ 2.5 years), MFS (n=9; 49.9$\pm$ 3.7years) and SFS subjects (n=9; 42.3 $\pm$ 3.9 years). Using flow cytometry NK cells were measured for their activity based on their ability to lyse K562 cells and cell surface expression of KIRs. ANOVA was the statistical method used to assess all data collected. Preliminary data from CFS subjects showed significant reductions NK cell activity and an increase in KIR3DL1 in CFS subjects when compared to the controls. Results suggest that CFS patients have further compromised immune function, particularly reduced NK cell activity, when compared to controls. Additionally, increased levels of KIR, particularly KIR3DL1 in CFS patients, may potentially explain why these patients have a decrease in NK lysis.

P1.03.05
Host response to murine CMV in class I MHC disparate mice reveals primacy of licensed NK cells in viral control

***M. G. Brown**, J. Prince, A. Lundgren, M. D. Stadnisky, S. D. Turner, W. T. Nash, A. Beeber;*
University of Virginia, Charlottesville, VA, United States.

Murine cytomegalovirus (MCMV) resistance in MA/My mice requires the class I MHC Dk molecule and inhibitory receptor Ly49G2+ NK cells. In MCMV-sensitive C57L mice without Dk, Ly49G2+ NK cells fail to deliver viral control. Expression of a Dk genomic transgene in C57L fully reverses MCMV-sensitivity. As a cognate ligand of Ly49G2, Dk licenses the NK subset for effector activity. Together the data suggest that Ly49G2+ NK cells restrain MCMV infection. However, the role of licensed NK cells in viral control is poorly defined. Hence, we combined classical genetics with flow cytometry to interrogate the NK cell response to MCMV infection in a diverse cohort of 200+ MA/My x C57L hybrid mice disparate for Dk. To identify NK cell features essential to viral control, we performed trait comparisons in R using Pearson's correlation test followed with a Bonferroni correction for multiple tests, hierarchical clustering and principal component analysis. The data show that Ly49G2 receptor display on naïve blood NK cells significantly predicted low viral burden. More remarkable, the frequency of licensed Ly49G2+ NK cells rapidly and selectively expanded in infected Dk mice and therefore represented the best possible index (of 109 traits examined) of viral control. From the data, we infer that licensed Ly49G2+ NK cells efficiently detected missing-self MHC cues on virus-infected targets, which elicited NK subset expansion and target cell killing. MHC polymorphism therefore regulates NK licensing and the early detection of viral targets by defined NK subsets, which ultimately determines their capacity to deliver innate viral control.

P1.03.06
ADAM10 contributes to MICA/B shedding from multiple myeloma cells in response to genotoxic stress

***F. Cecere**, A. Zingoni, R. Molfetta, A. Soriani, C. Fionda, M. T. Petrucci, M. R. Ricciardi, R. Paolini, M. Cippitelli, A. Santoni;*
University, Rome, Italy.

The MHC class I-related chain MICA/B ligands for the activating receptor NKG2D can be shed from tumor cells and their presence in sera is associated with impaired NK and CTL effector functions and disease progression. We showed that multiple myeloma (MM) cells up-regulate surface expression of NKG2D ligands after treatment with low doses of chemotherapeutic drugs and become more susceptible to NK cell lysis. Here, we investigated whether drug treatment of MM cells could result in MICA/B release. Soluble MICB was up-regulated after drug treatment and the ADAM10 specific inhibitor GI254023X dramatically reduced MICB shedding in a dose-dependent manner and was accompanied by a concomitant increase of cell-surface MICB. Similar results were obtained by shRNA-mediated gene silencing. Remarkably, chemotherapeutic agents increased ADAM10 expression either in MM cell lines or in *ex-vivo* malignant $CD138^+/CD38^+$ plasma cells. Regarding MICA, since its polymorphism can affect the shedding process, we investigated the effect of chemotherapeutic agents on the release of two allelic variants of MICA: MICA*019 and MICA*008 which represent the prototype of the long and short form of the MICA alleles, respectively. Similarly to MICB, drug treatment stimulated MICA*019 shedding with an ADAM10 dependent mechanism while didn't affect MICA*008 release. Our findings indicate that chemotherapeutic drugs not only enhance MICA/B surface expression on MM cells, but also promote their shedding. The MICA genotype and the relative contribution of membrane associated vs soluble MICA/B in NKG2D dependent mechanisms of NK cell recognition of MM cells, should be considered to design NK cell-based immunochemotherapeutic approaches.

P1.03.07
Sustained effector function of IL-12/15/18-preactivated NK cells against established tumors

*J. Ni, **M. Miller**, A. Cerwenka;*
DKFZ, Heidelberg, Germany.

Natural killer cell (NK cell)-based immunotherapy of cancer is hampered by the transient effector function of NK cells. Recently, mouse IL-12/15/18-preactivated NK cells were shown to persist with sustained effector function in vivo. Our study investigated the antitumor activity of such NK cells. A single injection of syngeneic IL-12/15/18-preactivated NK cells, but neither naive nor IL-15- or IL-2-pretreated NK cells, combined with irradiation substantially reduced growth of established mouse tumors. Radiation therapy (RT) was essential for the antitumor activity of transferred NK cells. IL-12/15/18-preactivated NK cells expressed high levels of IL-2Ralpha (CD25), and their rapid in vivo proliferation depended on IL-2 produced by CD4+ T cells. IL-12/15/18-preactivated NK cells accumulated in the tumor tissue and persisted at high cell numbers with potent effector function that required the presence of CD4+ T cells. Human IL-12/15/18-preactivated NK cells also displayed sustained effector function in vitro. Further results on human cytokine activated NK cells will be presented and responsible mechanisms will be discussed. Our study provides a better understanding for the rational design of immunotherapies of cancer that incorporate NK cells. Moreover, our results reveal an essential role of CD4+ T cell help for sustained antitumor activity by NK cells linking adaptive and innate immunity.

P1.03.08

N6-isopentenyladenosine, an endogenous isoprenoid end product, directly affects cytotoxic and regulatory functions of human NK cells through FDPS modulation

E. Ciaglia[1]*, S. Pisanti*[1]*, P. Picardi*[1]*, C. Laezza*[2]*, A. Malfitano*[1]*, A. D'Alessando*[1]*, P. Gazzerro*[1]*, E. Carbone*[3]*, M. Bifulco*[4]*;*
[1]University of Salerno, Department of Pharmaceutical and Biomedical Sciences, Fisciano, Italy, [2]Institute of Endocrinology and Experimental Oncology, IEOS CNR, Naples, Italy, [3]Tumor Immunology Laboratory, Department of Experimental and Clinical Medicine, University of Catanzaro "Magna Graecia", Catanzaro, Italy, [4]Department of Medicine and Surgery, University of Salerno, Baronissi, Italy.

N6-isopentenyladenosine (iPA) is a naturally occurring nucleoside with an isopentenyl moiety derived from mevalonate pathway, and well established anti-tumor activity. In analogy to the unique specificity for phosphoantigens like isopentenyl pyrophosphate (IPP), shown by human Vγ9Vδ2 T cells, here we report for the first time the ability of iPA to selectively expand and directly target human natural killer (NK) cells. Interestingly, submicromolar doses of iPA stimulate resting human NK cells and synergize with IL-2 to induce a their robust activation ex vivo with significant secretion of RANTES and MIP-1α and a large increase in TNF-α and IFN-γ production when compared with IL-2 single cytokine treatment. Moreover iPA promotes NK cell proliferation, upregulates the expression of NK cell activating receptor NKp30, as well as CD69 and CD107a expression. Accordingly this phenotype correlates with significant greater cytotoxicity against tumor targets. At the molecular level, iPA leads to a selective potent activation of MAPK signaling intermediaries downstream IL-2 receptor. The effect results at least in part from the fine modulation of the farnesyl diphosphate synthase (FDPS) activity, the same enzyme implicated in the stimulation of the human γδ T cells. The iPA-driven modulation of FDPS, can cause an enhancement of post-translational prenylation essential for the biological activity of key proteins in NK signaling and effector functions, such as Ras. These unanticipated properties of iPA provide additional piece of evidence of the immunoregulatory role of the intermediates of the mevalonate pathway and open novel therapeutic perspectives for this molecule as an immune modulatory drug.

P1.03.09

NK cells in dasatinib-treated chronic myeloid leukemia patients are terminally differentiated effector cells lacking homing and KIR receptors

B. Colom-Fernandez[1]*, A. Kreutzman*[1]*, B. Maestro Gutiérrez*[2]*, V. López Huete*[1]*, V. García-Gutiérrez*[3]*, J. Steegmann*[4]*, C. Muñoz Calleja*[1]*;*
[1]Instituto de Investigación Sanitaria Princesa, Servicio de Inmunología, Hospital Universitario de la Princesa, Madrid, Spain, [2]Unidad de Ensayos Clínicos, Hospital Universitario de La Princesa, Hospital Universitario de la Princesa, Madrid, Spain, [3]Servicio de Hematología, Hospital Universitario Ramón y Cajal, Spain, [4]Instituto de Investigación Sanitaria Princesa, Servicio de Hematología, Hospital Universitario de la Princesa, Madrid, Spain.

Dasatinib is a BCR-ABL1 inhibitor with important immunomodulatory effects, including mobilization of NK cells in the peripheral blood. Our aim was to analyze whether the dasatinib-induced mobilization correlates with a characteristic trafficking and differentiation phenotype in NK cells.
Peripheral blood samples were obtained from 9 healthy donors and 14 dasatinib-treated CML patients before their daily drug dose and phenotyped with a comprehensive flow cytometry panel. The patients had been using dasatinib for 1-60 months (mean 17).
Dasatinib-treated CML patients have equal proportions of NK cells (CD3negCD56+) of total lymphocytes as healthy (mean 19.5 vs. 11.1%; p=0.51). NK cells from patients expressed lower proportions of the trafficking receptors CCR7 (6 vs. 30%; p=0.007), CD62L (25.6 vs. 50.4%; p=0.037), and CD11b (23.9 vs. 79.5%; p=0.0002). Further, a lower frequency of the activation and proliferation markers CD27 (5.1 vs. 19.5; p=0.009), CD28 (0.4 vs. 3.3; p=0.001), and CD45RO (1.7% vs. 6.2%; p=0.030) were observed in the patients. Also, the patients had a lower frequency of NK cell receptors; NKp30 (33.4 vs. 75.7%; p=0.003), CD158i (9.1% vs. 32.9%; p=0.023), CD158d (1.1% vs. 10.9%; 0.007), NKG2D (67.8% vs. 87.4%; p=0.013), NKG2A (19.4% vs. 42.7%; p=0.023), NKB1 (6.3 vs. 18.4%; p=0.005) and CD161 (29.2 vs. 68.9%; p=0.002). Conversely, the frequency of CD57+ (61.6 vs. 35.3; p=0.018) NK cells was higher in patients than in healthy donors.
In summary, NK cells in dasatinib-treated patients are similar to chronically activated NK cells, characterized by terminally differentiated effector cells lacking homing and KIR receptors.

P1.03.10

Induction of functional NK receptors on peripheral blood CD8+ T cells

M. Correia*, M. Miller, A. Stojanovic, A. Cerwenka;*
DKFZ - German Cancer Reaseach Center, Heidelberg, Germany.

It has been shown for some time that a small subset of CD8+ T cells can express NK receptors (NKR) under specific conditions. However, the signals that might lead to that acquisition, the expression pattern and the role of NK activating receptors in T cells is a barely explored field in tumor immunology. We showed that IL-15 could induce or up-regulate certain activating receptors on peripheral blood CD8+ T cells, after long-term culture. Importantly, besides the acquisition of an NK-like phenotype, we found those receptors to be functional, namely leading to significantly increased levels of degranulation and IFN-gamma production after triggering. Those results suggest IL-15 as a signal capable of driving CD8+ T cells into a differentiation program towards the acquisition of functional NK receptors. Therefore, by potentially displaying dual innate and adaptive immune functions, CD8+ NKR+ T cells appear as promising for immunotherapy strategies against cancer.

P1.03.11

Receptors of NK cells and lymphocytes subsets in patients stage II and III breast cancer

L. J. Najar Acosta[1]*, A. Daneri Navarro*[1]*, G. Ramirez Rosales*[1]*, R. A. Franco Topete*[2]*, A. Oceguera Villanueva*[3]*, J. M. Castro Cervantes*[4]*, E. Salas Gonzalez*[5]*, J. C. Canton Romero*[5]*, A. Quintero Ramos*[1]***, A. del Toro Arreola***[1]*;*
[1]Centro Universitario de Ciencias de la Salud, U de G, Guadalajara, Mexico, [2]Hospital Civil de Guadalajara, Dr. Juan I. Menchaca, Guadalajara, Mexico, [3]Instituto Jalisciense de Cancerologia, Guadalajara, Mexico, [4]Hospital de Especialidades. CMNO, IMSS, Guadalajara, Mexico, [5]Hospital de Gineco-Obstetricia, UMAE, IMSS, Guadalajara, Mexico.

BACKGROUND. Breast Cancer is a global health problem. It is the most frequently diagnosed cancer in women, accounting for approximately 30% of all cancer diagnosed and about 16% of all cancer deaths. Breast cancer is a heterogeneous disease with a wide range of clinical presentations. NK cells are important during immunity response in cancer. There are different molecular and genetic factors; however, it remains to be elucidated whether immunological factors could be intervening in the clinical stage.
OBJECTIVE. Evaluate NK cell activating receptors and peripheral T and B cell percentage in patients stage II and III breast cancer.
METHODS. Breast cancer biopsies and peripheral whole blood were taken from all participants with prior written informed consent. Participants with breast cancer stage II and III histologically confirmed were enrolled in the study. NKp30, NKp46 and NKG2D receptors were measured by flow cytometry gating peripheral CD56+ cell population. Lymphocyte subsets were identified by stain of CD3+CD4+, CD3+CD8+, and CD19+ markers and were represented as positive cell percentage.
RESULTS. Fluorescence median intensity of NK cell activating receptors did not show any stastical diference in both groups. However, we observed that NKp46 tended to decrease.
CONCLUSIONS. Our preliminar results revealed a tendency to decrease in NKp46. To evaluate with more confidence the role of these receptors and cells it will be necessary to increase the patient in the study to demonstrate whether NK cell activating receptors could actually represent an useful immunological factor in breast cancer.

P1.03.12
An approach to the immunophenotypic signature of selected CD4+NKG2D+ T cell subsets

*M. Garcia-Chagollan[1], M. Bueno-Topete[1], L. Jave-Suarez[2], S. Fujimura-Hernandez[1], A. Cid-Arregui[3], A. Aguilar-Lemarroy[2], **S. del Toro-Arreola**[1];*
[1]Laboratorio de Inmunología, Departamento de Fisiología, CUCS, Universidad de Guadalajara, Guadalajara, Mexico, [2]División de Inmunología, Centro de Investigación Biomédica de Occidente, Instituto Mexicano del Seguro Social, Guadalajara, Mexico, [3]Translational Immunology Department, German Cancer Research Center (DKFZ), Heidelberg, Germany.

Background. Why do some CD4+ T cells exhibit cytotoxic behavior? This has been an important question resolved, in part, by the fact that these cells express the activating immunoreceptor NKG2D, which has traditionally been restricted to NK and CD8+ T cells. Contradictory evidence has tagged, however, this particular population with an immuno-suppressive role in cancer patients. These apparently confounding data have led to the proposal that two different CD4+NKG2D+ T cell subsets might be operating. Currently, there is still a poor immunophenotype description of these cells. Objective. To better characterize the phenotype expressed by the CD4+NKG2D+ T cell subset in healthy volunteers. Methods. Multicolor flow cytometry was used for exploration of TCRalpha/beta, CD28, CD158b, CD45RO, HLA-DR, CD161, and CD107a on gated CD3+CD4+NKG2D+ T cells. ELISA was used to quantify TNF-alpha, IL-15, IL-10 and IFN-gamma. Results. The gated CD3+CD4+NKG2D+ T cell subset effectively defines a “classical” population of TCRalpha/beta-expressing CD4+ T cells in healthy individuals (n=30), which is not higher than 3% of the total CD3+CD4+ T population. The expression of CD45RO suggests a memory and/or activated state. The activating markers HLA-DR, CD161, and CD107a were heterogeneously expressed. The costimulatory receptor CD28 was also expressed on this subset. Interestingly, five individuals showed an increased number of CD3+CD4+NKG2D+ T cells, which were mostly negative for both CD28 and activating markers. Conclusions. The present results reveal the existence of two separate CD4+NKG2D+ T cell subsets defined by the coexpression or absence of CD28, which might indicate a functional dichotomy within this particular subset.

P1.03.13
HMPV infection, immune evasion and its elimination

***M. Diab**, A. Vitenshtein, O. Mandelboim;*
Hebrew University, Jerusalem, Israel.

Human Metapneumovirus (HMPV) has become one of the main viral pathogens responsible for acute respiratory tract infections in children but also in the elderly and immuno-compromised patients. The pathogen most closely related to HMPV is human respiratory syncytial virus (HRSV), the most common cause of bronchiolitis and pneumonia in young children. HMPV has been classified into two main viral groups A and B and has a seasonal distribution in temperate countries with most cases occurring in winter and spring. Previous works showed that HMPV induces strong innate immune response in BALB/c mice as compared with RSV. In our study, we interested to test the HMPV reactivity to Natural Killer cells. As a start of this work we detected that HMPV infects A549 cells. Following this infection, cell-surface expression of CEACAM1 was detected 48 hours post infection. Our results also show an increase in MHC-Class I levels in the infected cells. Unlike previous results that show an increase of the inhibitory ligands, we also observed an increase of the activating NK receptor-(NCR1) ligands. Our finding raise a question what is the mechanism by which two opposite ligands are activated?.

P1.03.14
Neuroblastoma-derived transforming growth factor (TGF) β1 modulates the chemokine receptor repertoire of human resting Natural Killer Cells.

***A. Dondero**[1], F. Bellora[1], L. Moretta[2,3], A. Castellano[4], F. Locatelli[4], M. V. Corrias[2], A. Moretta[1,3], C. Bottino[1,2], R. Castriconi[1,3];*
[1]Dipartimento di Medicina Sperimentale, Università degli Studi di Genova, Italy, [2]Istituto Giannina Gaslini, Genova, Italy, [3]Centro di Eccellenza per le Ricerche Biomediche, Università degli Studi di Genova, Italy, [4]Dipartimento di Onco-Ematologia Pediatrica, Ospedale Bambino Gesù, Roma e Università di Pavia, Italy.

In this study we showed that chemokine receptor repertoire of human resting Natural Killer (NK) cells is altered by neuroblastoma (NB) cell conditioning. In particular, NB-conditioning resulted in the upregulation of CXCR4 and CXCR3 in all NK cells and in down-regulation of CX_3CR1 in the $CD56^{dim}$ subset. The expression of other chemokine receptors such as CXCR1 and CCR7 remained unaltered. NB-conditioned medium was analyzed for the presence of up to 50 soluble mediators using a Multiplex Assay. This analysis proposed a number of NB-derived soluble factors being possibly involved in the modulation of CXCR4, CXCR3 and CX_3CR1 in NK cells. Ab-mediated blocking of these factors in NB/NK cell cocultures revealed that the modulatory effect was dependent on TGFβ1. Moreover rTGFβ1 (and rTGFβ2) induced a chemokine receptor repertoire identical to that of neuroblastoma-conditioned NK cells. The TGFβ1 appears to work in a dose-dependent way since low-intermediate amounts of the cytokine were sufficient to modulate CXCR4, CX_3CR1 and CXCR3 expression while high amounts were necessary to down-regulate the expression of the NKp30 activating receptor. Finally, the analysis of NK cells from patients with stage 4 NB suggests that neuroblastoma conditioning could exert, *in vivo*, an immune modulatory similar to that emerged from *in vitro* experiments. Altogether our data propose a novel tumor escape-mechanism based on the modulation of chemokine receptors that play pivotal roles in NK cells bone marrow homing, egress or recruitment into peripheral tissues.

P1.03.15
Related Human Cytomegalovirus Genes US18 and US20 Target MICA for Lysosomal Degradation

***C. A. Fielding**[1], V. Prodhomme[1], R. Aicheler[1], S. Seirafian[2], J. Davies[1], R. Stanton[1], A. Davison[1], P. Lehner[1], P. Tomasec[1], G. Wilkinson[1];*
[1]Cardiff University, Cardiff, United Kingdom, [2]Cambridge University, Cambridge, United Kingdom.

NK cells play a crucial role in controlling human cytomegalovirus (HCMV) infection. The activating receptor NKG2D is expressed by all NK cells and binds 8 different ligands: MICA and MICB, and ULBP 1-6. In its turn, HCMV is known to encode at least 3 genes that target NKG2D ligands (i) UL16 sequesters MICB, ULBP1, 2, 4 and 6 in the ER (ii) UL142 retains MICA in the Golgi and (iii) the microRNA miR-UL112 suppresses MICB expression . Our studies using viral deletion mutants revealed that HCMV encoded functions, in addition to UL142, that targeted MICA. MICA expression during virus infection could be rescued by by lysosomal inhibitors. The function was first mapped to the US18-22 gene region by screening HCMV mutants with deletions in genomic ‘blocks’, and then to both US18 and US20 using a panel of Ad recombinants. The two genes were capable of acting independently, yet in combination clearly co-operated in both the suppression of MICA expression and NK cell activation. US18 and US20 are both members of the US12 gene family. All 12 members of the US12 family are arranged consecutively on the genome and constitute an ancient viral genomic expansion or ‘accordion’ potentially selected to enhance HCMV immune evasion. This gene family is defined by 7 transmembrane-spanning domains and have homology with the cellular TMBIMs (transmembrane bax-inhibitor 1 motif-containing proteins), excepting US19. This study provides the first insight into the function of the US12 gene family and potentially for its expansion in primate cytomegaloviruses.

P1.03.16
Abundant stage-dependent Ly49E expression by liver NK cells is not essential for their differentiation and function

***J. Filtjens**, S. Taveirne, A. Van Acker, E. Van Ammel, M. Van Hees, T. Kerre, T. Taghon, B. Vandekerckhove, J. Plum, G. Leclercq;*
Ghent University, Ghent, Belgium.

The NK receptor Ly49E has several unique characteristics. Unlike most NK receptors, Ly49E is highly expressed on fetal NK cells, whereas expression is decreased on bone marrow-derived NK cells in adult mice. To investigate a possible role for Ly49E in NK cell differentiation and function, we have generated an Ly49E KO mouse. Our results show that bone marrow and splenic NK cells are present in normal numbers in Ly49E KO mice, expressing an unaltered panel of NK receptors and differentiation markers. Furthermore, cytokine production and cytotoxicity by these cells is unaffected. Surprisingly, WT DX5-negative liver NK cells express high Ly49E levels, and this both in fetal and adult mice. $Ly49E^{+}DX5^{-}$ liver NK cells transferred into *Rag-2*$^{-/-}$*/gc*$^{-/-}$ mice maintain high Ly49E expression in the liver and differentiate into $DX5^{+}$ NK cells in spleen and bone marrow. Ly49E expression is not crucial for liver NK cell differentiation during ontogeny, as the $DX5^{-}/DX5^{+}$ ratio, the NK receptor repertoire, and the granzyme B and TRAIL levels are comparable in Ly49E KO versus WT mice, except for lower TRAIL expression on $DX5^{-}$ liver NK cells in 20-day-old mice. The TRAIL-, perforin- and FasL-mediated cytolysis by liver NK cells is unaffected in Ly49E KO mice. Collectively, we show that in addition to high Ly49E expression on fetal NK cells versus low Ly49E expression on conventional NK cells in adult life, Ly49E remains highly expressed on DX5-negative liver NK cells. However, Ly49E expression does not have a crucial role in differentiation and/or function of these NK cells.

P1.03.17
Inhibition of Glycogen Synthase Kinase-3 increases NKG2D Ligand MICA expression and sensitivity to NK cell-mediated cytotoxicity in Multiple Myeloma cells: role of STAT3.

***C. Fionda**, G. Malgarini, A. Soriani, A. Zingoni, F. Cecere, M. Iannitto, M. Ricciardi, M. Petrucci, A. Santoni, M. Cippitelli;*
SAPIENZA University of Rome, ROME, Italy.

Engagement of NKG2D and DNAM-1 receptors with their ligands on lymphocytes plays an important role for anticancer response and represents an interesting therapeutic target for pharmacological modulation. In this study, we investigated the effect of inhibitors targeting the Glycogen Synthase Kinase-3 (GSK3) on the expression of NKG2D and DNAM-1 ligands in human MM (Multiple Myeloma) cells. GSK3 is a serine-threonine kinase point of convergence of numerous cell-signaling pathways, able to regulate the proliferation and survival of cancer cells, including MM. We found that inhibition of GSK3 is able to up-regulate MICA protein surface, mRNA expression and promoter activity in MM cells without significant effects on the expression of MICB and DNAM-1 ligand PVR/CD155. Moreover, exposure to GSK-3 inhibitors renders myeloma cells more efficient to activate NK cell degranulation and trigger NK cell-mediated cytotoxicity. We could exclude that two transcription factors specifically inhibited by active GSK3, β-catenin or Heat Shock Factor-1 (HSF-1), are involved in the up-regulation of MICA expression by using RNA-interference or viral transduction of constitutive active forms. On the contrary, inhibition of GSK3 correlated with a significant downregulation of STAT3 activation, a negative regulator of MICA transcription. Both Tyr^{705} phosphorylation and in vivo binding of STAT3 on MICA promoter are reduced by drugs targeting GSK3; in addition, overexpression of a constitutively active form of STAT3 significantly inhibits MICA upregulation. Thus, we provide evidence that regulation of the NKG2D-ligand MICA expression may represent an additional mechanism supporting the anti-myeloma activity of GSK3 inhibitors, and suggest their possible immunotherapeutic value.

P1.03.18
Do NK cells play a role in the possible association between natalizumab treatment and the development of melanoma?

***I. Gandoglia**[1], A. Laroni[1], P. Carrega[2], G. L. Mancardi[3], G. Ferlazzo[4], A. Uccelli[1];*
[1]Neuroimmunology Unit, DINOGMI, University of Genoa, Genoa, Italy, [2]Laboratory of Clinical and Experimental Immunology, Istituto Giannina Gaslini, Genoa, Italy, [3]DINOGMI, University of Genoa, Genoa, Italy, [4]Laboratory of Immunology and Biotherapy, Department of Human Pathology, University of Messina, Messina, Italy.

Natalizumab (NTZ) is an anti-alfa4integrin (CD49d) antibody approved for treatment of multiple sclerosis (MS). A possible association between NTZ treatment and higher risk of melanoma is under debate. As NK cells (NK), which contribute to controlling melanoma development, express CD49d, we assessed if NK-mediated killing of melanoma cells and melanoma-driven NK migration are impaired upon exposure to NTZ. CD49d and its receptor, CD106, were similarly expressed on NK freshly isolated or in-vitro expanded (bulk NK) from healthy donors (HD). Their expression did not differ between HD and untreated MS patients; both were also expressed on melanoma cells. Upon exposure to NTZ, CD49d expression on bulk HD NK decreased, but NK cytotoxic activity towards melanoma, measured by degranulation (staining for CD107a), was not affected, either when NTZ was added to bulk NK/melanoma co-cultures or when bulk NK were pre-exposed to NTZ for 12 hours. Bulk NK generated from NTZ-treated MS patients retained the decrease on CD49d expression observed before in-vitro expansion. Preliminary data on bulk NK generated from MS patients before and after treatment indicate that NTZ treatment did not affect the cytotoxic activity of NK from these patients towards melanoma, suggesting that the possible increase in melanoma incidence in NTZ-treated MS patients might not be related to impairment of NK cytotoxic activity towards melanoma. Consequently, we are investigating the possibility that NTZ treatment might impair the ability of NK to migrate towards melanoma and are developing an endothelial barrier model to evaluate the effect of NTZ on melanoma-driven NK migration.

P1.03.19
Elucidating the role of the natural killer cell receptor, Ncr1, in controlling melanoma metastases using in vivo reflectance confocal microscopy

***A. Glasner**, A. Levi, J. Enk, T. Neuman, C. D. Enk, O. Mandelboim;*
Hebrew University, Jerusalem, Israel.

Background: Natural killer (NK) cells play a crucial role in early host responses against viruses, bacteria and malignancies mainly by killing of infected/transformed cells. NK cell activity is controlled by various inhibitory and activating receptors. Among the latter are proteins such as the natural cytotoxicity receptors [NCR (NKp44, NKp30 and NKp46)]. NKp46 is expressed almost exclusively on NK cells, and it is the only NK cell receptor with a mouse orthologue, the Ncr1.
Several publications have demonstrated the critical role of NKp46/Ncr1 in the eradication of various tumors including melanoma. However, the mechanism by which Ncr1 operates in-vivo is yet unclear. In-vivo reflectance confocal microscopy (RCM) is a novel technology enabling non-invasive visualization and mapping of time kinetics of changes in the structure of malignant skin lesions.
Objectives To investigate the mechanism by which Ncr1 is involved in melanoma development In-vivo using RCM.
Materials and methods: Using B16F10.9 tumors and an Ncr1 knockout mice we investigated the development of primary and metastatic melanoma by various in vitro and in vivo assays that includes visual inspection and RCM.
Results: Ncr1 was found to control tumor size and metastases in a dose dependent manner. Interestingly, high frequency of metastases was observed in the absence of Ncr1 even when the primary tumors demonstrated similar size features. Absence of Ncr1 also correlates to more aggressive structural RCM indices of the developing tumors in the absence of Ncr1.
Conclusions: Ncr1 is involved in the structural modulation of B16 melanoma and consequently in its metastases development.

P1.03.20
The receptor KIR3DS1 expressed by NK cell is associated with HCV viral clearance

***R. Gonzalez**, A. Rivero-Juarez, B. Manzanares, Á. Camacho, M. Frías, A. Martínez, L. Castro, A. Rivero, J. Peña;*
Hospital Reina Sofía, Córdoba, Spain.

Background: HCV treatment, leads to a massive activation of the innate immunity response due to the fact that IFN-α is a potent activator of NK cells. NK cell inhibitory receptors (KIRs) are associated either with activating or inhibiting NK cell action. The objective was to evaluate the influence of the presence of KIR-3DS1 on HCV treatment response in HIV/HCV genotype 1 co-infected patients.
Methods: KIR, HLA-B and the IL28B gene were genotyped. Reductions of plasma HCV RNA levels between baseline and week 1, week 2 and week 4 were analyzed for IL28B genotype and KIR3DS1. Rapid and sustained virological response (RVR and SVR) rates were also analyzed.
Results: Sixty HIV/HCV genotype 1 co-infected patients were included. Patients with KIR3DS1 and Bw4 had higher rates of HCV viral decline than those who were not carriers of KIR3DS1 (week1: p=0.01; week2: p=0.038; week 4: p=0.03). Patients carrying KIR3DS1/Bw4 had higher rates of RVR and SVR than those not carrying KIR3DS1 (RVR: 46.15% *versus* 17.02%, p= 0.012; SVR: 63.6% *versus* 13 26.5%, p = 0.031). With respect to patients carrying the IL28B-CC genotype, those with KIR3DS1/Bw4 had greater rates of HCV viral clearance (week1: p < 0.001; week2: p= 0.01; week 4: p = 0.02), RVR (%) and SVR (%) than those not carrying KIR3DS1.
Conclusion: Our results show that the KIR3DS1/Bw4 genotype has a positive effect on HCV viral clearance during the first weeks of Peg-IFN/RBV treatment in HCV/HCV co-infected patients bearing genotype 1, and higher RVR and SVR rates.

P1.03.21
Measurement of natural killer cell apoptotic inducing lytic proteins in peripheral blood mononuclear cells and isolated natural killer cells

***T. K. Huth**[1,2], E. W. Brenu[1], K. J. Ashton[2], D. Staines[1,3], S. M. Marshall-Gradisnik[1];*
[1]National Centre for Neuroimmunology and Emerging Diseases, Griffith Health Institute, Griffith University, Gold Coast, Australia, [2]Faculty of Health Sciences and Medicine, Bond University, Gold Coast, Australia, [3]Gold Coast Public Health Unit, Queensland Health, Gold Coast, Australia.

Natural Killer (NK) cells are immune cells responsible for protecting the body from infection and malignancy. Cytotoxic NK cells contain secretory granules which store and release apoptotic inducing proteins such as perforin, granzyme A (GrzA) and granzyme B (GrzB). The aim of this study was to measure lytic proteins in samples of peripheral blood mononuclear cells (PBMCs) and isolated NK cells to determine if there is a difference in lytic protein expression. PBMCs from 19 healthy participants (mean age: 31±7.2SD) were isolated using density gradient centrifugation and negative isolation was used to separate the NK cells. Intracellular staining determined the content of perforin, GrzA and GrzB via flow cytometry in control and K562 stimulated samples. Statistical analysis included a repeated measures analysis of variance and significance was set at p<0.05. No significant changes were identified in lytic protein content in the control and K562 stimulated samples between the PBMCs and isolated NK cells. A significant increase in lytic proteins was observed in the isolated NK cells. The lymphocyte composition of the PBMC samples may account for this increase. NK cells only comprise of 15±8% of total circulating lymphocytes in the PBMC sample. Compared to the number of NK cells present in the isolated sample, there were fewer NK cells in the PBMC sample, translating to reduced levels of lytic proteins. Measurement of lytic proteins provides a direct measurement of NK cytotoxic activity and it may be beneficial for identifying cytotoxic activity deficiencies in the clinical setting.

P1.03.22
Functional NK cells developed from human hematopoietic stem cell in human interleukin-2 transgenic NOG mice

***I. Katano**, R. Ito, T. Takahashi, M. Ito;*
Central Institute for Experimental Animals, Kawasaki, Japan.

We generated human interleukin-2 (hIL-2) transgenic NOD/Shi-*scid IL2rg*^{null} (NOG) mouse. We investigated human lymphocyte development *in vivo* in this hIL-2 transgenic NOG (hIL-2-NOG) strain after xeno-transplantation of human hematopoietic stem cells (HSC).
hIL-2-NOG and NOG mice were irradiated and intravenously inoculated with 2-5 x 10^4 cord-blood derived human CD34$^+$ HSC. After HSC transplantation, human cells in the peripheral blood and the various immune tissues of these HSC transferred mice were analyzed. Various developmental stages of human NK cells were detected, and especially, mature CD56$^+$ NK cell population was rapidly increased in hu-HSC-hIL-2-NOG mice. Human NK cells of hu-HSC-hIL-2-NOG mice consisted of both CD56^{high}CD16$^+$ and CD56^{high}CD16$^-$ cell populations, whereas most NK cells in human peripheral blood were CD56^{dull}CD16$^+$. The human NK cells of hu-HSC-hIL-2-NOG mice expressed various NK cell-specific surface markers involving activating and inhibitory receptors, such as NKp46, CD94, NKG2A, NKG2D and KIRs (Killer cell Immunoglobulin-like Receptors). Regarding cytotoxic activity of NK cells against K562, killing activity of purified human NK cells from hu-HSC-hIL-2-NOG were lower than that of normal human NK cells, but enhanced following stimulation with human cytokine for 2 days. Production of cytotoxic granule (perforin and granzyme A) and IFNg was detected in human NK cells of hu-HSC-hIL-2-NOG mice. Tumor growth in hu-HSC-hIL-2-NOG mice subcutaneously transplanted K562 was suppressed, but in hu-HSC-NOG mice was not.
These data suggest that hIL-2-NOG mice will become a useful tool for analyzing human NK cell development and function in vivo.

P1.03.23
Multi-step defect in NK cells and acute myeloid leukemia interaction

***Z. Khaznadar**[1,2], N. Setterblad[3], G. Henry[4], S. Agaugue[2], E. Raffoux[5,6], N. Boissel[5,6], H. Dombret[5,6], A. Toubert[2,4], N. Dulphy[2,4];*
[1]Universite Paris Diderot, Institut universitaire d'hematologie, Paris, France, [2]Inserm UMR940, Paris, France, [3]Universite Paris Diderot, Institut universitaire d'hematologie, Département d'Imagerie, Paris, France, [4]Assistance Publique–Hôpitaux de Paris (AP–HP), Hôpital Saint-Louis, Laboratoire d'Immunologie et Histocompatibilité, Paris, France, [5]AP–HP, Hôpital Saint-Louis, Laboratoire d'Hématologie Adulte, Paris, France, [6]Universite Paris Diderot, Paris, France.

Natural Killer cells (NKs) are candidates for acute myeloid leukemia (AML) immunotherapy since the demonstration of their ability to reduce relapse. Most cytotoxic activity of NKs is assured by direct killing via the release of lytic granules content into the contact area with target cells. However, down-regulation of activating receptors on NKs associated with a reduced cytotoxicity was shown in AML patients.
In this work in vitro study using AML cell lines (HL60 and THP1), AML patients' blasts and NKs from healthy unrelated individuals showed that receptors down-regulation requires NK/target contact and is associated with conjugate formation.
Contact-to-death kinetics in NK/target conjugates were calculated in time-lapse experiments where dying tumor cells were detected by emergence of a nucleic acid staining. Comparison between the highly NK-susceptible target K562 and HL60 showed no difference.
NKs synapses formed with AML or K562 cells were evaluated in conjugates showing opposite flat cell membranes and F-actin polymerization. NK cells showed proper recruitment of adhesion molecule LFA-1. However, we observed defective polarization of lytic granules with AML cell lines and patients' blasts, independently of HLA class-I expression. In addition, reduced recruitment of the adaptor protein CD3ζ suggested a defective activating signaling.
Attempts to correct NK/AML synapse defects using IL-2 or IL-15 activated NKs augmented conjugate formation but did not affect granules polarization. Unlike pre-treatment of AML cell lines with the immunomodulating molecule lenalidomide which significantly increased the lytic granules polarization. This last result justifies further studies to use immunomodulating drugs to improve NK-cell immunotherapy efficacy.

P1.03.24
Differential requirements of activating and inhibitory Ly49 receptors in recognition of MCMV-infected cells

*M. Babic-Cac[1], V. Juranic-Lisnic[1], M. Pyzik[2], B. Popovic[1], S. M. Vidal[2], S. Jonjic[1], **A. Krmpotic**[1];*
[1]Faculty of Medicine, Rijeka, Croatia, [2]McGill University, Montreal, QC, Canada.

NK cells have a prominent role in control of cytomegalovirus (CMV)infection during the time preceding the induction of the adaptive immune response. In order to prevent recognition by CD8 T cells, CMVs encode proteins that down-regulate expression of MHC-I molecules from the cell surface, which render infected cells prone to 'missing-self'-mediated killing by NK cells. We have shown that murine CMV (MCMV) developed a mechanism to prevent NK-cell activation by escaping 'missing-self' recognition. MCMV m04 protein binds to newly synthesized MHC-I molecules and escorts them to the cell surface to engage NK-cell inhibitory Ly49 receptors. Moreover, we provided evidence that several activating Ly49 receptors also depend on presence of m04 for their own recognition of infected cells. However, presence of m04 is necessary, but not sufficient for the recognition of infected cells by these activating Ly49 receptors. Beside m04, another unidentified viral factor encoded by gene in the region of m167-m170 is required for their triggering. Transcriptome analysis of m167-m170 region revealed the presence of a single, antisense, highly abundant 1.7 kb long transcript, which encodes protein of 17 kDa that corresponded to ORF m169. So far, we have no evidence that m169 protein represents the third component of MCMV required for m04/MHC-I-dependent recognition of infected cells by activating Ly49 receptors. Our results indicate that activating and inhibitory Ly49 receptors have differential requirements for m04/MHC-I-dependent recognition of MCMV-infected cells, suggesting more stringent conditions for allowing the activation of NK cells.

P1.03.25
Spinal Cord Injury-induced Immune Depression Syndrome - the role of NK and T cells

***I. Laginha**;*
Charité Universitätsmedizin - Berlin, Berlin, Germany.

The nervous and the immune systems interact in a bidirectional way. The nervous system "hardwires" the lymphatic organs and the immune system relays information to the CNS through cognate receptors.
This interplay between these "megasystems" becomes evident in case of lesions in the CNS as well as spinal cord injury (SCI). Following such an insult a downregulation of the immune system has been observed. This phenomenon is called CNS Injury-Induced Immune Depression Syndrome (CIDS) (Meisel 2005). In the frame of SCI, a fluctuation of several leukocyte subclasses has been observed during the first week after acute lesion both in humans and experimental model. This downregulation of the immune system is thought to underlie the increased susceptibility of these patients to infectious diseases. Nevertheless, this susceptibility remains elevated in SCI patients beyond the acute period, being the main cause of morbidity and mortality among SCI patients during the post-acute period post-lesion.
Based on the hypothesis that a functional deficit in certain classes of leukocyte subpopulations might be underlying the increased susceptibility to infections, NK cells have been identified as potential mediators of this immune depression.
Using a SCI transection model in rat, we perform a longitudinal analysis of the fluctuations of peripheral blood and immune relevant organs T and NK cells as well as immunophenotypic changes and capacity to produce IFN-γ and TNF-α along time. These measurements are performed by flow cytometry in 5 different time points: on day 1, 3, 7, 14 and 28 after spinal cord contusion.

P1.03.26
Cytomegalovirus regulation of mouse PVR

***T. Lenac Rovi**[1], N. Stanietsky[2], S. Jordan[3], V. Juranić Lisnić[4], A. Tomic[1], M. Babic[4], A. Krmpotic[4], P. Tsukerman[2], O. Mandelboim[2], S. Jonjić[1,4];*
[1]Center for Proteomics, Faculty of Medicine University of Rijeka, Rijeka, Croatia, [2]The Lautenberg Center for General and Tumor Immunology, The Hebrew University, The BioMedical Research Institute, Hadassah Medical School, Jerusalem, Israel, [3]Max von Pettenkofer-Institute, Ludwig Maximilians-University, Munich, Germany, [4]Department for Histology and Embryology, Faculty of Medicine University of Rijeka, Rijeka, Croatia.

Cytomegaloviruses (CMVs) are well known for their capacity to regulate the expression of cellular ligands of different immune receptors. Human CMV blocks the surface expression of CD155 (PVR) molecule, which serves as a ligand for activating receptors CD226 (DNAM-1) and CD96 (TACTILE), conserved between mice and humans and both expressed on NK cells and T cells. PVR is also a ligand for the inhibitory receptor, TIGIT. Here we demonstrate that mouse CMV (MCMV) negatively regulates PVR.
We showed significant upregulation of PVR mRNA after MCMV infection. In contrast, surface PVR was downregulated on infected cells, indicating the active role of MCMV in the control of PVR surface expression. We have identified two viral gene regions responsible: deletion of either m154 or m20 resulted in the rescuing of PVR on the surface. When both regions were deleted, upregulation of surface PVR was observed. Our results also indicated that MCMV inhibitors affect the maturation of PVR, rather than its active removal from the surface. We showed that m20 gene region is responsible for the ER retention of PVR, whereas the mechanism by which m154 affects the expression of PVR remained elusive. Both mature and retained PVR protein forms are subject to the proteasomal degradation route. We found that the transcriptional profile of m20 region is very complex, with multiple overlapping transcripts. We showed at least 3 transcripts which probably share 3' terminus and are differentially temporally expressed. The lack of any of the PVR regulators results in viral attenuation in vivo.

P1.03.27
Regulatory roles of novel NK-like CD56^{bright}CD11c^{+} cells on expansion of γδ T cells and memory CD8+ T cells

***W. Li**[1], H. Yammamoto[1], K. Yamanishi[1], H. Yamanishi[2], H. Okamura[1];*
[1]Laboratory of Tumor Immunology and Cell Therapy,Hyogo College of Medicine, Nishinomiya, Japan, [2]Hirakata General Hospital for Developmental Disorders, Osaka, Japan.

Human γδ T cells and memory CD8+ T cells have recently received much attention in cancer immunotherapy. However, it is well known that the responses of γδ T cells to antigenic stimulation are diminished in vitro as well as in vivo in some cancer patient. In this study, we examined the cellular mechanism underlying the regulation of human γδ T cells expansion and memory CD8+ T cells, focusing on the effect of IL-18 on CD56^{bright}CD11c^{+} cells. IL-18 and IL-2 induced the generation and proliferation of CD56^{bright}CD11c^{+}cells in the culture of CD14^{+} monocytes and CD56^{int}CD11c^{+}cells even in the absence of antigenic stimulation. The NK-like CD56^{bright}CD11c^{+}cells had the capacity to promote expansion of zoledronic acid (ZOL)-stimulated γδ T cells,and also to support the proliferation of CD8+ T cells. On the other hand, pDCs and IFN-α appeared to suppress the development of CD56^{bright}CD11c^{+} cells, finally leading to impaired expansion of γδ T cells and suppressed the proliferation of CD8+ T cells. The addition of mature CD56^{bright}CD11c^{+} cells to the culture overcame the regulatory effect of pDCs. These results demonstrate that CD56^{bright}CD11c^{+} cells and pDCs are involved in the regulation of γδ T cells and memory CD8+ T cells responses to antigenic stimulation. The manner of positive regulation by NK-like CD56^{bright}CD11c^{+}cells were dependent on IL-18.

P1.03.28

Structure of the human activating receptor NKp65 bound to its keratinocyte ligand KACL (CLEC2A) reveals basis for genetically linked recognition in the natural killer gene complex

Y. Li[1], *Q. Wang*[1], *S. Chen*[1], *P. H. Brown*[2], *R. A. Mariuzza*[1];
[1]*IBBR/Univ. of Maryland, Rockville, MD, United States,*
[2]*NIBIB/National Institutes of Health, Bethesda, MD, United States.*

The natural killer gene complex (NKC) encodes numerous C-type lectin-like receptors that govern the activity of natural killer (NK) cells. While some of these receptors (Ly49s, NKG2D, CD94/NKG2A) recognize MHC or MHC-like molecules, others (Nkrp1, NKRP1A, NKp80, NKp65) instead bind C-type lectin-like ligands to which they genetically linked in the NKC. To understand the basis for this recognition, we determined the structure of human NKp65, an activating receptor implicated in the immunosurveillance of skin, in complex with its NKC-encoded keratinocyte ligand KACL. Whereas KACL forms a homodimer resembling other C-type lectin family dimers (Ly49, CD69), NKp65 is monomeric. The KACL homodimer engages NKp65 bivalently, such that each KACL subunit constitutes an independent binding site for NKp65 and each NKp65 molecule makes identical contacts with KACL. This bivalent binding mode is completely distinct from those utilized by NKG2D, CD94/NKG2A or Ly49A to recognize MHC or MHC-like ligands. The structure explains the exceptionally high affinity of the NKp65-KACL interaction (KD = 6.7 × 10-10 M) compared with other interactions involving cell-cell recognition molecules, which may compensate for the monomeric nature of NKp65 to achieve NK cell activation. The NKp65-KACL complex provides the first binding toplogy template for genetically linked recognition within the NKC that can now be applied to other NKC-encoded receptor-ligand pairs (Nkrp1f-Clr-g, Nkrp1d-Clr-b, NKRP1A-LLT1, NKp80-AICL).

P1.03.29

Crosstalk between Dendritic Cells and NK cells in the Immune Response against the dimorphic fungus Paracoccidioides brasiliensis

L. N. A. Longhi*, M. C. Ferreira, M. H. S. L. Blotta, R. L. Mamoni;*
University of Campinas- Unicamp, Campinas, Brazil.

In a previous study we have demonstrated that NK cells can participate in the immune response in human Paracoccidioidomycosis (PCM). Recently, it have been shown that dendritic cells (DCs) and NK cells can interact, increasing their activities. The aim of this study was to evaluated whether DCs stimulated by Paracoccidioides brasiliensis (Pb) yeast cells are able to interact with NK cells, and how this interaction influence the activation, cytokine production and cytotoxic activity of NK cells against Pb. Our results showed that monocytes-derived DCs stimulated by Pb yeast cells produce cytokines (IL-12, IL-18, IL-23 and membrane associated IL-15), which are important for the activation of NK cells. NK stimulated by these cytokines or cocultured with DCs (previously stimulated by Pb yeast cells) presented increased expression of activation markers (CD25 and CD69), direct fungicidal capacity and augmented production of cytokines such as IFN-gamma and TNF-alpha. Furthermore, the interaction of DCs and NK cells leaded to the proliferation of NK cells (particularly the subpopulation expressing high levels of CD56 - CD56bright). These effects were dependent on the production of IL-15 and IL-12 by DCs, once the blockage of these cytokines abolished these responses. In clonclusion, our results demonstrate that the crosstalk between DCs and NK cells can influence the activity of NK cells, augmenting their cytotoxic activity and cytokine production, and hence can modulate the subsequent acquired immune response observed in PCM.

P1.03.30

Interleukin-21 promotes the differentiation of a population of natural killer lymphocytes expressing CD86 and HLA-DR with the ability to activate naive CD4 T cells

R. Loyon[1,2], *E. Picard*[1,2], *A. Claude*[1,2], *J. Pallandre*[1,3], *O. Adotevi*[1,4], *Y. Godet*[1,2], *C. Borg*[1,4];
[1]*UMR1098, Besançon, France,* [2]*Université de Franche-Comté, Besançon, France,* [3]*EFS Bourgogne Franche-Comté, Besançon, France,* [4]*CHRU Jean Minjoz, Besançon, France.*

Natural killer (NK) cell cytotoxic functions are involved in viral and cancer immunity. Moreover, NK-derived IFN-γ modulates CD4 T cell responses by promoting IL-12 production by dendritic cells and TH1 polarization. Here, we investigated the potential role of IL-21 in NK and CD4 T lymphocyte cross-talk.
In a first set of experiments, NK cell from healthy donors were cultured with IL-2 or IL-2 and IL-21 during 7 days. The transcriptome was analyzed and an increase of co-stimulatory molecules, CIITA and MHC class II molecules was observed. In addition, an over-expression of CD62L was observed suggesting an immunomodulating role of these cells. The expression of CD86 and HLA-DR on NK cells induced by IL-21 is dependent on the STAT3 pathway.
Surprisingly, these NK-CD86+ cells express NKp46 and NKp30 but are devoid of cytotoxic functions although they derived from the highly cytotoxic CD56bright NK cell population. Then, the ability of NK-CD86+ to activate CD4 T lymphocytes was investigated. NK-CD86+ cells were loaded with peptides and cultured with specific CD4 T cell clones. Interestingly, NK-CD86+ cells promote a particularly strong proliferation of specific CD4 T cells. Moreover, we have also shown that NK-CD86+ cells provide an effective co-stimulatory signal for naive CD4 T cell activation. In addition, these CD4 T cells activated in the presence of NK-CD86+ cells are maintained in central memory status. Unexpectedly, transwell experiments showed that this proliferation is not dependent on cell-cell contacts. Altogether, these results identified a new immunomodulatory NK cell population.

P1.03.31

NK cell reconstitution following manipulated or un-manipulated haploidentical hematopoietic stem cell transplantation in leukemia patients

R. Meazza[1], *M. Falco*[2], *C. Tuberosa*[3], *F. Loiacono*[2], *M. Mingari*[1,3], *A. Moretta*[3], *A. Bacigalupo*[1], *L. Moretta*[2], *F. Locatelli*[4], *D. Pende*[1];
[1]*IRCCS AOU San Martino-IST, Genova, Italy,* [2]*Istituto Giannina Gaslini, Genova, Italy,* [3]*Università degli Studi, Genova, Italy,* [4]*Ospedale Bambino Gesù, Roma, Italy.*

We analyzed the NK cell repertoire in leukemia patients transplanted from haploidentical donors comparing different graft preparations:
a) CD34+ or TCRαβ/CD19-depleted grafts in pediatric patients.
b) un-manipulated bone marrow in adults with post-transplant high dose cyclophosphamide (PT-CY BMT) to prevent graft vs host disease (GvHD).
Genetic, phenotypic and functional analyses have been performed to study the NK cell repertoire in the donor and in the recipient post-transplant.
At the 1st month post-transplant, NK cells in CD34+ grafts predominantly displayed an immature phenotype. Differently, in TCRαβ/CD19-depleted grafts we observed a high proportion of NK cells with a mature phenotype (CD56dim, KIR+/NKG2A- and CD57+) and a detectable alloreactive NK cell subset, when appropriate, suggesting the persistence of mature donor NK cells present in the graft; T lymphocytes were TCRγδ+.
We observed a fast immune reconstitution after PT-CY BMT: 1 month post-transplant, NK and T cells were 38% and 62% of lymphocytes, respectively. NK cells appeared phenotypically immature: CD56bright, CD94/NKG2A+, while CD16+, KIR+ and CD57+ cells were less represented. However, these NK cells displayed a normal cytolytic activity revealed by degranulation assay upon K562 stimulation. A more mature NK cell phenotype, could be frequently observed only several (6-12) months after transplant.
These preliminary data suggest that, in patients transplanted with TCRαβ/CD19-depleted cells, mature donor-derived NK cells, including alloreactive NK cells, persist at 1st month. Longer follow-up and larger group of patients are necessary to correlate these grafts

with clinical benefits in the control of leukemia relapse and infections and limited incidence of GvHD.

P1.03.32
Simultaneously expression of NKG2DL MICA/MICB and NKG2D receptor on human cervical cancer cells

***J. Mendoza-Rincon**, S. B. C. Bautista-Castillo, C. M. R. Mendoza-Rodriguez;*
National University Autonomous of Mexico, Mexico City, Mexico.

Cancer cells are known to secrete the stress molecules MICA and MICB that activate cytotoxicity by lymphocytes and NK cells through their NKG2D receptor as a mechanism of immunological defense. However, there is not know if cancer cells can also express this receptor as a possible mechanisms of depletion of NKG2DL MICA/MICB molecules and thus interfere with their immune recognition. The aim of this study was to analyse the expression of MICA and MICB and NKG2D receptor on human cervical cancer cells. CALO, INBL and Hela cell lines were evaluated by ELISA, Western Blot, FACS and immunocytochemestry to their capacity to express and secrete MICA and MICB and to be induced to proliferate by these molecules as well as to express their receptor NGK2D. Those cell lines produce and secrete the stress MICA and MICB as shown by Western Blot of lysed cells and by ELISA of their conditioned media. By Western Blot and flow cytometry we found that these cells also express the receptor NKG2D. When CALO, INBL and Hela were cultured with recombinant MICA and MICB they exhibited a dose dependent induction for their proliferation. By immunocytochemistry we also found that these cells express NKG2D. Our results show that tumor epithelial cells (non-leukocyte cells) can also express NKG2D receptor that was thought to be exclusive of NK and cytotoxic lymphocytes and could be considerate as a possible mechanism of immunological escape and of tumor growth induction.

P1.03.33
Characterisation of chicken NK cell receptors

***E. Meziane**[1], N. Potts[1], T. Pizzari[2], D. Richardson[3], K. Watson[4], T. Goebel[5], J. Kaufman[1,6];*
[1]University of Cambridge, Department of Pathology, Cambridge, United Kingdom, [2]University of Oxford, Department of Zoology, Oxford, United Kingdom, [3]University of East Anglia, School of Biological Sciences, Norwich, United Kingdom, [4]AVIAGEN, Edinburgh, United Kingdom, [5]Ludwig Maximilians University, DEPARTMENT OF Veterinary Science, Munich, Germany, [6]Department of Veterinary Medicine, Cambridge, United Kingdom.

Natural Killer (NK) cells are crucial for resistance to many diseases. Like mammals, chickens have two types of putative NK cell receptors (NKR), lectin-like or immunoglobulin (Ig)-like receptors.
There are only a few putative lectin-like NKR genes in the chicken genome, of which perhaps only one gene, BNK, present in the classical major histocompatibility complex (MHC), is an NKR. The putative ligand for BNK is Blec, another lectin-like gene in the MHC region next to BNK. BNK and Blec are most similar to NKR-P1 and its ligands LLT1 and clr, respectively. Using a bead binding assay, we identified a cell line which naturally expresses the BNK ligand that also stimulates a BNK reporter line. We now try to identify whether this ligand is Blec or not.
There are many chicken Ig-like receptor (CHIR) genes clustered on microchromosome 31 with features typical of human KIRs, LILRs and IgA Fc receptor. They have either one or two extracellular domains, and are activating, inhibitory, or bi-functional. We set up a typing method for CHIR-AB1 genes using reference strand-mediated conformational analysis (RSCA), originally used for high throughput genotyping of MHC genes. CHIR-AB1 genes are found throughout microchromosome 31, so they can act as genetic markers across the entire chromosome. We identified CHIR-AB1 haplotypes in experimental egg-layer lines, commercial broiler lines and a population of red jungle fowl, containing a variety of MHC haplotypes. We now investigate the effect of epistasis between MHC and CHIR on disease resistance and other traits.

P1.03.34
Dopaminergic D5 Receptor-mediated inhibition of NK cell proliferation and production of IFN-γ

***J. Mikulak**, L. Bozzo, A. Roberto, P. Tentorio, S. Bonaldo, D. Mavilio;*
Istituto Clinico Humanitas, Rozzano (MI), Italy.

Dopamine is a catecholamine neurotransmitter which plays an important role in the regulation of the function of many effectory immune cells. However, there is no report yet regarding the possible regulatory role of DA in human NK cells. The present study investigated the expression of different dopamine receptors and the effect of their activation on human NK cells activity. D2, D3, D4 and D5 dopamine receptors were found to be expressed in resting NK cells. An increased level of these receptors was followed by IL-2 activation, with the predominant enhancement found for D5 receptor. The augmented expression of D5 receptor was correlated to the increased sensitivity of human activated NK cells to dopamine treatment and resulted in the immunosuppression of NK cells activity. In particular, we have observed a dose-dependent effect of dopamine that resulted in D5-mediated inhibition of IL-2 induced NK proliferation and IFN-γ production. IFN-γ synthesis under dopamine treatment was altered post-transcriptionally and dependent on the increased transcription of the known IFN-γ suppressor factor miR-29a in NK cells. We have also observed that the suppressive action of miR-29a is correlated to the D5-mediated inhibition of NF-κB transcription factors activity, in particular the blocking of nuclear translocation of p50 protein. Our findings demonstrated that both Il-2 induced proliferation and IFN-γ synthesis in human NK cells is regulated through D5 dopaminergic receptor, which may play an important role in physiological NK cells immunoregulation, as well as having a therapeutic value in diseases with uncontrolled NK cells activity.

P1.03.35
Helicobacter pylori increases NK cell response increasing ULBP2 surface expression in adenocarcinoma gastric cell lines

***M. C. Molina**, C. J. Hernández, C. H. Ribeiro, M. Garrido-Tapia, K. Kramm;*
Programa Disciplinario de Inmunogía, Facultad de Medicina, Universidad de Chile, Santiago, Chile.

ULBP2 is an inducible molecule expressed in stressed cells. This molecule is part of the NKG2D ligands (NKG2DL) and its recognition allows damage cells to be eliminated by Natural Killer (NK) cells. Modification in its expression by tumor cells is associated to immune evasion and tumor establishment. Helicobacter pylori (HP) infection on gastric cancer (GC) development has not been associated, but its influence in chronic inflammation has been established through TLR stimulation in innate immune response. Our aim was to describe the effect of HP in NKG2DL expression on gastric adenocarcinoma cell lines and evaluate its functional effect on NK cell response. For this purpose MKN-45 gastric adenocarcinoma cell line were incubated with Heat killed Helicobacter pylori (HKHP) and then were co-incubated with NK cells purified from healthy donors in order to performed a cytotoxic assay. ULBP-2 expression and NK cell activation were analyzed by flow cytometry. HP infection is highly prevalent and it has been associated to GC. In this work we demonstrate that HKHP induce ULBP2 surface expression in gastric adenocarcinoma cell lines, augmenting NK cell activation against them. By this way tumor cells could be triggering a chronic NK cell response, associated to NK cell anergy and immune evasion. P1.03.36
Adenosine produced by a CD38-mediated pathway in CD56^{bright} CD16^{-} NK cells inhibits autologous CD4^{+}T cell proliferation

***F. Morandi**[1], A. L. Horenstein[2], A. Chillemi[2], G. Zaccarello[2], F. Malavasi[2], V. Pistoia[1];*
[1]Istituto Giannina Gaslini, Genoa, Italy, [2]University of Torino, Torino, Italy.

Recent studies have indicated that CD56^{bright}CD16^{-} natural killer (NK) cells play an important role in immunoregulation and autoimmunity by mechanisms that have yet to be elucidated. In this study, we

investigated the potential role of an extracellular nucleotide-metabolizing network that leads to production of adenosine (ADO), a multifunctional immunosuppressive nucleoside that binds to different specific receptors expressed by immune effector cells. The nucleotide-metabolizing ectoenzyme network includes the ADP-ribosyl cyclases CD38 and CD157, PC-1 [nucleotide pyrophosphatase/phosphodiesterase-1(ENPP-1)], CD39 (nucleoside triphosphate diphosphohydrolase-1) and CD73 (5'-nucleotidase). These ectoenzymes regulate the nucleotide/nucleoside balance and control the release of adenosine into the extracellular environment. We detected similar expression levels of CD38, CD39, CD73 and CD157 in peripheral blood $CD56^{dim}/CD16^{+}$ and $CD56^{bright}/CD16^{-}$ NK cells, whereas PC-1 was mostly expressed in $CD56^{dim}/CD16^{+}$ cells. $CD56^{bright}/CD16^{-}$ NK cells produced ADO when cultured in the presence of ATP, ADP (in progress), AMP or NAD^{+}. ADO inhibited the proliferation of autologous $CD4^{+}$ T cells. Pre-treatment with dipyridamole, which increases extracellular ADO by blocking ADO transporters, further inhibited $CD4^{+}$ T cell proliferation. On the contrary, ADO-mediated inhibition of autologous $CD4^{+}$ T cell proliferation was abrogated by blocking CD38 activity, but not by inhibiting CD39, CD73 or PC-1. These studies indicate that $CD56^{bright}/CD16^{-}$ NK cells can mediate immune regulation through ADO production, a process that requires the ADP-ribosyl cyclase CD38.

P1.03.37
Correlation between natural killer cells functionality and response to trastuzumab treatment in HER2+ breast cancer patients

***L. Morelli**, M. Ciranna, G. Curigliano, G. Penna, M. Rescigno;*
European Institute of Oncology, Milan, Italy.

In the first decade of the 21st century, the model of breast cancer (BC) has been redefined from that of one disease to a heterogeneous group of related diseases. The approval of trastuzumab in 1998 has significantly improved patients' outcomes and opened the way for the beginning of advent of targeted approaches in breast cancer treatment. However, primary or acquired resistance to trastuzumab has been increasingly recognized as a major obstacle in the clinical management of this disease. The main objective of this project is to shed light on the mechanism responsible for the development of resistance to trastuzumab treatment in HER-2 positive breast cancer patients. We demonstrated that, after one year of trastuzumab administration, patients who became resistant to the treatment showed an impaired NK cells activity. Further we showed that NK cells activity is modulated through the control of immunoreceptors and kinase in a complex interaction between intracellular signaling pathways. In order to predict acquisition of trastuzumab resistance before treatment, we identified a different signature of immuno-receptors/kinase activation status related to the BC patients' outcome. These results opened the way to a more detailed therapy focused on patients' NK cells functionality.

P1.03.38
Modulation of activatory and inhibitory receptors of NK cells by CD137 costimulation

***S. Navabi**, N. H. J. H. Doroudchi, M;*
Shiraz University Medical Of Sciences, Shiraz, Iran.

Background: Activated T lymphocytes and NK cells express CD137 (4-1BB) a member of TNFR family however the extent of its contribution in NK cell biology is not fully revealed. Here we investigated the effect of CD137-CD137L interaction on the expression of stimulatory and inhibitory receptors of human activated NK cells.
Methods: The MCF-7 breast cancer cells were infected by recombinant non-replicative adenovirus vectors to express 4-1BBL transgene or GFP (as control). NK cells from Peripheral blood were negatively purified, activated with sub-optimal concentrations of IL-2 and IL-15 and cocultured with the infected MCF-7 cells. The expressions of activation markers (NKG2D, NCR2, CD69) and inhibitory receptor (NKG2A) were assessed afterward.
Result: Results showed significant up-regulation of the NK cell activatory receptors while the expression of the inhibitory receptor diminished consequent to 4-1BBL interaction. Compared to the NK cells activated with IL-2/IL-15, CD137 signal increased the expression of NKG2D from 35% to 42%, NCR2 from 23% to 39%, and CD69 from 50% to 59% (P =0.02). Although frequency of NKG2A expressing cells did not change significantly, normalized MFI of NKG2A expression on the NK cells reduced by CD137treatment (P=0.01).
Conclusion: CD137 costimulation may regulate NK cells' activity by differential governing the expression of activatory and inhibitory receptors.

P1.03.39
Natural killer cells in upper respiratory airway

***K. Okada**[1,2], S. Sato[2], A. Sato[2], Y. Inoue[1], T. Yabe[1], H. Kiyono[2];*
[1]Tokyo Metropolitan Hiroo Hospital, Tokyo, Japan, [2]The Institute of Medical Science, The University of Tokyo, Tokyo, Japan.

Natural killer (NK) cells are important lymphocytes for their anti-viral and anti-tumor functions. Accumulating knowledge suggests that NK cells in mucosal compartments are quite unique in their phenotype and function. However, little is known about NK cells in upper respiratory airway, especially in nasal cavity and salivary glands. Here, we present analysis of murine NK cells in nasal cavity and salivary glands.
In case of mice, NK cells in nasal cavity and salivary glands show unique expression pattern of surface markers including NK cell receptors and others related to maturation and activation. These NK cells show hyporesponsiveness to extracellular stimuli such as IL-12 and IL-18. However, nasal NK cells have shown to play indispensable role for nasal Influenza viral infection. As to salivary gland NK cells, their hyporesponsiveness to Cytomegalovirus infection has been reported. We have found other unique functions as well. In addition, we show some data obtained from human nasal and salivary gland samples.

P1.03.40
Expression of Ly6C defines two subsets of mature mouse NK cells

***A. Omi**, T. Kiniwa, Y. Enomoto, A. Miyajima;*
Laboratory of Cell Growth and Differentiation, Institute of Molecular and Cellular Biosciences, The University of Tokyo, Bunkyo-ku, Tokyo, Japan.

NK cells are cytolytic and cytokine-producing effector cells that play crucial roles in the clearance of tumors and virus-infected cells. NK cells are classified into distinct populations according to the differentiation stages, but the roles of the each cell population and the factors that regulate the development and homeostasis of NK cells are unclear. In the present study, we report that mouse mature NK cells ($NK1.1^{+}/CD11b^{+}/CD3e^{-}$) in the spleen are subdivided into two populations based on the expression level of Ly6C, i.e. $Ly6C^{high}$ and $Ly6C^{low}$ subsets. We further show that these subsets are functionally distinct in their cytokine production and cytotoxic activity, i.e. IFNg production in response to IL-18 or IL-12 and cytotoxicity against the mouse T cell lymphoma Yac-1 were lower in $Ly6C^{high}$ NK cells than $Ly6C^{low}$ NK cells. In addition, $Ly6C^{high}$ NK cells were found in various tissues, including the liver, lung, peripheral blood and lymph node, but not in the bone marrow. Since NK cells develop in the bone marrow, $Ly6C^{high}$ NK cells were assumed to be differentiated from $Ly6C^{low}$ NK cells. Consistently, $Ly6C^{low}$ NK cells from the spleen were converted to $Ly6C^{high}$ NK cells upon transplantation. These results suggest that $Ly6C^{high}$ NK cells are mature cells in the peripheral tissues. While immune functions of the $Ly6C^{high}$ NK cells were lower than those of $Ly6C^{low}$ NK cells, $Ly6C^{high}$ NK cells became $Ly6C^{low}$ NK cells and produced more IFNg productions when stimulated with IL-15. These results collectively suggest plasticity of mature NK cells.

P1.03.41
Cervical cancer cells treated with EGCG inhibitor induces changes in IFN-gamma, TNF-alpha and perforin secretion in NK-92 cells

***P. C. Ortiz-Lazareno**, A. Bravo-Cuellar, P. Gomez-Lomeli, G. Hernandez-Flores, J. R. Dominguez-Rodriguez, L. F. Jave-Suarez, A. Aguilar-Lemarroy;*
CIBO-IMSS, Guadalajara, Mexico.

Background: NK cells play an important role in virus-infected and tumor cells elimination. However the tumor cells are known to have several mechanisms as the expression of molecules that regulate the immune response like histidine decarboxilase (HDC). This enzyme may represent another resistance mechanism in cervical cancer cells.
Objectives: To analyze the HDC expression in HeLa, SiHa and C33A cervical cancer cells and to evaluate the IFN-gamma, TNF-alpha, granzyme-B and perforin NK-92 cells expression in tumor cells co-cultures.
Methods: The HPV+ HeLa and SiHa cervical cancer cell lines and HPV- C33A cancer cells were treated with EGCG (HDC inhibitor) and co-cultured with NK-92 cells at ratios 1:1, 1:10, 1:20 and 1:40. We evaluate the HDC expression in cancer cells and IFN-gamma, TNF-alpha, granzyme-B and perforin expression in NK-92 cells by flow cytometry.
Results: There are no significant changes in the expression of IFN-gamma, TNF-alpha, granzyme-B and perforin when the HeLa, SiHa and C33A cervical cancer cells were co-cultured with NK-92 cells.
Conclusions: The presence of the EGCG HDC inhibitor does not induce significant changes in IFN-gamma, TNF-alpha, granzyme-B and perforin expression in NK-92 cells, however there is a tendency to increase of IFN-gamma, TNF-alpha and granzyme-B expression when cervical cancer cells are treated with HDC inhibitor.

P1.03.42
Multidisciplinary approaches to enhance BRAF targeted therapy in Melanoma

***P. Pangigadde**[1,2], T. Tan[3], S. Ferrone[4], K. Karre[1], F. Colucci[3], E. Carbone[2,1];*
[1]Karolinska Institutet, Stockholm, Sweden, [2]University Magna Graecia of Catanzaro, Catanzaro, Italy, [3]University of Cambridge Clinical School, Cambridge, United Kingdom, [4]University of Pittsburgh Cancer Institute, Pittsburg, PA, United States.

Mutations in the BRAF gene have been found in cancers, including melanoma in 40-50% of patients with melanoma disease. About 80% of the BRAF mutations carry the V600E mutation. These patients are treated with BRAF inhibitors alone or in combination with other cell signaling pathway inhibitors. However, a relapse of the disease is observed within 6-8 months after the commencement of the therapy. Some studies hint that NK cell based therapy can be effective in controlling melanoma. In this study multidisciplinary approaches were tested to understand the mechanism of Vemurafenib resistance by a BRAFV600E melanoma. Vemurafenib is a BRAFV600E inhibitor. Vemurafenib resistant melanoma cell lines were raised from the sensitive cell lines by drug treatment till 80-90% of cells showed resistance. Both the resistant and sensitive cell lines were tested in a NK cell cytotoxicity assay in vitro by standard 51Cr-release assay. The Vemurafenib resistant cell lines were found to have a reduced sensitivity to NK cell killing. Though there was no significant difference in expression of NK cell activating ligands on the surface between the resistant and sensitive cell lines, there was a tendency of higher expression of MHC class I on Vemurafenib resistant cell lines. BRAF exon15 sequencing shows no difference between Vemurafenib resistant and sensitive cell types. Experiments are in progress to understand the mechanism(s) of the reduced sensitivity of the Vemurafenib resistant cell lines to NK cell killing.

P1.03.43
KIR2DS1-dependent acquisition of CCR7 and migratory properties by human NK cells interacting with allogeneic HLA-C2+ DC or T cell blasts

***S. Pesce**[1], S. Sivori[1], S. Carlomagno[1], L. Moretta[2], A. Moretta[1], E. Marcenaro[1];*
[1]Università degli Studi di Genova, Genova, Italy, [2]Istituto Giannina Gaslini, Genova, Italy.

Natural killer (NK) cells may capture the CCR7 chemokine receptor from allogeneic $CCR7^+$ cells by a mechanism termed trogocytosis and acquire migrating properties in response to the CCL19/CCL21 lymph node chemokines. This event is negatively regulated by inhibitory KIRs and NKG2A. In this study, we analyzed the role of activating KIRs in the process of CCR7 uptake in NK cells interacting with different types of allogeneic $CCR7^+$ cells. Analysis of freshly isolated peripheral blood NK cells and NK cell clones revealed that in $KIR2DS1^+$ alloreactive NK cells, co-cultured with $HLA\text{-}C2^+$ $CCR7^+$ lymphoblastoid cell lines, the interaction of KIR2DS1 with HLA-C2 (its ligand) resulted in increased CCR7 uptake. We show that KIR2DS1 represents a remarkable advantage for the acquisition of CCR7 also from $HLA\text{-}C2^+$ allogeneic DC and T cell blasts because of its ability to override inhibition by NKG2A. These findings have important implications in haploidentical haematopoietic stem cell transplantation in which donor-derived (alloreactive) $KIR2DS1^+$ NK cells upon acquisition of CCR7 become able to migrate towards lymph nodes, where they may kill patient DCs and T cells, preventing graft-versus-host and host-versus-graft reactions.

P1.03.44
Regulation of NKG2D and DNAM-1 ligand expression in HCMV infected fibroblasts: role of the DNA damage response pathway and of viral replication

***B. Pignoloni**[1], V. Dell'Oste[2], G. Gribaudo[3], M. Cippitelli[1], G. Malgarini[1], C. Fionda[1], A. Zingoni[1], S. Landolfo[2], A. Santoni[1], C. Cerboni[1];*
[1]Department of Molecular Medicine, Sapienza University, Rome, Italy, [2]Department of Public Health and Microbiology, University of Turin, Turin, Italy, [3]Department of Life Sciences and Systems Biology, University of Turin, Turin, Italy.

Human cytomegalovirus (HCMV) evolved several strategies to evade NK and cytotoxic T cells, including the specific down-modulation of ligands of the activating receptors NKG2D and DNAM-1. Despite this, we believe that there is a window of opportunity to develop an adequate immune response, during which activating molecules can be expressed as a consequence of viral-induced stress response, and before immune-evasion events occurs. To this purpose we focused on MICA, ULBP3 (NKG2DL) and PVR (DNAM-1L) expression, and investigated the role of the DNA damage response (DDR) and its central mediator ATM, that is crucial in the regulation of NKG2DL and DNAM-1L expression. Human primary fibroblasts (HFF) infected with the AD169 strain significantly increased MICA, ULBP3 and PVR expression. However, if infected cells were treated with caffeine, an inhibitor of ATM/ATR kinases, ligand up-regulation was prevented, demonstrating that the DDR pathway was crucial in regulating these activating molecules also in the context of HCMV infection. Notably, DDR was necessary for HCMV productive replication as well, since little or no infectious virus was recovered from caffeine-treated cells. Ligand up-regulation was however observed to be HCMV replication-independent, as demonstrated by using Foscarnet, an inhibitor of viral DNA elongation, and related to HCMV-mediated exit from G0/G1 phases of the cell cycle. We are currently addressing the involvement of early viral proteins in ligand up-regulation capable of modulating early events responsible for an effective immune response.

P1.03.45
Deletion of IL-33 receptor reduces NK cell and CD8 T cell responses to herpesvirus infection

B. Popovic[1]*, M. Milovanovic*[2]*, A. Krmpotic*[1]*, M. Lukic*[2]*, S. Jonjic*[1]*;*
[1]Faculty of Medicine, University of Rijeka, Rijeka, Croatia, [2]Center for Molecular Medicine and Stem Cell Research, Faculty of Medicine, University of Kragujevac, Kragujevac, Serbia.

Interleukin-33 (IL-33), a recently identified member of IL-1 cytokine family, serves as a ligand for the ST2 receptor (Schmitz et al, Immunity, 2005). Following pro-inflammatory stimulation, it is expressed in nonhematopoietic cells and released on cell necrosis as an alarmin. Although ST2 receptor is expressed by many cell types, its expression is highest on mast cells and activated T helper 2 (T_H2) cells where it participates in T_H2 immune responses by stimulating production of IL-5, IL-6, IL-13 and GM-CSF. NK and NKT cells also respond to IL-33 with increased IFN-γ production, suggesting its role in T_H1 immune response, as well (Smithgall et al, Int Immunol, 2008). Recently it was shown that IL-33 is necessary for CD8 T cell (CTL) responses to lymphocytic choriomeningitis virus (Bonilla et al, Science, 2012). We have studied the role of IL-33/ST2 signaling in murine cytomegalovirus (MCMV) infection and found that ST2-deficient mice had weaker NK cell and CTL responses to MCMV than control wild-type mice. These results suggest that IL-33 signals through ST2 receptor to amplify NK cell and effector T cell responses to virus infection. In spite of this, ST2-deficient mice showed normal MCMV control, indicating alternative mechanism induced in absence of ST2. Moreover, newborn ST2-deficient mice infected with MCMV showed much milder liver pathology compared to control mice, suggesting involvement of ST2 signaling in inflammatory response.

P1.03.46
Down-regulation of the NKG2D receptor is differentially controlled by MICA and ULBP2 ligands.

L. Quatrini[1]*, R. Molfetta*[1]*, F. Gasparrini*[1]*, C. Capuano*[2]*, A. Zingoni*[1]*, R. Galandrini*[2]*, A. Santoni*[1]*, R. Paolini*[1]*;*
[1]Department of Molecular Medicine, Sapienza University of Rome, Rome, Italy, [2]Department of Experimental Medicine, Sapienza University of Rome, Rome, Italy.

The activating NKG2D receptor on human NK cells mediates “induced self recognition” in that its ligands are up-regulated by stressed or diseased cells. Evidence collected in the past years demonstrated that chronic exposure to NKG2DLs induces receptor down-modulation.
The aim of this study was to evaluate whether different NKG2D ligands (NKG2DLs), namely MICA and ULBP2, are equivalent in their capacities to down-modulate the surface receptor expression on human NK cells.
We analyzed the rate and kinetics of NKG2D down-modulation in primary cultured NK cells and in the NKL NK cell line upon stimulation with the Ba/F3 cell line stably overexpressing comparable levels of MICA or ULBP2 by FACS and fluorescence microscopic analysis. Although both ligands were able to reduce NKG2D expression, exposure to MICA over-expressing target cells resulted in a more rapid and efficient receptor down-modulation and in a more pronounced impairment of NKG2D-dependent cytotoxicity. MICA-experienced NK cells also showed a higher tyrosine phosphorylation of the ubiquitin ligase c-Cbl. Furthermore, ligand-induced receptor down-modulation affected the total NKG2D cellular levels, suggesting that the internalized receptor complexes were mainly subjected to degradation.
All together these results demonstrate that NKG2D down-regulation is influenced by the nature of its ligand and suggest a different contribution of the ubiquitin pathway in the control of NKG2D internalization and degradation in MICA- versus ULBP2-experienced cells.
Understanding the mechanisms of ligand-induced NKG2D down-modulation will be helpful to prevent evasion from NK cell-mediated immune response.

P1.03.47
Expression of ligands for NK cell receptors NKG2D and DNAM-1 on drug-induced senescent Multiple Myeloma cells depends on redox signaling

B. Ricci[1]*, A. Soriani*[1]*, M. Iannitto*[1]*, C. Fionda*[1]*, M. Cippitelli*[1]*, S. Morrone*[2]*, M. Petrucci*[3]*, M. Ricciardi*[3]*, A. Santoni*[1]*;*
[1]Dept. Molecular Medicine - "Sapienza", University of Rome, Rome, Italy, [2]Dept. Experimental Medicine - "Sapienza", University of Rome, Rome, Italy, [3]Dept. Cellular Biotechnologies and Hematology - "Sapienza", University of Rome, Rome, Italy.

Natural Killer (NK) cells represent a key component of anti-tumor immune response exhibiting cytotoxic functions and secreting several cytokines and chemokines. Particularly relevant for tumor cell recognition are the activating receptors NKG2D that binds MICA/B and ULBPs, and DNAM1 that recognizes nectin/nectin-like molecules (Nec2 and NecL5/PVR).
We have previously demonstrated that NK cells exhibit an enhanced cytotoxic activity against drug-induced senescent Multiple Myeloma (MM) cells due to an increased expression of NKG2DLs and DNAM1Ls. Little is known about the mechanisms underlying the up-regulation of these ligands induced by genotoxic agents.
The present study is focused on the identification of the molecular mechanisms underlying NKG2DL and DNAM-1L drug-induced expression on MM cells with particular attention to the role played by changes in the cellular redox state.
Our data indicate that low doses of doxorubicin and melphalan can trigger the activation of DNA Damage Response (DDR) and up-regulate NKG2DLs and DNAM1Ls, both at protein and mRNA levels, in an ATM/ATR and Chk1/2-dependent and p53-independent manner. Exposure of MM cells to free radical scavenger N-Acetyl-L-Cysteine (NAC) abrogates DDR activation and senescent associated-cell cycle G2M arrest, induced by doxorubicin and melphalan. Moreover, drug-dependent NKG2DLs and DNAM1Ls induction is inhibited by NAC on both MM cell lines and patient CD138+ malignant plasma cells. Finally, we have demonstrated the involvement of E2F1 transcription factor in the redox signaling-dependent induction of MICA and PVR genes following drug treatment.
The finding of new players regulating NK cell activating ligands on tumor cells might provide novel immunotherapeutic tools.

P1.03.48
Tumour-Priming of Natural Killer Cells

M. S. Sabry*, M. W. Lowdell;*
University College London, London, United Kingdom.

Natural killer (NK) cells play an important role in host protection against pathogens and tumours by means of cell cytotoxicity and cytokine secretion. Similar to other lymphocytes, NK cells need to be primed in order to acquire their full effector functions, overcome any inhibitory signals and exhibit natural cytotoxicity against target cells. NK cells can be primed *in vitro* by incubation with an activating cytokine such as IL-2 or a target cell expressing the appropriate combination and intensity of ligands. We have data suggesting that cytokine priming of NK cells is physiologically different from tumour priming, and that CD2-CD15 interactions are part of the tumour-priming signal. Building on this work, we aim to complete NK cell activation profiles after cytokine and tumour stimulation, and identify the second component of the tumour priming signal by studying NK cell tumour interactions. Using this knowledge of the key components of NK cell activation, we aim to develop a protocol for the artificial priming of NK cells using antibody-coated beads. Translated in to the clinic, this novel approach would resolve some of the major issues in current standard therapies including complications in manufacturing and the dose limiting cytotoxicity.

P1.03.49
Association of activating kir genes with the late-onset crohn's disease

S. Samarani[1], *D. Mack*[2], *C. Bernstain*[3], *C. Deslandres*[1], *C. Faure*[1], *D. Amre*[1], *A. Ahmad*[1];
[1]*Chu ste-Justine, Montreal, QC, Canada,* [2]*Ottawa hospital, Ottawa, ON, Canada,* [3]*Manitoba hospital, manitoba, MB, Canada.*

Crohn's Disease (CD) is a chronic inflammatory disease affecting gastro-intestinal tract in humans. It is believed that the genetic make-up of an individual plays an important role in the development of this disease. Several genetic determinants implicated in innate immunity (e.g., NOD2/CARD15, IL-23R, etc) have been shown to be associated with CD. It is noteworthy that due to haplotypic differences, humans differ from each other .The receptors encoded by these genes tend to increase immune activation status of an individual. We report here that the activating KIR genes can be associated with the development of the late-onset (adult) CD in humans.We have performed a case-control study using two ethnically distinct cohorts of adult CD patients. The presence or absence of the activating KIR genes was determined by PCR using gene-specific primers. The data were analyzed using Chi-square, uni- and multi-variate logistic regression with STATA software (version 10).Our results show some changes of activating KIR genes in the adult CD patients compared with those of healthy subjects

P1.03.50
In vitro culture with IL-15 increases NK cell degranulation and enhances NK cell-mediated dendritic cell maturation

B. Sanchez-Correa[1], *J. M. Bergua*[2], *C. Campos*[3], *M. J. Arcos*[2], *H. Bañas*[2], *S. Morgado*[1], *S. Sanchez Mateos*[1], *J. J. Gordillo*[1], *J. G. Casado*[1,4], ***R. Tarazona***[1];
[1]*Immunology Unit, University of Extremadura, Caceres, Spain,* [2]*Department of Hematology, Hospital San Pedro de Alcantara, Caceres, Spain,* [3]*Immunology Unit, Instituto Maimonides para la Investigacion Biomedica de Cordoba (IMIBIC)-University of Cordoba-Hospital Reina Sofia, Cordoba, Spain,* [4]*Stem Cell Therapy Unit, Minimally Invasive Surgery Centre, Caceres, Spain.*

Natural Killer (NK) cells may play an important role in the immune response against hematological malignancies as demonstrated in the setting of stem cell transplantation. However, abnormal NK cytolytic function is observed in several hematological malignancies, including acute myeloid leukemia (AML) and myelodysplastic syndromes (MDS). Several mechanisms are involved in this abnormal function including a decreased expression of NKp46, NKp30 and DNAM-1 activating receptors.
The aim of this study was to restore the expression of NK cell activating receptors that are downregulated in patients with hematological malignancies. Therefore, we have analyzed in vitro the effect of IL-15, IL-2 and TGF-β on NK cell phenotype and function in healthy donors and in AML and MDS patients. Our results showed that, similar to IL-2, IL-15 increased the surface expression of NKp30 whereas the expression of NKp46 and DNAM-1 was not affected. In contrast, TGF-β induced a decrease of NKp30 and did not affect the expression of NKp46 and NKG2D. IL-15 activated NK cells displayed a higher degranulation in response to the erythroleukemic cell line K562. We also observed an increased capacity of IL-15 activated NK cells to induce dendritic cell (DC) maturation probably due to the increased expression of NKp30, a receptor involved in NK-DC interactions.
In conclusion, our in vitro model supports the role of IL-15 regulating NK cell cytotoxic function and improving NK cell capacity to induce DC maturation. Further studies are required for integrating IL-15 activated NK cells into NK cell-based immunotherapeutic strategies.

P1.03.51
Immunosuppressed pre-metastatic niches are caused by hypoxic tumour-derived factors

J. Sceneay[1,2], *M. T. Chow*[1,2], *D. D. L. Bowtell*[1], *M. J. Smyth*[1,2], *A. Moeller*[2];
[1]*Peter MacCallum Cancer Centre, Melbourne, Australia,* [2]*Queensland Institute of Medical Research, Brisbane, Australia.*

Hypoxia is a common feature and poor prognostic factor in many solid cancers including breast cancer. Within the primary tumour, hypoxia acts as a strong selective pressure that promotes angiogenesis, invasion and metastatic spread of tumour cells. The pro-tumourigenic properties of future metastatic sites are determined by the interactions between factors secreted by the primary tumour and bone marrow-derived immune cells, which drives formation of pre-metastatic niches before the arrival of tumour cells.
Here, we demonstrate in different immune competent, syngeneic orthotopic breast cancer models, that primary tumour hypoxia promotes pre-metastatic niche formation. Cell-free supernatant derived from hypoxic breast tumour cells results in increased bone marrow-derived cell infiltration into the lungs and leads to increased metastatic burden in breast and melanoma experimental metastasis models; suggesting reduced immune surveillance in pre-metastatic niches.
We define bone marrow-derived $CD11b^{+}/Ly6C^{med}/Ly6G^{+}$ myeloid and $CD3^{-}/NK1.1^{+}$ NK cell lineages as main constituents of the pre-metastatic niche, and show that NK cell cytotoxicity and maturity is decreased. The $CD11b^{+}/Ly6C^{med}/Ly6G^{+}$ population is defined as a granulocytic subset of myeloid cells with increased secretion of IL-1β and TNF; whose mobilisation and recruitment to the pre-metastatic niche is controlled by the systemic soluble factor MCP-1/CCL2 produced by hypoxic breast cancer cells. Furthermore, this subset shows potential to suppress NK cell function, creating an immune-suppressed environment allowing for tumour cell expansion and metastatic growth. This data demonstrates a pivotal role for tumour-derived factors to orchestrate the recruitment and activity of bone marrow-derived cells to create an immunosuppressed pre-metastatic niche.

P1.03.52
Characterization of activated and expanded natural killer cells for the use in cancer therapy

M. Granzin[1], *S. Müller*[1], *B. Gerstmayer*[1], *S. Tomiuk*[1], *A. Jacobs*[2], *B. Wollscheid*[3], *V. Huppert*[1], ***J. Schmitz***[1];
[1]*Miltenyi Biotec GmbH, Bergisch Gladbach, Germany,* [2]*Institute of Molecular Life Sciences, University of Zurich, Zurich, Germany,* [3]*Institute of Molecular Systems Biology (IMSB), NCCR Neuro Center for Proteomics, ETH Zurich, Zurich, Germany.*

Natural killer (NK) cells detect and eliminate tumor cells and can be used for immunotherapy of cancer. Ex vivo NK cell expansion is an option to improve their clinical utility (cell number, functionality) and here we investigated the effect of the expansion process on the NK cell phenotype.
Different mechanisms for NK cell activation and expansion were used, including co-cultivation with feeder cells or magnetic beads (MACSiBeads) loaded with antibodies against NK cell activating receptors. 500-3000-fold NK cell expansion after two weeks was reached by co-cultivation with feeder cells. Using MACSiBead-particles loaded with anti-CD2/CD335 antibodies resulted in an 8-47-fold NK cell proliferation. Primary and CD2/CD335 MACSiBead expanded NK cells of 24 donors were analyzed on the surfacome level by CSC technology in combination with total gene expression analysis. The combined proteotranscriptomic analysis revealed widespread qualitative and quantitative differences on the surfaceome level in-between primary and expanded NK cells. Genexpression analysis confirmed and amended the great differences between both populations. Out of the differentially expressed surface receptors in the gene expression and surfacome analysis, 30 markers were selected for investigation by flow cytometry. NK cells, expanded by loaded MACSiBeads or by co-cultivation with feeder cells, significantly change the expression of CD11b, CD39, CD45, CD54, CD56, CD71, CD83, CD109, CD314 and CD337.
Analysis of primary NK cells upon their activation and expansion ex vivo revealed significant differences indicating a change in their

function. Furthermore, the detected marker panels could be used for cellular barcoding of primary NK cells and their manufactured counterparts.

P1.03.53
Conserved cellular miRNA-viral mRNA interactions in influenza A/H1N1: a bioinformatical approach

***E. Seidel**, M. Seidel, O. Mandelboim;*
Hebrew University, Jerusalem, Israel.

Influenza A virus (IAV) is a public health threat which causes epidemics and global pandemics. It encodes two major surface antigens: hemagglutinin (HA), which mediates viral entry into cells; and neuraminidase (NA), enables virion budding. Because of their targeting by the immune system, HA and NA are poorly conserved. MicroRNAs (miRNAs) are ~22 nt long non-coding RNAs which suppress gene expression post-transcriptionally by base pairing with a seed site on the targeted mRNA. Although viral miRNAs are known to target cellular genes, the existence of the opposite interaction between cellular miRNA and viral RNA remains a controversial issue. We decided to conduct a wide search to check whether seed sites of lung-expressed miRNAs are conserved in a high percentage of Influenza A/H1N1 HA and NA genes. For this purpose, we utilized the target prediction algorithm RNAHybrid, combined with our own script "miRNAflu", to process ~5500 HA and ~8600 NA sequences from various influenza A/H1N1 strains. This approach enables us to overcome the problem of genetic variation in the viral genes, and permits us to focus on interactions relevant to the vast majority of A/H1N1 influenza strains for further study and experimental validation. Our search has identified several candidate miRNAs, such as hsa-miR-34a, a tumor suppressor which was predicted to target the area encoding the proteolytic cleavage site of HA; and hsa-miR-15a, also a tumor suppressor, predicted to target viral NA.

P1.03.54
Improvement of NK cells functional activation after long-term IL-2 stimulation in vitro from ovarian neoplasia patients

***R. F. Silva**;*
University of Campinas-UNICAMP, Campinas, Brazil.

Introduction: NK cells are lymphocytes known by their ability to eliminate a variety of malignant cells without previous stimulation, in a process involving innate recognition by an array of stimulatory and inhibitory receptors. NK-like T lymphocytes has also been reported to eliminate tumor cells, but the process might involve innate or adaptive recognition. We evaluated the functional activation of NK and NK-like T cells, the expression of activating receptors DNAM-1, NKp30 and NKp44 (pre, short- and long-term IL-2 stimulated), from blood and ascites of ovarian neoplasia patients.
Results: NK functional activation of pre stimulated cells, seemed to be impaired as the disease develops, median/variation (Bng=13.86/ 2.25-21.78; Mlg=9.57/ 6.48-12.96; MlgMt=7.73/ 3.65-10.06; Asc=6.99/ 1.68-21.68). Short-term stimulation increased NK cells activation (Bng=24.19/ 9.52-57.03; Mlg=24.49/ 8.69-52.37; MlgMt=17.59/ 9.28-35.63; Asc=33.54/ 3.83-43.50). Long-term stimulation increased NK cells activation significantly ($p<0.001$) (Bng=58.04/ 40.39-74.48; Mlg=46.61/ 33.89-54.76). The percentage of the activating receptors on NK cells increased significantly ($p<0.05$) after long-term stimulation. NK-like T cells showed no activation on pre, short- and long-term stimulation.
Conclusion: The functional integrity of NK cells was impaired as ovarian malignancies develop. Long-term stimulation resulted in a higher number of functional NK cells compared to short-term, entitling this method for adoptive therapy. Long-term stimulation was efficient to up-regulate DNAM-1 activating receptor on NK cells, representing a way to overcome down-regulation demonstrated on patients with ovarian carcinoma. The lack of activation of NK-like T cells (pre, short- and long-term IL-2 stimulated) suggests that these cells are not activated through innate pathway but through adaptive pathway.

P1.03.55
Role of HLA-I molecules on NK cells' phenotype and functions

***M. C. Sleiman**[1], N. Brons[2], T. Kaoma[3], F. Bernardin[3], J. Zimmer[1];*
[1]CRP-Santé, Laboratory of Immunogenetics-Allergology (LIGA), Luxembourg, Luxembourg, [2]CRP-Santé, Core Facility Flow Cytometry (CFC), Luxembourg, Luxembourg, [3]CRP-Santé, Genomic Research Unit (GRU), Luxembourg, Luxembourg.

TAP-deficiency is a rare disease characterized by chronic upper respiratory bacterial infections and granulomatous skin ulcers. It is caused by a mutation in the TAP-1 or TAP-2 gene, leading to a significantly low expression of MHC class I molecules on the cell surface, affecting the immune system functions notably Natural Killer (NK) cells. The interaction between NK cells' KIR (killer immunoglobulin-like receptors) and HLA class I molecules is known to play an important role in these cells' function and education. But the effect of HLA-I molecules on their receptors' acquisition is still not entirely elucidated.
Trying to give more insight to this question, we carried out a detailed analysis of different KIR, NKG2A, CD8 and CD57 in 7 TAP-deficient patients and a pannel of healthy donors (HD) using 15-color flow cytometry. Functional studies were performed (cytotoxicity, IFN-γ production and CD107a expression), followed by microarrays before and after their incubation with K562 cells.
Phenotyping showed a significant increase in KIR co-expression on CD8+NKG2A+ TAP-deficient NK cells compared to HD demonstrating an effect of HLA class I molecules' expression on their receptors' acquisition. Functional studies comfirmed NK cells' hyporesponsiveness in the studied patients except for one, whose functional NK cells present different recpetors' distribution compared HD.
As for the transcriptomic studies, microarrays revealed significant differences between HD and TAP-deficient NK cells before co-incubation, but a matched one after, an unexpected result for hyporesponsive NK cells.

P1.03.56
Impairment of natural killer cell function in HIV-1 infected individuals from Brazil

***L. S. Soares**[1], M. S. Espíndola[1], L. J. G. Lima[1], M. C. Cacemiro[1], C. Fontanari[1], L. H. Faccioli[1], S. K. Haddad[2], V. R. Bolela[2], F. G. Frantz[1];*
[1]University of São Paulo, FCFRP, Ribeirao Preto, Brazil, [2]University of São Paulo, FMRP, Ribeirao Preto, Brazil.

In HIV infection, natural killer (NK) cells have shown potential in the control of viral replication and in the host protection against opportunistic infections. However, multiple studies have described several dysfunctions associated with NK cells in HIV-1 infected people. Thus, the objective of our work is to characterize the phenotype and function of NK cells from a group of Brazilian HIV-1 infected patients who have not started antiretroviral therapy. Control samples were obtained from healthy blood donors. Peripheral blood mononuclear cells were isolated from individuals by density gradient and NK cell frequency was determined by flow cytometry. NK cell was obtained by magnetic separation using CD56+ MicroBeads and its function was evaluated by cytotoxicity assay. Our preliminary results suggest a reduction in the frequency of NK cells (CD3-CD56+) from HIV-1 infected individuals compared to control ones. NK cell subpopulations determined according to CD56 and CD16 expression are also diminished in HIV-1 patients. NK cell from HIV-1 infected people showed lower percentage of cytotoxicity compared to control when analyzed in different effector:target cell ratio. Despite of having CD4+T cells above 300 cells/mm3, these HIV-1 patients showed impaired NK cell function that could contribute to their state of immunosupression. So, we suggest that by also analyzing NK cell function and phenotype, we could have a better perception of the individual immune defense system. Therefore, this study will contribute in the comprehension of immune mechanisms related to HIV-1 infection. Financial support: FAPESP.

P1.03.57
Influence of age and pro-inflammatory state on the frequency of NK cells subpopulations

*C. Campos[1], A. Pera[1], B. Sanchez-Correa[2], S. Morgado[2], I. López[3], C. Alonso[1], R. Tarazona[2], **R. Solana**[1];*
[1]IMIBIC-Reina Sofia Hospital-University of Cordoba, Cordoba, Spain,
[2]Dpto. Inmunología. Universidad de Extremadura, Cáceres, Spain,
[3]Residencia Municipal de Ancianos de Torrecampo, Cordoba, Spain.

Several previous studies have show that NK cells are affected by the process of immunosenescence. In this study, we analyzed the effect of age and pro-inflammatory state on the frequency of NK cells subpopulations in elderly donors. We have also studied if CMV-infection affects the distribution of these subpopulations in young donors.
A total of 30 young donors (16 CMV-seropositive and 14 CMV-seronegative; age range 19-35) and 26 elderly donors (age range 72-91) were included. NK cell subpopulations defined by the expression of CD56 and CD16 were studied by multiparametric flow cytometry. CMV serostatus and the levels of C-reactive protein (CRP) were studied.
Our results did not show significant different in the frequency of NK cells from CMV+ and CMV- young donors, indicating that CMV infection seropositivity does not affect the frequency of NK cells in healthy young individuals.
An increased percentage of total NK cells was observed in elderly individuals compared with young. The percentage of CD56dimCD16+ subpopulation was maintained while the percentage CD56-CD16+ subpopulation was increased with age. The frequency of the CD56brightCD16- and CD56brightCD16low subpopulations was decreased. The frequency of CD56brightCD16- subpopulation in the elderly was inversely associated with the levels of CRP, indicating that the frequency of NK cell subpopulations changes with age and that these changes are more pronounced in elderly donors with pro-inflammatory state.

P1.03.58
NKG2D ligand expression in glomeruli correlates with renal NK cell infiltration in the MRL mouse model

***R. Spada**, S. Perez, D. F. Barber;*
CSIC/CNB, Madrid, Spain.

Natural killer (NK) cells are a major part of the immune system, and alterations in their activity have been correlated with various autoimmune diseases. The role of NK cells in the immunopathogenesis of systemic lupus erythematosus (SLE) is nonetheless poorly understood, with reports focusing mainly on NK cell reduction in the periphery of SLE patients. Using the MRL/MpJ and MRL/MpJlpr SLE-like murine models, we report here that NK cells are reduced only in the spleen and not in bone marrow of diseased mice. In addition, phenotypically immature NK cells accumulate in the spleen and bone marrow of diseased mice, which correlated with reduced degranulation of the CD107a protein. We also show a higher degree of NK cell infiltration in kidneys of diseased mice with a heightened glomerulonephritic state. The phenotype of kidney NK cells from diseased mice is more activated compared to healthy mice, suggesting a role for distinct microenvironments in different organs in regulating NK cells in this SLE-like model. Activatory receptor NKG2D ligands Rae-1 and Mult-1 were expressed in all MRL mouse glomeruli, and at higher levels in diseased mice. Increased NKG2D ligand expression in the glomeruli correlated with a higher number of NK and CD8+ cell glomerular infiltrate. These results suggest a role for NKG2D ligands and NK cells in the initiation and progression of glomerulonephritic lesions in SLE.

P1.03.59
Phenotypic and functional characterization of the CD56dimCD16lowNK cell subset in bone marrow and peripheral blood of healthy donors

***H. Stabile**[1], S. Morrone[2], D. Pagliara[3], F. Locatelli[3], A. Santoni[1], A. Gismondi[1];*
[1]Dept. Molecular Medicine University of Rome "Sapienza", Rome, Italy, [2]Dept. Experimental Medicine, University of Rome "Sapienza", Rome, Italy, [3]Dept. Pediatric Hematology/Oncology, Ospedale Pediatrico Bambino Gesù, Rome, Italy.

In this study, we have dissected the mature CD56 NK cell subsets based on the expression levels of CD16, one of the major NK cell activating receptor. We analyzed the phenotypic and functional profile of CD56brightCD16low, CD56brightCD16high, CD56dimCD16high and CD56dimCD16low NK cells in the peripheral blood (PB) and bone marrow (BM) from healthy donors who donated BM for transplantation. The results obtained indicated that CD56bright and CD56dimCD16low NK cells are more abundant in the BM with respect to the PB. Activating, inhibitory and cytokine receptors are expressed at lower levels on CD56dimCD16low NK cells with respect to CD56brightCD16low/high. CD56dimCD16low NK cells express higher levels of CXCR4, whereas have no detectable expression of CX3CR1 as compared to CD56dimCD16high NK cells. Unlike CD56dimCD16high, CD56dimCD16low NK cells, either from BM or PB, can release IFN-γ following cytokine stimulation and are the major cytotoxic NK cell population upon binding to K562 target cells as evaluated by degranulating or 51Cr release assay using sorted distinct NK cell subsets. CD56dimCD16low NK cells are able to degranulate also in response to NKp46 or NKp46 plus DNAM1 triggering although to a lesser extent with respect to CD56brightCD16high/low NK cells. Finally, sorted CD56dimCD16low NK cells acquire a CD56 and CD16 receptor profile similar to that of CD56brightCD16low/high following 7 day-culture in the presence of IL-12 plus IL-15.
All these data suggest that CD56dimCD16low NK cells are multifunctional cells that represent an intermediate differentiation stage between the CD56brightCD16low/high and CD56dimCD16high and can differentiate into CD56bright NK cells upon cytokine stimulation.

P1.03.60
CD28 and CTLA-4 are expressed by mouse NK cells and differentially control NK cell IFN-γ production in response to mature dendritic cells

***A. Stojanovic**[1], N. Fiegler[1], M. Brunner-Weinzierl[2], A. Cerwenka[1];*
[1]German Cancer Research Center (DKFZ), Heidelberg, Germany,
[2]Otto-von-Guericke University, Magdeburg, Germany.

The receptors CD28 and CTLA-4 are important regulators of T cell activation, differentiation and survival. Triggering of CD28 co-stimulates T cell receptor-mediated signals. CTLA-4 is induced in T cells upon activation and inhibits T cell function. Accordingly, immunotherapies incorporating blocking anti-CTLA-4 mAbs improve the clinical outcome of certain cancer patients. The role of CD28 and CTLA-4 in NK cells is incompletely understood. Here, we show that activation of mouse NK cells with IL-2 leads to upregulation of CD28 and induction of CTLA-4. Other cytokines, such as IL-12 and TGF-β, further modulate CD28 and CTLA-4 expression in NK cells. Furthermore, using gene-deficient NK cells, we demonstrate that CD28 induces and CTLA-4 inhibits IFN-γ release in response to the recombinant ligand, B7-1, or to mature dendritic cells. Importantly, we show that mouse NK cells infiltrating solid tumors of different origin express CTLA-4 that could have implications for immunotherapies based on blocking anti-CTLA-4 mAbs.

P1.03.61
CRACC-CRACC interaction enhances NK cell-mediated liver injury *via* Kupffer cells

***R. Sun**, Y. Li, Z. Tian;*
University of Science & Technology of China, Hefei, China.

CRACC is known as a critical activating receptor of NK cells. We previously reported a fulminant hepatitis model which is induced by Poly I:C/D-GalN and mediated by circulating NK cells. Since NKG2D is considered critical but not the only activating receptor in this model, we investigated the role of CRACC in this model. We found that CRACC was abundant on hepatic NK cells but with low degree of expression on Kupffer cells in normal condition. The CRACC expression on NK cells and also Kupffer cells was up-regulated remarkably by Poly I:C injection, and the ALT level of Poly I:C/D-GalN-treated mice was correlated to the increased CRACC mRNA expression of liver. After the expression of CRACC on Kupffer cells was specifically silenced by nano-particle encapsulated siRNA in vivo, the liver injury induced by Poly I:C/D-GalN was largely alleviated. In co-culture experiments, it was further verified that silencing CRACC expression or blockade of CRACC activation by mAb reduced the production of IFN-γ and TNF-α, a similar blocking effect on NKG2D-Rea1 recognition between NK cells and Kupffer cells by anti-NKG2D mAb. So, CRACC-CRACC interaction between circulating NK cells and resident Kupffer cells is also involved in Poly I:C/D-GalN-induced fulminate hepatitis.

P1.03.62
Immunoregulatory effects of Natural Killer cells in Multiple Sclerosis

***I. Tahrali**[1], U. Kucuksezer[1], E. Aktas Cetin[1], N. Okumus Akdeniz[1], A. Yilmaz[1], U. Uygunoglu[2], A. Altintas[2], G. Deniz[1];*
[1]Institute of Experimental Medical Research, Istanbul, Turkey, [2]Cerrahpasa Medical Faculty, Istanbul, Turkey.

Objectives: Multiple sclerosis (MS) is an autoimmune neural disease with inflammation, demyelination, axonal/neuronal loss and gliosis. Although the ethiology of the disease is not defined clearly, there are findings indicate the contribution of the immune system. Natural Killer (NK) cells have immunoregulatory role in the pathogenesis of autoimmune diseases, but the actual role of NK cells in MS pathology is not clear. The frequency
and effector functions of NK cells in different MS subgroups were investigated.
Methods: Surface expression of CD3, CD4, CD8, CD19, CD16 and CD56 were detected in peripheral blood samples, and peripheral blood mononuclear cells were cultured for 24 and 72 h in the presence and absence of hrIL-2, hrIL-4 & hr IL-12. After 24 h, IFN-γ, IL-10 and IL-22 contents of $CD56^{bright}CD16^{-}$ and $CD56^{dim}CD16^{+}$ NK cell subsets were measured by flow cytometry. NK cytotoxicity was measured using erythromyeloblastoid leukemia cell line K562, and the frequencies of NK cell subsets were detected after 72 h of culture.
Results: In comparison with healthy subjects, higher IL-10 and IL-22 levels in $CD56^{dim}CD16^{+}$ and $CD56^{bright}CD16^{-}$ NK cell were detected in MS patients. Cytotoxic activity of NK cells was significantly decreased in untreated patients with relapsing-remitting MS and clinically isolated syndrome.
Discussion: Increased IL-10 secretion by NK cell subsets in MS patients revealed that IL-10 might have a suppressive effect such as inhibiting synthesis of pro-inflammatory cytokines. In addition, increased cytotoxic activity of NK cells in untreated patients may indicate that NK cells could be associated with autoimmunity.

P1.03.63
NK cell degranulation against human melanoma cell lines is correlated with the expression of NKG2D ligands

*S. Morgado[1], B. Sanchez-Correa[1], J. G. Casado[1,2], F. Sierra[1], E. Durán[3], S. Sanchez Mateos[1], J. J. Gordillo[1], A. Pera[4], R. Solana[4], **R. Tarazona**[1];*
[1]Immunology Unit, University of Extremadura, Caceres, Spain, [2]Stem Cell Therapy Unit, Minimally Invasive Surgery Centre, Caceres, Spain, [3]Histology and Pathology Unit, University of Extremadura, Caceres, Spain, [4]Immunology Unit, Instituto Maimonides para la Investigacion Biomedica de Cordoba (IMIBIC)-University of Cordoba-Hospital Reina Sofia, Cordoba, Spain.

The role of Natural Killer (NK) cells in immune surveillance against tumours has been recently underlined. Recent studies have demonstrated the expression of ligands for activating NK cell receptors in tumour cells from different histological origin. The fact that NK cells exert their cytotoxic function without previous sensitization to antigen places these cells as a key component of the immune response against cancer. Melanoma cells can be recognized and killed by NK cells, however previous studies did not clarify if there is a major activating receptor implicated in NK cell activation against melanoma. Here we analyze the role of different activating receptors in NK cell activation against a wide range of melanoma cell lines with different ligand expression levels. We found a positive correlation between NK cell activation and the expression on melanoma cells of MICA/B, ULBP2 and ULBP3, ligands for NKG2D, and CD155, a DNAM-1 ligand. Our results point to NKG2D as the most important NK cell activating receptor involved in NK cell response against this tumour, with a cooperation with DNAM-1 and Natural Cytotoxicity Receptors (NCRs). Thus, DNAM-1 and NCRs participated in the recognition of melanoma cell lines with low expression of NKG2D ligands. We have also observed that shedding of soluble forms of MICA/B constitutes an escape mechanism frequently used by melanoma cells to avoid NKG2D-mediated recognition. In conclusion, our results support the participation of multiple receptor-ligand interactions in NK cell response to melanoma with a pivotal role for NKG2D.

P1.03.64
Phenotypic Evaluation of NK and NKT-like cells in peptic ulcer and gastric adenocarcinoma caused by Helicobacter pylori infection

***M. Tehrani**[1], A. Ajami[1], M. Shadman[1], A. Rafiei[1], H. Hussein-Nattaj[1], V. Hosseini[2], T. Taghvaei[2], H. Mesali[1], H. Asgarian[1];*
[1]Department of Immunology, Faculty of Medicine, Mazandaran University of Medical Sciences, Sari, Iran, [2]Department of Internal Medicine, Faculty of Medicine, Mazandaran University of Medical Sciences, Sari, Iran.

Background: The role of mucosal immunity in developing Helicobacter pylori-mediated dyspeptic disorders such as peptic ulcer and gastric adenocarcinoma has been recently identified. The aim of this study was to compare the proportion of NK cells and NKT-like cells in dyspeptic disorders caused by H. pylori infection.
Materials and methods: In a case-control study, 27 patients with gastric carcinoma (GC), 25 patients with peptic ulcer (PUD), and 22 patients with non-ulcer dyspepsia (NUD) were enrolled. After endoscopic diagnosis, the proportions of NK cells subsets (CD3-CD56+ and CD3-CD16+), as well as NKT-like cells (CD3+CD56+) were determined using a four-color flow cytometry. The presence of CD8+ and CD8-NK cell subsets in peripheral blood of all groups was also determined. Data were analyzed by CELL QUEST software.
Results: The frequencies of CD3-CD16+NK, CD3-CD56+NK, and CD3+CD56+NKT-like cells in GC patients infected with H. pylori significantly were lowered than those in NUD subjects ($p<0.01$, $p=0.05$, and $p=0.02$, respectively). Further analysis showed that a high number of CD8-NK cells in the blood was CD56+ and CD16+ phenotypes.
Conclusion: Decreased numbers of NK Cell and NKT-like cell populations in patients with gastric adenocarcinoma compared to those with non-ulcer dyspepsia may confirm the role of these cells as effector cells in dyspeptic disorders caused by H. pylori infection.

P1.03.65
Fluorescent tagged NK cell receptors expressed in vivo using retrogenic mice to study the delivery of signals in NK cells

***D. Tomaz**, N. Guerra, J. Dyson, K. Gould;*
Imperial College London, London, United Kingdom.

NK cells display both activating and inhibitory receptors which recognize different ligands, and it is the integration of signals from these two classes of receptors that ultimately determines NK cell effector activity. Nevertheless, how exactly the signal integration occurs is still not well understood.
Our approach is to employ retrogenic mice to generate authentic primary NK cells expressing two fluorescent tagged receptors, NKG2D (short or long isoform) and Ly49A, prototypical activating and inhibitory NK cell receptors, respectively. The aim is to use NKG2D-GFP/Ly49A-RFP Forster resonance energy transfer (FRET) to study the co-localisation of these receptors in synapses at NK-target cell-cell contact interfaces. Also, we will test the consequences of altering ligand dimensions in the synapse formation and NK cell activation.
Our results show that GFP-NKG2D (short and long isoform) interacts with both adaptor molecules DAP10 and DAP12 in vitro, allowing efficient cell surface expression of fluorescent NKG2D. Also, we reconstituted irradiated C57BL/6 recipients with GFP-NKG2D transduced bone marrow cells from NKG2D-deficient C57BL/6 donor mice. Two weeks post reconstitution, we detected cell surface expression of GFP-NKG2D predominantly in NK cells. The functionality of the fluorescent receptors and their interaction with the adaptor proteins DAP10 and DAP12 are now being investigated in NK cells generated in vivo. Data on the functionality of the fluorescent receptors and the generation of NK cells in retrogenic mice will be presented.

P1.03.66
MiR-10b downregulates the stress-induced cell surface molecule MICB, a critical ligand for cancer cell recognition by natural killer cells

***P. Tsukerman**, O. Mandelboim;*
Hebrew University, Jerusalem, Israel.

Natural killer cells (NK) are a component of innate immunity well known for their potent ability to kill virus-infected or neoplastically transformed cells following stimulation of the NK cell receptor NKG2D. One of the various ligands of NKG2D is MICB, a stress-induced ligand that has been found to be upregulated on the surface of tumor cells. However, there is little knowledge about how this upregulation may occur or how it may be selected against in tumors as a mechanism of immune escape. Here, we report that the metastasis-associated microRNA (metastamir) miR-10b directly binds to the 3' untranslated region of MICB and downregulates its expression. Notably, antagonizing miR-10b action enhanced NKG2D-mediated killing of tumor cells in vitro and enhanced clearance of tumors in vivo. Conversely, overexpression of miR-10b downregulated MICB and impaired elimination of tumor cells. Together, our results define MICB as a novel immune target of miR-10b, implying a direct link between metastasis capability and immune escape from NK cells

P1.03.67
Phenotypic and functional assays based on NK cells to address the diagnosis of X-linked lymphoproliferative disease 1

***C. Tuberosa**[1], R. Meazza[2], M. Falco[3], V. Cetica[4], C. Bottino[1,3], M. Aricò[4], M. Mingari[1,2], A. Moretta[1], L. Moretta[3], D. Pende[2];*
[1]University of Genoa, Genoa, Italy, [2]IRCCS A.O.U. San Martino-IST, Genoa, Italy, [3]Giannina Gaslini Institute, Genoa, Italy, [4]A.O.U. Meyer, Florence, Italy.

X-linked lymphoproliferative disease 1 (XLP1) is caused by mutations in SH2D1A (Xq25) encoding a 14kDa adaptor protein known as signaling lymphocyte activation molecule (SLAM)-associated protein (SAP). SAP is expressed in NK and T lymphocytes. When SAP is mutated, SLAM receptors (e.g. 2B4) recruit phosphatases leading to inhibitory instead of activating signaling. For diagnosis we combined SAP expression with cytotoxic assays to detect the paradoxic function of 2B4. We evaluated a group of twelve XLP1 patients in comparison to healthy controls. Intra-cytoplasmic staining of healthy PBL with anti-SAP 1C9 mAb showed a range of 4±36 mean ratio fluorescence intensity (MRFI). No staining was found in ten patients (MRFI=1). Interestingly, a weak staining (MRFI=3) was observed in one patient characterized by a missense mutation, described to shorten the half-life of the protein. Another patient showed a normal pattern of SAP expression (MRFI=8), as also confirmed by transiently transfecting HEK-293T cells with plasmid encoding this mutated SAP. A rapid functional assay was set-up using short term IL-2 activated PBMC effector cells against the FcγRc+ P815 target cells and anti-2B4 mAb (R-ADCC). Confirmatory assays was performed using purified NK effector cells expanded in culture. While in control cells anti-2B4 mAb always induced enhancement of killing, in XLP cells from all patients (including SAP+ sample) an inhibition was observed. Thus, 1C9 mAb can stain a mutated protein with abnormal function, indicating that both assays should be performed to correctly address the diagnosis. The status of female carrier was also studied.

P1.03.68
Establishment of a humanized mouse model to investigate the impact of mixed xenogeneic hematopoietic chimerism on the tolerance of human NK cells to pig cells

***P. Vishwasrao**[1], H. Li[1], M. Hölzl[1], G. Choi[2], M. Sykes[1];*
[1]CCTI, New York, NY, United States, [2]Amsterdam Medical Center, Amterdam, Netherlands.

Mixed hematopoietic chimerism permits durable tolerance of T, B and NK cells to xenoantigens in a rat to mouse bone marrow transplant model. However, it is unclear whether tolerance of human NK cells to pig xenoantigens can be induced by mixed hematopoietic chimerism. We assessed the tolerance of human NK cells towards pig cells in a humanized mice model with established pig and human mixed xenogeneic chimerism.
Pig and human mixed chimeras (MCs) were generated by injection of young pig bone marrow cells to irradiated pig cytokine (IL3, GMCSF and SCF) transgenic NOD-scid common gamma chain knockout (NSG) mice transplanted with cryopreserved human fetal thymic tissue under the kidney capsule. They received anti-CD2 antibody and human fetal liver CD34+ cells from the same donor. Hydrodynamic injection of plasmids encoding human IL-15 and Flt3L was performed to promote human NK cell reconstitution. About two weeks post-injection of plasmids, NK cells from MCs were analyzed for their cytotoxic responses to pig cells using a chromium release assay.
Expression of human IL-15 and Flt3L led to an increase in the total number of human NK cells in lymphoid tissues, including peripheral blood, liver, spleen and bone marrow on Day 12 post-injection. Splenic human NK cells from the plasmid-injected MCs were able to kill K562 cells and xenogeneic pig lymphoblasts with or without ex vivo stimulation by human IL-2. Preliminary data suggest that human NK cells from MCs are not tolerant to xenogenic pig cells in vitro following IL-2 activation.

P1.03.69
The human cytomegalovirus induces the CEACAM1 expression to escape immune elimination

***A. Vitenshtein**, O. Mandelboim;*
Hebrew University, Jerusalem, Israel.

Human Cytomegalovirus (HCMV) employs numerous and diverse strategies to evade immune recognition and destruction. Here we show that HCMV induces CEACAM1 (Carcino Embryonic Antigen Cell Adhesion Molecule 1) expression on the cell surface of infected fibroblasts. The CEACAM1 induction was very rapid with induction of both short and long intracellular domain isoforms of CEACAM1, the latter comprising two ITIM (Immuno Tyrosine Inhibitory Motif) domains. Additionaly, the CEACAM1 upregulation was specific as it was not observed with fibroblasts infected with other dsDNA species such as Adeno and HSV viruses. Previous studies have established that CEACAM1 functions as an immunoinhibitory molecule via homotypic interactions and that those interactions suppress

CEACAM1 positive T cell and NK cell functions. Indeed we show that the upregulation of CEACAM1 on infected fibroblasts inhibited the cytotoxic activity of CEACAM1+ NK cells and further demonstrated that around 50% of all NK cells derived from various donors express CEACAM1 following activation. Finally we demonstrate that a component prepackaged into the HCMV viral particle directly triggers the CEACAM1 expression in infected cells and initial screening experiments ruled out several important viral components.

P1.03.70
The Rac activator DOCK2 regulates natural killer cell-mediated cytotoxicity through the lytic synapse formation

T. Yanagihara[1,2]*, Y. Sakai*[1,2]*, Y. Tanaka*[1,2,3]*, Y. Fukui*[1,2,3]*;*
[1]Division of Immunogenetics, Medical Institute of Bioregulation, Kyushu University, Fukuoka city, Japan, [2]Japan Science and Technology agency, CREST, Tokyo, Japan, [3]Research Center for Advanced Immunology, Kyushu University, Fukuoka city, Japan.

Natural killer (NK) cells play an important role in protective immunity against viral infection and tumor progression, but also contribute to rejection of bone marrow grafts, via contact-dependent cytotoxicity. Ligation of activating NK receptors with their ligands expressed on target cells induces receptor clustering and actin reorganization at the interface, and triggers polarized movement of lytic granules to the contact site. Although activation of the small GTPase Rac has been implicated in NK cell-mediated cytotoxicity, its precise role and the upstream regulator remain elusive.
In this study, we show that DOCK2, an atypical guanine nucleotide exchange factor (GEF) for Rac, plays a key role in NK cell-mediated cytotoxicity. We found that, although DOCK2 deficiency in NK cells did not affect conjugate formation with target cells, DOCK2-deficienct NK cells failed to kill effectively leukemia cells in vitro and MHC class I-deficient bone marrow cells in vivo, regardless of the sorts of activating receptors. In DOCK2-deficient NK cells, NKG2D-mediated Rac activation was almost completely lost, resulting in a severe defect in the lytic synapse formation. Similar results were obtained when the Rac GEF activity of DOCK2 was selectively abrogated. These results indicate that DOCK2-Rac axis controls NK cell-mediated cytotoxicity through the lytic synapse formation.

P1.03.71
Dimerization of NKp46 receptor is essential for NKp46-mediated lysis: characterization of the dimerization site by epitope mapping

R. Yossef*, M. Jaron-Mendelson, A. Porgador;*
Ben-Gurion university of the Negev, Beer-Sheva, Israel.

NKp46 is a primary activating receptor of natural killer (NK) cells that is involved in lysis of target cells by NK cells. Previous studies showed that the membrane-proximal domain of NKp46 (NKp46D2) retained the binding of NKp46 to its ligands and is involved in lysis. We studied NKp46D2 by employing a peptide-based epitope mapping approach and identified an NKp46D2-derived linear epitope that inhibited NKp46-mediated lysis. The epitope, designated as pep4 (AA 136 to 155), interacted with NKp46 and lysis by NK cells was inhibited by the presence of pep4. Through modeling and mutagenesis we showed that it could be involved in NKp46 homodimerization. R145 and D147 contribute to the function of pep4 and R145Q mutation in recombinant NKp46 reduced its binding to target cells. At the cellular level, FRET analysis revealed that pep4 is indeed involved in dimerization of cell membrane-associated NKp46. We suggest that NKp46-derived pep4 site is part of the dimerization surface of NKp46 and that NKp46 dimerization contributes to NKp46-mediated lysis by NK cells.

CD2/CD3/CD28 stimulation augments Granzyme B-dependent tumor clearance of Ph+ B-Acute Lymphoblastic Leukemia by ex-vivo expanded human iNKT cells

C. A. Alves de Araujo*, W. Luszczek, C. Calabrese, G. Neale, A. Seth, A. Pillai;*
St Jude Children's Research Hospital, Memphis, TN, United States.

Innate invariant natural killer T (iNKT) cells are regulatory and cytotoxic and play critical roles in tumor surveillance. Here we report mechanisms to augment these effector functions in human CD3+Vα24+ iNKT cells. PBMC were stimulated with alpha-galactosylceramide (α-GalCer) and human IL-2 and IL-7. CD3+Vα24+ cells were sorted to >98% purity (day 7), co-cultured with irradiated allogeneic PBMC feeders with IL-2 and IL-7, and resorted at day 21 for functional assays including Luminex® 26-plex array, mRNA profiling, BADTA® cytotoxicity, and in vivo Nalm6 leukemia xenograft clearance under different iNKT stimulation conditions. iNKT cells robustly expanded (mean day 21 yield $6.7x10^6 \pm 0.8x10^6$ from $8.9x10^3 \pm 0.6x10^3$ day 0 iNKT) from n = 49 total blood donor apheresis units. Day 21 anti-CD2/CD3/CD28-stimulated iNKT cells expressed significant IL-4, IL-5, IL-13, GM-CSF and IFN-γ by Luminex® and high levels of GranzymeB and FasL by FACS and mRNA profiling. Day 21 iNKT cells displayed cytotoxicity against Ph+ Nalm6 B-ALL but not K562 myeloblasts in BADTA® assays which augmented by iNKT activation with anti-CD2/CD3/CD28 (mean±SEM 60.8%±2.8) versus α-GalCer (11.5%±5.0), when compared to unstimulated day 21 iNKT cells (11.0%±4.1). Inhibition of GranzymeB with Z-AAD-CMK abrogated iNKT cytotoxicity against Nalm6 in vitro (16.5% ± 2.8). Anti-CD2/CD3/CD28 stimulated day 21 iNKT cells without but not with Z-AAD-CMK pre-treatment induced clearance of Nalm6 xenografts by bioluminescent imaging compared to vehicle and unstimulated day 21 iNKT-treated controls. These findings identify a specific mechanism to optimize cytotoxic function of expanded human iNKT cells, identifying novel strategies to apply them in immunotherapy of high-risk B-ALL.

P1.04.02
Interaction between iNKT and B-1 cells after P.acnes adjuvant stimulus

L. Butin*, M. Gambero, M. E. Ishimura, D. Teixeira, A. C. Keller, I. M. Longo-Maugeri;*
Unifesp, São Paulo, Brazil.

The invariant natural killer T lymphocytes and B1 cells participate in the early stages of the innate immunity migrating to inflammatory focus and modulating adaptative response. iNKT TCR recognizes glycosphingolipid presented via CD1d expressed in antigen presenting cells (APC), and is able to secrete a large number of cytokines. B1 are predominant in the peritoneal and pleural cavities, and simultaneously express macrophage and lymphocyte markers. B1 are able to derive into phagocitic cells, and also show APC function. The interaction between both cells is poorly understood, mainly under antigen or adjuvant stimuli. Killed-Propionibacterium acnes increases the absolute number of CD3+NK1.1+, B1 and macrophages in mice peritoneal cavity. Herein we studied the adjuvant effect of P. acnes on the interaction between B1 and iNKT. BALB/c, BALB/cXid and BALB/cJalpha18-/- were treated with one i.p. injection of killed-P. acnes or saline. After 24 hours, the peritoneal frequencies of B1 and iNKT were analysed by flow cytometry. We also evaluated CD1d expression on B1 and CD44 and CD69 in iNKT related with APC function and activation respectively.
P.acnes increased both iNKT and B1 cells in WT mice and also elevated iNKT CD69 expression when compared to controls. In absence of B1 bacteria didn't modify the absolute number of iNKT but increased its CD69 expression and decreased CD44 levels. In the absence of iNKT, P.acnes didn't increase the number of B1 or its CD1d expression. Our results suggest that the adjuvant effect of P.acnes in both iNKT and B1 depends on the interaction between them.

P1.04.03
Phenotypic and functional dynamics of invariant Natural Killer T ($CD3^+6B11^+$iNKT) cells in patients with tobacco-related oral carcinoma

A. K. Singh, N. K. Shukla, ***S. N. Das****;*
All India Institute of Medical Sciences, New Delhi, India.

Invariant natural killer T (iNKT) cells are glycolipid-reactive T lymphocytes that share receptors and functions with natural killer (NK) cells, and reportedly play a pivotal role in various immune responses. We for the first time report abnormalities in iNKT cell, their proliferative response to lipid ligand, Th-like cytokine profile and antitumor response from patients with tobacco-related oral carcinoma (OSCC) using multi-color flow cytometry and MTT assays.
iNKT cells were significantly lower (p<0.004) in patients as compared to healthy donors and further showed significant decrease (p<0.01) in patients with late stage (III & IV) as compared to the early stage (I & II) tumors. The subsets analysis from peripheral blood revealed a marked decrease in $CD4^-CD8^-$ (double negative, DN) and concomitant increase in $CD8^+$ subset in patients as compared to healthy donors. OSCC patients showed impaired proliferative response to α-GalCer and reduced expression of IFN-γ and IL-4. However, *in vitro* activation with α-GalCer-pulsed DCs tended to restore both IFN-γ and IL-4-expression and increased cytotoxicity to human oral (SCC-4, KB) and breast cancer (MCF7) cell lines.
Results of the present study suggest that reduced frequency and skewed cytokine production by iNKT cells may be related to progression and dissemination of OSCC. Selective expansion and modulation of their functions by specific ligand/agonist may enhance their therapeutic potentials.

P1.04.04
Role of excessive thymic differentiation of RORgt+NKT17 cells in the pathogenesis of autoimmune diabetes

C. Di Pietro*, A. Rezzonico, M. Fedeli, G. Casorati, M. Falcone;*
San Raffaele Scientific Institute, Milan, Italy.

Invariant NKT cells (iNKT) represent a unique subset of innate lymphocytes that play a crucial role in autoimmune diseases by exerting pro-inflammatory or regulatory functions. Conventional NKT cells act as regulatory cells in autoimmune diseases and their αGalCer-induced activation prevent pre-clinical models of Type 1 Diabetes (T1D) and Multiple Sclerosis (EAE). Recently, a new subset of NKT cells characterized by predominant secretion of IL-17 (NKT17 cells) and strong pro-inflammatory function was identified but its role in the pathogenesis of autoimmune diseases like T1D is still unclear. Here we show that the NOD mice have a significant increase in the percentages of NKT17 in the periphery (p<0.05) and in the thymus (p<0.001). The increase percentage of NKT17 in the NOD mice compared to control strains is particularly evident in the thymus where 30-40% of total αGC-CD1d-dim+ CD3+ NKT cells are IL-17+ (NKT17 cells) against 2-5% in the control strains. While conventional NKT cells down-regulate RORγt expression when maturing from stage 0 to stage 1 in the thymus, in the NOD mice a large percentage of thymic NKT cells maintain RORγt expression and are blocked in the maturation stage 1 (CD24-, CD44low). RORγt expression and NKT17 cell differentiation are negatively regulated by the transcription factor Th-POK. We are currently testing the hypothesis that epigenetic factors (miRNAs) that control Th-POK expression are altered in the NOD mice. Moreover, we are investigating whether the large number of NKT17 cells present in the periphery of NOD mice contributes to the pathogenesis of autoimmune diabetes.

P1.04.05
Interleukin-7 Receptor α-dependent thymopoiesis regulates thymic invariant natural killer T cell retention

M. B. Drennan*[1], F. Pattyn[1], S. Govindarajan[1], K. De Wilde[1], S. Schlenner[2], C. Ware[3], S. Nedospasov[4], H. Rodewald[5], D. Elewaut[1];*
[1]Ghent University, Ghent, Belgium, [2]University of Leuven, Leuven, Belgium, [3]La Jolla Institute for Allergy and Immunology, La Jolla, CA, United States, [4]Engelhardt Institute of Molecular Biology, Moscow, Russian Federation, [5]German Cancer Research Center, Heidelberg, Germany.

Invariant natural killer T cells (iNKT) represent an innate T cell lineage that differentiate in the thymus and are responsive towards lipid antigens. Seeding of the peripheral compartment is accompanied by gradual retention of mature iNKT cells in the thymus, however, the mechanisms governing thymic iNKT cell retention are poorly understood. We show that a chemotactic profile associated with active iNKT cell emigration is skewed towards retention in mice deficient for lymphotoxin β (LTβ). The requirement for LTβ was found to be non cell-autonomous and independent of LTαβ expression within the majority of mature hematopoietic and stromal cell lineages. Surprisingly, IL-7Rα-dependent fetal thymopoiesis was found to regulate iNKT cell retention in a manner coincident with secondary lymphoid organ formation. We propose that thymic iNKT cell retention in adult mice is a functional consequence of IL-7Rα-dependent thymopoiesis in the developing thymus organ.

P1.04.06
Difluoro substituted CD1d ligands as optimal adjuvants for the priming of multifunctional CD4 T cells

Y. Gao*[1], B. Linclau[2], S. Gadola[1], T. Elliott[1], A. Williams[1];*
[1]Southampton General Hospital, University of Southampton, Southampton, United Kingdom, [2]School of Chemistry, University of Southampton, Southampton, United Kingdom.

The differentiation of naïve T cells to distinct effector populations is central to the development of effective immune responses. We developed an in vitro assay to study CD4 naïve T cell commitment to effector cell differentiation with the purpose of investigating the influence of different adjuvants. We analysed compounds known to have distinctive Th1:Th2 biasing influences and as well 2 novel CD1d glycolipid ligands, engineered for increased binding affinity and activation of human invariant NKT cells.
We studied the naïve T cell differentiation at day 10, in healthy controls following co-culture of whole blood with index adjuvants for 24 hours and transfer of WB supernatants to CD3/CD28 bead activated naïve CD4 T cells.
In the absence of adjuvant the default differentiation pathway was biased to Th1, with a Th1:Th2 ratio of 5:1 and a Th1:Th17 ratio of 25:1. In cultures with the toll like ligands R848 the Th1:Th2 ratio increased to 10:1 whilst the Th1:Th17 reduced to 20:1. The Th2 adjuvant alum generated a 1:1 Th1:Th2 ratio and 2:1 Th1:Th17 response. In the presence of the prototypic iNKT glycolipid, α-Galactosylceramide, a 3:1 Th1:Th2 and 2:1 Th1:Th17 response was seen. Finally, one of our novel difluoro glycolipid compounds (43) gave a unique profile with a 1:1 Th1:Th2 and 5:1 Th1:Th17 response whilst another (44) gave a enhanced pattern compared to α-GalCer with a 2:1 Th1:Th2 and 5:1 Th1/Th17 response. Biomarker correlates of novel adjuvants may provide a useful adjunct to vaccine design strategies for distinct pathogen targets requiring bespoke effector responses.

P1.04.07
Dynamics of iNKT cell-mediated provision of B cell help for antibody production

Y. G. Ghnewa*, G. S. Zeng, V. G. Lyons, D. G. Doherty;*
Trinity College Dublin, Dublin, Ireland.

Human invariant natural killer T (iNKT) cells can provide help for antibody production by B cells. We investigated the molecular interactions, ligand and cytokine requirements, and B cell subtypes affected during provision of human B cell help by expanded and

sorted $CD4^+$, $CD8\alpha^+$ and $CD4^-CD8\alpha^-$ iNKT cell subsets *in vitro*. All subsets of iNKT cells, in the absence of the iNKT cell agonist glycolipid, α-galactosylceramide (α-GC), induced IgG, IgM and IgA production by B cells within 10 days of co-culture. Antibody production was prevented by separation of the cells using transwell systems or by antibody blocking of CD1d, but not by blocking IL-4, IL-13 or CD40-CD154 interactions. Phenotypic analysis indicated that all iNKT cell subsets induced the expansion of marginal zone-like ($IgD^+IgM^+CD27^+$) unswitched memory B (MZB) cells but not switched memory B cells, suggesting that iNKT cells do not promote antibody isotype switching. All iNKT subsets induced the expression of CD40, CD69, and IL-21 receptor by B cells. A minority (~2%) of iNKT cells expressed follicular helper T cell (T_{FH}) markers including CXCR5, PD-1 and IL-21 but T_{FH} cells were not expanded by culture with B cells. Interestingly, addition of α-GC to the iNKT-B cell co-cultures did not lead to enhanced B cell activation in any of the above-mentioned assays. These data suggest that $CD4^+$, $CD8\alpha^+$ and $CD4^-CD8\alpha^-$ iNKT cells can activate and induce expansion of MZB cells and antibody production by isotype switched B cells by a mechanism that requires CD1d but not exogenous glycolipid antigen.

P1.04.08
iNKT cells can promote differentiation of B cells into cells with regulatory B cell phenotypes

***Y. G. Ghnewa**, G. S. Zeng, V. P. O'Reilly, D. G. Doherty;*
Trinity College Dublin, Dublin, Ireland.

Human B cells express CD1d and therefore are likely to present glycolipid antigens to iNKT cells. We previously found that iNKT cells can provide help for antibody production by B cells *in vitro,* but that the iNKT cell agonist glycolipid, α-galactosylceramide (α-GC) was not required. Here we investigated if B cells could present α-GC to expanded iNKT cells *in vitro* and if α-GC-stimulated iNKT cells could reciprocally activate the B cells. Since iNKT cells comprise functionally-distinct subsets based on CD4 and CD8α expression, we analysed the effects of co-culturing sorted $CD4^+$, $CD8\alpha^+$ and $CD4^-CD8\alpha^-$ double negative (DN) iNKT cells with B cells. B cells were capable of presenting α-GC to $CD4^+$ and DN (and to a lesser degree $CD8\alpha^+$) iNKT cells resulting in IFN-γ, TNF-α, IL-4, IL-5 and IL-13 secretion by iNKT cells. However, B cells were 10-200-fold less efficient than DC at inducing cytokine production by iNKT cells. Culture of B cells with $CD4^+$ or DN iNKT cells resulted in the expansions of cells with regulatory B cell (B_{REG}; $CD1d^{hi}CD5^+$, $CD24^{hi}CD38^{hi}$) phenotypes and $CD4^+$ iNKT cells promoted IL-10 production by some B cells, without the need for α-GC. These results suggest that human iNKT cells can differentially control adaptive immune responses, depending on whether or not stimulatory glycolipid ligands are present. In the presence of α-GC, human B cells can weakly activate iNKT cells, resulting in Th1 and Th2 cytokine secretion. In the absence of α-GC, some iNKT cell subsets can promote differentiation of B cells into B_{REG} cells.

P1.04.09
Effective stimulation of invariant natural killer T cells by oligomannose-coated liposomes

***M. Ishii**, N. Kokima;*
Tokai University, Hiratsuka, Japan.

The invariant natural killer T (NKT) cells recognize glycolipid antigens presented by CD1d on antigen presenting cells, DCs, and α-galactosylceramide (αGC) has been used as an exogenous ligand for CD1d to stimulate NKT cells. Although systemic administration of αGC produces anti-tumor effects, soluble αGC induced anergy in NKT cells. Therefore, establishment of a method to deliver αGC adequately to DCs is required. Since DCs express number of mannose-recognized C-type lectins, decoration of αGC-formulated particles with oligomannose is promising approach for preferential delivery of αGC to DCs. However, such attempts have not yet been undertaken. The current study showed that oligomannose-decorated, αGC-formulated liposomes (αGC-OMLs) could activate NKT cells much more effectively both in vitro and in vivo than liposomes without coating oligomannose (αGC-BLs).

Splenocytes stimulated with αGC-OMLs in vitro produced higher levels of IFN-γ compared to those stimulated with αGC-BLs. The ratio of IFN-γ/IL-4 produced from an αGC-OML-treated cells was higher than those produced from αGC-BL-treated cells. αGC-OMLs were incorporated into splenic DCs and BMDCs more effectively than αGC-BLs. NKT cells stimulated with αGC-OML-treated BMDCs produced more significant levels of IFN-γ from NKT cells than αGC-BL-treated BMDC.
Systemic administration of αGC-OMLs led to modification of the kinetics of IFN-γ production in vivo. In addition, iNKT cells proliferated and expanded upon administration of αGC-OMLs much more extensively than with αGC-BLs or soluble αGC. Collectively, our results suggest that αGC-OMLs can be used as a preferential delivery system for lipid antigens to DCs to activate iNKT cells in vivo and ex vivo.

P1.04.10
Sterol carrier protein 2 is required for the maturation of iNKT cells and their stimulation by endogenous lipids

***L. Mori**[1,2], F. Facciotti[2], G. S. Ramanjaneyulu[2], R. B. Chan[3], M. R. Wenk[3], U. Seedorf[4], G. De Libero[1,2];*
[1]SIgN, Singapore, Singapore, [2]Department of Biomedicine, University Hospital Basel, Basel, Switzerland, [3]National University of Singapore, Singapore, Singapore, [4]University of Münster, Münster, Germany.

The development and maturation of semi-invariant Natural Killer T (iNKT) cells rely on recognition of self-antigens presented by CD1d-restriction molecules within thymus. An important class of peroxisome-derived lipids are self-antigens required for generation of full iNKT cell repertoire.
The lipid transfer protein Sterol carrier protein 2 (SCP-2) shuttles lipids between peroxisomes, ER and mitochondria, and is involved in the synthesis of ether-bonded lipids. Mice lacking SCP-2 have reduced numbers of iNKT cells in thymus and in peripheral organs. Residual iNKT cells from Scp2-/- mice are functionally normal as well as the antigen-presentation capacity of thymocytes and dendritic cells. Endogenous lipids of Scp2-/- mice differ from those of wild-type mice and stimulate iNKT cells less efficiently than endogenous lipids from wild-type mice. The reduced iNKT cell number is the consequence of altered proliferation and increased apoptosis of maturing thymocytes causing partial block in selection processes. Thus, SCP-2 is important in shaping the lipid antigen repertoire required for the generation of normal numbers of iNKT cells.

P1.04.11
Octaarginine-modified liposomes enhance α-galactosylceramide based antitumor therapy

***T. Nakamura**, D. Yamazaki, J. Yamauchi, H. Harashima;*
Faculty of Pharmaceutical Sciences, Hokkaido University, Sapporo, Japan.

Alpha-galactosylceramide (αGC), a lipid antigen presented on CD1d molecules, is predicted to have clinical applications as a new class adjuvant, because αGC strongly activates natural killer T (NKT) cells. Moreover, there is very little individual difference between T cell receptors of NKT cells, that is, the effect would be similar, irrespective of patient. Although αGC therapy has prominent advantages, an intravenous administration of soluble αGC did not result in measurable clinical benefits. Thus, an efficient delivery system is needed to achieve efficient αGC therapy by systemic injection. Here, we incorporated αGC into stearylated octaarginine-modified liposomes (R8-Lip) which is our original delivery system for vaccine, and investigated the effect of nanoparticulation. Unexpectedly, systemic administered R8-Lip incorporating αGC (αGC/R8-Lip) failed to improve the immune responses mediated by αGC compared with soluble αGC in vivo, although αGC/R8-Lip drastically enhanced αGC presentation on CD1d in antigen presenting cells in vitro. Thus, we optimized αGC/R8-Lip in vivo to overcome the inverse correlation. In optimization in vivo, we found that size control of liposome and R8-modification were critical for enhancement of the production of IFN-γ. The optimization led to accumulation of αGC/R8-Lip in the spleen and therapeutic effect against highly malignant B16 melanoma cells. The optimized αGC/R8-Lip also enhanced αGC presentation on CD1d in

antigen presenting cells and expanded the population of NKT cells. Herein, we shows that R8-Lip is a potent delivery system, and size control and R8-modification in liposomal construction are promising techniques for systemic αGC therapy.

P1.04.12
Roles of NKT cells in human gastric cancer

C. H. Ribeiro[1], *F. Cristi*[1], *G. Pérez*[1], *K. Kramm*[1], *M. Bustamante*[1,2], *F. Gálvez*[1], *M. Garrido-Tapia*[1], *C. J. Hernández*[1], *J. C. Aguillón*[1,3], *M. C. Molina*[1];
[1]*University of Chile, Santiago, Chile,* [2]*Hospital del Salvador, Santiago, Chile,* [3]*Millennium Institute on Immunology and Immunotherapy, Santiago, Chile.*

Natural killer T (NKT) cells are a small subset of T lymphocytes that participate in both, innate and adaptive immune responses. Once activated, they release large amounts of cytokines that regulate cellular immune responses. Although NKT cells contribute to tumor immunosurveillance in several disease settings, they can also act as suppressors of anti-tumor immunity. In gastric cancer, the second most common cause of cancer death worldwide, the role of NKT cell functions still remains to be established. Using flow cytometry, we studied the frequency and cytokine production by circulating NKT cells in patients with gastric adenocarcinoma. The cytotoxic activity of NKT cells challenged with gastric adenocarcinoma cell lines was evaluated by CD107a degranulation assays. Patients with gastric cancer showed a significantly increased percentage of peripheral NKT cells. Upon PMA-Ionomycin stimulus, we detected a lower percentage of NKT cells that produce IFN-γ, while a higher frequency of NKT cells that secrete IL-10 was found in the blood of gastric cancer patients as compared to healthy donors. Peripheral NKT cells from patients presented compromised cytotoxic function towards gastric adenocarcinoma cells as compared to controls. Tumor infiltrating NKT cells could be detected, which also expressed IL-10. Our results suggest that, by promoting a tumor-associated suppressive microenvironment, the regulatory function of NKT cells in gastric cancer may dampen the anti-tumor immune response, thus contributing to tumor evasion. The mechanisms that trigger the regulatory effects of NKT cells in gastric adenocarcinoma are under our current investigation.

P1.04.13
CD1d-restricted invariant natural killer T (iNKT) cells mediate airway inflammation through IL-25 and IL-18

H. Watarai[1,2];
[1]*Riken Research Center for Allergy and Immunology, Yokohama, Japan,* [2]*PRESTO, Japan Science and Technology Agency, Tokyo, Japan.*

iNKT cells are characterized by their expression of an invariant T cell receptor (TCR) that recognizes glycolipid antigen presented by MHC class I-like molecule CD1d. Another distinguishing feature of iNKT cells is their promiscuous production of Th1, Th2, Th9 and Th17 cytokines. Here we identified iNKT cells consist from distinct functional subtypes based on the expression of IL-17 receptor B (IL-17RB), a receptor for IL-25/IL-17E: IL-17RB+ iNKT cells are “helper”-like cells and produce robust IL-13 and IL-9 with moderate IL-4, IL-10, IL-17A and IL-22 in response to IL-25, which is phenotypically and functionally distinct from classical IL-12-reactive IFN-γ-producing iNKT cells bearing CD122 without IL-17RB. In the in vivo experimental settings, IL-17RB+ iNKT cells play a crucial role in the induction of airway inflammation both of OVA (allergen) and of RSV (virus infection) model. Interestingly, however, the recruited and activated effector cells in a chronic phase were completely different between these two models: eosinophils and neutrophils in OVA, and macrophages in RSV. Through the elucidation of the mechanisms in a different type of activation of IL-17RB+ iNKT cells, IL-18 instead of IL-25 is responsible for the activation of these cells in RSV model, resulting in an acute and robust production of Th2 and Th17 cytokines. Our findings reveal that IL-17RB+ iNKT cells and leading effector cells as target cells of IL-25 and IL-18 in the pathogenesis of airway diseases, illustrating the clinical potential of severe exacerbation of developing asthma by IL-17RB+ iNKT cell-dependent cellular cascade targeted therapy in humans.

P1.04.14
Signal control of iNKT development and effector lineage differentiation

X. Zhong, *S. Wang, J. Shin, J. Wu;*
Duke University Medical Center, Durham, NC, United States.

The type I or invariant NKT iNKT) cells are among the first responders in various infectious and inflammatory settings and bridge innate and adaptive immunity. iNKT cells quickly producing numerous cytokines such as IFNγ, IL-17, IL-4, IL-13, and IL-10 to regulates innate and adaptive immune responses. iNKT cells contribute to the pathogenesis of allergy and asthma, autoimmune diseases, graft-versus-host disease, infections, cancer, and obesity as well as other diseases. While it is well established that the iVα14 T cell receptor and IL-15 receptor and numerous transcription factors are critically involved in iNKT cell development and effector lineage differentiation, the signaling events bridging the receptors and the transcription factors are poorly understood. We have recently demonstrated that diacylglycerol kinases α and ζ play crucial roles in iNKT cell development and that DGKα and ζ negatively control not only the well-known Ras-Erk1/2 and PKCθ-IKK-NFκB pathways but also mTOR signaling in T cells. We now reveal that mTOR signaling and its tight regulation play crucial roles in iNKT cells as deficiency of either mTOR or its regulator TSC1 profoundly impacts iNKT cell development and effector lineage differentiation.

P1.05 Innate lymphocytes

P1.05.01
Role of γδ T cells in neuronal injury

K. Derkow, *C. Krüger, S. Lehnardt;*
Charite Universitätsmedizin Berlin, Berlin, Germany.

Γδ T cells are an important innate source of IL-17. IL-17-producing γδ T cells were found at high frequency in brains of mice suffering central nervous system (CNS) injury. APC-derived IL-23 stabilizes and expands IL-17 production by γδ T cells. Toll-like receptors (TLRs) expressed in microglia, the brain’s resident macrophages, are involved in various CNS diseases. To investigate the crosstalk between microglia activated by TLRs, γδ T cells and neurons experiments in co-cultures of these cell types isolated from wildtype mice were performed. In a first step, IL-17+ γδ T cells generated in vitro were co-cultured with neurons. The presence of increasing numbers of IL-17+ γδ T cells but not supernatant alone or naive γδ T cells led to a time-dependent decrease of neuronal viability. Secondly, supernatants of microglia stimulated by ligands specific for TLR2, 4, 7 or 9 but not TLR3, induced activation of γδ T cells indicated by up-regulation of CD69 and CD25 as well as down-regulation of CD62L. Also, γδ T cells cultured with microglia-derived supernatant secreted high amounts of IL-17. Direct stimulation of γδ T cells with TLR ligands did not up-regulate CD69, CD25 or IL-17. In summary, TLR-activated microglia secrete factors promoting polarization towards IL-17+ γδ T cells. Direct cell-cell contact is necessary for neurotoxic effects mediated IL-17+ γδ T cells. The exact mechanism by which microglia recruit naïve and induce IL-17+ γδ T cells remains to be determined.

P1.05.02
IL-22 promotes bacteria-driven colon cancer

F. Franchini, *S. Kirchberger, N. West, D. J. Royston, F. M. Powrie;*
University of Oxford, Oxford, United Kingdom.

There is now abundant evidence that chronic inflammation can promote tumorigenesis and patients with inflammatory bowel disease have an increased risk of developing colitis-associated cancer (CAC). Although inflammatory pathways that drive colitis are well-described

much less is known about the cellular and molecular mechanisms that induce and sustain cancerous lesions in the intestine.
Using a mouse model of CAC in which 129.RAG-/- mice were infected with Helicobacter hepaticus (Hh) and treated with the carcinogen 2-azoxymethane (AOM), we found that the treated mice develop invasive adenocarcinoma after 5 months, which was shown to be dependent on a colonic Innate Lymphoid Cell population (cILC). These cells accumulated in treated mice compared to uninfected controls and produced interleukin-17 (IL-17) and interleukin-22 (IL-22). Depletion of cILCs and blocking of IL-22 reversed established invasive adenocarcinoma and inflammation. Morever, we were able to show that IL-22 was driving STAT3 phosphorylation in colonic epithelial cells and promoted secretion of anti-microbial peptides as well as cell proliferation.
Transfer of regulatory T cells (Tregs) deficient for interleukin-10 markedly exacerbated the tumour-promoting inflammatory response suggesting dysregulated repair mechanisms may promote bacteria-driven cancer in a genetically susceptible background.

P1.05.03
B1 cells provide immunosurveillance of healthy and inflamed skin

***S. A. Geherin**, M. H. Lee, R. P. Wilson, G. F. Debes;*
University of Pennsylvania, Philadelphia, PA, United States.

B1 cells are innate-like lymphocytes that provide important effector functions during infection and inflammation by rapidly secreting pro- and anti-inflammatory cytokines and efficiently mounting T cell-independent (TI) antibody responses. Despite their importance, however, the migratory paths, target organs, and trafficking molecules involved in B1 cell migration are poorly-defined. Our comparative studies in humans, mice, and sheep reveal that innate-like B1 cells are a so far uncharacterized part of the normal cutaneous immune system. In addition, we find that B1 cells, unlike conventional follicular B2 cells are efficiently deployed into the inflamed skin. Consistent with this, B1 cells and follicular B cells differentially express trafficking molecules. One such differentially expressed molecule is α4β1 integrin (VLA-4), which is required for B1 cell entry into the inflamed skin and other effector sites. As VCAM-1, the endothelial binding partner of α4β1 integrin, is upregulated in most inflammatory responses, the data suggest that B1 cells are universally recruited into sites of inflammation. In summary, the data support a model in which B1 cells, through the constitutive expression of inflammation-seeking homing molecules, are poised to migrate into barrier sites, such as the skin, and to sites of inflammation, where they rapidly provide innate effector functions, including production of TI antibodies, cytokines, and antimicrobial factors, and fulfill a so far unappreciated role in skin immunity.

P1.05.04
Activating receptor engagement elicits inflammatory signatures in RORγt+ innate lymphoid cells

***T. Glatzer**[1], M. Killig[1], I. Ommert[1], M. Luetke-Eversloh[1], M. Babic[1], D. Paclik[1], J. Gröne[2], J. Meisig[3], K. Stölzel[4], C. Romagnani[1];*
[1]German Rheumatism Research Center, Berlin, Germany, [2]Chirurgische Klinik und Hochschulambulanz I, Charité Universitätsmedizin Berlin, Berlin, Germany, [3]Institute of Theoretical Biology, Humboldt Universität, Berlin, Germany, [4]HNO-Klinik, Charité Universitätsmedizin Berlin, Berlin, Germany.

RORγt+ innate lymphoid cells (ILC) are crucial players of innate immune responses and represent a major source of IL-22, which has an important role in host defense against bacterial infection, mucosal wound healing, and intestinal epithelial cell homeostasis. Although expression of IL-22 by ILC was shown to be protective in inflammatory bowel disease (IBD), RORγt+ ILC can also produce pro-inflammatory cytokines and contribute to the pathogenesis of IBD. The signals required by RORγt+ ILC to express IL-22 and/or pro-inflammatory cytokines have been elucidated only partially. Here we show that RORγt+ ILC can directly sense the environment by the engagement of activating receptors (actR). Activating receptor triggering in RORγt+ ILC selectively activates a coordinated pro-inflammatory program, including TNF, while cytokine stimulation preferentially induces IL-22 expression. However, combined engagement of activating and cytokine receptors results in a strong synergistic effect. These data support the concept that actR+ RORγt+ ILC can be activated without cytokines and are able to switch between IL-22 or TNF production, depending on the triggering stimulus.

P1.05.05
The regulatory effect of IL-4 on the anti-tumor immune response mediated by human γδ T cells

*Y. Mao, J. Zhang, Y. Hu, L. Cui, N. Kang, **W. He**;*
Institute of Basic Medical Sciences, Chinese Academy of Medical Sciences, and School of Basic Medicine, Peking Union Medical College, Beijing, China.

IL-4 has been shown to affect a number of immune processes such as Th cells differentiation and innate immune responses. However, the impact of IL-4 on γδ T cell responses remains unclear. In this study, we investigated the effects of IL-4 on the activation and proliferation of γδ T cell and the balance between Vδ1 T cell and Vδ2 T cell in human. We demonstrated that IL-4 inhibited the activation of γδ T cell in the presence of γδ TCR stimulation in a STAT6-dependent manner. However, IL-4 had growth-promoting effect on the activated γδ T cells. Furthermore, IL-4 polarized γδ T cells toward Vδ1 T cells, which in turn inhibited the growth of Vδ2 cells through the secretion of large amount of IL-10. In addtion, IL-4 can downregulate the expression of NKG2D of Vδ1 T cell. Compared to Vδ2 T cell, Vδ1 T cell secreted much less IFNγ and more IL-10 and had relatively low NKG2D expression in the presence of IL-4. Therefore, Vδ1 T cells bias weakened the overall anti-tumor immune response mediated by γδ T cells. Our results established for the first time a thoroughly negative regulatory role of IL-4 in γδ T cell-mediated anti-tumor immunity. Selective depletion of IL-4 or Vδ1 T cells in tumor tissue may be beneficial for tumor immune therapy.

P1.05.06
Intestinal epitherial NK cells produce α-defensin, but convetional NK cells do not

***T. Hori**, N. Nagaoka, M. Yamamoto, M. Ando, S. Matsumoto;*
Yakult Central Institute, Tokyo, Japan.

NK cells are the innate lymphoid cells and retain functions such as anti-tumor and anti-viral activity. Recent studies show that $NKp46^+$ NK-like cells exist in lamina propria and play an important role to maintain gut homeostasis. There are several reports that NK-like cytolytic activity was confirmed in small intestinal IELs. However, the function of these NK-like IELs is still not known. This study aimed to reveal the role of NK-like IELs in the small intestine (si-NK). We prepared both si-NK and splenic NK cells (sp-NK) which defined as $CD3^-CD49b^+NK1.1^+$ cells from C57BL/6 mice. After fixation, we observed them under TEM. Thereafter we compared cytolytic activity of both NK cells. Finally, we compared the gene expressions of both NK cells by microarray. Morphologically, si-NK had more granules than sp-NK. The cytolytic activity of si-NK was lower than that of sp-NK. As a result of microarray, *Itgae* in si-NK (590-fold) and *vcam1* in sp-NK (1750-fold) were highly expressed respectively. No significant differences of gene expressions were found between si-NK and sp-NK in terms of cytolysis. A typical difference was the gene expressions of bactericidal peptides. The gene expressions of *Defa1* and *a3* in si-NK were much higher than those in sp-NK (1920 and 3350-fold) and furthermore, there were some cells stained with anti-αDef3 antibody in si-NK but not sp-NK subset. These results suggested that anti-microbial activity in addition to cytolytic activity is the new property of the function of si-NK.

P1.05.07
TCRγδ signal activation is required to overcome inhibition by ubiquitin ligase Cbl-b during γδT cell cytotoxicity

*S. Yin, J. Zhang, L. Cui, Y. Hu, **N. Kang**, W. He;*
Institute of Basic Medical Sciences, Chinese Academy of Medical Sciences, and School of Basic Medicine, Peking Union Medical College, Beijing, China.

T cell antigen receptor γδ (TCRγδ) and natural killer group 2, member D (NKG2D) are two crucial receptors for γδT cell cytotoxicity. Compelling evidences suggest that γδT cell cytotoxicity is TCRγδ dependent and can be costimulated by NKG2D. However, the molecular mechanism of underlying TCRγδ dependent activation of γδT cells remains unclear. In this study, we demonstrated that TCRγδ but not NKG2D engagement induced lytic granule polarization and promoted γδT cell cytotoxicity. TCRγδ activation alone was sufficient to trigger Vav1-dependent phospholipase C-γ1 (PLC-γ1) signaling, resulting in lytic granule polarization and effective killing, whereas NKG2D engagement alone failed to trigger cytotoxicity-related signaling due to the inhibitory effect of Cbl-b on Vav1. However, NKG2D ligation augmented the activation of γδT cell cytotoxicity through the Vav1-PLC-γ1 pathway. Vav1 overexpression or Cbl-b knockdown enabled NKG2D alone to induce γδT cell cytotoxicity. Taken together, these results suggest that the activation of γδT cell cytotoxicity requires a strong signal to overcome a signaling threshold set by the inhibitory effect of Cbl-b. Our finding provides new insights into the molecular mechanisms underlying the initiation of γδT cell cytotoxicity and likely implications for optimizing γδT cell-based cancer immunotherapy.

P1.05.08
Innate lymphoid cells mediate IL-33 dependent fibrosis

***T. Mchedlidze**[1], S. Pflanz[2], M. Schuchmann[3], M. Neurath[1], S. Wirtz[1];*
[1]Medical Department 1, Erlangen, Germany, [2]Gilead, Foster City, CA, United States, [3]Medical Clinic 1, Mainz, Germany.

Liver fibrosis, an accumulation of connective tissue due to an imbalance between production and degradation of extracellular matrix proteins, can be triggered by tissue damage by virtue of various causes like infection, drugs, metabolic disorders or immune attack. In case of persistent or recurrent damage signal fibrogenesis might progress towards cirrhosis, liver failure or hepatocellular carcinoma. Nowadays hepatic fibrosis is considered as a world-wide health problem, although no accepted anti-fibrotic agents are available in routine clinical use.
We found significant upregulation of IL-33, the alarmin-like cytokine in three independent models of mouse liver fibrosis: chemically induced (CCL4, TAA), infection related (S.mansoni) and cholestatic one (Bile duct ligation). Moreover analysis of human cirrhosis patients showed elevated secreted IL-33 in serum as well as protein level in liver. Using IL-33-/-, IL-33R-/- mice, a conditional IL-33 transgenic mouse strain and a novel DNA minicircle-based liver specific in vivo overexpression system, we demonstrate that IL-33 is sufficient to drive to excess extracellular matrix deposition in liver. This profibrotic function of IL-33 is mediated by IL-13-secreting liver resident type 2 innate lymphoid cells (ILC2). Moreover, we show that ILC2-derived IL-13 is acting through type II IL-4R-dependent STAT6 signaling, leading to hepatic stellate cell activation, and herewith represents the critical downstream cytokine of IL-33-dependent tissue remodeling and fibrosis. We suppose that IL-33 and its signal-associated pathways have considerable role in the development of hepatic fibrosis and therefore our findings may have important implications for therapeutic interventions across wide range of fibrotic diseases.

P1.05.09
Morphologic, flow cytometric, functional, and molecular analyses of S100B positive lymphocytes, unique cytotoxic lymphocytes containing S100B protein

***Y. Miki**[1], Y. Gion[2], Y. Mukae[3], A. Hayashi[4], K. Takahashi[2];*
[1]Kagawa prefectural University of Health Sciences, Kagawa, Japan, [2]Okayama University, Okayama, Japan, [3]Kawasaki College of Allied Health Professions, Okayama, Japan, [4]Okayama Red Cross Hospital, Okayama, Japan.

Little is known about the $S100B^+$ lymphocytes, which are unique human peripheral blood lymphocytes (PBL) containing the S100B protein. It has recently been shown that S100B is released from various types of $S100B^+$ cells and exhibits varied cytokine-like activities. In this study, we precisely characterized the $S100B^+$ lymphocytes of healthy adults with respect to the proportion in the whole PBL, immunophenotypes, function, and their S100B mRNA expression and also evaluated their S100B-releasing activity upon stimulation. $S100B^+$ lymphocytes were detected in all individuals examined, and the proportion of $S100B^+$ lymphocytes in the whole PBL ranged from 0.42 to 16.15% (mean 4.21%). In addition, two subtypes of $S100B^+$ lymphocytes, CTL subtype ($CD3^+$ $CD8^+$ $CD16^-$) and NK subtype ($CD3^-$ $CD8^-$ $CD16^+$) were detected. The majority of the CTL subtype of $S100B^+$ lymphocytes expressed the αβ-T cell receptor. Surprisingly, S100B mRNA was detected not only in $S100B^+$ lymphocytes, but also in every $S100B^-$ lymphocytes, although the expression levels of S100B mRNA in S100B- lymphocytes were much lower than those of $S100B^+$ lymphocytes. The CTL subtype of $S100B^+$ lymphocytes exhibited blastic morphological changes, proliferated and released S100B upon stimulation with PHA. The NK subtype of $S100B^+$ lymphocytes exhibited morphological NK activity when co-cultivated with NK-sensitive target, K-562 cells. Thus, the CTL subtype $S100B^+$ lymphocytes exhibit the biological characteristics of T cells, while the NK subtype $S100B^+$ lymphocytes exhibit the characteristics of NK cells. These results suggest that $S100B^+$ lymphocytes are a particular subtype of cytotoxic lymphocytes that play a unique role in anti-tumor immunity.

P1.05.10
Type I Interferon signaling in a mouse de novo glioma model

***T. Ohkuri**, A. Ghosh, A. Kosaka, J. Zhu, M. Ikeura, S. C. Watkins, H. Okada, S. N. Sarkar;*
University of Pittsburgh Cancer institute, Pittsburgh, PA, United States.

We have previously demonstrated the protective role of type I interferon (IFN) signaling against glioma progression using a clinically relevant de novo mouse glioma model. However, the molecular factors responsible for inducing the IFN response (“sterile infection”) remain elusive. Here we report our initial findings on in vivo induction of IFN and its effects on glioma microenvironment. When we induced de novo glioma by Sleeping Beauty (SB) system in mice transgenic for IFNβ promoter-driven yellow fluorescence protein (YFP), robust YFP signals were detected in brain of the mice. Analysis of brain-infiltrating leukocytes showed CD11b+ myeloid cells expressed high levels of type I IFN. Furthermore, The CD11b+ myeloid cells upregulated expression levels of type I IFN by stimulating with glioma-derived genomic DNA via partially STING. In experiments using transgenic mice for loxP-tomato-loxP-EGFP/Mx1-Cre, whose cells turn from RFP+ to GFP+ after receiving IFN-signal, we observed approximately 50% of glioma-infiltrating lymphocytes turned into EGFP+ in the glioma microenvironment. Moreover, in CD4+ T-cells, EGFP+ cells expressed lower levels of Foxp3 and TGF-β1 than RFP+ cells. And in CD8+ T-cells, EGFP+ cells expressed higher levels of Tbx21 and IFN-γ and showed higher cytotoxicity than RFP+ cells. This suggests that type I IFN-signal would directly confer antitumor activity on T-cells in vivo. These demonstrate that use of the SB-induced de novo glioma model in these transgenic mice allow us to determine how type I IFN signals operate glioma development. Furthermore, these models will likely contribute to development of type I IFN-enhancing therapeutic strategies for gliomas.

P1.05.11
Insight into interaction innate immune response: Role for Asn40Asp allele of OPRM1 gene

***A. Pal**, S. Kapur;*
Birla Institute of Technology and Science Pilani- Hyderabad Campus, Hyderabad, India.

A functional immune system depends on the appropriate activation and proliferation of lymphocytes following antigen encounter, and this results in modulation of both innate (cellular) and acquired immune (humoral) responses. Present knowledge of interactions between opiates and the immune system is based on pharmacological studies and several mechanisms have been proposed for this interaction. Administration of opioids that bind to the classical mu opioid receptor has been shown to lead to unintended alterations in immune function, namely, immunosuppression. A growing body of evidence indicates that A118G polymorphism of the mu opiate receptor shows association with increased survival rates in breast cancer as well as use of opiate drugs for anticancer therapy. Recent evidence shows that activation of the opiate signaling plays a critical role in maintaining cell differentiation and loss of signaling results in cell proliferation. Taking a cue from the above report the present study was undertaken to understand the role of mu opiate signaling and the effect of A118G mutation (rs1799971) on cell proliferation. Our results show that an alteration of the allele from A to G leads to an arrest in cell cycle. As immune responses are a function of clonal expansion of immune cell types this mutation will result in an altered signaling causing arrest in cell cycle progression and hence lower immune response leading to immunosuppression. Indeed a decrease in circulating immunoglobulin levels and increased incidence of opportunistic infections in subjects following use of opioid drugs has been reported by several groups including ours.

P1.05.12
Human B-1 cell frequency and aging from cord blood to the elderly

***A. A. Pourfathollah**, M. Jazayeri;*
Tarbiat Modares university, Tehran, Iran.

B-1 cells play a crucial role in innate immune responses. They are also involved in the pathogenesis of autoimmune diseases through producing natural auto-antibodies. The present study was aimed at determining the percentage of B-1 cells in blood samples of different Iranian age groups.
Blood samples were obtained from 7 separate groups comprising cord blood, under one year old, 2-12, 13-19, 20-39, 40-64 and over 65 years old normal individuals. The samples were assessed for the percentage of B-1 cells using two-color CD5/CD19 flowcytometry. Furthermore, the correlation between B-1 frequency and aging was evaluated using generalized additive model (GAM).
B-1 cell frequency was significantly higher in cord blood and blood samples obtained from under one year old infants compared with other groups. Under one year old infants possessed the highest levels of B-1 cells in their peripheral blood. Furthermore, B-1 cell percentage diminished with advancing age. This is the first study to present a detailed evaluation of B-1 cell frequency in seven human age groups and revealed that the percentage of B-1 cells in the human blood varies at different age intervals. Moreover, aging inversely affected B-1cell frequency so that the blood samples from the elderly contained the lowest number of B-1 cells which could result in a more susceptibility to certain diseases. A better understanding of age-dependent impacts on human B-1 cell frequency would shed new light on the exact role these cells play in human diseases.

P1.05.13
An innate-like CD4+ T cell expressing complement receptor 1

***B. Reilly**[1], K. Rasberry[1], J. Atkinson[2];*
[1]Texas Tech, Lubbock, TX, United States, [2]Washington University SOM, St. Louis, MO, United States.

CD35, also known as the C3b/C4b or immune adherence receptor, has the widest range of activities of any of the complement regulatory proteins and functions in immune complex clearance, inhibition of complement activation, phagocytosis and humoral immunity. Previous studies have shown that CD35 is on a minor (6 to 12%) population of human thymocytes and peripheral blood CD4+ T cells. It has not been determined whether this receptor marks a separate thymic-derived T cell lineage or whether its expression is inducible. Given the importance of both complement and T cells to immune homeostasis, we examined the basis for CD35 expression on CD4+ T cells. We found a small number (1 to 3%) of CD35+ cells in more than one subset of CD4+ T cells, with the largest number (4 to 8%) being present within the naïve cell population. Also, when labeled T cells were activated by TCR cross-linking, the division index was almost twice that of the CD35- T cells, with no intra- or extracellular expression of CD35 in the CD35- population. The faster response rate, coupled with the absence of inducible expression and less dependency on IL-2, suggests that CD35+ T cells are physiologically unique with innate-like capabilities. They may develop separately from conventional CD4+ T cells and play a prominent role during the induction phase of a T cell response to targets opsonized with C4b and C3b.

P1.05.14
The C-terminal region of the Activation Induced Cytidine Deaminase (AID) is required for the gene conversion and mediates the end joining during class switch recombination

***S. Sabouri**, M. Kobayashi, T. Honjo;*
Graduate School of Medicine, Kyoto University, Kyoto, Japan.

Activation-induced cytidine deaminase (AID) is essential factor for the class switch recombination (CSR) and somatic hypermutation (SHM) of Immunoglobulin genes. To complete CSR, it is speculated that the C-terminal region of AID is necessary for synapse formation between Sμ and an appropriate S region. Among several C-terminal mutants, P20 which has 34 amino acid insertion at 182th amino acid residue, preserves NES and shuttles between nucleus and cytoplasm. Moreover, P20-mediated SHM is observed, although CSR efficiency is remarkably low.
In order to gain insight into the mechanism of AID in DNA repair and find out which end joining (EJ) pathway is involved in P20 mediated CSR, we analyzed junction microhomology mediated by P20 between Sμ and Sγ1 regions of AID-/- spleen B cells infected by P20. Interestingly, we found that most of the sμ-sγ1 junctions in P20 cells favour longer microhomology compared to the wtAID over-expressed cells. This finding is strongly further supported by the reduced level of C-NHEJ factors and essential synapsis factors at the Sμ region in C-terminal mutant JP8Bdel cells.
Gene conversion (GC) is another event which requires AID. Therefore, we tested the involvement of the AID C-terminus region in GC. Our sequencing data using DT40 cells over-expressing P20 also shows that the C-terminal region of AID is required for the recombination step in GC.
Taken altogether, our results using the two different systems, spleen and DT40 cells, demonstrate that the C-terminal region of AID is required for efficient pairing during CSR and possibly homologous recombination.

P1.05.15
HIV infection inhibits the crosstalk between monocytes-derived dendritic cells and Vγ9δ2 T cells

***A. Sacchi**[1], N. Tumino[1,2], R. Casetti[1], A. Rinaldi[1], F. Turchi[1], F. Martini[1];*
[1]National Institute for Infectious Diseases "Lazzaro Spallanzani", Rome, Italy, [2]University of Rome "Tor Vergata", Rome, Italy.

DCs act as sentinel cells against incoming pathogens and represent the most potent antigen presenting cells, having the unique capability to prime naïve T cells. Innate immune lymphocytes as Vγ9Vδ2 T cells are able to sense pathogens and it has been demonstrated that they induce DC maturation, in turn expanding functions of both innate and adaptive immunity. Activated Vγ9Vδ2 T cells are able to induce DCs maturation as evidenced by increased up-regulation of CD86, IL-12 production and priming of T cell responses. However, whether HIV-infected DC are still able to be activated by Vγ9Vδ2 T cells is unknown. To clarify this issue, we cultured activated Vγ9Vδ2 T cells

with HIV infected monocyte derived DC (MDC). After 5 days we evaluated MDC phenotype, and Vγ9Vδ2 T cells activation and proliferation. We found that HIV-infected MDC are not able to up-regulate CD86 molecules when co-cultured with activated Vγ9Vδ2 T cells, compared with not infected MDC. Moreover, we observed that, independently from HIV infection, activated Vγ9Vδ2 T cells induced CCR5 up-regulation, and CCR7 and HLA-DR down-modulation. We also observed that Vγ9Vδ2 T cells were not able to proliferate in response to HIV-infected MDC, although an up-regulation of CD69 was observed. Furthermore, upon phosphoantigens stimulation, Vγ9Vδ2 T cells proliferation was inhibited when co-culture with HIV-infected MDC. These data indicate that HIV infection could alter DC-Vγ9Vδ2 T cells crosstalk, inhibiting on one hand the presentation and migration capacities of DC, and, on the other hand, rendering Vγ9Vδ2 T cells unable to respond to antigen stimulation.

P1.05.16
Type 2 Innate Lymphoid cells (ILC2) reside in the human skin and contribute to atopic dermatitis

M. Salimi[1], *J. L. Barlow*[2], *S. P. Saunders*[3], *L. Xue*[1], *D. Gutowska-Owsiak*[1], *X. Wang*[1], *D. Johnson*[4], *S. C. Scanlon*[2], *A. N. J. McKenzie2*[2], *P. G. Fallon*[5], *G. S. Ogg*[1];
[1]*OXFORD UNIVERSITY, Oxford, United Kingdom,* [2]*MRC Laboratory of Molecular Biology, Cambridge, United Kingdom,* [3]*Trinity Biomedical Sciences Institute, Dublin, Ireland,* [4]*Department of Plastic and Reconstructive Surgery, Oxford, United Kingdom,* [5]*Trinity Biomedical Sciences Institute, Dublin, United Kingdom.*

Type 2 innate lymphoid cells (nuocytes, NHC) are a recently characterized RORγt independent subset of innate lymphoid cells (ILC) that require transcription factors RORα and GATA3 for their development. Their response to epithelial cytokines and production of IL-13 and IL-5 has raised the possibility of their role in atopic diseases. Here we show that ILC2s reside in human skin, but are enriched within lesional skin of atopic dermatitis and infiltrate the skin after allergen challenge. They associate with the production of type 2 cytokines in vivo in human skin and they migrate and produce high levels of type 2 cytokines in response to IL-33 in vitro. These data suggest that human type 2 ILCs may play a role in the pathogenesis of atopic dermatitis.

P1.05.17
The role of gamma-delta T lymphocytes in the switch of Ig isotypes in B-1 cells under the influence of TI-2 antigens

N. Snegireva*, M. Gavrilova, E. Sidorova;*
Mechnikov Institute of Vaccine and Sera of RAMS, Moscow, Russian Federation.

B-1 cells respond to T-independent antigens type 2 (TI-2 Ag) by formation of IgM antibodies/total Ig. At the same time in the small intestine B-1 cells may switch from IgM to IgA. Mechanism of the switch in the absence of T help is unknown. Now the role of gamma-delta T cells in the switch of Ig isotypes in B-1 cells under the influence of TI-2 Ags was studied.
CBA mice were used. B-1 cells were isolated from peritoneal cavity, and intraepithelial gamma-delta T cells from small intestine. The purity of cell populations was determined by cytometry. Alpha (1→3) dextran (Dex) was used as TI-2 Ag.
B-1 and gamma-delta T cells (10:1) were cultured in the round-bottom 96-well plates in RPMI 1640 medium with 10% of FCS and all necessary supplements in CO2-incubator for 4 days with or without Dex. The number of IgM- and IgA-forming cells were determined by ELISPOT method.
It was found that: 1) the addition of Dex to peritoneal B-1 cells induced some increase in the numbers of IgM and IgA antibody- and Ig-forming cells (AFC and IFC, respectively; 2) the addition of gamma-delta T cells resulted in the decrease of the IgM-AFC and IgM-IFC number, and 3) the addition of gamma-delta T cells increased the quantities of IgA-AFC and IFC. The data obtained point to the possible role of intraepithelial gamma-delta T cells in the isotype switch in B-1 cells in response to TI-2 Ag.

P1.05.18
Innate protective responses of B1 cells dependent on activation-induced cytidine deaminase (AID) and interleukin-13

N. Yamamoto[1], *N. Nakazawa*[1], *S. Kerfoot*[2], *C. DelaCruz*[3], *M. Majewska-Szczepanik*[4], *M. Szczepanik*[4], *Y. Abe*[1], *N. Ohana*[1], *K. Kanemitsu*[1], *P. Askenase*[3];
[1]*Fukushima Medical University, Fukushima, Japan,* [2]*Dept. of Microbiology & Immunology, University of Western Ontario, London, ON, Canada,* [3]*School of Medicine, Yale University, NewHaven, CT, United States,* [4]*Jagiellonian University College of Medicine, Krakow, Poland.*

We describe a similarity between two early immune responses: protection from bacterial pneumonia, and initiation of contact sensitivity (CS). *AID*$^{-/-}$ (activation induced cytidine deaminase), *Jα18*$^{-/-}$ (iNKT cell), *xid* (B1 B cell), and *IL-13*$^{-/-}$ mice had impaired early pathogen clearance, similar to defective early initiation in CS, except that CS-initiation depends on IL-4. Transfer of sorted wild type peritoneal B1 cells reconstituted protection in *AID*$^{-/-}$ and *xid* mice, but not in iNKT cell deficients. This suggested that, early bacterial clearance was dependent on AID, IL-13 and IgM antibodies produced by activated normal B1 cells, and that NKT cells also are required in both pneumonia and CS.
T15 idiotype, anti-phosphorylcholine (PC) IgM, previously claimed protective in pneumoccal sepsis, were abundant but actually unprotective as "natural" T15^{+} IgM in the serum of *AID*$^{-/-}$ mice, against *S. pneumoniae* lower airway infection. Higher affinity IgM derived of activated normal B1 cells appeared superior in resolution of pneumonia compared to abundant but less potential affinity, and actually ineffective T15^{+} IgM in *AID*$^{-/-}$ mice.

T cell derived IL-3 enhances the pro- and anti-inflammatory properties of human macrophages dependent of the activation status

R. M. Allen*, N. A. Kittan, S. Mukherjee, A. Dhaliwal, S. L. Kunkel, C. M. Hogaboam;*
University of Michigan, Ann Arbor, MI, United States.

Macrophages play a critical role in regulating the local immune response, contributing to both the initiation and resolution of inflammatory processes. Depending on their activation mode, macrophages secrete a broad repertoire of pro- or anti-inflammatory cytokines and are able to interact and activate bystander immune cells. Conversely, macrophages activation is dependent on the cytokines produced by other leukocytes. One example is T cell derived IFN-γ driving classical macrophage activation. In addition, T cells are able to secrete IL-3 upon T cell receptor engagement. Here we demonstrate that activated human macrophages up-regulate the IL-3 receptor. Furthermore IL-3 treatment induces specific changes in the macrophage phenotype and differentially enhances its function depending on the pre-treatment activation status. In classically activated macrophages IL-3 promoted an inflammasome response measured by elevated IL-1β levels and increased the expression of the co-stimulatory molecule CD86. In contrast, non-activated resting macrophages displayed signs of alternative activation upon IL-3 treatment demonstrated by increased surface expression of CD206 and CD163 and high IL-10 production. Interestingly, IL-3 also enhanced the secretion of IL-12p40 which was more pronounced in resting and alternatively activated macrophages. In conclusion, we demonstrate that T cell derived IL-3 is an important regulator of macrophage function and that this regulation is highly dependent on the preexisting activation status of the macrophage. Overall, these findings suggest a role for IL-3 being part of a positive feedback loop from T cells to macrophages regulating the course of adaptive immune responses.

P1.06.02
Dissociation of innate immune responses in microglia infected with Listeria monocytogenes limits activation and neuronal damage

C. Alvarez-Dominguez[1], *E. Rodriguez-Del Rio*[1], *M. Lopez-Fanarraga*[2];
[1]*Instituto de Formacion e Investigación Marques de Valdecilla, Santander, Spain,* [2]*Universidad de Cantabria, Santander, Spain.*

Microglia are innate immune cells of the brain and here we present that they are the cellular targets of Listeria in murine hippocampal cultures. Using murine cell-lines, we report that microglia handle Listeria infection differently than other well-known macrophages. Infection of microglia with Listeria dissociates two gene expression programs involved in innate immunity, while both transcriptional responses are linked in macrophages and regulated by the bacterial virulence factor, LLO. In microglia, Listeria induces the TNF regulated early innate immune genes but represses the late innate immune genes grouped in two clusters, microbial degradation and IFN responses. ActA gene seems responsible for both gene transcriptional responses with participation of LLO in repressing IFN genes. As a consequence of this transcriptional strategy, microglia phagosomes transform into innate immunity platforms deficient in IFN-regulated microbicidal mechanisms responsible for Listeria destruction in macrophages. Second, the dissociation of macrophage innate immunity produces high levels of TNF-α and MCP-1 pro-inflammatory factors and certain neuronal destruction, but to a lesser extent than in macrophages. Finally, analysis of Listeria infected primary hypocampal cultures confirmed the high levels of TNF-α and MCP-1, the low listericidal potency and a limited induction of inflammation to preserve neuron integrity.

P1.06.03
Copper nanoparticles inhibit LPS-mediated nitric oxide and IL-12p40 production in macrophages

A. Barrientos[1], ***S. Arancibia***[1,2];
[1]*Laboratorios Centrovet, Santiago, Chile,* [2]*Fundación Ciencia y Tecnología para el Desarrollo, Santiago, Chile.*

In biomedicine, nanoparticles have been utilized in different applications such as drug delivery, image contrast agents and diagnostic purposes. Depending on their unique physicochemical properties some nanoparticles can stimulate the immune system triggering strong pro-inflammatory reactions. The use of copper nanoparticles is relatively new; therefore there is an increasing interest in thorough characterization of their impact on the immune system. CuNP have shown to induce one of the most potent acute inflammatory reactions among several types of nanoparticles. Recently, in a pulmonary infection model, it was demonstrated that mice, which had been previously exposed to CuNP, presented an impaired bacterial clearance. These effects were due to a reduction in macrophage and neutrophil function; however, the precise molecular mechanism underlying these effects is still unknown. Here, we described the effects of CuNP in the functioning of thioglycollate-elicited mouse peritoneal macrophages in response to lipopolysaccharide (LPS). Transmission electron microscopy (TEM) data showed that CuNP are rapidly internalized by macrophages. The challenge with CuNP inhibited LPS-mediated nitric oxide (NO) production in a dose dependent manner. The reduction of NO generation was related with a diminished expression of inducible nitric oxide synthase (iNOS) upon CuNP treatment. In addition, CuNP significantly reduced the expression of IL-12p40 but not IL-6 in response to LPS. These results showed that CuNP reduce the expression of key inflammatory mediators that are crucial to mount an appropriated immune response against bacterial infection.

P1.06.04
Impact of acute and chronic stress on innate immune system in elderly

S. Baëhl[1], *G. Dupuis*[2], *D. Lorrain*[3], *F. Cabana*[4], *I. Viens*[3], *A. Svotelis*[5], *T. Fülöp*[6];
[1]*Centre de recherche sur le vieillissement-Immunology program, Sherbrooke, QC, Canada,* [2]*Department of Biochemistry, Immunology program, Sherbrooke, QC, Canada,* [3]*Centre de recherche sur le vieillissement, Sherbrooke, QC, Canada,* [4]*Centre de recherche sur le vieillissement, Department of surgery, Sherbrooke, QC, Canada,* [5]*Orthopedic surgery, Sherbrooke, QC, Canada,* [6]*Centre de recherche sur le vieillissement, Department of medicine, Immunology program, Sherbrooke, QC, Canada.*

Catastrophic events like hip fractures or certain inflammatory diseases like Type 2 Diabetes Mellitus (T2DM) are quite common amongst elderly subjects. Those inflammatory conditions are usually associated with a deregulated immune response.
In this study, we aim to compare the impact of inflammatory stress on the innate immune response. We define 3 different stages of inflammatory stress: acute stress (at the moment of a hip fracture: T_0), short-term chronic stress (6 months after the hip fracture: T_{6m}) and long-term chronic stress (T2DM).
From whole blood, we evaluated the capacity of neutrophils and monocytes to phagocyte. After e-coli stimulation, we also tested their ability to produce reactive oxygen species (ROS). We also determined the fate of monocytes in differentiating in MI or MII under various stimulations.
Our findings suggest that neutrophils and monocytes exposed to acute or long-term chronic stress show less capacity of phagocytosis when compared to neutrophils and monocytes of healthy subjects. Furthermore, ROS production is overall reduced in the three stress categories in comparison with the control group. MI and MII differentiations are different in these stress situations.
We conclude that acute and both short- and long-term chronic stresses alter the functionality of the innate immune system.

P1.06.05
Modulation by lipoxin of tumor-associated macrophages profile

R. L. Simões*, N. M. de Brito, I. M. Fierro, C. Barja-Fidalgo; Department of Cell Biology, Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil.*

In tumor microenvironment, pro-inflammatory macrophages (M1) acquire anti-inflammatory and pro-tumor characteristics. Those tumor-associated macrophages (TAM) exhibit a M2-like profile, with low cytotoxic properties, as an impairment of NO and ROS production. Lipoxins (LX) are lipid mediators with anti-inflammatory and pro-resolution activities in mononuclear cells, but its effects on TAM are not well investigated. In this study, we demonstrated the effects of ATL-1, a synthetic analog of 15-epi-lipoxin A4, on TAM activity profile.
Human macrophages were differentiated in TAM after incubation with the conditioned medium of MV3, a human melanoma lineage cell. The treatment with ATL-1 (10nM) does not alter TAM viability, as demonstrated by Trypan Blue exclusion and MTT assays, but decrease CD200 and CD206 expression, both characteristic markers of M2 macrophages. In parallel, ATL-1 (1-100nM) stimulates TAM to produce NO, by increasing iNOS/arginase ratio, an also triggers ROS production, which is inhibited in the presence of DPI, an NADPH oxidase inhibitor. These results suggested that lipoxin may restore the antitumoral properties of TAM, activating iNOS and NADPH oxidase system. The alterations in TAM profile and the recovery of their cytotoxic properties could control tumor progression trough promotion of tumor cell apoptosis. Accordingly, ATL-1 (10nM) reverts TAM anti-apoptotic effect on MV3 and also inhibits endothelial cell tubulogenesis propitiated by TAM, a crucial step in angiogenesis process.
Our results suggest that lipoxin down-modulates the tumor progression stimulated by TAM, inducing the shift from M2 to M1 profile, leading to tumor cell apoptosis.

P1.06.06
The tyrosine kinase Abl is a component of macrophage podosomes and is required for podosome formation and macrophage migration

*A. Baruzzi, S. Remelli, **G. Berton**;*
Department of Pathology and Diagnostics, University of Verona, Verona, Italy.

Tyrosine kinases of the Abl family regulate cytoskeleton dynamics in different cell types. We found that in murine bone-marrow derived (BMDM) macrophages, the tyrosine kinase Abl is associated with the integrin-bound Src-family kinases (SFKs) Hck and Fgr and expression and kinase activity of both Hck/Fgr and Abl are indispensable for macrophage migration. Abl-silenced BMDM displayed a marked alteration in two-dimentional cell migration (in vitro wound healing assays) and trans-endothelial migration. Additionally, inhibition of Abl kinase activity an/or silencing of Abl expression resulted in reduction of podosome formation in both BMDM and monocyte-derived macrophages. Consistently with a cross-talk between SFKs and Abl in the regulation of actin dynamics, both the single Fgr and the double Fgr/Hck deficiency reduced podosome formation in BMDM. Overexpression of Fgr or a constitutively active form of Abl in COS-7 cells resulted in increased tyrosine phosphorylation of Vav proteins and Sos-1, two guanine nucletotide exchange factors (GEFs) for Rac. Additionally, deficiency of Fgr/Hck in BMDM resulted in reduced phosphorylation of Vav and Sos-1. Silencing of Sos-1 in BMDM resulted in profound alterations of the cytoskeleton whose impact on cell migration and podosome formation are under investigation. Considering that Abl regulates cytoskeleton dynamics leading to invadopodia formation in cancer cells and our studies implicates Abl in macrophage podosome formation and migratory ability, we propose that Abl targeting may represent a double-edged sword, acting simultaneously on tumor cells and cancer-related inflammation.

P1.06.07
Oncogene-induced senescence in histiocytes: role of BRAFV600E in the pathogenesis of Erdheim-Chester disease

***R. Biavasco**[1], M. Cangi[2], L. Pecciarini[2], G. Grassini[2], G. Cavalli[1], C. Campochiaro[2], B. Guglielmi[2], M. Ferrarini[2], C. Doglioni[2,1], L. Dagna[2,1];*
[1]Vita-Salute San Raffaele University, Milan, Italy, [2]San Raffaele Scientific Institute, Milan, Italy.

Erdheim-Chester disease (ECD) is a rare form of non-Langerhans cell histiocytosis of yet unknown etiology, characterized by infiltration of lipid-laden CD68+CD1a- histiocytes. It is still under debate whether ECD is a clonal/neoplastic disease or the expression of a deregulated immune/inflammatory response. Recently, the presence of the oncogenic BRAFV600E mutation has been described in patients with ECD: so far, the largest published report disclosed this mutation in lesions from 19/37 studied patients by means of pyrosequencing. BRAFV600 has also been implicated in oncogene-induced senescence (OIS), a mechanism that prevents cellular proliferation by activating the p16Ink4a oncosuppressor.
In this study we found the BRAFV600E mutation in ECD lesions from 19/23 patients from our cohort by means of pyrosequencing. Furthermore, when coupling pyrosequencing with a minor allele amplification technique, we were able to demonstrate the mutation in the lesions of all the 23 studied patients, in the peripheral blood monocytes obtained from 15/15 ECD patients and from 0/15 controls. We further investigated the possible association of the BRAFV600E mutation with cellular proliferation or OIS in ECD biopsies: indeed, mutated histiocytes expressed senescence markers including p16Ink4a, p21 and β-Gal, whereas they were negative for the proliferation marker Ki67.
Taken altogether, our data provide further evidence that a constitutively activated RAS/RAF pathway have a role in ECD pathogenesis, also by conferring a senescence phenotype to mutated histiocytes in the lesions. Although further investigations are needed, the detection of BRAFV600E in peripheral blood monocytes may help to further support the diagnosis of ECD.

P1.06.08
Jacalin drives macrophage polarization toward an anti-tumor M1-like phenotype

***G. S. Bisson**[1], C. D. Polli[2], T. H. Geraldino[2], L. C. Veronez[2], L. P. Ruas[3], M. C. Roque-Barreira[3];*
[1]Depto. Enfermagem Materno-Infantil e Saúde Pública, EERP/USP, Ribeirão Preto, Brazil, [2]Programa de Pós-graduação em Imunologia Básica e Aplicada, FMRP/USP, Ribeirão Preto, Brazil, [3]Depto. Biologia Celular e Molecular e Bioagentes Patogênicos, FMRP/USP, Ribeirão Preto, Brazil.

Tumor-associated macrophages (TAMs) have an ambiguous and complex role in the carcinogenic process, since these cells can be polarized into different phenotypes by the tumor microenvironment. As the interactions between tumor cells and TAMs involve several players, a better understanding of the function and regulation of TAMs is crucial to drive their differentiation into cells with an anti-tumor phenotype. In this study, we investigated the modulation of macrophage tumoricidal activities by jacalin. The lectin bound to macrophage surface through its carbohydrate recognition domains, and induced cytokine production by these cells. Jacalin stimulation increased the expression of TNF-α, IL-1β and MIP-1α mRNA. As measured by ELISA, higher levels of TNF, IL-6, IL-12, IL-1β and IL-10 were detected in the supernatant from jacalin-stimulated macrophages. Given that pro-inflammatory cytokines were predominantly produced by macrophages in response to stimulation with jacalin, we next investigated whether NF-κB signaling is activated by the lectin. We found that jacalin was able to activate the transcription factor. The results obtained indicate that the lectin polarize macrophages toward the pro-inflammatory, anti-tumor M1-like phenotype. Therefore, we studied the tumoricidal activities of jacalin-stimulated macrophages. Incubation of HT-29 or MCF-7 cells with supernatants from macrophages stimulated with jacalin resulted in a reduction of cell viability, as assessed by MTT assays. Furthermore, flow cytometric analysis showed that the reduction of cell viability was due to apoptosis of tumor cells. Taken together, these results indicate that jacalin, through its ability to exert a pro-inflammatory activity, can direct macrophages to an anti-tumor phenotype.
