In the resting state, T-reg from subcutaneous lymph nodes showed similar lectin binding profiles to splenic T-reg. However, T-reg from thymus and bone marrow had additional variances in lectin binding levels compared to T-conv from the same sites. In 5-day cultures of eFluor670®-labeled $CD4^+$ splenic cells stimulated with a low concentration of Concavalin A preferential proliferation of T-reg occurred and the proportion of GFP^+ cells increased from an average of 17% at baseline to 37% of the total cells.
Differential surface glycosylation profiles of T-reg and T-conv may reflect an inherently higher *in vivo* activation status of T-reg which varies across anatomical location.

Immunological consequences of HIV co-infection with M. Leprae

K. I. Carvalho[1]*, F. R. Bruno*[1]*, J. Tomimori*[2]*, L. Nogueira*[1]*, E. Moreira*[1]*, E. Cunha-Neto*[1]*, M. B. Xavier*[3]*, J. Kalil*[1]*, D. Nixon*[4]*, E. G. Kallas*[1]*;*
[1]USP, São Paulo, Brazil, [2]UNIFESP, São Paulo, Brazil, [3]UFPA, Belem, Brazil, [4]UCSF, San Francisco, CA, United States.

Brazil is one of the countries considered highly endemic for leprosy infection. Brazil also has the largest number of HIV infections in South America. Co-infection of *M. Tuberculosis* with HIV is known to impact the immunopathology of both pathogens. However, little is known about the impact of *M. leprae* on HIV-induced disease and vice versa. In this study, we assessed the immunological impact of HIV/*M. Leprae* co-infection in subjects in the state of Pará, Brazil. The study subjects were divided into four groups: healthy controls, HIV seropositive patients, patients with leprosy alone, and leprosy and HIV-1coinfected patients. We quantified T cell activation, regulatory T cells (T_{regs}) and assessed Th-17 cells. We found higher immune activation and negatively correlation between T_{regs} and activation markers in co-infected patients. An increase of T_{reg} cells in the periphery, and a loss of the Th17 to T_{reg} ratio in HIV. In conclusion, we believe these findings can be related to disease progression for HIV and Leprosy infection.

P3.13.09
PDCD5 negatively regulates autoimmunity by upregulating $FOXP3^+$ regulatory T cells and suppressing Th17 and Th1 responses

J. Xiao, C. Liu, G. Li, J. Hu, Y. Zhang, D. Ma, ***Y. Chen****;*
Key Laboratory of Medical Immunology, Ministry of Health, Peking University Health Science Center, Beijing, China.

Maintenance of FOXP3 protein expression is crucial for differentiation and maturation of regulatory T (Treg) cells, which play important roles in immune homeostasis and immune tolerance. Emerging evidence indicates that Histone acetyltransferase (HAT) Tip60 can enhance FOXP3 stability by upregulating its acetylation in regulatory T cells. We have previously demonstrated that programmed cell death 5 (PDCD5) interacts with Tip60, enhances its stability and HAT activity. In the present study, We demonstrate that PDCD5 interacts with FOXP3, increases acetylation of FOXP3 in synergy with Tip60 and enhances the repressive function of FOXP3. In PDCD5 transgenic (PDCD5tg) mice, overexpression of PDCD5 enhanced the level of FOXP3 protein and percentage of $CD4^+CD25^+FOXP3^+$ cells. Naïve $CD4^+$ T cells from PDCD5tg mice were more sensitive to TGF-β-induced Treg polarization and expansion. These induced Tregs retained normal suppressive function *in vitro*. We further investigated the role of PDCD5 in experimentally-induced autoimmune encephalomyelitis (EAE). Severity of EAE in PDCD5tg mice was significantly reduced relative to that of wild-type mice. The beneficial effect of PDCD5 likely resulted from increases of Treg cell frequency, accompanied by a switch from the predominant pathogenic Th17/Th1 response to the protective Th2-type immune activity. Activation-induced cell death enhanced by PDCD5 was also linked to this process. This is the first report revealing that PDCD5 activity in T cells suppresses autoimmunity by modulating Tregs. This work was supported by a grant from the National Key Basic Research Program of China (973, 2011CB910103) and the National Natural Science Foundation of China (30871263).

P3.13.10
The endocannabinoid 2-Arachidonoylglycerol potentiates Foxp3 expression and Regulatory T cell functions through its metabolism

V. Chiurchiu[1]*, M. Lanuti*[1,2]*, M. De Bardi*[1]*, N. Battista*[2]*, E. Bisicchia*[1]*, G. Borsellino*[1]*, M. Maccarrone*[1,3]*, L. Battistini*[1]*;*
[1]Santa Lucia Foundation, Rome, Italy, [2]University of Teramo, Teramo, Italy, [3]Campus Bio-Medico, University of Rome, Rome, Italy.

The CD4+CD25+ regulatory T cells (Tregs) are a unique population of T cells that maintain peripheral immune tolerance and inhibit autoreactive T cells. At least two subpopulations of Tregs exist, named naturally occurring Tregs (nTregs) and induced Tregs (iTregs). Several in vitro and in vivo models demonstrating the induction of iTregs from CD4+CD25- naive T cells by prolonged or repeated antigenic stimulation or by IL-10 or TGF-β support the possibility that Tregs can be generated in the periphery. Although the transcription factor Foxp3 is considered one of the specific markers of Tregs, the immunosuppressive mechanisms exerted by Tregs are not fully known. Given the recent evidences demonstrating the important role of the endocannabinoid system (ECS) in the modulation of several immune responses, we investigated for the first time whether endocannabinoids may interfere with Tregs induction and function. Herein, not only we show that nTregs express several members of the ECS (cannabinoid receptors and endocannabinoid-metabolizing enzymes), but also that the endocannabinoid 2-arachidonoylglycerol (2-AG) up-regulates Foxp3 and potentiates the regulatory phenotype of iTregs, in a mechanism which is independent by cannabinoid receptors. This 2-AG-induced effect in driving a “super-Treg” phenotype is blocked by selective COX-2 inhibition, suggesting that 2-AG could participate in the physiopathological regulation of iTregs induction and maintenance through one of the lipid intermediates derived from COX-2-induced 2-AG metabolism.

P3.13.11
Altered expression of miR-146a and miR-155 in Th2 and IgG expressing B cells in the autoimmune disease pemphigus foliaceus

G. A. Cipolla*, M. Petzl-Erler;*
Federal University of Paraná, Curitiba, Brazil.

MicroRNAs are a class of small non-coding RNAs ranging from 18 to 25 nucleotides that regulate gene expression by complementary binding to mRNA sites. MicroRNAs have been increasingly implicated in normal immune function. Pemphigus foliaceus (PF) is a blistering autoimmune skin disease characterized by a Th2-dependet production of pathogenic IgG autoantibodies. We quantified by qRT-PCR six candidate microRNAs (miR-145, miR-146a, miR-148a, miR-155, miR-338-5p, and miR-1321) in three lymphocyte subpopulations ($CD4^+CD294^+$ Th2-like, $CD4^+C25^+$ T, and IgG expressing B cells [IgG^+ B cells]) from six healthy controls, six patients with inactive disease (iPF) and seven patients with active lesions (aPF). In Th2-like cells, miR-146a was 4-fold upregulated in patients with inactive disease compared to patients with active lesions (P=0.014), suggesting that the expression of this microRNA might be negatively related to disease activity. In IgG^+ B cells, miR-155 was 2-fold upregulated in patients with inactive disease compared to healthy controls (P=0.009) and exhibited a tendency for upregulation in these patients when compared to those with active lesions (P=0.082), allowing us to hypothesize that this microRNA might have a relevant role in PF remission. Moreover, miR-1321 revealed a tendency of upregulation in Th2-like cells of PF patients (iPF+aPF) compared to healthy controls (P=0.079). Expression of miR-1321 in these cells negatively correlated to that of its predicted target BLYS (BAFF), a B cell stimulator known to be important for PF pathogenesis (iPF, r_S=-1.00, P<0.05; aPF, r_S=-0.49, ns). In conclusion, miR-146a, miR-155 and miR-1321 arise as potentially new mediators of therapeutic intervention for PF.

P3.13.12
DX5+ CD4+ T cells modulate CD4+ T-cell response via inhibition of IL-12 production by DCs

H. el Bannoudi[1]*, W. G. Han*[1]*, J. N. Stoop*[1]*, P. Louis-Plence*[2]*, T. W. J. Huizinga*[1]*, R. E. M. Toes*[1]*;*
[1]Leiden |University Center, Leiden, Netherlands, [2]Inserm U844, Université Montpellier I, Montpellier, France.

DX5+CD4+ T cells have been shown to dampen collagen-induced arthritis and delayedtype hypersensitivity reactions in mice. These cells are also potent modulators of T-helper cell responses through direct effects on CD4+ T cells in an IL-4 dependent manner. To further characterize this T-cell population, we studied their effect on DCs and the potential consequences on T-cell activation. Here, we show that mouse DX5+CD4+ T cells modulate DCs by robustly inhibiting IL-12 production. This modulation is IL-10 dependent and does not require cell contact. Furthermore, DX5+CD4+ T cells modulate the surface phenotype of LPS-matured DCs. DCs modulated by DX5+CD4+ T-cell supernatant express high levels of the co-inhibitor molecules PDL-1 and PDL-2. OVA-specific CD4+ T cells primed with DCs exposed to DX5+CD4+ T-cell supernatant produce less IFN-γ than CD4+ T cells primed by DCs exposed to either medium or DX5−CD4+ T-cell supernatant. The addition of IL-12 to the co-culture with DX5+ DCs restores IFN-γ production. When IL-10 present in the DX5+CD4+ T-cell supernatant is blocked, DCs re-establish their ability to produce IL-12 and to efficiently prime CD4+ T cells. These data show that DX5+CD4+ T cells can indirectly affect the outcome of the T-cell response by inducing DCs that have poor Th-1 stimulatory function.

P3.13.13
T regulatory cells in cancer

E. Elkord[1,2,3]*;*
[1]United Arab Emirates University, Al Ain, United Arab Emirates, [2]University of Salford, Manchester, United Kingdom, [3]University of Manchester, Manchester, United Kingdom.

Recent evidences show that anti-tumour immunity and cancer immunotherapy are negatively impacted by effects of T regulatory cells (Tregs). We and others showed that Tregs are expanded in peripheral blood and tumour microenvironment of cancer patients, which correlates with poor prognosis and reduced survival. Our recent work has further established that Treg infiltration of tumours is correlated with a lack of some patients' responsiveness to therapy. Additionally, we found that adoptive transfer of Treg-depleted autologous T cells in renal cell carcinoma (RCC) patients following conditioning chemotherapy provided a transient reduction of circulating Treg levels which was associated with improved antitumor immune response to the tumour-associated antigen 5T4.
There are two main populations of $CD4^+$ Tregs with different origins: thymus-derived natural Tregs (nTregs) and peripherally induced Tregs (iTregs). Conversion of conventional T cells into iTregs is proposed as a potential mechanism for Treg expansion in cancer. Discovery of markers that distinguish iTregs from the natural ones is of great importance and currently under intensive investigations; this might allow targeting iTregs in specific protocols. We found that the majority of peripheral and tumour-infiltrating $FoxP3^+$ Tregs expresses Helios, an Ikaros family transcription factor, and $FoxP3^+Helios^+$ Tregs possess more suppressive phenotype and characteristic, as compared to $FoxP3^+Helios^-$ Tregs. Despite the recent debate of the suitability of Helios as a marker of nTregs, Helios expression could be a potential target in cancer.
These observations suggest that Tregs are implicated in the immunopathology of cancer and their specific targeting may improve the efficacy of immunotherapeutic modalities.

P3.13.14
Regulatory T cells in acute lymphoblastic leukemia

M. H. Garcia Hernandez[1], *S. Godina Gonzalez*[2], *M. N. Medina Rosales*[1];
[1]*Unidad de Investigacion Médica Zacatecas-IMSS, Zacatecas, Mexico,* [2]*Universidad Autónoma de Zacatecas, Zacatecas, Mexico.*

T regulatory cells have an important and specific role in malignant diseases such as acute lymphoblastic leukemia (ALL); these cells participate in a negative regulation of immunologic response, limiting the capacity to eliminate carcinogenic clones. Objective. The purpose of this study is to assess the percentage and function of T regulatory cells because it is suggested that function or expression increased in these cells in patients with ALL could be inhibiting an adequate anti-tumor response. Materials an Methods. We evaluated of percentage and function of T regulatory cells CD4+CD25+FOXP3+, CD4+CD39+FOXP3+ and CD4+CD25+CTLA-4+ in peripheral blood pediatric patient with acute lymphoblastic leukemia and healthy volunteers by Flow cytometry. Results. We observed significantly diminished CD4+CD25highCTLA-4+ cells levels and augmented FOXP3+ and CD39+ expression in CD4+ T cells in patients in LLA patients compared to healthy controls. Only three samples have been analyzed for the cell function of T regulatory cells, the remaining samples will be eventually evaluated Discussion. These results suggest LLA patient's exhibit an important activation of the immune response, possibly against carcinogenic clones and the absence of CD4+CD25highCTLA-4+ T regulatory cells could be contribute to the pathology observed in LLA patients.

P3.13.15
T Lymphocyte-mediated suppression of murine granulopoiesis by oral allergen pretreatment of sensitized/challenged mice

M. Gaspar-Elsas[1], *T. Queto*[1], *B. de Luca*[1], *B. Vieira*[1], *C. L. C. A. Silva*[2], *R. A. Luz*[3], *R. Ferreira*[1], *P. P. Xavier-Elsas*[2], *D. Masid-de-Brito*[3];
[1]*FIOCRUZ-IFF, Rio de Janeiro, Brazil,* [2]*Universidade federal do rio de Janeiro, Rio de Janeiro, Brazil,* [3]*Universidade federal do Rio de Janeiro, Rio de Janeiro, Brazil.*

Oral ovalbumin pre-exposure (oral OVA), also termed "oral tolerance induction", effectively prevents the subsequent allergic pulmonary inflammation in sensitized/challenged (S/C) mice, reducing lung eosinophil (Eos) infiltration. In OVA-S/C mice, bone-marrow (BM) eosinophilopoiesis is suppressed by the antihelminthic and antiallergic agent diethylcarbamazine, a 5-lipoxygenase inhibitor, through a proapoptotic mechanism requiring both inducible Nitric Oxide Synthase (iNOS) and CD95L, the ligand for death receptor CD95/Fas. The role of BM regulation by iNOS/CD95L in the effects of oral OVA, remains to be established. We examined oral OVA effects on granulopoiesis in S/C mice. BP-2, BALB/c and C57BL/6 wild-type (WT) mice, and BALB/c mutants lacking CD95L (*gld*), were orally given OVA in water, and subsequently S/C with OVA. Granulopoiesis was evaluated in liquid and semisolid BM cultures. Spleen T cells from oral OVA/S/C donors, or from Water/S/C controls, were transferred to syngeneic recipients, which were subsequently S/C with OVA before evaluation of BM eosinopoiesis. Oral OVA/S/C BP-2 mice had significantly decreased, relative to Water/S/C controls: a) Eos numbers in BM; b) IL-5-stimulated eosinophilopoiesis and GM-CSF-stimulated neutrophilopoiesis; c) GM-CSF-stimulated Eos colony formation; d) OVA-specific circulating IgE levels. Oral OVA was effective in BM CD95L-deficient mice. The effects of oral OVA on BM Eos numbers were duplicated by transfer of splenic T cells from oral OVA/S/C donors to syngeneic recipients, which were subsequently S/C, demonstrating a novel regulatory effect of oral OVA-induced T cells on granulopoiesis. **support:** CNPq-FAPERJ-CAPES

P3.13.16
Augmented levels of CD4+CD25high Treg cells in peripheral blood of patients with acute and chronic brucellosis

H. Ghazanfari[1], *N. Hassannejad*[2], *A. Bahador*[3], *A. Bahador*[3], *J. Hajati*[4];
[1]*Isfahan University of Medical Sciences, Isfahan, Iran,* [2]*Department of Cellular and Molecular Biology; Faculty of Sciences, Science and Research Branch of Islamic Azad University, Tehran, Iran,* [3]*Department of Microbiology , Faculty of Medicine, Tehran University of Medical Sciences, Tehran, Iran,* [4]*Department of Immunology, Faculty of Medicine, Tehran University of Medical Sciences, Tehran, Iran.*

Brucellosis remains one of the most common zoonotic diseases worldwide. In humans, Brucellosis can be a serious, debilitating and sometimes chronic disease. Different mechanisms can be postulated as to the basis for the induction of the chronic status of infectious diseases that T regulatory cells are one of the most important related mechanisms. For the first time, the current study was designed to determine whether percentage of CD4+CD25+ Treg cells in peripheral blood is changed in human Brucellosis samples (Acute form:n=16, Chronic form: n=10) in comparison to control group(n=15). In brief, Heparinized venous blood was obtained from both patients and healthy donors. Peripheral blood mononuclear cells (PBMCs) were isolated using Ficoll-Hypaque density gradient centrifugation. For surface staining, cells were incubated with the respective mAbs for CD4, CD25 and finally $CD4+CD25^{high}$Treg cells are evaluated by FACS. The results have revealed a new finding in relation to Treg cells and human Brucellosis. Our study indicates that the number of $CD4^{+}CD25^{high}$Treg increases in the peripheral blood of acute and chronic forms of Brucellosis samples compared with healthy groups and this increase in chronic group is further. $CD4^{+}CD25^{+}$ regulatory T cells (Treg) play a central role in the prevention of autoimmunity and in the control of immune responses to transplants, allergens, tumors, and infectious microbes by down-regulating the function of effector $CD4^{+}$ or $CD8^{+}$ T cells. In conclusion, a correlation seems to exist between increased $CD4+CD25^{high}$Treg cells and disease progression from healthy state to acute and chronic brucellosis.

P3.13.17
Association of circulating regulatory T cell number with the incidence and prognosis of diffuse large B cell lymphoma

M. Głowala-Kosińska[1], *A. Chwieduk*[1], *J. Nieckula*[2], *M. Saduś-Wojciechowska*[1], *S. Grosicki*[3], *A. Rusin*[4], *E. Nowara*[2], *S. Giebel*[1];
[1]*1Department of Bone Marrow Transplantation, Maria Sklodowska-Curie Memorial Cancer Center and Instit, Gliwice, Poland,* [2]*2Department of Clinical and Experimental Oncology, Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Gliwice, Poland, Gliwice, Poland,* [3]*4Department of Haematology, Municipal Hospital, Chorzow, Poland, Chorzów, Poland,* [4]*3Center for Translational Research and Molecular Biology of Cancer, Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Gliwice, Poland, Gliwice, Poland.*

Regulatory T (Treg) cells are essential for maintaining immune tolerance. High Treg frequencies have been reported in peripheral blood and tissue samples of patients with solid tumors while their role in lymhomas, including diffuse large B cell lymphoma (DLBCL) has not been clearly established. In this study we analyzed the circulating Treg numbers in 27 patients with newly diagnosed DLBCL and 17 healthy individuals. Tregs were detected by flow cytometry based on CD4+CD25highFoxP3+ phenotype. In addition, the expression of CD45RA, HLA-DR, CD62L, CD39, and CTLA4 was analyzed. The number of circulating Treg cells was lower in DLBCL patients than in healthy controls: median 23 (range, 4-107)/μL versus 41 (19-104)/μL ($p=0.04$). In particular, the number of Tregs expressing CD45RA (naïve Tregs), HLA-DR (marker of activation) and CD62L (L-selectin) was decreased in the DLBCL group. Lower (below median) number of circulating Tregs was associated with reduced chance of achieving complete remission (29% versus 69%, $p=0.05$) and reduced probability of even-free survival (24% versus 84% at one year, $p=0.0004$), independently on the International Prognostic Index. We conclude that low number of circulating Tregs may be associated with susceptibility to DLBCL incidence and poor prognosis. Our observations require confirmation in larger patient population.

P3.13.18

Maintenance of memory regulatory T cells in peripheral tissues

***I. K. Gratz**, M. D. Rosenblum, H. Truong, M. M. Maurano, A. K. Abbas;*
UCSF, San Francisco, CA, United States.

The skin has unique immunological characteristics and is especially plagued by T cell mediated inflammatory disorders. To study CD4+ T cell responses to epidermal self-antigen, which are largely undefined, we established a mouse model that features tetracycline-inducible expression of chicken ovalbumin (Ova) in the epidermis under the control of the keratin K5 promoter. Expression of antigen in the skin elicits a T cell (DO11.10) dependent inflammatory dermatitis, which is associated with IFN-γ and IL-17 production by DO11 T cells. This disease develops despite the presence of high starting numbers of natural DO11 Foxp3-expressing regulatory T cells (Tregs), and, in fact, these Tregs proliferate in response to skin-Ag recognition. Treg are activated by peripheral self-antigen to increase their suppressive function, and a fraction of these cells survive as memory regulatory T cells (mTregs). mTregs persist in nonlymphoid tissue after cessation of Ag expression and have enhanced capacity to suppress tissue-specific autoimmunity. These mTregs express specific effector memory T cell markers and localize preferentially to hair follicles in skin. Memory Tregs express high levels of both IL-2Rα and IL-7Rα. Using a genetic-deletion approach, we show that IL-2 is required to generate mTregs from naive CD4+ T cell precursors in vivo. However, IL-2 is not required to maintain these cells in the skin and skin-draining lymph nodes. Conversely, IL-7 is essential for maintaining mTregs in skin in the steady state. These results elucidate the fundamental biology of mTregs and show that IL-7 plays an important role in their survival in skin.

P3.13.19
Beta2 adrenergic receptor signaling in $CD4^+$ $Foxp3^+$ regulatory T cells enhances their suppressive function in vitro

***M. G. Guereschi**, L. P. Araujo, J. T. Maricato, M. C. Takenaka, V. M. Nascimento, B. C. Vivanco, V. O. Reis, A. C. Keller, A. S. Basso;*
Federal University of São Paulo, São Paulo, Brazil.

Beta2 adrenergic receptor (B2AR) signaling is known to impair Th1-cell differentiation and function in a cAMP-dependent way. $Foxp3^+CD4^+$ regulatory T (Treg) cells play a key role in the regulation of immune responses and are essential for maintenance of self-tolerance. Nevertheless, very little is known about adrenergic receptor expression in Treg cells or the influence of noradrenaline on their function. We showed by qPCR, immunofluorescence and western blot that sorted $Foxp3^+$ Treg cells express B2AR. B2AR activation by specific agonist in Treg cells leads to increased intracellular cAMP levels and to PKA-dependent
CREB phosphorylation. For suppression assays, sorted naïve T cells and Treg cells were cultured (proportion 1:0,25) with irradiated splenocytes and soluble anti-CD3. Before setting up the cultures, Treg cells were treated or not with B2AR agonist. After 3 days, naïve T cell proliferation was analyzed by flow cytometry. We found that B2AR signaling enhances the suppressive activity of Treg cells since naïve T cell proliferation was about 40% lower than the one observed in control cultures. B2AR-mediated increase in Treg-cell suppressive function was associated with decreased IL-2 mRNA levels in responder $CD4^+$ T cells and improved Treg-cell-induced conversion of $CD4^+$ $Foxp3^-$ cells into $Foxp3^+$ iTreg cells. Moreover, B2AR signaling increased CTLA-4 expression in Treg cells in a PKA-dependent way. Finally, we found that PKA inhibition totally prevented the B2AR-mediated increase in Treg-cell suppressive function. Our data suggest that sympathetic fibers are able to regulate Treg-cell suppressive activity in a positive manner through B2AR signaling.

P3.13.20
Role of cutatneous regulatory T cells in regulation of immune homeostasis and contact hypersensitivity reaction in the skin

***S. Hanakawa**, A. Kitoh, Y. Miyachi, K. Kabashima;*
Department of Dermatology, Kyoto university Graduate School of Medicine, Kyoto, Japan.

There is accumulating evidence that $CD4^+Foxp3^+$ regulatory T (Treg) cells actively suppress pathological and physiological immune responses, thereby contributing to the maintenance of immunological self-tolerance and immune homeostasis and to suppressive control of a broad spectrum of immune responses. We and others have previously shown that there are a substantial number of Treg cells in the skin even in a steady state. However, it remains unclear whether Treg cells in non-immunized skin contribute to the maintenance of immune homeostasis and the suppression of antigen-specific immune responses, e.g., contact hypersensitivity (CHS). To address this issue, we investigated whether the selective elimination of cutaneous Treg cells would lead to the dysregulation of immune homeostasis in the skin and exacerbate CHS reaction. Intradermal injection of an immunotoxin targeting human CD2 (hCD2) into ear skin of $Foxp3^{hCD2}$ mice, in which Treg cells specifically express hCD2 on their cell surface, markedly reduced Treg cells only in the treated skin, but neither in other organs nor in the blood. Selective depletion of Treg cells in the skin led to the spontaneous development of inflammation in the treated skin. In addition, CHS reaction elicited at the Treg cell-depleted ear was exacerbated and prolonged, accompanied by increase of immune cell invasion and overproduction of Th1- and Th2-related cytokines. These results indicate that Treg cells existing in the skin are essential for the proper regulation of immune homeostasis and antigen-specific immune response in the skin.

P3.13.21
Genome-wide DNA methylation profiling identifies hypomethylated genes with the Forkhead-binding motif in human regulatory T cells

*Y. Zhang[1], J. Maksimovic[2], G. Naselli[1], J. Qian[3], M. E. Blewitt[1], A. Oshlack[2], **L. C. Harrison**[1];*
[1]Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia, [2]Murdoch Childrens Research Institute, Melbourne, Australia, [3]Peking Union Medical College, Beijing, China.

Regulatory T cells (Tregs) prevent the emergence of autoimmune disease. Prototypic natural Treg (nTreg) are programmed by the transcription factor Forkhead-box P3 (FOXP3) and can be identified by demethylation at the FOXP3 locus. To further explore the methylation landscape of nTregs we performed genome-wide methylation profiling of human resting nTregs (rTreg) and conventional naïve CD4+ T cells (Naïve). We detected 2,315 differentially methylated CpGs between these two cell types, many of which clustered into 127 regions of differential methylation (RDM). T cell activation induced changes in 466 individual CpGs and 18 RDMs in Naïve but did not alter DNA methylation in rTreg. Gene set testing of these 127 RDMs revealed enrichment for common Treg signature genes, genes that bind FOXP3 and genes upregulated by FOXP3, predominantly in hypomethylated RDMs. A putative Forkhead-binding motif was overrepresented in promoter-associated RDMs, suggesting that methylation regulates gene expression by influencing FOXP3 binding. To exemplify this we showed that TIGIT, coding for an immune suppressive receptor, was hypomethylated and upregulated in Treg, but its expression was reduced in individuals at risk for autoimmune type 1 diabetes. These findings provide new insight into epigenetic regulation of human nTreg and the potential to exploit differential methylation as an immune biomarker in human diseases.

P3.13.22
Identification of PLAU as a critical gene for the suppressive function of memory-like CD4+ regulatory T cells

F. He[1,2]*, H. Chen*[2]*, M. Probst-Kepper*[3]*, R. Geffers*[2]*, S. Eifes*[1]*, A. del Sol*[1]*, K. Schughart*[2]*, A. Zeng*[4]*, R. Balling*[1]*;*
[1]Luxembourg Centre for Systems Biomedicine, Esch-Belval, Luxembourg, [2]Helmholtz Centre for Infection Research, Braunschweig, Germany, [3]Städtisches Klinikum Braunschweig GmbH, Braunschweig, Germany, [4]Hamburg University of Technology, Hamburg, Germany.

The plasminogen activator urokinase (*PLAU*) is known for its role in fibrinolysis and late-onset Alzheimer diseases. However, we here demonstrate that *PLAU* is also important for the suppressor function of both human and murine CD4+ regulatory T cells (Tregs). The prediction of PLAU as an important gene is made through a systems biological network strategy directly from an undirected Treg-specific correlation network which we reconstruct from a high-time-resolution transcriptome during the very early activation process of human Tregs/$CD4^+$ T-effector cells (Teffs). The validation results show that the membrane-bound PLAU regulates the expression of several known Treg key genes, e.g., FOXP3 and EOS. Moreover, our analysis unveils that *PLAU* is particularly important for memory-like $CD44^{high}CD62L^{low}$ but not $CD44^{low}CD62L^{high}$ Tregs. Detailed mechanistic investigation shows that PLAU mediates Treg suppressor function via STAT5 and ERK signaling pathways but not via PLAU-PLAUR interaction between Treg and Teffs. Further analysis also shows that the development of the thymic $Cd4^+Cd25^+Foxp3^+$ Tregs was significantly enhanced in $Plau^{-/-}$mice, which might compensate the impaired suppressive function of memory-like Tregs and consequently not generate spontaneous autoimmune disorders. Our study highlights not only the power of the proposed network strategy but also a critical role for *PLAU* in Treg suppressor function.

P3.13.23
CD2-mediated regulation of peripheral CD4+CD25+ regulatory T cell apoptosis accompanied by downregulation of Bim

Y. Kashiwakura*, D. Sakurai, Y. Kanno, M. Hashiguchi, A. Kobayashi, A. Kurosu, S. Tokudome, T. Kobata, H. Kojima;*
Dokkyo Medical University, School of Medicine, Mibu, Shimotsuga, Tochigi, Japan.

Extensive studies on CD4+CD25+ regulatory T (Treg) cells suggest they are important in regulating immune responses. However, mechanisms of peripheral Treg cell homeostasis are unknown. We found that stromal cells isolated from secondary lymphoid organs such as spleen and lymph nodes could support the survival of Treg cells. This was dependent on CD2 engagement and a direct interaction between Treg cells and stromal cells. In the presence of stromal cells, Bim, a pro-apoptotic factor, was partially decreased in Treg cells. This effect could be inhibited by anti-CD2 blocking antibodies, indicating that stimulation through CD2 on Treg cells regulates Bim expression, which may be relevant to Treg cell apoptosis. Therefore, Treg cell interactions with stromal cells through CD2 may be essential for Treg cell survival. Surprisingly, the expression of CD2 ligands on stromal cells was not detected. Thus, it is not clear how CD2 on Treg cells contributes to a direct interaction with the stromal cells and participates in survival support for Treg cells. Taken together, CD2 stimuli were mandatory for Treg cell survival with reduced Bim expression, but CD2 may not function as a direct receptor for molecules on stromal cells.

P3.13.24
Diurnal changes in trafficking receptor expression on thymus-deriving natural regulatory T cells

E. Kiernozek*, A. Kowalik, K. Niedzielska, M. Markowska, N. Drela;*
University of Warsaw, Warsaw, Poland.

Natural $CD4^+CD25^+Foxp3^+$ regulatory T (nTreg) cells play a crucial role in the maintenance of self-tolerance and immune homeostasis. nTregs develop in the thymus and migrate to the periphery as a mature population of T lymphocytes. nTregs can suppress activation, proliferation and effector functions of various immune cells. Currently, the mechanisms regulating nTreg development, migration to peripheral lymphoid organs and suppressive function are still explored. As we have shown in our previous study various aspects of nTreg biology are controlled by circadian rhythms. Here we demonstrate that the expression of trafficking receptors show diurnal rhythmicity suggesting the involvement of hormonal regulation in nTreg migration. The aim of the study was to analyse the expression of CD62L and CCR9 on thymus-deriving nTregs of C57BL/6 mice in time intervals correlated with the circadian rhythm of endogenous glucocorticoids synthesis. CD62L direct nTregs to secondary lymphoid tissue and CCR9 to non-lymphoid tissue. We also analysed the expression of these markers after treatment of mice with the synthetic glucocorticoid, dexamethasone. C57BL/6 mice were injected i.p. with Dex at the dose of 1,25mg/kg/day. The analysis of nTreg markers expression was synchronized with the circadian rhythm of glucocorticoids synthesis. The results of the first part our studies in brief indicate that after administration of dexamethasone 1/ the differences in trafficking receptor expression were gender-dependent 2/ trafficking receptors expression on nTregs reveal diurnal rhythmicity, which was in accordance to circadian rhythm of glucocorticoids synthesis.

Dexamethasone dose-dependent effect on nTreg generation in vitro in thymocytes co-cultures with JAWSII cells

A. Kowalik*, K. Gugala, E. Kiernozek, E. Kozlowska, N. Drela;*
University of Warsaw, Warsaw, Poland.

Endogenous glucocorticoids have a broad impact on immune cells development and function because of their immunosuppressive activity, ability to induce apoptosis and modulate the maturation of antigen-presenting cells. In our research we have examined the effect of dexamethasone, a synthetic glucocorticoid, on thymocyte development *in vitro*. We have created an *in vitro* model promoting CD4+CD25+Foxp3+ thymocyte development using anti-CD3 antibodies and JAWSII immature dendritic cells as the sources of activatory signals. In experiments we have used thymocytes derived from C.Cg-*Foxp3*^{tm2Tch}/J mice. The aim of the study was to establish conditions for maintaining the appropriate level of JAWSII cells activation basing on the expression of their costimulatory molecules and MHCII. Moreover, using this model we have examined the effect of dexamethasone (in range of concentrations 10^{-12} - 10^{-6} M) onto: JAWSII cell line viability and costimulatory markers expression, viability of thymocytes co-cultured with JAWSII cells, distribution of major thymocytes subsets and CD4+CD25+Foxp3+ cells generation *in vitro*. Our research indicate that dexamethasone used at low concentrations, which do not induce apoptosis of thymocytes and maintain a weak expression of MHCII and costimulatory molecules on JAWSII cells, may play a role of a selection factor for nTreg generation in vitro.

P3.13.26
Donor-specific regulatory t cells generated on donor b cells are superior to CD4+CD25high cells in controlling alloimmune responses in humanized mice

Y. Lee[1]*, F. Noyan*[1]*, M. Hardtke-Wolenski*[1]*, A. Knoefel*[1]*, R. Taubert*[1]*, U. Baron*[2]*, M. P. Manns*[1]*, E. Jaeckel*[1]*;*
[1]Hannover Medical School, Hannover, Germany, [2]epiontis, Berlin, Germany.

Regulatory T cells have been proposed as important players in controlling donor reactive immune responses after transplantation. Several clinical trials had evaluated their safety in the treatment of GVHD after hematopoietic stem cell transplantation. As opposed to this lymphopenic setting a variety of animal studies had shown, that the impact of polyclonal Tregs in organ transplantation is small. Rather, the antigen-specificity of Tregs plays a major role, since

transplant tolerance is - as shown in animals models - related to donor-specific regulatory T cells. Direct comparison of polyclonal with alloreactive Tregs revealed the solely effectiveness of antigen-specific Tregs in respect to the inhibition of graft rejections.
Yet, due to the lack of a specific alloreactive Treg marker currently polyspecific CD4+CD25high Tregs are being tested in clinical trials in autoimmunity and transplantation. For the generation of donor-specific Tregs donor material is usually limited. Here we developed a method to generate large quantities of activated donor B cells by stimulation of donor PBMCs with 3T3 fibroblast expressing CD40L. These activated donor B cells were potent stimulators of CD4+CD25 high Tregs, which could be efficiently expanded. These donor reactive Tregs inhibited an allo-MLR in a donor-specific way and were far more potent in inhibiting an alloimmune response in humanized mice compared to the current gold standard of polyspecific CD4+CD25high Tregs. The generation of donor-specific Tregs could all be performed under GMP conditions. Donor-reactive Tregs could be a valuable tool to control immune responses after transplantation where polyspecific Tregs have failed so far.

P3.13.27
TIP60 Positively Regulates ThPOK-Mediated Repression of Eomesodermin in Human CD4+ T Cells

***B. LI**, Y. Li;*
Institut Pasteur of Shanghai, Chinese Academy of Sciences, Shanghai, China.

The abundant expression of IFNγ in ThPOK-deficient CD4+ T cells requires the activation of Eomesodermin (Eomes); however, the underlying mechanism of this phenomenon remains unclear. Here we report that ThPOK directly binds to the promoter region of the Eomes gene to repress its expression in CD4+ T cells. We identified the histone acetyltransferase TIP60 as a corepressor of ThPOK-target genes, where ectopically expressed TIP60 increased ThPOK protein stability by promoting its acetylation at its K360 residue to then augment the transcriptional repression of Eomes. Moreover, knockdown of endogenous TIP60 abolished the stabilization of ThPOK in CD4+ T cells, which led to the transcriptional activation of Eomes and increased production of IFNγ. Our results reveal a novel pathway by which TIP60 and ThPOK synergistically suppresses Eomes function and IFNγ production, which could contribute to the regulation of inflammation.

P3.13.28
The effects of 5-azacytidine on the enhancement of CD4+CD25highFOXP3+ T cells from the cultures of human CD4+CD25- T cells

***C. Lu**, C. Wu, M. Kuo;*
Graduate Institute of Biomedical Sciences, Chang Gung University, Taoyuan, Taiwan.

FOXP3 is a master transcription factor for regulatory T (Treg) cells. Stable FOXP3 expression is required for the maintenance of Treg cell function. Epigenetic regulation of FOXP3 expression has been proposed to be important for the development and suppressive function of Treg cells. However, the induction of human Treg cells through epigenetic manipulation has not been demonstrated. We found that human $CD4^+CD25^-$ T cells partially differentiated into $CD4^+CD25^{high}FOXP3^+$ cells upon suboptimal stimulation. The addition of 5-azacytidine (AzaC), a DNA methyltransferase inhibitor, alone enhanced this $CD4^+CD25^{high}FOXP3^+$ T cell population. The production of interleukin (IL)-2 was elicited as activating $CD4^+CD25^-$ T cells treated with AzaC. However, similar level of transforming growth factor (TGF)-β and reduced IL-10 was detected. By examining FOXP3 expression in AzaC-treated cells with neutralizing anti-IL-2 antibody, the increased IL-2 was important for enhancing FOXP3 expression. Furthermore, AzaC-treated $CD4^+CD25^{high}$ T cells expressed higher FOXP3, CTLA-4 and GITR at the comparable level to natural Treg cells. Unlike TGF-β-induced $FOXP3^+$ T cells that were indicated to lack regulatory function, AzaC-treated $CD4^+CD25^{high}$ T cells potently suppressed the proliferation of allogeneic $CD4^+$ T cells. The suppression was cell contact-dependent. Together, the results have significant implication for using epigenetic strategy to enhance functional Treg cells for clinical application.

P3.13.29
Ctirical roles of the transcriptional regulator IκB-ζ in regulatory T cells

***T. Maruyama**, T. Muta;*
Tohoku University, Sendai, Japan.

The transcriptional regulator IκB-ζ is a nuclear IκB protein harboring ankyrin-repeats that interact with NF-κB. It is robustly induced in macrophages upon stimulation with lipopolysaccharide and plays an essential role in expression of the secondary response genes represented by interleukin (IL)-6. Previous studies have shown that IκB-ζ is also induced in T cells in response to transforming growth factor (TGF)-β + IL-6 and cooperates with the transcriptional factor RORγt to express IL-17. Accordingly, IκB-ζ-deficient mice are resistant to experimental autoimmune encephalomyelitis. Here we show that IκB-ζ plays critical roles in the immune homeostasis through regulatory T cells (Tregs). T cell-specific IκB-ζ-deficient mice exhibited reduced numbers of Tregs and, along with aging, developed splenomegary and lymphocytic infiltration into various tissues including the lung and saliva along. It was found that stimulation of T cells with TGF-β alone up-regulated IκB-ζ expression and that co-expression of the NF-κB subunit p65 and IκB-ζ synergistically activated the Foxp3 promoter. In fact, IκB-ζ-deficient T cells exhibited impaired generation of $Foxp3^+$ Tregs in response to TGF-β *in vitro*. In addition, adoptive transfer of IκB-ζ-deficient Tregs, but not the wild-type Tregs, failed to prevent colitis induced by $CD4^+CD25^-CD45RB^{hi}$ T cells. These results indicate crucial roles of IκB-ζ in generation and effector functions of Tregs.

P3.13.30
Differential sialylation dictates the fate of regulatory T cells

***S. P. Mendez Huergo**, T. D´Alotto Moreno, M. Toscano, J. P. Cerliani, D. O. Croci, K. Mariño, G. A. Rabinovich;*
Instituto de Biologia y Medicina Expermiental - CONICET, Buenos Aires, Argentina.

Galectin-1 (Gal-1), an endogenous lectin found at sites of inflammation and tumor growth, plays key roles in immune tolerance and homeostasis. This lectin specifically interacts with lactosamine-enriched N-glycans and core-2-O-glycans on cell surface glycoproteins. Here we investigated the impact of Gal1-glycan interactions in the physiology of regulatory T (Treg) cells. Using a panel of plant lectins, we analyzed the glycosylation profile of naturally-occurring Treg cells (nTregs) isolated from the spleen of C57BL/6 mice. Glycophenotypic analysis revealed higher frequency of asialo-core-1-O-glycans and complex N-glycans with terminal a2-3-linked sialic acid (SA) on LacNAc residues on nTregs. This effect was accompanied by the presence of large amounts of a2-6-linked sialic acid (SAa2-6), a glyco-epitope that is restrictive for Gal1 binding in both nTregs and inducible Tregs (iTregs), versus to Tact cells. Similar results were obtained using lectin binding assays and mass spectrometric analysis. Notably, iTregs exhibited lower capacity to bind Gal1 compared to Tact cells ($p<0,01$), and increased expression of the a-2,6-sialyltransferase 1 (ST6Gal1), an enzyme responsible of incorporating SAa2-6 residues. When naive CD4+T cells were differentiated into iTregs, binding of Gal1 decreased and SAα-2,6 increased in a time-dependent manner. In an in vivo model, effector T cells from mice immunized with ovalbumin (OVA) exhibited a higher capacity to bind Gal1 as compared to iTregs ($p<0,01$). Moreover, iTregs were considerably more resistant to Gal1-induced cell death than Th17 and Tact cells. Our results uncover a glycosylation-dependent mechanism which selectively dictates the fate of Treg cells.

P3.13.31

Thymic precursors of T regulatory cells are resistant to caspase/granzyme B mediated degradation of Linker for activation of T cells.

*M. Klossowicz, B. Scirka, K. Marek-Bukowiec, P. Kisielow, **A. Miazek**; Institute of Immunology and Experimental Therapy, Wroclaw, Poland.*

Partial proteolysis of T cell receptor (TCR) signalosome plays a role in modulating the strength and duration of signaling. Using a newly developed method for assessment of LAT proteolytic degradation, we provided evidence that thymic T regulatory cell precursors (tT-regs) are resistant to LAT degradation upon TCR cross linking. We found that this resistance is partially due to the defect in Caspase 8 activation upon TCR engagement. In line with this finding we also observed that other extrinsic pro apoptotic signals delivered to thymocytes (i.e. Fas ligation or dexamethasone treatment) are unable to activate Caspase 8 selectively in tT-regs. In order to gain a better insight into mechanisms responsible for this phenomenon we evaluated the expression of several molecules that may counteract Caspase 8 activation or its external membrane targeting in tT-regs. Our data may shed light on mechanisms responsible for tT-reg resistance to the strong TCR mediated signals otherwise leading to negative selection of conventional, FoxP3 negative, thymocytes.

P3.13.32
Effect of gestational age and mode of delivery on CD4+ T cells and regulatory T cells (Treg) in neonatal cord blood

D. Mukhopadhyay[1]*, L. Weaver*[2]*, R. Tobin*[2]*, D. Jupiter*[1]*, M. K. Newell-Rogers*[3]*, L. Perger*[4]*;*
[1]*Texas A&M University/Scott & White, Temple, TX, United States,* [2]*Texas A&M University, Temple, TX, United States,* [3]*Scott & White Memorial Hospital, Temple, TX, United States,* [4]*Texas A&M University/McLane Children's Hospital, Temple, TX, United States.*

Purpose: Regulatory T cells (Treg), a subset of CD4+ T cells expressing FoxP3 and CD25, comprise 1-3% of CD4+ T cells in adult peripheral blood and have been shown to suppress immune responses. The aim is to determine the effect of gestational age and mode of birth on Tregs in cord blood of human newborns.
Methods: Cord blood of 200 newborns was collected between June 2012 and January 2013 and mononuclear cells (CBMCs) were analyzed using four-color flow cytometry. Tregs (CD3+, CD4+, CD25high, FoxP3high) were identified, and FoxP3 mean fluorescence intensity (MFI) measured. Suppressive index (SI) was calculated as MFI of FoxP3/Treg for individual Treg suppressive capacity.
Results: CD4+ percentage of CBMCs was 19±9% at 23-32 weeks gestational age (n=14), 12±10% between 33-36 weeks (n=35) and 12±9% at term (n=72) (p=0.03). Tregs remained at 11±5% until completion of gestation, then diminished to 7±5% (p<0.001). SI increased over 10-fold during gestation (55±10635 at 23-32 weeks, 111±11863 at 33-36 weeks, 1679±12963 at term, p=0.7). Mode of delivery did not affect Treg levels (vaginal delivery (n=30): 6±4% vs. caesarean section (n=42): 8±6%; p=0.13).
Conclusions: CD4+ T cells in cord blood decrease significantly at mid-third trimester. Tregs are significantly lower in term newborns but had higher suppressive activity. Gestational age and mode of birth effects on Treg suppressive activity may have implications for pre-term infants who cannot suppress an antigen-specific response to newly acquired gut flora or intestinal epithelium, potentially leading to symptoms of necrotizing enterocolitis.

P3.13.33
Adenosine production through CD39 and CD73 mediates development of sepsis-induced immunossupression via A2a receptor

D. C. B. Nascimento*, P. H. Melo, R. G. Ferreira, R. S. Peres, D. S. Zamboni, F. Q. Cunha, J. F. Alves-Filho;*
University of Sao Paulo, Ribeirão Preto, Brazil.

Introduction and Aim: Sepsis is regularly accompanied by the development of a pronounced immunosuppression, which is characterized by expansion of regulatory T cells (Treg cells), reduced proliferation and function of effector T cells and increased susceptibility to secondary infection. Adenosine is a purine nucleoside that has been implicated in the modulation the immune system. Here, we investigate the role of ectonucleotidases (CD39 and CD73) and adenosine in the establishment of sepsis-induced immunosuppression. **Methods and Results:** C57BL/6 mice were subjected to severe sepsis induced by cecal ligation and puncture and treated with antibiotic (ertapenem), resulting in 50% of survival. At 15th day after CLP, sepsis-surviving mice showed an enhanced number of Treg cells in spleen and impaired T cell proliferative response, which was associated with high susceptibility to secondary infection induced by *L. pneumophila*. Notably, sepsis-surviving mice treated with CD39 inhibitor (ARL671516) and CD73 inhibitor [adenosine 5΄-(α,β-methylene)diphosphate] had reduced number of Treg cells, improved of T cells proliferative response, low bacterial load in lungs and spleen and improved survival to secondary infection compared to control mice. Moreover, sepsis-surviving mice treated with A2aR antagonist [8-(3-chloro-styryl)caffeine] also showed reduced number of Treg cells and improved of T cells proliferative response, which was associated with reduced levels of bacteria in lungs and spleen and an improved survival after secondary infection. **Conclusion:** Our studies demonstrate that extracellular production of adenosine by ectonucleotidases orchestrates the establishment of sepsis-induced immunosuppression. **Financial support:** FAPESP.

P3.13.34
CD4+ regulatory T lymphocytes in preeclamptic women and in their newborns: preliminary results

D. Navarro Barquín[1]*, L. Daza Benitez*[2]*, S. López Briones*[1]*, A. Macías Rocha*[2]*, P. González*[2]*;*
[1]*University of Guanajuato, León de los Aldamas, Mexico,* [2]*Mexican Institute of Social Security (I.M.S.S), León de los Aldamas, Mexico.*

Objective: Our aim was to study the proportion of regulatory T cells in preeclamptic women and in their newborns.
Methods: The CD4+CD25+high T-reg cells, and hormone profile were analyzed in 23 women with preeclampsia (PE) and in 14 newborns. Also, fourteen healthy women (HC) and 5 newborns were included as controls.
Results: The T-regs cells proportion was 2.93% in PE and vs. 5.54% in HC (p = 0.031). The CD4+CD25+high cells were in PE 3.71% vs. HC 7.41% in HC, (p= 0.020); Total IgG level was 847 in PE vs. 955 in HC (p= 0.117). In the umbilical cord blood samples we found 4.56% in T regs cells in PE vs.8.54% in HC (p = 0.201). While gamma-delta T-cells were 3.61 in PE vs. 20.87% in HC, (p= 0.063). Interestingly, CD4+CD69+ cells were 10.03% in PE and 28.22% in HC (p=0.190).
Conclusions: We found decreased proportion of T-regs cells in preeclamptic women as previously have been reported. Also we observed a tendency of decreasing levels of IgG in women with PE, in relation to the hypothesis of the increased of immunologic response mediated by T-cells. Regarding, hormone profiles we found no statistical significance. In the newborns we found a tendency of decreased T-regs cells, gamma-delta T-cells, and a low expression of CD69CD4 cells, an important early activation marker expressed by lymphocytes. Nevertheless, the number of patients included in this study is still small, but we can suggest that PE has a repercussion in the immunological cell profile of their newborns.

P3.13.35
The influence of regulatory T cells on the response to the measles and DTP vaccines in Gambian infants

J. Ndure[1]*, F. Noho-Konteh*[1]*, J. Adetifa*[1]*, S. Rowland-Jones*[2]*, E. Clarke*[1]*, J. Sutherland*[1]*, H. Whittle*[1]*, M. Plebanski*[3]*, M. Ota*[1]*, K. Flanagan*[3]*;*
[1]*Vaccinology Theme, Medical Research Council Unit, The Gambia, Banjul, Gambia,* [2]*Weatherall Institute of Molecular Medicine, Oxford University, Oxford, United Kingdom,* [3]*Department of Immunology, Monash University, Melbourne, Australia.*

Despite the key role of Regulatory T cells (Tregs) in regulating immune responses to infections, very few studies have reported on their role in controlling the immunogenicity of vaccines in infants. It is still not clear if pre-existing Tregs interfere with the generation of

vaccine-induced immunity, and whether they are induced following vaccination in infants.
Using a dataset from a randomized trial of 9 month-old infants vaccinated with either measles vaccine (MV) alone, MV + DTwP (diptheria, tetanus, whole cell pertussis combined vaccine) or DTwP alone; Treg frequencies were examined overtime. The influence of the baseline Tregs on the measles antibody response, response to DTP antigens; and the production of both inhibitory and pro-inflammatory cytokines following overnight stimulation with vaccine specific/non-specific antigens were evaluated.
We observed a weak negative correlation between circulating Tregs and measles antibody levels ($r = -0.2077$; $p=0.0482$); but not with response to the DTP antigens. Following overnight stimulation with the TT antigen, there was a weak yet significant inverse correlation between the Treg frequencies and production of IL-4, IL10 and TNFα ($p<0.001$). We also showed that there was a significant decline in Treg frequencies in all donors by 19 months of age ($p<0.001$).
These data suggest that Tregs may have a role to play in controlling the immunogenicity of vaccines in infants. The influence of pre-existing Tregs on the MV response may differ from that of DTP. These findings provide useful background data for further studies looking to provide strategies to improve vaccine immunogenicity in infants.

P3.13.36
Homeostatic competition of regulatory T cells in the peripheral compartment of syngeneic and semi-allogeneic hosts

J. S. Nogueira[1], *C. F. C. G. Nunes*[1], *F. B. Canto*[1], *P. H. O. Vianna*[2], *M. M. C. Ferreira*[2], *A. Nóbrega*[1], *M. Bellio*[1], *R. Fucs*[2];
[1]*Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil,*
[2]*Universidade Federal Fluminense, Niterói, Brazil.*

The $CD4^+CD25^+Foxp3^+$ regulatory T cells (Treg) population is kept in stable frequencies in the secondary lymphoid organs for the majority of lifetime, despite permanent thymic emigration or in face of thymic involution. A continuous competition is expected, thus, among recently thymus-emigrated and resident Treg cells (either natural or post-thymically-induced). In the present work, we analyzed the kinetics of Treg and non-Treg cell renewal, using a protocol of successive syngeneic or semi-allogeneic T cell transfers into athymic hosts as a model to understand the physiological competition between newly thymus emigrated T cells and resident T cells in the periphery. Our results showed a preferential incorporation of Treg cells into the previously colonized environment, in comparison to conventional $CD4^+$ T cells (non-Treg). In the semi-allogeneic condition, the Treg turnover kinetics was even more expressive, suggesting that a different density of MHC-peptides complexes in the periphery may affect the level of Treg cell colonization. In the syngeneic hosts, although the first-transferred population did not attain numbers seen in euthymic hosts, the entry of subsequently transferred Treg cells was apparently impaired. These findings are in accordance with a permanent evolution of Treg cell repertoire throughout life and suggest that Treg renewal is linked to the diversity of TCR repertoire. To know the rules determining Treg cell survival versus replacement in the periphery is crucial for the understanding of their repertoire evolution and for the envisaged use of Treg cell transfer as a therapy to restore tolerance to self-antigens in autoimmune diseases.

P3.13.37
Regulatory T cells are preferentially preserved over non-Tregs within neonatal-derived T cells present in adult mice

C. F. Nunes[1], *J. S. Nogueira*[1], *F. B. Canto*[1], *P. Vianna*[2], *M. Martins*[2], *M. Bellio*[1], *A. Nóbrega*[1], *J. Mengel*[3], *R. Fucs*[2];
[1]*Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil,*
[2]*Universidade Federal Fluminense, Rio de Janeiro, Brazil,* [3]*Fundação Oswaldo Cruz, Rio de Janeiro, Brazil.*

Regulatory T cells (Treg), essential to control self/nonself responses, were also associated with neonatal acquired tolerance. Peculiar features of the neonatal lymphoid compartment might influence the substitution kinetics of the thymic-derived Treg population, affecting the maintenance of self-tolerance acquired in the neonatal period and the preservation of Treg repertoire diversity. To evaluate Treg and non-Treg cell peripheral homeostasis at different ages, athymic mice (Thy1.2+) were grafted with colonized thymic lobes from either neonatal or adult congenic donors (Thy1.1+) and the frequencies of donor- and host-derived T cells were followed by FACS. Neonatal-derived T cells were widely replaced by host-derived lymphocytes after the second month, while a substantial proportion (>30%) of donor T cells remained in the adult thymus-grafted hosts. Donor- and host-derived T cells contained similar proportions of Tregs in mice grafted with adult thymus. In contrast, the residual fraction of Thy1.1 neonatal-derived T cells contained a two-fold enrichment in Tregs when compared to the Thy1.2 host-derived T cells, and persisted for at least ten months. We obtained similar data using a co-transfer model of neonatal and adult T cell suspensions into athymic mice. Our results suggest that when facing adult competitors, an event expected during ontogeny, resident neonate-derived T lymphocytes are mostly replaced, but a Treg-enriched cohort is long-term preserved among the reminiscent cells. A higher affinity for peripheral self-peptides, in comparison to non-Treg cells, may promote this preferential long-term survival of neonatal Treg cells, which can be important for maintenance of self-tolerance memory.

P3.13.38
Identification of an endogenous subpopulation of regulatory CD8+ T cells specific for a tissue-restricted tumor associated antigen in tumor-bearing TRAMP mice

S. Parigi*, N. Rigamonti, E. Degl'Innocenti, E. Jachetti, M. Grioni, M. Bellone;*
San Raffaele Scientific Institute, Milan, Italy.

The immune system exerts a dual host-protective and tumor-promoting action in cancer patients and, in this scenario, prostate cancer (PC) has been largely studied for defining new immunotherapeutic strategies that also target immunosuppressive mechanisms. Regulatory CD8+ T cells have been reported in PC patients but their real role in cancer progression still remains elusive. Here we provide evidences that endogenous low avidity CD8+ regulatory T cells from the spleen of tumor-bearing transgenic adenocarcinoma of the mouse prostate (TRAMP) mice are responsible for the establishment of specific tolerance against Tag, which in this model behaves like a tissue-restricted tumor associated antigen. In vitro, splenic CD8+ T cells from tumor-bearing TRAMP and not from age-matched wild-type males or healthy TRAMP mice inhibited priming of T cells by altering the antigen presenting capacity of matured dendritic cells. When adoptive transferred into wild-type recipients, only splenic CD8+ T cells from tumor-bearing TRAMP mice significantly impaired the Tag-specific CTL response induced by vaccination with dendritic cells pulsed with Tag. Moreover, this effect appeared to be antigen-specific, since these cells did not weaken the immune response induced by vaccination against the exogenous antigen ovalbumin. The CD8-mediated suppression directly correlated with Tag overexpression and tumor progression in TRAMP mice. All together, our data confirm and extend previous findings showing that indeed, an endogenous population of regulatory CD8+ T cells exists in tumor-bearing TRAMP mice that may contribute to tumor-associated tolerance in this model. A further characterization of this population will likely identify novel therapeutic targets for PC.

P3.13.39
CD39 is highly involved in mediating the suppressive activity of tumor-infiltrating CD8+ T regulatory lymphocytes

A. Parodi[1], *F. Battaglia*[1], *F. Kalli*[1], *F. Ferrera*[1], *G. Conteduca*[1], *G. Borgonovo*[2], *P. Traverso*[3], *G. Carmignani*[2], *D. Fenoglio*[4], *G. Filaci*[5];
[1]*CEBR, University of Genoa, Genova, Italy,* [2]*Dep of surgical sciences, University of Genoa, Genova, Italy,* [3]*University of Genoa, Genova, Italy,* [4]*Cebr and Dimi,University of Genoa, Genova, Italy,* [5]*Cebr and Dimi, University of Genoa, Genova, Italy.*

CD39 is an ectoenzyme, present on different immune cell subsets, which mediates immunosuppressive functions catalyzing ATP degradation. It is not known whether CD39 is expressed and implicated in the activity of CD8+ regulatory T lymphocytes (Treg). In this study, CD39 expression and function was analyzed in both CD8+ and $CD4+CD25^{hi}$ Treg from the peripheral blood of healthy donors as well as from tumor specimens. CD39 was found expressed by both

CD8+ (from the majority of healthy donors and tumor patients) and CD4+CD25^{hi} Treg, and CD39 expression correlated with suppression activity mediated by CD8+ Treg. Importantly, CD39 counteraction remarkably inhibited the suppression activity of CD8+ Treg (both from peripheral blood and tumor microenvironment) suggesting that CD39-mediated inhibition constitutes a prevalent hallmark of their function. Collectively, these findings, unveiling a new mechanism of action for CD8+ Treg, provide new knowledge on intratumoral molecular pathways related to tumor immune escape, which could be exploited in the future for designing new biological tools for anticancer immune intervention.

P3.13.40
The hunt for a natural regulatory T cell ligand

M. Phillips[1]*, J. Scott-Browne*[2]*, J. Kappler*[1]*, P. Marrack*[1]*;*
[1]*HHMI / National Jewish Health, Denver, CO, United States,* [2]*La Jolla Institute for Allergy and Immunology, La Jolla, CA, United States.*

Natural T regulatory cells (nTregs) develop in the thymus along with conventional T cells (Tcons) in a similar fashion. While the exact cues for nTreg cell differentiation in the thymus is still a topic of rigorous study, it is widely accepted that TCR signal strength during positive selection is an important determinant. Various data provide evidence that nTreg TCR signal strength against self-peptide MHC falls someplace in between the level at which Tcon TCRs just pass positive selection and the level at which cells are deleted due to negative selection. This is reflective of the fact that mature Tregs are reactive to self antigens while mature Tcons are ideally reactive to foreign antigens in the context of MHC. A useful tool to help understand nTreg differentiation and function would be to find a natural antigen for nTregs; however, finding a natural antigen has proven elusive. Here we propose a technique to search for a natural Treg antigen by making nTreg TCRs “more” autoreactive followed by screening of a peptide library.

P3.13.41
CD8+ regulatory T cells recognize donor MHC class II-derived immunomodulatory epitopes in an allotransplantation model

E. Picarda[1]*, S. Bézie*[1]*, A. Delhumeau*[1]*, K. Renaudin*[2]*, E. Mérieau*[1]*, I. Anegon*[1]*,* ***C. Guillonneau***[1]*;*
[1]*Inserm UMR1064, Nantes, France,* [2]*Service d'Anatomopathologie, CHU Hôtel Dieu Nantes, France.*

We recently reported that in a rat MHC mismatched heart allograft model, treatment with CD40Ig leads to indefinite allograft survival mediated by CD8+CD45RClow Tregs. Although essential, the exact role of TCR/MHC/peptide interaction in Treg activity is still unknown. We therefore studied their recognition properties by characterizing the allogeneic peptide(s) recognized.
Allogeneic peptides were derived from polymorphic regions of donor MHC molecules (RT1.A, RT1.B, RT1.D). 82 overlapping peptides of 16 aa were tested in a coculture of Tregs with syngeneic pDCs (ratio 1:4) and facs analysis was performed at day 6. Two peptides led to a strong activation of Tregs, as shown by the upregulation of CD25 (24.4% to 28.9% of expression). These antigen-specific Tregs displayed a modified phenotype (MHC-II, CD28, CD71 upregulated). For suppression assay, peptide-activated Tregs were sorted at day 6 and cocultured with CFSE+CD4+ effector T cells and allogeneic pDCs. Thus, allospecific Tregs were shown to maintain their suppressive activity in vitro after stimulation. For in vivo study, 0.5 mg/day of peptide was delivered continuously by a mini osmotic pump implanted intraperitoneally in recipients. Interestingly, we showed that administration of the dominant allopeptide, from day -7 to day 21 after transplantation, resulted in prolongation of allograft acceptance with an indefinite survival in 25% of the recipients. These rats showed a higher number of Tregs in spleen compared to untreated ones, an inhibition of alloantibody responses and no sign of chronic rejection.
This study demonstrated that antigen specific CD8+CD45RClow Tregs recognize 2 allogeneic epitopes with a therapeutic potential.

P3.13.42
Interferon-alpha plays complex roles in human regulatory T cell deprogramming into Th1-like cells

S. Piconese*, Y. Pacella, E. Timperi, D. Accapezzato, G. Labbadia, V. Barnaba;*
"Sapienza" Università di Roma, Roma, Italy.

Regulatory T cells (Treg) are classically viewed as immune suppressive cells tipping the balance between host defense from pathogens and prevention of excessive immunity. Recent data indicate that Treg can dynamically adapt to different contexts and even acquire the competence for unexpected inflammatory functions in peculiar cytokine contexts. The purpose of this study was to characterize the functional changes induced in Treg upon exposure to IFN-alpha, a cytokine with well-known antiviral properties. In vitro, in neutral culture conditions, IFN-alpha slightly increased Tbet and IFN-gamma expression by Treg; in a Th1-prone (IL2 plus IL12) condition, the addition of IFN-alpha further enhanced IL-12-driven IFN-gamma production, suggesting a role for IFN-alpha in supporting Treg deprogramming into Th1-like cells. IFN-alpha also exerted an anti-proliferative effect against both conventional T cells (Tconv) and Treg, without affecting the Treg-intrinsic suppressive function in Tconv-Treg cocultures. To evaluate the effects of Treg exposure to IFN-alpha in vivo, Treg were analysed by flow cytometry in patients with chronic HCV infection undergoing peginterferon/ribavirin therapy, before and 2 days after the starting of therapy. In the majority of patients, we could observe a decreased Treg frequency and an enhanced IFN-gamma production by both Tconv and Treg after treatment. IFN-gamma secretion by the two cell subsets showed a linear correlation, suggesting that Tconv-derived IFN-gamma may play a role in Treg diversion into Th1-like cells. Our data indicate that, under Th1 conditions, IFN-alpha may amplify Th1-type inflammation by inhibiting Treg expansion and fostering Treg deprogramming into Th1-like cells.

P3.13.43
Inducible IL-10 secreting CD49b+Treg cells as cell based-therapy for rheumatoid arthritis

J. Quentin[1]*, R. Vicente*[2,1]*, D. Martire*[1]*, A. Mausset-Bonnefont*[1]*, C. Jorgensen*[1]*, P. Louis-Plence*[1]*;*
[1]*INSERM U844, Montpellier, France,* [2]*CNRS UMR 5253, Montpellier, France.*

Adoptive transfer of Tregs is a promising approach to restore tolerance in autoimmune disease. However several subsets of Tregs need to be precisely defined to clearly establish which Tregs will be able to dampen efficiently the immune response in the various settings. We previously showed the potential of IL10-secreting induced CD49b+ Tregs to protect and prevent an experimental model of arthritis. Nevertheless the optimal dose, the phenotype and the in vivo-suppressive mechanism of these Tregs remain unknown. Here, we investigated and compared the therapeutic potential of CD25+FoxP3+ and induced CD49b+ FoxP3- Tregs in experimental models of arthritis or inflammation. Tregs were generated in naïve mice following repetitive injections of immature DCs. Tregs purification was based on the negative selection of CD4 T cells isolated from spleen and liver of vaccinated mice. Several doses of CD49b+ Tregs were intravenously injected at day 28 in established arthritis. We observed that the injection of 105 CD49b+ or CD25+ cells reverse clinical symptoms of arthritis while interestingly, a lack of efficacy of higher doses was observed. In vitro suppressive experiments confirmed the similar efficiency of both populations and phenotype analyses of CD49b Tregs showed expression profile of several Tregs specific markers (LAP+, LAG+, CTLA-4high). Moreover, in an OVA-specific model of inflammation, we demonstrated the higher impact of the CD49b Tregs on the proliferation of effector cells. Altogether, our results confirm the therapeutic potential of IL-10 secreting T cells in experimental model of arthritis in curative settings and unravel their mechanism of suppression.

P3.13.44
Systems analysis of innate activation reveals IL-1 family members as key modulators of T cells susceptibility to regulation and novel targets for therapeutic intervention

G. Raimondi[1], *Y. T. Nicholson*[2], *C. Ziraldo*[3], *R. Starzl*[4], *S. Schneeberger*[1], *A. W. Thomson*[2], *G. Brandacher*[1], *Y. Vodovotz*[3];
[1]*Johns Hopkins School of Medicine, Baltimore, MD, United States,* [2]*Starzl Transplantation Institute - University of Pittsburgh School of Medicine, Pittsburgh, PA, United States,* [3]*University of Pittsburgh, Pittsburgh, PA, United States,* [4]*Carnegie Mellon University, Pittsburgh, PA, United States.*

Rational regulation of T cells responses is the ideal goal of tolerance promoting therapies. However, our understanding of the factors and mechanisms that modulate the susceptibility of T cells to regulation is limited. We and others have demonstrated that regulatory T cells (Treg)-mediated suppression of T cells is compromised in an inflamed environment. We aimed to identify inflammatory mediators that lessen T cell regulation. We implemented a bio-informatic analysis to evaluate the secretion of 23 cytokines by maturing murine dendritic cells. This analysis suggested that IL-1α and IL-1β could parallel IL-6 in reducing the efficacy of Treg. Using a CFSE-based, in vitro mouse T cell activation system, we confirmed that both IL-1α and β exert a profound negative effect on Treg-mediated suppression. In a mouse model of inflammatory bowel disease based on adoptive transfer of T cells +/- Treg, Ab-mediated blockade of IL-6 signaling delayed disease development through a process dependent on the presence of Treg. When Myd88-KO T cells (unable to respond to IL-1 family members) were used in this model, we observed a significant delay of weight loss, corroborating the involvement of this family of cytokines in modulating immune-regulation. Finally, we investigated the production of inflammatory cytokines following orthotopic vascularized composite (hind-limb) allotransplantation. IL-6, IL-1α, IL-1β, and particularly IL-18 (an IL-1 family member) accumulated at significant levels and for prolonged time in transplanted tissues. These observations provide evidence that these cytokines play an important role in promoting rejection, by antagonizing immune-regulation, and are necessary targets for therapeutic interventions.

P3.13.45
CD39 expression on Treg cells is genetically determined and can be further modulated upon activation

A. Rissiek[1], *A. Cuapio*[1], *I. Baumann*[1], *A. Dodge-Khatami*[2], *P. C. Arck*[3], *F. Koch-Nolte*[1], *F. Haag*[1], *E. Tolosa*[1];
[1]*UKE - Dept. of Immunology, Hamburg, Germany,* [2]*UKE - Dept. of Paediatric Cardiac Surgery, Hamburg, Germany,* [3]*UKE - Laboratory for Experimental Feto-Maternal Medicine, Hamburg, Germany.*

CD39 defines a subset of regulatory T cells (Treg) with high suppressive capacity, and has been often associated with an activated status of regulatory T cells. The fraction of CD39-expressing cells within the Treg compartment varies widely (5% to 80%) in the human population, increasing slowly with age. However, the expression of CD39 on Tregs over time in one individual is very stable, and clonality analysis shows an unbiased repertoire. Moreover, in vitro activation of primary CD39-negative Treg cells using a Treg-tracking system resulted in only minor upregulation of CD39 in less than one third of the cells, making it unlikely that activation alone is responsible for the very high percentages of CD39+ Tregs found in some donors. We show here that CD39+ Treg are present in early compartments such as thymus and cord blood. CD39+ Treg in healthy adults express higher levels of CD25, FOXP3, memory markers and chemokine receptors involved in migration to inflammatory sites compared to their CD39-negative counterparts. However, in cord blood and young infants they exist as naïve cells, suggesting that -at least in part- they egress the thymus already as CD39 positive Tregs. Of note, thymic CD39+ Treg already show superior suppressive activity compared to CD39- Tregs. Finally, we show that donors with different levels of CD39 on Tregs can be segregated according to a SNP in the CD39/ENTPD1 gene, clearly indicating that the expression of CD39 on Tregs is genetically determined.

P3.13.46
ART2 blockade during cell preparation preserves the vitality and function of Tregs and iNKT cells

B. Rissiek, *W. Danquah, F. Haag, F. Koch-Nolte;*
University Medical Center Hamburg-Eppendorf, Hamburg, Germany.

Release of NAD+ during preparation of murine T cells causes ADP-ribosylation of cell surface proteins, which is catalyzed by the ecto-enzyme ADP-ribosyltransferase-2 (ART2). ART2 mediated ADP-ribosylation of the P2X7 ion channel induces gating of P2X7. This in turn mediates a cascade of downstream events including ecto-domain shedding of CD27/CD62L, externalization of phosphatidylserine, and ultimately cell death. ART2 shows catalytic activity even at 4 °C when cells are prepared on ice. Gating of P2X7, in contrast, occurs efficiently only when the cells are brought to 37 °C. Thus, the phenotypic and functional changes induced by ADP-ribosylation of P2X7 only become visible when cells are returned to 37 °C, e.g. in vitro for functional assays or in vivo for adoptive transfer studies. P2X7 is predominantly expressed by Foxp3+ regulatory T cells (Tregs) and invariant natural killer T cells (iNKTs). These cells are highly sensitive to activation of P2X7 via ART2. Using a Nanobody (clone s+16a) that blocks the enzymatic activity of ART2 during cell preparation we were able to markedly increase the vitality of Tregs and iNKTs in vitro. Further, we were able to greatly enhance the sensitivity of in vitro T suppression assays and to expand liver iNKTs in vitro. Finally, we observed that blockade of ART2 during cell preparation was also beneficial for the adoptive transfer of Tregs and indispensible for the successfull adoptive transfer of liver iNKTs. Therefore, our findings underscore the potential of Nanobody s+16a as valuable tool to improve and facilitate research on Tregs and iNKT cells.

P3.13.47
miR-21 transfection can differentiate human naïve T cells to regulatory phenotype

E. Salehi, *H. Namdari, M. Ghayedi, P. Rahimzadeh, S. Mortezagholi, Z. Gheflati, J. Hajati, B. Dolatshah Earaghi;*
Tehran University of Medical Sciences, Tehran, Iran.

Regulatory T cells are important players of the immune system that downregulate the immune responses. T regs are considered the main mediators of peripheral tolerance. Their mechanisms of action and clinical applications are subjects of considerable debate currently. These cells are involved in preventing autoimmunity and defective development and function of these cells can result in autoimmune disease.
Increasing evidence supports the role of miR-21 in the regulation of Foxp3 expression in Treg cells. In this research we tried to clarify whether miR-21 transfection to naïve CD4+ T cells is useful in the generation of iTregs in vitro. We separated naïve T cells using negative isolation magnetic kit and cultured them in the presence of anti-CD3, anti-CD28 and Treg polarizing cytokines or miR-21 transfection. We investigated in vitro differentiation of miR-21-transfected naïve CD4+ T cells to iTregs and then compared these iTregs to cytokine-differentiated iTregs and negative controls. We showed that expression of Foxp3, TGF-b, and IL-10 are increased in miR-21 transfected naïve T cells in comparison to cytokine-differentiated iTregs and negative controls.
Conclusion: Our data demonstrate that mir-21 is effective in the in vitro differentiation of naïve T cells to iTregs.

P3.13.48
Nr4a nuclear orphan receptors are essential for thymic regulatory T cell development and immune homeostasis

T. Sekiya, *A. Yoshimura;*
Keio University, Tokyo, Japan.

Regulatory T cells (Treg) develop from progenitor thymocytes following engagement of the T cell receptors (TCR) with high affinity ligands, but the underlying molecular mechanisms are still unclear. Here, we demonstrate that the Nr4a orphan nuclear receptors, which are immediate-early genes up-regulated by TCR stimulation in

thymocytes, had an essential roles in Treg development. Mice that lack all Nr4a factors could not produce Treg cells and died within three weeks after birth due to systemic multi organ autoimmunity. Nr4a receptors directly activated the Foxp3 promoter, and forced activation of Nr4a receptors bypassed low-strength TCR signaling to drive the Treg developmental program. Our results our observations not only identified Nr4a receptors as critical components of Treg development, but also suggest that they act as the coordinators of the proper fate decision of CD4+ T cells in the thymus, by translating the strength of TCR signaling to transcriptional programs, thus working as crucial contributors to immune homeostasis.

P3.13.49
CD8+CD122+CD49d- regulatory T cells maintain immune homeostasis by Fas/FasL pathway-mediated killing of activated T cells

***H. Suzuki**, K. Akane, K. Isobe;*
Nagoya University, Nagoya, Japan.

One of the best-characterized $CD8^+$ regulatory T cells are $CD8^+CD122^+$regulatory T cells that were proved to play important roles in maintaining the immune homeostasis. However, $CD8^+CD122^+$ cells also contain a considerable percentage of memory T cells. Therefore, some marker(s) to distinguish regulatory T cells from memory T cells are needed. We found that CD49d, the α-chain of integrin, can separate $CD8^+CD122^+$ cells into two populations ($CD49d^-$ and $CD49d^+$). In this study, we established 2 assay systems, i.e. in vitro co-culture of $CD8^+CD122^-$ T cells and candidate cells of Treg, and in vivo co-transfer of $CD8^+CD122^-$ T cells and candidate cells of Treg. In the in vitro assay, the number of $CD8^+CD122^-$ indicator cells dramatically decreased after 48-72 h of co-culture if the candidate cells had the regulatory activity. In the in vivo assay, $RAG\text{-}2^{-/-}$ mice transferred with $CD8^+CD122^-$ T cells alone died within 14 weeks after the T cell transfer whereas mice transferred with a mixture of $CD8^+CD122^-$ T cells and $CD8^+$ Treg survived longer than 14 weeks. When the regulatory function of $CD8^+CD122^+CD49d^-$ cells and $CD8^+CD122^+CD49d^+$ cells was tested, $CD49d^-$ cells showed regulatory function both in vitro and in vivo experiments but $CD49d^+$ cells did not. Furthermore, $CD8^+CD122^-$ cells taken from *lpr* mice were not well regulated by wild type mice-derived $CD8^+CD122^+CD49d^-$ cells and $CD8^+CD122^+CD49d^-$ cells taken from *gld* mice did not regulate wild type mice-derived $CD8^+CD122^-$ cells. These results indicate that the regulation between $CD8^+CD122^+CD49d^-$ cells and $CD8^+CD122^-$ cells is mediated by Fas-FasL dependent cytotoxicty.

P3.13.50
Regulatory T cells in peripheral blood and tissue of active generalized vitiligo

***M. K. Tembhre**, V. K. Sharma, A. Sharma, P. Chattopadhyay, S. Gupta;*
All India Institute of Medical Sciences, New Delhi, India.

Vitiligo is an organ specific autoimmune depigmentation disease. Enhanced T cell mediated immunity and deficiency in regulatory T cells (Tregs) function has been implicated in the pathogenesis of generalized vitiligo (GV).
Tregs were characterized as CD3+ CD4+ CD25+ FOXP3+ in peripheral blood by flow cytometry, and the mRNA transcript levels of FOXP3, TGF-β and IL-10 were determined in peripheral blood and lesional, perilesional and non-lesional tissue by quantitative real time RT-PCR and immunolocalized by confocal microscopy.
Significant decrease in the frequency of Tregs was observed in active GV compared to healthy controls ($P < 0.05$). In peripheral blood, no siginificant difference was observed for mRNA transcript levels of FOXP3 and IL-10 ($P > 0.05$) but mRNA levels of TGF-β ($P < 0.05$) were significantly decreased in patients with active GV and healthy controls. Significant differential expression levels were observed for FOXP3 and TGF-β in lesional, peri-lesional non-lesional tissue of active GV.
Decrease in the percentage of Tregs in peripheral blood of active vitiligo patients suggests that there is deficiency in Treg frequency. Reduced mRNA levels of FOXP3 and TGF-β in lesional tissue suggests that there may be defect in their suppressive function or homing to skin leading to breakdown of peripheral tolerance and T cell mediated selective killing of melanocytes.

P3.13.51
Characterization of the role of hydroxyprostaglandin dehydrogenase in regulatory T cells

***Y. Thabet**[1], E. Schönfeld[1], M. Mai[1], T. Sadlon[2], K. Subbaramaiah[3], A. J. Dannenberg[3], T. Sparwasser[4], S. C. Barry[2], J. L. Schultze[1], M. Beyer[1];*
[1]LIMES, Genomics & Immunoregulation, University of Bonn, Bonn, Germany, [2]Women's and Children's Health Research Institute, University of Adelaide, Adelaide, Australia, [3]Department of Medicine and Weill Cornell Cancer Center, Cornell University, New York, NY, United States, [4]Institute for Infection Immunology, TWINCORE, Hannover, Germany.

Regulatory T cells (T_{reg} cells) are indispensable for self-tolerance and immune homeostasis. The forkhead transcription factor FOXP3 is essential for T_{reg}-cell development and function. We could identify hydroxyprostaglandin dehydrogenase (HPGD) as significantly higher expressed in human T_{reg} cells compared to conventional $CD4^+CD25^-$ T cells. HPGD fulfills an important function in the metabolism of eicosanoids and prostaglandins and is one of the major PGE_2-metabolizing enzymes. Notably, HPGD expression was specific for naturally occurring T_{reg} cells as HPGD was not upregulated during $CD4^+$ T-cell differentiation and even induced T_{reg} cells. Furthermore, exclusively in T_{reg} cells, HPGD expression could be specifically modulated by Interleukin-2. Minuscule amounts of IL-2 were sufficient to strongly upregulate HPGD expression. Blockade of JAK3/STAT5 signaling inhibited HPGD upregulation in T_{reg} cells. Moreover, the dependency of HPGD expression on IL-2-dependent signaling could be confirmed using reporter assays. Interestingly, FOXP3-ChIP experiments showed binding of FOXP3 to the HPGD promoter and loss of function experiments as well as reporter assays revealed that FOXP3 modulates rather than suppresses expression of HPGD. Furthermore, the dependency of HPGD expression on the extracellular microenvironment also indicates a tissue-specific expression and potential function of HPGD within T_{reg} cells. Taken together, the present study demonstrates that HPGD represents a novel gene, which is specific for human T_{reg} cells. Although the relevance of HPGD for T_{reg}-cell function remains to be elucidated, the present study indicates a tissue-specific role of HPGD in T_{reg} cells and provides a basis for further research to determine the role of HPGD for T_{reg}-cell function.

P3.13.52
Regulatory T cell plasticity in HCV-related liver inflammation and tumor

***E. Timperi**[1], Y. Pacella[1], M. Rossi[2], G. Grazi[3], S. Brozzetti[4], V. Barnaba[1,5], S. Piconese[1];*
[1]Dipartimento di Medicina Interna e Specialità Mediche, "Sapienza" Università di Roma, Roma, Italy, [2]Department of General Surgery and Organ Transplantation, Roma, Italy, [3]Chirurgia Epatobiliopancreatica, Istituto Nazionale Tumori Regina Elena, Roma, Italy, [4]Department of Surgery "Pietro Valdoni", Roma, Italy, [5]Istituto Pasteur-Fondazione Cenci Bolognetti, Roma, Italy.

Several evidences suggest that regulatory T cells (Treg) are functionally heterogeneous and plastic. For instance, in inflammatory milieus, Treg can produce pro-inflammatory cytokines, while a suppressive program characterizes tumor-associated Treg. Coinhibitory/costimulatory receptors expressed by Treg in particular conditions, such as PD-1 and OX40, may influence Treg sensitivity to cytokines and Treg program.
The aim of our study is to characterize the features of Treg in peripheral blood, hepatocellular carcinoma (HCC) and the surrounding tumor-free liver tissue, obtained from patients with chronic HCV infection.
Few Treg can be detected in tumor-free not cirrhotic liver tissue, expressing PD-1 and secreting IFN-γ ex vivo. Instead HCC and tumor-free cirrhotic liver tissues are infiltrated by abundant Treg that poorly secrete IFN-γ, despite a high expression of T-bet (Th1-related

factor). Interestingly, these Treg upregulate OX40, which is not constitutive in human Treg cells. OX40 expression and IFN-γ secretion are mutually exclusive, suggesting that OX40 correlates with protection from Treg deprogramming into Th1-direction. OX40L, the ligand for OX40, can be detected on a variety of immune cells at the HCC site.
These observations have been recapitulated in experiments in vitro. Indeed, Treg of healthy donors upregulate OX40 when stimulated with IL-2 and/or TNF-α in vitro. These OX40+ Treg are protected from the acquisition of IFN-γ production under Th1 conditions.
In conclusion, Treg can reprogram their functions toward suppression or inflammation; moreover, HCV-related cirrhosis may orchestrate a immunosuppressive signals fostering Treg expansion and favoring tumorigenesis.

P3.13.53
Application of novel Brilliant Violet™ fluorophores for multicolor flow cytometric analysis: phenotyping of regulatory T cells and conventional T cell subsets by surface and intracellular staining

C. Wiethe[1], *E. Tolosa*[2], *D. Nguyen*[1], *J. Ransom*[1], *C. Monell*[1], *X. Xiang*[1], *N. Jiang*[1], *G. Lay*[1];
[1]*BioLegend, San Diego, CA, United States,* [2]*Department of Immunology, University Medical Centre Hamburg-Eppendorf, Hamburg, Germany.*

Multicolor flow cytometry (MCFC) is one primary technology for identification of lymphocyte subsets such as regulatory T cells (Tregs). Many MCFC users remain restricted by limited fluorophore availability, and the increasingly common violet laser (405nm) is still under-exploited by most users.
Here, we introduce usage of the highly sensitive polymeric molecule family excited by the violet laser that BioLegend first introduced with the following members: Brilliant Violet (BV) 421™, BV510™, BV570™, BV605™, BV650™, BV711™, and BV785™. All BV fluorophores are excited at 405nm and differ in their emission spectra, making them ideal candidates for MCFC. All new BV molecules yielded antibody conjugates with significantly increased brightnesses and signal-to-noise-ratios as compared to spectrally equivalent fluorophores.
BV-conjugated antibodies were used to analyze Tregs. In a 15-color surface marker panel, we demonstrated that all seven BV molecules can be multiplexed to analyze up to 7 different markers (CD25, CD3, CD19, CD161, CD27, HLA-DR, and CD127) off the violet laser. Despite using additional fluorophores excited by other laser lines, whose emissions contribute further to spectral overlap, the compensation range remained acceptable, and target populations were clearly resolvable. BV-conjugated antibodies were also successful in a 15-color panel for detection of intracellular cytokines (IFNγ, IL-2, IL-4, IL-10, IL-17A, IL-22), Foxp3 and surface antigens due to their excellent stability following fixation and permeabilization.
Thus, the novel family of Brilliant Violet™ fluorescent molecules provides superior tools for the violet laser, further enhancing the capabilities of MCFC for studying the phenotypic and functional heterogeneity of the immune system.

P3.13.54
PPAR-alpha deficiency modulates Treg cell functions and contributes to inhibit tumor growth in mice

A. Yessoufou[1,2], *A. Hichami*[3], *F. Salvadori*[3], *K. Moutairou*[1,2], *W. Wahli*[4], *N. A. Khan*[3];
[1]*University of Abomey-Calavi, Cotonou, Benin,* [2]*Institute of Applied Biomedical Sciences (ISBA), Cotonou, Benin,* [3]*University of Bourgogne, Dijon, France,* [4]*University of Lausanne, Lausanne, Switzerland.*

Background: There is a paucity of studies presenting the association of cancer progression with $CD4^+CD25^+$ regulatory T cell (Treg) prevalence. Increase inflammation in tumor bed can inhibit tumor growth, and peroxisome proliferator-activated receptor-alpha (PPARα), known as one regulator of inflammation, may therefore modulate tumor growth. Objectives: Here, we investigate the modulation by PPARα deficient-Treg cells of melanoma tumor growth in mice. Methods: CD4+ or CD8+ T cells isolated from spleen of wild type and PPARα-null mice were co-cultured with Treg cells of both types of mice. Cell migration was analyzed and cytolitic molecule release by CD8+ T cells was measured. Furthermore, B16 melanoma cells were sub-cutanously implanted in wild type (WT), PPARα-null and lymphopenic RAG2-/- mice in order to examine their tumorigenicities. Results: PPARα deficiency decreased the capacity of Treg cell to suppress CD4+ and CD8+ T cell proliferation. PPARα deficiency also diminished the ability of Treg cells to migrate toward chemokines. Moreover, melanoma tumor growth rate was much higher in WT mice than in PPARα-null animals. Dynamic analysis showed that Treg cells suppressed degranulation of perforin-release marker by CD8+ T cells and PPARα deficiency increases this cytolytic molecule release which participates to tumor rejection. Interestingly, adoptive transfer of splenic T cells into lymphopenic RAG2-/- mice inhibited tumor progression in these animals. Conclusion: Our findings suggest that PPARα deficiency increases the suppressive capacity of Treg cells and enhances the efficacy of CD4+ helper and cytotoxic CD8+ T cells and, thus, may provide a target for inhibiting tumor growth.

Immunoglobulins, Zn and NO in newly diagnosed children with type 1 diabetes

M. Aribi[1,2], *I. Benghalem*[2], *K. Labadi*[2], *L. Hamouda*[2], *W. Meziane*[2], *M. Lammani*[1];
[1]*University of Tlemcen, Tlemcen, Algeria,* [2]*Laboratory of Applied Molecular Biology and Immunology, Tlemcen, Algeria.*

Background: Type 1 diabetes (T1D) is characterized by autoimmune aggression against pancreatic beta cells. Abnormalities in immunoglobulins and reactive oxygen and nitrogen species were reported especially in adult patients. Additionally, the human beta-cell-specific zinc (Zn) transporter Slc30A8 (ZnT8) has been recently defined as a major target of humoral autoimmunity in human T1D.
Objectives: To determine the levels of immunoglobulins, nitric oxide (NO), and Zn in newly diagnosed children with T1D.
Materials and methods: A retrospective matched-case control study was conducted at the Department of Pediatrics of Mother & Child Medical Center of Tlemcen (Northwest of Algeria).
Results: The levels of immunoglobulins, NO, Zn and albumin/globulin ratio were altered in type 1 diabetic patients as compared to healthy subjects; while, those of alpha-1, alpha-2, beta and gamma globulins were similar in both groups.
Conclusions: The alterations in Zn uptake and the excess of NO production and immunoglobulins could play key roles in the immuno-inflammatory response involved in the autoimmune process of T1D.

P3.14.02
Fibrinogen-like protein 2 (FGL2)/fibroleukin induces long-term allograft survival through regulatory B cells

S. Bézie*, E. Picarda, L. Tesson, K. Renaudin, J. Durand, E. Meriau, E. Chiffoleau, C. Guillonneau, L. Caron, I. Anegon;*
INSERM U1064, Nantes, France.

Fibrinogen-like protein 2 (FGL2)/fibroleukin has been previously described as being produced by CD4+ Tregs and to prolong graft survival. We recently showed in a rat model of heart transplantation tolerance dependent on regulatory CD8+ T cells that these cells showed overexpression of FGL2. In the present manuscript we show that in vivo overexpression of FGL2 through gene transfer without any further treatment resulted in inhibition of graft rejection. Adoptive cell transfer of splenocytes from FGL2-treated rats with long-term survival (> 100 days) inhibited acute and chronic rejection in a donor-specific and infectious tolerance manner since adoptive transfer up to a fourth consecutive recipient resulted in transplantation tolerance. Adoptive cell transfer also efficiently inhibited anti-donor antibody production. Analysis of all possible cell populations among splenocytes revealed that B lymphocytes were sufficient and enough for this adoptive cell tolerance. These B cells were also capable of inhibiting the

proliferation of CD4+ T cells in response to allogenic stimuli. This is the first description of regulatory B cells generated by FGL2 and capable of inducing infectious tolerance.

P3.14.03
FcγRIIb modulates IL-10 secretion by regulatory B cells: Implications for systemic sclerosis

*A. Ferrier[1,2], O. Aravena[1,2], K. Pino-Lagos[1], J. Aguillón[1,2], L. Soto[1,3], **D. F. Catalan**[1,2];*
[1]Immune Regulation and Tolerance Research Group, Programa Disciplinario de Inmunología, ICBM, Facultad de Medicina, Universidad de Chile, Santiago, Chile, [2]Millennium Institute on Immunology and Immunotherapy, Santiago, Chile, [3]Hospital Clínico, Universidad de Chile, Santiago, Chile.

An IL-10-secreting subset of B cells, called regulatory B cells or Bregs, which participates in tolerance preservation in humans and mice, has been recently described. In humans, most Bregs are contained within the population of CD19+ CD24high CD38high transitional B cells. FcγRIIb is a receptor that inhibits the activation of B cells when recognizing the Fc fraction of IgG-containing immune complexes that are simultaneously bound to the BCR. Systemic sclerosis (SSc) is an autoimmune disease characterized by an extensive fibrosis of skin and organs. Activated B cells have a major role on SSc pathogenesis through the secretion of pro-fibrotic cytokines and disease-associated autoantibodies, however the molecular basis accounting for this B cell hyperactivity remains poorly understood. Our aim is to study the effect of FcγRIIB activation on BCR-mediated IL-10 secretion by B cells, and to analyze the frequency of transitional B lymphocytes and the expression of FcγRIIB in these cells among SSc patients. We demonstrate that stimulation of B cells with the F(ab)'2 fraction of an anti-BCR antibody induces an increased IL-10 production compared to the complete immunoglobulin. We also observed an increased population of transitional B cells in SSc patients, with a higher FcγRIIB expression, related to healthy controls. These results suggest that FcγRIIB expressed on Bregs inhibits BCR-mediated IL-10 secretion, and that SSc patients could have a misregulation in IL-10 production due to an increased FcγRIIB expression on transitional B cells.

P3.14.04
Effects of fingolimod therapy on B cell biology in multiple sclerosis

***N. Claes**[1], J. Fraussen[1], B. Van Wijmeersch[1], P. Stinissen[1], R. Hupperts[2], V. Somers[1];*
[1]Hasselt University, Diepenbeek, Belgium, [2]Orbis Medical Center, Sittard, Netherlands.

Fingolimod is the first oral immunotherapy for multiple sclerosis (MS). It is a sphingosine-1-phosphate receptor modulator that sequesters lymphocytes inside the lymph nodes. In this study, we aimed to investigate the effect of fingolimod on B cell subtypes and antigen presentation capacity in MS.
Peripheral blood mononuclear cells were isolated from the peripheral blood of 43 MS patients, collected before the first administration of fingolimod, after 1 month and then every 3 months for 18 months. Flow cytometry was performed to analyze ex vivo B cell subtypes (naive B cells, memory B cells, double negative cells, plasmablasts) and expression of costimulatory (CD80, CD86) and antigen presentation markers (HLA DR/DP/DQ).
After 1 month, fingolimod caused a decrease in the total number of lymphocytes and the percentage of B cells. The amount of cells remained low during follow-up. No changes were observed regarding B cell subtype distribution or antigen presentation capacity. After 3 months of treatment, an increase in the percentage of naive B cells (40% to 56%) was accompanied by a decrease in the percentage of memory B cells (20% to 10%). Furthermore, the percentage of HLA-DR/DP/DQ expressing B cells was significantly decreased, while a trend was observed towards a higher percentage of CD80 and CD86 expressing B cells.
To conclude, fingolimod causes a redistribution of B cell subtypes and a change in antigen presentation function of B cells in MS. The effects of fingolimod on B cell biology will be further studied both ex vivo and in vitro.

P3.14.05
Altered lymphoid organogenesis yet normal development of T-cell mediated autoimmunity in mice with skewed B-cell differentiation

***E. Colombo**[1,2], P. Tentorio[1,2], S. Musio[2], K. Rajewsky[3], R. Pedotti[2], S. Casola[4], C. Farina[1,2];*
[1]San Raffaele Scientific Institute, Milan, Italy, [2]Foundation IRCCS-Neurological Institute Carlo Besta, Milan, Italy, [3]Children's Hospital and Immune Disease Institute, Boston, MA, United States, [4]IFOM, The FIRC Institute of Molecular Oncology Foundation, Milan, Italy.

B cell receptor (BCR) signaling determines B cell differentiation, maturation and activation, and may potentially alter T cell-mediated immune responses. The Epstein-Barr virus latent membrane protein 2A (LMP2A) supports the activation and survival of B cells by mimicking a constitutively activated BCR, and its expression levels modulate peripheral differentiation of B cells. In this study we used two transgenic strains of BCR-deficient mice expressing LMP2A in mature B cells, where either follicular and marginal zone differentiation (D_HLMP2A mice) or B-1 cell development (V_HLMP2A mice) were supported, and evaluated the effects of skewed B lymphocyte differentiation on lymphoid organogenesis and T cell responses in vivo. Compared to naïve wild type animals, naïve transgenic strains displayed alterations in the composition of lymphoid organs. Immunization with the self antigen $PLP_{185-206}$ was also characterized by changes in the dynamics of distinct innate and adaptive immune cell subsets in transgenic mice. However, ex vivo T cell proliferation to $PLP_{185-206}$ peptide measured in immunized D_HLMP2A and V_HLMP2A mice was similar to that detected in immunized control mice. Finally, clinical expression of experimental autoimmune encephalitis in both LMP2A strains was identical to that of wild type mice. In conclusion, mice with skewed B cell differentiation driven by LMP2A expression in BCR-negative B cells display normal development of a T-cell mediated disease model of autoimmunity, suggesting that compensatory mechanisms support the generation of T cell responses. This study was supported by the Italian Ministry for Health (Ricerca Corrente and Progetto Giovani Ricercatori 2009-1607206)

P3.14.06
Accumulation of circulating autoreactive naïve B cells reveal defects of early B cell tolerance checkpoints in patients with Sjögren's syndrome

***E. Corsiero**[1], N. Sutcliffe[1], H. Wardemann[2], C. Pitzalis[1], M. Bombardieri[1];*
[1]William Harvey Research Institute, London, United Kingdom, [2]Max Planck Institute for Infection Biology, Berlin, Germany.

Sjögren's syndrome (SS) is an autoimmune disease characterised by high affinity circulating autoantibodies and peripheral B cell disturbances with predominance of naïve and reduction of memory B cells. The stage at which errors in B cell tolerance checkpoints accumulate in SS is unknown. Here we determined the frequency of self- and poly-reactive circulating naïve and memory B cells of SS patients.
Single B cells were sorted by FACS from peripheral blood of SS patients and healthy donors (HD). RNA was used to amplify Ig VH and VL genes and PCR products were cloned and expressed as recombinant monoclonal antibodies displaying identical specificity of the original B cells. Recombinant antibodies were tested towards different antigens to determine the frequency of autoreactivity and polyreactivity.
We analysed 353 VH and 293 VL sequences and obtained 114 recombinant antibodies from naïve (n=66) and memory (n=48) B cells of 4 SS patients and compared their autoreactive profile to 45 clones from 2 HD. Analysis of the VH and VL gene usage showed no significant differences between SS and HD. Conversely, we observed accumulation of circulating autoreactive naïve B cells in SS as

demonstrated by increased reactivity towards Hep2 cells (43.1% SS vs 25% HD) and ENA (19.6% SS vs none), Ro/SSA and/or La/SSB.
Here using an efficient strategy to express recombinant antibodies from single B cells we demonstrated an elevated frequency of autoreactive naïve B cells in the circulation of SS patients supporting the existence of early defects in B cell tolerance checkpoints in SS.

P3.14.07
Characterization of regulatory B cells in rodent model, able to transfer allograft tolerance via the TGFbeta pathway

***J. Durand**, C. Usal, E. Merieau, M. Heslan, E. Chiffoleau;*
Inserm U1064, NANTES, France.

Numerous reports have highlighted the central role of T_{reg} in tolerance, but few studies have investigated the B cell aspect. We described in a model of cardiac allograft tolerance in rat, induced by a short-term treatment, the accumulation in the blood and grafts of inhibited mature B cells ($sIgM^{int}$ IgD^{neg} IgG^{neg} $CD27^{het}$ $CD5^{neg}$ $CD24^{neg}$) blocked at the switch recombination process and over-expressing BANK-1, an inhibitor of the CD40-mediated B cell activation.
Interestingly, we demonstrated the presence of mature B_{reg} in the tolerant spleen, able to transfer a TGFβ-dependant donor-specific tolerance to a new recipient. In addition, *in vitro*, these B_{reg} suppress TNFα secretion in a MLR. Moreover, following transfer, these B_{reg} migrate or generate new B_{reg} and T_{reg} that accumulate locally in the graft but not in the spleen. Furthermore, following *in vitro* anti-CD40 stimulation, these B_{reg} are refractory to modulate Prdm1 and Bcl6 expression and express high level of granzyme B and BANK-1, suggesting partially anergic B cells with a killer phenotype. We observed in a similar mouse model of skin-graft tolerance the accumulation, in the draining lymph node, of activated $GL7^+$ $CD95^+$ B cells with $FoxP3^+$ T_{reg}, without an expansion of T_{eff}, suggesting a crosstalk between T_{reg} and B_{reg}.
These data demonstrate the presence of mature/memory B_{reg} able to transfer donor-specific allograft tolerance, with a phenotype similarly reported in patients operationally tolerant to kidney transplant. Therefore, our rodent models offer the opportunity to decipher the mechanisms of action of Breg in transplantation and to study their therapeutical potential.

P3.14.08
Protection from autoimmune nephritis in mice transgenic for BAFF, but lacking CD19

***K. A. Fairfax**, F. MacKay-Fisson;*
Monash University, Melbourne, Australia.

B cell activating factor belonging to the TNF family (BAFF or BLys) is required for B cell survival and maturation. However, mice transgenic for BAFF (BAFFTg) develop spontaneous autoimmunity, resembling Systemic Lupus Erythematosus (SLE), in a T cell-independent manner. The autoantibodies which trigger disease in BAFFTg mice, are produced by marginal zone (MZ) and B1 cells, but not follicular B cells. Experiments using BAFFTg splenectomized mice suggested that it was not MZ or B1a B cells, but rather B1b B cells that were important in the development of autoimmune nephritis. We have developed a mouse cross between BAFFTg and CD19 knockout (ko) mice, in which MZ, B1a and B1b B cells are reduced. We observed that BAFFTgxCD19ko mice had reduced titres of autoantibodies compared to BAFFTg mice, and these mice resembled CD19ko animals with respect to autoantibody development. The BAFFTgxCD19ko animals were also protected from the splenomegaly observed in the BAFFTg animals. In aged mice BAFFTg display complement deposition in the glomeruli within the kidney, whilst BAFFTgxCD19ko were protected from this (as were the CD19ko mice). In addition, the BAFFTg glomeruli were larger, and more segmented than the BAFFTgxCD19ko, both signs of impaired function. Together these results point towards the pathogenic role of B1b B cells in autoimmune nephritis. This work also raises the prospect that targeting CD19 in SLE patients may prove efficacious.

P3.14.09
BAFF polymorphisms in Tunisian systemic lupus erythematosus patients

***Y. Gorgi**[1], I. Sfar[1], T. Dhaouadi[1], N. Laamiri[1], S. Turki[2], L. Ben Hassine[3], T. Ben Abdallah[1];*
[1]Laboratory of Research in Renal Transplantation and Immunopathology (LR03SP01)., Tunis, Tunisia, [2]Internal Medicine Department A. Charles Nicolle Hospital, Tunis, Tunisia, [3]Internal Medicine Department B. Charles Nicolle Hospital, Tunis, Tunisia.

Introduction: To investigate the association between polymorphisms in the 5' regulatory region of the B-lymphocyte activating factor (BAFF) gene, disease susceptibility and serum BAFF (s-BAFF) levels in Tunisian systemic lupus erythematosus (SLE) patients.
Methods: A case-control study including 124 patients with SLE and 152 healthy volunteers. The molecular study was done by PCR-RFLP although the s-BAFF was done by ELISA (Quantikinine ®, R & D Systems).
Results: The frequency distribution of genotypic and allelic polymorphisms -2701 T/A and -871 C/T BAFF was similar for patients and controls, while, the variant allele C of the polymorphism -2841 T/C of BAFF gene seems to be associated to susceptibility to SLE in Tunisian patients. The analytical study of polymorphism -2841 T/C of BAFF gene, based on clinical and biological manifestations of SLE, shows that the homozygous genotype T/T was significantly less prevalent in SLE patients expressing anti-dsDNA compared to those who do not express this type of self-Ac (p=0,021). Also, the homozygous genotype T/T (-2701) were significantly more prevalent in SLE patients with cutaneous vasculitis (p= 0,036). s-BAFF levels were elevated in SLE Tunisians patients more than in healthy subjects and it was also significantly higher in SLE patients positive for anti-dsDNA (s-BAFF levels = 1948,28 pg/ml) compared to those who do not express this type of self-Ac (s-BAFF levels = 1281,51 pg/ml) (p=0.007).
Conclusion: -2841 T/C polymorphism of BAFF gene could be a susceptibility factor in Tunisian SLE population and seems to influence the regulation of the production of anti-dsDNA.

P3.14.10
Direct PD-1-mediated suppression of autoreactive B cells by regulatory T cells

***J. Gotot**[1], C. Gottschalk[1], P. A. Knolle[1], H. Yagita[2], C. Kurts[1], I. Ludwig-Portugall[1];*
[1]Instituts for Molecular Medicine and Experimental Immunology, Bonn, Germany, [2]Department of Immunology, Juntendo University School of Medicine, Tokyo, Japan.

Autoantibodies mediate various and heterogeneous forms of autoimmune diseases. On the one hand they can induce general autoimmunity like e.g. in systemic lupus erythematosus (SLE). On the other hand disease manifestations can affect just a single organ like e.g. the kidney, in certain forms of glomerulonephritis. T_{regs} are known to contribute to the maintenance of peripheral tolerance by suppressing the T helper cells and therefore T_{regs} can also control B cells, albeit indirectly [1,2]. This does not rule out the possibility of a direct (Treg - B cell) suppression, supported by several *in vitro* studies [3,4], but strict *in vivo* evidence is lacking. In previous studies we showed that B cells are suppressed in an antigen-specific manner *in vivo* [5,6], but the molecular mechanism remained unknown. Here, we report that most of such B cell suppression was mediated through the inhibitory cell surface molecule programmed death-1 (PD-1). Suppression required PD-1 expression on autoreactive B cells and expression of one of the two PD-1 ligands on T_{regs}. PD-1 ligation inhibited activation of autoreactive B cells, suppressed their proliferation and induced their apoptosis. Intermediate $PD\text{-}1^+$ cells, such as T helper cells, were dispensable for suppression. These findings demonstrate *in vivo* that T_{regs} use PD-1 ligands to directly suppress autoreactive B cells and identify a previously undescribed peripheral B cell tolerance mechanism against tissue autoantigens.

P3.14.11

Zap70+ b cells and plasmablasts as markers of disease activity and remission in systemic lupus erythematosus renal involvement

***E. Gremese**, M. Nowik, L. Petricca, M. Gigante, L. Messutti, S. Canestri, C. Di Mario, G. Marino, B. Tolusso, G. Ferraccioli;*
Division of Rheumatology, Catholic University of the Sacred Heart, Rome, Italy.

The study aim was to analyze differences in B-cells subsets in patients with renal systemic lupus erythematosus (SLE) based on disease activity and to evaluate possible biomarkers of active nephritis and remission.
60 SLE patients with renal involvement (49 females; mean age 36.9±11.0 years; 37 with active and 23 with inactive nephritis) were analyzed for distribution of circulating peripheral blood B-cell subpopulations by staining for surface markers CD45, CD19, CD38, IgD, CD27 (CD27/IgD classification (1)) and intracellular marker ZAP-70 (2) by flow cytometry. All patients had a WHO class III or IV nephritis. Fourteen active patients were reassessed for PB B-cell subpopulations at renal remission achievement.
The 37 patients with active nephritis showed higher percentages of CD19/ZAP70+cells compared to 23 with renal remission (13.1±10.5%vs5.4±4.5%, respectively; p=0.002), and of plasmablasts (CD19+CD27/CD38+ cells: 10.6±7.4%vs6.3±5.8%, respectively; p=0.03).
In the 60 SLE renal patients, the percentage of CD19+/ZAP-70+cells correlated with disease activity index (SLEDAI) (r=0.44, p=0.002), inversely with complement fractions (C3: r=-0.44, p=0.001, C4: -0.45, p=0.001), the number of lymphocytes (r=-0.55, p<0.001) and of the CD19+B-cells (r=-0.61, p<0.001). Moreover, ZAP70+B-cells directly correlated with the memory cells subsets (CD27+IgD-: p=0.002, CD27-IgD-: p=0.01) and with plasmablasts (p=0.004).
The 14 patients evaluated at remission achievement showed a reduction of ZAP70+ B-cells percentage with respect to nephritis onset (p=0.002), and of plasmablasts (p=0.05).
The pool of CD19+/ZAP70+cells is associated with SLE activity parameters and B-cell memory compartment in lupus nephritis patients. Expansion of ZAP70+B-cells and plasmablasts characterize active renal disease and their reduction the remission state.

P3.14.12
The precursor BCR suppresses T cell-dependent autoimmune responses

***O. Grimsholm**[1], W. Ren[1], A. I. Bernardi[1], N. Höök[1], B. Bergmann[1], A. Stern[1], N. Cavallini[1], A. De Riva[2], I. Gjertsson[1], I. Mårtensson[1];*
[1]University of Gothenburg/Dept of Rheumatology and Inflammation Research, Gothenburg, Sweden, [2]University of Cambridge/Dept of Medicine, Cambridge, United Kingdom.

A hallmark of autoimmune diseases is the production of isotype-switched autoantibodies derived from T cell-independent (TI) and/or -dependent (TD) responses. Typically TI responses take place extrafollicularly and TD responses in germinal centers (GC). GCs are structures found in peripheral lymphoid organs requiring T follicular helper (TFH) cell differentiation and cognate B:T cell interactions. The precursor B cell receptor (pre-BCR), assembled from antibody heavy chains together with surrogate light chain, is involved in positive selection of the VH repertoire. It is also involved in negative selection of the antibody repertoire, an unexpected finding as this receptor is expressed on precursor-B cells. Its absence leads to the production of isotype-switched autoantibodies. The autoreactive B cells in pre-BCR-deficient mice lack markers of known B cell subsets (CD21-23-), whereas little else is known about these. Because pre-BCR-deficiency represents a B-cell intrinsic defect we hypothesized that the isotype-switched autoantibodies would arise from TI reactions. Here, we show that in pre-BCR-deficient mice the autoreactive CD21-23- population, unexpectedly, consists of GC B cells, and that GCs containing TFH and follicular dendritic cells develop spontaneously. GCs appear normal supporting B cell survival and expansion, and Ig isotype-switching and somatic hypermutation. Inhibition of B:T cell interactions completely abolishes these structures leading to reduced serum IgG2b/c autoantibody levels. Our results suggest that inadequate pre-BCR expression not only cell intrinsically subverts the central and peripheral selection of the BCR repertoire, but also influences the peripheral TCR repertoire with major implications for the development of autoimmunity.

P3.14.13
Functional properties of resident B cells in arterial walls of human atherosclerotic patients

***M. Hamze**[1], C. Desmetz[1], C. Guzman[1], P. Roger[2], M. Berthe[3], N. Boulle[3], P. Branchereau[4], E. Picard[4], C. Tolza[1], P. Guglielmi[1];*
[1]CPID- Centre de pharmacologie et d'innovation dans le diabète, Montpellier, France, [2]Service d'Anatomie et Cytologie Pathologiques CHU Carémeau, Nimes, France, [3]Laboratoire de Biologie Cellulaire et Hormonale, CHU Arnaud de Villeneuve, Montpellier, France, [4]Service de chirurgie vasculaire CHU Carémeau, Nimes, France.

Ig repertoires were analyzed by RT-PCR on tissue extracts from carotid endarterectomy samples of 13 atherosclerotic patients. Cytokine, surface marker and transcription factor expression was studied on adventitial lymphocytes isolated by laser capture microdissection (LCM).
In adventitia, B lymphocytes constituted diffuse infiltrates or formed small cell clusters. BCR sequence analysis revealed that individual samples contained each a limited number of B cell clones. Functional α1, α2, γ1 and γ2 mRNAs comprised the majority of H chain mRNAs. IgA could be the only expressed H chain isotype whereas IgM was frequently absent. The λ/κ ratio of L chain usage was inverted. Ig V regions were hyper mutated and used recurrent V(D)J associations with some noticeable sequence convergences toward identical CDRs. AID was expressed in several arterial walls, in keeping with the observation of a local H chain class switch. Using CDR3 sequences as clonotypic markers, we found that plaque and adventitia repertoires were different and that B cells were trafficking between adventitia and draining lymph nodes. Three adventitial B cell antibodies reconstructed by genetic engineering proved to be autoantibodies recognizing discrete arterial wall proteins.
Most resident B lymphocytes were CD20 negative plasmablasts. However, they lacked markers of terminal differentiation to plasma cell (CD138 and Blimp-1). LCM isolated adventitial B lymphocytes expressed IL-6, GM-CSF and TNF-α whereas IL-2, IL-4, IL-10, M-CSF and IFN-γ were not detected.
These features witness for a local and antigen-driven maturation selecting activated oligoclonal adventitial B lymphocytes able to act on inflammation and disease progression.

P3.14.14
Epigenetic manipulation of protective and pathogenic antibody responses with histone deacetylase inhibitors

***E. D. Hawkins**[1,2], M. Waibel[2], A. Frew[2], M. Hibbs[3], J. Shortt[2], R. Tothill[2], D. Tarlinton[4], R. Johnstone[2];*
[1]Imperial College London, London, United Kingdom, [2]Peter MacCallum Cancer Center, Melbourne, Australia, [3]Monash University, Melbourne, Australia, [4]Walter and Eliza Hall Institute, Melbourne, Australia.

Histone deacetylase inhibitors (HDACi) are new anti-cancer agents capable of remodeling chromatin and inducing widespread expression changes in gene expression. Although approved for the treatment of certain hematological malignancies, we understand little about their effect on the protective immune system. As HDACi have been demonstrated to be particularly potent against malignancies originating from the B lymphocyte lineage, we examined the ability of this class of compounds to modify naïve, pathogenic and memory B cell responses. We found that HDACi were capable of inducing a broad range of biological effects on normal lymphocytes including apoptosis, proliferation and differentiation. Importantly, treatment of autoimmune mice with HDACi significantly reduced B cells and pathogenic plasma cell numbers whilst other immune components were relatively unaffected. As predicted from these results, wildtype immunized mice treated with HDACi had a significantly impaired primary antibody response and were not capable of forming functional germinal centers. However, treatment with HDACi had no significant effect on circulating memory cells leaving secondary antibody responses intact. These studies suggest that HDACi may have a potential for the treatment of patients with B cell driven autoimmune conditions. Additionally, they suggest that although treatment with HDACi induces short-term immunosuppressive effects, there is no

long-term detrimental effect on the host immunological memory response.

P3.14.15
Systemic immunoglobulin G to human dentin fractions decreases during orthodontic treatment

***E. N. Itano**, C. E. O. Lima, L. A. Nagashima, M. S. Kaminami, F. A. Nakanishi-Ito, E. T. Carlotto, E. O. Tanaka, T. T. M. P. Costa;*
State University of Londrina, Londrina, PR, Brazil.

Limited data exists regarding the systemic immune response and orthodontic treatment. The objective of this study was to evaluate serum IgG levels to human dentin extract (HDE) and its fractions during orthodontic treatment. The study included 34 patients before orthodontic treatment (T0), at 6-7 months of treatment (T1) and at 12-13 months of treatment (T2). Serum IgG levels were determined by ELISA, using human dentine extract and its fractions as antigens. Periapical radiographs of maxillary incisors were analyzed by digital subtraction radiography. Dentine extract samples were submitted to chromatography and analyzed by SDS -PAGE. The two main chromatography fractions (I and II) analysis by SDS-PAGE resulted in components with MM > 200 kDa (I) and less than 50 kDa (II). The IgG levels to HDE were similar in all period analyzed ($p>0.05$), but decreased levels of IgG in T1 or T2 than T0 to fraction I ($p<0.05$) and decreased IgG levels in T2 than T1 and T1 than T0 ($p<0.05$) to fraction II were detected. In conclusion, orthodontic treatment modulated the IgG levels to dentin components with MM > 200 kDa and less than 50 kDa, regardless of root resorption degree.

P3.14.16
Inhibition of formation of IgA1-containing immune complexes in IgA1 nephropathy

***A. Kasperova**[1,2], H. Ueda[2], M. Stuchlova-Horynova[1,2], B. Julian[3], J. Novak[2], M. Raska[1,2];*
[1]Department of immunology, Faculty of medicine, Palacky University, Olomouc, Czech Republic, [2]Department of Microbiology, University of Alabama at Birmingham, Birmingham, AL, United States,
[3]Department of Medicine, University of Alabama at Birmingham, Birmingham, AL, United States.

IgA nephropathy (IgAN) is the most common primary glomerulonephritis worldwide characterized by glomerular deposition of galactose (Gal)-deficient IgA1 (Gd-IgA1)-containing immune complexes (ICs). These deposits that activate mesangial cells are likely derived from the circulating ICs consisting of Gd-IgA1 bound by antiglycan antibodies. Here, we tested a new strategy for potential disease-specific therapy of IgAN. The approach was based on disrupting ICs formation to lessen their deposition and pathological impact. We tested various fragments derived from IgA1 antibody as competitors of IC formation. The competitors were prepared as recombinant proteins expressed in E. coli subsequently glycosylated in vitro using recombinant glycosyltransferases. The system used sera of IgAN patients containing anti-glycan IgG that were supplemented with Gd-IgA1 with or without a competing inhibitor. The inhibitors included non-glycosylated or Gal-deficient heavy chain and CH1-CH2 fragment of heavy chain of IgA1. Our results showed that glycosylated CH1-CH2 fragment of Gd-IgA1 blocked formation of new ICs in a glycan-specific manner. Further analyses indicated, that glycosylated CH1-CH2 could contribute also to partial disruption of ICs presented in the IgAN patient's serum. In contrast, nonglycosylated fragments CH1-CH2 did not interfere with ICs formation or stability. Thus, utilization of such competitors may open new avenues for future disease-specific therapeutic approaches for IgAN.

P3.14.17
Can B cells induce the generation of regulatory T cells?

*H. H. Mohammed Ali, **A. Kowalik**, E. Kiernozek, E. Kozlowska, N. Drela;*
University of Warsaw, Warsaw, Poland.

Regulatory CD4+CD25+Foxp3+ T cells (Tregs) develop in thymus as natural regulatory T cells or are generated in lymphoid organs as induced Tregs. Generation of Tregs involves antigen-presenting cells (APC), mostly immature dendritic cells. It was demonstrated that Foxp3+ Tregs were found in T-B area of peripheral lymphoid organs pointing on the role of Tregs in inhibition of adaptive immunity or on a role of B cells in Treg generation. B cells can also play a role of APC in adaptive immunity to protein antigens. B cells, similarly to dendritic cells can be activated through Toll-like receptors, which dependently of signal strength modulate the expression of costimulatory molecules resulting in inhibition of activation of conventional T helper cells or Tregs induction. The aim of the study was to analyze the kinetics of the expression of B cell molecules crucial for antigen presentation process (CD80, CD86, CD40, MHCII) to T cells in conditions of B cell activation through Ig receptors, TLR4 and TLR7. C.Cg-*Foxp3*^{tm2Tch}/J mice were used in experiments. Distribution of CD4+CD25+Foxp3+ T cells was analyzed in co-cultured activated B cells and peripheral CD4+ T cells. Similar examination was performed with co-cultures with thymocytes as a source of natural Tregs. The results of our study demonstrated the constant expression of MHCII, while expression of costimulatory molecules changed depending on stimuli dose and incubation time resulting in changes of Foxp3+ T cells distribution.
Supported by 501/86-102337 Warsaw University Intramural Grant and Iraqi Ph.D. Students Support by Ministry of Higher Education and Scientific Research.

P3.14.18
IL-7 modulates B cells survival and activation by inducing BAFF and CD70 expression in T cells

***R. Lantto**, S. Sammicheli, N. Ruffin, N. Vivar, F. Chiodi, B. Rethi;*
Department of Microbiology Tumor and Cellbiology, Karolinska institutet, Stockholm, Sweden.

Interleukin-7 (IL-7) promotes the maintenance and activation of peripheral T cells, whereas it does not act directly on mature B cells due to the lack of IL-7Ra expression on these. We report here that, in spite of the insensitivity of B cells to IL-7, high concentration of IL-7 can lead to increased B cell survival and antibody production in the presence of T cells, without the use of any further B cell stimulatory signal. IL- 7 promoted B cell activation through inducing CD70 expression on resting T cells, particularly on CD4þ memory cells. The interaction of CD70 molecules with the B cell costimulatory receptor CD27 led to B cell proliferation, the accumulation of CD38 þ CD20- plasmablasts and antibody production. In addition, IL-7 treatment induced BAFF secretion from resting peripheral T cells thereby promoting B cell survival. IL-7 levels can increase in lymphopenic conditions, in autoimmune diseases or in patients receiving T cell regenerative IL-7 therapy. Based on our findings high IL-7 levels can lead to increased B cell activation by inducing the B cell regulatory proteins CD70 and BAFF in resting T cells. Such activity might be beneficial in short term immune-stimulatory IL-7 therapies; permanently increased IL-7 levels, on the other hand, can contribute to impaired B cell tolerance.

P3.14.19
Bendamustine increases interleukin-10 secretion from B cells

L. Le[1]*, A. Morita*[2]*, K. Yoshimoto*[1]*, H. Kameda*[1]*, T. Takeuchi*[1]*;*
[1]Division of Rheumatology, Department of Internal Medicine, Keio University School of Medcine, Tokyo, Japan, [2]Keio University School of Medcine, Tokyo, Japan.

Background and Purpose: Bendamustine is an alkylating agent approved for B cell malignancies such as lymphoma and chronic lymphocytic leukemia. However, the mechanisms of its action to B cells have not been fully clarified. The objective of this study is to investigate the effects of bendamustine on B cell function and to explore a possible clinical application of bendamustine to systemic autoimmune diseases.
Materials and Methods: A human B cell line, Ramos, was cultured in the presence of various concentrations of bendamustine for four days. The proliferation of the cells was analyzed by XTT assay and the secretions of IgM and cytokines by the cells were measured by ELISA.
Results and Discussion: The cellular proliferation of Ramos cells by 10% fetal bovine serum was significantly inhibited in the presence of 25-100 μM of bendamustine in a dose-dependent manner. Concordantly, IgM secretion from Ramos cells was significantly inhibited with 25-100 μM of bendamustine (by approximately 40%-70%). Interestingly, the secretion of IL-10 by Ramos cells was dramatically (at least >10-fold) increased in the presence of 25-100 μM of bendamustine. Although bendamustine has been known to inhibit the dimerization of STAT3, two STAT3 inhibitors (S3I-201 and Stattic) did not increase IL-10 from Ramos cells, suggesting the involvement of other mechanisms than STAT3. Our results suggest that bendamustine may provide a novel therapeutic tool for autoimmune diseases through anti-inflammatory effects of IL-10, in addition to the suppression of B cell growth and activation. The underlying molecular mechanism of our findings should be further elucidated.

B-1 lymphocytes modify global gene expression by murine melanoma cells

P. Xander[1]*, R. R. Novaes e Brito*[2]*, E. C. Pérez*[3]*, J. M. Pozzibon*[4]*, C. F. Souza*[4]*, R. Pelegrino*[4]*, V. Bernardo*[4]*, M. G. Jasulionis*[4]*, M. Mariano*[4]*, **J. D. Lopes***[4]*;*
[1]Universidade Federal de São Paulo campus Diadema, São Paulo, Brazil, [2]Centro Educacional São Camilo, São Paulo, Brazil, [3]Universidade Paulista, São Paulo, Brazil, [4]Universidade Federal de São Paulo, São Paulo, Brazil.

It is known that immune system components can contribute to tumor progression and inflammatory cells can influence almost all aspects of cancer progression, including the ability to form metastasis. Recent studies have attributed an important role to B-1 cells, a subset of B lymphocytes, in melanoma progression. In vitro interaction between B16 melanoma cells and B-1 lymphocytes lead to an increased in metastatic potential of B16 lineage but the molecular effects induced by B-1 cells in B16 have not yet been elucidated. In this study we used a microarray approach to assess gene expression profile in B16 melanoma cells after contacting B-1 lymphocytes. The microarray analysis identified upregulation in genes involved with metastatic progression, such as ctss, ccl5, cxcl2 and stat3. RT-qPCR confirmed increase in mRNA expression in B16B1 samples. Considering that previous studies showed the role of ERK1/2 MAPK cascade in melanoma cells after contacting with B-1, RT-qPCR was performed with RNA from melanoma cells before and after contacting B-1 cells and treated or not with inhibitors of ERK phosphorylation. The results showed that stat3, ctss and cxcl2 increased expression in B16B1 but their expression decreased when ERK / MAPK inhibitor was used. Stat3 was verified and validated at the protein level by Western blot analysis. Results showed that STAT3 expression was significantly increased in B16B1, suggesting that this pathway can also contribute to increase metastatic phenotype in our model. These results showed that B-1 cells induce important changes in the global gene expression of B16 melanoma cells.

P3.14.21
A novel flow-cytometry-based method to evaluate autoreactivity enables the study of B cell tolerance checkpoints in mice

E. Marasco*, N. Manjarrez-Orduño, T. Hopkins, A. Athanassiou, J. Kiridly, P. Gregersen, B. Diamond;*
Feinstein Institute for Medical Research, Manhasset, NY, United States.

During maturation, B cells rearrange their V(D)J segments to produce functional immunoglobulins.
Along the developmental pathway, there are checkpoints to censor autoreactive B cells that may arise. In autoimmune diseases, these checkpoints are not effective and autoreactive B cells enter the mature B cell pool. Here we present a new approach to study censoring checkpoints.
Nuclear antigens were extracted from Hep-2 cells, labeled and used to stain splenocytes. The fraction of nuclear antigen-reactive (ANA+) cells is higher in the immature compartments and decreases with the maturation stage. The innate-like compartments of MZ and B1 B cells contain a significant fraction of ANA+ B cells.
To prove that the ANA+ B cells bear autoreactive antibodies, ANA+ and ANA- B cells were sorted and stimulated in vitro to secrete antibodies. Only antibodies from ANA+ B cells react with dsDNA and exhibit a rim nuclear pattern on Hep-2 slides.
The frequency of ANA+ B cells was compared between non-autoimmune (BALB/c, C57B/6) and lupus-prone (NZBxNZW/F1, MRL/lpr) mice. B cells from lupus-prone mice contain a higher percentage of ANA+ B cells than healthy mice, highlighting the altered censoring checkpoints present in lupus.
Our method allows for the studying censoring checkpoints in a fast and inexpensive manner. We propose this approach in order to expand the knowledge acquired from transgenic models, and overcome the limitation of studying tolerance one B cell receptor at a time.

P3.14.22
Strain-specific positive and negative regulatory roles for TLR9 in a mouse model of SLE

R. E. Mills*, V. Lam, A. Weiss, M. L. Hermiston;*
UCSF, San Francisco, CA, United States.

Antinuclear antibodies (ANA), particularly against double stranded DNA (dsDNA), are a hallmark of Systemic Lupus Erythematosus (SLE). A point mutation dysregulating CD45 phosphatase activity (CD45E613R) results in a SLE-like phenotype on a 129-C57BL/6 (B6) genetic background. However, CD45E613R mice backcrossed to a B6 genetic background fail to develop ANA while CD45E613R mice on a BALB/c background develop anti-dsDNA IgG antibodies at 100% penetrance. Despite similar hyperresponsive ITAM signaling in multiple immune cell lineages, neither strain develops glomerulonephritis. A genetic modifier screen between B6 and BALB/c CD45E613R mice identified the pattern recognition receptor TLR9 as a potential mediator of anti-dsDNA antibodies. Interestingly, regardless of the presence or absence of the CD45E613R mutation, BALB/c B cells are hyporesponsive to CpG stimulation relative to B6 B cells. Here, we use the CD45E613R.BALB/c model, which lacks the interference and feedback of end organ disease, to elucidate which cellular immune compartments must be dysregulated for autoantibody production. We find that CD45E613R B cells are necessary and sufficient for anti-dsDNA IgG antibodies, while αβ T cells are dispensable. Mixed bone marrow chimeras demonstrate an intrinsic requirement for TLR9 in polyclonal B cells for anti-dsDNA IgG antibody production, indicating a positive regulatory role for TLR9 in BALB/c. Surprisingly, genetic ablation of TLR9 in the autoimmune-resistant B6 background permits ANA production, indicating TLR9 can also play a negative regulatory role. Taken together, our data support the hypothesis that the net strength of signal during B cell development dictates the autoreactivity of the B cell repertoire.

P3.14.23
Mast cells contribute to the expansion and differentiation of IL-10-producing B cells

F. Mion[1], *F. D'Incà*[1], *L. Danelli*[1], *B. Frossi*[1], *C. Guarnotta*[2], *A. Burocchi*[3], *C. Tripodo*[2], *M. P. Colombo*[3], *G. Vitale*[1], *C. E. Pucillo*[1];
[1]*Department of Medical and Biological Sciences - University of Udine, Udine, Italy,* [2]*Department of Human Pathology - University of Palermo, Palermo, Italy,* [3]*Molecular Immunology Unit, Department of Experimental Oncology and Molecular Medicine, Fondazione IRCCS Istituto Nazionale Tumori, Milano, Italy.*

B cells are classically considered as positive regulators of the immune response, however the regulatory suppressive function of distinct B-cell populations has been recently described. Several studies have demonstrated that B cells acquire the ability to suppress immune responses in an IL-10-dependent manner, but the cell types involved in the induction of regulatory B cells are currently unknown. The evidence of a direct B-mast cell (MC) interaction together with data demonstrating the role of MCs as important regulators of immune responses, led us to investigate whether MCs could favor the development of IL-10-producing B cells.
We observed that MCs are able to increase the percentage of IL-10$^+$ B cells, regardless of their activation status, while they do not influence IL-10 secretion. MCs-induced IL-10$^+$ B cells are predominantly found within the CD1d$^+$CD5$^-$ B-cell subset; moreover they are CD23$^+$ and express high levels of CD19 and CD21, suggesting that they could derive from T2-MZP B cells. Among the different mechanisms that could be responsible for the expansion of IL-10-producing B cells by MCs we show the importance of both the CD40-CD40 ligand interaction and of soluble factors released by MCs even in the absence of activation. Furthermore, the *in vivo* absence of MCs reduces the percentage of CD19$^+$IL-10$^+$ cells in mouse bone marrow, lymph nodes and peritoneum. Altogether our data show that MCs can influence the differentiation of IL-10-producing B cells and this can be seen as a very relevant observation in the context of immunologically mediated inflammatory reactions.

P3.14.24
Abnormal distribution of B-cells populations associated with impaired regulatory functions in the Chronic Humoral Rejection

A. Nouël[1], *I. Segalen*[2], *A. Grall*[2], *J. O. Pers*[1], *Y. Le Meur*[2], *S. Hillion*[1];
[1]*EA2216 Immunology and Pathology, University of Brest, Brest, France,* [2]*Nephrology, Cavale Blanche Brest, Brest, France.*

In kidney transplantation, the composition of the B cell compartment is increasingly being identified as an important determinant for graft outcome. Whereas naïve and transitional B cells have been associated with long term allograft survival and operational tolerance, memory B cells have been linked to graft rejection and graft loss. Chronic antibody mediated rejection (cABMR) now represents a major complication in transplantation and is a challenge in current therapeutics. In this study, we show that patients with cABMR display a unique B cell phenotype with a reduction in the ratio of "activated B cells"/"memory B cells" associated with an impaired immunosuppressive activity. We further show that the regulatory functions of B cells depend on their maturation status. We established that "activated B cells" were able to induce the expansion of regulatory T cells and to mediate durable suppressive function on autologous T cell proliferation through a TGFb/IDO axis, that was deficient in B cells from cABMR patients. Phenotypic and functional analysis of the B cell compartment could be indicated for appropriate follow-up after transplantation and drive therapy in the establishment of transplant tolerance processes.

P3.14.25
The autoantibodies to GM-CSF found in pulmonary alveolar proteinosis are generated through somatic mutations

L. Piccoli[1], *D. Corti*[1], *I. Campo*[2], *M. Luisetti*[2], *L. Varani*[1], *F. Sallusto*[1], *A. Lanzavecchia*[1];
[1]*Institute for Research in Biomedicine, Bellinzona, Switzerland,* [2]*Respiratory Disease Unit, IRCCS San Matteo Hospital Foundation, Pavia, Italy.*

Pulmonary alveolar proteinosis (PAP) is a rare and severe autoimmune disease caused by the production of autoantibodies that neutralize GM-CSF causing the loss of alveolar macrophages and the accumulation of lipoproteinaceous material within the alveoli. By immortalizing memory B cells from several PAP patients we isolated 17 monoclonal antibodies that bind to human GM-CSF with high affinity. By cross-competition experiments using surface plasmon resonance we established a map of the antigenic sites of GM-CSF and showed that 3 antibodies can bind simultaneously to a single GM-CSF molecule. Interestingly, the recombinant germlined version of the antibodies did not bind to GM-CSF, indicating that somatic mutations are essential for binding. Finally, using a site-specific serological assay we identified rare healthy blood donors with low levels of non-neutralizing GM-CSF antibodies. These findings support a stochastic model where autoantibodies are generated by accidental somatic mutations that occur in the course of the response to irrelevant antigens.

P3.14.26
CD38 and splenic B lymphocytes involvement in autoimmune disease using a murine model for systemic lupus erythematosus

H. Romero Ramirez[1], *M. Dominguez Pantoja*[2], *A. Dominguez Rívas*[2], *L. Santos Argumedo*[1], ***J. C. Rodríguez Alba***[2];
[1]*CINVESTAV, Distrito Federal, Mexico,* [2]*Universidad Veracruzana, Xalapa, Veracruz, Mexico.*

Mouse models contribute to our understanding of human diseases. Several strains of systemic lupus erythematosus (SLE)-prone mice, including New Zealand Black (NZB), F1 hybrids of NZB x New Zealand White (NZW) (B/W F1), MRL/Mp-lpr/lpr (MRL/lpr) and BXSB mice, are important in the research of this autoimmune disease. Furthermore, several genes and signaling molecules have shown to have a role in SLE pathologies such as: Lyn, CD22, SHP-1 or the sle1, sle2 and sle3 congenic models. CD38 is a transmembrane receptor able to induce activation, proliferation, and survival of human and mouse lymphocytes; this molecule is expressed along the B cell ontogeny, in addition, CD38 is an ectoenzyme involved cell adhesion and is used as a disease marker for leukemia and myeloma, also is a dependable negative prognostic marker for chronic lymphocytic leukemia (CLL). Some reports suggest a function for CD38 in autoimmunity of human and mice, but there are not reports that clarify the role of this molecule in SLE. To study the implication of CD38 in the SLE pathogenesis we compared proteinuria, serum ANA and anti-dsDNA antibody production, body-weight, nephritis and mortality in the CD38-deficient (CD38-/-) compared to the wild type (WT) mice. We expect that the pathologic manifestations of nephritis will appear significantly earlier in the CD38-/- mouse as well as changes in the survival rate.

P3.14.27
Generation of autoreactive and poly-reactive antibody producing cells during gamma-herpesvirus infection

S. Sakakibara[1,2], *T. Yasui*[1,2], *T. Minamitani*[1], *H. Jinzai*[1], *H. Kikutani*[1,2];
[1]*Department of Molecular Immunology, Research Institute for Microbial Diseases, Osaka University, Suita, Osaka, Japan,* [2]*WPI Immunology Frontier Research Center (iFReC), Osaka University, Suita, Osaka, Japan.*

Autoantibody production is sometimes associated with persistent infections such as HIV, hepatitis C virus and Epstein-Barr virus (EBV) in humans. However, little is known about the underlying mechanisms how peripheral B cell tolerance is compromised during such viral infections. Murine γ-herpesvirus 68 (MHV68), a closely related virus

to EBV, induces serum IgG autoantibodies, which are vigorously produced at two or three weeks after infection, and gradually reduced following weeks, while high titer of serum anti-MHV68 antibodies are maintained for months. By employing this infection model, we investigated how virus- and autoreactive B cells are generated and selected during the germinal center (GC) reaction. To this end, we cloned and expressed monoclonal antibodies from splenic IgG+ GC B cells, which MHV68 preferentially targets in the latent infection. Reactivity profiles of cloned antibodies revealed that in addition to MHV68-reactive clones, a significant proportion (~20%) of GC B cells exhibited dsDNA autoreactivity. Intriguingly, one third of virus-reactive clones were polyreactive to dsDNA, insulin and/or cardiolipin. However, autoreactive prevalence in MHV68-infected cells was not found. Furthermore, higher frequencies of autoreactive and polyreactive clones were found in the plasma cell fraction than in GC B cells, indicating that these clones were positively selected to be plasma cells. PCR-based reversion of somatic hypermutations (SHMs) to germline sequences diminished autoreactivities of several polyreactive clones. Taken together, MHV68-induced auto- and polyreactive antibodies are, at least in part, attributed to SHMs given in the GC reaction.

P3.14.28
B cell-derived IL-10 suppresses inflammatory disease in Lyn-deficient mice

P. Scapini[1], *C. Lamagna*[2], *M. A. Cassatella*[1], *A. L. DeFranco*[3], *C. A. Lowell*[2];
[1]*Department of Pathology-Division of General Pathology, University of Verona, Verona, Italy,* [2]*Department of Laboratory Medicine-University of California San Francisco, San Francisco, CA, United States,* [3]*Department of Microbiology/Immunology, University of California San Francisco, San Francisco, CA, United States.*

Lyn kinase deficient mice represent a well-established genetic model of autoimmune/autoinflammatory disease that resembles systemic lupus erythematosus (SLE). We report that interleukin-10 (IL-10) plays a crucial immunosuppressive role in this model, modulating the inflammatory component of the disease caused by myeloid and T cell activation. Double mutant *lyn*$^{-/-}$*IL-10*$^{-/-}$ mice manifested severe splenomegaly and lymphadenopathy, dramatically increased pro-inflammatory cytokine production and severe tissue inflammation. Single mutant *lyn*$^{-/-}$mice showed expansion of IL-10-producing B cells. Interestingly, WT B cells adoptively transferred in *lyn*$^{-/-}$ mice showed increased differentiation into IL-10-producing B cells that assumed a similar phenotype to endogenous *lyn*$^{-/-}$ IL-10-producing B cells, suggesting that the inflammatory environment present in *lyn*$^{-/-}$mice induces IL-10-producing B cell differentiation. B cells, but not T or myeloid cells, were the critical source of IL-10 able to reduce inflammation and autoimmunity in double mutant *lyn*$^{-/-}$*IL-10*$^{-/-}$ mice. IL-10 secretion by B cells was also crucial to sustain transcription factor Forkhead Box P3 (Foxp3) expression in Tregs during disease development. These data reveal a dominant immunosuppressive function of B cell-derived IL-10 in the Lyn-deficient model of autoimmunity, extending our current understanding of the role of IL-10 and IL-10-producing B cells in SLE.

P3.14.29
B-cell delivery of tolerogenic fusion proteins via anti-CD20 targeting

A. Zhang, ***D. W. Scott****;*
Uniformed Services University of the Health Sciences, Bethesda, MD, United States.

We previously demonstrated that retroviral delivery of IgG fusion proteins in B cells ex vivo could block or reverse immune responses in rodent models of multiple sclerosis, type 1 diabetes and hemophilia. Our model was based on the tolerogenic antigen-presenting capacity (APC) of B cells and the exquisite tolerogenicity of IgG carriers demonstrated decades ago, and shown to be effective in preventing and/or treating autoimmune disease models. We recently rendered this gene therapy model B-cell specific in vivo by engineering a viral vector that was pseudotyped with a single chain anti-CD20 (scCD20). In order to create a non-viral¬ delivery system taking advantage of the tolerogenicity of IgG fusion proteins directed into B cells, we have prepared an scCD20 fusion with target peptides on a human IgG4 scaffold. We term this fusion a B-cell-specific antigen IgG fusion tolerogen (BAIT). Thus, in principle, CD20+ B cells could be directly "infected" in vivo with this BAIT to deliver target epitopes in tolerogenic B cells. In this report, the scCD20 murine anti-huCD20 BAIT was constructed with myelin oligodendrocyte glycoprotein (MOG) immunodominant peptide 35-55 (or a control OVA peptide) at the C-terminus. Herein, we show that these BAITs could specifically "infect" normal human B cells and Raji B lymphoma. Expression of an immunodominant peptide was determined by presentation to T-cell receptor transgenic T cells, and the effect on EAE will be presented using huCD20 transgenic B cells as tolerogenic APCs. The BAIT approach should be a novel therapeutic for MS. (Supported by NIH grant AI035622)

P3.14.30
CD19 expression on B cells controls type 1 diabetes (T1D)

R. M. Slattery*;*
Monash University, Melbourne, Australia.

Type 1 diabetes (T1D) is an autoimmune disease that results from mononuclear infiltration of pancreatic islets and targeted destruction of the insulin producing beta cells. The inflammatory infiltrate consists of many cell types including B lymphocytes capable of processing and presenting antigen to the T cells that kill beta cells. A crucial role for B lymphocytes in T1D pathogenesis has been established since non-obese diabetic (NOD) mice lacking B cells are protected from developing T1D. We show that CD19 expression on B cells, important for the internalization of membrane-bound antigens, is elevated in NOD mice, and results in increased signaling. Furthermore, while NOD B cells deficient in CD19 can adequately present peptide antigen and promote the expansion of T cells with specificity for the soluble beta cell protein pro-insulin, they possess significantly diminished capacity to expand T cells with specificity for the membrane-bound autoantigen, islet-specific glucose-6-phosphatase catalytic subunit-related protein (IGRP). We propose that elevated CD19 on NOD B cells leads to increased uptake of membrane-bound antigen, mediating the expansion of autoreactive T cells specific for membrane-bound autoantigens which are critical for invasive insulitis, beta cell destruction and T1D.

P3.14.31
Limited somatic hypermutation in IgA of transglutaminase 2 specific as well as gluten specific plasma cells of celiac disease intestinal lesions

Ø. Steinsbø[1], *C. Dunand*[2], *L. Mesin*[1], *M. Huang*[2], *M. Ferrer*[2], *K. Lundin*[1], *J. Jahnsen*[3], *P. Wilson*[2], *L. Sollid*[1];
[1]*University of Oslo, Faculty of Medicine, Oslo, Norway,* [2]*Section of Rheumatology, The Department of Medicine, 5The Committee on Immunology, University of Chicago, Chicago, IL, United States,* [3]*Department of Gastroenterology, Oslo University Hospital - Ullevål, Oslo, Norway.*

Celiac disease (CD) is an immune-mediated disorder with a strong HLA association to HLA-DQ2 and HLA-DQ8 that is caused by intolerance to cereal gluten proteins. A hallmark of the disease is IgA and IgG antibodies to the autoantigen transglutaminase 2 (TG2) as well as the exogenous antigen gluten. The generation of both anti-TG2 and anti-gluten antibodies are dependent on intake of gluten and associated with HLA-DQ2 and HLA-DQ8. A model where TG2-specific B cells receive help from gluten-specific T cells by taking up complexes of gluten and TG2 could explain the gluten and HLA dependent formation of anti-TG2 antibodies.
The consequence of this model is that TG2-specific and gluten-specific B cells may receive help from the same gluten-specific T cells, despite their different B cell receptor specificities. We have previously shown that intestinal TG2-specific IgA+ plasma cells show limited degree of somatic hypermutation, restricted VH gene usage and are highly abundant in the disease lesions. Here we compare intestinal gluten-specific and TG2-specific IgA+ plasma cells. Gluten-specific plasma cells have restricted VH and VL gene usage. As for the TG2-specific plasma cells, the somatic hypermutation is limited as

compared to gut IgA plasma cells with other specificities. The low degree of somatic mutation in gluten is surprising and may suggest that gluten-specific T cells influence the degree of mutations in antibodies produced by the exposure to gluten in celiac disease.

P3.14.32
Hydrodynamic DNA vaccination for induction of mouse monoclonal antibodies specifically reacting with N-acetylgalactosaminide α2,6-sialyltransferase II (ST6GalNAc II)

*M. Stuchlova Horynova[1,2], **A. Kasperova**[1,2], Z. Smrzova[3], E. Weigl[1], H. Suzuki[2,4], J. Novak[2], M. Raska[1,2];*
[1]Department of Immunology, Faculty of Medicine, Palacky University in Olomouc, Olomouc, Czech Republic, [2]Department of Microbiology, University of Alabama at Birmingham, Birmingham, AL, United States, [3]Department of Virology and Diagnostics, Veterinary Research Institute, Brno, Czech Republic, [4]Juntendo University, Faculty of Medicine, Tokyo, Japan.

IgA nephropathy (IgAN) is associated with galactose (Gal) deficiency of some IgA1 hinge-region (HR) O-glycans. Gal-deficient IgA1 plays a key role in IgAN, as such molecules are recognized by anti-glycan antibodies, form immune complexes that deposit in the glomerular mesangium and induce glomerular injury. O-glycosylation of IgA1 is initiated in Golgi apparatus of IgA1-producing cells by attachment of N-acetylgalactosamine (GalNAc) to some Ser/Thr residues in the HR, followed by addition of Gal to the GalNAc. Sialic acid (SA) could be attached to Gal by an α2,3-sialyltransferase and/or to GalNAc by α2,6-sialyltransferase II (ST6GalNAc II). Premature SA attachment to GalNAc would prevent addition of Gal, thus resulting in Gal deficiency.
The goal of our study is to determine whether overexpression of ST6GalNAc II, described in IgA1-producing cells from IgAN patients, is associated with abnormal localization of the enzyme, i.e., a shift from trans-Golgi toward cis-Golgi apparatus, and thus contributes to production of Gal-deficient IgA1. We developed ST6GalNAc II-specific monoclonal antibody for fluorescence-microscopy analysis of ST6GalNAc II intracellular localization. cDNA of human ST6GalNAc II was cloned into DNA vaccination plasmid and hydrodynamically administered to mice. Recombinant ST6GalNAc II protein was used for screening of ST6GalNAc II-specific antibodies from sera of DNA-immunized mice and monoclonal antibodies secreted by hybridoma cells. Analyses by fluorescence microscopy revealed that IgA1-producing cells from IgAN patients have increased fluorescence signal for ST6GalNAc II in trans-Golgi and a partial shift toward the cis-Golgi compared to IgA1-producing cells from healthy controls.

P3.14.33
B cell extrinsic MyD88 and FcR common gamma chain control contraction of the autoreactive extrafollicular B cell response

***R. A. Sweet**[1,2], J. L. Cullen[1], M. J. Shlomchik[1];*
[1]Yale University School of Medicine, New Haven, CT, United States, [2]Present Address: John Curtin School of Medical Research, Canberra, Australia.

Both MyD88 and Fc Receptor (FcR) common gamma chain signaling drive proinflammatory responses. In B cells, MyD88 is required for anti-DNA and anti-RNA autoantibody responses in vivo. Mechanisms within innate immune cell types during this response are not well understood. Transgenic mice have been useful in elucidating how autoreactive Rheumatoid Factor (RF) B cells are activated. In lupus-prone mice, RF B cells undergo an isotype-switched extrafollicular (EF) plasmablast response. A similar response ensues when these cells are exposed in vivo to anti-chromatin antibodies, which presumably form immune complexes (ICs) with chromatin shed from dying cells. ICs could also stimulate myeloid cells via FcR and TLRs, which in turn could influence the EF response. To investigate this, we transferred RF B cells and anti-chromatin antibodies into mice lacking FcR common gamma chain, MyD88 or both. Initially, expansion and differentiation of RF B cells was equivalent in all hosts. Unexpectedly, by day 7, the response contracted in the WT environment, whereas dysregulated expansion continued in the deficient environments. Furthermore, MyD88 and FcR are non-redundant, as responses were larger and more prolonged in mice lacking both compared with mice deficient in either factor alone. By day 10, the AFC frequency was 40-fold larger in double-deficient compared to WT recipients. These results reveal novel regulatory roles in the EF B cell response for receptors that are typically proinflammatory. Targeting these pathways may provide a way to curtail dysregulated autoreactive B cell activation.

P3.14.34
Renal Transplant Recipients lack circulating CD19+CD24hiCD38hi Interleukin-10 producing Regulatory B-Lymphocytes

***B. Tebbe**[1,2], J. Wang[2], S. Dolff[2], A. Kribben[2], P. Hoyer[1], O. Witzke[2], A. Hoerning[1];*
[1]Clinic for Pediatrics II, Pediatric Nephrology, Gastroenterology and Transplantation Medicine, University Hospital Essen, Essen, Germany, [2]Department for Nephrology, University Hospital Essen, Essen, Germany.

Introduction: B-lymphocytes are commonly associated with antibody mediated acute or chronic allograft rejection. However, recent studies have demonstrated that CD19+CD24hiCD38hi regulatory B-Lymphocytes (Breg) appear to suppress immune effector mechanisms by cell-cell contact or via production of IL-10. Here, we characterized and analyzed peripherally circulating Bregs by flow cytometry in healthy subjects (n=18) and renal transplant recipients receiving a calcineurine inhibitor based immunosuppression (n=41).
Methods: Freshly isolated PBMCs from healthy subjects (HS) and renal transplant recipients receiving a CNI-based immunosuppression were isolated. Four color FACS was performed for CD19, CD24, CD38 and IL-10 either after isolation or after 72hrs co-culture in presence of PMA/Ionomycin and TLR9-ligand. Patients that previously received thymoglobuline or rituximab or exhibited acute infections (CrP>0.5 mg/dL) were excluded from analysis.
Results: The amount of CD19+B-cells among lymphocytes was 11% in HS (n=18), 3% in CsA (n=6, $p<0.05$) and 7% in tacrolimus (TAC, n=35, $p<0.05$) treated patients. Among B cells, a distinct subset of CD24hiCD38hi Breg cells was found to be ~5% in HS, 2.4% in TAC-patients and almost blunted in patients receiving CsA. After stimulation, only ~4% of Bregs in HS and even fewer in CsA/TAC patients produced IL-10 (1.2% and 1.5%, $p<0.05$). Co-culture of positively isolated mitogen stimulated CD19+ B cells in presence of CsA (1, 10 and 100 ng/mL) or TAC (1, 5 and 10 ng/mL) confirmed these results.
Conclusion: CNI-based immunosuppression reduces the amount of Bregs and inhibits their IL-10 production. Whether this affects allograft function needs to be analyzed in further studies.

P3.14.35
Endosomal TLR triggering hyperactivates B cells, induces plasma cells differentiation, class switch and immunoglobulin production in Sjögren's syndrome

*S. Brauner[1], M. Kvarnström[1], L. Folkersen[1], S. Görgen[1], K. Brokstad[2], R. Jonsson[2], C. Trollmo[1], V. Malmström[1], G. Nordmark[3], **M. Wahren-Herlenius**[1];*
[1]Karolinska Institute, Stockholm, Sweden, [2]University of Bergen, Bergen, Norway, [3]Uppsala university, Uppsala, Sweden.

Patients with primary Sjögren's syndrome have B cell disturbances resulting in hypergammaglobulinemia and autoantibody production. Most patients are untreated, enabling studies of an unmanipulated human autoreactive immune system. Here we used vaccination as a tool to analyze immune responses in vivo. Untreated Sjögren's patients and healthy controls were vaccinated twice against the H1N1 influenza, and monitored by multiple sampling. Surprisingly, patients developed higher titers of IgG H1N1 antibodies, increased total IgG and increased autoantibody levels in response to vaccination. In addition, an expansion of CD138+ plasmablasts was observed, and up-regulation of several pro-inflammatory cytokines. To dissect the B cell hyperreactivity, immunoglobulin class switch was induced in vitro in CD19+IgD+ B cells from patients and controls. Significantly more plasmablasts and higher titers of IgM and IgG were observed in TLR9

stimulated Sjögren-patient derived cultures. Similar results were obtained by TLR7 stimulation, but not by α-CD40 or BAFF. The importance of the endosomal TLR pathways was further demonstrated by analyzing B cells from patients treated with the drug chloroquine, which targets the endosome. In these patients, no differences were observed in class switch and plasma cell differentiation compared to healthy individuals. This observation was further confirmed by in vitro treatment of IgD+ B cells with chloroquine which significantly inhibited class switch and plasma cell differentiation. In conclusion, we demonstrate for the first time that B cell activation via endosomal TLRs leads to enhanced plasma cell differentiation and class-switch in patients with Sjögren's syndrome, explaining the induction of hypergammaglobulinemia in Sjögren's syndrome patients.

P3.14.36
The role of B cells as antigen presenting cells in allergic inflammation

***T. Wypych**;*
Institute for Research in Biomedicine, Bellinzona, Switzerland.

Allergy is one of the leading health problems in industrialized countries, affecting around 50 million people in the United States only. The hallmark of this disorder is a strong Th2 response with upregulated levels of IL-4, IL-5 and IL-13, which leads to enhanced IgE production, cell recruitment to the site of allergen entry and exaggerated immune response leading to tissue damage. The pathological role of B cells in allergic disorders as the source of immunoglobulin E has been known for many years. In contrast, B cell capacity to regulate T helper cell responses via MHC class II dependent presentation of allergenic peptides in ongoing airway inflammation remains elusive. Using a mouse model of house dust mite induced allergic asthma, we seek to determine if B cells residing in lungs are able to stimulate effector T helper cells in the lungs to proliferate and secrete cytokines. This approach may help us determine if B cells may contribute to allergic inflammation via presentation of antigens to resting memory Th2 and/or effector Th2 cells during a secondary immune response.

P3.14.37
Anti-thrombin antibodies induced by dengue virus with both anti-thrombotic and pro-fibrinolytic activities

***T. Yeh**;*
National Cheng Kung University, Tainan, Taiwan.

Dengue virus (DENV) infection may result in severe dengue hemorrhagic fever (DHF). However, the mechanisms that cause hemorrhage in DHF are unclear. In this study, we demonstrated that antibodies against human thrombin were increased in the sera of dengue patients but not in other virus-infected patients. Thrombin cross-reacted antibodies were also found in the sera of DENV immunized mice and rabbits. To further characterize the properties of these antibodies, affinity-purified anti-thrombin antibodies (ATA) were collected from both DENV patients' sera and DENV immune rabbit's sera by thrombin and protein A/L affinity columns. We found both human and rabbit ATA bound not only to DENV, human thrombin, but also cross-reacted to human plasminogen (Plg). ATA from both sources could inhibit thrombin activity as determined by chromogenic assay, thrombin time, and fibrin formation. To our surprise, both rabbit and human ATA could also enhance Plg activation in vitro. The anti-thrombotic and pro-fibrinolytic activities of rabbit ATA were further confirmed in vivo by passive transferring into mice. Taken together, these results suggest that the anti-thrombotic and pro-fibrinolytic effects of ATA induced by DENV may contribute to hemorrhage in DHF.

P3.15 B and T cell memory

***In vivo* imaging of calcium signaling in B cells of mice expressing the genetically encoded YC3.60 calcium indicator**

***T. Adachi**[1], S. Yoshikawa[2], H. Karasuyama[2];*
[1]Department of Immunology, Medical Research Institute, Tokyo Medical and Dental University, Tokyo, Japan, [2]Department of Immune Regulation, Tokyo Medical and Dental University, Tokyo, Japan.

B cell signaling especially through the B-cell antigen receptor (BCR) has been studied intensively by using cell lines and purified primary B cells *in vitro*. Upon antigen stimulation, BCR signaling such as calcium mobilization and MAP kinase activation is induced, which is supposed to be crucial for B cell fate such as proliferation, differentiation and apoptosis. To assess calcium signaling in B cells, synthetic calcium indicators such as Fluo-4, Indo-1 and Fura-2 are commonly used. However, they have significant drawbacks, damaging cells and showing a short half-life. It is also difficult to label the cells homogenously *in vivo* using them. To overcome these problems, we employed the genetically encoded calcium indicator YC3.60 for the analysis of B cell signaling. We established transgenic mice with the genetically encoded calcium indicator YC3.60 based on the Cre/loxP system. After crossing with various Cre lines, the YC3.60 reporter mice exhibited robust YC3.60 expression in a wide variety of immune cells. We labeled B cells by crossing YC3.60 mice to CD19-Cre mice. In YC3.60/CD19-Cre mice, most of mature B cells in various lymphoid tissues such as spleen, lymph node, and Peyer's patches expressed YC3.60 without significantly altering B-cell function. After cross-linking of the BCR, calcium mobilization could be induced in spleen B cells from YC3.60/CD19-Cre mice. By *in vivo* imaging, calcium mobilization in B cells was observed in spleen. Thus, with this system, we will be able to validate B cell activation *in vivo* under physiological conditions.

P3.15.02
A triple positive staining to capture B cells expressing anti-tetanus toxoid IgG in human blood

***E. Aliprandini**[1], W. Quintilio[2], J. Kalil[3,4], S. B. Boscardin[5], A. M. Moro[1,4];*
[1]Laboratório de Biofármacos em Células Animais, Instituto Butantan, São Paulo, Brazil, [2]Controle de Qualidade, Instituto Butantan, São Paulo, Brazil, [3]Instituto Butantan, São Paulo, Brazil, [4]INCT/iii – Instituto de Investigação em Imunologia, São Paulo, Brazil, [5]Departmento de Parasitologia, ICB/USP, São Paulo, Brazil.

Aiming to sort B cells expressing anti-tetanus toxoid IgG from human blood that could be used for heavy and light chain amplification and cloning, this work started by the preliminary detection of such cells in 10mL of human peripheral blood. After informed consent, blood was drawn from six volunteers and the mononuclear cells (PBMC) were stained using anti CD19-FITC, anti IgG-APC, and streptavidin-PerCP-Cy5.5, following analysis by flow cytometry. Tetanus toxoid (TT) conjugated to biotin (TT-bio) was included or not in the mixture. Five donors were selected based on their high anti-TT antibody titers: 12.0, 16.1, 13.3, 13.0 and 12.2 UI/mL; a sixth donor did not receive tetanus booster immunization after infant vaccination (titer 1.2 UI/mL). Despite the fact that all donors presented protective anti-TT antibody titers (>0,1 UI/mL), neither donor (1) or (6) showed detectable anti-TT producing B-lymphocytes in the blood. The other 4 donors presented variable responses, expressed as anti-TT B lymphocytes/106 PBMC as 16.13, 36.18, 11.15 and 2.82. The frequency of anti-TT lymphocytes did not correlate with frequency of total lymphocytes in PBMC, which varied between 35 to 62%. The individual variability of the immunological response denotes the importance of testing several donors, even with a small volume of blood. The possibility of detection of the desired cells by the above mentioned triple staining protocol prompted us to drawn a large volume of blood from the donors in order to start the sorting protocols.

***Ex vivo* analysis of human memory B lymphocytes specific for A and B influenza hemagglutinin by polychromatic flow-cytometry**

L. Alleri[1]*, F. Angiolini*[1]*, F. Buricchi*[1]*, E. Degl'Innocenti*[2]*, I. Isnardi*[2]*, E. Fragapane*[1]*, G. Del Giudice*[1]*, F. Castellino*[1]*, G. Galli*[1]*, M. Bardelli*[1]*;*
[1]Novartis Vaccines & Diagnostics, Siena, Italy, [2]Novartis Institutes for Biomedical Research, Basel, Switzerland.

Understanding the impact that human memory Bcells (MBC), primed by previous infections or vaccination, exert on neutralizing antibody responses against drifted influenza hemagglutinin (HA) is key to design more protective vaccines. A major obstacle to these studies is the lack of practical tools to analyze HAspecific MBCs in human PBMCs *ex vivo*. We report here an efficient method to identify MBCs carrying HAspecific BCR in frozen PBMC samples. By using fluorochrometagged recombinant HA baits and vaccine antigens from mismatched influenza strains to block BCRindependent binding, we developed a protocol suitable for quantitative, functional and molecular analysis of single MBCs specific for HA from up to two different influenza strains in the same tube. This approach will permit the identification of the naive and MBC precursors of plasmablasts and novel MBCs appearing in the blood following infection or vaccination, thus clarifying the actual contribution of preexisting MBCs to antibody responses against novel influenza viruses. Finally, this protocol can enable the use of high throughput deep sequencing to analyze changes in the repertoire of HA^+ Bcells in longitudinal samples from large cohorts of vaccinees and infected subjects with the ultimate goal of understanding the *in vivo* Bcell dynamics driving the evolution of broadly crossprotective antibody responses.

P3.15.04

Innate signals control the binary cell fate choice between CD8+ effector and memory T cell differentiation via Notch

R. A. Backer[1]*, C. Helbig*[2]*, M. Willemsen*[2]*, A. Kent*[3]*, A. van Kampen*[2]*, K. van Gisbergen*[1]*, J. Magarian Blander*[3]*,* ***D. Amsen***[1]*;*
[1]Sanquin Blood Research, Amsterdam, Netherlands, [2]Academic Medical Center, Amsterdam, Netherlands, [3]Mount Sinai School of Medicine, New York, NY, United States.

The adaptive immune system must simultaneously remove the acute threat of microbial infections and lay the foundation for immunological memory. To this end, activation of naive CD8 T cells yields both short lived effector cells (SLECs), which provide immediate protection, and memory precursor effector cells (MPECs). This process involves a binary cell fate decision by bipotent precursors and is controlled by external signals. In particular, strong inflammation implies high infectious load and calls for generation of immediately protective SLECs. To unravel the mechanisms governing the cell fate choice between SLECs and MPECs, we focused on Notch, a conserved regulator of binary cell fate decisions. We find that surface expression of this receptor is induced in CD8 T cells by type I Interferons, while expression of its ligands is induced on migratory tissue derived dendritic cells upon viral infection. Genetic loss of Notch in CD8 T cells leads to an inability to generate SLECs, whereas generation of MPECs is increased. Genome wide transcriptome analysis showed that Notch controls expression of almost half the SLEC-specific gene expression program, while repressing a similar fraction of the MPEC program. Notch uses a multipronged mechanism to drive SLEC differentiation, involving induction of SLEC specific transcription factors such as Tbet and Blimp1 as well as enhancement of receptivity to IL-2. Thus, our findings identify Notch as a critical translator of the inflammatory cues, which control the decision of activated CD8 T cells to commit to the effector or the memory fate.

P3.15.05

Optimized fluorescent labeling to identify memory B cells specific for Neisseria meningitidis serogroup B antigens *ex vivo*

N. Nair, E. Faenzi, F. Buricchi, ***L. Bonoli****, F. Castellino, O. Finco, R. Rappuoli, G. Del Giudice, G. Galli, M. Bardelli;*
Novartis Vaccines & diagnostics, Siena, Italy.

Antigen (Ag)-specific memory B cells (MBC) generate anamnestic responses and high affinity antibodies (Ab) upon re-exposure to pathogens. Attempts to isolate rare Ag-specific MBC for in depth functional analysis at the single-cell level have been hindered by the lack of tools with adequate sensitivity. We applied two independent methods of protein labeling to sensitive and specific ex vivo identification of Ag-specific MBC by flow cytometry: stringently controlled amine labeling, and sortagging, a novel method whereby a single nucleophilic fluorochrome molecule is added onto an LPETG motif carried by the target protein. We show that amine-labeled or sortagged NadA, a major Ag in the meningococcal B vaccine, identify NadA-specific MBC with high and comparable sensitivity and specificity in a mouse model of vaccination. We distinguish NadA-specific switched MBC induced by vaccination from the background signal contributed by splenic transitional and marginal zone B cells.
In conclusion, we demonstrated that protein structural data coupled to sortag-technology allows the development of engineered Ags that are as sensitive and specific as chemically-labeled protein in detecting rare MBC, decreasing the possibility to disrupt conformational B cell epitopes.

P3.15.06

Modulation of heme oxygenase (HO)-1 enzyme activity by metalloporphyrins affects the antiviral T-cell response

V. Fortmeier, ***C. Bunse****, S. Tischer, N. Moraw, C. Figueiredo, E. Zilian, R. Blasczyk, S. Immenschuh, B. Eiz-Vesper;*
Hannover Medical School, Hannover, Germany.

Adoptive transfer of virus-specific cytotoxic T cells (CTLs) can prevent reactivation of latent viruses such as cytomegalovirus (CMV) and Epstein-Barr virus (EBV) and have been demonstrated to lead to a sustainable and rapid reconstitution of antiviral immunity. *In vitro* stimulation and expansion of virus-specific T cells is required for clinical applications. In the present study we asked whether modulation of the immunomodulatory enzyme heme oxygenase-1 (HO-1), which is the inducible isoform of enzymatic heme degradation, might have effects on *in vitro* T cell activation. To this end we investigated whether (1) induction by cobalt-protoporphyrin (CoPP) or inhibition by tin-mesoporphyrin (SnMP) can affect expansion of virus-specific CD8+ T cells *in vitro*, (2) modified HO-1 activity modulates proliferation and functional activity, (3) *in vitro* application influences other cell populations within the group of PBMCs (DCs, Tregs, natural killer cells) mediating effects on proliferating T cells, (4) HO-1-modulated antigen-specific T cells would be suitable for the purpose of adoptive immunotherapy. Inhibition of HO-1 via SnMP in peptide-pulsed PBMCs results in a significant enhanced virus-specific $CD8^+$ T-cell proliferation, whereas increase of HO-1 activity by CoPP did not impaired T-cell responses. Transcription and secretion of IFN-γ in response to viral peptides is up-regulated upon inhibiting HO-1. Inhibition of HO-1 has no effect on mDCs and NK cells, but depletion of Tregs and additional application of SnMP multiplies virus-specific T-cell frequencies. Taken together we found, that SnMP-treatment may be suitable for the purpose of adoptive T-cell therapy.

P3.15.07

Pou6f1 is dispensable for mouse T cell development and virus-specific memory CD8+ T cell generation

M. J. Carrasco-Alfonso*, W. Jiang, J. Luckey;*
Brigham and Women's Hospital and Harvard Medical School, Boston, MA, United States.

Pou6f1 is a POU-domain transcription factor whose paralogs control self-renewal (e.g. Oct-4) and cell fate determination (e.g. Pit-1, Brn3a). It has been shown to be selectively upregulated at the DN3a

to DP stages in thymocytes; and across different models in antigen-specific memory/memory-precursors relative to shorter-lived mature CD8+ T lymphocytes. On these bases, we hypothesized that it is required for maintaining a multipotent and/or differentiation-poised state in T cells. To test this, we quantitatively validated its differential expression in lymphocytes, and generated and characterized conditional (Cre/loxP-based) Pou6f1 knockout mice. Germ-line deletion (EIIa-Cre-driven) resulted in viable and fertile progeny with no obvious morphological or behavioral abnormalities. Mice with an early deletion in thymocytes (Lck-Cre-driven) showed normal frequency and phenotype of thymic populations (DN, DP, SP4 and SP8) and peripheral CD4+ and CD8+ T cells, according to the expression of TCRβ, CD3, and activation (CD5, CD44, CD69), differentiation (CD25, CD27, CD28, CD62L, CD122), survival (CD127) and senescence (Klrg1) markers. Likewise, specific deletion in CD8+ cells (E8I/CD8a-Cre-driven) did not affect either antigen-specific CD8+ T cell effector response (*ex-vivo* OVA-induced IFN-γ synthesis), or memory generation (pentamer binder frequency) and response upon infection with vaccinia-OVA virus. The effects on both memory formation in a competitive adoptive transfer setting and secondary responses are under study. In conclusion, this is the first description of a Pou6f1 knockout mouse. Results to date suggest that Pou6f1 may not be involved in lineage commitment of thymocytes or CD8+ T lymphocytes, or that in the current experimental models its loss is compensated.

P3.15.08
Unique features of protective cytotoxic T cell response during chronic T. gondii infection

***H. Chu**, N. Shastri, E. Robey;*
UC Berkeley, Berkeley, CA, United States.

Protective immunity against T. gondii reactivation during the chronic phase of infection relies on the presence of immunodominant antigen-specific cytotoxic T cells. How the immunodominant cytotoxic T cell populations emerge and are maintained compared to subdominant populations is poorly understood. With the recently identified MHCI-restricted T. gondii epitopes, we were able to track various epitope-specific cytotoxic T cell populations throughout the course of infection. We discovered that the immunodominant population: 1) exhibited an unusual kinetics without a contraction phase, partially due to prolonged antigen presentation in the lymphoid organs; 2) maintained the effector functions and phenotypes without exhaustion over a long period of time; 3) was driven by different transcriptional programs in lymph nodes and in the spleen. We will discuss potential factors that cause these unique features of the protective T. gondii-specific cytotoxic T cell population. Our studies describe a novel cytotoxic T cell behavior during chronic protozoan infection that differs from other well-studied persistent infection such as LCMV and HCV.

P3.15.09
Dividing and non-dividing CD27^{low} and CD27^{high} human memory B-cells are differently induced depending on the stimulus

***A. Clemente**, J. Pons, N. Lanio, N. Matamoros, J. M. Ferrer;*
Son Espases Hospital, Palma de Mallorca, Spain.

Protective antibody responses depend on efficient memory B-cells activation. Heterogeneity among responding memory B cells has been shown greater than previously appreciated. According to their proliferating status and intensity of CD27 expression, different subpopulations, endowed with distinct functional characteristics, have been described in memory B-cells stimulated with CpG-ODN and interleukins.
OBJECTIVES: To evaluate the proportion of dividing and non-dividing functionally distinct CD27^{high} or CD27^{low} memory B-cells generated after stimulation with a surrogate T-dependent (CD40) or T-independent (TLR9) stimulus in the presence or absence of IL-21 and/or BCR signaling.
METHODS: B-cells from healthy donors were purified from PBMC by magnetic negative selection. CFSE-labelled B-cells were stimulated with anti-CD40 or CpG-ODN, with or without anti-IgM, in the presence or absence of IL-21. B-cell proliferation and phenotype were evaluated by flow cytometry.
RESULTS: We found that neither anti-CD40 nor anti-IgM alone or in combination induced proliferating memory B-cells. However, CpG-ODN alone induced proliferation, with a higher proportion of dividing CD27^{low} than CD27^{high} memory B-cells.
IL-21 induced equal proportions of non-dividing CD27^{low} or dividing CD27^{low} and CD27^{high} on CD40-activated memory B-cells. In contrast, IL-21 increased dividing CD27^{high} and markedly decreased dividing CD27^{low} on CpG-ODN-activated memory B-cells.
Addition of anti-IgM consistently increased the proportion of dividing CD27^{low} on memory B-cells costimulated with either anti-CD40+IL-21 or CpG-ODN.
CONCLUSIONS: Distinct proportions of dividing and non-dividing CD27$^{high/low}$ memory B-cells are generated depending on stimulus. Given the different functional capabilities of these subpopulations, this has to be taken into account when trying to bias immune responses.

P3.15.10
Distinct memory T- cell-subsets secrete IFN- and IL2 in response to CD4+ T-cell HIV-1 epitopes from a vaccine candidate

*A. C. S. Borgo[1], L. Martí[2], S. L. Moraes[1], A. Segurado[1], L. Fonseca[1], E. G. Kallas[1], J. Kalil[3], E. Cunha-Neto[1], **S. G. Fonseca**[4];*
[1]University of Sao Paulo, Sao Paulo, Brazil, [2]Albert Eistein Hospital, Sao Paulo, Brazil, [3]University of Sao Paulo, Sao Pauo, Brazil, [4]Federal University of Goias, Goiania, Brazil.

The persistence of functional memory T cell is important to ensure a protective immunity to Human Immunodeficiency Virus (HIV) infection. Recently, we have described 18 HLA-DR promiscuous epitopes from HIV-1 consensus B sequences that have been successfully tested in HLA-DR transgenic mice. To investigate the functionality of the subsets of memory T cells that respond to these peptides among PBMC from HIV-infected patients. 14 healthy donors and 61 HIV-infected patients with CD4$^+$ lymphocytes counts higher than 250 cells/mm3. Six clinical groups were included according to the stage of infection, plasma viral load (VL) and antiretroviral therapy use (ART): long-term non-progressors (LTNP), aviremic under ART (AV-ART), viremic under ART (VI-ART), viremic without ART (VI without ART), recently infected viremic without using ART (VI-RI) and controllers. The cellular phenotype and cytokine production were evaluated by multiparameter flow cytometry. Our peptide set was able to activate central memory (TCM), effector memory (TEM) and highly differentiated effector memory (TEMRA) functional memory subsets that secrete IFN-γ and IL-2 in 100% of the HIV-patient tested. The HIV-1 peptide set also induced memory T lymphocyte subsets proliferation. TEMRA-CD4$^+$IFN-γ$^+$, total TEMRA-CD4$^+$IFN-γ$^+$, TCM-CD8$^+$IFN-γ$^+$, total TCM-CD8$^+$IFN-γ$^+$, total TEM-CD8$^+$IFN-γ$^+$, TEM-CD8$^+$IFN-γ$^+$ and TEMRA CD8$^+$IFN-γ$^+$ frequencies negatively correlated with HIV viral load in viremic patients. These data suggest that these functional memory subsets are important to control the viremia. Our results suggest a functional heterogeneity of T memory subsets in response to the set HIV-1 peptides, which may constitute a new vaccine candidate to HIV infection. Supported by DST/AIDS-Brazilian Program/Unesco

P3.15.11
Higher cytotoxic capacity in peripheral blood of sarcoidosis patients

***H. Forsslund**, T. Enger, D. Lorenz, R. Rao, J. Rahman, A. Eklund, M. Sköld, S. Brighenti, J. Grunewald, J. Wahlström;*
Karolinska Institutet, Stockholm, Sweden.

BACKGROUND. Sarcoidosis is a granulomatous disease of unknown etiology, mainly affecting the lungs, where greatly increased numbers of CD4+ T cells typically are seen. However, CD8+ T cells can sometimes make up the majority of cells recovered by bronchoalveolar lavage (BAL). Previous studies have extensively studied Th1 cytokine-producing T cells and established their role in the pathological process. Little is however known about cytotoxic cells in sarcoidosis. METHODS: Peripheral blood (from 17 sarcoidosis patients and 11 healthy controls) and BAL fluid (from 19 patients and 4 controls) was obtained. Flow cytometric analysis of cell subsets was performed after staining with antibodies against the surface molecules CD3, CD4 and CD8 as well as antibodies against the

cytotoxic intracellular mediators perforin, granzyme B and granulysine. The PBMC cytotoxic activity was quantified with the 51Cr release assay. RESULTS: Sarcoidosis patients had a significantly higher percentage of both perforin+ ($p < 0.001$) and granzyme B+ ($p < 0.05$) CD8+ T cells in blood. In BAL, however, a tendency in the opposite direction was seen. Higher cytotoxic activity was observed in PBMC from patients with sarcoidosis compared to controls. CONCLUSION: Cytotoxic cells, including CD8+ T cells, may be involved in the propagation or regulation of the inflammatory process in sarcoidosis, but further studies are needed to delineate their role in this disease.

P3.15.12
Interleukin-33 is dispensable for the maintenance of memory CD8 T cells

A. Froehlich[1,2]*, W. V. Bonilla*[3]*, S. Nakae*[4]*, D. D. Pinschewer*[3]*, M. Loehning*[1,2]*;*
[1]Charité University Medicine, Berlin, Germany, [2]German Rheumatism Research Center (DRFZ), Berlin, Germany, [3]University of Geneva, Geneva, Switzerland, [4]University of Tokyo, Tokyo, Japan.

Generation and maintenance of effector and memory T cells is tightly regulated by cytokines. We have shown recently that the alarmin interleukin-33 (IL-33) is essential for the generation of a fully functional and potent anti-viral CD8 T cell response against infection with lymphocytic choriomeningitis virus (LCMV). Moreover, IL-33-deprived cytotoxic CD8 T cells express less KLRG1 indicating a reduced frequency of short-lived terminally differentiated effector cells (SLEC), but show an increased expression of IL-7receptor (IL-7R), which is characteristic of memory precursor cells (MPECs) in this model. These results indicate, that memory generation and maintenance might be dysregulated in the absence of IL-33 signalling. Therefore, we infected WT and IL-33receptor (ST2)-deficient mice with LCMV and followed the faith of virus-specific CD8 T cells in the blood over time. Although we found drastic differences in frequencies of these cells and their expression of effector/memory-associated surface molecules at the onset of infection, these differences vanished over time and became undetectable by day 60 post infection. To exclude influence of viral antigen on memory maintenance in the absence of IL-33 signalling, we sorted TCR-transgenic P14 cells from infected WT mice and adoptively transferred them into naive WT or IL-33-deficient recipients. In both hosts, effector P14 cells turned into memory cells with similar kinetics and phenotype. These data indicate a redundant role for IL-33 in the maintenance of anti-viral CD8 T cell memory.

P3.15.13
Phenotypic and functional heterogeneity of circulating CD4+ and CD8+ T cell subsets and their age related changes

N. D. Marín, M. Rojas, S. C. París, ***L. F. García****;*
Universidad de Antioquia, Medellín, Colombia.

The phenotypic heterogeneity of human CD4+ and CD8+ T cell subsets has been widely reported. Many different surface markers are currently used to identify T cell subsets, resulting in a rather confuse panorama. We analyzed the phenotype of circulating CD4+ and CD8+ T cell subsets in healthy individuals, based on the expression of CD45RO and CD27. Thus, four CD4+ and CD8+ T cell subsets were initially identified: CD45RO+CD27+ (T_{CM}), CD45RO+CD27- (T_{EM}), CD45RO-CD27+ ($T_{naïve/early}$) and CD45RO-CD27- (T_{EF}). The percentage of circulating CD4+ and CD8+ T cell subsets showed a higher frequency of circulating CD4+T_{CM} compared to CD8+ cells, and of CD8+T_{EF} cells compared to CD4+ cells. There was a significant negative correlation between CD4+ $T_{naïve/early}$ and CD4+$T_{EM,\ and\ between}$ CD8+ $T_{naïve/early}$ cells and CD8+T_{CM}. Further analysis confirmed a high heterogeneity regarding the expression CD127, CD62L, CD45RA, CD28 and CD57; the later mainly expressed by CD27- T cells. The functional evaluation of T cell subsets showed that memory T cells (T_{CM} and T_{EM}) were the main responders to the stimulation with anti-CD3 plus anti-CD28 and PPD. Finally, significant age-related changes in the frequency of T cell subsets were associated with a reduction in the frequency of $T_{naïve/early}$ and an increase in the frequency of memory T cells, mainly T_{EM}. Our results corroborate the heterogeneity of CD4+ and CD8+ T cell subsets and their age-related changes; however, their biological meaning requires careful analysis and interpretation.

P3.15.14
Lung APCs of influenza memory mice challenged with influenza virus contain less virus compared to primary infected mice

K. Grönvik*, A. Daggfeldt;*
National Veterinary Institute, Uppsala, Sweden.

Aim: To study phenotype, function and localization of influenza virus APCs and virus specific memory T cells.
Methods: Mice were infected intranasally with a sublethal dose of live H_1N_1 PR8 influenza virus. After three months animals were challenged with a lethal dose of the homologous virus and three months post challenge T cells were isolated from sacrificed mice. APCs were isolated from naive and immune syngeneic mice at 36 hours post infection and virus RNA was detected by RT-PCR. Purified APCs and T cells were co-cultured *in vitro* and cytokines were determined by immunoaffinity with Gyrolab Bioaffy and with FACS.
Results: After primary infection virus RNA was detected in lungs and in mediastinal lymph nodes but not in spleen or in inguinal lymph nodes. Virus challenge of protected mice showed a low or no PCR signal in lungs and in lymph nodes similar to primary infected mice treated intranasally with homologous influenza immune serum. Challenge of immune mice rapidly induced IFN-γ containing T cells in lung and spleen and stimulation *in vitro* with $CD11c^+$ dendritic cells of virus infected lungs resulted in poor proliferation of immune $CD4^+CD44^+$ T helper cells while retaining a high production of IFN-γ, IL-17 and IL-13. The inhibited proliferation was enhanced by removal of $CD4^+CD25^+$ Regulatory T cells.
Conclusion: Anti-influenza antibodies of immune mice inhibit excess virus uptake by airway associated APC.s without affecting the pro-inflammatory cytokine response of memory T cells in lung and spleen.

Upon an encounter with cognate antigen, naïve T cells undergo extensive cell divisions associated with functional and phenotype change. The kinetics and mechanisms that result in the generation of effector and memory CD8+ T cells have remained controversial. Here we made use of a novel approach to dissect the proliferative behavior of activated CD8+ T cells, that is single cell tracking of cell cycle progression of OVA-specific T cells transgenically expressing the fluorescent ubiquitination-based cell-cycle indicator (FUCCI). The naïve T cells in G0 phase express red fluorescent protein and turn to yellow and green according to progression to S/G2/M. Following infection with OVA expressing influenza virus in vivo, FUCCI/OTI T cells vigorously divided with decreasing red+ cells from 99% to 5% and increasing green+ cells up to 44.6% by day4 post infection. Unexpectedly, red+ FUCCI/OTI cells reappeared at the peak of infection with early memory phenotype. These cells had a history of vigorous prior proliferation indicated by cell trace dye dilution, suggesting they derived from the fast dividing effector T cell pool. Next, we tracked divisions of single cells trapped in microwells. Mathematical modeling revealed strong kinship in cell cycle time of progeny derived from a single cell. Strikingly, in later divisions (generation ≥8), a slow cycling subpopulation detected with smaller cell size and expression of memory markers. Collectively, we report a novel developmental process whereby at the height of the immune response T cells segregate into populations within distinct proliferative histories characteristic of terminal effector and memory T cells.

P3.15.16
Molecular mechanisms for memory B-cell development and function

D. Kitamura[1], *K. Haniuda*[1], *S. Fukao*[1], *S. Horiuchi*[1], *S. Takatsuka*[1], *T. Moutai*[1], *T. Nojima*[2];
[1]*RIBS, Tokyo University of Science, Noda, Chiba, Japan,* [2]*Duke University, Durham, NC, United States.*

Upon immunization with T-cell dependent antigens, antigen-bound B cells proliferate extensively to form germinal centers (GC) in the peripheral lymphoid organs and then differentiate into either long-lived plasma cells (LLPCs) or memory B (Bmem) cells, both of which constitute a B-cell part of the immunological memory. However, molecular mechanisms for the development of Bmem cells remain poorly understood, partly due to the lack of an in vitro model system. Recently, we have established a culture system in which mouse naïve B cells can be extensively propagated on feeder cells expressing CD40L and BAFF to generate GC-phenotype B (iGB) cells undergoing immunoglobulin class switching. The iGB cells after primary culture with IL-4 develop into Bmem cells in vivo that elicit rapid immune responses, whereas after the secondary culture with IL-21, they develop in vivo into LLPCs that produce antibodies in the bone marrow, but not Bmem cells. The tertiary culture without cytokines partially restores the Bmem development and abolishes the LLPC development. Thus, this novel system has enabled in vitro differentiation from naïve B cells into Bmem or LLPC precursors that maturate in vivo, and therefore will be useful to study the mechanisms for the development and function of Bmem and LLPCs. In this workshop, I will discuss newly discovered molecular requirements for the Bmem cell development and function.

P3.15.17
Isolation of mouse B cells and T cell subsets in as little as 15 minutes

A. I. Kokaji*, V. Posarac, L. Tonelli, J. W. Dixon, D. W. Kellerman, P. T. Morin, S. Clarke, M. A. Fairhurst, K. L. McQueen, T. E. Thomas;*
STEMCELL Technologies Inc., Vancouver, BC, Canada.

Following an immune challenge, innate and adaptive immune cells undergo a series of orchestrated events culminating in an effective immune response. Within the adaptive branch, effector functions are carried out by antibody producing B cells, and CD4+ and CD8+ T cells that produce cytokines and cytolytic effector proteins which function to coordinate immune responses or directly eliminate infected cells. While most effector cells become senescent and apoptotic, some B- and T cells further differentiate into memory cells that provide long lasting immunity. The signals that regulate these processes have been widely investigated and continued efforts will help construct a definitive model for the role B- and T cells in adaptive immunity. For most of these studies, highly purified cells are required and current methods for isolating these cells from mice require either lengthy protocols or flow based cell sorting. To address these limitations, we have developed new column-free, immunomagnetic cell isolation kits to isolate untouched B cells and naïve and memory T cell subsets in as little as 15 minutes. Purities of up to 98% can be achieved using the manual EasySep™ pour-off method or using the fully automated RoboSep™ cell separator. Isolated cells can be immediately used for downstream assays and are fully functional as assessed by in vitro proliferation and cytokine production assays.

P3.15.18
AID dependent memory response in unimmunized mice

S. Le Gallou*, R. Fritzen, J. Weill, C. Reynaud;*
INSERM U783, Paris, France.

We constructed a knock-in transgenic mouse model, which allowed the irreversible expression of EYFP in AID expressing B cells after tamoxifen regimen (AID-Cre-EYFP mice). We observed a systemic response in absence of any immunization, with EYFP+ B cells detectable at different frequency in Peyer's patches, peritoneal cavity, spleen and bone marrow up to 6 months after tamoxifen-induced labelling. All these tissues presented different proportion between plasma cells (B220- YFP+) and memory B cells (B220+ EYFP+). Around 60 to 80 % of the YFP+ plasma cells in bone marrow, but also in spleen, were IgA+, whereas the EYFP+ memory B cells were mainly IgM+ in these two tissues. Adoptive transfers with bone marrow (as source of B2 cells) and peritoneal cavity (as source of B1 cells) showed that EYFP+ B cells seemed to have a B2 origin. To fully understand this endogenous response, we are presently analyzing AID-Cre-EYFP mice on a germ-free background in order to evaluate the role of commensal microbiota in the generation of these memory responses. In the same way, we are currently crossing AID-Cre-EYFP mice with FoxP3-DTR mice to determine whether the generation of EYFP+ cells in absence of immunization could have an autoimmune origin.

P3.15.19
In vivo IL-6 inhibition using anti-IL-6 receptor antibodies modulates double negative (CD19+IgD-CD27-) B cells in Rheumatoid Arthritis patients

Z. Mahmood[1], *K. Muhammad*[1], *P. Roll*[1], *M. Schmalzing*[1], *T. Dörner*[2], *H. Tony*[1];
[1]*Department of Internal Medicine, University of Wuerzburg, Würzburg, Germany,* [2]*University of Berlin, Berlin, Germany.*

Purpose. The role of IL-6 during the differentiation of B cells has been appreciated. Although phenotypic reports on double negative (CD19+IgD-CD27-) memory B cells in autoimmune disease are increasing, precise molecular analyses of their immunoglobulin (Ig) genes are sparse. Therefore, we analyzed the in vivo effect of therapeutic IL-6 inhibition using tocilizumab (TCZ) in patients with rheumatoid arthritis.
Methods. DN B cells were analyzed from RA patients at baseline and 12, 24 and 48 weeks during TCZ treatment phenotypically and using single B cell PCR to study the mutational pattern of Ig- receptors VH genes.
Results. RA patients (n=42) showed a significantly higher percentage ($P<0.0001$) of DN B cells compared to healthy individuals. These cells comprise a heterogeneous mixture of IgA, IgG and IgM expressing cells with clear dominance of IgG+ cells. Analysis of rearranged IgR sequences from healthy donors (n=3) and pre-therapy RA patients (n=7) revealed a comparable but diversified mutational pattern of DN B cells with mutated and non-mutated sequences. Under IL-6R inhibition a significantly reduced mutational frequency in their Ig-receptors at week 12 ($P<0.0001$), 24 ($p= 0.0147$) and 48 ($p= 0.0021$) was observed. In contrast, therapeutic TNF-inhibition did not produce significant changes in the mutational frequency of DN Ig-receptors.
Conclusions. Our data suggest expanded DN B-cells populations in RA which are susceptible to IL-6R inhibition by reduced mutational frequencies of single Ig-receptors. These results indicate that DN B cells have dependence on the IL6/IL6R system for differentiation in vivo which can be modulated by anti-IL6R therapy.

P3.15.20
Characterising PI16-positive T helper cells

A. P. Mohandas[1,2,3], *H. Zola*[1,2], *S. Barry*[1,3,2], *D. Krumbiegel*[1];
[1]*University of Adelaide, Adelaide, Australia,* [2]*Women's and Children's Health Research Institute, North Adelaide, Australia,* [3]*Co-operative Research Centre for Biomarker Translation, Melbourne, Australia.*

T helper (Th) cells play a major role in protecting the body against pathogens. Any imbalance in Th cell subsets (Th1, Th2, Th17, Th22, Th9 and T follicular helper cell) could lead to autoimmune and inflammatory diseases. Peptidase inhibitor 16 (PI16), also known as prostate secretory protein of 94 amino acid - binding protein, was discovered to be expressed on memory regulatory T cells. This study investigates the expression and function of PI16 on Th cells. In healthy adults, 5-25% of CD4+ Th cells express PI16 with over 90% having a memory phenotype. In contrast, more than 40% of PI16+ Th cells have naive phenotype in patients with scleroderma. Furthermore, PI16+ Th cells have an increased expression of chemokine receptors CCR4, CCR5 and CCR6 compared with PI16- Th cells. Transwell migration assays showed that more PI16+ Th cells migrated towards the CCR4 and CCR6 ligands (CCL17 and CCL20) compared with PI16- Th cells. After 7 day stimulation using CD3 / CD28 beads, with and without Th17 polarizing cytokines, PI16+ Th cells produce more IL-17A and less IFN-g compared with PI16- Th cells. PI16+ Th cells also have a higher expression of ROR-gt compared to PI16- Th cells. The memory phenotype of PI16+ Th cells and high expression of Th17-like chemokine receptors, increased ROR-gt expression and high production of IL-17A suggest that PI16 could play an active role at the site of infection or inflammation. Further studies are ongoing to understand the functional role of PI16 on Th cells.

P3.15.21
Functional genomic characterization of murine CD8+ CD103+ tissue resident memory T cells

B. Molnár-Érsek[1], *E. Buzás*[2], *T. Simon*[2], *A. Nagy*[2], *B. Bagita*[2], *A. Falus*[2], *Z. Pós*[1,2];
[1]*MTA-Semmelweis University "Lendület '' Experimental and Translational Immunomics Research Group, Budapest, Hungary,* [2]*Department of Genetics, Cell and Immunbiology, Semmelweis University, Budapest, Hungary, Budapest, Hungary.*

Recent research focusing on memory T lymphocytes suggests the existence of several, highly specialized tissue-resident memory T cell (Trm) subsets instructed to preferentially home to, subsequently become resident in, and rapidly respond upon recall antigen challenge in distinct organ environments.
Although there is consensus that all CD8+ Trm cell subsets are characterized by integrin alphaE (CD103) expression, they are also known to express unique markers in a tissue-specific fashion, depending on their organ residence. Nevertheless, the full spectrum of these markers is unknown, leaving much room to speculation about possible differences between Trm functions in distinct organs.
The aim of this study was a comprehensive enumeration of both consensus and organ specific biomarkers of murine CD8+ Trm cells resident in the small intestine, lung and liver. We show that pure fractions of intact, viable murine CD8+ CD103+ Trm cells can be isolated from these organs using automated tissue processing followed by a two-step MACS sorting method. Using circulating CD8+ CD62L- T effector cells as reference, we also present initial findings obtained from a whole-genome gene expression profiling study describing common features of, and organ-specific differences between these Trm cell subsets.
Our data contribute to a better understanding of memory T cell homeostasis and also may support the further development of recently introduced human therapies targeting T cell-mediated, organ-limited diseases, such as certain forms of transplant rejection, graft versus host disease, some organ-specific autoimmune, or chronic inflammatory disorders.
This study was supported by the Hungarian Academy of Sciences "Lendület" grant LP2012-49/2012.

P3.15.22
Identification of dominant B & T cell epitopes of E2 glycoprotein:a way towards vaccine preparation for chikungunya

P. K. Nagar;
All India Institute of Medical Sciences, New Delhi, India.

Introduction: Chikungunya virus (CHIKV) is a worldwide emerging pathogen. CHIKV is an *Alphavirus* that is transmitted to humans by virus-carrying *Aedes* mosquitoes.Growing evidence indicates that the innate immune response plays a role in controlling CHIKV infection.To date formalin inactivated virus vaccine, attenuated vaccine & chimeric vaccine have been developed. The peptide based vaccine concept is based on the identification and chemical synthesis of B-cell and T-cell epitopes having immuno-dominant functions.
Objectives: Selection and chemical synthesis of peptides of E2 protein of chikungunya virus.Competitive immunoassay of selected peptides. Direct binding assay, end point titre & IgG subclass estimation of peptide antisera. In vitro T cell proliferation by thymidine assay.
Methodology: Based on DNA star & tepitope software, peptide sequences were selected & synthesized by Fmoc chemistry. Competitive immunoassay of peptides were performed with E2 protein. Inbred mice were immunized with peptides. Direct binding assays were performed at a fixed dilution. Antibody peak titers were determeined with serial dilution of peptide antisera.
Results: Out of seventeen peptides ten peptides were showing competitive immunoassay shows high end point titre. IgG2a & IgG2b were dominant compared to other IgG subclasses.Three peptide shows higher stimulation index compare to others in vitro T cell proliferation assay.
Conclusion: These B & T cell immune-dominant sequences can be exploited for the development of a subunit vaccine against CHIKV.

P3.15.23
Comparison of four established cell culture conditions to assess antigen-specific memory B cell responses in humans and nonhuman primates

S. Pichyangkul[1], *U. Kum-Arb*[1], *A. Limsalakpetch*[1], *K. Yongvanitchit*[1], *E. Angov*[2], *E. S. Bergmann-Leitner*[2], *R. Im-Erbsin*[1], *C. Ockenhouse*[2], *C. J. Mason*[1], *D. L. Saunders*[1];
[1]*AFRIMS, Bangkok, Thailand,* [2]*WRAIR, Silver Spring, MD, United States.*

Effective vaccines should elicit protective primary effector immune responses and immunological memory that is characterized by the ability of the immune system to respond rapidly upon subsequent encounter with a pathogen or antigen. Serum antibody levels usually wane over time after a vaccination series while memory B and T cell responses are long-lived and therefore may play a crucial role in long-term protection. Assessment of serum antibody and memory T cell is commonly employed to evaluate vaccine immunogenicity and the duration of immune response, however the measurement of memory B cell response generated by vaccination has been very limited. In this study, we evaluated four previously published cell culture conditions used for *in vitro* induction of antibody secreting cells, including: 1) PWM+SAC+CpG, 2) PWM+SAC+CpG+IL-10, 3) R848+IL-2, and 4) CD40L+CpG+IL-21. We found the combination of R848 and IL-2 to be optimal for the assessment of tetanus-specific memory B cell response in humans as well as malaria antigen CelTOS-specific memory B cell response in vaccinated rhesus monkeys. The assay was then used to investigate the kinetics of antigen-specific memory B cell response in animals after receiving three doses of the CelTOS vaccine. Peripheral blood memory B cells specific to CelTOS were detected after the 2nd dose and markedly increased after the 3rd dose of vaccine. Our results suggest that a combination of R848 + IL-2 is an optimal culture condition to assess antigen-specific memory B cell response for both humans and rhesus monkeys.

P3.15.24

Evaluation of IgA antibody, Melatonin and Cortisol levels in diurnal and nocturnal colostrum samples from healthy puerperae that delivery by vaginal and caesarean partum

***G. N. Pontes**, M. M. S. Carneiro-Sampaio, R. P. Markus;*
Universidade de São Paulo, São Paulo, Brazil.

Human breast milk is rich in maternal leukocytes, immunoglobulins, and hormones, and therefore transfer immunity passively for the newborn. Here we compared the diurnal and nocturnal IgA, melatonin and cortisol levels in colostrum from healthy mothers that delivery by vaginal (n = 11) and caesarean (n = 9) partum. Melatonin levels of colostrum from mothers, who had vaginal delivery, was significantly higher at night when compared with day values (day = 4.1±0.4; night = 39.9±3.3 pg/ml, $P < 0.0001$, paired t-test). Whereas, cortisol levels of colostrum from mothers, who had vaginal delivery, was significantly higher at day when compared with night values (day = 3.0±0.5; night = 1.6±0.2 ng/ml, $P = 0.005$, paired t-test). However, melatonin and cortisol levels in colostrum obtained from mothers, who had caesarean delivery did not show a diurnal variation (day = 20.7±0.7; night = 24.6±2.3 pg/ml and day = 6.2±0.2; night = 5.7±0.5 ng/ml, respectively). On the other hand, no significant difference between diurnal and nocturnal IgA levels from mothers, who had vaginal or caesarean delivery were detected: (diurnal = 2.6±0.3; nocturnal = 2.7±0.9 g/l and diurnal = 3.2±0.5; nocturnal = 3.2±1.3 g/l, respectively). In conclusion, we show that healthy puerperae, who had vaginal delivery, present a significant day/night rhythms of melatonin and cortisol. Furthermore, melatonin and cortisol are inversely related, the peak of cortisol is observed in the morning and the melatonin peak is observed in the night. On the other hand, we observed no rise in diurnal or nocturnal IgA.

P3.15.25

High frequency of T memory stem cells precedes T cell immune-reconstitution following human bone marrow transplantation

***A. Roberto**[1], L. Castagna[1], S. Gandolfi[1], P. Tentorio[1], M. Roederer[2], D. Mavilio[1,3], E. Lugli[1];*
[1]Humanitas Clinical and Research Institute, Rozzano (MI), Italy, [2]Vaccine Research Center, NIAID, NIH, Bethesda, MD, United States, [3]Department of Medical Biotechnologies and Translational Medicine (BioMeTra), University of Milan, Milan, Italy.

Bone marrow transplantation (BMT) is a potential curative approach for the treatment of haematological malignancies. Before transplantation, a chemotherapeutic conditioning regimen ablates the immune system almost completely. In this scenario, the T-cell immune-reconstitution post BMT is initially dependent on the thymic-independent peripheral expansion of donor and chemotherapy-resistant recipient T-cells. This process requires several months, during which the patients are highly susceptible to infections and disease relapse.

Recent data suggest that T-cells at the early stages of differentiation, and, above all, the self-renewing and multipotent T Stem Cell Memory (TSCM), are endowed with superior T-cell immune-reconstitution capacity in preclinical models. However, whether TSCM are involved in T-cell recovery following immunodeficiency in humans still needs to be defined.

Here we show that cells with TSCM phenotype (CD45RA+CD27+CCR7+CD57-CD95+) are present at very high frequency in the host at 7 days post haploidentical T-repleted BMT. The TSCM preferentially survive cyclophosphamide treatment, employed early post BMT to prevent graft versus host disease. Polychromatic flow cytometry-assisted sorting of T cells subsets combined with TREC quantification revealed that the TSCM derive from the differentiation of donor naïve T cells transferred with the graft. In the following weeks, a gradual repopulation of the T cell compartment by central memory, effector memory and effector cells occurs.

Our data strongly suggest that TSCM preferentially mediate T-cell immune-reconstitution in lymphopenic host. These results examine in depth the human T-cell differentiation process and will have important implications in the development of clinical strategies to improve immune recovery in the post BMT setting.

P3.15.26

Regulation of epigenetic modifications for AID-accession to the IgV-locus by histone acetyltransferase activity of GANP in germinal center B-cells

***N. Sakaguchi**[1], S. K. Singh[2], M. M. A. Eid[2], S. A. Almofty[2], M. Shimoda[2], K. Maeda[1];*
[1]Department of Immunology, Graduate School of Medical Sciences, Kumamoto University, Kumamoto City, Japan, [2]Department of Immunology, Faculty of Life Sciences, Kumamoto University, Kumamoto City, Japan.

Antigen-driven B-cells undergo immunoglobulin (Ig) variable (V)-region somatic hypermutation (SHM) that is initiated by activation-induced cytidine deaminase (AID). We have shown that germinal center-associated nuclear protein GANP forms a functional complex with AID in B-cells. AID is recruited from cytoplasm to the IgV-region locus by the help of GANP. Here, we investigate the molecular mechanism how GANP assists AID-accession to the rearranged IgV-region locus. The histone acetyltransferase domain of GANP is necessary for chromatin modification at the IgV-loci through selective binding to the terminal region of the rearranged exon with VH-DH-JH. GANP is physically interacted with active form of RNA polymerase II (Pol-II) and its stall factor Spt5. Chromatin-bound GANP modulates nucleosome occupancy for AID positioning at the IgV-locus with altered positioning of Pol-II and DSIF, presumably providing ssDNA substrate in the transcription bubbles for AID-mediated IgV-region SHM. These data suggest that GANP modifies the epigenetic status of IgV-region for induction of efficient SHM.

P3.15.27

Expression of TCR transgenic b-chain leads to contraction of T lymphocytes pools with surface phenotypes of effector and central memory cells.

***Y. Silaeva**[1], A. Kalinina[1], M. Vagida[1], L. Khromykh[1], A. Deikin[2], T. Ermolkevich[2], E. Sadchikova[2], I. Goldman[2], D. Kazansky[1];*
[1]Federal State Budgetary Institution"N.N.Blokhin Cancer Research Center, Moscow, Russian Federation, [2]Institute of Gene Biology, Russian Academy of Sciences, Moscow, Russian Federation.

Naive T lymphocytes in mice can be distinguished from antigen-experienced T cells by different coexpression of activation markers, such as CD44 and CD62L. These markers determine different traffic of T lymphocytes in the organism, but hardly reproduce real antigenic experience of a T lymphocyte. Mechanisms maintaining homeostasis of T lymphocytes with different activation phenotypes remain largely unknown. To investigate impact of transgenic chains of T cell receptor (TCR) on formation of T lymphocytes, their peripheral survival and activation surface phenotypes, we have generated transgenic mouse strain expressing transgenic b-chain of TCR 1D1 (belonging to the Vb6 family) on the genetic background B10.D2(R101). Intrathymic development of T cells in these transgenic mice is not impaired. 70-80% of peripheral T cells express transgenic b-chain and only 20-30% of peripheral T cells express endogenous b-chains. The ratio of peripheral CD4+CD8- and CD4-CD8+ T lymphocytes stays unchanged in transgenic animals. However the percentage of T lymphocytes with the “naive” phenotype CD44-CD62L+ is significantly increased and the levels of effector memory CD44+CD62L- and central memory CD44+CD62L+ T lymphocytes are markedly decreased in both subpopulations. On the contrary, T lymphocytes expressing endogenous b-chains have the surface phenotype of activated T cells CD44+. Thus, we have shown for the first time that pools size of T lymphocytes with different activation phenotypes depends on the structure of T cell receptors.

P3.15.28
Modulation of mTOR by Respiratory Syncytial virus and its contribution to CD8 T cells memory differentiation

***A. Souza**, R. Czepielewski, S. Muraro, B. Porto, M. Cunha, C. Bonorino, R. Stein;*
Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre, Brazil.

Respiratory Syncytial Virus (RSV) is the most common cause of serious lower respiratory tract disease in infants and is a high priority for vaccine development. RSV-specific adaptive immune responses did not confer protection and the infection suppresses lung memory CD8 T cells. mTOR exhibits immunostimulatory effects on memory CD8 T cells. Our objective was to evaluate if RSV can modulate mTOR on CD8 T cells contributing to diminish memory T cell generation and protection. We found the UV inactivated RSV phosphorylated mTOR on Human PMBC at Ser2448 5-fold higher than the control, but it not altered the phosphorylation of Ser2481 and Thr2446. mTOR activation by RSV was completed inhibited using rapamycin, but it was partially inhibited using a PI3K inhibitor. TLRs agonists can activate mTOR. RSV F protein interacts with TLR4 and RSV G protein antagonizes the effects of RSV F protein. We found that RSV F protein slight stimulated mTOR phosphorylation and RSV G protein decreased mTOR activation. We evaluated memory CD8 T cells phenotype cultured with RSV for 4 days plus rapamycin during 24hs. The frequency of CD8+CD122+CD127+ and CD8+KLRG1^{Low}+ T cells increased around 3-fold when mTOR was inhibited comparing to cells culture with only the virus. The results demonstrated that RSV modulated mTOR activation, and it was partially dependent on TLR4 stimulation and PI3K signaling. The modulation of mTOR by RSV is probably implicated on the generation of memory CD8 T cells since the phenotype of these cells changed in the presence of rapamycin.

P3.15.29
Tsc2 controls the generation of virus-specific memory CD8 T cells

***R. T. Sowell**, M. Rogozinska, A. L. Marzo;*
Rush University Medical Center, Chicago, IL, United States.

Inhibition of the mTOR pathway with the pharmacological inhibitor rapamycin, can enhance the formation of virus-specific memory CD8 T cells. mTOR signals through two separate protein complexes, mTORC1 and mTORC2 but the role of each in CD8 T cell differentiation remains unclear. Activation of mTORC1 is inhibited by the Tsc1/2 protein complex, and genetic deletion or inactivation of Tsc1/Tsc2 leads to hyperactivation of downstream mTORC1 targets. Therefore, we sought to characterize the role of Tsc1/2-mTOR signaling in the formation of memory CD8 T cells. We attenuated Tsc2 signaling in CD8 T cells by crossing mice that express a dominant negative form of Tsc2 with OT-I transgenic mice (Tsc2-DN OT-I). We report that disruption of Tsc2 lead to impaired generation and/or maintenance of memory CD8 T cells. An increased proportion of Tsc2-DN OT-I effectors expressed KLRG1 compared to wild-type OT-I cells. Prior to adoptive transfer, we observed an increase in naïve CD44hi CD8 T cells in Tsc2-DN OT-I mice. Earlier studies reported that Tsc1-deficient mice have decreased numbers of naïve CD8 T cells and increased frequency of CD44hi expression that could be reversed with prolonged rapamycin treatment. However, rapamycin was unable to rescue naïve T cell survival. Acute rapamycin exposure selectively inhibits mTORC1 but prolonged treatment can also disrupt the assembly of mTORC2. Moreover, while Tsc2 negatively regulates mTORC1, it can bind to and positively regulate mTORC2. Taken together these data suggest the possibility that CD8 T cells rely on mTORC1 and mTORC2 signaling to control effector and memory differentiation respectively.

P3.15.30
Memory B Cell and Plasma Cell Development in Response to Vaccination

***D. Tarlinton**, V. Peperzak, I. Vikstrom, D. Zotos;*
Walter and Eliza Hall Institute, Parkville, Australia.

Successful vaccination relies almost completely on the long-term production of high affinity, neutralising antibody. The plasma cells secreting this antibody typically originate in germinal centers, transient structures that also give rise to recirculating memory B cells, which in turn can supplement the number of plasma cells if required. The rate with which B-lineage cells emigrate from the GC, the duration of the migration period and the capacity of these cells to survive in a competitive environment will ultimately determine whether an immunization is successful.
We have examined factors considered important in determining attributes of humoral memory. For memory B-cells this has included the relationship between antigen dose and memory frequency, GC-origin and persistence, and the requirements of particular survival proteins during memory development. For plasma cells, the study has included analysis of their maturation, turnover in relation to production and identifying the relationship between external survival factors, survival and the survival program ultimately enacted, including the identification of the survival proteins required for plasma cell persistence. While these studies are yet to provide an holistic explanation of immunological memory, they do provide insight into its formation and maintenance, suggesting how outcomes favourable to vaccination may be achieved.

P3.15.31
Newly identified MHC class I epitopes from common human Adenovirus serotypes to improve diagnostic and therapeutic options in adoptive T-cell therapy

***S. Tischer**[1], C. Bunse[1], N. Moraw[1], M. Kramer[1], A. Heim[1], R. Geyeregger[2], R. Blasczyk[1], B. Maecker-Kolhoff[1], B. Eiz-Vesper[1];*
[1]Hannover Medical School, Hannover, Germany, [2]Children's Cancer Research Institute, St. Anna Kinderkrebsforschung, Vienna, Austria.

The adoptive transfer of donor-derived T lymphocytes from adenovirus (ADV)-seropositive donors can safely and effectively reduce or prevent the clinical manifestation of ADV in patients with low or absent frequencies of ADV-specific T cells. So far only a few peptides derived from the major capsid protein hexon have been identified as immunodominant targets. To increase the number of immunogenic targets, more intensive ADV epitope screening is essential.
Candidate viral target epitopes from the hexon, penton, fiber and E3 proteins of the predominant serotypes 1, 2, 5 and 31 in frequent HLA alleles (A*01, 02, 03 and B*08) were preselected by reverse immunology. 27 candidate epitopes were identified and the respective nonamer peptides were synthesized. The candidate peptides were verified by IFN-γ ELISPOT and pMHC multimer staining using cells from 56 healthy donors and 9 patients with ADV infection. ADV-specific T cells against the preselected peptides were further analyzed in phenotype and function.
Functional active CD8+ T cells specific for 5/27 peptides were detected. Among these peptides, A*02_Hexon$_{TLL}$ and A*01_Penton$_{STD}$ elicited significant IFN-γ secretion in donor and patient T cells. 64% of healthy A*02-positive donors showed A*02_Hexon$_{TLL}$-positive memory T cells, while in 53% of A*01-expressing donors A*01_Penton$_{STD}$-specific T cells were found. The immunogenicity of these epitopes could be confirmed in ADV-infected patients.
In conclusion, the newly described epitopes allow multimer staining of ADV-specific T cells to follow the clearance of ADV in patients after HSCT and represent promising candidates for adoptive immunotherapy, making this approach applicable for a broader patient cohort.

P3.15.32
Histamer-based selection and separation of functionally active ADV-specific CD8+ T lymphocytes

***S. Tischer**, T. Kaireit, N. Moraw, C. Bunse, C. Figueiredo, O. Hiller, B. Maecker-Kolhoff, S. Immenschuh, R. Blasczyk, B. Eiz-Vesper;*
Hannover Medical School, Hannover, Germany.

Multimers of soluble peptide-major histocompatibilty complexes (pMHC) allow a specific visualization, phenotype characterization and reversible isolation of antigen-specific T cells from *ex vivo* samples. Adoptive transfer of antigen-specific T cells sorted by pMHC multimers is an effective therapeutic strategy for treatment of patients with malignancies or infectious diseases after transplantation.
The reversible pMHC Histamer technology was developed enabling a specific detection and isolation of antiviral T cells from peripheral blood mononuclear cells. The HLA-A01/ADV5_Hexon Histamer was generated by coupling 6xHis-tagged pMHC molecules onto cobalt-magnetic beads. The specificity and sensitivity of the magnetic bead-based Histamer was evaluated by flow cytometry. Sorting of ADV-specific CD8+ cytotoxic T cells (CTLs) was performed by immunomagnetic separation, followed by the monomerization of the pMHC Histamer in the presence of L-histidine. Sorted T cells were analyzed in phenotype and function.
The reversible Histamer showed high specificity and sensitivity (up to 99.5%). Antigen-specific T cells were isolated by this technology with a high purity of up to 99.6%. A rapid and complete disassembly of the T-cell surface-bound pMHC Histamer followed by the subsequent dissociation of the pMHC monomers from CD8+ CTL receptors was achieved using 100mM L-histidine. The function of antiviral T cells enriched by Histamer staining did not differ from CTLs induced by standard T-cell assays.
This reversible T-cell staining procedure preserves the functionality of antigen-specific T cells and can be adapted to GMP conditions. The pMHC Histamer technology offers full flexibility and fulfills all requirements to generate clinical grade T lymphocytes.

P3.15.33
Evaluation of B cell subpopulations over time upon immunization against Streptococcus pneumoniae in HIV-1 patients - A 48 week study

***O. Tsachouridou**[1], L. Skoura[1,2], S. Metallidis[1,3], P. Zembekakis[1,3], D. Pilalas[1], A. Margariti[2], A. Kourelis[2], N. Malisiovas[1,2], P. Nikolaidis[1,3];*
[1]Medical School of Aristotle University of Thessaloniki, Thessaloniki, Greece, [2]HIV/AIDS Reference Centre of Northern Greece, Thessaloniki, Greece, [3]1st Internal Medicine Department of AHEPA University Hospital, Thessaloniki, Greece.

Alterations of B cell population and subsets have been confirmed during HIV infection. Ongoing HIV replication disrupts this cell population causing reduced memory and reduced naïve resting B cells leading to impaired responses to vaccines. To what extent antiretroviral agents reverse these changes remains uncertain. Evaluation of memory B cells is important in determining the capacity of the immune system in producing functional antibodies. Aim of this study was to detect changes in B cells over time post vaccination with the 23-valent polysaccharide pneumococcal vaccine in a cohort of 66 HIV-1 patients with preserved CD4+ T cell counts (>350 cells/μL). Patients were divided into treated and antiretroviral naïve. Frequency of total B cells and memory B (CD21highCD27+) cell was higher in successfully treated patients, though parallel profiles were described over time. Similar expansion was revealed in resting memory (CD27intCD21high) B cells. IgM memory (CD19+CD27+IgMhigh)B cells fluctuated in a resembling way during time irrespective of antiretroviral intake. Activated mature B cells (CD20+CD21lowCD27+) were higher in HAART naïve patients and their decline differed significantly after 4 weeks (p=0,018) and 24 weeks (p=0,035). These facts are consistent with few previous studies which suggest that loss of memory B cells cannot by restored by antiretroviral therapy since immune impairment might occur early after infection with the HIV. Memory B-cell subpopulations might predict the risk of pneumococcal disease more accurately than antibody levels.

P3.15.34
Blockade or deletion of FcγR2B (CD32) prevents FVIII-specific memory B cells response in Haemophilia A mouse model

***N. Vollack**, M. von Hornung, K. Kalippke, A. Trummer, A. Ganser, A. Tiede, S. Werwitzke;*
Medical School of Hanover, Hanover, Germany.

Formation of inhibitory antibodies to FVIII is a frequent and severe complication of replacement therapy in haemophilia A. Cross linking of B cell receptor (BCR) and FcγR2B on B cells inhibits BCR signalling leading to a suppressed antibody production. Here, we investigate the role of FcγR2B to modulate FVIII-specific memory B cell response using $F8^{-/-}$ single deficient (B6;129S4-*F8*^{tm2Kaz}/J) and $F8^{-/-}$FcγR2B$^{-/-}$ double deficient mice (B6;129S4-*F8*^{tm2Kaz}/J/B6;129S4-Fcγr2b^{tm1Ttk}/J). Anti-FVIII antibody titres and initial amounts of FVIII-specific splenocytes were similar in $F8^{-/-}$FcγR2B$^{-/-}$ mice compared to $F8^{-/-}$ mice after intravenous exposure to 4 weekly doses of 80 or 400 IU/kg human FVIII. In contrast, *in-vitro* differentiation of FVIII-specific memory B cells into antibody secreting cells (ASCs) was diminished in splenocytes from $F8^{-/-}$FcγR2B$^{-/-}$ mice upon FVIII re-stimulation over 6 days. This effect could be mimicked by blocking FcγR2B using monoclonal antibodies (mAb) or $F(ab)_2$ fragments against CD16/32 on splenocytes from immunized $F8^{-/-}$ mice thereby confirming the memory B cell defect seen in $F8^{-/-}$FcγR2B$^{-/-}$ mice. Staining with caspase 3 antibodies indicated increased rates of B cell apoptosis when FcγR2B was blocked by mAb during FVIII re-stimulation. Transfer of B220-depleted but comprising FcγR2B expressing antigen presenting cells (APCs) did not restore FVIII-specific memory B cells function in $F8^{-/-}$FcγR2B$^{-/-}$ mice. In conclusion, FcγR2B plays a crucial role for the FVIII-specific recall response, possibly by preventing apoptosis of memory B cells during antigen re-stimulation.

P3.15.35
CD8 T cell effector and memory fate decisions are differentially regulated by CD27 and 4-1BB costimulation

***J. E. Willoughby**, J. P. Kerr, V. Y. Taraban, A. Rogel, S. L. Buchan, P. W. Johnson, A. Al-Shamkhani;*
University of Southampton, Southampton, United Kingdom.

Much of our knowledge of memory CD8 T cell generation has come from studies of immunity to viruses and bacteria. Translating such knowledge into universal vaccination strategies, however, has yet to be achieved. Here we have analyzed the CD8 T cell response elicited by two experimental vaccines comprising a peptide/protein antigen and an agonist that delivers a costimulatory signal via CD27 or 4-1BB. Although both vaccines primed a comparable CD8 T cell response, their capacity to generate memory differed, an effect that occurred independently of CD4 T cell help. Priming with 4-1BB agonists generated a long-lived memory cell pool, whereas memory T cells generated using CD27 agonists were short-lived. T cell transfer experiments showed that continued stimulation through CD27 or 4-1BB beyond the primary response was not required for these differences, suggesting that the effects on memory were due to differences in early activation events. Consistent with this notion we demonstrated that CD27 triggering during priming preferentially enhanced IL-2 secretion by CD8 T cells. Furthermore, CD27 activation of CD8 T cells resulted in prolonged expression of CD25 and higher expression of perforin, gp49b and the transferrin receptor, indicative of sustained IL-2 signaling and increased effector cell differentiation. Neutralizing IL-2 during priming did not affect CD27-mediated T cell expansion but had a detrimental effect on perforin expression and caused accelerated effector cell death. Our study, therefore, demonstrates that the balance between vaccine-induced effector and memory CD8 T cells can be manipulated by targeting different costimulatory receptors.

Analysis of factors that induce memory T cells

T. Yamano[1,2], *T. Soh*[3], *Y. Oki*[3], *K. Fukuda*[4], *H. Kishimoto*[4];
[1]*Institute for Immunology, Ludwig-Maximilians-Universität, Munich, Germany,* [2]*Institute of Health Biosciences,University of Tokushima Graduate School, Tokushima, Japan,* [3]*Research Institute for Biological Sciences, Tokyo University of Science, Chiba, Japan,* [4]*Department of Parasitology & International Health Faculty of Medicine, University of the Ryukyus, Okinawa, Japan.*

Naïve T cells recirculate between blood, lymph ducts and secondary lymphoid organs. Consequently, it should be different time that required for Ag-specific T cells, which are located in the various tissues, to populate and enter the draining lymph nodes in late time of an immune response were primed in different environments and preferred to differentiate into memory T cells. We have investigated the kinetics of both OVA specific TCR Tg (OT-1 and OT-2)T cells stimulated earlier (early-stimulated T cells)and later in an immune response (late-stimulated T cells). To ascertain above studies, naïve T cells isolated earlier from lymph nodes of OT-1/CD45.2+ mice and OT-2/CD45.2+ mice were injected i.v. into CD45.1+/CD45.2+ host mice. For immunization of mice, GM-CSF induced bone marrow derived DCs were incubated with OVA protein and LPS, and were injected s.c. into host mice. The early-stimulated T cells were developed by adoptive-transfer of Tg T cells into host mice before Ag-pulsed activated DCs were injected and the late-stimulated T cells were developed by adoptive-transfer of Tg T cells into mice 5-7 days after injection of Ag-pulsed activated DCs. The late-stimulated T cells seemed to divide slower and proliferate less than the early-stimulated T cells. Particularly, CD4+ T cells stimulated in late time found to have little-cell division. Contraction phase of the late-stimulated T cells happened slowly. These results suggest that the timing of recruitment of T cells into the draining lymph nodes affects T cells-fate that are influenced by different environments, i.e. co-stimulation molecules, soluble factors, APCs.

P3.15.37
Identification of T-lymphocyte responses and long-term immunological memory in survivors of ebolavirus infection

S. Mulangu[1], *H. Marcus*[1], *J. Ledgerwood*[1], *N. Kisalu*[2], *M. Roederer*[1], *R. Koup*[1], *B. Graham*[1], *J. Muyembe*[1], ***N. J. Sullivan***[1];
[1]*NIH, Bethesda, MD, United States,* [2]*INRB, Kinshasa, Congo, Democratic Republic of the.*

Ebolaviruse (EBOV) causes hemorrhagic fever disease in humans and non-human primates, with high case-fatality rates and there is currently no licensed vaccine or approved specific treatment for human use against EBOV infection. An important parameter for vaccine development is the induction of long-term immunologic memory. To define specific elements of durable immunity that might be relevant to vaccine-mediated protection, we investigated the persistence and quality of EBOV-specific T-cell immune responses in two survivors from the Kikwit, Zaire species EBOV (ZEBOV) hemorrhagic fever outbreak, 11 years after resolution of their symptoms. Here we show for the first time, long-term persistence of ZEBOV-specific $CD4^+$ and $CD8^+$ T-cell memory and identified T-cell epitopes targets in survivors of infection. Antigen-specific $CD4^+$ and $CD8^+$ T cells comprised mainly central memory-like ($CD45RO^+$ $CD27^+$), and not terminally differentiated ($CD57^-$) cells. Furthermore, these cells exhibited a cytokine-producing profile (IL-2, IFN-γ and TNF-α) characteristic of polyfunctional T-cells. Finally, we define HLA-A02 and -A24 restricted epitopes on ZEBOV GP, the protein target of gene-based preclinical vaccine candidates. These results demonstrate that long-term immunity to ZEBOV is achievable in humans and provide a framework for rational vaccine design.

T-and B-cell responses to human rhinovirus infection

A. Aab*, W. van de Veen, S. Söllner, O. Wirz, B. Stanic, M. Akdis, C. Akdis;*
SIAF, Davos Platz, Switzerland.

Background: The infection of existing and also emerging rhinoviruses (HRV) pose severe health risks for patients with asthma or chronic obstructive pulmonary disease and is the leading cause of exacerbation of airway diseases. Here, we studied the effect of HRV1B, HRV14, HRV16 and HRV29 infection to human peripheral blood mononuclear cells (PBMC-s). We hypothesize that HRV activate inflammatory cells, what might be the reason for airway dysfunction during asthma exacerbation.
Methods: We infected PBMC-s with four different HRV-s. Using assays of thymidine incorporation, flow cytometry, in-situ hybridization, immunofluorescence, imagestream, multiplex bead-based immunoassay and qPCR, we measured PBMC activation, rhinovirus expression, cell proliferation, morphology and death rate.
Results: Different serotypes of HRV induced proliferation of plasmablasts (CD19+, CD27++ and CD38++), but not the CD4(+) and CD8(+) T-cells. Cytokine production was more characteristic to innate immune response with elevated IL6 and IL8 production. UV inactivation did block the rhinovirus effect. We also found that from CD20+ B-cells could be infected by HRV1B in vitro. We developed the in-situ hybridization method for detection of HRV1B, HRV16 and HRV29 with combination of immunofluorescence staining for aCD20.
Conclusion: Rhinovirus has the unique ability to bypass antigen presentation and directly infect human B-cells and activate human plasmablasts. This could explain the strong association of rhinovirus with exacerbation of airway diseases.

P4.01.002
Tax-1-mediated HTLV-1 replication and NF-kB activation is inhibited by the MHC-II transactivator CIITA

R. Abdallah, G. Forlani, ***R. S. Accolla****, G. Tosi;*
University of Insubria, Varese, Italy.

Human T-cell Lymphotropic Virus type-1 (HTLV-1) is the causative agent of an aggressive malignancy of CD4+ T lymphocytes. Many evidences have shown that constitutive activation of NF-kB pathway by Tax-1 is crucial for T-cell transformation.
We demonstrated that CIITA, the master regulator of MHC class II gene transcription, inhibits HTLV-1 replication by blocking the function of the viral transactivator Tax-1. Interestingly, CIITA suppresses also Tax-1-mediated activation of the NF-kB pathway. CIITA interacts with both Tax-1 and RelA and inhibits the recruitment of RelA into Tax-1-containing nuclear bodies. It is known that both Tax-1 and Tax-2 stimulate the classical NF-kB pathway, whereas only Tax-1 induces the non-canonical NF-kB pathway. We found that CIITA inhibits also Tax-2-mediated NF-kB activation demonstrating that it acts by suppressing at least the classic NF-kB pathway.
Future studies will be focused to define the minimal region of CIITA inhibiting NF-kB activation by Tax-1 and to elucidate which step of NF[[Unsupported Character - Codename]]-KB signaling pathway is targeted by CIITA.
All these findings suggest that CIITA, a viral restriction factor against HTLV-1 replication, may also counteract Tax-1 transforming activity.
Thus, assessing the molecular basis of CIITA-mediated Tax-1 inhibition may be important in defining new strategies to control HTLV-1 spreading and oncogenic potential.

P4.01.003
Detection of the autoimmunity in primary Epstein-Barr virus infection by indirect immunofluorescence

*A. Sener, **I. Afsar**, H. Er, B. Karaayak Uzun, S. Kaya;*
Izmir Katip Celebi University IAEH, Department of Microbiology, Izmir, Turkey.

Introduction: Epidemiological data suggest that the Epstein-Barr virus (EBV) is associated with several autoimmune diseases, such as systemic lupus erythematosus, rheumatoid arthritis and multiple sclerosis. The aim of this study was to investigate the autoantibodies in primary Epstein-Barr virus infection by indirect immunofluorescence assay (IFA).
Methods: Sera from 32 subjects (F/M=14/18, median age 21±9 years) with primary acute EBV infection were analysed using IFA for anti nuclear antibody (ANA). The sera were characterized by the presence of anti-early antigen (anti-EA) seropositivity, both IgM and IgG types, and by the absence of anti-Epstein Barr nuclear antigen-1 antibodies (anti-EBNA-1) and with the negativity of IgG avidity. ANA was detected by IFA. Serum samples were processed in dilution of 1:100 using HEp-2010/liver biochip (Euroimmun AG, Germany) and conjugated with specific anti-human IgG. The fluorescence intensity was scored at x 400, semi-quantitatively from 1+ to 4+ relative to the intensity of the positive (4+) and negative control.
Results: Of the 32 individuals investigated, the screening by immunofluorescence on Hep-2010 cells revealed 12 ANA-positive sera (37.5%), with speckled, homogen, nucleolar and cytoplasmic fluorescence patterns. The percentage of positive sera was 5/12 (41.6%) in males and 7/12 (58.3%) in females.
Conclusion: Due to the limited sample, the present study should be considered as a preliminary study. Further researches should continue to investigate hypotheses of EBV as a causative risk factor in autoimmunity.

P4.01.004
Human cytomegalovirus UL141 targets the TRAIL death receptors to inhibit host NK cell responses

***R. J. Aicheler**[1], P. Tomasec[1], W. Smith[2], E. C. Y. Wang[1], R. J. Stanton[1], C. A. Benedict[2], G. W. Wilkinson[1];*
[1]Cardiff University, Cardiff, United Kingdom, [2]La Jolla Institute for Allergy and Immunology, California, CA, United States.

Human Cytomegalovirus (HCMV) is the leading infectious cause of congenital malformation and a major cause of mortality and morbidity in the immunocompromised. Death receptors (DRs) of the TNFR-superfamily make a major contribution to antiviral immunity by promoting apoptosis and regulating immune homeostasis during infection. Consequently, signalling through DRs constitutes a key target for viral immune evasion functions. We have identified the HCMV UL141 glycoprotein as necessary and sufficient to restrict cell surface expression of the TRAIL Death Receptor 2 (TR-2). UL141 binds TR-2 to promote its intracellular retention and desensitises cells to apoptosis mediated not only by soluble TRAIL but also to TRAIL expressed on the surface of NK cells. NK cells play a critical role in control of viral infection in the immunocompetent host. UL141 was originally identified as a potent inhibitor of NK cell function by sequestering the NK-activating ligands CD155 and CD112 in the ER, thereby inhibiting NK cell degranulation mediated through ligation of the activating receptor DNAM-1. Here we show that in the context of HCMV infection, sequestration of TR-2 by UL141 is also able to inhibit NK cell mediated cell death and highlights UL141 as a pleiotropic inhibitor of NK activation and effector function.

P4.01.005
ERAP deficiency leads to absence of anti-influenza immune response to known immunodominant HLA-B27 peptide

***A. Akram**, R. Inman;*
University of Toronto and University Health Network, Toronto, ON, Canada.

The role of HLA-B27 in modulating host response to infection is undefined, yet B27 confers susceptibility to arthritis. Immune response to viral infections is characterized by immunodominance (ImDc). Defining factors contributing to ImDc is difficult due to multiple MHC-I allele co-expression in humans and mice. To overcome this limitation, we generated human MHC-I transgenic (Tg) mice deficient for endogenous mouse MHC-I molecules (i.e., DKO) and express only one human MHC-I allele. To assess whether co-expression of additional MHC-I alleles influences the pattern of anti-flu CTL epitope recognition and ImDc, novel double and triple MHC-I Tg mice were established on a DKO. In flu-infected, double Tg A2/B7 or A2/B27 mice, IFN-γ ELISpot assays with the flu epitopes A2/M1.58-66 and B7/NP418-426 or B27/NP383-391 showed specific recognition of both peptides by both alleles respectively. In contrast, in flu-infected B7/B27 Tg mice a significantly reduced NP383-restricted CTL response was detected while there was no change in the response level of NP418-restricted CTL. Subsequent flu-specific studies revealed that co-expression of B7 and B27 is associated with i) a partial deletion of Vβ8.1+ B27/NP383-restricted CD8+ T cells and ii) a failure of Vβ12+ CD8+ T cell expansion following flu infection in B7/B27 Tg mice. Further studies with flu-infected ERAP deficient B27/ERAP and B7/B27/ERAP mice revealed complete ablation of the B27/NP383-391 CTL response indicating importance of ERAP in B27 peptide generation. The selective deletion of B27-restricted T cells has important implications for models defining the role that HLA-B27 plays in susceptibility to reactive arthritis and ankylosing spondylitis.

P4.01.006
NF-kappaB1 is required for virus-specific CD8+ T cell responses, and prevents excessive inflammation and lethality during chronic infection

***C. C. Allison**[1], R. Gugasyan[2], S. P. Preston[1], J. P. Cooney[1], J. G. Toe[1], G. Ebert[1], M. Pellegrini[1];*
[1]Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia, [2]Burnet Institute, Melbourne, Australia.

Background: The NF-kappaB family regulates numerous cellular functions that vary depending on cellular context and specific subunit composition. In particular, inflammation and immunity are broad processes for which different NF-κB dimers may serve opposing roles, the intricacies of which are slowly being unraveled. NF-kappaB1 knock-out (p50-/-) mice were previously shown to display no overt haematopoietic developmental nor functional abnormalities, yet given the potential for diverging roles of p50 in immune responses, we hypothesised that p50 plays an important chronic during chronic immune activation. The aim of our study was to investigate the role of p50 in chronic persistent infection.
Design: We chronically infected p50-/- mice with lymphocytic choriomeningitis virus docile strain and examined immunological and virological outcomes. Results: Upon infection p50-/- mice showed a profound defect in virus specific CD8 T cell expansion and function. The blunted adaptive response observed in p50-/- animals is associated with an overwhelming, non-specific and lethal inflammatory reaction. Intriguingly, we found that naïve p50-/- mice exhibit a previously unreported neutrophilia, and that both neutrophils and macrophages from p50-/- mice display aberrant pro-inflammatory cytokine profiles following LCMV infection, which is likely responsible for mortality in these animals. Conclusion: Although p50 is a component of the pro-inflammatory NF-kappaB dimer, its ablation also disrupts many regulatory and anti-inflammatory processes. Our findings demonstrate that p50 is a crucial regulator of inflammatory responses during chronic infection. This has important implications for infections such as HIV-1 that are associated with immune activation and counterproductive inflammatory responses.

P4.01.007
CD56+CD3+ T cells in relation to CMV infection in normal subjects and kidney transplant patients

M. M. Almehmadi[1], *S. Christams*[1], *B. Flangan*[1], *S. Heyworth*[2], *A. Hammad*[3];
[1]*Institute of Infection and Global Health, LIVERPOOL, United Kingdom,* [2]*Renal Transplant Unit, Royal Liverpool hospital, Liverpool, United Kingdom,* [3]*Renal Transplant Unit, Royal Liverpool, Liverpool, United Kingdom.*

Background: CD56+CD3+ cells are a small subset of T cells of unknown function but with cytotoxic capacity following activation *in vitro*. In preliminary work, we found that levels were higher in normal subjects positive for cytomegalovirus (CMV) than in CMV negative subjects. Kidney transplant patients are particularly prone to reactivation of CMV infection which, as well as causing acute disease, may play a role in triggering the rejection process.
Aims: This work aims to investigate the role of CD56+CD3+ T cells and their response to CMV and other pathogens, and their possible role in triggering the immune system toward the transplanted organ.
Material and Methods: Phenotypic studies of memory and activation markers of CD56+CD3+ in normal CMV+ and CMV-. Functional analysis, consisting of the response of these cells to stimulation with CMV and SEB antigens will be tested by measuring cytokine production and cell proliferation (CFSE labelling).
Results and Conclusion: CD56+CD3+ cells are found to be higher in both healthy and post-transplant patients the same as has been found in the preliminary study. Several markers such as CD8, CD4, NKG2C and CD45RO were significantly found to be higher in CMV+ than CMV-. Moreover, CD161, CD28, CD62L and CD127 were significantly found to be lower in CMV + than CMV -. When cytokines production were compared between CMV+ and CMV- donors, IFN-γ and TNF α are significantly produced more in CD3+CD56+ cells from CMV+ than CMV-. These results indicate that CD3+CD56+ cells play a major role in response to CMV infection.

P4.01.008
Involvement of NK cells in the acute lung injury of H1N1 influenza infection

X. Zhang[1], *W. Deng*[2], *L. Bao*[2], *M. Wen*[1], *B. Cao*[3], *C. Wang*[4], ***Y. An***[1];
[1]*Department of Immunology, School of Basic Medical Sciences, Capital Medical University, Beijing, China,* [2]*Institute of Laboratory Animal Sciences, Chinese Academy of Medical Sciences, Beijing, China,* [3]*Beijing Chao-Yang Hospital, Beijing Institute of Respiratory Medicine, Capital Medical University, Beijing, China,* [4]*Beijing Key Laboratory of Respiratory and Pulmonary Circulation Disorders, Beijing Institute of Respiratory Medicine, Capital Medical University, Beijing, China.*

The outbreak of 2009 pandemic swine-origin H1N1 influenza virus represented a major threat to global health. Acute lung injury, characterized by pulmonary edema, capillary leak, and lymphocyte infiltration was main cause of death. NK cells played important roles in the pathogenesis not only by direct cytotoxicity, but also by rapidly producing proinflammatory cytokines. SAα2,3Gal- and SAα2,6Gal, H1N1 virus receptors, were expressed on epithelial cell of trachea, bronchus and alveolus. Following virus challenge, the body weight was loss from 1day-post-infection (dpi) and decreased only 67% of initial weight on 7 dpi. Meanwhile, survival rate was decreased to only 27% on 7 dpi. A large number of infiltrating lymphocytes were recruited to perivascular and parenchyma areas. Total lymphocytes in lung tissue peaked at 2 dpi, and were 4-fold compared with normal control. The ratio of NK cells was increased on 1 dpi; and 80% of them were rapidly activated. The number of NK cells also rapidly rose to 3-fold of control. Especially, the activated NK were 21-fold of control. Total karyocytes in BALF increased and peaked at 3 dpi. The ratio of total NK cells in BALF was continued increase, and 92% of NK cells were activated on 2 dpi. The number of total NK cells and activated NK cells in BALF peaked at 3 dpi. Proinflammatory cytokines and chemokines, such as IL-6, TNF-α, IL-17, KC, MIP-1α, RANTES, were increased in serum and BALF. Our data demonstrated NK cells and proinflammatory cytokines played critical role in lung injury during H1N1 virus infection.

P4.01.009
Human cytomegalovirus viral IL-10 polarizes monocytes towards a deactivated M2c phenotype to repress host immune responses

S. Avdic, *J. Z. Cao, B. P. MsSharry, L. E. Clancy, R. Brown, M. Steain, D. J. Gottlieb, A. Abendroth, B. Slobedman;*
The University of Sydney, Sydney, Australia.

Several human cytomegalovirus (HCMV) genes encode products that modulate cellular functions in a manner likely to enhance viral pathogenesis. This includes UL111A, which encodes homologs of human interleukin-10 (hIL-10). Depending upon signals received, monocytes and macrophages become polarized to either classically activated (M1 pro-inflammatory) or alternatively activated (M2 anti-inflammatory) subsets. Skewing of polarization towards an M2 subset may benefit the virus by limiting the pro-inflammatory responses to infection and so we determined whether HCMV encoded viral IL-10 influenced monocyte polarization. Recombinant viral IL-10 protein polarized CD14+ monocytes towards an anti-inflammatory M2 subset with an M2c phenotype, as demonstrated by high expression of CD163 and CD14, and suppression of MHC class II. Significantly, in the context of productive HCMV infection, viral IL-10 produced by infected cells polarized uninfected monocytes towards an M2c phenotype. To explore mechanism, we assessed the impact of viral IL-10 on heme oxygenase 1 (HO-1), which is an enzyme linked with suppression of inflammatory responses. Polarization of monocytes by viral IL-10 resulted in upregulation of HO-1 and inhibition of HO-1 function resulted in a loss of capacity of viral IL-10 to suppress TNF-α and IL-1β, implicating HO-1 in viral IL-10 induced suppression of pro-inflammatory cytokines by M2c monocytes. In addition, a functional consequence of monocytes polarized with viral IL-10 was a decreased capacity to activate CD4+ T cells. This study identifies a novel role for viral IL-10 in driving M2c polarization which may limit virus clearance by restricting pro-inflammatory and CD4+ T cell responses at sites of infection.

P4.01.010
Quantitation of mRNA cytokine levels in ferrets following influenza infection

L. A. Carolan[1], *J. Butler*[1], *S. Rockman*[2], *A. C. Hurt*[1], *A. Kelso*[1], ***I. G. Barr***[1], *K. L. Laurie*[1];
[1]*WHO Collaborating Centre for Reference and Research on Influenza, North Melbourne, Australia,* [2]*bioCSL, Parkville, Australia.*

After infection with influenza virus, a rapid inflammatory response is generated by the innate immune response, followed by an antigen-specific adaptive immune response that uses different effector mechanisms to help clear the virus/infection. Analysis of cytokine profiles can enable characterization of this immune response at the sites of infection. Highly pathogenic influenza viruses typically induce altered cytokine profiles compared to low pathogenic viruses (Cameron J Virol 2008, 82:11308). Thus cytokine profiling may provide valuable information on the level of the immune response as well as give insights into virulence and pathogenesis of different influenza viruses.

In vivo analysis of novel human influenza viruses often uses the ferret model as they can easily be infected with most human influenza viruses and display similar symptoms as humans. The aim of this study was to develop a high-throughput real time RT-PCR TaqMan assay to quantify a full range of cytokine mRNA profiles in the respiratory tract of influenza-infected ferrets.
Ferret-specific primer/probe sets to IL1a, IL1b, IL2, IL4, IL6, IL8, IL10, IL12p40, IL17, MCP1, TNFa, IFNg, IFNa, IFNb were designed to target cytokines of the innate and adaptive immune systems. These assays were optimized to maximize sensitivity and specificity and the multiplexing of primer/probe sets was also examined. The resulting assays now enable us to analyse the ferret's immune response during any influenza infection. Work is ongoing to determine if one or more of these assays can be used to measure the severity of an infection and the level of these cytokines following vaccination.

P4.01.011
Reproducibility of Pentamer and Streptamer staining of CMV-specific CD8+ T-cells: defining the optimal multimer concentration and incubation conditions.

L. Beloki[1], *N. Ramirez*[1], *M. Ciaurriz*[1], *C. Mansilla*[1], *A. Zabalza*[2], *E. Bandres*[2], *M. Rodriguez-Calvillo*[2], *E. Olavarria*[1,2];
[1]*Biomedical Research Center NavarraBiomed, Pamplona, Spain,*
[2]*Complejo Hospitalario de Navarra, Pamplona, Spain.*

Pentamers (PM) and Streptamers (ST) are widely used to detect CMV-specific CD8+T-cells. However, the optimal staining conditions remain to be established. We analysed different concentrations of PM/ST and temperatures for PM staining, and assessed the reproducibility of both techniques.
PBMCs were isolated from six HLA-A*02:01 CMV-seropositive healthy donors. After multimeric staining of $1x10^6$ PBMCs, anti-human CD3/CD8/CD45 were added. Cells were acquired in a FACSCalibur and CMV-specific T-cell percentage was examined.
PM/ST titration: For PM, 2.5/5/10 µl of HLA-A*02:01/PMpp65$_{495-503}$ were incubated with PBMCs for 10 minutes at room temperature (RT). For ST, 0.75 µg PE-labelled Strep-Tactin were mixed with 0.25/0.5/0.75/1 µg of HLA-A*02:01/STpp65$_{495-503}$ to form the ST complex. From those, 0.1/0.2/0.3/0.4 µg were incubated with PBMCs for 45 minutes at 4ºC.
PM staining temperature: PBMCs were stained with 5µl of HLA-A*02:01/PMpp65$_{495-503}$ for 30 minutes at 37 ºC, 10 minutes at 4ºC, or 10 minutes at RT.
PM/ST staining reproducibility: Per donor, six tubes per multimer (PM/ST) were incubated with PBMCs. The percentage of variance associated with the technique was estimated using a random effects model, separately for PM or ST.
The best results for PM were obtained using 5µl (median=0.56%;IQR=0.41-0.99) during 10 minutes at RT (median=0.48%;IQR=0.13-0.93), while 0.2µg of ST complex gave the best results for ST (median=0.51%;IQR=0.44-0.88), although statistical significance was not reached (Mann-Whitney test, p>0.05). Furthermore, the percentage of variance showed low values of variability (PM:0.3%;ST:0.7%), proving the reproducibility of both techniques.
In summary, staining conditions do not seem to alter the reproducibility of PM/ST quantification of CMV-specific CD8+T-cells.

P4.01.012
KIR2DL2 overexpression influences NK cell response to CpG

D. Bortolotti*, A. Rotola, D. Di Luca, R. Rizzo;*
University of Ferrara, Ferrara, Italy.

NK cells are one of the most important innate immunity effectors towards viral infections. In particular, these cells are activated by viral CpG motifs through TLR9. For this, NK cell deficiency is responsible for viral increased susceptibility. Rizzo et al. (J Neuroimmunol, 2012; 251: 55-64) reported a 40% of Multiple Sclerosis patients with NK cells unable to counteract herpesvirus infection after CpG treatment. These NK cells showed an increased expression of the inhibitory receptor KIR2DL2 and of its ligand HLA-C1. Since it has been previously demonstrated that KIR3DL2 can directly bind CpG and facilitate its entry into the cell and it is known that CpG is able to modulate KIRs expression, we evaluated the ways of uptake of CpG treatment in NK cell lines, the effect on KIRs expression and NK activity status. We confirmed the role of KIR3DL2 in CpG uptake and we observed, for the first time, the induction of KIR2DL2 expression that reduced the cytotoxic activity of NK cells towards HLA-C1+ target cells and the secretion of pro-inflammatory molecules (IFN-gamma). This modulation via KIR3DL2-CpG is mediated by specific transcription factors and could explain the KIR2DL2+ NK cell unresponsiveness to the viral infection after CpG treatment.
Our results demonstrate the mechanistic basis of the lower responsiveness to CpG of KIR2DL2 expressing NK cells, suggesting a potential role in identifying new therapeutic strategies in herpesvirus susceptible individuals.
This study was supported by FISM grant.

P4.01.013
HLA-G influences nasal polyp relapse in HPV positive patients.

R. Rizzo, ***D. Bortolotti****, N. Malagutti, V. Gentili, A. Rotola, T. Pezzolo, C. Fabbri, C. Aimoni, S. Pelucchi, D. Di Luca;*
University of Ferrara, Ferrara, Italy.

The underlying mechanisms of nasal polyp development have yet to be determined. Human papilloma virus (HPV) infection is considered as a possible candidate, as associated with nasal inverted papilloma1. HLA-G molecule, an antigen with membrane-bound and soluble isoforms that interact with immune cell inhibitory receptors, is up-modulated by intrleukin-10 (IL-10), an anti-inflammatory cytokine, and increases during viral infection as immune-escape mechanism2. HPV infection is known to influence IL-10 and HLA-G expression3, suggesting a possible implication in nasal polyps. We investigated the influence of high risk HPV infection, IL-10 and HLA-G in nasal polyp relapses. We enrolled ten non-allergic patients with nasal polyps and analysed the presence of high-risk HPV by PCR (Sacace), the expression of HLA-G and IL-10 receptor on nasal epithelial cells by immunofluorescence (87G-PE, IL-10R-FITC) and of sHLA-G and IL-10 by ELISA. Our results evidenced high risk HPV infection in 50% of polyps, of which the 80% presented polyp relapse (OR:15). Only HPV positive polyps expressed mHLA-G and IL-10R on epithelial cells. The analysis of nasal epithelial cell culture supernatants showed a correlation between IL-10 and sHLA-G secretion in HPV positive samples. No expression was observed in HPV negative polyps. These data suggest an association between HPV infection, up-modulation of IL-10 and HLA-G expression in nasal epithelial cells and polyp relapses.

Beta-amyloidogenic peptides protect against Herpes Simplex Virus-1 (HSV-1) infections

K. Bourgade-Navarro*, G. Giroux, C. Bocti, A. Le Page, G. Dupuis, E. H. Frost, T. Fülöp;*
University of Sherbrooke, Sherbrooke, QC, Canada.

The causes of Alzheimer's disease (AD) are debated. Experimental data and epidemiological studies suggest that Herpes Simplex Virus-1 (HSV-1) infection is a risk factor. HSV-1 stays latent in trigeminal neurons and can be reactivated under low immune status of the host. AD is characterized by deposits of neurofibrillar tangles and senile plaques which lead to cortical neurodegenerescence. Senile plaques found extracellularly in brains of patients contain the fibrillar form of beta-amyloidogenic Aβ1-40 and Aβ1-42 peptides generated by presenelin cleavage of amyloid precursor protein (APP). Interestingly, herpetic encephalitis caused by Herpes viruses affects the same brain regions as AD. The question is open whether beta-amyloidogenic peptides also possess a physiological role. In this connection, they display anti-bacterial and anti-yeast activities in vitro. We cultured fibroblast (MRC5) and epithelial (A549) cell lines in the presence of amyloidogenic peptides Aβ1-40 and Aβ1-42 added before, simultaneously or after challenge with HSV-1. DNA was extracted and viral replication quantified by real-time PCR 24 h later. Controls were scrambled peptides and antimicrobial peptide LL-37.
Results showed that peptides Aβ1-40 and Aβ1-42 inhibited HSV-1 replication, depending on their sequence of addition. For instance, they showed efficiency when added 2 h before or simultaneously to virus challenge. However, they were inefficient when added 2 h or 6 h after HSV-1. In contrast, LL-37 inhibited viral replication under all conditions. Scrambled peptides had no activity.
Our data suggest that amyloidogenic peptides Aβ1-40 and Aβ1-42 may belong to a novel class of antimicrobial peptides (AMP) that possess antiviral activity.

HSV-1 infection causes reduced surface expression of MHCII and co-stimulatory molecules on infected DC and suppressed T cell activation in vitro

R. Budida[1], *M. V. Stankov*[1], *K. Doehner*[2], *A. Buch*[2], *B. Sodeik*[2], *G. M. N. Behrens*[1];
[1]*Department of Clinical Immunology and Rheumatology, Hannover Medical School, Hannover, Germany,* [2]*Institute of Virology, Hannover Medical School, Hannover, Germany.*

Introduction: Herpes Simplex Virus 1 (HSV-1) causes a lifelong persistent infection of the peripheral nerve tissue, which can lead to life threatening encephalitis or disseminated infection in immunocompromised persons. HSV-1 developed numerous mechanisms to evade immune response. The main target for HSV-1 is the MHC class II (MHCII) processing pathway in dendritic cells (DC). We used a HSV-1 construct with Gaussia luciferase and mCherry, which can allow differentiating infected cells from uninfected (Bystanders). Results: Our studies on infected murine spleen- and bone marrow-derived DCs revealed increased apoptosis in bystander cells (mCherry negative), when compared to infected cells (mCherry positive) and a reduction in DC maturation status as based on diminished expression of MHCII, CD80 and CD86. We observed a reduced T cell activation in samples containing infected DC with ovalbumin (OVA) through OVA-specific T cell proliferation assays. We have also observed a decreased autophagic flux in bystander cells and no significant change in infected cells when compared to uninfected sample. Addition of PP242, an activator of autophagy, revealed an increased autophagic flux in infected cells, when compared to uninfected and bystanders, which can be due to synergistic effect from virus and PP242. Further studies revealed a reduction in HSV-1 viral gene expression in infected neurons when activated antigen specific T cells were present. Conclusion: HSV-1 infection of DC causes apoptosis of bystander cells and reduced DC activation status, which suppresses both CD4+ and CD8+ T cell activation.

Lethal immune mediated-disease after LCMV infection in STAT1 KO mice requires interferon regulatory factor 7 and is driven by type I interferon

I. L. Campbell*, W. Li, M. J. Hofer;*
University of Sydney, Sydney, Australia.

STAT1 KO but not WT, STAT2 KO, IRF9 KO or IFNAR KO mice succumb to a lethal CD4+ T cell-mediated disease following systemic infection with lymphocytic choriomeningitis virus (LCMV). Here we determined the role of the key transcriptional activator of type I interferon (IFN-I) production, interferon regulatory factor 7 (IRF7), in this lethal host response by generating STAT1/IRF7 KO double mutant mice. In contrast to STAT1 KO mice, STAT1/IRF7 KO mice as well as IRF7 KO mice survived LCMV infection and STAT1/IRF7 KO mice also developed a persistent infection. LCMV infection in STAT1 KO mice was associated with the marked induction of a number of cytokines in the serum including IFN-α, IFN-β, IFN-γ, IL-5, IL-6 and MCP1 which was absent in STAT1/IRF7 KO mice which had a modest increase in MCP-1 only. In addition, in the spleen of LCMV-infected STAT1 KO mice, IFN-β and IFN-γ mRNAs were also much more highly induced when compared with WT mice, while in STAT1/IRF7 KO mice, IFN-γ mRNA induction was similar to WT animals, there was no induction of IFN-β mRNA. To elucidate further a possible role of IFN-I in lethal disease, we examined STAT1/IFNAR KO mice. In contrast to STAT1 KO mice that all succumbed, STAT1/IFNAR KO mice all survived infection with LCMV. In conclusion, lethality resulting from LCMV infection in STAT1 KO mice is dependent on IRF7 through a mechanism that likely involves IFN-I which is a key driver of a catastrophic antiviral response.

P4.01.017
Influenza vaccination leads to dramatic redistribution of lymph node resident dendritic cells into inter-follicular regions

M. C. Woodruff[1,2], *S. Turley*[3,4], ***M. C. Carroll***[1,5];
[1]*Program in Cellular and Molecular Medicine, Boston Children's Hospital, Boston, MA, United States,* [2]*Graduate Program in Immunology, Harvard Medical School, Boston, MA, United States,* [3]*Dana Farber Cancer Institute, Boston, MA, United States,* [4]*Microbiology and Immunobiology, Harvard Medical School, Boston, MA, United States,* [5]*The Departments of Pediatrics, Harvard Medical School, Boston, MA, United States.*

Multi-photon live imaging has become a powerful tool in dissecting immune response to viral antigen, though to date little attention has been paid to lymphoid-resident dendritic cell (LNDC) populations. Initially described as sessile networks within the T cell compartment, we have observed a robust activation and relocation of LNDCs within minutes of UV-inactivated Influenza A arrival in draining lymph nodes (LNs). Combining live imaging with three-dimensional fluorescent reconstruction of draining lymph nodes, LNDCs were tracked in rapid migration beginning in the T cell cortex and resolving in medullary projections within inter-follicular regions (IFRs). LNDCs become activated and acquire antigen within IFRs where viral antigen concentrates. With a slightly delayed kinetics, antigen specific naïve CD4+ T cells are identified within 12 hours of immunization into IFRs where they make direct contact with LNDC and viral antigen. Strikingly, viral specific (but not naïve) CD4+ T cells express activation markers CD69 and CXCR3 and develop a Th 1 phenotype prior to skin draining DC arrival. Together, we believe that these data elucidate the importance of the LNDC population within draining LNs, provide insight into antigen drainage and early T cell activation after viral vaccine administration, and highlight the previously unappreciated magnitude of activity within draining LNs prior to the arrival of canonical migratory DCs from the periphery.

HTLV-1 infected thymic epithelial cells convey the virus to CD4$^+$ lymphocytes

L. R. Carvalho[1], *K. Ramos-Pedroza*[2], *F. M. de Castro*[1], *N. Santucci*[3], *L. L. Lacerda*[1], *M. Ribeiro-Alves*[1], *W. Savino*[1];
[1]*FIOCRUZ, Rio de Janeiro, Brazil,* [2]*Institute of Health Sciences, Alagoas State University, Alagoas, Brazil,* [3]*Facultad de Cs Médicas, Rosario, Argentina.*

Human T Lymphotropic Virus type 1 (HTLV-1) can lead to development of lymphoma and leukemia (ATL) or to commitment of muscular/nervous systems (HAM/TSP). It remains unknown what triggers these diseases. Although the virus has T lymphocyte tropism, it can infect other cells by cell contact and cell-free virus. Activated T lymphocytes re-circulate in lymphoid organs, including the thymus, where the thymic epithelial cells (TEC) interact with recirculating cells. Accordingly, infected lymphocytes might transmit the virus to TEC. Interestingly, TEC express molecules related to the HTLV-1 transmission (GLUT-1, CCR4, Neuropilin 1). *In vitro* experiments showed that TEC could be infected by cell line derived from ATL and HAM/TSP patients. These infections happened from cell contact and by cell-free virus derived from cell supernatants. The virus can be seen after 24h and 10 days, when virtually all cells in the culture are infected. A microarray assay was performed comparing TEC treated with non-infected and HTLV-1$^+$ cells supernatants. The results revealed an increase of chemokine and adhesion molecule gene expression confirmed by RT-PCRq. Nevertheless, no difference in non-infected lymphocyte attraction was observed in a Transwell migration model. Lastly, HTLV-1 infected TEC were capable to spread the virus through the culture and infect target lymphocytes. Together these results show that TEC can be infected by HTLV-1+ lymphocytes and cell-free virus, can infect other TEC and convey the virus to non-infected T lymphocytes.

P4.01.019
Rapid T cell activation following Epstein-Barr virus transformed lymphoblastoid cell line co-culture with peripheral blood mononuclear cells from cytomegalovirus positive but Epstein-Barr virus naïve children

C. Carvalho-Queiroz[1], *S. Saghafian-Hedengren*[1], *N. Nagy*[2], *C. Nilsson*[3], *E. Sverremark-Ekström*[1];
[1]*Department of Molecular Biosciences, Wenner-Gren Institute, Stockholm University, Stockholm, Sweden,* [2]*Microbiology, Tumor and Cell Biology, Karolinska Institute, Stockholm, Sweden,* [3]*Clinical Science and Education, Karolinska Institute and Sachs' Children's Hospital, Stockholm, Sweden.*

Cytomegalovirus (CMV) and Epstein-Barr virus (EBV) are common and persistent herpesviruses known to influence immune cell maturation. We have earlier shown that CMV related imprint on NK- and T cells in children is boosted by co-infection with EBV. To better understand the mechanisms involved in the synergistic effect of co-infection on the T cell compartment, peripheral-blood mononuclear cells (PBMCs) from CMV+ EBV naïve children were co-cultured with EBV+ transformed lymphoblastoid cell lines (LCLs) directly or with the supernatant derived from LCLs pre-cultured for 72 hours. PBMCs in medium only or in culture with Ramos (EBV- Burkitt's lymphoma cell line), or with Ramos supernatants were included as controls. After culture, the cytokines IL-2, IFN-γ and TNF-α, were investigated in the supernatants through ELISA. ELISA results for the co-culture experiments showed that PBMCs cultured in medium alone, in Ramos supernatants or with Ramos cells failed to stimulate cytokine production. In contrast, PBMCs cultured with LCL supernatants or with LCLs produced IFN-γ and TNF-α, the levels of which were higher when PBMCs were cultured with LCLs rather than with LCL-derived supernatant. High levels of IL-2 was seen only when PBMCs were co-cultured with LCLs. Data herein suggests that as early as 3 days following culture, CMV+EBV naïve T cells become activated and produce cytokines in response to EBV co-infection. The characteristics of the responding T cells and their molecular triggers are currently being investigated.

P4.01.020
Seroprevalence against pandemic influenza virus A/H1N1/2009 in pregnant women

A. Cérbulo-Vázquez[1], *G. Cruz-Cureño*[2], *I. Garate-Bosco*[2], *C. López Macías*[2], *A. Isibasi*[2], *L. Arriaga-Pizano*[2], *J. Mancilla*[1];
[1]*Instituto Nacional de Perinatología, INPer, Mexico City, Mexico,* [2]*Unidad de Investigación Médica en Inmunoquímica, Hospital de Especialidades "Bernardo Sepúlveda", Centro Médico Nacional Siglo XXI IMSS., Mexico City, Mexico.*

For influenza virus infection, vulnerable groups include people with morbid obesity, chronic obstructive pulmonary disease and pregnant women. It is speculated that the increased rate of morbidity and mortality in pregnant women is due to a status of "temporary deficiency", induced to avoid rejection of the product of conception. However, production of antibodies during pregnancy does not decrease and could be transferred to the product by transplacental pathway. For the A/H1N1/2009 pandemic influenza virus, antibodies response against the virus during pregnancy has not been investigated. We determined seroprevalence of A/H1N1/2009 in pregnant women during different trimesters and transplacental transfer of antibodies to umbilical cord blood (UCB), using hemmaglutination inhibition (HAI), and using serum from 249 pregnant women, 25 non-pregnant women and 5 UCB post-partum, collected from December 2009 to February 2010. Sixteen percent from pregnant and 24% non-pregnant women had antibodies against A/H1N1/2009 with titers ≥1:40. The highest prevalence was found in third trimester pregnant women (23%, titers between 1:40 to 1:5120). UCB samples have equal antibody titers as the corresponding choridecidual space. This results show that during third trimester, when morbidity and mortality rates are the highest in pregnant women infected with A/H1N1/2009, pregnant women have protective titers as those found in non-pregnant women. Differences in responsiveness facing A/H1N1/2009 does not seem to be related to the presence of protective titers of hemmaglutinating antibodies in pregnant women, but could be related to neutralizing specific antibodies against A/H1N1/2009. Also, these antibodies seem that could be transferred transplacentally.

P4.01.021
Role of CD48 in regulation of T-cell mediated immunity in HTLV-1 infection

C. E. Chibueze[1], *Y. White*[2], *M. Yoshimitsu*[3], *K. Uozumi*[3], *N. Arima*[3];
[1]*Graduate School of Medical and Dental Sciences,Kagoshima University, Kagoshima, Japan,* [2]*University Of West Indies, Mona Kingston Jamaica, Mona Kingston, Jamaica,* [3]*Division of Hematology and Immunology, Center for Chronic Viral Diseases, Graduate School of Medical and Dental Sciences, Kagoshima University, Kagoshima, Japan.*

HTLV-1 (Human T cell lymphotropic virus type 1) infection is associated with an aggressive T cell malignancy ATLL (Adult T-cell leukemia/lymphoma), the virus also establishes lifelong persistent infection in humans resulting in a carrier state (clinically asymptomatic).
CD48 is a GPI anchored cell surface molecule ubiquitously expressed on various hematopoietic cells, its expression has been shown to be up-regulated in viral infections as a sign of ongoing breach of immunity and therefore facilitates immune response. In HTLV-1 infection, one of the factors suggested to play a role in its persistence is the increased expression of the trans-activating viral gene encoding HTLV-1 tax among others; tax protein is the dominant target antigen of the T cell response to HTLV-1 in infected individuals.
In this study, we investigate the role of CD48 in HTLV-infection, we show that it is down regulated in HTLV-1 infection; the presence of HTLV-1 tax protein also suppresses CD48 expression. On blockade using anti-CD48 AB, the effector function of T cells in terms of cytokine production improved. Thus, we propose a possible means of immune evasion by HTLV-1 virus by Cd48 down-regulation and a possible inhibitory role in HTLV-1 infection.

Identification of Antiviral-related Genes Up-regulated in Response to *Bombyx mori* Nucleopolyhedrovirus

T. Goo, S. Kim, ***K. Choi****, S. Kim, S. Park, S. Kang, E. Yun;*
NAAS, Suwon, Republic of Korea.

Silkworm larvae often suffer from viral infections causing heavy losses to the economy of silk industry. Insects exhibit both humoral and cellular immune responses that are effective against various pathogens like bacteria, fungi, protozoa, etc., but no insect immune responses are effective against viral infection. To obtain genes related to insect antiviral immunity from *Bombyx mori*, the cDNA library was constructed from *B. mori* nucleopolyhedrovirus (BmNPV)-infected *B. mori*. From the cDNA library, we selected 411 differentially expressed clones, and the 5' ends of the inserts were sequenced to generate ESTs. In this work, 135 unigenes were generated after the assembly of 411 differentially expressed clones ESTs. Of these 135 unigenes, we selected 109 antiviral response-related candidates except 26 clones that high similarity with genes derived from BmNPV. Among 109 unigenes, a total of 80% had significant matches to genes from other organisms in the database, whereas 20% of the unigenes had not matched in the database. Functional groups of these sequences with matches in database were constructed according to their putative biological function. Three largest categories were control of cellular organization (52%), metabolism (20%), and protein fate (10%). The genetic information reported in this study will provide more information about antiviral-related genes in silkworms.

P4.01.023
CD8$^+$ T-cell memory: forward genetic analysis by germline mutagenesis and screening

O. Choi[1]*, O. M. Siggs*[2]*, P. Mueller*[1]*, R. J. Cornall*[2]*, P. G. Ashton-Rickardt*[1]*, S. Rutschmann*[1]*;*
[1]Imperial College London, London, United Kingdom, [2]Oxford University, Oxford, United Kingdom.

The development and long-term memory maintenance of antigen-specific CD8$^+$ cytotoxic T-lymphocytes (AgCD8) is genetically controlled. However, not all the genes involved in this process are known to date. To identify new memory regulators, we have undertaken an *in vivo* forward genetic approach based on germline mutagenesis and screening. Genome-wide random Ethyl-(N)Nitroso-Urea (ENU)-induced point mutations were created and a library of third generation mutant mice screened for genetic defects affecting the development of Lymphocytic Choriomeningitis virus (LCMV)-specific AgCD8 and their survival into long-term memory cells. By screening 1263 mice, we have isolated 3 mutant strains named memi, binu and alois.
We recently reported that memi, a null mutation in the nucleotide salvage enzyme deoxycytidine kinase, affects T-lymphocyte thymic development, peripheral homeostasis and AgCD8 response to LCMV infection. binu and alois mutants do not develop observable spontaneous phenotypes, but upon infection present enhanced quantity and impaired quality of AgCD8 memory, respectively. Whole-genome sequencing and identity by descent analysis of binu and alois mutants has narrowed down the list of candidates to 4 and 10 genes, respectively. binu is currently being confirmed as a mutation in a known T-cell regulator, whereas alois affects an as yet un-described novel immune gene. Although alois mutant mice retain wild-type LCMV-specific AgCD8 numbers, their AgCD8 cells present impaired memory qualities after primary and secondary infections, indicating that *alois* controls the memory potential of AgCD8. Our non-hypothesis driven approach has therefore unraveled new avenues to investigate and understand what finely tunes the quality of CD8$^+$ T-cell memory response.

Cross-reactive antibodies to swine influenza viruses in adults after vaccination with trivalent inactivated influenza vaccine in Korea

J. Choi*, N. Lee, K. Shin, C. Kang;*
Korea National Institute of Health, Osong-eup, Republic of Korea.

A number of human infection cases of swine influenza virus A(H3N2)v have been reported in the United States since 2011. We evaluated levels of cross-reactive antibody to swine influenza viruses (H1N1, H1N2, H3N2 and H3N2pM) isolated in Korean swine herd, and assessed whether seasonal trivalent inactivated influenza vaccine (TIV) induces seroprotection in human adult group against these swine influenza viruses. Cross-reactive antibody to four swine influenza subtypes was evaluated by hemagglutination inhibition (HI) assay and microneutralization assay (MN). The analysis included 55 paired sera collected during 2011-2012 and 2012-2013 season in adults aged >20. Seroprotection was defined as an HI titer of ≥40 and MN titer of ≥80. Vaccine-induced antibody levels were assessed with paired sera before and after seasonal TIV vaccination. The overall seroconversion (4-fold increase in antibody level) rate, by HI assay, after TIV immunization against swine influenza viruses were swH1N1 (64%), swH1N2 (62%), swH3N2 (44%) and swH3NpM (45%), respectively. The overall seroprotection rate of HI and MN were ≥56% and ≥60% following TIV vaccination. Therefore the enhorced seasonal influenza vaccination might provide protective effect to swine influenza virus human infection.
*This study was supported by a grant from Korea Centers for Disease Control Prevention (4834-300-210-13) and Transgovermental Enterprise for Pandemic Influenza in Korea (TEPIK) grant (A103001-1112-1160200) partially.

P4.01.025
Pentamers and streptamers for the monitoring of CMV-specific CD8+ T-cell immune reconstitution after allogeneic stem cell transplantation: a comparative analysis

M. Ciaurriz[1]*, N. Ramirez*[1]*, L. Beloki*[1]*, C. Mansilla*[1]*, A. Zabalza*[2]*, E. Bandres*[2]*, M. Rodriguez*[2]*, E. Olavarria*[1,2]*;*
[1]Biomedical Research Center NavarraBiomed, Pamplona, Spain, [2]Complejo Hospitalario de Navarra, Pamplona, Spain.

Reconstitution of CMV-specific CD8+ T-cells (CTLs) is crucial for patients after allogeneic Stem Cell Transplantation (allo-SCT). The aim of this study is to evaluate the correlation between staining with two different multimers (Pentamers (PM) and Streptamers (ST)) in the monitoring of immune reconstitution.
A total of 94 PBMCs samples were isolated from 14 CMV-seropositive HLA-A*02:01 patients. To form the ST complex, 0.75 µg PE-labelled Strep-Tactin and 0.5 µg Streptamer HLA I were mixed. In addition, 0.2µg HLA-A*02:01/STpp65$_{495\text{-}503}$ or 5 µl HLA-A*02:01/PMpp65$_{495\text{-}503}$ were incubated with 1x10^6 human AB serum-blocked PBMCs for 45 minutes at 4ºC or 10 minutes at room temperature, respectively. After multimeric staining, anti-human CD3/CD8/CD45/CD4 were added and 500,000 cells were acquired in a FACSCanto II. CMV-specific CTLs response was monitored monthly during a median of 11.4 months after SCT with a median of 8 samples analysed per patient. Correlation between both techniques was determined by Rho Spearman test.
The median frequencies of CMV-specific CTLs detected by PM and ST were 31.58x10^5/L (IQR=4.04-267.24) and 42.85x10^5/L (IQR=3.52-288.31), respectively. Both techniques correlate each other ($r_{Spearman}$ = 0.982; p<0.01). Nevertheless, ST showed higher mean values than PM looking at the median value of the difference PM-ST (-1.42 [-23.5, 1.35]. The correlation between the difference PM-ST and the PM/ST mean showed that the higher CMV-specific CTLs quantity the larger differences PM-ST ($r_{Spearman}$=-0.331; p<0.01).
We concluded that both techniques may be equally useful to examine immune reconstitution, although detection levels are higher with ST staining possibly due to a larger sensitivity of this technique.

P4.01.026
Targeted PGE_2 inhibition enhances anti-influenza immunity through induction of type I IFN in Macrophages

M. Divangahi[1]*, F. Coulombe*[1]*, J. Jaworska*[1]*, M. Verway*[1]*, F. Tzalepis*[1]*, G. Kobinger*[2]*, P. Joubert*[3]*, J. H. Fritz*[1]*, Z. Xing*[4]*, W. S. Powell*[1]*;*
[1]McGill University, Montreal, QC, Canada, [2]National Microbiology Laboratory, Winnipeg, MB, Canada, [3]Laval University, Quebec, QC, Canada, [4]McMaster University, Hamilton, ON, Canada.

The 1918 Spanish Influenza virus pandemic had a major impact on the rise in popularity of non-steroidal anti-inflammatory drugs (NSAIDs). Although these drugs are used extensively for the management of Influenza symptoms, their role in anti-viral immunity is poorly understood. NSAIDs act mainly by inhibiting cyclooxygenase enzymes involved in the synthesis of all prostaglandins, including PGE_2. We now show that during Influenza infection, upregulated PGE_2 inhibited macrophage type I interferon production and apoptosis via EP2 and EP4 receptors, thereby increasing virus replication. This inhibitory role of PGE_2 was not limited to innate immunity since both antigen presentation and T cell mediated immunity were also suppressed. Inhibition of microsomal prostaglandin E-synthase 1 (mPGES-1), and thereby PGE_2, in human Mφ was protective against Flu infection. These data show that the mPGES-1/PGE_2 pathway is specifically targeted by Influenza virus to evade host anti-viral immunity and propose that specific inhibition of PGE_2 may serve as a new treatment for viral infection.

Serological survey of BTV in Morocco

K. Drif[1], *O. Fassi Fihri*[1], *C. Loutfi*[2], *G. Sebbar*[1], *M. Moulay Ennaji*[3], *M. Elharrak*[2];
[1]*IAV Hassan II, Rabat, Morocco,* [2]*Biopharma, Rabat, Morocco,* [3]*FST, Mohammadia, Morocco.*

The bluetongue (BT) is a non-contagious disease transmitted by blood-sucking arthropods of the genus Culicoides. The disease affects small ruminants, especially sheep which are very sensitive.
Since 2004 two serotypes circulating in Morocco BTV-1 and 4, several samples were collected during different epidemics, the strains were isolated but no thorough phylogenetic study has been established to characterize and reveal different reassortants have been able to generate from parental strains.
The first year of our study involved a serological survey of sheep and cattle to define the epidemiological situation with respect to this arbovirus, also reveal the rate of coinfection by differents serotypes.
Out of the 429 sera that were collected, 216 are from the cattle of the Gharb region, 109 were collected in 2009 from different regions of Morocco, and the rest was collected in 2012 from sheep of other regions of the country. All the sera collected were tested by neutralization using reference viruses of serotype 1 and 4 and the result is that the rate of co infection was high especially among cattle. Hence the results prove the importance of a molecular study involving BTV isolates that represents different regions of Morocco and different years since the first outbreak.
The next step is mainly based on the sequencing of BTV isolates to better understand the evolution of this virus through the years, then a study of the pathogenesis and immune response of animals would also assess whose goal is to classify different reassortants in Morocco.

P4.01.028
Prevalence of human papillomavirus subtypes in breast cancer in Moroccan woman

A. Elamrani[1,2], *M. Ennaji*[3], *M. Benhassou*[4], *M. Attaleb*[5], *M. Mzibri*[5], *M. Corbex*[6], *M. Tomassino*[2], *T. Gheit*[2], *M. Khyatti*[1];
[1]*Institut Pasteur du Maroc, Casablanca, Morocco,* [2]*International agency for research on cancer, Lyon, France,* [3]*Laboratory of Virology, Hygiene & Microbiology, Faculty of Sciences & Technics, University Hassan II Mohammedia, Mohammedia, Morocco,* [4]*Centre Hospitalier Universitaire Ibn Rochd, Casablanca, Morocco,* [5]*Centre National de l'Energie des Sciences et des Techniques Nucléaires, Rabat, Morocco,* [6]*Department of Public health, Institute of Tropical Medicine, Antwerp, Belgium.*

Breast cancer is one of the most frequently diagnosed cancers in women in Morocco, but its aetiology remains unknown. Viruses including Epstein-Barr virus, a human equivalent of murine mammary tumour virus and human papillomavirus have been detected in benign breast tissues and breast tumours and are considered to be involved in the aetiology of breast cancer. Two clinically relevant high-risk HPV (HR-HPV) types 16 and 18 are etiologically associated with the development of cervical carcinoma and are also reported to be present in many other carcinomas in extra-genital organ sites. However, there are controversial data on the meaning of viral induction of breast cancer. Human papillomaviruses HPVs could be important risk factors for breast carcinogenesis and metastasis. Based on this hypothesis, we evaluate the prevalence of broad range of HPVs in a Moroccan breast carcinoma cases. We have analyzed 88 Snap frozen breast tumor tissues by using type-specific multiplex genotyping (TS-MPG) assays which combine multiplex PCR and a bead-based technology the multiplex genotype. Our study revealed that 20 (22.7%) of the 88 samples are HPV positive and the high-risk HPV types 16 and 18 were not detected in our samples, but 4.54% others probable/high risk types were detected.

P4.01.029
Lung CD8+ T cell impairment during acute viral respiratory infection is associated with a unique gene expression profile

J. J. Erickson, *P. Lu, P. Gilchuk, S. Joyce, Y. Shyr, J. V. Williams; Vanderbilt University, Nashville, TN, United States.*

Viral acute lower respiratory infections (vLRI) generate pulmonary $CD8^+$ cytotoxic T lymphocytes (CTLs) that are functionally impaired, while virus-specific CTLs in the spleen remain functionally competent. We have shown that the inability of lung CTLs to maintain effector functions resulted in impaired viral clearance in a murine vLRI model (*J Clin Invest* 2012) and may therefore contribute to recurrent vLRI. Here we show a cell-intrinsic role for the inhibitory receptor Programmed Death-1 (PD-1) in mediating lung CTL impairment. To further define differences between impaired lung and unimpaired spleen CTLs during vLRI, we performed gene expression analysis on epitope-specific cells from the lung and spleen and naïve $CD8^+$ T cells. The expression of ~2000 genes changed as cells differentiated from naïve to effector lung CTLs. Surprisingly, >350 genes were differentially expressed between lung and spleen CTLs. The lung-specific genes encode proteins with diverse functions, including cytokine production, transcriptional regulation, trafficking, cell cycle and metabolism. Notably, several genes associated with CTL exhaustion were upregulated, including TIM-3, LAG-3, 2B4, IL-10 and BLIMP-1. We then compared lung CTLs in this study to exhausted spleen CTLs present during chronic LCMV clone-13 infection (Doering et al *Immunity* 2012) in a separate analysis. We found that lung CTL gene expression represents a unique state of $CD8^+$ T cell differentiation that shares some aspects of both early and late chronic LCMV gene profiles. These data demonstrate that impaired lung CTLs represent a unique physiologic state. Further characterization of lung-specific genes may lead to novel therapeutics against serious vLRI.

P4.01.030
The complement system has a critical role in the inflammatory reaction that follows influenza virus infection

S. F. Gonzalez[1,2], *C. Herndon*[2], *J. Ortin*[3], *M. Carroll*[2];
[1]*Institute for Research in Biomedicine, Bellinzona, Switzerland,* [2]*Harvard Medical School, Boston, MA, United States,* [3]*Centro Nacional de Biotecnologia, Madrid, Spain.*

In this work we evaluated the functions of some of the major complement proteins in the response to influenza using mice deficient in C3, C1q and C4. We observed that all of the complement deficient strains show higher mortality and morbidity rates compared to wild type animals after a sublethal infection with influenza. In addition, complement C3 was necessary to promote the phagocytosis of the virus and/or viral infected cells by the major phagocytic cells in the lungs (alveolar macrophages, neutrophils and monocytes) at early time points after infection. We also observed a clear reduction in the number of viral positive respiratory dendritic cells in the complement deficient animals compared to B6 controls that correlate with a deficient T cell activation in the draining mediastinal lymph node. However, the levels of the pro-inflammatory cytokines IL1β, MCP1, MIP2 and TNFα in the lung of mice at day 2 post-infection were significantly higher in C3-/- and C4-/- animals compared with the control group.
From these results we can conclude that the pronounced decrease in the phagocytic activity of lymphocytes in the lungs from complement deficient animals facilitates the dissemination of the virus and increases the epithelial damage, augmenting at the same time the cytokine storm that leads to the dead of the animal. In addition, the adaptive immune responses are impaired mainly due to a deficient activation of the migratory respiratory dendritic cells that fail to activate efficiently antiviral T cell responses in the draining lymph node.

Human cytomegalovirus directly supress CD4 T-lymfocyte activation and proliferation

***O. Fornara**, J. Odeberg, Z. Khan, G. Stragliotto, I. Peredo, L. Butler, C. Söderberg Nauclér;*
Karolinska Institute, Stockholm, Sweden.

CD4 T cells are important regulators of the immune system and are vital for mounting a strong immune response against viral infections. Human cytomegalovirus (HCMV) is known to be a strong modulator of the innate as well as adaptive immune responses. In this study, we found that HCMV directly inhibited proliferation of CD4 T cells and rendered them unresponsive to immunological stimuli. This effect was not observed when CD4 T cells were treated with Herpes Simplex Virus-1/ 2 or measles virus. When stimulated with phytohemagglutinin, concanavalin A, or phorbol myristate acetate, HCMV-treated T cells were unable to proliferate, revealing an ability of HCMV to inhibit CD4 T cell response. Furthermore, HCMV also prevented proliferation of leukemic T-cell lines. HCMV-treated CD4 T cells expressed the activation markers CD45RO and CD69, were not apoptotic and produced decreased levels of the cytokines IL-4, IFN-γ and TNF-α, compared to untreated controls. The inhibitory effect of HCMV on CD4 T cell proliferation was not mediated by HCMV gH, gB or other immunogenic glycoproteins, since intravenous immunoglobulins or gB- or gH-specific neutralizing antibodies did not prevent the suppression of T-cell proliferation. Our observations show that HCMV inhibits CD4 T cell function with potential clinical consequences for both humoral and cell-mediated immune responses.

P4.01.032
Narrowing of influenza A virus specific T-cell receptor alpha and beta repertoire with increasing age

*A. Gil[1], M. B. Yassai[2], Y. N. Naumov[1], **L. K. Selin**[1];*
[1]University of Massachusetts Medical School, Worcester, MA, United States, [2]Blood Center of Wisconsin, Milwaukee, WI, United States.

Alterations in memory CD8 T cell responses may contribute to the high morbidity and mortality caused by seasonal influenza A virus (IAV) infections in older individuals. We questioned whether memory CD8 responses to this non-persistent virus, to which recurrent exposure with new strains is common. will change overtime with increasing age Here, for the first time we show that the HLA-A2-restricted IAV $M1_{58-66}$-specific Vα T cell repertoire was significantly narrowed leading to oligoclonal expansions including the usage of a single identical VA12 clonotype with age . This was the case for all 8 older donors. The VA repertoire of older individuals also had longer CDR3 regions with increased usage of alanine/glycine runs which may enhance TCR promiscuity. Collectively these results suggest that CD8 memory responses in humans to non-persistent viruses like IAV are dynamic, and become narrower with preferential retention of T cell repertoires with features of enhanced promiscuity with age.

P4.01.033
Study of humoral immune response in patients with tick-borne encephalitis against the background of virus circulation

***A. P. Godovalov**, L. P. Bykova;*
Acad. E.A. Wagner Perm State Medical Academy, Perm, Russian Federation.

The aim was to identify antibodies to tick-borne encephalitis virus and its RNA in patients with acute and chronic infection. Serum of patients with acute and chronic form of encephalitis were examined by EIA to determine titers of specific immunoglobulin M (IgM) and G (IgG) and by polymerase chain reaction to determine virus RNA. A relationship between antibody formation and circulation of tick-borne encephalitis virus was detected. Simultaneous circulation of the virus and IgM was indicated in the acute form of encephalitis. The immune response of 22% of the patients was ill-defined in the presence of circulating virus in the blood. The absence of IgG may indicate the realization of the primary immune response and the beginning of the circulation of immune complexes. In late convalescence period the circulating virus in the majority of the patients (75%) was not found against the background of circulating antibodies M and G. In 25% of cases in the complete absence of free antibody, the virus was detected in blood cells. 40% of patients with the chronic form had no virus in the blood, and the IgG titer was high. In 60% of cases there was opposite situation, with low IgG the virus circulation was found in the blood, that indicated its output into the blood stream and the next stage of viremia. These results may indicate preferential localization of tick-borne encephalitis virus in the tissues of the nervous system with periodic reactivation and induction of humoral immune response to polymorphic classes of immunoglobulins.

P4.01.034
Some liquorogic features of meningeal form of tick-borne encephalitis

***A. P. Godovalov**, L. P. Bykova;*
Acad. E.A. Wagner Perm State Medical Academy, Perm, Russian Federation.

The aim of our work was to study liquorologic indexes in case of meningeal form of tick-borne encephalitis.
We examined samples of cerebrospinal fluid and serum of patients with meningeal form of encephalitis. In the samples of cerebrospinal fluid we identified the level of white blood cell, protein and specific immunoglobulin M. In blood serum we identified the presence of specific immunoglobulin M and G (IgM and IgG).
It was found that the meningism occurred immediately at admission and were traced for an average 5-8 days. For meningism occurrence all patients had cytosis 125,8±30,5 cells in 1 mm^3, while relieving them - 27,1±9,4 cells in 1 mm^3 ($p<0,05$). Pleocytosis was mainly lymphocytic. The protein level in the height of meningism was 0,49±0,08, and with its disappearance it was 0,34±0,01 g/l ($p>0,05$). The geometric mean titer of specific IgM in cerebrospinal fluid was 7,37÷0,35. The increased amount of leukocytes in cerebrospinal fluid at admission was associated with high protein level (r=+0,52) and presence of specific IgM (r=+0,50) in cerebrospinal fluid. High level of protein in cerebrospinal fluid during the second study correlated with prolonged circulation of specific IgM in cerebrospinal fluid and serum (r=+0,88, and r=+0,56, respectively), reflecting the preservation of inflammations. We noted the close relationship between the level of specific IgM in serum and cerebrospinal fluid (r=+0,82).
Thus, complex study of cerebrospinal fluid in the dynamics is still an important piece of monitoring the progress of infection.

P4.01.035
EBV infection leads to activation of chronic lymphocytic leukemia (CLL) cells and worsen clinical prognosis in CLL patients

*J. Rolinski[1], **E. Grywalska**[1], A. Bojarska-Junak[1], P. Grabarczyk[2];*
[1]Medical University of Lublin, Lublin, Poland, [2]Institute of Haematology and Transfusion Medicine, Warszawa, Poland.

Chronic lymphocytic leukemia (CLL) is a heterogenic disease in clinical outcome, but the reason of heterogeneity remains not understood. The role of chronic immune stimulation, leading to the activation of B lymphocytes is under investigation. Preliminary observations indicate a possibility of facilitate clonal expansion and leukemic transformation of B cells by exoantigens. The aim of the study was an assessment of the influence of Epstein-Barr virus (EBV) infection on activation of CLL cells and determination of the relationship between the presence of viral DNA and CLL clinical outcome. The assessment of the immunophenotype of peripheral blood (PB) lymphocytes, focusing on lymphocyte activation markers, such as CD25 and CD69, with the use of flow cytometric method, and the assessment of the presence of the EBV DNA with the use of RT-PCR method, was conducted in blood samples (PBMC) of 80 untreated CLL patients. Significantly higher percentage of activated B cells CD19+CD25+ and T cells CD3+CD25+ was found in PB of those CLL patients in whom DNA EBV was found in PBMC ($p<0.0000001$ and $p=0.024$, respectively). Positive correlation between the number of copies DNA EBV and the percentage of CD19+CD25+ B cells ($r=0.502$, $p=0.033$), CD19+ZAP-70+ B cells ($r=0.751$, $p=0.0003$), and CD19+CD38+ B cells ($r=0.476$, $p=0.038$).

Moreover, those patients whose lymphocyte counts doubled in less than 12 months had more DNA EBV copies (p=0.0003). Obtained results suggest that EBV plays an important role in the stimulation of CLL lymphocytes and may induce B-CLL cells proliferation, leading to the fatal outcome of the disease.

P4.01.036
Activation of type III interferon response by human paramyxovirus infection

***M. Guerrero-Plata**, R. Banos-Lara, L. Harvey, A. Mendoza;*
Louisiana State University, Baton Rouge, LA, United States.

Human Metapneumovirus (hMPV), is a paramyxovirus considered a major respiratory pathogen responsible for up to 15% of low respiratory tract infections hospitalizations in infants and young children. It is also causes bronchiolitis and pneumonia. Currently, there is not vaccine available against hMPV. Knowledge of the critical aspects of the host immune response is crucial to understanding the pathology associated with hMPV infection. We have recently found that hMPV induce type III interferon (IFN). However, the role of this antiviral cytokine in hMPV infection is unknown. In this work, we investigate the production of IFN-lambda in vitro and in vivo using lung epithelial cells and an experimental mouse model of infection. Our data indicate that hMPV induce IFN lambda in epithelial cells in vitro and its production is dependent of viral replication. hMPV is susceptible to the activity of the three isoforms of IFN-lambda. In the mouse model, we observed that hMPV induced IFN-lambda in vivo. Moreover, treatment of mice with IFN-lambda prior hMPV infection resulted in a reduced lung virus titer and a decreased number of inflammatory cells in the lung. Overall, these findings highlight the importance of the interferon responses in hMPV infection and suggest that IFN lambda play a role in the antiviral immune response to paramyxovirus infection.

P4.01.037
Influenza virus NS1 protein counteracts ZAPS function to evade RIG-I-mediated antiviral defence

***S. Hayakawa**, T. Kameyama, T. Yamada, A. Takaoka;*
Hokkaido University, Sapporo, Japan.

Type I IFNs are produced in response to viral infection and are key cytokines for the activation of innate immunity. The induction of type I IFNs is triggered by the detection of viral nucleic acids through pattern recognition receptors. In particular, the cytosolic RNA sensors, retinoic acid-inducible gene-I (RIG-I) and its family members essentially mediate the recognition of a variety of viruses by host cells. These RNA sensors are frequently targeted by viral proteins for the evasion of host antiviral activities. It was previously reported that influenza virus derived nonstructured protein 1 (NS1) interacts with RIG-I to inhibit its downstream signalings. However, little is known about its detailed mechanism. In this study, we show that influenza virus NS1 protein inhibits RIG-I-mediated antiviral signaling through the counteraction against ZAPS. The association of ZAPS with RIG-I was found to be inhibited by NS1 protein. Conversely, upregulation of ZAPS levels resulted in disinhibition of the NS1 effect on RIG-I activity, and promoted the activation of IRF-3 and NF-κB pathways. Furthermore, the transgenic mice with upregulation of in vivo expression levels of ZAPS exhibited a resistance to lethal infection with influenza A virus. Thus, these findings indicate that the interaction of RIG-I and ZAPS is one of the key points, wherein NS1 inhibit RIG-I-mediated antiviral activity, which provides a mechanistic insight into innate immune evasion by influenza virus.

P4.01.038
Virus-associated activation of innate immunity induces rapid disruption of Peyer's patches in mice

***S. Heidegger**[1,2], D. Anz[2], N. Stephan[2], B. Bohn[2], T. Herbst[3], K. Eisenächer[1], C. Hotz[2,3], S. Endres[2], C. Bourquin[2,3];*
[1]TU München, Munich, Germany, [2]Ludwig-Maximilian-University, Munich, Germany, [3]University Fribourg, Fribourg, Switzerland.

Early in the course of infection, detection of conserved pathogen-associated molecular patterns by innate immune receptors can critically shape the subsequent adaptive immune response. Here we investigate the influence of virus-associated innate immune activation on lymphocyte distribution in secondary lymphoid organs. We show that virus infection of mice leads to rapid disruption of the Peyer's patches which form the main inductive site of intestinal immune responses. In contrast, other secondary lymphoid organs such as peripheral skin-draining lymph nodes were not affected. The observed effect was not dependent on an active infectious process but was due to innate immune activation and could be mimicked by virus-associated molecular patterns such as the synthetic double-stranded RNA poly(I:C). Profound histomorphological changes in Peyer's patches were associated with depletion of organ cellularity, most prominent among the B-cell subset. We demonstrate that the disruption is entirely dependent on type I interferon signaling. At the cellular level, we show that virus-associated immune activation by IFN-α blocks B-cell trafficking to the Peyer's patches. We further identified downregulated expression of the gut-homing molecule α4β7-integrin as the underlying molecular mechanism. We observed that B-cell distribution within the intestinal lamina propria, which is also dependent on the α4β7-integrin, was not altered following virus-associated innate immune stimulation. In summary, our data identify a mechanism that results in type I IFN-dependent rapid but reversible disruption of intestinal lymphoid organs during systemic viral immune activation. We suggest that such re-routed lymphocyte trafficking may impact the development of B-cell immunity during systemic viral infections.

P4.01.039
Aged-related changes in the immune response to influenza infection

***E. A. Hernandez-Vargas**[1], T. Ebensen[2], S. Binder[1], C. Guzman[2], M. Meyer-Hermann[1];*
[1]Department of Systems Immunology, Helmholtz Centre for Infection Research, Braunschweig, Germany, [2]Department of Vaccinology and Applied Microbiology, Helmholtz Centre for Infection Research, Braunschweig, Germany.

Elderly people are more susceptible to viral infections and response poorly to vaccination. In this regard, influenza virus infection is a worldwide health problem, which aggravates in individuals over 65 years of age. Therefore, the understanding of how influenza virus infection activates the immune system is crucial to design prophylactic and immune therapeutic strategies to reduce morbidity and mortality in the elderly. Nevertheless, the immune response to influenza virus infection is complex and remains largely unknown. Using experimental data for young and aged mice, we propose a mathematical model for influenza infection to reveal the relevant mechanisms which contribute to the impaired immune responses in the elderly. Experimental data revealed different kinetics for viral replication between young and elderly. The aged mice showed 1-2 days delay for the clearance of the virus. Results suggest that a reduced viral replication in epithelial cells as well as the impaired immune mechanisms directed by CD8+T cells may be responsible for the poor immune responses in the elderly. This work provides new insights for vaccination and immune intervention in the elderly.

Myeloid derived supressor cells restrain Natural Killer cell activity in CVB3 myocarditis

***L. M. Holz**, M. Sauter, N. Ettischer, R. Kandolf, K. Klingel;*
Molecular Pathology, University Hospital Tuebingen, Tuebingen, Germany.

Enteroviruses, especially coxsackievirus B3 (CVB3), are considered as most relevant agents of acute and chronic myocarditis. Underlying pathogenic mechanisms determining the course of enteroviral myocarditis are mainly investigated in murine models which perfectly match the different outcome of enteroviral myocarditis in humans. While the innate immunity of the host determines the first line of defense against the virus infection, the presence of ongoing inflammation indicates that acquired immunity plays an important role in the pathogenesis of chronic myocarditis.
The importance of Natural Killer (NK) cells for the efficiency of viral clearance and disease progression has been suggested a long time ago. Recently we could show that C57BL/6 mice which are resistant for chronic myocarditis enable more mature NK cells at any time of CVB3 infection in spleen and heart. NK cells from C57BL/6 mice also exert more IFN-γ and cytotoxicity and express more of the activating receptor NKG2D than those of permissive A.BY/SnJ mice. Myeloid derived suppressor cells (MDSC) are known to restrain NK cell activity in viral infections by inhibiting cytotoxicity, NKG2D expression and IFN-γ production. In order to investigate whether MDSC influence NK cell function in CVB3 myocarditis we compared expression profiles of MDSC subsets in A.BY/SnJ, C57BL/6 and NKG2D knock out mice in the course of CVB3 infection. The obvious variation in MDSC populations in these mouse strains denotes their role in the progression of viral myocarditis. Moreover, we confirmed these data by investigating the influence of MDSC on NK cells in in vitro experiments.

Influenza-specific B cell response in the human challenge model for influenza A virus

***A. K. Y. Huang**[1,2], C. Li[2], C. Chui[2], T. Wilkinson[3], R. Lambkin-Williams[4], A. Gilbert[4], J. Oxford[4], A. J. McMichael[2], X. Xu[2];*
[1]Department of Paediatrics, Chang Gung Children's Hospital, Taoyuan, Taiwan, [2]The Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, United Kingdom, [3]Clinical & Experimental Sciences, Faculty of Medicine, University of Southampton, Southampton, United Kingdom, [4]Retroscreen Virology, London, United Kingdom.

Influenza A virus is one of the major viruses causing acute respiratory infection in humans. Neutralising antibodies, measured by the haemagglutinin-inhibition assay, have been shown to be the protective correlate of influenza vaccination. Protective antibody levels might however be short-lived, because the antibody titre fades from the peak level at the first month of inactivated influenza immunisation or natural infection. Establishing new correlates of immunity, especially cellular aspects, could contribute to the evaluation of efficacy of new influenza vaccines. Studying the B cell response in adults may be useful to benchmark the response for other age extremities, in which the induction of antibody is relatively impaired and ineffective. Here, we studied the kinetics and magnitude of influenza virus-specific B cell and antibody responses, over the course of 28 days in sero-negative healthy adult volunteers experimentally infected with seasonal influenza H1N1 (A/Brisbane/59/07) virus. We demonstrated a robust strain-specific plasmablast and memory B cell responses in the peripheral blood, which correlated with the throat viral load and the duration of viral shedding, indicating an antigen-specific response. On day 28 post-infection, influenza virus-specific B cells were further identified from the circulating compartment of isotype-switched B cells. Our results clearly define the cellular basis of antibody response in human influenza infection and provide information that may assist in optimising the vaccine for the maintenance of protective antibody level in susceptible adults.

Inhibition of monocyte differentiation into dendritic cells by HTLV-I-infected breast milk macrophages

***S. Inagaki**[1,2], M. Takahashi[1], Y. Fukunaga[2], H. Takahashi[1];*
[1]Nippon Medical School,Departments of Microbiology and Immunology, Tokyo, Japan, [2]Nippon Medical School,Departments of Pediatrics, Tokyo, Japan.

Human T cell leukemia virus type I (HTLV-I), a causative agent of adult T-cell leukemia (ATL), is transmitted from mother to child predominantly by breastfeeding. Oral HTLV-I infection early in life is associated with a subsequent risk of ATL. Although the pathogenic mechanisms of ATL remain largely unknown, previous studies have shown that monocytes from ATL patients had reduced capacity for DC differentiation. In order to clarify the mechanisms responsible for the impairment of DC differentiation, we have established an immortalized macrophage cell line (HTLV-BrMMΦ: HTLV-I-infected breast milk macrophage) from BrMMΦ by persistent infection with HTLV-I. Because HTLV-I is transmissible from HTLV-BrMMΦ to peripheral blood mononuclear cells (PBMC), HTLV-BrMMΦ is a possible source of infection in mother to child transmission (MTCT). When CD14+ monocytes were cultured with GM-CSF and IL-4 in the presence of HTLV-BrMMø, they altered the surface phenotype of immature DC and reduced stimulatory capacity of T cell proliferation. Also, the expression of CD1a, CD1b, CD11b, DC-SIGN, and HLA-DR were CD1a, CD1b, CD11b, DC-SIGN, and HLA-DR were significantly blocked in the presence of HTLV-BrMMø. The impairment of monocyte differentiation might be not due to HTLV-I infection of monocytes but due to unknown soluble factors. Since other HTLV-I-infected cells exhibited similar inhibitory effects on monocyte differentiation to DCs, we speculated that HTLV-I infection might cause the production of some inhibitory cytokines in infected cells. Identifying the factors responsible for the impairment of monocyte differentiation to DCs may be helpful to understand ATL pathogenesis (244 words).

Dengue and other flavi virus specific T cell specific responses in healthy individuals in Sri Lanka

***K. C. Jeewandara**[1], G. N. Malavige[1,2], T. N. Adikari[1], M. Salimi[2], M. H. J. D. Ariyaratne[1], M. Peellawate[1], V. Jayasuriya[1], G. S. Ogg[2];*
[1]Centre for Dengue Research, Faculty of Medical Sciences, University of Sri Jayawardanapura,, Nugegoda, Sri Lanka, [2]MRC Human Immunology Unit, Weatherall Institute of Molecular Medicine, Oxford, United Kingdom.

Objective: Although infection with the dengue viras (DV) cause severe clinical disease in some individuals, it results in mild or asymptomatic infection in the majority of individuals. Therefore, we set out to determine correlates of a DV-specific protective immune response.
Methods: T cell responses to the DV NS3 peptides, Japanese encephalitis virus (JEV) and non dengue viral proteins were determined by Ex vivo IFNY ELISpot assays, in a 67 healthy volunteers. IFNY cultured ELISpot assays for serotype specific (SS) DV peptides were carried out using a previously defined panel of SS peptides for all 4 DV serotypes.
Results: SS T cell responses to at least one DV serotype were detected in 46/47 seropositive individuals but absent in all dengue seronegative(n=20) individuals. 23/46(53%) responded to only 1 DVserotype, 18/46(39.1%) to 2 serotypes and 3/46(6.5%) to 3 serotypes.
DV-NS3 specific responses were seen in 24(51.06%) and JEV responses in 18(38.3%) seropositive individuals. DV-NS3 responses were also seen in 3(15%), seronegative individuals. A significant and positive correlation was observed with the number of DV-serotypes a person responded to and ex vivo DV-NS3 responses (Spearman r = 0.65, p=0.001). A significant and positive correlation was also seen with the number of DV serotypes a person responded to and DV antibody titres (Spearman R=0.70,p<0.0001)
Conclusions: Our data suggest that this panel of SS peptides are useful in determining the past infecting DV serotypes. The frequency of DV- NS3 appear to rise with the number of DV infections a person has had.

Release of interleukin-1alpha from herpes simplex virus 1 infected keratinocytes provides a functional danger signal

*K. A. Milora, **L. E. Jensen**;*
Temple University School of Medicine, Philadelphia, PA, United States.

Herpes simplex virus-1 (HSV-1) is a human pathogen that utilizes several strategies to circumvent the host immune response. It has been reported that HSV-1 inhibits both apoptotic and inflammatory pathways in infected cells. We here document that HSV-1 infected keratinocytes release the pro-inflammatory cytokine interleukin-1 (IL-1), hence preserving the ability of the infected cells to signal danger to the surrounding tissue. During its lifecycle HSV-1 generates double stranded RNA. We have previously reported that the double stranded RNA analogue poly(I:C) induces pyroptosis in keratinocytes and extracellular release of IL-36. In a similar manner we here show that poly(I:C) triggers release of IL-1 from keratinocytes through a mechanism involving the inflammatory caspases, caspase-1 and/or caspase-4. Inflammatory caspases are activated in HSV-1 infected keratinocytes; however, the extracellular release of IL-1 is independent of this activity. To explore the *in vivo* role of the released IL-1 we employed a mouse model involving primary infections on flank skin, local spread to sensory nerves, retrograde axonal transport to the dorsal root ganglion, and secondary shingles-like blistering around nerves infected through anterograde migration of the virus. We observed no difference in secondary lesion sizes in wild type and IL-1 receptor (IL-1R1) knockout mice. However, a trend towards increased mortality of IL-1R1 knockout mice was observed, as mice ultimately developed encephalitis and/or disseminate disease. Hence, IL-1 signaling may be an important danger signal during HSV-1 skin infections.

Elevated plasma soluble Sema4D/CD100 level in patients with hemorrhagic fever with renal syndrome: positive correlation with disease severity

***B. Jin**[1], B. Liu[1], Y. Ma[1], J. Yi[1,2], Z. Xu[1], Y. Zhang[1], C. Zhang[1], R. Zhuang[1], J. Wang[3], Y. Zhang[1];*
[1]Department of Immunology, The Fourth Military Medical University, Xi'an, China, [2]Department of Blood Transfusion, Xijing Hospital,Fourth Military Medical University, Xi 'an, China, [3]Department of Infectious Disease, Tangdu Hospital, The Fourth Military Medical University, Xi'an, China.

Semaphorin 4D (Sema4D/CD100), which is broadly expressed on immune cells and could be cleaved proteolytically, generating a biologically active soluble form, is considered to be involved in several aspects of immunity, and also in some diseases such as tumors, autoimmune diseases, and HIV infection. However, the detection of CD100 and its pathological significance in patients with many other acute infectious diseases have not been reported. To investigate the pathological significance of soluble CD100 (sCD100) in patients after Hantaan virus infection, we detected the level of sCD100 in plasma samples from 99 patients and 27 healthy controls and found that the sCD100 level in acute phase was higher in patients than that in healthy controls (P<0.001), and declined in convalescent phase. Moreover, the sCD100 level was negative correlated with the platelet count and positive correlated with white blood cell count, serum creatinine or blood urea nitrogen of the patients. Overall, for the first time we reported the level of plasma sCD100 in patients with acute infectious disease. These results demonstrated that plasma sCD100 might be a novel biomarker for the severity of the disease.

Evaluation of the immune response of live attenuated mumps vaccines (RS-12 strain) produced with different stabilizers in guinea pigs

***R. Kamali Jamil**, Z. Sadigh, M. Taqavian, M. Shahkarami, F. Esna-Ashari;*
Razi Vaccine and Serum research Institute, Karaj, Iran.

Background and Aim: Mumps is a contagious disease belonging to Paramyxoviridae family. Although vaccination against mumps has been significantly beneficial, sensitivity to temperature is one of major obstacles in mumps vaccination. In the present study, two new stabilizers were used for manufacturing of live attenuated mumps vaccine, and immune response of this vaccines was evaluated after administration to guinea pigs.
Methods: Fist, mumps virus was harvested and blended with different stabilizers separately to prepare the final bulk. Then, the final product was prepared by lyophilization of final bulk. The final product subjected to quality control tests including: accelerated stability test, potency test, as well as in vivo test. For evaluation of immune response of the 3 mumps vaccines in experimental animals, vaccines were administered to guinea pigs. Furthermore mumps specific antibody level was measured in guinea pigs sera using Hemagglutination inhibition method (HI).
Results: Virus titration results of the vaccine containing new stabilizer showed that titer loss, before and after lyophilization, and after reconstitution was within WHO acceptable range. Analysis of results showed appropriate immune response in guinea pigs. Based on our findings the HI titer after administration of mumps vaccines with TD stabilizer was more than the two other stabilized live mumps vaccines.
Conclusion: increasing thermal stability of live attenuated viral vaccines such as mumps, can help to eradicate the disease, and can be useful economically. After long term stability tests, this mumps vaccine strain can be a suitable candidate for developing new mumps virus live attenuated vaccine.

A NK complex-linked locus restricts the spread of Herpes simplex virus type 1 (HSV-1) in the central nervous system (CNS) of C57BL/6 mice

L. F. Kastrukoff[1]*, A. S. Lau*[1]*, F. Takei*[2]*, A. A. Scalzo*[3]*, F. R. Carbone*[4]*;*
[1]University of British Columbia, Vancouver, BC, Canada, [2]British Columbia Cancer Research Centre, Vancouver, BC, Canada, [3]University of Western Australia, Nedlands, Australia, [4]University of Melbourne, Melbourne, Australia.

Natural resistance to mortality in mice infected with Herpes simplex virus type 1 (HSV-1) is mouse strain dependent and an autosomal dominant trait. In mice infected with virus via the oral mucosa, HSV-1 spreads throughout the central nervous system (CNS) of susceptible strains but is restricted to the brainstem of resistant mice. In resistant C57BL/6 (BL/6) mice, viral restriction is mediated by natural killer (NK) cells and $CD8^+$ T-lymphocytes.
We combined mendelian analysis, studies of congenic and intra-NKC recombinant mice, along with antibody depleted mice to further examine the restriction of viral spread in the brains of BL/6 mice.
We report a NK complex-linked genetic locus, *Hrl2*, whose alleles determine the restriction of viral spread in the CNS. Mendelian analysis determined that restriction of viral spread is a dominant trait and consistent with a single gene effect. Studies with congenic mice determined that the locus maps to the NKC on chromosome 6 but is separate from previously identified loci; *Hrl1* and *Rhs1*. Studies with intra-NKC recombinants determined that the locus maps to a segment between CD69 and D6Wum34. Studies with antibody depleted mice determined the effect of this locus is mediated by NK1.1 expressing cells.
A NK complex-linked locus (*Hrl2*) restricts the spread of HSV-1 in the CNS of BL/6 mice however the precise mode of action of the locus remains unknown.

P4.01.049

The importance of cross-strain protective human TCR signatures for universal immunity against influenza

S. Valkenburg[1]*, S. Quinones Parra*[1]*, L. Loh*[1]*, S. Gras*[2]*, L. Kedzierski*[3]*, J. Rossjohn*[2]*, P. C. Doherty*[1]*, S. Turner*[1]*, P. G. Thomas*[4]*,* ***K. Kedzierska***[1]*;*
[1]University of Melbourne, Parkville, Australia, [2]Monash University, Clayton, Australia, [3]WEHI, Parkville, Australia, [4]St Jude Children's Research Hospital, Memphis, TN, United States.

In contrast to the current antibody-mediated and strain-specific influenza vaccines, T-cells directed at conserved internal proteins elicit broad immunity against seasonal and pandemic influenza viruses. Here, we dissected the optimal human influenza-specific $CD8^+$ T-cell populations across different HLAs, both at functional and clonal levels, to provide insights into universal immunity against influenza. We have generated a database of the influenza-specific antigenic regions restricted by the majority of human HLA-A and HLA-B alleles, and determined how conserved these regions were in influenza viruses circulating over the last century. We found that although sporadic variations can be found across many peptides, mutations 'escaping' T-cell recognition get fixed only for selected $CD8^+$ T-cell populations. Using a human single-cell multiplex RT-PCR for TCRαβ, we found that specific TCRs can recognize multiple variants derived from different influenza strains. For example, a dominant public TCR clone (TRAV27 GGSQGNL; TRBV19 SIRSSYEQ) found at high frequency within $M1_{58}{}^+CD8^+$ T-cell responses in all HLA-A*0201^+ individuals can recognize the naturally-occurring variants of the peptide. This suggests that the HLA-$A2^+$ population (30-50% global coverage) have universal T-cell immunity to any $M1_{58}$ variant, which can, at least in part, explain high conservation level for $M1_{58}$. Conversely, TCR clones within the $B7^+NP_{418}{}^+CD8^+$ populations differentially recognise distinct peptides from either the pandemic or seasonal influenza viruses. Our current analyses across other HLAs extend these findings. Thus, our studies suggest that a pre-emptive influenza vaccine that elicits TCR pools, which recognize distinct antigenic variants can provide universal immunity against any future influenza strain or subtype.

T cell mediated mortality in neonatal mice upon LCMV infection

L. L. Kenney*, E. P. Carter, L. K. Selin;*
University of Massachusetts Medical School, Worcester, MA, United States.

Newborns are more susceptible to infections due to their lack of immunological memory and under-developed immune systems. Passive maternal immunity protects neonates until their immune systems have matured. We questioned if a noncytolytic virus that produces strong T cell responses in adults would also induce a response in neonates. Neonates were infected with LCMV at 5e4, 500, 50, 5 and 0.5 PFU. Surprisingly, at all doses the majority of pups succumbed to infection during the peak of the T cell response. Death was caused by T cell-dependent pathology and not viral load as 100% of T cell deficient pups survived with minimal lung and liver pathology. However, passive immunity from LCMV-immune mothers protected 100% of pups from death by helping control viral load early in infection. In adult mice high antigenic stimulation can cause over-activation of T cells leading to clonal exhaustion, where cells undergo a stepwise loss of function. Clonal exhaustion allows for survival from some high dose viral infections and results in persistent infection. We found that neonates without passive immunity that survived to day 14 did not show signs of T cell clonal exhaustion. Furthermore, surviving pups were not persistently infected, clearing virus by week 3. Neonates are commonly thought to have less functional immature immune systems, but these results show that neonates are capable of producing strong T cell responses that contribute to increased mortality.

P4.01.051

Association between IL-28B(rs12979860) polymorphisms of interferon-λ (IFN- λ) family with Hepatitis C virus infection outcome

R. Khajavi(M.Sc)*, A. Rafiei(Ph.D);*
Molecular and Cell Biology Research Center, mazandaran university of medical sciences, sari, mazandaran, Iran, Sari, Iran.

Background&Aim: Hepatitis C infection is a global health problem There are several factors, which is effective on developing diseases outcome in individuals infected with HCV such as, environmental condition, host genetic factors. Single nucleotide polymorphisms near the human IL-28B gene are associated with sustained virologic response.The aim of this study was to evaluate the influence of IL28B genotypes on SVR rates in a group of patients with chronic hepatitis C. Materials and methods: In this study, 133 HCV-RNA positive patients, 96 samples (72.2%) males and 37 samples (27.8%) females with mean age of 36.38±12.49 years,and 173 healthy volunteers with age, sex and geographical area matched with patients were recruited. DNA was extracted and genomic DNA were amplifed for IL-28B gene polymorphism by Tetra-ARMS-PCR.
Results: In the present study, the frequencies of the IL-28B genotypes (rs-12979860) in patients were as follows: C/C, 41.4%; C/T, 41.6% and T/T, 17.3%. Frequencies of the IL-28B genotypes in healthy control were in healthy control as follows: C/C, 42.5%; C/T, 40.6% and T/T, 16.9%. 85.5% patients with the C/C genotype achieved a sustained virologic response (SVR), compared with 44.4% with the C/T and 21.7% with the T/T genotype ($p<0.0001$).
Conclusion: There was not a significant difference in polymorphism of IL-28B between patients and controls. IL-28B (rs12979860) CC genotype was associated with a better treatment response rate. The SVR rate significantly associated with the C allele Genetic change in IL-28B gene as an independent variable in determining the efficiency of response to antiviral therapy will be important.

P4.01.052

Regulatory T cells in persistently virus infected hosts influenced immune responses against superinfection with unrelated viruses

*J. Duppach[1], S. Francois[1], T. Sparwasser[2], U. Dittmer[1], **A. R. M. Kraft**[3,1];*
[1]Department of Virology, University Duisburg-Essen, Essen, Germany, [2]Institute for Infection Immunology, TWINCORE, Centre for Experimental and Clinical Infection Research, Medical School Hanover-MHH-Helmholtz Centre for Infection Research-HZI, Hannover, Germany, [3]MMH Gastroenterology, Hannover, Germany.

Expansion of regulatory T cells (Tregs) and dysfunctional T cell responses are found in chronic virus infections (e.g. HIV, HCV). It is still unclear whether Tregs from chronic infections may influence immune responses against superinfections with unrelated viruses in vivo.
Therefore we established a mouse model: mice persistently infected with Friend Virus (FV), a murine retrovirus, were superinfected with the murine cytomegalovirus (mCMV). We found that FV expanded Treg cells significantly decreased mCMV-specific T cell responses during primary mCMV superinfection in persistently FV infected mice. In addition, we detected that a primary mCMV infection led to 'reactivation' of FV resulting in functional FV-specific T cells. However, FV expanded Tregs were not influenced during mCMV infection and were rapidly able to dampen the 'newly' generated FV-specific T cell responses.
Here, we show for the first time that Treg cells expanded in a chronic virus infection played an important role during superinfection with unrelated viruses.

P4.01.053

Granzyme B mediated T-cell immunity against small DNA viruses

***A. Kumar**[1], A. Kantele[2,3], L. Hedman[1], K. Hedman[1], R. Franssila[1];*
[1]Department of Virology, Haartman Institute, University of Helsinki, Helsinki, Finland, [2]Department of Bacteriology and Immunology, Haartman Institute, University of Helsinki, Helsinki, Finland, [3]Division of Infectious Diseases, Helsinki University Central Hospital, Helsinki, Finland.

Objectives. A novel role for CD4+ T cells with cytolytic potential (CD4+ CTL) is emerging. These cells appear to have a role in controlling malignancies and chronic infections. Human parvovirus B19 establishes a persistent infection, yet no data has been reported whether B19 -specific CD4+ CTLs are present. Such cells could have a role in the pathogenesis of autoimmune disorders and possibly in some thyroid malignancies associated with B19.
Methods. Cytolytic responses of human parvovirus B19 specific T cells were explored by, stimulating peripheral blood mononuclear cells (PBMC) with recombinant B19-VP2 virus like particles (VLPs). Human bocavirus 2 (HBoV2) VLPs and *Candida albicans* antigens served as control antigens. Cytolytic potential was evaluated by EIA-based quantitation of Granzyme B (GrB) from tissue culture supernatants.
Results. GrB responses induced by the B19 antigen were readily detectable and stronger than the responses with the HBoV control antigen. T cell depletion and HLA blocking experiments showed that the GrB was secreted by CD4+ T cells. Interestingly, some B19 seronegative subjects also showed GrB responses with B19 VLPs.
Conclusion. A vigorous B19-specific GrB response was found in seropositive individuals suggesting role for CD4+ CTLs in B19 immunity. Such cells could potentially function in, immune regulation and triggering of autoimmune phenomena, possibly including even some cases of SLE or rheumatoid arthritis.

P4.01.054

TLRs expression dynamics in patients with herpes-associated erythema multiforme due to immunotherapy

*E. A. Sorokina[1], N. K. Akhmatova[1], S. Skhodova[1], **O. V. Lebedinskaya**[2];*
[1]I.I. Mechnikov Research Institute for Vaccines and Sera RAMS, Moscow, Russian Federation, [2]Acad. E.A. Wagner Perm State Medical Academy, Perm, Russian Federation.

Herpes-associated erythema multiforme (GAEM) is the most common form among erythemas. Long-term virus persistence in the body leads to development of secondary immunodeficient states. Defects in the mechanisms of recognition of various microbial PAMPs by TLRs expression changes may impair the immune response. The aim of investigation was to study the TLRs expression on PBMC and in the skin of GAEM-affected patients and dynamics of these indicators in the course of therapy. TLRs expression levels were determined by flow cytometry. In study of 39 GAEM-affected patients there was observed high TLRs level in their sera, which confirms the obvious role of viruses in the pathogenesis of dermatosis. In patients with disease duration of less than 6 months there were low values of TLR2 (up to 0.05%) and TLR4 (0.1%) due to increased expression of TLR3 (up to 96.7%) and TLR9 (up to 97.8%). In patients with combined GAEM HSV1 and HSV2 infection in the form of recurrent facial herpes and genital herpes the expression levels of TLR4 and TLR9 in the sera were by 4-fold greater than the values of healthy subjects. Immunovac-VP-4 therapy favored to increase the TLR2, 3,9 expression in sera. Overexpression of these TLRs may be a laboratory marker of the outbreak, the severity of infection and the effectiveness of the therapy. Along with the appointment of antiviral complex the therapy with immunomodulators restores cell cooperation in the immune response of GAEM-affected patients. This work was supported by RFBR grant №11-04-96037r_ural_a and administrative body of Perm Region.

P4.01.055

Interferon-γ regulates contraction of the influenza-specific CD8 T cell response and limits the size of the memory population

*N. Prabhu[1], **D. C. P. Lee**[1], A. W. Ho[1], K. H. S. Wong[1], P. E. Hutchinson[1], Y. Chua[1], S. Baalasubramanian[2], D. M. Kemeny[1];*
[1]National University of Singapore, Singapore, Singapore, [2]Agency for Science, Technology and Research (A STAR) Singapore, Singapore, Singapore.*

Understanding the mechanisms of virus-host interactions and the factors that regulate memory T cell responses are important for the generation of efficient vaccines. The factors that regulate the contraction of CD8 T cell responses and the magnitude of the memory population against localized mucosal infections such as influenza are currently undefined. Using a mouse model of influenza infection we demonstrate that the absence of IFN-γ or IFN-γR1 leads to aberrant contraction of antigen-specific CD8 T cell responses. The increased accumulation of the effector CD8 T cell population was independent of viral load. Direct *ex vivo* analysis
revealed an increased amount of cell death in influenza-specific-CD8 T cells from infected wild type (WT) mice compared to IFN-$\gamma^{-/-}$ mice.
The absence of contraction was associated with an increased fraction of CD8 T cells expressing the interleukin-7 receptor at the peak of the response, indicating enhanced numbers of memory/precursor cells in IFN-$\gamma^{-/-}$ and IFN-γR1$^{-/-}$ mice compared to WT after the peak of the CD8 T cell response. Re-challenge of the infected mice with a heterologous strain of influenza enhanced the CD8 T cell recall response in the IFN-$\gamma^{-/-}$ and IFN-γR1$^{-/-}$ compared to WT mice, confirming that higher frequencies of memory precursors are indeed formed in the absence of IFN-γ signaling. In summary, we have identified IFN-γ as an important regulator of
localized viral immunity that promotes the contraction of antigen-specific CD8 T cells and inhibits memory precursor formation, thereby limiting the size of the memory cell population after influenza infection.

P4.01.056
Regulation of inducible expression of syncytin-1 following influenza A/WSN/33 virus infection

F. Li[1], C. Nellåker[2], A. Johansson[1], B. Owe-Larsson[1], S. Sabunciyan[3], H. Karlsson[1];
[1]Karolinska Institutet, Stockholm, Sweden, [2]Oxford University, Oxford, United Kingdom, [3]Johns Hopkins School of Medicine, Baltimore, MD, United States.

Syncytin-1, a highly fusogenic envelope protein encoded by a human endogenous retrovirus (HERV-W) element (*ERVWE1* locus) on chromosome 7q21, is normally expressed exclusively in the syncytiotrophoblast layer of the human placenta. Whereas syncytin-1 appears crucially involved in the development and functioning of the human placenta, its ectopic expression in adult tissue has been associated to a range of pathological conditions, such as cancer, multiple sclerosis (MS), amyotrophic lateral sclerosis (ALS), preeclampsia and schizophrenia. We previously reported on the transactivation of HERV-W elements, including that encoding syncytin-1 by influenza A/WSN/33 virus infection in a range of human cell-lines of non-placental origin. The mechanisms underlying the transactivation by virus infection were, however, not identified. qPCR analysis indicated up-regulation of transcripts encoding transcription factor glial cells missing 1 (GCM1) and syncytin-1 in response to influenza A/WSN/33 virus infection in both malignant cell-lines and primary fibroblast cells. Knock-down expression of GCM1 by siRNA, followed by viral infection suppressed the transactivation of the gene encoding syncytin-1 in CCF-STTG1 cells. Pyrosequencing analysis revealed high methylation levels of *ERVWE1* promoter and enhancer regions in non-placental cells in comparison with human choriocarcinoma JEG-3 cells. No alteration of methylation status was observed between uninfected and virus infected non-placental cells. Our results indicated that inducible expression of syncytin-1 following influenza A/WSN/33 virus infection in non-placental cells come from elevation of both unspliced (corresponding to retro-viral genomes) and spliced *ERVWE1* transcipts (encoding syncytin-1). Expression of syncytin-1 appear critically linked to GCM1 during both physiological and pathological conditions. Expression of the transcription factor GCM1 is required for expression of syncytin-1.

P4.01.057
Profile of NAb responses in HIV-1-infected individuals in China and epitope analysis of viral envelope from broad neutralizers

*C. Ren[1], S. Liu[1], Y. Li[1], H. Yu[1], J. Wang[1], Z. Chen[2], F. Sun[2], W. Liu[3], S. Liang[3], P. Zhong[4], M. Zhuang[1], **H. Ling**[1];*
[1]Harbin Medical University, Harbin, China, [2]Xinjiang Yili Prefecture CDC, Yili, China, [3]Guangxi CDC, Nanning, China, [4]Shanghai CDC, Shanghai, China.

To clarify the profile of neutralizing antibody (NAb) responses in HIV-1-infected individuals in China and the epitopes of viral envelopes from broad neutralizers, the neutralizing ability of plasmas from chronic infected individuals from Xinjiang and Guangxi Province, against pseudoviruses of subtypes B, C, CRF07_BC, CRF01_AE and B' using the TZM-b1 pseudovirus assay were analyzed. Breadth and strength of neutralization of the plasmas were evaluated. Viral species in infected individuals with broad NAb responses (broad neutralizers) were analyzed using a single genome amplification (SGA) of envelope genes and sequencing followed by bioinformatics analysis. We found that in Xingjiang Province, where most samples were derived from IDUs, 3.2% of the plasmas can neutralize four subtype B viruses and 5.3% can neutralize four subtype C viruses at inhibition higher than 80% of infection. Only 1.6% and 0.8% of the plasmas were able to neutralize the viruses of both B and C subtypes. 0.8% of the plasmas were able to neutralize all 11 viruses of three different subtypes, B, C, and CRF01_AE at higher than 80% of infection. However, in individuals from Guangxi province where most samples were derived from sexual contact infection, lower neutralization titers were found with same virus set. Unique epitopes were identified within viral envelope glycoprotein of broad neutralizers. (This work was supported by the National key project 2008ZX10001-012).

P4.01.058
Delivery of human EV71 receptor by adeno-associated virus increase EV71 infection in adult mice

***S. Liu**[1], H. Shiao[1], A. Chou[1], S. Lin[1], I. Chen[1], P. Chong[1], M. Tao[2];*
[1]National Health Research Institutes, Miaoli County, Taiwan, [2]Academia Sinica, Taipei, Taiwan.

Enterovirus 71 (EV71) is responsible for hand, foot, and mouth disease in children under 6 years of age. Recently, there are two EV71 receptors in human have been identified human P-selectin glycoprotein ligand-1 (hPSGL-1) and human scavenger receptor class B, member 2 (hSCARB2) as the functional EV71 receptors. We hypothesized that delivery of hPSGL-1 by adeno-associated virus (AAV) could increase EV71 infection in adult mice. To prove this hypothesis, both green hSCARB2 and hPSGL-1 gene was cloned into AAV vector to generate rAAV- hSCARB2 and rAAV-hPSGL-1 virus. We found that oral and intravenous administration of rAAV-GFP can express highest level of GFP in the intestine and other organs. Based on this result, rAAV-hSCARB2 and rAAV-hPSGL-1 were administered by oral and intravenous route for gene transfer. The expression levels of both hSCARB2 and hPSGL-1 in the intestine and brain were analyzed using real-time PCR and Immunohistochemistry. Histopathological examination revealed that the expression of hSCARB2 and hPSGL-1 in brain and intestine were detected after 4 weeks. After EV 71 infections, we also found that both hSCARB2 and rAAV-hPSGL-1 infected mice could up-regulate cytokines secretion in brain or intestine. Moreover, the infectious EV71 viral particles were detected in the brain and intestine from the infected animals. Although the increased EV71 infection did not show neurological manifestations, this technology could be applied to innate receptor-deficient mice to increase their infection and pathogenesis in adult mice.

P4.01.059
Double-stranded RNA (dsRNA)-induced IP-10/CXCL-10 production is augmented by Fas activation

***C. Lyons**[1], R. Moran[2], A. Houston[3], E. Brint[1];*
[1]Dept. of Pathology, University College Cork, Cork, Ireland, [2]University College Cork, Cork, Ireland, [3]Dept. of Medicine, University College Cork, Cork, Ireland.

Viral double-stranded RNA (dsRNA) is recognised by Pathogen Recognition Receptors (PRRs) including RIGI-like Receptors (RLRs) and Toll-Like Receptors (TLRs) and results in cytokine/chemokine production. Fas, a well characterised death receptor, may also mediate inflammation. Our aim was to investigate potential crosstalk between the Fas signalling pathway and anti-viral signalling pathways.
THP-1 monocyte-derived macrophages (THP1-Mø's) were stimulated with poly(I:C) (dsRNA mimetic) +/-agonistic anti-Fas antibody (CH-11). Co-stimulation resulted in a 50% reduction in IL-8, TNFα, IFNβ and IL-10, relative to poly(I:C) alone, as assessed by qRT-PCR. In contrast, IP-10/CXCL-10 production increased by 50% following co-stimulation relative to poly(I:C) alone. Results were confirmed using human monocyte-derived macrophages.
Fas-associated death domain (FADD) is recruited to Fas following Fas activation and is required for Fas signalling. Overexpression of FADD inhibited poly(I:C)-induced IP-10 luciferase production, while inhibiting FADD signalling by overexpressing the FADD death-domain augmented poly(I:C)-induced IP-10 luciferase. To further confirm the role of FADD in poly(I:C)-induced IP-10/CXCL-10 production, wild-type and $FADD^{-/-}$MEFs were treated with increasing doses of poly(I:C). IP-10/CXCL-10 production in $FADD^{-/-}$MEFs was increased compared to wild-type MEFs.
Our results indicate that activation of the Fas signalling pathway, may be necessary for optimal poly(I:C) induced IP-10/CXCL-10 production. As IP-10/CXCL-10 is a potent T-cell chemo-attractant, cross-talk between these pathways may potentially promote the recruitment of T-cells to sites of viral infection.

P4.01.060
Contribution of Hantaan virus-specific CD4$^+$ T cells to anti-viral T-cell response in humans

***Y. Ma**, B. Yuan, Y. Zhang, Y. Zhang, B. Liu, C. Zhang, R. Zhuang, B. Jin;*
Department of Immunology,Fourth Military Medical University, Xi'an, China.

Hantaan virus (HTNV), the prototype of genus Hantavirus, could cause the lethal hemorrhagic fever with renal syndrome in human. Our previous studies have shown that the HTNV-specific CD8$^+$ T-cell responses were essential to control the HTNV infection. However, the contribution of CD4$^+$ T cells to the host response against HTNV infection has not been clear. Here, we mapped the CD4$^+$ T-cell epitopes with IFN-γ ELISPOT assays, using 351 overlapping peptides spanning the entire structure protein of HTNV in a large cohort of HTNV-infected individuals. A total of 65 novel 15-mer CD4$^+$ T-cell epitopes of the HTNV were identified, among which 24 peptides were dominant target epitopes. Using intracellular cytokine staining and proliferative assays, we found that the epitopes-specific CD4$^+$ T cells showed an effector memory and differentiation phenotype (CD27$^-$ CD28$^{+/-}$CCR7$^-$CD45RA$^-$), and displayed multiple-cytokine patterns including IFN-γ and TNF-α, meanwhile the CD107a, granzyme B and perforin, suggesting the effective and cytotoxic ability against HTNV infection. Furthermore, the HTNV-specific CD4$^+$ T cells derived from more severe patients with much higher viral load displayed narrower antigenic repertoire and much weaker responses, meanwhile, an impaired proliferative capacity than those from patients with milder outcome. Taken together, these results indicate that the effective HTNV-specific CD4$^+$ T-cell response is important for virus control, which would add weight to understanding the important role of CD4$^+$ T-cell response after HTNV infection and provide a rationale foundation to speed up the process of effective vaccine development.

P4.01.061
CD200R1 is required for sustained HSV-1 infection and for HSV-induced and TLR2-dependent response

***C. R. MacKay**, E. Kurt-Jones;*
University of Massachusetts Medical School, Worcester, MA, United States.

Herpes Simplex Virus (HSV) is a highly prevalent human pathogen and is the most common cause of sporadic encephalitis, a devastating disease of the central nervous system (CNS). Herpes Simplex Encephalitis (HSE) results in tremendous damage to the CNS, which is thought to be caused by both direct viral damage to the brain and the body's immune response to the infection. CD200R1 is expressed on myeloid cells and on brain microglia. We have found that CD200R1-deficient cells are not able to support robust HSV replication, when compared to wild-type cells. HSV-1 infection of the brains of wild type but not CD200R1 knockout mice resulted in sustained virus replication suggesting that CD200R1 expression is pro-viral. CD200R1 was also important for the TLR2 response induced by HSV-1. Without CD200R1, cells are unable to secrete IL-6 upon either HSV-1 infection or upon TLR2 stimulation with lipopeptides. Our studies demonstrate that CD200R1 is an important component of both the replication cycle of HSV-1 and the innate immune response of the host to herpesvirus infection and TLR2-stimulation..

P4.01.062
α-defensin-induced MxA expression in healthy human periodontal tissue

***R. Mahanonda**[1], N. Sa-Ard-Iam[1], P. Rerkyen[1], A. Thitithanyanont[2], K. Subbalekha[1], S. Pichyangkul[3];*
[1]Chulalongkorn University, Bangkok, Thailand, [2]Mahidol University, Bangkok, Thailand, [3]USAMC-AFRIMS, Bangkok, Thailand.

Although periodontal tissue is continually challenged by microbial plaque, it is generally maintained in a healthy state. To understand the basis for this, we investigated innate antiviral immunity in human periodontal tissue. The expression of mRNA encoding different antiviral proteins, myxovirus resistance A (MxA), protein kinase R (PKR), oligoadenylate synthetase (OAS), and secretory leukocyte protease inhibitor (SLPI) were detected in both healthy tissue and that with periodontitis. Immunostaining data consistently showed higher MxA protein expression in the epithelial layer of healthy gingiva as compared with tissue with periodontitis. Human MxA is thought to be induced by type I and III IFNs but neither cytokine type was detected in healthy periodontal tissues. Treatment *in vitro* of primary human gingival epithelial cells (HGECs) with α-defensins, but not with the antimicrobial peptides β-defensins or LL37, led to MxA protein expression. α-defensin was also detected in healthy periodontal tissue. In addition, MxA in α-defensin-treated HGECs was associated with protection against avian influenza H5N1infection and silencing of the MxA gene using MxA-targeted-siRNA abolished this antiviral activity. To our knowledge, this is the first study to uncover a novel pathway of human MxA induction, which is initiated by an endogenous antimicrobial peptide, namely α-defensin. This pathway may play an important role in the first line of antiviral defense in periodontal tissue.

P4.01.063
Immflammation in Influenza A H1N1 pandemic virus

***P. Martinez-Orellana**[1], R. Almansa[2], B. Bidana[1,3], L. Cordoba[1], J. Martínez[3], J. Bermejo-Martin[2], M. Montoya[1,4];*
[1]Centre de Recerca en Sanitat Animal (CReSA), UAB-IRTA, Campus de la Universitat Autònoma de Barcelona, Barcelona, Spain, [2]Infection and Immunity Medical Investigation Unit, Hospital Clínico Universitario - Instituto de Estudios de Ciencias de la Salud de Castilla y León,, Valladolid, Spain, [3]Departament de Sanitat i d'Anatomia Animals, Universitat Autònoma de Barcelona (UAB), Barcelona, Spain, [4]Institut de Recerca i Tecnologia Agroalimentàries (IRTA), Barcelona, Spain.

Objective: Evaluate how overproduction of proinflammatory cytokines induced by LPS might affect host immune response and clinical course of infection in C57/Bl6 H1N1 influenza A pandemic virus infected mice.
Material and methods: Four groups of mice were compared, based upon the challenge they were exposed to: 1) LPS 2) pandemic H1N1 Influenza A virus (pH1N1) + LPS 3) pH1N1 4) mock. LPS intraperitoneally inoculum dose were 200 µg/mice and pH1N1 infection dose was $2*10^5$ PFU/mice. Samples of serum, lung and spleen were collected at different time-points in order to assess levels of IL-6 by ELISA. Histopathological studies, body weight changes and clinical signs were evaluated daily.
Results: Mice infected with H1N1 and treated with LPS showed a higher percentage of weight loss and a longer recovery period related with a higher histophatological score as compared with LPS-untreated mice. Levels of IL-6 in lung of infected animals were similar within groups, large amounts of this protein was observed at day 5pi.
Conclusion: Results so far indicated that treated with LPS and infected with H1N1 showed a more virulent/pathogenic disease progression, by an IL-6 independent mechanism. Further analysis are in progress.

Strategies eliciting cross-reactive CD8+ T cell immunity by increasing cross presentation of nonreplicating viral immunogens

***C. Martire**[1], B. Garulli[2,3], G. Di Mario[2], M. R. Castrucci[2], V. Barnaba[1], D. Accapezzato[1];*
[1]Department of Internal Medicine and Medical Specialties, "Sapienza" University of Rome, Rome, Italy, [2]Department of Infectious, Parasitic and Immune-Mediated Diseases, Istituto Superiore di Sanità, Rome, Italy, [3]Department of Biology and Biotechnology "Charles Darwin", "Sapienza" University of Rome, Rome, Italy.

Studies of humoral immunity indicate that influenza virus evades antibody response directed exclusively against haemagglutinin and neuraminidase, by varying targeted epitopes and antigenic shift. Cytotoxic T lymphocytes (CTL) directed to more conserved structure proteins may result in a cross protective immunity against different influenza strains or pandemic viruses.

The annual vaccine, based on whole inactivated influenza virus is incapable to elicit a consistent CD8 influenza specific response. The ideal influenza vaccine would generate CTL that recognizes highly conserved viral peptides presented by HLA class I of infected cell. To this end the cross reactive CD8 memory response was evaluate in healthy individuals to different HLA supertype restricted epitopes derived from avian influenza virus isolated in poultry worker in northern Italy, (A/turkey/Italy/214845/2002(H7N3)). The highest CTL frequency recognized epitopes derived from matrix protein, basic polymerase complex and nucleoprotein. Several epitope-specific clones were generated and used in cross presentation assay to evaluate the recognition of peptide from dendritic cell pulsed with whole inactivated PR8, X31, H7N3 viruses. So we set up an efficient antigen presentation assay aimed to identify novel molecules or drugs improving cross presentation. Preliminary data demonstrate the ability of lysosomotrophic drug (chloroquine) to improve cross-presentation by inhibition of endosomal protease. Chloroquine may represent possible adjuvant in vaccine formulation that can recall CD8 and antibody response resulting in more vaccine efficiency.

P4.01.065
mTOR-dependent regulation of mucosal CD8 T cell immunity

*R. T. Sowell[1], M. Rogozinska[1], C. E. Nelson[2], V. Vezys[2], **A. L. Marzo**[1];*
[1]Rush University Medical Center, Chicago, IL, United States,
[2]University of Minnesota, Minneapolis, MN, United States.

Mucosal tissues are sites of frequent pathogen exposure and major routes for the transmission of infectious diseases. Migration of virus-specific memory CD8 T cells into mucosal tissues such as the small intestine and vaginal mucosa is highly restricted to non-circulating tissue resident memory CD8 T cells. Resident mucosal memory CD8 T cells are sufficient to protect against the establishment of mucosa-acquired viral infections, and thus it is essential to develop vaccine strategies that elicit long-lived mucosal CD8 T cells. CD8 T cells residing in mucosal tissues are phenotypically distinct from those in secondary lymphoid tissues and factors critical for their formation are poorly defined. It is also unclear whether mucosal CD8 T cells possess a unique requirement for their generation and maintenance from that of circulating memory CD8 T cells. We report that unlike in the secondary lymphoid tissues, the formation of virus-specific memory CD8 T cells in the small intestine and vaginal mucosa is dependent on mTOR signaling. In addition, we demonstrate using a CD8 T cell mediated model of intestinal autoimmune disease that inhibiting mTOR results in a loss of CD8 T cells in the small intestine and protects mice from lethality. Furthermore, we will discuss data that targets mTOR signaling intrinsically within the CD8 T cells to provide mechanistic insight into how the mTOR pathway specifically controls the generation of mucosal CD8 T cells in response to viral infections.

mTOR regulates protection against a lethal H5N1 influenza infection by modulating the antibody response

***M. A. McGargill**[1], R. Keating[1], T. Hertz[2], M. Wehenkel[1], T. L. Harris[1], B. A. Edwards[1], J. L. McClaren[1], S. A. Brown[1], P. C. Doherty[1], P. Thomas[1];*
[1]St. Jude Children's Research Hospital, Memphis, TN, United States,
[2]Fred Hutchinson Cancer Research Center, Seattle, WA, United States.

Highly pathogenic H5N1 avian influenza A viruses pose a serious threat for global catastrophe. Current vaccines do not provide protection against novel influenza A viruses that have emerged through genetic reassortment across different species, and attempts to create universal influenza vaccines have, as yet, been unsuccessful. We show here that rapamycin, an immunosuppressive drug that inhibits mTOR, promoted cross-strain protection against lethal H5N1 infection when administered during immunization with a serologically different H3N2 influenza virus. Rapamycin treatment reduced germinal center formation and B cell class-switching, yielding a unique repertoire of antibodies that enhanced protection against a lethal, heterosubtypic influenza infection. These data not only establish a requirement for mTOR in B cell class-switching, but also demonstrate that a broader antibody repertoire, which provides better protection against multiple strains of influenza, can be achieved by reducing germinal center formation during the primary infection. These findings have important implications in designing universal influenza vaccines.

P4.01.067
Influence of the factors OCT3/4, SOX2, KLF4 or c-Myc on cell transformation promoted by the oncoprotein tax from HTLV-I

***G. E. A. B. Melo**, K. T. Jeang, L. Zane, E. R. Vieira;*
Federal University of Jequitinhonha and Mucuri Valleys, Diamantina, Brazil.

Human T-cell leukemia virus type 1 (HTLV-I) infects approximately 15-20 milion people worldwide and is able to cause Adult T-cell Leukemia (ATL). The virus encodes the oncoprotein Tax wich can immortalize human T-lymphocytes and transform rodent cells in vitro. However the mechanism involved in cell tranformation by Tax are not fully understood. It has been shown that cancers are comprised of two broad categories of cells: those with high- and those with limited-proliferative potential. Cells in the former category are termed cancer stem cells. CSCs share several properties with adult stem cells, particularly the abilities to self-renew and differentiate into multiple cell types. Our new research proposal addresses a key question "Can the HTLV-1 Tax oncoprotein transform embryonic stem cells better than primary cells?" In the present study NIH3T3 cells were transfected with both Tax and individual pluripotence-associated factors (OCT3/4, SOX2, KLF4 and cMYC into CMV3.1 expression plasmid) communly used for cell reprograming. Hella cells were used as tranformed cell control. The cell growing of the transfected cells was kept on soft agar and the cell colony counting (UFC) was achieved using ImageJ software. According to the results, cell transfection using Tax plus KLF4 (mean=197±13.4) and Tax plus OCT3/4 (mean=94.7±18.0) promoted a higher UFC counting as compared to the cells trasfected with Tax (mean=21,3±8,7) or the other factors, isolately. Althouth very preliminar, the results presented here point to an interessting way for future investigations on cell transformation pathways observed in HTLV-I infection.
Support: FAPEMIG CNPq and CAPES.

IDO activity by langerin-negative dendritic cells contributes to local immune suppression in the skin expressing HPV oncoprotein E7

***D. Mittal**[1], A. Kassianos[2], G. Leggatt[1], I. Frazer[1];*
[1]Translational Research Institute, The University of Queensland Diamantina Institute, Brisbane, Australia, [2]Queensland Institute of Medical Research, Brisbane, Australia.

Chronic infection of anogenital epithelium with human papillomavirus (HPV) promotes development of cancer. Many pathogens evoke immunosuppressive mechanisms to enable persistent infection. We have previously shown that grafted skin expressing HPV16 E7 oncoprotein from a keratin-14 promoter (K14E7) is not rejected by a syngeneic, immunocompetent host. In this study we show that indoleamine 2, 3-dioxygenase (IDO) 1, an IFN- inducible immunoregulatory molecule, is more highly expressed by dendritic cells from K14E7 skin than nontransgenic control skin. Furthermore, inhibiting IDO activity using 1-D/L-methyl tryptophan promotes K14E7 skin graft rejection. Increased IDO1 expression and activity in K14E7 skin requires IFN- and iNKT cells, both of which have been shown to negatively regulate T-cell effector function and suppress K14E7 graft rejection. Further, $CD11b^{hi}$ $Langerin^{-}$ dendritic cells from K14E7 skin express high level of IFN- receptor (IFN-R). K14E7 transgenic skin recruits significantly higher number of dendritic cells, independent of IFN- and IFN-R expression. Consistent with these observations in a murine model, we found higher expression of IDO1 and IFN- but not IDO2 in the cervical epithelium of patients with HPV-associated cervical intraepithelial neoplasia (CIN) 2/3. Our data support a hypothesis that induction of IDO1 in HPV infected skin contributes to evasion of host immunity.

P4.01.069
Immune deficiency in newborns and infants with cytomegalovirus infections

***N. O. Mollayeva**;*
Azerbaijan Medical University, Baku, Azerbaijan.

The problem of children born on infected mothers is one of the main problems in modern neonatology and pediatrics. Wide dissemination of cytomegalovirus infections in the adult population represents a high risk of becoming infected pregnant woman and newborns. According to the results of autopsies 37,5% of children died of infectious pathology and the main cause of death, accompanied or complicate the course of the underlying disease.
Aim of investigation: studying the clinical and immunological features of children with cytomegalovirus infections and to examine the effectiveness of immunotherapy. We have examined 89 infants with cytomegalovirus born from mothers with positive cytomegalovirus serological tests.
Results: It was established that the humoral type of IDS was detected by increased levels of specific IgM, IgG and IgA antibodies and activation of pro-inflammatory cytokine synthesis of IL-1, IL-6, TNF-α in serum. These patients had characteristic disturbances in cellular immunity - the quantitative deficit of T- and B-cells and increase the percentage of NK cells. After treatment by immune modulator Licopid they had normalization of peripheral blood leukocytes, revealed a significant increase in absolute and relative numbers of CD3+ and CD4+ lymphocytes, normalization of CD4/CD8 ratio and levels of IgM, IgG, IgA, which changed to the normal indexes.
Thus, it was found that the treatment by Licopid in infants with immunodeficiency leads to the reduction of the duration of disease, contributes to a more rapid improvement of children and this drug can be used as very effective immune modulator.

P4.01.070
APOBEC3 deaminases induce hypermutation in human papillomavirus 16 viral genomic DNA upon interferon-β stimulation

***M. Muramatsu**[1], Z. Wang[1], K. Wakae[1], K. Kitamura[1], M. Nakamura[1], S. Kyo[1], I. Kukimoto[2];*
[1]Kanazawa University, Kanazawa, Japan, [2]National Institute of Infectious Diseases, Tokyo, Japan.

APOBEC3 deaminases are interferon-inducible antiviral factors that suppress a wide range of viruses and retroelements, including human immunodeficiency virus-1, possibly by accumulating cytidine (C)-to-uracil (U) mutations in viral genomic DNA. Currently, it remains unknown whether APOBEC3 proteins are involved in the pathogenesis of human papillomavirus (HPV) infection. Here, we examined the possible role of APOBEC3 deaminases in pathophysiological processes in HPV infection. W12 cells are derived from an earlier phase of HPV16 infection, and they retain the viral episome in the nucleus. When W12 cells were stimulated by interferon-β (IFN-β), the expression of APOBEC3 proteins, including APOBEC3A, 3G, and 3F, was upregulated. IFN-β stimulation induced C-to-T and G-to-A hypermutations in the HPV16 E2 gene when uracil DNA glycosylase (UNG) was inhibited by the expression of UNG-inhibitory protein (UGI). The overexpression of APOBEC3 proteins also induced hypermutations in UGI-expressing W12 cells. Furthermore, hypermutations by IFN-β were blocked by transfection of small interfering RNA against APOBEC3G and 3A. However, antiproliferative activity or restriction of HPV16 DNA by IFN-β was not impaired by knocking down APOBEC3G and 3A. The overexpression of APOBEC3 caused the activation of DNA damage stress responders such as γ-H2AX. We found that clinical samples from pre-cancerous (CIN1) patients also accumulated hypermutation on HPV viral DNA. These data suggest that IFN-β induces both HPV hypermutations and cellular DNA damage response through APOBEC3 expression, but APOBEC3 may not require antiviral activities by IFN-β. APOBEC3 protein could be a risk factor in facilitating oncogenesis in HPV infection.

P4.01.071
Rapid method to screen for CMV, EBV, and AdV specific T cells in multiple samples

***M. Niemöller**, K. Lange, S. Weber-Lohmann, S. Höher-Peters, M. Assenmacher, A. Richter;*
Miltenyi Biotec GmbH, Bergisch Gladbach, Germany.

Flow cytometric analysis of activation markers and cytokines after short-term in vitro T cell stimulation is well established for research studies to identify and characterize antigen-specific T cells. But its routine use for immune monitoring applications is hampered, because screening of a lot of samples is time-consuming, requires many manual handling steps, and analysis experience. We worked out a complete strategy to rapidly study with a semi-automated process in multiple samples the functional profile of T cells.
For simultaneous analysis of multiple human PBMC samples we established an antigen-coated 96-strip-well culture system to stimulate T cells. This flexible ready-to-use format allows screening either for single antigens or in parallel for several specificities by combining 8-well-strips possessing different antigens. To reduce time and work load, we developed a rapid and easy-to-handle intracellular staining protocol for the 96-strip-well plate and defined reagents. Without cell harvesting and washing steps, cells are fixed and stained within 50 minutes. Furthermore, we integrated an automated flow cytometric analysis process, including a hands-free measurement using pre-defined experiment settings and acquisition templates. We also applied an automated gating strategy for data analysis and a final report summarizes the results. This standardized process, including reagents, protocol, and analysis decreases inter- and intra-assay variations.
In summary, with our newly developed tools and protocols for in vitro T cell stimulation, staining of activation markers and cytokines, and automated flow cytometric analysis we have set up a fast and convenient procedure to routinely monitor antigen-specific T cell responses.

P4.01.072
Polyfunctional T cells are generated concurrent with the establishment of immunodominance hierarchy during the evolution of the T cell responses to Epstein-Barr virus

***J. Ning**[1], K. H. Chan[2], A. K. S. Chiang[1];*
[1]Department of Paediatrics and Adolescent Medicine, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong, China, [2]Department of Microbiology, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong, China.

Background: Whether immunodominance corresponds to the functions of the antigen-specific T cells during the evolution of the T cell responses towards Epstein-Barr virus (EBV) remains unclear. This study aims to characterize the functions of EBV lytic- and latent-protein-specific T cells in relation to the immunodominance hierarchy from early to persistent phase of infection.
Methods: PBMCs of ten patients with infectious mononucleosis (IM) and four with asymptomatic primary infection (AS) collected from diagnosis through 12-months post-infection were stimulated with overlapping peptides of four lytic-(BZLF1, BRLF1, BMLF1,and GP350) and five latent-(EBNA1, EBNA3A, 3B, 3C and LMP2) proteins, followed by multi-color flow cytometric assay examining the co-expression of three cytokines (IFN-γ, TNF-α and IL-2), perforin and CD107a in CD4+ and CD8+ T cells as well as cytotoxicity and proliferation assays.
Results: Both lytic and latent peptide-specific CD4+ and CD8+ T cells showed increased proportion of polyfunctional T cells capable of producing multiple cytokines simultaneously with enhanced cytotoxic and proliferative capacity over time in all IM and AS patients. The CD8+ T cell responses shifted from the lytic BZLF1/BRLF1 peptides to the latent EBNA3 family peptides and the CD4+ T cell responses from broad range to more focused reactivity towards EBNA1 peptides during the progression from early to persistent phase of infection. Importantly, the immunodominant T cell responses also demonstrated concurrent increase in their functionality.
Conclusions: Polyfunctional T cells are generated concurrent with the establishment of immunodominance hierarchy during the evolution of the T cell responses to EBV.

P4.01.073
Neuroimmunological characterization of children suffering from psychomotor retardation due to Cytomegalovirus infection

*E. Noris- Garcia[1], M. Interian[2], D. Padron[2], E. Aguero[2], M. Gonzalez[2], **G. Penton Rol**[3];*
[1]National Institute Nephrology, La Havana, Cuba, [2]Pediatric Hospital of San Miguel del Padron, La Havana, Cuba, [3]Clinical Trial Department, Center for Biological Research, La Havana, Cuba.

Cytomegalovirus (CMV) infection is the most frequent congenital infection in humans. The 90% of babies asymptomatic at birth but may develop severe neurological deficits during early childhood, when the diagnosis is no longer possible. This diagnostic problem is linked to incomplete clinical characterization of this disease. From this experience we wanted to study childhood bearing psychomotor retardation, looking for the probable role of CMV infection in psychomotor development as an immunological mechanism involved in this process. 70 children from 6 to 36 month of age with disabilities of unknown cause and group controls sex/age-matched were analyzed. CMV, rubella and toxoplasmosis specific IgG were determinate in serum/cerebrospinal fluid paired samples and the antibody index (AI) were quantified. Rubella and Toxoplasmosis AI were not detected in any patients while pathologic CMV-AI was found in 24 patients with psychomotor retardation. Only, one patient from control group was positive to CMV-AI. Matched polymerase chain reaction (PCR) on filter paper used for biochemical screening that was kept from the neonatal period and AI data were available in 15 patients. PCR was simultaneously positive or negative in fourteen cases only one patients belonged a control group show PCR positive with AI negative(p=0.0037). The main clinical manifestations of the patients with congenital infection were seizure (70%), chorioretinitis(28%), hepatosplenomegaly (20%) microcephaly/macrocephaly (20%) and thymus hypoplasia (19%), humoral immunodeficiency(43%), cellular immunodeficiency 95% .IgG-CMVAI and cellular immunodeficiency should be considered as an important tool to determinate if CMV infection is involved in patients suffer from psychomotor congenital impairment.

P4.01.074
Role of the FCGR2A Polymorphism in Susceptibility to Dengue in a Venezuelan Population

***V. Ogando**, A. Guadarrama, E. V. Salazar, M. T. Fernandez-Mestre; Instituto Venezolano de Investigaciones Cientificas, Caracas, Venezuela.*

Dengue virus infection is a health public problem. Virus serotypes, viral load, antibody-dependent enhancement (ADE) of infection and IFN-gamma/TNFalpha-mediated immunopathogenesis have been suggested to contribute to the progression and severity of dengue disease. The FCGRIIA gene (CD32) displays a functional A G single nucleotide polymorphism in the region encoding its ligand-binding domain, defining two allotypes which differ in their avidity for complexed human IgG2 and IgG3. Two studies show the role of a polymorphism that affect the function of the receptor for the Fc domain of IgG, which facilitates antibody-dependent enhancement of dengue infection, show associations with to the most severe form of DF in Vietnam and Cubans. In this study we studied the association between FCGRIIA polymorphism and susceptibility to dengue infection. Whole blood was collected from patients with dengue (n= 136; DF=87 and DHF=38) and healthy individuals (n= 132). A PCR with sequence-specific primers (SSP) was applied to establish FCGR polymorphism. Frequencies were determined by direct counting and X2 test was applied to determine frequency differences between groups. Statistically significant differences were found when the control group was compared with virally infected patients (DF+DHF), or with DF clinical form. The frequency of the R/R131 genotype was increased in healthy individuals compared with the whole series of dengue (30.60% vs. 18.25%, respectively; OR=0.51; IC 95%: 0.2893-0.9020; p= 0.0098; pc=0.0294) and DF patients (30.6% vs. 17.24%, respectively; OR=0.47; IC 95%: 0.2426-0.9203; p=0.013; pc= 0.039). This data suggest that, R/R131 genotype seems to confer protection to the development of dengue infection.

P4.01.075
Poly-γ-glutamic acid, a polypeptide secreted by *Bacillus sp*., induces CD14-dependent type I interferon responses through the TLR4-MD2 complex

*W. Lee, H. Cho, **J. Oh**;*
Yonsei University, Seoul, Republic of Korea.

Poly-γ-glutamic acid (γ-PGA) is an anionic polypeptide secreted by *Bacillus* sp. that has been shown to activate immune cells through interactions with toll-like receptor 4 (TLR4). However, its ability to induce the type I interferon (IFN) response has not yet been characterized. Here, we report that γ-PGA induces type I IFN via the TLR4 signaling pathway. The induction requires two TLR4-associated accessary proteins: myeloid differentiation factor 2 (MD2) and the pattern-recognition receptor CD14. The induction of IFN-β depends on the molecular weight of γ-PGA. IFN-β production and the expression of the type I IFN-response genes, 2'-5' OAS and ISG56, were stimulated by γ-PGA with a molecular weight of 2,000 kDa or greater. The type I IFN responses induced by γ-PGA had antiviral activity against the SARS coronavirus, as assessed using a SARS coronavirus replicon *in vitro*. Our results identify high-molecular weight γ-PGA as a novel TLR4 ligand requiring CD14 and MD2 for the activation of type I IFN responses, and suggest that the microbial biopolymer γ-PGA is a potential broad-spectrum antiviral agent protecting against virus infections that are sensitive to type I IFN.

P4.01.076
Phosphorylation dependent 14-3-3 protein interactions in innate immune response

***T. Öhman**[1], S. Söderholm[1], P. Hintsanen[2], E. Välimäki[1,3], N. Lietzén[1], T. Aittokallio[2], S. Matikainen[3], T. A. Nyman[1];*
[1]Institution of Biotechnology, University of Helsinki, Helsinki, Finland, [2]Institute of Molecular Medicine, Helsinki, Finland, [3]Finnish Institute of Occupational Health, Helsinki, Finland.

The innate immune system plays an essential role in protecting the host against infections. Viral RNA is the most important viral structure that is recognized by specific receptors of the host, resulting in activation of innate immune response, including antiviral interferon and pro-inflammatory cytokine production, as well as apoptosis of virus-infected cells. The 14-3-3 proteins are a family of acidic regulatory proteins found in all eukaryotes that participate in a variety of cellular processes including metabolism, apoptosis, signal transduction and cell-cycle regulation. We have previously shown that 14-3-3 signaling pathways are activated by viral dsRNA in human keratinocytes. However, the functional role of 14-3-3 proteins in viral infection has not been defined. The aim of this study is to characterize the role of 14-3-3 proteins in innate immune response using high-throughput proteomics combined with bioinformatics and functional studies. First, we have characterized the global changes in protein phosphorylation in human keratinocytes after viral dsRNA transfection. Then, we have used 14-3-3-affinity chromatography combined with quantitative proteomics to identify 14-3-3 interacting phosphoproteins during viral infection. Ingenuity Pathway Analysis shows that many signaling pathways related to apoptosis and cytokine signaling were clearly upregulated after stimulation. Network analysis shows that NFκB and p38 signaling pathways are major targets of 14-3-3 mediated signaling. Sirtuin 1 and MAPKAPK2 are two of the most central component of this signaling network, and the functional contribution of sirtuin 1 and MAPKAPK2 is currently assessed by functional studies.

Indigenous chickens infected by avian paramyxovirus type 1 strain express pathways involved in innate immunity and epigenetics

S. C. Ommeh[1], *H. Noyes*[2], *J. K. Lichoti*[3], *J. Williams*[4], *M. Ogugo*[5], *A. Orth*[5], *A. Valentini*[6], *O. Hannote*[7], *S. Kemp*[5];
[1]*Jomo Kenyatta University of Agriculture and Technology, Nairobi, Kenya,* [2]*Liverpool University, Liverpool, United Kingdom,* [3]*Ministry of veterinary Services, Nairobi, Kenya,* [4]*Paco Tecnologico Padano, Lodi, Italy,* [5]*International Livestock Research Institute, Nairobi, Kenya,* [6]*Tuscia University, Viterbo, Italy,* [7]*Nottingham University, Nottingham, United Kingdom.*

Newcastle disease is devastating to backyard poultry in Africa owned by rural farmers mostly women and youth. It's caused by avian paramyxovirus type 1- APMV-1. The disease has no effective cure and the current vaccines have no practical delivery systems to farmers in rural settings. The aim was to study the innate immune virus response genes expressed by indigenous chicken and if these play a role in providing natural immunity. Airway epithelial cells were obtained and cultured and infected with a virulent APMV-1 Kenyan strain. RNA was extracted after 36 hours and RNASeq method was used for gene expression studies. Mapping, quality control and statistical analysis was done on the raw data using the CLC genomics workbench. Comparisons of the indigenous and commercial gene expression profiles showed the nucleocapsid gene was highly expressed for the APMV-1. In indigenous chickens after the gene set enrichment analysis, the inflammatory pathway had 16 genes expressed, the immune response pathway had 10 genes, the protein kinase pathway had 9 genes and the NF kappa B cascade had 7 genes expressed. Most of the genes according to the gene ontology definition are involved in innate immunity. Pathways also involved in post-translational modifications were also expressed in indigenous poultry implying an epigenetic role towards disease response. In conclusion, indigenous chickens have expressed natural immunity that needs to be explored further. This has implications for research into diagnostic and vaccination kits that would be useful in Africa for controlling not only Newcastle disease, but other poultry diseases.

P4.01.078

Expression of retinoic acid-inducible gene I (RIG-I)-like receptors (RLRs) in the human term placenta

A. Jabłońska[1], *P. Suski*[1], *M. Studzińska*[1], *J. Kalinka*[2], ***E. Paradowska***[1];
[1]*Laboratory of Molecular Virology and Biological Chemistry, Institute of Medical Biology of the Polish Academy of Sciences, Łódź, Poland,* [2]*Department of Perinatology, First Chair of Gynecology and Obstetrics, Medical University, Łódź, Poland.*

Innate recognition of viruses is mediated by germline-encoded pattern recognition receptors (PRRs) that initiate signaling events, resulting in the production of type I interferon and proinflammatory cytokines. Double-stranded RNA and 5'triphosphate group of ssRNA generated during viral replication are detected by sensory molecules, named RIG-I-like receptors (RLRs). Three members of the RLRs family have been characterized so far, including RIG-I (retinoic acid-inducible gene-I), MDA5 (melanoma differentation-associated gene 5) and LGP2 (laboratory of genetics and physiology 2). RIG-I participates in the recognition of Paramyxoviruses, Rhabdoviruses, Flaviviruses and Orthomyxoviruses, whereas MDA-5 is essential for the recognition of Picornaviruses.
In this study, we investigated the RLRs gene expression in fetal and maternal parts of the human placentas during viral infection. The explants of third-trimester chorionic villi and deciduas were exposed to infection with dsDNA viruses (human cytomegalovirus, HCMV; herpes simplex virus type 1, HSV1) or ssRNA virus (vesicular stomatitis virus, VSV). RIG-I, MDA5 and LGP2 mRNA levels were assessed by real-time PCR.
Our results demonstrated that all RLRs were expressed in term human placentas with the highest level of LGP2. RIG-I and MDA5 (in fetal part) have been identified as the main mediators of VSV recognition, whereas RLRs were not involved in the identification of dsDNA viruses. The expression of LGP2 in HCMV-infected explants was decreased compared to mock-infected. The results clearly indicated that RLRs play essential role in RNA viruses' recognition in term placenta.

Immune response to Apeu virus (orthobunyavirus) infection in murine model

P. C. Peregrino Ferreira[1], *A. T. Chaves*[1], *A. Bozzi*[1], *J. G. Oliveira*[2], *F. C. Costa*[2], *J. R. Santos*[1], *O. A. Martins-Filho*[2], *E. G. Kroon*[1], *R. Correa-Oliveira*[1];
[1]*Federal University of Minas Gerais, Belo Horizonte, Brazil,* [2]*Centro de Pesquisa Rene Rachou, Belo Horizonte, Brazil.*

Introduction and Objectives: Arthropod-borne viruses have emerged as a major human health concern. Viruses transmitted by mosquitoes are the cause of the most serious and widespread human diseases worldwide and are ubiquitous in areas where man lives. The Apeu virus (APEUV) belongs to group C arboviruses, member of Bunyaviridae family and Orthobunyavirus genus. Although APEUV has already been isolated for more than five decades, the role of the in vivo or in vitro immune response in the pathogenesis of APEUV remains unknown. The aim of this study was to investigate the infection kinetics of as well as the immune response profile triggered by APEUV infected Swiss and C57BL/6 mice. Methods and Results: The animals were experimentally infected with APEUV at different periods (12, 24, 48, 72 and 120 hours). The spleen cells proliferative response was evaluated in vitro using the MTT [3-(4,5-dimethylthiazolyl-2)-2,5-diphenyltetrazolium bromide] colorimetric assay. A cytometric bead array (CBA) immunoassay kit was used for semi-quantitative analysis of several cytokines (IL-2, IL-4, IL-6, IFN-γ, TNF, IL-17A and IL-10) in the serum of infected mice. We observed an increase ($p < 0.05$) in the secretion of pro-inflammatory cytokines (IL-6, IFN-γ, TNF) in serum of animals 72 hours post-APEUV infection. Supporting the hypothesis that the 72 hours after infection follows the peak of infection by these viruses. Conclusion: The APEUV induces an early response in Swiss mice and late inflammatory in C57BL / 6.

Vaccinia and Apeu virus activation of human double-negative T cells stimulated in vitro

P. C. Peregrino Ferreira[1], *F. N. A. Villani*[2], *T. E. Silva*[2], *E. G. Kroon*[1], *J. G. Oliveira*[2], *O. A. Martins-Filho*[2], *R. Correa-Oliveira*[2];
[1]*Federal University of Minas Gerais, Belo Horizonte, Brazil,* [2]*Centro de Pesquisa Rene Rachou, Belo Horizonte, Brazil.*

The Apeu virus (APEUV), a Orthobunyavirus of group C, has been described in human infections. Zoonotic human infections caused by Vaccinia virus (VACV), a Orthopoxvirus, in Brazil reached worldwide recognition. Antiviral immune response mechanisms target CD4+ T lymphocytes (T helper), CD8+ T lymphocytes (cytotoxic) and NK cells (natural killer). Monkeys infected with SIV do not develop clinical disease and the CD4-CD8- T cell population (double-negative-DN) was responsible for compensating, the function of CD4+ cell depleted in this disease. This suggests that the DN T cells play an important role in the antiviral immune response. The aim of this work was to evaluate the activation profile of DN T cells expressing alpha-beta (αβ TCR) or gamma-delta T-cell receptors (γδ TCR) from healthy humans. The peripheral blood mononuclear cells were isolated from four donors and exposed to UV-inactivated APEUV and VACV (WR). The expression of surface markers (CD4, CD8, αβ TCR and γδ TCR) and the intracellular cytokines (IL-1β. IL-6, IL-10, IL-17A, IFN-α, IFN-β, IFN-γ and TNF-α) were assessed by flow cytometry. We observed a higher frequency of αβ DN T cells expressing IL-10, IFN-α and TNF-α in VACV stimulated cells. IFN-γ expression was higher in VACV-stimulated γδ DN T cells compared to non-stimulated cells. We did not observe differences in the expression of these markers in APEUV's stimulated cells. These results show that DN T cells from healthy humans are highly activated in vitro by VACV and no responsive to APEUV.

P4.01.081
Mkk4 is not essential for negative selection but is required for optimal T cell activation and function during acute but not chronic infection

***S. P. Preston**, J. P. Cooney, M. Pellegrini;*
Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia.

Background: Our immune system is continuously poised on the edge of activation and has developed numerous checkpoints to inhibit overt autoimmunity but permit swift and robust responses to bona fide infections. Mitogen-activated protein kinase kinase 4 (Mkk4) is responsible for the phosphorylation of JNK 1/2, which regulate a vast array of cellular processes. JNK1 has been reported to play an important role in negative selection but the role of Mkk4 during this process is controversial. We hypothesized that Mkk4 plays a role in immunity and particularly immune responses to infection. The aim of our study was to determine the role of Mkk4 in immune homeostasis and infection.
Design: We analysed conditionally gene-targeted mice, and infected animals with acute and chronic forms LCMV.
Results: We show for the first time that Mkk4 is not required for development and homeostasis of the T cells. However, during an acute infection, mice with a deficiency of Mkk4 in T cells showed a blunted CD8 T cell response. In contrast, during chronic overwhelming infection loss of Mkk4 did not contribute further to the inefficient T cell responses that have been observed in wild-type mice.
Conclusion: These data clearly identify an important role for Mkk4 in the initial activation and proliferation of CD8 T cells during an acute infection, which is required for the production of an effective adaptive immune response. During chronic infection, however, the overwhelming inflammatory milieu appears to override the role of Mkk4 during the production of a T cell response.

P4.01.082
Human APOBEC3 cytidine deaminases: not simply antiviral defense?

***A. Räthe**, T. Kehl, M. Löchelt;*
German Cancer Research Center, Heidelberg, Germany.

Host-encoded restriction factors are important players in innate antiviral immunity. Human APOBEC3 (apolipoprotein B mRNA-editing enzyme catalytic polypeptide) proteins induce dC-to-dU-mutations, leading to DNA degradation or hypermutation and subsequent loss of viral genetic integrity. The APOBEC3 expression pattern in the host is ill-defined and regulated by inflammatory mediators secreted upon viral infection.
APOBEC3 deaminases have the capacity to edit host DNA, which may influence cellular genome stability and potentially play a role in the onset of cancer. We hypothesize that inflammatory processes induced by virus infections enhance the expression of APOBEC3 deaminases and may represent a novel mechanism of virus-induced oncogenesis.
In order to investigate the mutagenic potential of the different human APOBEC3 deaminases, we established stable, isogenic cells lines driving tetracycline-regulated APOBEC3 gene expression. As a readout for APOBEC3-mediated host genome mutagenesis, we use counterselection against herpes simplex virus thymidine kinase (HSV-TK): APOBEC3-mediated DNA editing leads to HSV-TK reporter gene inactivation and allows survival of ganciclovir (GCV)-resistant colonies. At first, a founder line of Flp-In-T-Rex cells stably expressing the HSV-TK reporter gene was established and functionally characterized. The integrated copy number of HSV-TK genes was determined by Southern blotting. After successful integration of APOBEC3 genes via FLPase-mediated DNA recombination, a phenotypic analysis based on DNA damage repair and cell cycle progression was performed to obtain deeper insight into APOBEC3 functions.
In addition, we profiled hepatitis virus-induced tumor samples to elucidate APOBEC3 involvement in inflammation-associated carcinogenesis. Immunohistochemical studies showed a slight increase in APOBEC3 protein expression in hepatocellular carcinoma groups.

P4.01.083
An evidence for the pathogenic role for virus-specific T cells in the mouse model of coxsackievirus B3-induced myocarditis

*A. Gangaplara[1], C. Massilamany[1], D. Steffen[1], A. Pattnaik[1], S. Huber[2], **J. Reddy**[1];*
[1]University of Nebraska-Lincoln, Lincoln, NE, United States,
[2]University of Vermont College of Medicine, Burlington, VT, United States.

A long-standing question exists as to whether the chronic inflammatory process that occurs in coxsackievirus B3 infection (CVB) is due to an autoimmune response to cardiac antigens or to a virus-specific immune response. We recently reported that myocarditis-susceptible, A/J mice infected with CVB generate cardiac myosin-specific CD4 T cells that transfer the disease into naïve recipients. We now present evidence that the virus-specific T cells persist during the chronic phase of the disease as evaluated by measuring the T cell responses based on tritiated ^{3}[H] thymidine-incorporation assay and IA^{k} dextramer staining for three immunodominant epitopes of CVB viral protein (VP)1 namely, VP1 681-700, VP1 721-740, and VP1 771-790. In an adoptive transfer protocol, we tested the pathogenic role of virus-specific T cells by transferring the CD4 T cells stimulated with viral peptides into whole body irradiated naïve mice.
The preliminary data indicate that the animals receiving the cells stimulated with VP1 771-790 but not VP1 680-700 and VP1 721-740 showed myocardial necrosis, whereas pancreases remain unaffected, suggesting that virus-specific T cells might have targeted cardiac antigens.
Using bioinformatics tools, we noted that VP1 771-790 contains sequences partially identical (30%) to a protein fragment of actin, alpha cardiac muscle 1 (ACTC1 292-311), pointing to a possibility that VP1 771-790-specific T cells can cross-react with ACTC1 292-311. Taken together, our data support the notion that the immune pathogenesis of viral myocarditis may involve generation of cross-reactive immune responses to cardiac antigens.

P4.01.084
Effects of inoculum size on memory T cell inflation during cytomegalovirus infection

***A. Redeker**, S. P. M. Welten, R. Arens;*
Leiden University Medical Center, Leiden, Netherlands.

Cytomegalovirus (CMV) infection of immunocompetent individuals leads to a lifelong state of latency that is controlled in part by $CD8^{+}$ and $CD4^{+}$ T cells. The persistent phase of CMV infection is typified by the accumulation of large numbers of memory T cells that display an effector-memory phenotype. This phenomenon called memory T cell inflation is driven by low level exposure to viral antigen and induction of such responses might be useful in protection against infections and cancers. In an experimental CMV model we examined the impact of the viral dose on the outcome of memory T cell inflation. We observed that low-dose inoculum of mouse CMV, as compared to intermediate dosages, impacts the kinetics of inflationary T cell responses, whereas the kinetics of non-inflationary T cell responses was unaltered. Remarkably, already early after infection the phenotype of inflationary T cells after low dose inoculum is more central-memory-like as evidenced by increased IL-2 production and decreased KLRG-1 expression. Both after low and intermediate viral inoculum inflationary T cells did not show signs of T cell exhaustion. These results suggest that the viral dose influences the outcome of persistent CMV infection by influencing memory T cell inflation. This could have implications for the development of CMV- based vaccine strategies.

P4.01.085
Investigation of ELISA and PCR for diagnosis of Infectious Mononucleosis

***R. Roghanian**, S. Taleifard, H. Salehi, M. Salehi; University of Isfahan, Isfahan, Iran.*

Infectious mononucleosis (IM) is an infectious disease that is characterized by fever, sore throat, lymphoadenopathy, swollen liver and swollen spleen. The etiology of IM is *Epstein-Barr virus* (EBV). Humans are the only known reservoir of EBV. The transmission of virus requires a close contact with the saliva of an infected person. After primary infection, EBV remains latent in the epithelial cells of the normal salivary glands and peripheral blood B cells and becomes reactivated. The aim of this study was to assess ELISA and Nested PCR as a diagnostic tool for IM. In this study, 50 samples were collected from the suspicious patients with EBV and 50 samples from the healthy individuals as the control. Both techniques were applied for the collected samples. The results driven from PCR showed that 76% of the patients and 14% of the control samples had EBV DNA in serum. Statistical analysis showed significant difference between the patient and the control samples (P<0.0001). O ur results suggest that serology may be more sensitive and could be performed as the initial screening test for acute EBV infection. Although, the PCR test is routinely used as an accurate method for detection of pathogens with a higher specificity and sensitivity comparing the immunoassay, but in IM, according to our data, not only ELISA seems to be the best assay for detecting antibodies against EBV but also, it is a cost effective test with less consuming time.

P4.01.086
Virus detection within leucocytes of Atlantic salmon (*Salmo salar* L.) by flow cytometry.

***A. Rønneseth**, G. T. Haugland, H. I. Wergeland;*
University of Bergen, Bergen, Norway.

Virus infections have the most serious ethical and economic impact on fish farming worldwide. No virus vaccines available on the market provide adequate protection. Infectious pancreatic necrosis virus (IPNV) is a birnavirus harming salmonids. This virus resides within the immune cells and during persistent infection replicates in adherent leucocytes, presumably macrophages. In the fight against viral infections in fish the innate cellular activities have central roles, and it has been shown that IPNV causes reductions in the levels of neutrophils in carrier fish. By using flow cytometry we have developed an assay to analyze the presence of IPNV within leucocytes of Atlantic salmon. Particularly, we have analyzed the presence of virus within B-cells and neutrophils from head kidney (primary and secondary lymphoid tissue) and from peripheral blood after *in vitro* challenge of leucocytes by IPNV. IPNV was detected within B-cells and neutrophils as well as in other leucocytes that could not be identified due to lack of cell specific antibodies. The sensitivity of the method was verified by analysis of virus within a persistent infected cells derived from the cell line CHSE-214 (Chinook salmon embryo cells). The consistence of the assay was also verified in an extensive *in vivo* challenge of salmon and subsequent detection of IPNV in leucocyte populations. Presence of IPNV within the immune cells may influence on the cells functions involved in immune response. Identification of immune cells harboring virus during acute and persistent stages of infection may give valuable information concerning immune stimulation and vaccine development.

P4.01.087
Human papillomavirus-associated induction of human β-defensins in cervical intraepithelial lesions

***C. D. Rusanu**[1], I. Iancu[2], A. Botezatu[2], I. Huica[2], G. Anton[2];*
[1]Ixia Medica Research Centre, Bucharest, Romania, [2]Stefan S Nicolau Institute of Virology, Bucharest, Romania.

Cervical cancer is the second most common malignant neoplasm in women worldwide. HrHPV (high-risk human papillomavirus) E6 and E7 oncoproteins play a key role in the deregulation of innate immunity antimicrobial peptides and proteins (AMPs). Therefore, the present study was performed to analyse AMPs expression in HPV-induced cervical lesions.
60 cervical specimens were analysed for the presence of LL-37, RNase 7, and human β-defensin (hBD)-1, hBD-2 and hBD-3 using TaqMan Real Time PCR mRNA expression. Isolated DNAs were tested for HPV presence. Moreover, HPV 16, 18, 31 and 33 DNA load was performed to evaluate possible correlations between AMPs expression and HPV types.
Our study showed that in women with normal cytology and ASCUS (Atypical Squamous Cells of Undetermined Significance), hrHPV was absent. On the other hand, 72.2% (13/18) LGSIL (Low-Grade Intraepithelial Lesion) and 93.3% (14/15) HGSIL (High- Grade Intraepithelial Lesion) patients presented infection with hrHPV in single or co-infection represented mainly by HPV16, 18, 31 and 33. hBD-2 and hBD-3 mRNA expression was significantly increased (P<0.003) in both LGSIL and HGSIL patients whereas LL-37, RNase 7 and hBD-1 gene expression did not differ significantly from normal epithelium. AMP expression correlated neither with the number of HPV types nor with the high-risk and low-risk HPV DNA loads of the quantified types.
hBD-2 and hBD-3 expression was shown to be significantly upregulated in HPV-induced cervical lesions. These findings suggest a possible biological significance in the innate immunity against these lesions but their role remains to be solved.

P4.01.088
PD-1 induces anti-viral T cell motility paralysis: the immunological synapse perspective.

***C. Sacristan**[1], M. Cammer[1], B. H. Zinselmeyer[2], S. Heydari[2], D. Nayak[2], J. Herz[2], X. Cheng[3], S. J. Davis[3], M. L. Dustin[1], D. B. McGavern[2];*
[1]Skirball Inst. Biomolecular Med, NYU School of Medicine, New York, NY, United States, [2]National Institute of Neurological Disorders and Stroke, NIH, Bethesda, MD, United States, [3]Nuffield Dept of Clinical Med and MRC Human Immunology Unit, The University of Oxford, Oxford, United Kingdom.

During persistent viral infection with lymphocytic choriomeningitis virus (LCMV) - as with numerous other viruses - CD8 T-cell differentiation leads to a unique subset of antigen-specific T-cells which are impaired in their ability to mount effective immune responses. This process is termed immune exhaustion. The suboptimal effector function of exhausted cells is partly due to sustained expression of the inhibitory receptor 'programmed-death-1' (PD-1). In order to gain some understanding into the molecular mechanisms governing the induction phases of T cell exhaustion during infection, using total internal reflection microscopy, we examined the behavior of LCMV-specific CD8 T cells placed on artificial planar lipid bilayers. Specifically, we compared CD8 T cells from acute and chronically infected mice (7 days post-infection) in their ability to form immunological synapses when engaging PD-1 with its ligand, PD-L1. Our results demonstrate that PD-L1 localizes to the central supramolecular activation cluster, and importantly, that PD-L1/PD-1 engagement promotes stable, mature immunological synapse formation while decreasing anti-viral T cell motility, despite reduced phosphorylation of proximal TCR signaling molecules like ZAP-70. These results corroborate in vivo two-photon microscopy data showing that immune exhaustion during viral persistence is defined by prolonged motility paralysis in the splenic marginal zone / red pulp and is restored by therapeutic blockade of PD-1 /PD-L1. We propose that motility paralysis during persistent viral infection decreases T cell scanning efficiency and facilitates engagement of regulatory pathways that negatively impact anti-viral T cell function as a manifestation of immune exhaustion induced by PD-1.

P4.01.089
Immunologic response among adults infected by different HIV-1 Subtypes who on anti-retroviral drugs in Northern Tanzania

E. R. P. N. Shao[1,2,3], *B. M. R. Nyombi*[1], *J. B. Sabuni*[1];
[1]*Kilimanjaro Christian Medical Center, MOSHI, Tanzania, United Republic of,* [2]*Kilimanjaro christian medical university college, Moshi, Tanzania, United Republic of,* [3]*Kilimanjaro clinical research Institute, Moshi, Tanzania, United Republic of.*

Background: Human immunodeficiency virus (HIV) is characterized by great genetic diversity due to its high mutations that occur during replication. HIV-1 infections are characterized by high rates of viral turnover and extensive viral diversity that has implications on disease progression, vaccine development as well as treatment response to antiretroviral drugs.
Objective: The aim of this study was to determine immune response among adults infected by different HIV-1 subtypes who are receiving ARV in Northern Tanzania
Methods and materials: A retrospective study on 63 patients from PRIOR-6 study which were characterized using peptide ELISA representing HIV-1 subtypes A, B, C, D and E. The CD4+T-lymphocyte cell counts were recorded at the baseline, at six and twelve months.
Results: All 63 samples were successfully sub typed with adherence of >92% where analyzed. HIV-1 subtype A was the most prevalent and was 30(47.62%), followed by subtype C= 23(36.51%) and subtype D 10(15.87%). Subtype D showed a higher immunological failure as compared to subtype A and C with the Hazard Ratio (HR, 5.6;) and 95% CI=1.3-23.52, P=0.02) or to the World Health Organization stage >2 of illness (HR, 4.7; 95% CI, 1.20-18.6), P=0.02 compared to A and C.
Conclusion and recommendations:HIV-1 Subtype A was the most predominant, stable and less virulent while C is increasing compared to D which is decreasing. HIV-1 Subtype D showed significantly immunological failure relative to other categories of the viruses. Further studies are needed to address mutations associated with ARV drug resistance among HIV-1 subtypes.

P4.01.090
Development of a new generation smallpox vaccines

S. N. Shchelkunov*, R. Maksyutov, I. Kolosova, S. Yakubitskiy, E. Gavrilova, G. Shchelkunova;*
State Research Center of Virology and Biotechnology VECTOR, Koltsovo, Russian Federation.

Vaccinia virus (VACV) strain LIVP earlier was used for smallpox vaccination in Russia. Cloned variants of VACV LIVP were isolated and compared in biological properties with parental virus. One of these VACV variants was chosen for next step of the research. Mutant variants of the selected cloned VACV with targeted deletions of one to four genes encoding virulence factors (B8R, C3L, N1L, and A56R) were constructed. Excision of one or more target genes failed to reduce reproduction of the virus in the cell cultures CV-1 or Vero. Created VACV variants could be used as new generation safe smallpox vaccines. Comparative analyses of attenuation and immunogenicity of the created VACV mutants are under study. DNA vaccine combining plasmids carrying the variola virus genes M1R, A30L, and F8L of intracellular virion surface membrane proteins as well as A36R and B7R of the extracellular virus envelope proteins under control of cytomegalovirus promoter has been constructed. This DNA vaccine induced production of a high titers of vaccinia virus-neutralizing antibodies in mice similar to those elicited by the live vaccinia virus immunization. Mice vaccinated by created DNA vaccine were completely protected against a lethal (10 LD_{50}) challenge with highly pathogenic ectromelia virus. These results suggest that such vaccine will be efficient in immunization of humans against smallpox.

P4.01.091
Plasticity of uterine Natural Killer cells during maternal cytomegalovirus infection

N. Jabrane-Ferrat, ***J. Siewiera****;*
INSERM/CNRS, Toulouse, France.

Circulating Natural Killer cells constitute the first line of defense against invading pathogens. These effectors of the innate immune system recognize and kill tumor or viral-infected cells. In addition to peripheral blood and lymphoid organs, NK cells are found in the decidua basalis of the human pregnant uterus. Decidual NK cells secrete a large variety of cytokines, chemokines and growth factors but are poorly cytotoxic. We previously showed that dNK cells freshly isolated from the 1st trimester decidua basalis are able to kill target cells upon ligation of NKp46 activating receptor. This cytotoxic capacity is under the control of CD94/NKG2A inhibiting receptor. We challenged the hypothesis that upon viral infection, dNK cells receive activating signals that overcome the inhibitory signals and trigger their cytotoxic effector function. Using an ex vivo autologous system, we describe a mechanism by which dNK cells kill HCMV infected targets. We show that dNK cells engage activating immune synapse with HCMV-infected autologous targets. dNK cells stimulated with HCMV-infected targets are able to reorganize rapidly both their microtubule organizing center and their Golgi apparatus. These changes in cell morphology result in focused delivery of lytic granules and subsequent killing of target cells. Furthermore, dNK cells stimulated with infected autologous fibroblasts acquired a cytotoxic phenotype. Taken together our data provide the first evidence that dNK cells may be involved in the protection of the fetus against maternal viral infections.

Susceptibility and response of human lymphocytes to dengue virus infection

G. F. Silveira*, P. Wowk, M. A. Stimamiglio, C. N. D. dos Santos, J. Bordignon;*
Carlos Chagas Institute, Curitiba, Brazil.

The Dengue represents one of the most important arboviruses in the world with more than 2 billion people living in endemic areas. WHO estimates about 50 million of DENV cases/year with 25000 deaths/year. Dengue infection can be asymptomatic or varies from a dengue fever (DF) to a more serious condition like dengue hemorrhagic fever (DHF)/dengue shock syndrome (DSS). The occurrence of severe DENV cases could be explained by low avidity of T lymphocytes and antibodies, which generated a deficient antiviral response and contributed to high viraemia and cytokine storm observed in severe DENV cases. In this context, lymphocyte susceptibility and response to dengue virus infection would contribute to understand of dengue pathogenesis and vaccine development. Here, we demonstrated that T (CD4+ and CD8+) and B (CD19+) lymphocytes are susceptible to dengue virus infection, however, CD8+ cells presents higher susceptibility to infection. Additionally infected lymphocytes enhance the expression of CD69, an activation marker. We also demonstrated that DENV infection of lymphocytes is mediated by heparan sulfate receptors and that apoptosis of lymphocytes is not dependent of viral replication. Additionally, we have demonstrated that infection of CD8+ cells by DENV does not impact the function of degranulation with the expression of CD107a in surface of these cells, after stimuli with PHA . The next steps will be determine if infected CD4+ and CD19+ are still function after a infection with DENV. Finally, we intent to validate the *in vitro* data in patients infected with dengue virus.

P4.01.093
Severe tuberculosis is associated with a mixed (Th1, Th2, Th17) defective cytokine response to *Mycobacterium.tuberculosis* antigens in children

*M. Armand[1], V. Chhor[2], A. de Lauzanne[3], V. Guérin-El Khourouj[1], B. Pédron[1], P. Gressens[2], A. Faye[4], **G. Sterkers**[1];*
[1]Robert Debré Hospital - Laboratory of Immunology, Paris, France, [2]Inserm, U676, Univ. Paris Diderot, Sorbonne Paris Cité, UMRS 676, Paris, France, [3]Robert Debré Hospital - Department of Pediatric Infectious Diseases, Paris, France, [4]Department of Pediatric Infectious Diseases, Robert Debré Hospital, Paris, France.

Background: Assessment of cytokine/chemokine responses to *Mycobacterium tuberculosis* (M.tb) peptides in children may provide alternative infection markers, help for discrimination between latent (LTBI) and active tuberculosis (TB-disease) and explanation for TB severity status.
Methods: Fifteen cytokines/chemokines were quantified in a multiplexed microsphere-based assay following whole-blood stimulation with M.tb antigens (contained in the commercial quantiFERON kit) in 47 children (median age: 8 years). Concentrations were compared between LTBI (n=12, median age: 10 years) and TB-disease (n=28, median age: 8 years) and between non-severe pulmonary TB (n=11, median age: 7 years) and severe-TB (n=17, median age: 8 years). Seven non-infected children were simultaneously analysed as controls.
Results: Beside IFNγ, IP10 and IL13 appeared to be sensitive biomarkers to diagnose M.tb infection (area under ROC curve: 0.96, 95%CI, 0.91-1 and 0.97, 95%CI, 0.93-1.00 respectively). No studied analytes distinguished LTBI from TB disease.
TB-disease severity was associated with a decrease of M.tb antigen-induced Th1 cytokines (IL-12: p=0.09; IFNγ: p=0.07) and a clearly defective Th2 cytokine levels (IL5: p=0.02; IL13: p=0.02; IL4: p=0.08). IL17, IL10 and MCP-1 levels appeared depressed in severe TB (p=0.07, 0.09 and 0.08 respectively).
Conclusions: This study confirmed IP-10 and identified IL13 as potential biomarkers for M.tb infection diagnosis but no cytokine/chemokine for TB staging in pediatric tuberculosis. Severe pediatric TB-disease was associated with defective mixed cytokine responses rather than the presumed unbalanced Th1/Th2/regulatory cytokine network.

P4.01.095
Expression profiles of Toll-like receptors 1-10 in human placenta during viral infection

***P. Suski**[1], J. Kalinka[2], M. Studzińska[1], A. Jabłońska[1], Z. Leśnikowski[1], E. Paradowska[1];*
[1]Laboratory of Molecular Virology and Biological Chemistry, Institute of Medical Biology Polish Academy of Sciences, Łódź, Poland, [2]Department of Perinatology, First Chair of Gynecology and Obstetrics, Medical University, Łódź, Poland.

Placenta provides an important physical and immunological barrier against infectious agents and a pregnancy-specific component of the innate immune system. Toll-like receptors (TLRs) are essential for the induction of innate immunity responses in different human tissues including the maternal and fetal interface. The objective of this study was to investigate the TLR1-10 gene expressions in the human term placentas during viral infection.
The explants of third-trimester chorionic villi and deciduas were exposed to infection with laboratory strains of HCMV, HSV-1 or VSV. Gene expression of TLR1-10 was assessed by quantitative real-time PCR using Power SYBR Green PCR Master Mix. The relative gene expression values were calculated using the comparative Ct method, and data were normalized against YWHAZ levels.
This study clearly demonstrated that the human term placenta differentially expressed functional TLR1-10, indicating that these receptors are believed to be important for placental immune responses against viruses.
We found that TLR3 mRNA levels were lower than other receptors in all examined placentas. We observed increased expression of TLR1, 9 and 10 in HCMV-infected decidua compared to unstimulated tissue. These findings demonstrated that the decidua was a critical component of the innate immunity response during HCMV infection. In contrast, infection with HSV-1 or VSV did not affect the expression of TLRs.
Our results suggest that the TLRs could be important immune regulators in placenta during viral infection.

Blimp-1 as a major transcription factor for the generation and function of cytotoxic CD4 effector T cells (ThCTL)

***S. L. Swain**, N. B. Marshall, M. D. Brauner, K. Kuang, L. Berg;*
U. Massachusetts Medical Sch, Worcester, MA, United States.

CD4 T cells are best known for helper roles in immunity, but they can also become cytotoxic cells (ThCTL) that kill MHC class II$^+$ targets presenting cognate Ag. We find that a subset of CD4 effectors peaks in the lung of influenza A/PR8 (IAV)-infected mice at 8 days post-infection, expresses the NK cell-associated receptors NKG2A/C/E and has potent perforin-dependent, Fas-independent Ag/MHC class II-specific cytotoxic activity. CD4 T cells from lung, spleen and draining lymph nodes express mRNA for the NKG2A, inhibitory receptor while mRNAs for the activating receptors, NKG2C and NKG2E, are only detected in the lung. Interestingly, Ab to NKG2A/C/E receptors or their ligand, non-classical MHC class I molecule Qa-1, significantly block ThCTL-mediated target cells killing. The NKG2A/C/E$^+$ ThCTL subset co-expresses PD-1, CD27, PSGL-1, GrB and Ly6c, but not CD103, as well as high levels of transcription factors Blimp-1 and Eomes. Since it is involved in development of non-follicular CD4 effectors, we analyzed the role of the transcriptional repressor Blimp-1. Conditional KO of Blimp-1 in T cells did not affect total numbers of CD4 effector cells in IAV-infected lung, but did reduce the number of ThCTL, their expression of the many characteristic phenotypic markers and their cytotolytic function. Thus ThCTL are generated during an acute anti-viral response by a unique program involving Blimp-1 as a major transcription factor, supporting their identity as a defined CD4 subset. Moreover, their use of NKG2A/C/E provides a valuable marker and suggests a unique target specificity for this novel subset.

P4.01.097
Chronic exposure to IFNα reduces T helper-dependent antiviral CD8+ T cell responses

***K. Taleb**, P. Villefroy, A. Hosmalin, A. Le Bon;*
Cochin Institute, Paris, France.

Type I interferons (IFNa/b) are produced by most cells upon viral infection. They have undeniable potent natural anti-viral effect and they promote effective anti-viral immune responses. However, comparative studies on HIV and pathogenic or non-pathogenic Simian Immunodeficiency virus infections in non-human primates show correlations between immune hyperactivation, chronic IFN signature, and pathogenesis. Therefore, in the context of chronic infection, IFN I might have a negative impact on the host by maintaining the innate immune system in a chronic state of activation. In conditions mimicking a chronic viral infection by repeated exposure to IFNα, we found that virus-specific CD8+ T cell responses dependent on CD4+ T cell help were strongly reduced. The reduced ability of mice chronically exposed to IFNα to mount efficient anti-viral CD8 T cell responses was due to decreased CD4 T cell help related to a strong reduction of conventional dendritic cells. Our data suggest that chronic exposure to IFNα occurring during chronic infection may support viral persistence and/or opportunistic infections by reducing conventional dendritic cells, therefore inducing poor T helper-dependent CD8+ T cell responses.

P4.01.098

Differential cytokine and chemokine signatures produced by human innate immune cells after *in vitro* infection with West Nile virus isolates

A. Teixeira-Carvalho[1,2], *L. M. Espina-Gomez*[1,3], *C. Chancey*[1], *A. Grinev*[1], *K. Bernard*[4], *L. D. Kramer*[5], *M. Rios*[1];
[1]*Food and Drug Administration, Bethesda, MD, United States,* [2]*Oswaldo Cruz Foundation, Belo Horizonte, Brazil,* [3]*Zulia University, Maracaibo, Venezuela,* [4]*University of Wisconsin, Madison, WI, United States,* [5]*New York State Department Health, Albany, NY, United States.*

Background. West Nile virus (WNV) is an enveloped positive-strand RNA virus transmitted by mosquitoes. The outcome of infection varies from asymptomatic (80%) to severe disease (<1%), and fatality. The role of the immune response in the clinical outcomes is poorly understood. We hypothesize that different viral isolates may induce distinct cytokine/chemokine profiles, which may influence disease progression, risk for death, and development of specific clinical outcomes.
Methods. We determined *in vitro* the kinetics of infection of monocyte-derived macrophage and dendritic cells by different WNV isolates: WNV02 1956 (the prototype), and two other isolates presenting higher (ARC13-2006) or lower (BSL2-05) virulence than the prototype in C3H and C57Bl6 mice. The infection was performed using a MOI of 0.01.
Results. In both macrophages and dendritic cells, ARC13-2006 induced the highest levels of IL-6, IL-8 and TNF-α, and the lowest levels of CXCL10 and CCL2 of the studied isolates. Also, it induced higher levels of CCL5 than BSL2-05. In contrast, BSL2-05 induced the highest level of IL-10 among the isolates, and presented higher levels of CXCL10 and CCL2 than ARC13-2006.
Conclusion. The three WNV isolates presented distinct kinetics of infection, which were associated with distinct immune profiles. Infection of innate cells with ARC13-2006 was associated with a pro-inflammatory immune response, while infection with BSL2-05 was associated with a mixed immune profile, suggesting that the variability of the isolates may play a role in the clinical outcome of infection.

Pro-apoptotic BH3-only proteins Noxa and Bim co-operate to negatively regulate CD8+ T cells during chronic active infection

J. G. Toe[1,2], *S. P. Preston*[1,2], *J. P. Cooney*[1], *H. W. Scott*[1], *G. Ebert*[1], *C. C. Allison*[1], *M. Pellegrini*[1,2];
[1]*Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia,* [2]*Department of Medical Biology, University of Melbourne, Melbourne, Australia.*

Background: The inability of T cells to eradicate HIV-1 is attributed to a functional impairment that eventually leads to their demise. Apoptosis plays dual roles in infection. Death of infected cells is beneficial but death of uninfected T cells is deleterious. Collateral death is mediated by non-specific inflammatory responses. We hypothesize that by promoting death in infected cells and by antagonizing death in uninfected T cells we can eliminate chronic persistent infections. The aim of our study was to investigate the role of pro-survival and pro-apoptotic proteins during chronic infection. Additionally we investigate the efficacy of small drug molecules that modulate cell death.
Design: We chronically infected mice conditionally deficient in Bcl-2, Mcl-1, Bim or Noxa with LCMV docile. We specifically deleted genes in effector T cells coincident with their activation. Additionally, we used pro-apoptotic small molecules to determine effects on virological and immunological outcomes.
Results: We demonstrate a previously undiscovered role for Noxa in the attrition of antigen-specific CD8+ T cells during chronic active infection and a synergistic co-operation between Noxa and Bim. We also elucidate the role of Mcl-1 and define the therapeutic efficacy of a combination of small molecule drugs that modulate apoptosis during chronic infection.
Conclusions: These studies provide important mechanistic insights into the dual role of apoptosis during chronic active viral infection with implications for the use of novel small molecule drugs that modulate apoptosis.

Differential Responses of Immune Cells to Type I Interferon Contribute to Host Resistance to Viral Infection

T. Baranek[1,2,3], *T. Vu Manh*[1,2,3], *Y. Alexandre*[1,2,3], *M. Maqbool*[1,2,3], *J. Cabeza*[1], ***E. Tomasello***[1,2,3], *K. Crozat*[1,2,3], *G. Bessou*[1,2,3], *M. Dalod*[1,2,3];
[1]*Centre d'Immunologie de Marseille-Luminy, UNIV UM2, Université de la Méditerranée, Parc scientifique et technologique de Luminy, 13288 Marseille, France, Marseille, France,* [2]*Institut National de la Santé et de la Recherche Medicale (Inserm), UMR1104, 13288 Marseille, France, Marseille, France,* [3]*Centre National de la Recherche Scientifique (CNRS), UMR7280, 13288 Marseille, France, Marseille, France.*

Type I interferons (type I IFN) play a major role in antiviral defense. However, how they orchestrate *in vivo* the functions of distinct immune cells is not well understood. We determined that type I IFNs produced during murine cytomegalovirus (MCMV) infection differentially affect dendritic cells (DCs) and natural killer (NK) cells. Type I IFNs induce cell-intrinsic responses in DCs, activating antiproliferative, antiviral, and lymphocyte-activating gene networks, consistent with high activity of the transcription factor STAT1 in these cells. By comparison, NK cells exhibit lower STAT1 expression and reduced type I IFN responsiveness. Rather, type I IFN indirectly affect NK cells by inducing IL-15, which activates the transcription factor E2F and stimulates genes promoting cell expansion. Type I IFN cell-intrinsic responses are necessary in DCs, but not NK cells, for MCMV resistance. Thus, sensitivity to type I IFN-induced cytokines and differences in type I IFN receptor signaling program immune cells to mount distinct responses that promote viral control.

P4.01.101

The study of genes encoding interleukin-1β, 2, 8,10 expression in the rabbit infected with RHD (rabbit haemorrhagic disease)

A. Trzeciak-Ryczek[1], *B. Tokarz-Deptuła*[1], *W. Deptuła*[2];
[1]*University of Szczecin, Department of Immunology, Szczecin, Poland,* [2]*University of Szczecin, Department of Microbiology, Szczecin, Poland.*

Interleukins (IL) play an important role in antiviral immunity, for example in infection of rabbits with RHDV, which is an etiological factor of viral haemorrhagic disease. Studies on the changes in the expression of genes encoding IL are few, and applies only to liver cells. Thus, the aim was to assess changes in the expression of genes encoding IL-1β, 2,8,10 in peripheral blood leukocytes (components of the immune system) in rabbits experimentally infected with RHD virus- strain V-411. The analysis was performed with real-time PCR, and the results were analyzed by relative quantification method by Livak, using two reference genes (HPRT and β-actin). The study was performed on 6 rabbits (4 individuals infected intramuscularly with RHDV and 2 control) and the blood was sampled from ear's marginal vein in "0" (ie. before administration of antigen and placebo), and then in 8,12,24,28,36 p.i.
Studies have shown the increased expression of the genes encoding IL-2 in the 8 and 12 h p.i. and decrease in the 24-36h p.i. A similar, but not identical picture of changes was registered in the expression of gene for IL 1β. For IL-10, the decrease of expression was registered in 8 and 12h p.i. and the increase between 24-36h. There have been no changes in the expression of genes encoding IL-8 registered.

P4.01.102

CytoDiffTM panel allowing monitoring effectiveness of the highly active antiretroviral therapy on HIV infected patients

V. E. Tseylikman[1], *I. Reshetnikov*[1], *G. Bouvier*[2], *S. Kvyatkovskaya*[3], *S. Kvyatkovskaya*[1], *D. Faye*[2], *&. Mirkina*[1], *E. Gautherot*[2], *&. Shatirko*[1], *E. Sukhacheva*[4];
[1]*Chelyabinsk State Medical Academy, Chelyabinsk, Russian Federation,* [2]*Beckman Coulter. Immunotech, Marseille, France,* [34]*Beckman Coulter Eurocenter,, Nyon, Switzerland.*

Background: It has been shown that the CytoDiff™ panel, a 5-color/6marker reagent, which provides a 10-part white blood cell differential allows more efficient monitoring of immune status in HIV

patients; however the ability of the CytoDiff panel for monitoring effectiveness of the highly active antiretroviral therapy (HAART) has not been tested.
The aim of this study was to analyze the leucocyte subsets provided by the CytoDiff application on a cohort of HIV patients with and without HAART.
Methods: Samples from 199 HIV infected patients and 33 normal blood donors were analyzed. The viral load, the CD4 lymphocyte count, manual differential and a detailed clinical status of these patients were obtained. Samples were stained with the CytoDiff panel (CD36-FITC, (CD2+CD294)-PE, CD19-ECD, CD16-PC5 and CD45-PC7), lysed and 20 000 leucocytes were analyzed on a FC500 Flow Cytometer (Beckman Coulter) using CytoDiff CXP software.
Results: A comparison between control group and HIV patients was performed on each leucocyte sub-population identified with CytoDiff. A significant decrease from the control group was observed for the Lymphocytes total, Lymphocytes CD16+, B Lymphocytes and Eosinophils with simultaneous increase for the CD16+ monocytes and neutrophils. HAART decreased viral load and softened these shifts in HIV infected patients. HIV infected patients with HAART exhibited higher levels of the Lymphocytes total, Lymphocytes CD16+, B Lymphocytes as well as lower levels CD16+ monocytes and neutrophils if compared with HIV infected patients without HAART.
Conclusion: CytoDiff panel can be used to monitor the effectiveness of HAART.

P4.01.103
Universal influenza vaccine requires CD4 T cells for heterosubtypic protection

***S. A. Valkenburg**, O. T. W. Li, L. L. M. Poon;*
University of Hong Kong, Pokfulam, Hong Kong.

Current influenza vaccines are ineffective against new viruses and the source or strain of the next outbreak strain of influenza is unpredictable, therefore establishing universal immunity by vaccination is fundamental to limiting the impact of influenza. Virus specific CD4 and CD8 T cells are able to directly kill virus infected cells and co-ordinate local innate immune responses. Importantly, T cells are able to react against different strains and subtypes of influenza. A novel vaccine has been developed using a Vaccinia vector encoding H5N1 derived proteins and a molecular IL-15 adjuvant. The vaccine has proven effective against different H5N1 clades, and most importantly group 1 and group 2 influenza viruses, which have widely different HA and NA proteins. Here we establish the role of T cells in providing universal protection against influenza established by a vaccinia-H5N1 vaccine. The vaccine is able to induce robust immunological memory, enabling the survival of mice against many different influenza viruses, such as seasonal H3N2, 2009 pandemic H1N1, lethal avian H5N1 and H7N7 influenza viruses. Influenza specific CD4 and CD8 T cell responses are elicited by the vaccine, and recruited following viral challenge in the lung and periphery. Selective depletion experiments for T cell subsets has established an important role of CD4 T cells in heterosubtypic protection depsite low epitope sequence conservation across different influenza viruses. Unraveling how this vaccine is able to protect against different unrelated influenza strains is key to designing and improving future vaccine strategies and public health.

P4.01.104
BCG restores antiviral immune response in patients with recurrent respiratory papillomatosis by affecting dendritic cell differentiation

***E. Vetskova**[1], T. Avramov[2], M. Muhtarova[1], T. Stefanova[3], M. Nikolova[1];*
[1]National Center for Infectious and Parasitic Diseases, Sofia, Bulgaria, [2]II ORL Department, University Hospital for Active Treatment "Tsaritsa Joanna ", Sofia, Bulgaria, [3]BB-NCIPD Ltd., Sofia, Bulgaria.

Recurrent respiratory papillomatosis (RRP) is characterized by a high relapse frequency after standard surgery due to inefficient immune response to chronic HPV infection. Additional immunotherapy with ,,Calgevax" (BCG) considerably improves the outcome. The present study investigates the effects of BCG on cellular immune responses in RRP.
RRP patients (n = 17) subjected to combined CO2 laser microsurgery / BCG-immunotherapy were studied before (0), 6, 12 and 20 months after the start of immunomodulation. Percentages of circulating plasmacytoid dendritic cells (pDC), mature (CD86+) DCs, and regulatory (CD4+FoxP3+) T cells, as well as the level of in vitro PHA-stimulated Th17 effectors and Th1/Th2 cytokine secretion were determined by flow cytometry (FACSCanto II, BD), in comparison to healthy controls.
At point 0, significantly decreased pDCs and CD86+DCs levels were established (average 4.8% and 32% respectively), that approached healthy control levels after 12 months of BCG application (8.5vs.8, and 55vs.60, p >0.5 for both). Further on, 12 months of BCG immunotherapy significantly decreased the share of proinflammatory Th17 (0.4 vs. 0.69, $p<0.05$) and increased the level of circulating Treg (4.6 vs. 7.1, $p<0.05$). Finally, the initially decreased IFNγ/IL-4, and IFNγ /IL-10 ratios, were restored after 20 months of BCG application.
BCG increases the efficiency of antiviral T-cell response by stimulating the maturation and differentiation of pDCs, resulting in efficient antigen presentation, restoration of Th1/Th17 disbalance, and induction of Treg preventing the terminal differentiation of T cell clones in the settings of chronic infection.

P4.01.105
The influence of antibodies on the immune response to respiratory syncytial virus infection

***M. Vissers**, I. Schreurs, M. I. de Jonge, R. de Groot, G. Ferwerda;*
Radboud University Medical Centre, Nijmegen, Netherlands.

Respiratory Syncytial Virus (RSV) can cause severe bronchiolitis in young infants. Approximately 50% of severe RSV infections can be explained by currently known risk factors. Hence, the pathogenesis of disease severity is still poorly defined. Evidence suggests that maternal antibodies might have an influence on severity of infection. This study tries to identify the influence of antibodies on the immune response to RSV infection.
Previous experiments have shown that antibodies (Ig's) present in human serum (HS) prevent RSV from infecting cells. However, stimulation of human peripheral blood mononuclear cells (PBMCs) with RSV in combination with HS induced a synergistic increase in interferon-γ (IFN-γ) production. To study whether the enhanced IFN-γ production is depended on immune complexes, other HS components or infectious versus antibody-neutralized virus, we stimulated human PBMCs with RSV and BPL-inactivated RSV in combination with HS and Ig depleted HS. Measurement of cytokine levels indicates that antibodies are the main cause of this synergistic increase in IFN-γ production. In both monocyte and NK cell depleted fractions of PBMCs this synergistic response persisted. IFN-γ could already be measured after 4 hours on mRNA level and after 24 hours on protein level, possibly suggesting a direct stimulation of T cells by opsonized RSV.
This study shows that anti-RSV antibodies present in human serum enhance the induction of IFN-γ by PBMCs stimulated with RSV. These data indicate that the presence of (maternal) neutralizing antibodies during a primary RSV infection might enhance inflammation and affect disease severity.

P4.01.106
Lipopolysaccharide stimulation inhibits viral infection of human macrophages with two distinct mechanisms

M. Vissers[1], *K. R. Short*[2], *P. W. M. Hermans*[1], *D. A. Diavatopoulos*[1], *G. Ferwerda*[1];
[1]*Radboud University Medical Centre, Nijmegen, Netherlands,* [2]*The University of Melbourne, Melbourne, Australia.*

It is well known that respiratory viral infections enable commensal bacteria in the nasopharynx to disseminate to other sites in the body and cause disease. However, this is not a uni-directional interaction and several studies have shown that substantive crosstalk exists between bacterial pathogen-associated molecular patterns (PAMP)-signalling pathways and the induction of anti-viral immunity. Studies so far have been performed in murine models and it is unclear how far these findings can be extrapolated to human infections. Therefore, we use influenza A virus (IAV) and respiratory syncytial virus (RSV) to examine how bacterial ligands can affect the subsequent viral infection of human monocyte-derived macrophages (MDMs) and epithelial cells.
Human epithelial cells (A549) stimulated by a panel of different bacterial ligands did not display any significant alteration in susceptibility to RSV or IAV. However, pre-stimulation of human MDMs with lipopolysaccharide (LPS) reduced the infection rate of both RSV and IAV with approximately 80%. Interestingly, our results show that LPS protects against viral infection in two distinct mechanisms. The inhibition of IAV infection was associated with the ability of LPS to induce a type I interferon and anti-viral response, which results in a reduced transcription of viral RNA. In contrast, LPS triggered a short-term, RSV-specific response preventing RSV entry early in the infection.
Taken together, these data demonstrate the bi-directional nature of viral-bacterial interactions and suggest that the composition of an individual's nasopharyngeal flora may help determine their susceptibility to viral respiratory infections.

P4.01.107
A novel RSV genetic vaccine based on chimpanzee Adenovirus and MVA vectors is safe and highly immunogenic in animal model and fully protects cotton rats and newborn calves from RSV challenge

A. Vitelli[1], *A. Pierantoni*[1], *S. Capone*[1], *S. Colloca*[1], *A. Folgori*[1], *E. Scarselli*[1], *G. Taylor*[2], *M. Thom*[2], *R. Cortese*[1,3], *A. Nicosia*[1,3,4];
[1]*Okairos Srl, Rome, Italy,* [2]*Institute for Animal Health, Compton, United Kingdom,* [3]*CEINGE, Naples, Italy,* [4]*University of Naples Federico II, Naples, Italy.*

Chimpanzee-derived Adenovirus (ChAd) vectors are insensitive to pre-existing immunity and have been used in heterologous prime/boost regimens with Modified Vaccinia Ankara (MVA) vectors encoding the same antigen, leading to unprecedented immune responses in humans.
We have generated ChAd and MVA vectors encoding for the F, N and M2-1 RSV antigens to induce a full spectrum of immune responses including neutralizing antibodies and T cells.
The vaccine vectors were tested in pre-clinical animal models by different regimens and routes, including mucosal delivery by intranasal spray. When tested in the cotton rat model, the vaccine completely prevented replication of the virus in the lung and in the nasal cavity. The results of lung histopathology analysis showed that the vaccine was safe and did not induce enhanced pulmonary pathology.
BRSV-seronegative calves were vaccinated intranasally (i.n.) with ChAd/RSV and boosted 8 weeks later with MVA/RSV intramuscularly (i.m.). Calves were challenged with BRSV 4 weeks after boosting. Mucosal vaccination with ChAd/RSV primed BRSV-specific IFNγ-producing cells in peripheral blood and BRSV-specific serum antibodies, which were boosted by i.m. vaccination with MVA/RSV. Following challenge with BRSV, calves were completely protected against virus replication in the nasopharynx and lungs and were completely protected against the development of pulmonary pathology.
Formal GLP toxicology study in mice showed no vaccine related safety concern and GMP grade RSV genetic vectors have been prepared and are ready to be tested in clinical trials.

P4.01.108
Molecular characterization of rotavirus detected in diarrhoeic children less than five years of age in Kano State, Nigeria

A. Wada-Kura[1], *O. S. Olonitola*[2], *S. Mijatovic-Rustempasic*[3], *M. D. Esona*[3], *A. G. Abubakar*[4], *M. D. Bowen*[3], *M. Aminu*[2];
[1]*Department of Molecular Biology and Bioinformatics, National Biotechnology Development Agency, Abuja, Nigeria,* [2]*Department of Microbiology, Ahmadu Bello University, Zaria, Nigeria,* [3]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [4]*Institute of Human Virology, Abuja, Nigeria.*

Background: Rotavirus is the most common cause of severe diarrhoeal illness in infants and young children 0-5 years of age in both developing and developed countries.This Study was aimed at determining the prevalence and genotyping of rotavirus among these children using ELISA and RT-PCR
Methods: A total of 285 stool samples were collected from infants and children 0-5 years of age. The diarrhoeic Stools were analyzed for rotavirus antigen and the rotavirus positive stools were further subjected to VP7 and VP4 genotyping using gene specific primers.
Results: Rotavirus was detected in 36.5% of the diarrhoeic children. The infection occurred throughout the study period with higher peaks in the drier month of April 77.6% and lowest in July 12.2% (Pearson Chi Square analysis: X^2= 27.720, P<0.05, df=1). No statistically significant difference was observed (P>0.05). Three different rotavirus P-genotypes (P[8], P[4], and P[6]) were detected in this study and Mixed infection were detected. Six different G-genotypes were detected.
Conclusion: Rotavirus was found to be an important cause of diarrhoea in children 0-5 years of age in Kano, North-Western Nigeria.

P4.01.109
A Critical Role of IL-17 in Modulating B Cell Response During H5N1 Influenza Virus Infection

X. Wang, *L. Lu;*
The University of Hong Kong, Hong Kong, China.

Interleukin-17 (IL-17), a member of IL-17 family, plays a crucial role in mediating immune response against extracellular bacteria and fungi in the lung. Although there is increasing evidence that IL-17 is involved in the protective immunity against H1 and H3 influenza virus infections, little is known about the role of IL-17 in the high pathogenic H5N1 influenza virus infection. In this study, we found that H5N1-infected IL-17 knockout (KO) mice showed markedly increased weight loss with severer lung immunopathology and significantly reduced survival rate as compared with wild-type controls. Moreover, a substantially decreased frequency of B cells was observed in the lung of IL-17 KO mice after virus infection, which was correlated with reduced CXCR5 expression on B cells and decreased CXCL13 production in the lung tissues of IL-17 KO mice. Consistently, B cells from IL-17 KO mice exhibited a significant reduction in chemokine-mediated migration in culture. Taken together, our findings have demonstrated a critical role of IL-17 in mediating the recruitment of B cells to the site of pulmonary influenza virus infection in mice.

P4.01.110
Early growth response genes (Egr) -2 and -3 are essential for the activation of naïve B and T cell and primary response against virus infection

P. Wang;
Institute of Cell and Molecular Science, London, United Kingdom.

T cells robustly respond to virus infection. However, the inflammatory effects of responding T cells are controlled to minimize immunopathology. Egr-2 and -3 are zinc-finger transcription factors rapidly induced in naïve B and T cells (1, 2, 3). The deficiency of Egr-2 and -3 specifically in B and T cells results in severe autoimmunity (3). It is however unknown whether they also play roles in protective immmunoresponses. We have now shown that Egr-2 and -3 are required for naïve B and T cell activation in response to virus infection. Defects in the induction of Egr-2 and -3 restrain the IL-2

production and the expansion of viral specific CD4 and CD8 T cells leading to the development of chronic infection. We found that Egr-2 and -3 are transactivated by AP-1. The induced Egr-2 and -3 are essential for the maintenance of optimal AP-1 activation and AP-1 mediated IL-2 production leading to the rapid expansion of viral specific B and T cells. In addition to the proliferation of viral specific T cells, Egr-2 and -3 control the production of pro-inflammatory cytokines of T cells at early stages of infection to limit inflammatory pathology leading to robust anti-viral effect with minimum immunopathology. The functions of Egr-2 and -3 are limited in naïve T cells in primary immunoresponses and are not involved in the development of the memory pool and secondary responses. In conclusion, in addition to the maintenance of immunohomeostasis, Egr-2 and -3 are important to primary immune responses against virus infection.

P4.01.111
PERIPHERAL BLOOD MONOCYTES IN ACUTE AND STABLE COPD HAVE IMPAIRED RESPONSES TO RESPIRATORY VIRUSES

P. Wark[1], *H. V. See*[1], *J. Simpson*[1], *P. Hansbro*[2];
[1]*Respiratory Medicine Hunter Medical Research Institute University of Newcastle, New Lambton, Australia,* [2]*Respiratory Medicine Hunter Medical Research Institute School of Biomedical Science University of Newcastle, New Lambton, Australia.*

Patients with chronic obstructive pulmonary disease (COPD), suffer frequent exacerbations due to respiratory virus infections. Our aim was to determine if peripheral blood monocytes (PBMCs) from exacerbating and stable COPD patients had impaired immune responses when exposed to influenza (H1N1pdm09) and rhinovirus (RV-1B). Methods; we recruited 10 subjects who had been admitted to hospital with acute exacerbations of COPD and then 6-8 weeks later when recovered and 10 age matched healthy controls with no lung disease. Subjects had blood drawn and monocytes selected using Ficoll-paque centrifugation. Cells were stained with CD3, CD4, CD8, CD56, CD14, CD11c and CD303 and identified with flow cytometry. PBMCs were then exposed to H1N1 and RV-1B, expression of PD-1, PDL-1 was measured as well as release of interferon (IFN)-α, IFN-λ, IFN-γ, TNF-α and IL-1β. Results; PBMCs from subjects with COPD when acutely unwell demonstrated reduced release of IFN-α, IFN-λ, IFN-γ, TNF-α when exposed to H1N1 and RV-1B, in convalescence release of IFN-λ, and TNF-α remained impaired compared to controls. PBMCs in COPD acute and convalescent samples demonstrated increased expression of PDL-1 on plasmacytoid dendritic cells at baseline. Following exposure to virus there was increased expression of PD-1 in COPD CD4 and CD8 cells. Conclusions; PBMCS in acute and stable COPD demonstrate impaired IFN responses to virus infection with altered expression of PD-1/PDL-1.

P4.01.112
Distinct immunity between pandemic H1N1 and seasonal H3N2 influenza infections in humans

C. Wei[1,2], *L. Wang*[3], *P. Huang*[4], *K. D. Yang*[5];
[1]*Show Chwan Health Care System, ChangHua, Taiwan,* [2]*Institute of Biotechnology, Central Taiwan University of Science and Technology, Taichung, Taiwan,* [3]*Department of Pediatrics, Kaohsiung Chang Gung Memorial Hospital and Chang Gung University College of Medicine, Kaohsiung, Taiwan,* [4]*Departments of Medical Research, Kaohsiung Chang Gung Memorial Hospital and Chang Gung University College of Medicine, Kaohsiung, Taiwan,* [5]*Show Chwan Health Care System, ChangHua County, Taiwan.*

Results from the immunopathogenetic studies of different influenza infections in humans may provide useful information concerning the appropriate measures to be taken for preventing complications and fatality of an emerging influenza infection. In this study, we investigated the innate and adaptive immune responses of pandemic (H1N1) 2009 influenza in comparison to seasonal H3N2 and other febrile infection. In a cohort of 159 patients, we studied different infection immunity between the pandemic (H1N1) 2009 and H3N2 seasonal infections. Both H1N1 and H3N2 patients had lymphopenia, but the H1N1 patients had prominent lower $CD8^+$ cells and the H3N2 patients had lower $CD19^+$ cells. Lower NK-cell perforin content and plasma bactericidal activity were prominently found in the H1N1 patients. The H1N1 patients also had higher Treg cells with augmented Foxp3 expression as well as TGF-beta 1 production but lower interferon-gamma production. The H3N2 patients, however, had higher T-bet expression with lower TGF-beta1 production. In conclusion, impaired NK-cell function and bactericidal activity associated with augmented Treg-cell function might render the H1N1 patients more susceptible to bacterial superinfection.

P4.01.113
Role of host and viral factors in negative antibody response of seronegative occult hepatitis B virus infection

R. S. Wijaya[1,2], *S. I. Ie*[2], *Y. A*[3,2], *T. Turyadi*[2], *K. E. El-Khobar*[2], *A. R. Harahap*[2,4], *D. H. Muljono*[2,5,6];
[1]*Faculty of Medicine, Pelita Harapan University, Tangerang, Indonesia,* [2]*Eijkman Institute for Molecular Biology, Jakarta, Indonesia,* [3]*Faculty of Medicine, Atma Jaya University, Jakarta, Indonesia,* [4]*Department of Clinical Pathology, Faculty of Medicine, University of Indonesia, Jakarta, Indonesia,* [5]*Hassanuddin University, Makassar, Indonesia,* [6]*Sydney Medical School, University of Sydney, Sydney, Australia.*

Background The lack of antibody response in seronegative occult hepatitis B virus (HBV) infection or OBI can be caused by host and viral factors. The polymorphism of human leukocyte antigen (HLA) class II gene, especially in HLA-DRB1 locus, will determine host antibody immune response whereas mutation in HBV surface (S) gene, which overlaps the HBV polymerase (P) gen, potentially affects the replication ability of HBV. This study aims to investigate the HLA-DRB1 genotypes and the HBV S gene characteristics from OBI seronegative individuals in Ternate.
Methods Host DNA were extracted by salting out method, and further analyzed for HLA-DRB1 alleles together with 9 anti-HBc positive OBI individuals as controls using LABType® SSO Typing Test (One Lambda, USA). HBV S gene of 9 OBI seronegative isolates were detected by PCR, cloned and analyzed for the presence of amino acid variation
Results HLA-DRB1*12 and *15 were the most common alleles. The distribution of these alleles was not statistically different between seropositive and seronegative OBI groups. HBV DNA was found in second round of amplification (<200 IU/mL). From 67 sequenced clones, 60 (89.6%) showed the presence of S gene mutations.
Conclusions Our results suggest that there was no significant difference in HLA-DRB1 allele distribution among OBI seropositive and seronegative groups. The lack of antibody response in OBI seronegative is more likely due to the low level of HBV DNA. This could be caused by mutations in the S gene and its overlapping P gene, which may affect HBV replication.

P4.01.114
Viral dsRNA and ssRNA analogues directly activate mast cells to cysteinyl leukotriene generation and modulate their IgE-dependent releasability

P. Witczak, *K. Wódz, E. Bąbolewska, A. Słodka, E. Brzezińska-Błaszczyk;*
Department of Experimental Immunology, Medical University of Łódź, Łódź, Poland.

Mast cells (MCs) are particularly abundant at anatomical sites close to external environment and express functional Toll-like receptors (TLRs) by which detect invading bacteria. Recently, a few reports indicated that MCs also possess cytoplasmic TLRs, including TLR3 and TLR7/8, that recognize by-products of viral replication, i.e. dsRNA and ssRNA, respectively. Accordingly, MCs might be involved in anti-viral defense or/and in patomechanisms of viral-related diseases. Therefore, the study aim was to examine MC response to TLR3 and TLR7 agonists, i.e. poly(I:C) and R848, respectively. Due to MC central role in allergic reactions, we also investigated effect of TLR3- and TLR7-depended activation on IgE-mediated MC response. Experiments were performed *in vitro* on freshly isolated fully mature rat peritoneal MCs (rPMCs). We used western blot and flow

cytometry to determine TLR3 and TLR7 protein expression, histamine release assay to examine degranulation, and ELISA tests to study cysLT and CXCL8 synthesis. Our results indicated that rPMCs constitutively express TLR3 and TLR7 proteins and selectively respond to poly(I:C) and R848 stimulation. TLR3- and TLR7-mediated MC activation led to dose- and time-dependent cysLT synthesis without degranulation and CXCL8 generation. Moreover, MC co-stimulation with poly(I:C) and anti-IgE amplified cysLT secretion, whereas MC priming with R848 resulted in decrease of anti-IgE-induced degranulation. Our results suggest that dsRNA and ssRNA viruses could activate MCs to release of potent proinflammatory mediators and modulate IgE-mediated allergic processes. This work was supported by the National Science Centre in Poland (Grant No. 2011/03/N/NZ6/03528) and by the Medical University of Łódź (Grant No. 502-03/6-164-01/502-64-005).

P4.01.115

Secondary *Streptococcus pnuemoniae* infection impairs the immunity to influenza virus by down-regulating the adaptive immune response

Y. Wu[1], *K. H. Chow*[2], *P. L. Ho*[2], *W. Tu*[1], *Y. L. Lau*[1];
[1]*The University of Hong Kong, Department of Paediatrics and Adolescent Medicine, Hong Kong, Hong Kong,* [2]*The University of Hong Kong, Department of Microbiology, Hong Kong, Hong Kong.*

Background: During pandemic and seasonal influenza, secondary bacterial infections often enhance mortality. Given the clinical importance of the co-infection and increasing risk of influenza outbreak, it is important to understand how the immune system would be affected in dealing with the dual infections.
Methods: Mice were sequentially infected with influenza virus and *Streptococcus pneumoniae*. Survival and weight lost were recorded. The lungs from infected mice were examined for virus titre, bacterial cell counts. The spleens and lymph nodes from infected mice were examined for cellular immune response against the pathogens.
Results: Co-infected mice lost their body weight significantly and had 100% morality, whereas mice infected with either influenza or pneumococcus alone lost their body weight transiently and all recovered from the infections. Co-infected mice had significantly higher virus titre, bacterial cell counts in their lung when compared to the mice infected with either of the pathogens alone. When compared to single influenza infection, secondary pneumococcal infection significantly accelerated disease kinetic of influenza to cause lymphopenia, and suppressed the virus specific IgG response by down-regulating follicular B cells and follicular T helper cells. The suppression of the humoral immunity was critical to cause excess mortality as adaptive transfer of “immune serum” against influenza after secondary pneumococcal infection rescued co-infected mice from death.
Conclusion: In the co-infection,secondary pneumococus suppressed the adaptive immunity to the initial influenza virus, which impaired the control of influenza and caused excess mortality. This study contributes to the understanding of the pathogenesis of the co-infection.

P4.01.116

Irreversibly skewed development of B cells towards terminal stages during HIV-1 infection and resulted in their functional impairment

J. Yan[1], *C. Qiu*[1,2], *L. Li*[1,2], *C. Qiu*[1], *J. Sun*[1], *J. Xu*[1,2,3], ***X. Zhang***[1,2,3];
[1]*Shanghai Public Health Clinical Center, Fudan University, Shanghai, China,* [2]*Institutes of Biomedical Sciences, Fudan University, Shanghai, China,* [3]*Key laboratory of Medical Molecules Virology of Ministry of Education/Health, Fudan University, Shanghai, China.*

Background: HIV-1 infection results in the abnormalities of B cells. Here we defined the skewed differentiation of B cells and their functionality in HIV-1 chronically infected subjects.
Methods: We employed flow cytometry to determine the differences in the frequencies and the phenotypes of B-cell subpopulations among32 HIV-1 viremic subjects naïve to antiretroviral therapy (ART), 34 ART successfully treated patients and 12 HIV-seronegative donors. Furthermore, HIV Env specific or influenza HA specific antibody secreting cells (ASCs) were quantified.
Results: $CD19^+$ B-cell counts were significantly less in the chronically HIV-1 infected than the HIV-seronegative group ($p=0.05$), which was manifested in naïve, immature, resting memory B cells and plasmablasts($p<0.01$, $p=0.02$, $p=0.02$ and $p<0.01$, respectively); In contrast, the frequencies of tissue-like memory B cells, defined as dysfunctional B cells, was elevated in chronically HIV infected subjects ($p<0.01$). Activation markers CD38 and CD95 expressing B cells increased in chronically HIV infected subjects ($p<0.01$ and $p<0.01$, respectively) whereas Bcl-2 decreased comparing to HIV-seronegative subjects ($p<0.01$). Successful ART only partially restored the skewed development of B cells. Furthermore, B cells from HIV infected subjects showed impaired responses to influenza HA ($p=0.03$) and the suppression of HIV replication by ART led to the decreased HIV-specific ASCs ($p<0.01$).
Conclusions: HIV infection resulted in the skewed differentiation of B-cell subpopulations towards terminal stage, which was accompanied by a functional impairment; ART only partially restored the abnormality. It remains a challenge to revoke B cell functionalities.

P4.01.117

Immunological pressure by monoclonal antibodies targeting glycoproteins of the 2009 pandemic influenza A(H1N1) virus drives quasi-species with increased virulence in mice

H. Yi*, M. Lee, C. Kang;*
Division of Influenza Virus, Korea National Institute of Health, Chungcheongbuk-do, Republic of Korea.

In 2009, a pandemic influenza virus (H1N1pdm09) emerged and was spread to world-wide. A panel of monoclonal antibodies (D319, D360, D383, D430, I38-7), specific for the H1N1pdm09 virus hemagglutinin (HA) or Neuraminidase (NA), was generated from B-cells of the H1N1pdm09-infected mice. To indentify the antibody-binding sites (epitopes), the mAbs were used for the selection of escape-mutants which were generated by cultivation of a H1N1pdm09 strain (A/Korea/01/2009) with excess of the mAbs in embryonic eggs. The sequence-analysis of escape-mutants revealed 10 amino-acid positions recognized by the mAbs. The positions were distributed in the epitopes belonging to antigenic sites Sa (172, 173, 178 and 180), Sb (201 and 203) and novel epitopes (56, 144 and 146) in HA and 272 in NA. The escape-mutants with G172E and N173D in HA showed significantly reduced reactivity to mAb-D383 and sera from H1N1pdm09-infected ferrets. The escape mutants with D144E, N146D, T201N and A203D in HA were proved to have drastically lower reactivity to mAb-D360 and -D430. The escape mutants having D144E in HA were revealed to have weak reactivity to human sera from vaccinated individuals against H1N1pdm09 and enhanced binding avidity to host cells through RDE avidity assay, compared with mother strain and other variants. Furthermore, the escape mutant viruses showed increased virulence in mice, compared with the mother strain. Collectively, these results demonstrate that immunological pressure by monoclonal antibodies targeting H1N1pdm09 can drive the virus to increased virulence with altered host-cell binding properties. This work was supported by #2012-N43003-00 (intramural research fund)

Adaptive Immunity Restricts Replication of Novel Murine Astroviruses

C. C. Yokoyama*, J. Loh, G. Zhao, T. S. Stappenbeck, D. Wang, H. V. Huang, H. W. Virgin, L. B. Thackray;*
Washington University in St. Louis, Saint Louis, MO, United States.

The mechanisms of astrovirus pathogenesis are largely unknown, in part due to a lack of a small-animal model of disease. Using shotgun sequencing and a custom analysis pipeline, we identified two novel astroviruses capable of infecting research mice, murine astrovirus (MuAstV) STL1 and STL2. Subsequent analysis revealed the presence of at least two additional viruses (MuAstV STL3 and STL4), suggestive of a diverse population of murine astroviruses in research mice. Complete genomic characterization and subsequent phylogenetic analysis showed that MuAstV STL1 to STL4 are

members of the mamastrovirus genus and are likely members of a new mamastrovirus genogroup. Using Rag1−/− mice deficient in B and T cells, we demonstrate that adaptive immunity is required to control MuAstV infection. Furthermore, using Stat1−/− mice deficient in innate signaling, we demonstrate a role for the innate immune response in the control of MuAstV replication. Our results demonstrate that MuAstV STL permits the study of the mechanisms of astrovirus infection and host-pathogen interactions in a genetically manipulable small-animal model. Finally, we detected MuAstV in commercially available mice, suggesting that these viruses may be present in academic and commercial research mouse facilities, with possible implications for interpretation of data generated in current mouse models of disease.

Hepatitis C virus-infected cells induce down-regulation of natural killer cell activating receptors through modulation of receptor traffic

J. Yoon[1,2], *D. Choi*[1,2], *J. Park*[3], *J. Lee*[3];
[1]*Department of Microbiology, Ewha Womans University School of Medicine, Seoul, Republic of Korea,* [2]*Tissue Injury Defense Research Center, Ewha Womans University School of Medicine, Seoul, Republic of Korea,* [3]*Department of Microbiology, Yonsei University College of Medicine, Seoul, Republic of Korea.*

Natural killer (NK) cells play an important role in the defense against virus infections. We previously reported that cell-to-cell contact with hepatitis C virus (HCV)-infected cells reduces functional capacity of NK cells. Decreased cytotoxicity is correlated with down-regulation of NK cell activating receptors, NKG2D and NKp30, on NK cells. In this study, we investigated whether the traffic of the activating receptors to or from NK cell surfaces is modulated by the interaction of NK cells with HCV-infected cells. HCV-permissive human liver cell lines were infected with HCV virions and co-cultured with primary human NK cells. Degranulation of NK cells and surface or total (surface and intracelluar) expression of NKG2D and NKp30 were measured. Redirected degranulation assays proved that down-regulation of NKG2D and NKp30 was direct cause of the decreased cytotoxic capacity of NK cells. Considerable amount of both receptors were found in cytoplasm as well as on plasma membrane, suggesting that they recycle from cytoplasm to plasma membrane. After cell-to-cell contact of NK cells with HCV-infected cells, both surface and total expression of the activating receptors diminished. It implied that receptor traffic in the NK cells contacted with HCV-infected cells was modulated by degradation of intracellular pools of the receptors. Suppression of protein degradation using chemical inhibitors resulted in restoration of NKG2D and NKp30 expression on the surface of NK cells. In conclusion, the interaction between NK cells and HCV-infected cells modulated the traffic of NK cell activating receptors and thereby suppressed functional capacity of NK cells.

[1]*Department of Laboratory Medicine and Biotechnology, Tzu Chi University, College of Medicine, Hualien, Taiwan,* [2]*Division of Hematology/Oncology, Department of Medicine, Tri-Service General Hospital. National Defense Medical Center, Taipei, Taiwan,* [3]*Division of Hematology/Oncology, Department of Internal Medicine, Taipei Medical University-Shuang-Ho Hospital, Taipei, Taiwan.*

IDO is an important intracellular heme protein enzyme in tryptophan metabolism with immunoregulatory and antiviral function. It has been recognized as an antimicrobial biostatic defense through tryptophan deprivation. IDO expression has been reported in flavivirus infection. The role of IDO in virus infection might play roles in the inhibition of growth of micro-organisms and has profound effects on T cell proliferation and immune tolerance. We have demonstrated that interferon regulatory factors could induce IDO expression in interferon-gamma induced THP1 cells to regulate T cell immune response. The expression level of IDO was decreased in hepatitis C virus replicon cell lines which knockdown of interferon regulatory factors. IDO activity in culture supernatant of interferon regulatory factors knockdown cell lines were decreased in chemical method by spectrophotometer analysis. However, the expression levels of viral non-structural proteins were not changed. These results give hint that interferon regulatory factors are responsible for IDO induction at hepatitis virus C infection.

Immunogenicity of two measles-mumps-rubella vaccines in Iranian pre-school children, a randomized controlled trial

S. Zarei[1,2], *M. Jeddi-Tehrani*[3,4,5], *H. Zeraati*[6], *F. Pourheidari*[7], *A. A. Ferydonfar*[7], *J. Nasernia*[7], *B. Tavangar*[1], *Y. Vojgani*[1], *M. M. Akhondi*[5], *F. Shokri*[8];
[1]*Monoclonal Antibody Research Center , Avicenna Research Institute , ACECR, Tehran, Iran,* [2]*Reproductive Immunology Research Center, Avicenna Research Institute, ACECR, Tehran, Iran,* [3]*Monoclonal Antibody Research Center, Avicenna Research Institute, ACECR, Tehran, Iran,* [4]*Immune and Gene Therapy Lab, Cancer Center Karolinska, Karolinska University Hospital, Stockholm, Sweden,* [5]*Reproductive Biotechnology Research Center, Avicenna Research Institute, ACECR, Tehran, Iran,* [6]*Department of Epidemiology and Biostatistics, School of Public Health, Medical Sciences/University of Tehran, Tehran, Iran,* [7]*East Health Center, Shahid Beheshti University of Medical Sciences, Tehran, Iran,* [8]*Department of Immunology, School of Public Health, Medical Sciences/University of Tehran, Tehran, Iran.*

Objectives: The prevalence of measles, mumps and rubella (MMR) diseases has declined dramatically over recent years as a result of universal immunization programs. The present study was undertaken to compare the immunogenicity of two MMR vaccines administered to Iranian preschool children.
Methods: In this randomized, double-blind and multicenter prospective study, 820 children aged 6 years were injected with either a local MMR vaccine (MMR-Local, n=383) or a commercial vaccine manufactured by GlaxoSmithKline (MMR-GSK, n=437). All subjects received MMR vaccine at 1 and 6 years of age, following the national vaccination schedule of Iran. Blood samples were collected before and one month after the 2nd vaccine dose. Immunogenicity of the vaccines was assessed by ELISA using commercial kits.
Results: The geometric mean titers (GMT) of the antibodies induced against measles and rubella by MMR-Local were 1.2 and 5.6 IU/ml and those of MMR-GSK were 1.5 (p=0.029) and 97.9 IU/ml (p<0.001), respectively. The GMTs of antibodies produced against mumps were 99.2 RU/ml for MMR-Local and 98.9 RU/ml for MMR-GSK vaccines, respectively. No significant differences were observed between the two vaccines components regarding the GMT obtained for samples collected before administration of the 2nd vaccine dose.
Conclusion: Immunogenicity against mumps was similar for the two vaccines, but immunogenicity of the local vaccine against rubella and to a lesser extent measles was significantly less efficient than that of the MMR-GSK. This difference could be attributed to the virus strain or the preparation or formulation protocol of the local vaccine.

P4.01.122

HCV-specific CD8+ T-cells are abundant in HCV-seronegatives but show private TCR repertoires

S. Zhang, *R. K. Bakshi, P. Fytili, R. Jacobs, M. P. Manns, H. Wedemeyer, A. Kraft, M. Cornberg, V. Schlaphoff;
Hannover medical school, Hannover, Germany.*

Introduction: Presence of virus-specific CD8+ T-cells has been frequently detected in uninfected individuals, but detailed characteristics have been poorly defined. This study aimed to detect phenotype, T-cell receptor (TCR) repertoire and functionally characterize T-cells specific for the immunodominant HCV NS3-1073 epitope in HCV seronegative individuals (HCV-SNs) with different risk factors of HCV exposure.
Results: NS3-1073-specific CD8+ T-cells were frequently detected in HCV-SNs by ex vivo tetramer enrichment and showed a highly variable memory phenotype (CD45RA- 5-42%). After in vitro expansion, significant HCV NS3-1073-specific T-cells were detected in 31.8% (21/66) of HCV-SNs. Unexpectedly, no differences between

the different risk groups were observed. The TCR α and β repertoire of sorted NS3-1073 specific CD8+ T-cells demonstrated a high variability between individuals. Some HCV-SNs showed highly oligoclonal TCRs while others were rather diverse. Of note, some TCR β repertoires included CDR3 motifs could also be found in patients with acute HCV infection. Importantly, detection of NS3-1073-specific T-cells in one HCV-SN correlated with rapid and strong response to the peptide vaccine IC-41 that includes the NS3-1073 epitope.
Conclusion: Our data show that in HCV uninfected individuals memory T-cells specific for NS3-1073 are abundant and display private TCR specificities. One mechanism for this phenomenon can be T-cell cross-reactivity as previously shown for this epitope. The oligoclonal TCRs and the similarity of CDR3 motifs between HCV-SNs and acute HCV patients support this hypothesis. Thus, the presence and variability of pre-existing cross-reactive memory T-cells may help to explain the varying responses to HCV infection and vaccination.

MAP kinase phosphatase 5 targets IRF3 to regulate type I interferon production in response to influenza infection

***Y. Zhang**, S. J. James, H. Teh, H. Takahshi;*
National University of Singapore, Singapore, Singapore.

MAP kinase phosphatase 5 (MKP5), one member of MAPK phosphatase (MKP) protein family, plays critical roles in both innate and adaptive immune responses. However, the role of this protein in anti-viral immune responses has not been well studied. To investigate the role of MKP5 in innate immune response against influenza, wild-type (WT) and MKP5 knockout (KO) mice were infected with A/Putero Rico/8/34 (PR8, H1N1) viruses. We found that viral titers in the lung of MKP5 KO mice are significantly lower on day 3 and day 5 post-infection than those in the lung of WT mice, which is associated with increased expression of IFN-beta in the lung and IFN-beta concentrations in the BAL from KO mice compared with those from WT mice. Macrophages from MKP5 KO mice produced significantly higher amount of IFN-alpha and IFN-beta in response to PR8 virus infection than cells from WT mice. The increased expression of type I interferon in KO cells is associated with increased IRF3 phosphorylation and nuclear translocation compared with WT cells in response to influenza infection. Immunoprecipitation and *in vitro* binding assays demonstrated that MKP5 interacts with IRF3 *in vitro* and *in vivo*. Our study demonstrated that MKP5 regulates IRF3 to control type I interferon production in response to virus infection.

P4.01.124
2009 H1N1 infection primes for strong immunological memory in human nasal-associated lymphoid tissue that offers cross-reactive immunity to H1N1 and avian H5N1 viruses

*W. Mahallawi[1], A. Kasbekar[2], M. McCormick[3], K. Hoschler[4], N. Temperton[5], S. C. Leong[6], H. Beer[7], F. Ferrara[5], P. S. McNamara[1], **Q. Zhang**[1];*
[1]University of Liverpool, Liverpool, United Kingdom, [2]Alder Hey Children's Hospital, Liverpool, United Kingdom, [3]Royal Liverpool University Hospital, Liverpool, United Kingdom, [4]Health Protection Agency, London, London, United Kingdom, [5]University of Kent, Kent, United Kingdom, [6]Royal Liverpool University of Liverpool, Liverpool, United Kingdom, [7]Royal Liverpool University Liverpool, Liverpool, United Kingdom.

Background: Influenza is a highly contagious mucosal infection in the respiratory tract. 2009 pandemic H1N1 (pH1N1) virus infection resulted in substantial morbidity and mortality in humans. Little is known on whether immunological memory develops following pH1N1 infection and whether it provides protection against other virus subtypes. Methods: Enzyme-linked immunosorbent spot assay was used to analyze hemagglutinin (HA)-specific memory B cell responses after virus antigen stimulation in nasal-associated lymphoid tissues (NALT) from children and adults. Results: Individuals with serological evidence of previous exposure to pH1N1 showed significant cross-reactive HA-specific memory B responses to pH1N1, seasonal H1N1(sH1N1) and avian H5N1(aH5N1) viruses upon pH1N1 virus stimulation. pH1N1 virus antigen elicited stronger cross-reactive memory B cell responses than sH1N1 virus. Intriguingly, aH5N1 virus also activated cross-reactive memory responses to sH1N1 and pH1N1 HAs in those who had previous pH1N1 exposure, and that correlated well with the memory response stimulated by pH1N1 virus antigen. These memory B cell responses resulted in cross-reactive neutralizing antibodies against sH1N1, 1918 H1N1 and aH5N1viruses. Conclusion: 2009 pH1N1 infection appeared to have primed human host with B cell memory in NALT that offers cross-protective mucosal immunity against not only H1N1 but also aH5N1 viruses. These findings may have important implications to future vaccination strategies against influenza. It will be important to induce and/or enhance such cross-protective mucosal memory B cells.

P4.01.125
Impact of vaccination route and chosen adjuvant on immune responses and host-pathogen interplay during influenza infection.

***V. Zurli**, M. Taccone, M. Brazzoli, S. Gallorini, C. Galeone, A. Bonci, D. Casini, B. Baudner, S. Bertholet, A. Seubert;*
Novartis Vaccines and Diagnostics, Siena, Italy.

Influenza causes an acute infection in the host and initiates a cascade of immune reactions activating almost all components of the immune system. Most of the initial innate response, including cytokine release, influx of granulocytes or natural killer cells and cell activation, is responsible for the acute onset of the clinical symptoms. On the other hand, innate immunity is an essential prerequisite for the development of adaptive immune responses leading to disease resolution.
In this study, we evaluated the immunological response to influenza virus A/PR/8/34 (H1N1) infection of naïve Balb/c mice in comparison to virus pre-exposed or differently immunized mice. Using a panel of different vaccination routes and adjuvants, we characterized the impact of different vaccination-induced immune responses during actual pathogen encounter, and how it contributes to disease resolution or pathology.
We immunized Balb/c mice systemically or mucosally with an influenza subunit vaccine (HA/NA proteins from A/California/7/2009/H1N1) formulated with i) MF59 to induce a mixed Th1/Th2 response, ii) a combination of MF59 and CpG to get a more Th1-prone response and iii) LTK63 to obtain a Th1/Th17 polarized response. We assessed antibody titers and individual T helper profiles after vaccination and dissected the complex host-pathogen interplay at different timepoints after infection. To that end, we determined ex-vivo CD4 T helper responses in the lung, characterized differential lung cell composition and cytokine environments.
Our studies should help to better understand how immune responses and ultimately vaccination success can be steered via different administration routes and adjuvant formulations.

P4.02.01
A deficient translocation of CD3ζ, ZAP-70 and Grb2 to lipid raft, as a hallmark of defective adaptive immune response during chronic hepatitis B infection

***L. Barboza**[1], S. Salmen[1], G. Teran-Angel[1], D. L. Peterson[2], L. Berrueta[1];*
[1]Institute of Clinical Immunology, University of Los Andes, Mérida, Venezuela, [2]Department of Biochemistry and Molecular Biology, Virginia Commonwealth University, Richmond, VA, United States.

Hepatitis B is considered to be a worldwide public health problem. An immunosuppressor microenvironment has been proposed to contribute to viral persistence during chronic disease. Understanding the intracellular signaling cascade in T-cells from HBV infected patients, will contribute to unravel the mechanisms that control the development of immune response during Hepatitis B. We analyze lipid rafts formation and early activation signals in chronically HBV infected patients, compared to naturally immune subjects (NIS).

Patients show: 1) diminished GM1 clustering, 2) A deficient lipid rafts recruitment of CD3ζ/ ZAP-70/ Grb2, and 3) these proteins do not merge with GM1 within the lipid rafts. Finally, immunoprecipitation assays proved that ZAP-70 does not associate to CD3 ζ. These results show for the first time, defects regarding early key events in T-cell activation, in chronically infected HBV patients, which may contribute not only to understand HBV immune tolerance, but to reveal new potential therapeutic targets to control the infection

P4.02.02
HCV genotype 3 infected patients: Resistant and the relapsers

*R. S. A. Khan[1], **Q. Bashir**[2], H. Bashir[3], I. A. Khawar[4], M. A. Rathore[3], A. Younis[2], S. Razak[2];*
[1]Military Hospital, Rawalpindi, Pakistan, [2]National University of Sciences and Technology, Islamabad, Pakistan, [3]Combined Military Hospital, Rawalpindi, Pakistan, [4]Kampala International University, Kampala, Uganda.

Hepatitis C virus (HCV) has infected about 7 million Pakistani. Standard interferon in combination with ribavirin is the widely used approved therapy for HCV genotype 3 (~75-90% prevalence in Pakistan). A study was conducted to determine the relapsers and resistant to interferon treatment in HCV genotype 3 infected patients. Institute's Ethical Committee approval was granted for the study. All the patients included in the study were those who received recombinant IFN-α plus ribavirin with 24 weeks therapy duration. Serum markers i.e., liver function tests (LFTs), HCV viral load, genotyping, pre-biopsy tests and liver histopathology were taken into consideration. The investigation showed that 20% of the patients were non-responder to the interferon treatment and 28% of the patients among responders were relapsers. There is a need to conduct studies taking into consideration viral as well as host factors that can help us evaluate the reasons behind relapse/ non-response to interferon therapy.

P4.02.03
Possible routes of transmission among HCV infected Pakistani subjects

***Q. Bashir**[1], R. S. A. Khan[2], H. Bashir[3], I. A. Khawar[4], A. Younis[1], S. Razak[1];*
[1]National University of Sciences and Technology, Islamabad, Pakistan, [2]Military Hospital, Rawalpindi, Pakistan, [3]Combined Military Hospital, Rawalpindi, Pakistan, [4]Kampala International University, Kampala, Uganda.

In Pakistan, the viral hepatitis infections are mounting day by day especially HCV. The route of transmission and the risk factors associated are critical to evaluate the factors resulting in high infection prevalence. We conducted a study, where after taking the consent from the patients, data was gathered in order to figure out the possible routs of transmission in HCV patients. Hence 168 HCV patients from 22-65 years (divided into 3 groups i.e., group I: 21-35 yrs, group II: 36-50 yrs and group III: 51-65 yrs) were included in the study. About 46% of the patients (55 females and 22 males) were in group I, 45% (35 females and 41 males) in group II and 9% (8 females and 7 males) in group III. About 40% of the patients had undergone surgery, 51% visited the dentist for treatment, 58% practiced unsafe sex, 54% of the patients had ear piercing, 20% had blood transfusions, 2 % had needle stick injuries, 1% was drug user, and 43% were used to shave from barbers. There was only one case of tattooing among the patients and only one male shared the blades. So the dental treatment, surgery, unsafe sex, ear piercing and blood transfusions are the major risks of HCV transmission. There is a need to prevent HCV by educating and brining awareness in our society and also focusing on HCV management practices.

P4.02.04
Surface receptors and cytokines in CD4+ T cells upon HCV core transduction

***C. Fernández Ponce**, M. Dominguez-Villar, J. Muñoz-Miranda, M. Duran, E. Aguado, F. Garcia-Cozar;*
University of Cadiz, Cadiz, Spain.

Regulatory T cells have been identified as a specialized T cell subset that suppresses auto-reactive cells to maintaining immunological tolerance and inhibit autoimmunity. The role of Treg in some viral infections, particularly Hepatitis C virus infection, range from suppressing T-cell responses directed against the virus to down-regulating immune responses causing liver damage. Treg play a prominent role in maintaining the delicate balance between an immune response that is sufficiently robust to clear the infection and the immunopathological consequences of sustained immune activation and inflammation.
As there is evidence indicating that HCV can be present in cells either than the hepatocyte, including CD4+ T lymphocytes, we have analyzed the effect of expressing HCV-core as a single viral protein in CD4+ primary lymphocytes. Previously, we and others have shown that HCV-core induces suppression when expressed in the CD4+ tumor T cell line Jurkat, the NK cell line YTS, or when added to CD4+ T cell cultures.
Materials and methods: CD4+ primary lymphocytes were transduced with lentiviral supernatants expressing an HCV-core-GFP expression cassette.
Results: HCV-core transduced CD4+ T cells acquire a regulatory phenotype upregulating several molecules such as Foxp3, CTLA4 or PD1; expressing low levels of IL-7R (CD127) and suppressing the response of bystander T cells.
Conclusions: Our results add a new element to understanding Treg populations in the context of Hepatitis C virus expression and give the opportunity to explore a mechanism to generate CD4+ T cells with regulatory activity by the expression of a single viral protein.

P4.02.05
Cytokine profiles are modulated through the STAT family and define distinct clinical courses during hepatitis A virus infection

*F. P. Castro-Garcia[1], G. Escobedo-Melendez[1], K. Corral[1], M. A. Sandoval-Hernandez[2], M. Realpe[1], S. Roman[1], Y. Rosenstein[2], A. Panduro[1], **N. A. Fierro**[1];*
[1]Universidad de Guadalajara, Cucs, Hospital Civil de Guadalajara, Guadalajara, Mexico, [2]Instituto de Biotecnologia, Universidad Nacional Autonoma de Mexico, Cuernavaca, Morelos, Mexico.

The hepatitis A virus (HAV) infection is the major cause of acute liver failure and liver transplantation in pediatric patients. Although the incidence of hepatitis A has fallen since the introduction of vaccines, it remains as a public health problem especially in developing countries. The clinical spectrum of HAV infection ranges from mild or asymptomatic liver disease to acute liver falilure. However, the reasons for this variability are not clearly defined yet.
In this study, a statistically robust approach was used to retrospectively analyze cytokine expression in type A virus-infected children, allowing us to develop a structured model that can generate biological testable hypothesis. The resulting model suggested that modulation of the activity of Signal Transducers and Activators of Transcription proteins (STATs) occupied a central role during HAV infection, leading us to compare the degree of STATs phosphorylation in peripheral blood lymphoid cells from pediatric patients with minor and intermediate HAV-induced liver damage. Interestingly, we found that TGF-beta and IL-8 overexpression related to HAV-induced minor liver disease was associated with increased STAT-3 phosphorylation. In contrast, overexpression of IL-6, TNF-alpha and MCP-1 related to intermediate liver disease, correlated with increased STAT-3 and -5 phosphorylation. Our data suggests that different members of the STATs family may interplay to adjust the balance between immune response and infection by modulating cytokine profiles, playing an essential role in the differential progress of HAV-induced pathology. This work was partially funded by the 127229, INFR-2012 and 849 grants from the CONACyT and COECyTJAL to FNA.

P4.02.06
Transcriptome profile of HCV-specific CD8 cells in early HCV infection

P. Fisicaro[1], *V. Barili*[1], *B. Montanini*[2], *A. Orlandini*[1], *E. Negri*[1], *F. Bianchi*[3], *G. Missale*[1], *S. Ottonello*[2], *C. Ferrari*[1];
[1]*Azienda Ospedaliero-Universitaria di Parma, Parma, Italy,* [2]*University of Parma, Parma, Italy,* [3]*S. Orsola – Malpighi Hospital, University of Bologna, Bologna, Italy.*

Background and aims: In chronic HCV infection, virus-specific T cells are dysfunctional, and reconstitution of their function may represent a rational strategy to improve available therapeutic options.
Different co-stimulatory pathways may be involved in T cell exhaustion, but a comprehensive analysis of their role in HCV-related CD8 cell dysfunction is still lacking. Aim of our study was to perform a transcriptome analysis of HCV-specific CD8+ T cells, in order to obtain a genome-wide repertoire of misregulated genes potentially involved in T cell dysfunction, to be used as a knowledge basis for the development of a tailored, chronic HCV therapeutic approach based on their correction.
Results: Differential gene expression signatures distinguishing HCV- and FLU-specific CD8 cells sorted from acutely HCV infected patients with self-limited or chronically evolving infection were revealed by transcriptome (oligo-microarray) analysis. A significant difference in the expression profiles of 499 misregulated genes also emerged from the comparison of HCV-specific CD8 cells from patients with different evolution/outcome of infection (self-limited vs. chronic). This gene set is enriched in pathways related to apoptosis, cell stress, negative regulation of proliferation and cytokine production.
Conclusions: Ongoing analyses and data-mining within the above described experimental framework will provide novel insights into HCV infection pathogenesis, which will deepen our understanding of the molecular mechanisms underlying HCV persistence. A detailed analysis of differentially expressed genes will allow the identification of new molecular targets for the restoration of a functionally efficient anti-viral CD8 response as well as novel predictors of disease evolution.

P4.02.07
The role of Foxp3+ regulatory T cells in the inhibition of an adaptive immune response in a persistent HBV mouse model

Y. Gäbel[1], *L. Huang*[1], *N. Garbi*[1], *U. Protzer*[2], *P. Knolle*[1];
[1]*Institutes of Molecular Medicine and Experimental Immunology, Bonn, Germany,* [2]*Institute of Virology, TU München/Helmholtz Zentrum München, Munich, Germany.*

Worldwide more than 400 million people suffer from chronic HBV infection and have a high risk factor to develop liver cirrhosis and hepatocellular carcinoma. We applied adenoviral genome transfer (AdHBV) to overcome the species-barrier of HBV infection and successfully developed an immune-competent murine model for persistent HBV infection (Huang et al., Gastroenterology 2012). The forkhead box P3 transcription factor (Foxp3) has been shown to influence several adaptive immune responses, for example in the context of LCMV, where protective roles for regulatory T cells (Treg) have been uncovered (Rowe et al., Immunology 2012).
Here we analyse the role of Foxp3+ Treg on HBV persistence using Foxp3.LuciDTR-4 mice. The mice display 95% Treg depletion following injection of diphtheria toxin (DT) (Suffner et al., J. Immunology 2009). In AdHBV-infected and DT-treated Foxp3.LuciDTR-4 mice we observed a dramatic decline of the serum HBsAg at d10, whereas the control groups remained positive for HBsAg. They also showed an increase in HBs190-97 -specific CTLs, which suggests a strong cytotoxic function of these HBs-specific CD8+ T cells in liver and spleen. Additionally, the serum ALT level of those mice peaked at d7 by 4-fold. During persistent HBV infection, Treg seem to play a role in the inhibition of HBs-specific CTL responses. Further analysis for revealing the detailed mechanism of how Treg act on tolerance induction towards HBV has to be investigated.

P4.02.08
Monoclonal antibodies to various epitopes of HBs antigen inhibit HBV replication

F. Golsaz Shirazi[1], *H. Mohammadi*[1], *M. Amiri*[1], *K. Singethan*[2], *Y. Xia*[2], *A. Bayat*[3], *M. Bahadori*[3], *M. Jeddi –Tehrani*[3], *U. Protzer*[2], *F. Shokri*[1,3];
[1]*Department of Pathobiology, School of Public Health, Tehran University of Medical Sciences, Tehran, Iran,* [2]*Institute of Virology, Technical University of München / Helmholtz Zentrum München, Munich, Germany,* [3]*Monoclonal Antibody Research Center, Avicenna Research Institute, ACECR, Tehran, Iran.*

Antibodies against the 'a' determinant of hepatitis B surface antigen (HBsAg) are able to neutralize circulating HBV particles. It has been reported, that single mutation within this region coincide with the emergence of mutants escaping the immune response. Since multiple immunodominant epitopes are present within this region, we investigated whether a single mutation may account for virus escape from humoral immunity.
Nine murine HBsAg specific monoclonal antibodies (MAbs) were produced. Reactivity of all antibodies with 11 recombinant escape mutants of HBsAg was assessed by ELISA. HepaRG cells were used as an *in vitro* model to evaluate viral neutralization capacity of MAbs. Viral infection markers, cccDNA and HBeAg, were analyzed by real time PCR and ELISA, respectively.
The MAbs were classified into 4 subgroups based on their pattern of reactivity to the mutant HBsAg. Accordingly, 3 MAbs react with all mutants, 3 MAbs failed to recognize the T126N and Q129L mutants, 2 MAbs did not bind to the D144A mutant and finally 1 MAb did not react with the T143K, D144A and P142S mutants. All MAbs, however, were able to inhibit the establishment of HBV infection dose dependently.
Our results indicate that antibodies against different epitopes of the 'a' determinant are able to neutralize HBV. Since the antibody response to HBsAg is normally directed against multiple epitopes within the 'a' determinant, it seems that mutations within a single or a limited number of epitopes can hardly result in viral escape. Therefore, cellular mechanisms may contribute to the HBV immune escape.

P4.02.09
Impact of cytokines and apoptosis genes polymorphisms on the outcome of hepatitis C virus infection in Tunisian hemodialysed patients

Y. Gorgi, *L. Ksiaa Cheikh Rouhou, H. Aouadi, S. Jendoubi Ayed, I. Sfar, T. Ben Abdallah, K. Ayed;*
Laboratory of Research in Renal Transplantation and Immunopathology (LR03SP01)., Tunis, Tunisia.

Introduction: The aim of this study was to investigate the possibility of a significant relationship between the spontaneous clearance or the persistence of HCV infection and cytokines, and apoptosis genes polymorphisms in Tunisian hemodialysed patients.
Methods: The polymorphisms of genes: IL-1 (-889 IL-1α, -511 and +3954 IL-1β, IL-1-Ra), IL-18 (-137 and -607), IL-12p40 (-1188) and Apo1/Fas (-670) were determined by PCRRFLP, PCR-SSP and PCR-VNTR, at 100 healthy blood donors and 100 hemodialysed patients infected by the HCV. The patients were classified in two groups: G1 included 76 active chronic hepatitis patients (positive RNA-HCV) and G2: 24 hemodialysed having eliminated spontaneously virus (negative RNA-HCV).
Results: The frequency of genotype association [-37GC/-607CA] IL-18 is statistically higher among G2 patients (41,7%) compared to that at G1 hemodialysed (15,8%) (p=0,008, OR: 0.26, 95%CI: [0.10-0.73]). We found also, a significant increased frequency of AA genotype of Apo1/Fas gene in G2 patients (41,6%) than in G1 (17,5%) (p=0,026, OR=3,49, 95% CI [1,13-10,69]). Adjustment for known covariates factors (age, gender and genotypes) confirmed these univariate findings and revealed that the genotype association GC-CA of (-137and-607) IL-18 gene and AA genotype of Apo1/Fas gene were associated to the clearance
of HCV (p=0.041 and p=0.017 respectively).
Conclusion: The two genotypes GC-CA of (-137and-607) IL-18 polymorphism and the AA genotype of Apol/Fas gene seem to influence the outcome of the HCV infection in Tunisian hemodialysed patients.

P4.02.10

Immunogenetic factors of chronic hepatitis C and hepatocellular carcinoma development observed in atomic-bomb survivors

T. Hayashi[1], *W. Ohishi*[1], *K. Imai*[1], *K. Yoshida*[1], *I. Hayashi*[2], *Y. Hu*[1], *J. Kajimura*[1], *S. Kyoizumi*[1], *Y. Kusunoki*[1], *K. Nakachi*[1];
[1]*Radiation Effects Research Foundation, Hiroshima, Japan,*
[2]*Hiroshima University Faculty of Dentistry, Hiroshima, Japan.*

A series of host immune responses are thought to be involved in the course of disease development after infection, presuming that individuals' course of infection depends in part on inter-individual variation of immune responses. In this study, we examined association of *NKG2D* gene haplotypes with persistent HCV infection and hepatocellular carcinoma (HCC) development. First, we conducted a case-control study of persistent HCV infection by comparing the frequencies of *NKG2D* haplotypes between 160 cases with persistent HCV infection and 106 HCV clearance persons (controls) within a cohort of atomic-bomb survivors and found that the frequency of *HNK1/HNK1* haplotype (18%) in the HCV clearance group was about 2-times higher than that in the persistent HCV infection group (8.8%) (*HNK1* and *LNK1* alleles being associated with high and low NK activity, respectively). Second, a case-cohort genome association analysis of HCC was conducted with 115 HCC cases and a sub-cohort of 2,132 persons in the same cohort. When the subjects were divided into three radiation dose categories (non-exposure, <0.7Gy≥0.7Gy) combined with *NKG2D* haplotypes, relative risk (RR) of HCC was the highest in atomic-bomb survivors who have *HNK1/LNK1* or *LNK1/LNK1* and exposed to the highest dose (≥0.7Gy) (RR = 4.6, 95% CI: 1.1-19.2), relative to the reference category (*HNK1/HNK1* and non-exposure). These results suggest that *NKG2D* haplotypes affected the binary decision of HCV clearance or persistent infection in atomic-bomb survivors following HCV infection, and that radiation exposure as well, not only *NKG2D* haplotypes, was involved in development of HCC.

P4.02.11

Prevalence of GBV-C/HGV and HCV among HIV infected populations in South Iran

M. Jafari*, M. Mohsenzadeh, M. r. Fathi, A. Pirouzi;*
Gerash Research Center, Shiraz University of Medical Sciences, Shiraz, Iran.

Introduction: Individuals infected with the human immunodeficiency virus (HIV) are often co-infected with other pathogens, especially hepatitis viruses. HCV and GBV-C/HGV are blood-borne viruses that are highly prevalent among HIV/AIDS patients.
Methods: One hundred and fifty eight HIV-infected patients (98 men and 60 women) were included in this study. Patients were categorized into four different high risk groups: intravenous drug users (N=109), hemophiliacs (N=13), homosexual (N=8) and heterosexuals (N=28). RNA extraction from 100 µl of serum or plasma was performed with the RNX plus kit. Detection of GBV-C/HGV-RNA and HCV-RNA were performed by using reverse transcription and nested PCR.
Results: GBV-C/HGV-RNA and HCV-RNA were found in 40 (25.31%) and 58 (36.7%) patients, respectively. The prevalence of GBV-C/HGV and HCV RNA in intravenous drug users, hemophiliacs, homosexual and heterosexuals group was 57.1% (N = 56), 11.22% (N = 11), 3.03% (N = 3) and 28.57% (N = 28), respectively.
Discussion: According to our data the prevalence of GBV-C and HCV in HIV infected case was different in different groups; therefore we may be concluded that the route of HIV transmission may affect the prevalence of HCV and GBV-C/HGV co-infections in HIV infected individuals.

P4.02.12

Serum IP-10 profiles over time in treatment-experienced hepatitis C patients treated with a HCV NS3/4A protease inhibitor in combination with peginterferon and ribavirin

S. Johansson*, L. Vijgen, W. Talloen, M. Beumont-Mauviel, M. Peeters, O. Lenz, J. Aerssens;*
Janssen Research and Development, Beerse, Belgium.

Pre-treatment IP-10 (CXCL10) levels in hepatitis C virus (HCV) infected patients have been associated with treatment outcome upon peginterferon (pegIFN)/ribavirin (RBV) therapy, similar as *IL28B* genotype. Here we assessed on- and post-treatment changes in IP-10 serum levels in pegIFN/RBV treatment-experienced HCV-infected patients treated with pegIFNα-2a/RBV (n=65) or with a HCV NS3/4A protease inhibitor (PI) (simeprevir) together with pegIFNα-2a/RBV (n=195). Samples collected pre-treatment, at week 2 and 4 after treatment start, and 24 weeks after end of treatment were assessed.
Pre-treatment IP-10 levels were significantly lower in patients that relapsed during previous pegIFN/RBV treatment as compared to prior null and partial responders. After treatment start, serum IP-10 decreased over time. While serum IP-10 levels lower than at baseline were maintained in sustained virologic response (SVR) patients, in non-SVR patients the initial on-treatment IP-10 decline was reversed 24 weeks post-treatment. The treatment-induced IP-10 decrease versus baseline mirrored on-treatment HCV RNA declines and was observed already 2 weeks after initiation of PI/pegIFN/RBV therapy, whereas noticeable only after 4 weeks or later in subjects treated with pegIFN/RBV alone.
In line with earlier studies in treatment-naïve pegIFN/RBV treated patients, HCV RNA and IP-10 levels in treatment-experienced patients returned to baseline in patients who did not clear their HCV infection. Together with the faster decrease of IP-10 in patients treated with PI/pegIFN/RBV as compared to pegIFN/RBV alone, these findings suggest that on- and post-treatment changes in IP-10 levels in HCV-infected patients reflect alterations in the host immune response driven by the dynamics in viral load.

P4.02.13

Infectious diseases: Viral infections prevalence among gastroenterology patients

I. A. Khawar[1], *R. S. A. Khan*[2], *H. Bashir*[2], *Q. Bashir*[3], *A. Younis*[4], *S. Razak*[4];
[1]*Kampala International University, Kampala, Uganda,* [2]*Military Hospital, Rawalpindi, Pakistan,* [3]*National University of Sciences and Technology, Islamabad, Uganda,* [4]*National University of Sciences and Technology, Islamabad, Pakistan.*

Infectious diseases burden is mounting day by day. A number of viral infections are common in nowadays. In order to evaluate the infectious diseases and the viral hepatitis infections, a study was conducted to determine the proportion of the viral hepatitis infection among the patients that visit gastroenterology. The serum markers were evaluated and diagnosis was performed to figure out the ratio of different infectious diseases prevalent. The data was gathered from July to December 2012 among 550 patients. About 29% of the patients were infected with HCV infection, 6% HBV infection and 0.5% HBV and HDV infection. The blood borne viral hepatitis infections constitute 35.5% of all the infections. HIV infection was found in 3% of the patients, malaria 33%, enteric fever 10%, brucellosis 2%, tuberculosis enteritis 7%, tuberculosis ascites 1% and Giardiasis 8%. The viral hepatitis infections are the most prevalent infectious diseases among gastroenterology patients. There is a need of intervention to control viral hepatitis infectious.

P4.02.14

TLR-2 promotes both mouse hepatitis virus (MHV) replication and inflammatory responses in hepatocytes leading to fulminant hepatitis

*C. Bleau[1], M. Burnette[1], A. Jacques[1], M. Samson[2], C. Piquet-Pellorce[2], **L. Lamontagne**[1];*
[1]Université du Québec à Montréal, Montréal, QC, Canada, [2]Université de Rennes, Rennes, France.

Acute viral hepatitis results from an inefficient innate immune response to clear the virus and a delayed immune adaptive response. Murine hepatitis virus (MHV) infection represents a unique animal model to identify new escape mechanisms in liver of innate immune responses. The objective of this study was to identify early disorders in TLRs, helicases, cytokines and chemokines favoring the development of a fulminant hepatitis. Groups of C57BL/6 WT and TLR2-/- mice were infected with highly hepatotropic MHV3 and/or weakly hepatotropic MHV-A59 viruses. Histopathological analysis of liver and mRNA expression levels of viral nucleoprotein, viral sensors, interferons, cytokines and chemokines assessed by RT-qPCR were done in the first 3 days of infection. The results showed that liver damages, viral replication and mRNA levels of TLR-2, TLR-3, RIG-1, MDA-5, IL-33, IFN-β, CXCL1, CXCL9, CXCL-10, CXCL-11, CCL3, CCL5, IL-6 and TNF-α increased higher or appeared sooner in MHV3-infected WT than in MHV-A59 and TLR2-/- mice. To address the role of hepatocytes in TLR2-dependent viral replication and innate immune factors, *in vitro* viral infections were performed on FL83B cells. The results showed that viral replication and mRNA levels of TLR-2 and IL-6 occurred sooner than those of other innate immune parameters. Moreover, blockade of TLR-2 by siRNA decreased IFN-β, TNF-α, CXCL-1, CXCL-10 and CCL-2 expression in infected hepatocytes and also inhibited the viral replication of MHV-A59, and at a lesser extent of MHV3, suggesting that TLR-2 signaling promotes simultaneously the viral replication and the production of innate immune factors in hepatocytes, exacerbating viral hepatitis.

P4.02.15

The altered phenotype of $CD4^+CXCR5^+$ T cells and B cells is associated with the chronic hepatitis B virus infection

***Y. Lei**[1,2], T. Hu[1], X. Song[1], M. Chen[1], Z. Zhou[2], D. Zhang[2], H. Hu[2], P. Hu[2], H. Ren[1,2];*
[1]Institute of Viral Hepatitis, the Second Affiliated Hospital, Chongqing Medical University, Chongqing, China, [2]Center for liver diseases, the Second Affiliated Hospital, Chongqing Medical University, Chongqing, China.

Both germinal center and blood derived $CD4^+CXCR5^+$ T cells have been established as a T helper cell subset (T follicular helper cells, Tfh) specialized for providing help to B cells. However, the role of $CD4^+CXCR5^+$ T cells and B cells in chronic hepatitis B virus infection (CHB) is poorly defined. In this research, we examined the frequency and phenotype of $CD4^+CXCR5^+$ T cells and B cells in CHB patients (n=65) and health control (HC) (n=34) by flow cytometry. Our results showed that the general frequency of $CD4^+CXCR5^+$ T cells and B cells was not changed in peripheral blood of CHB patients when compared with HC. Although the expression of surface molecules essential for helper functions like ICOS, CD40 was significantly increased in the CD4+CXCR5+ T cells of CHB patients, the expression of ICOSL was significantly decreased in both memory B cells and plasmablastes of CHB patients versus HC. The expression of cytokines IL-4, IL-21 and cytokine receptors IL-6R, IL-21R was also increased in blood $CD4^+CXCR5^+$ T cells isolated from CHB patients. In CHB patients, the frequency of blood $CD4^+CXCR5^+$ T cells was significantly correlated with, while the $CD40^+CD19^+$ B cells was negatively correlated with serum ALT and AST. Our results indicated that the altered phenotype of $CD4^+CXCR5^+$ T cells and B cells might be associated with the lack of protective antibody responses and liver injury in persisted HBV infection. The function of $CD4^+CXCR5^+$ T cells and B cells in chronic hepatitis B virus infection need to be further investigated.

P4.02.16

Interleukin-6, tumor necrosis factor-α and interleukin -10 polymorphisms are associated with the cytokines serum levels of hepatitis C virus infection in Brazilian Population

*A. M. Tarragô[1,2], A. G. da Costa[1,2], J. P. D. Pimentel[1,2], S. Gomes[3], P. Lalwani[2], A. S. de Araújo[2], R. A. Marie[1], A. C. Vallinoto[3], A. Sadahiro[2,4], **A. Malheiro**[1,2];*
[1]Fundação de Hematologia e Hemoterapia do Amazonas - HEMOAM, Manaus, Brazil, [2]Universidade Federal do Amazonas, Manaus, Brazil, [3]Universidade Federal do Pará, Belem do Pará, Brazil, [4]Instituto Nacional de Pesquisa do Amazonas, Manaus, Brazil.

We investigated the effects of polymorphisms in IL-6, TNF-α and IL -10 in chronic hepatitis C patients newly diagnosed and before they start the treatment in Manaus, Amazonas, Brazil. A total of 116 individual were genotyped for the genes encoding IL6 (-174), TNFα (-308) and IL10 (-1082) and the IL-2, IL-4, IL-6, IL-10, TNF-α, IFN-γ and IL17A were measured. We examined the relationships between polymorphisms variations and the cytokines profile. For the IL6(-174) SNP : the cytokines serum of IL-2 , IFN- γ , TNF-α and IL-10 were higher in subjects carrying the GG allele than GC /CC and IL-6 and IL-17A were higher in subjects carrying the GG/ GC than CC. For the TNFα (-308) SNP the cytokines serum of IL-2, IFN- γ, TNF-α, IL-10 and IL-6 were higher in subjects carrying the GG allele than GA. The cytokines serum of IL-17A was higher in subjects carrying the GG and GA. It is important to say that the AA allele was not found in this population. For the IL10 (-1082) SNP the cytokines serum of IL-2 and IFN- γ were higher in subjects carrying the AA allele than AG and GG. The cytokines serum of IL-10, IL-6 and IL-17A were higher in subjects carrying the AA and AG than GG. We conclude that the relationship between the variations of IL6, TNFα and IL10 could possible modify the cytokines serum levels and also changes the dynamics of the TH17- TH1 profiles.

P4.02.17

HHV-8 and hepatitis infections in pemphigus

***K. Mejri**[1], M. Kallel Sellami[1], I. Zarraa[2], L. Laadhar[1], W. Tombari[1], M. Mokni[1], I. Mokhtar[3], B. Fazaa[4], M. Zitouni[1], S. Makni[1];*
[1]Immunology Department, La Rabta Hospital, Tunis, Tunisia,
[2]Dermatology Department, La Rabta Hospital, Tunis, Tunisia,
[3]Dermatology Department, Habib thameur Hospital, Tunis, Tunisia,
[4]Dermatology Department, Charles Nicolle Hospital, Tunis, Tunisia.

Background: Viral infection was widely associated with autoimmune diseases. In pemphigus, associations with human herpes virus 8 (HHV-8) and hepatitis C virus (HCV) were reported suggesting that these viruses may be involved in the pathogenesis of pemphigus. The aim of this study was to analyse the prevalence of HHV-8, HCV and HBV infections in pemphigus.
Methods: We enrolled 62 pemphigus foliaceus (PF), 52 pemphigus vulgaris (PV), 27 bullous pemphigoid (BP) patients and 50 controls. Anti-HHV-8 antibodies were tested by indirect immunofluorescence Kit. Serological markers of HBV infection and anti-HCV antibodies were analysed by ELISA kits.
Results: Anti-HHV-8 antibodies were observed in 12 (19%) PF, 16 (30%) PV, 12 (44%) BP patients and 18 controls (36%) with no significant difference. HCV infection was rare among patients with no significant difference with controls. High frequency of anti-HBc (41%) antibodies was observed in the PF group compared to controls (p=0.055). Inversely, a vaccinated statue was more prevalent in controls than in patients (p=0.053 and p=0,004 for PV and PF patients respectively).
Conclusion: In this case-control study we found that anti-HHV-8 and HCV infections are not associated with pemphigus. The high frequency of anti-HBc antibodies, as well as the protective effect of vaccination, suggest the involvement of HBV in pemphigus pathogenesis.

P4.02.18
Epitope mapping and identification of mutated hepatitis B surface antigens by mouse monoclonal antibodies

H. Mohammadi[1], *F. Golsaz-Shirazi*[1], *A. Roohi*[1], *M. Amiri*[1], *A. Bayat*[2], *J. Mahmoudian*[2], *M. Jeddi-Tehrani*[2], *F. Shokri*[1];
[1]*Tehran University of Medical Sciences, Tehran, Iran,* [2]*Monoclonal Antibody Research Center, Avicenna Research Institute, ACECR, Tehran, Iran.*

Selection of hepatitis B virus (HBV) by host immunity may give rise to variants with amino acid substitutions at or around the immunodominant "a" determinant of the hepatitis B surface antigen (HBsAg), the main target of antibody neutralization and diagnostic assays. The aim of this study was to generate and characterize murine monoclonal antibodies (MAbs) against HBsAg mutants and their application for identification of these antigens.
Stable hybridoma cells were established from BALB/c mice immunized with recombinant HBsAg of the “adw” subtype and cloned by limiting dilution. Specificity of MAbs was studied by indirect ELISA and Western blotting. Topology of the epitopes was analyzed by competitive ELISA.
2C5 and 2A7 hybridoma clones producing MAbs specific for HBsAg were established. Both MAbs recognized overlapping linear epitopes within the "a" determinant. Reactivity with a panel of mutated HBsAgs revealed that two MAbs loose their binding activity upon amino acid substitution at position M133H or P142S or D144A of the HBsAg.
Our findings indicate that the amino acids at positions 133 and 142 and 144 are crucial for expression of the epitope(s) recognized by our MAbs. These MAbs are useful serological tools for identification and epitope mapping of the mutant HBsAgs.

P4.02.19
The diverse roles of necroptosis and inflammatory signaling during chronic overwhelming infections

S. P. Preston*, G. Ebert, J. P. Cooney, M. Pellegrini;*
Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia.

Background: Pattern recognition receptors, TNF-alpha (and other death receptors), and IL-1 are involved in inflammation, apoptosis, necroptosis and pyroptosis signaling. Two members of the receptor interacting protein kinase (RIPK) family RIPK1 and RIPK3 along with caspase-8 are important signaling molecules in the aforementioned processes that determine inflammatory and cell death outcomes. Chronic overwhelming infections, such as HIV-1 and hepatitis B (HBV), are characterized by a non-specific deleterious inflammatory responses that cause death of bystander T cells in HIV infection, or bystander hepatocytes in HBV infection, yet infected cells are less sensitive to cell death. We hypothesized that RIPK3 and caspase-8 may conspire in the development of a pro-inflammatory milieu and death signaling of uninfected cells. The aim of our study was to investigate the role of RIPK3 and caspase-8 in chronic overwhelming infection.
Design: We utilized conditionally gene targeted animals and compound mutant animals and two infection models. We chronically infected animals with LCMV or used a highly novel HBV chronic infection model.
Results: Contrary to other studies, which defined a role for RIPK3 in vaccinia, murine cytomegalovirus and S. enterica acute infection, we found that RIPK3 alone and RIPK3 together with compound loss of caspase-8 plays no role in outcomes to chronic LCMV infection. In contrast we describe a highly significant phenotype in HBV infected mutant animals that impacts on infectious outcomes.
Conclusion: We have identified infection specific and cell specific roles of RIPK3 and caspase-8 that provide potential therapeutic insights with implications for chronic HBV infection.

P4.02.20
Human APOBEC3 Cytidine Deaminases: not simply antiviral defense?

A. Räthe*, T. Kehl, M. Löchelt;*
German Cancer Research Center, Heidelberg, Germany.

Host-encoded restriction factors are important players in innate antiviral immunity. Human APOBEC3 (apolipoprotein B mRNA-editing enzyme catalytic polypeptide) proteins induce dC-to-dU-mutations, leading to DNA degradation or hypermutation and subsequent loss of viral genetic integrity. The APOBEC3 expression pattern in the host is ill-defined and regulated by inflammatory mediators secreted upon viral infection.
APOBEC3 deaminases have the capacity to edit host DNA, which may influence cellular genome stability and potentially play a role in the onset of cancer. We hypothesize that inflammatory processes induced by virus infections enhance the expression of APOBEC3 deaminases and may represent a novel mechanism of virus-induced oncogenesis.
In order to investigate the mutagenic potential of the different human APOBEC3 deaminases, we established stable, isogenic cells lines driving tetracycline-regulated APOBEC3 gene expression. As a readout for APOBEC3-mediated host genome mutagenesis, we use counterselection against herpes simplex virus thymidine kinase (HSV-TK): APOBEC3-mediated DNA editing leads to HSV-TK reporter gene inactivation and allows survival of ganciclovir (GCV)-resistant colonies. At first, a founder line of Flp-In-T-Rex cells stably expressing the HSV-TK reporter gene was established and functionally characterized. The integrated copy number of HSV-TK genes was determined by Southern blotting. After successful integration of APOBEC3 genes via FLPase-mediated DNA recombination, a phenotypic analysis based on DNA damage repair and cell cycle progression was performed to obtain deeper insight into APOBEC3 functions.
In addition, we profiled hepatitis virus-induced tumor samples to elucidate APOBEC3 involvement in inflammation-associated carcinogenesis. Immunohistochemical studies showed a slight increase in APOBEC3 protein expression in hepatocellular carcinoma groups.

P4.02.21
Polarized effector function of NK cells in chronic hepatitis C is partially dependent on the IL28B genotype

M. Rogalska-Taranta[1,2], *A. A. Markova*[1], *S. Westhaus*[1], *S. Lunemann*[1], *A. Taranta*[1], *V. Schlaphoff*[1], *M. P. Manns*[1], *M. Cornberg*[1], *S. Ciesek*[1], *H. Wedemeyer*[1];
[1]*Hannover Medical School, Department of Gastroenterology, Hepatology and Endocrinology, Hannover, Germany,* [2]*Medical University of Bialystok, Department of Infectious Diseases and Hepatology, Bialystok, Poland.*

Background: IFN-a-induced expression of TRAIL on NK cells correlates with HCV-RNA decline during interferon alpha-based therapy. A polymorphism close to the IL28B genotype has been identified to be the most important factor in determining treatment response. However, the role of the IL28B genotype in type-I-interferon-dependent regulation of NK cells function is unknown.
Methods: NK cells from healthy controls and chronic hepatitis C (CHC) patients were studied in vitro after IFNa-stimulation. Upregulation of TRAIL, CD107a and intracellular cytokine production were investigated by flow-cytometry after co-cultering with K562 or Huh7.5 cells. NK cells were also co-cultured with Huh7.5-JFH1-(Luc-NS3-5B) replicon cells to assess antiviral effector functions. The IL28B SNP rs12979860 was determined by melting curve analysis.
Results: NK cells of CHC patients showed a marked polarization towards cytotoxicity in response to IFNa stimulation with significantly higher TRAIL upregulation but lower IFNg and TNFa production. Co-cultering HCV replicon cells with resting NK cells had modest antiviral effects while IFN-a-stimulated NK cells significantly reduced HCV replication. Cytokine production but not TRAIL expression was higher in healthy subjects carrying the IL28B-CC allele. In contrast, CHC patients with an IL28B-CT or -TT genotype showed higher interferon-gamma expression. The percentage of interferon-gamma-positive NK cells after IFNa-stimulation correlated with ALT levels only in IL28B-TT-patients.

Discussion: Higher cytokine production of NK cells in IL28B-CC healthy individuals may reflect better early effector functions supporting spontaneous HCV clearance in acute hepatitis-C. In contrast, the increased activity of NK cells in IL28B-TT CHC patients may contribute to the activity of liver disease.

P4.02.22
Programmed hepatocytes cell death associated with FLIP dowregulation and Bid activation in response to extracellular PreS1/2

S. Salmen[1]*, M. D. Rojas*[1]*, D. L. Peterson*[2]*, L. Berrueta*[1]*;*
[1]Institute of Clinical Immunology, University of Los Andes, Merida, Venezuela, [2]Department of Biochemistry and Molecular Biology, Virginia Commonwealth University, Richmond, VA, United States.

Chronic hepatitis B virus (HBV) infection involves liver damage and cirrhosis, resulting in continuous cell injury and death. Cirrhosis are considered to be the most important pre-cancerous etiological factor associated with hepatocellular carcinoma (HCC). During HBV infection, hepatocytes exhibit changes in death receptor expression and in their susceptibility to death. These changes are observed not only in infected cells but also in bystander cells. Because the viral surface protein is extensively secreted and it is found in considerable amount in soluble particles, we explored the possible role of soluble preS1/2 in hepatocyte (HepG2) death modulation. We observed an increase of cell death induced by preS1/2, which was associated with down-regulation of FLIP and activation of caspase 8, caspase 9 and BID. Additionally, hepatocytes exhibit a sensitization to death mediated by the Fas receptor. These results, may contribute to understanding the role of envelope proteins (preS1/2) on pathogenesis of HBV infection

P4.02.23
Detection of hepatitis B virus variants in Tunisian patients

L. Satouri*;*
Viral and Molecular Tumor Diagnosis Unit, Habib Thameur Hospital, Tunis, Tunisia.

The HBV genome is organized in four major overlapping open reading frames (ORF): S, C, P and X.
In this study we looked for genetic variations in genes S and P of HBV isolates from Tunisian patients. HBV serological markers were detected by ELISA and viral DNA was amplified by PCR. DNA sequencing was performed using Big Dye Terminator technology. Serologic data from 41 patients showed all patients except one were positive for HBsAg. The over all prevalence of HBeAg was 21.9%. PCR results indicated that 48.7% of the patients were positive for HBV DNA including the HBeAg positives. Ten sequenced amplicons showed all corresponding isolates to be of the D genotype. A characteristic profile of point mutations at the DNA level was found for each isolate and a 9 bp deletion in one isolate. It is noteworthy that some of these mutations were significant in ORF S but silent in ORF P and vice versa. Amino acid substitutions in the major hydrophilic region of the small S protein were identified in three isolates. Another point mutation was observed at the preS2 start codon in the middle protein . Several mutations were identified in the P protein of all isolates, most of them being located in the spacer domain. Four mutations were located in the conserved RT domains and two in the conserved motif. In conclusion, we describe for the first time a set of mutations located in highly conserved regions of both the polymerase and surface antigen proteins.

P4.02.24
The Cytotoxic T Lymphocyte Response to HLA-Cw08-restricted Envelope Epitope in Resolved Hepatitis B Infection

P. Sodsai[1]*, A. T. Tan*[2]*, N. Kirankarn*[3]*, A. Bertoletti*[2]*;*
*[1]Medical Microbiology Interdisciplinary Program, Graduate School,Chulalongkorn University, Bangkok, Thailand, [2]Singapore Institute for Clinical Sciences, Agency for Science Technology and Research (A*STAR), Singapore, Singapore, [3]Lupus Research Unit, Department of Microbiology, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand.*

The effective immunity is important strategy for HBV viral clearance particularly CTL which powerfully contribute to control HBV in acute and self-limited patient but not in chronic infection. Here, we firstly identified HLA-C-restricted CTL epitope of HBV antigen in acute patient using a panel of overlapping synthetic peptides covering the entire amino acid sequence of whole HBV antigens of genotype C to stimulate and analyze HBV-specific CTL response. CTL response to 10-residue peptide corresponding to amino acids 171-180 of envelope antigen restricted by HLA-Cw*08:01 molecule was characterized which presented responsiveness 53% of all patients with resolved HBV infection to this epitope and the cross-activity of this CTL response occurred between HBV genotype B and C. The comparative specific CTL response against Env171-180 versus the known-HLA-A or -B-restricted epitopes indicated that HLA-Cw*08:01-restricted Env171-180 CTL response had mostly frequency and magnitude compared with single well-characterized epitope stimulation as well as pooled overlapping HBV peptides. It is suggested that Env171-180 is likely HBV immunodominant epitope which is probably a candidate for immune-based therapy in defective immune response patient with chronicity.

P4.02.25
Association of MICA variants and hepatitis B virus induced hepatocellular carcinoma

H. V. Tong[1]*, N. L. Toan*[2]*, L. H. Song*[3]*, T. Bock*[4]*, P. G. Kremsner*[1]*, V. TP*[1]*;*
[1]Institute of Tropical Medicine, Tuebingen, Germany, [2]Department of Pathophysiology, Vietnam Military Medical University, Hanoi, Viet Nam, [3]Tran Hung Dao Hospital, Hanoi, Viet Nam, [4]Robert Koch Institute, Berlin, Germany.

Hepatitis B virus infects approximately 350 million people worldwide and is the leading cause of liver disease including hepatocellular carcinoma. Host genetics has been postulated to play an important role during HBV infection and HCC progression. The human major histocompatibility complex class I chain-related gene A (MICA) modulates the NK and T cell mediated immune responses through NKG2D receptor and is associated with several autoimmune, cancers and infectious diseases. The aim of this study is to determine the effects of MICA polymorphisms during HBV infection.
Ten functional MICA polymorphisms including the microsatellite were genotyped in 552 patients infected with HBV and 418 healthy controls by real-time PCR, sequencing and capillary-based electrophoresis. The serum soluble MICA levels (sMICA) were measured by ELISA and correlated to MICA variants and liver enzyme levels.
The MICA rs2596542G/A promoter SNP and non-synonymous substitutions MICA-129Met/Val, MICA-251Gln/Arg, MICA-175Gly/Ser, triplet repeat microsatellites and respective reconstructed haplotypes were associated with HBV-induced HCC and HBV persistence. The minor allele rs2596542A, MICA-129Met, and MICA-251Gln contributed to an increased susceptibility to hepatocellular carcinoma from liver cirrhosis. Therefore, MICA polymorphisms could play a crucial role in tumor surveillance and disease susceptibility during HBV infection. The soluble sMICA levels were elevated significantly in patients compared to healthy controls. The studied MICA variants were observed to influence the sMICA levels. The liver enzymes such as alanine amino transferase (ALT), aspartate transaminase (AST), total bilirubin and direct bilirubin were positively correlated to sMICA levels suggesting sMICA as a biomarker for liver injury.

P4.02.26
Enhancement of anti-HCV T cell immunity by immunization with an adenoviral vector encoding a TLR4-targeted NS3 protein

***L. Villanueva**, F. Aranda, A. Pereboev, L. Silva, D. Llopiz, A. Zabaleta, L. Arribillaga, J. Prieto, J. J. Lasarte, P. Sarobe;*
Fundación para la Investigación Médica Aplicada, Pamplona, Spain.

Induction of T cell immunity against hepatitis C virus (HCV) has been proposed as a useful strategy to treat this infection. To enhance the immunogenicity of a vaccine against HCV we designed the recombinant adenovirus AdEDA-NS3 encoding a fusion protein containing HCV NS3 antigen bound to the extra domain A (EDA) of fibronectin, a moiety which targets antigens to TLR4 expressing cells. Immunization of C57BL/6 mice with AdEDA-NS3 induced stronger CD4 and CD8 T cell responses against NS3 than those induced by an equivalent adenovirus (AdNS3) encoding untargeted NS3 or by the recombinant EDA-NS3 protein plus adjuvants poly(I:C) and antiCD40. These responses were higher in magnitude and included polyfunctional T cells which cross-reacted with NS3 belonging to other HCV genotypes. Similar enhanced responses were also obtained in outbred mice. Interestingly, immunization with AdEDA-NS3 not only conferred a higher protection against infection with a vaccinia virus encoding NS3, but also induced more potent responses in transgenic mice expressing HCV polyprotein in the liver. These results show the superior immunogenicity of AdEDA-NS3 and suggest that it could be useful in vaccination protocols against HCV.

P4.02.27
Fulminant hepatitis caused by virus infection was controlled by BTLA signaling

***Y. Wu**, Y. Chen, C. Yang, S. Wu;*
Institute of Immunology,PLA, Chongqing, China.

Fulminant viral hepatitis (FH) remains an difficult clinical problem in which the underlying pathogenesis is still unclear. Here we report that the B and T lymphocyte attenuator (BTLA), a member of CD28 superfamily, appears to be determining factors in the pathogenesis of FH mediated by the murine hepatitis virus strain 3 (MHV-3). We found that the production of the procoagulant molecule fibrinogen-like protein 2 (FGL2), the liver damage as well as the mortality was significantly reduced in MHV-3 infected BTLA-deficient ($BTLA^{-/-}$) mice. This effect was due to a rapid loss of infected macrophages following infection, thus reduced levels of TNF-α and FGL2 in these mice. An important role of TNF-α was demonstrated as the treatment of MHV-3 infected $BTLA^{-/-}$ mice with TNF-α which significantly increased the mortality and by the finding that FGL2 levels, tissue damage and mortality was dramatically decreased in TNF-$\alpha^{-/-}$ mice following MHV-3 infection. In addition, adoptively transferred $BTLA^{+}$ macrophages into resistant $BTLA^{-/-}$ mice resulted in an increased mortality after MHV-3 infection, while blocking BTLA signal prolonged the WT mouse survival time. Those findings indicate that BTLA-/- macrophages have stronger proinflammatory factors including IL-6, IFN-γ and TNF-α secretion in early infection, thus resulted in an upregulation of Fas and cell apoptosis. Our combined results demonstrate that maintaining macrophage survival by BTLA signaling is a decisive factor for the development of immunopathological damage induced by MHV-3. Targeting BTLA may be a novel strategy for the treatment of fulminant viral hepatitis.

P4.02.28
P300, but not PCAF, collaborates with IRF-1 in stimulating TRIM22 expression, that is independent on its histone acetyltransferase activity

***S. Xiong**[1,2], B. Gao[2], W. Xu[1];*
[1]Institutes of Biology and Medical Sciences, Soochow University, Suzhou, Jiangsu Province, China, [2]Institute for Immunobiology, Fudan University, Shanghai, China.

TRIM 22 plays an important role in IFNs-mediated antiviral activity. We previously demonstrated that IRF-1 was crucial for constitutive and IFNs-induced TRIM22 expression. Here, we further investigated the molecular mechanisms of IRF-1 in promoting TRIM22 expression. Using in vitro DNA affinity binding assay and in vivo chromatin immunoprecipitation assay, we found that IFN-γ stimulation significantly enhanced the binding of p300 and PCAF, but not other co-activators such as GCN-5, SRC-1 and ACTR, to the 5' extended IFN-stimulating response element-containing region of TRIM22 promoter together with IRF-1. Overexpression and knockdown analysis demonstrated that it was p300, but not PCAF, that functioned as a transcriptional co-activator of IRF-1 in IFN-γ-mediated TRIM22 production. Further study revealed that p300 mainly participated in the IRF-1-mediated TRIM22 expression by recruiting RNA polymerase II to TRIM22 promoter, and this effect was independent on its histone acetyltransferases activity. Our study indicated that p300 might serve as a bridge between IRF-1 and the basal transcriptional apparatus in TRIM22 induction.

P4.02.29
Intrahepatic CXCR3-associated chemokines and circulating autoantibody profiles in patients chronically infected with hepatitis C virus

***A. Q. Yu**, M. Ghabril, Z. Meng, S. Hu, T. Amet, D. Byrd, J. Lan, N. Chalasani;*
Indiana University School of Medicine, Indianapolis, IN, United States.

The liver injury in hepatitis C virus (HCV) infection is thought to be mainly due to immunological disorders and attacks of inflammatory factors rather than a direct cytopathic effect of the virus itself. To investigate whether intrahepatic inflammation and immunological disorders are correlated in HCV-infected patients, we used a real-time RT-PCR-based array and a slide-based autoantigen array to analyze intrahepatic inflammation gene profiles in liver biopsy specimens from HCV-infected (n=16) and uninfected (n=8) individuals and their circulating autoantibody profiles, respectively. Compared with uninfected individuals, HCV infection markedly altered expression of 59.5% of 84 inflammation-related genes tested. Among these genes affected, the CXCR3-associated chemokines (CXCL9, CXCL10, and CXCL11) were among the most up-regulated genes. Patients chronically infected with HCV have 2-fold or greater increase in circulating autoantibodies of IgG and IgM to 28 and 23 of 84 autoantigens tested, respectively, than that in uninfected individuals. The antinuclear antibody IgG titers correlated significantly with the levels of intrahepatic CXCR3-associated chemokines ($p = 0.002$). Given that CXCR3-associated chemokines are involved in the development of autoimmune diseases including rheumatoid arthritis and systemic lupus erythematosus, these chemokines may also play a key role in the pathogenesis of HCV-related liver disease through enhancement of autoimmune responses.

The MHC class II transactivator CIITA inhibits HIV-1 replication in monocytic cells

*G. Forlani[1], E. Vicenzi[2], S. Ghezzi[2], G. Poli[3], **R. S. Accolla**[1], G. Tosi[1];*
[1]University of Insubria, Varese, Italy, [2]San Raffaele Scientific Institute, Milano, Italy, [3]University Vita-Salute San Raffaele, Milano, Italy.

We previously showed that the MHC-II transactivator CIITA inhibits HIV-1 replication in human T cells by competing with the viral transactivator Tat for the binding to Cyclin T1 of P-TEFb.
Here we analyzed the possible anti-viral function of CIITA in the U937 promonocytic *Plus* and *Minus* clones, characterized by efficient or inefficient capacity to support HIV-1 replication, respectively. We found that U937 *Minus* cells express MHC-II molecules on the cell surface whereas *Plus* cells do not. This correlates with CIITA expression restricted to *Minus* cells. Importantly, we show that Tat-dependent HIV-1 LTR transactivation is reduced in *Minus* cells compared to *Plus* cells. The expression of exogenous CIITA in *Plus* cells inhibits Tat-mediated activation of the viral LTR reverting the *Plus* phenotype into a *Minus* "like" phenotype. Accordingly, HIV-1

replication was significantly reduced in *Plus*-CIITA transfected cells compared to *Plus* cells.
Recently, the host factor TRIM22 exclusively expressed in *Minus* cells was shown to inhibit basal HIV-1 transcription. We found that CIITA does not induce TRIM22 expression in *Plus*-CIITA transfectants. Nevertheless, the two factors interact and co-localize *in vivo,* suggesting that they might cooperate to inhibit HIV-1 replication.
Overall our findings confirm that CIITA acts as a viral restriction factor against HIV-1 in both T cells and monocytes and may explain previous observations on the refractory state of monocyte-macrophages to HIV-1 replication when stimulated with INF-g, the most potent activator of both CIITA and TRIM22 expression.

Antinuclear antibodies in HIV infected Turkish patients

***I. Afsar**, H. H. Er, A. Sener, S. Kaya;*
IKC Ataturk Training and Research Hospital Department of Microbiology, Karabaglar/Izmir, Turkey.

Background: Antinuclear antibodies (ANA) can be observed in human immunodeficiency virus (HIV) infected patients. Although it has been reported that ANA positivity rate was high in HIV infected patients, several other studies have not detected ANA in the presence of HIV infection.
Objective: The aim of this study was to investigate ANA positivity in HIV infected patients.
Methods: Forty four HIV infected patients with positive HIV RNA were enrolled in the study. Indirect immunoflorescence assay (IFA) was used for detection of ANA in the sera of the patients.
Results: Of the 44 HIV RNA positive HIV infected patients, only 1 (2.2%) was found to have ANA positivity, with a cytoplasm filamentous pattern.
Conclusion: HIV infected patients have less commonly ANA positivity compared to the normal population.

P4.03.03
HLA-A68 and HLA-B15 Alleles are Correlated with Poor Immune Response to Highly Active Antiretroviral Therapy among Omani AIDS Patients

***A. A. Al-Jabri**, M. El-Beeli;*
Sultan Qaboos University, Muscat, Oman.

Background: A proportion of Omani AIDS patients do not immunologically respond to HAART and their CD4 cells never hit the normal level despite viral replication is fully controlled by the treatment. This variation in the immunological response has been attributed to some host genes including those which encode Human Leukocyte Antigens (HLA). **Study Objectives:** To determine the frequency of HLA Class I and II alleles among good and poor AIDS responders to HAART and to investigate whether an association exists between a particular HLA allele and immunological response to treatment.
Methods: A total of 102 Omani healthy individuals and 81 Omani AIDS male and female patients, attending Sultan Qaboos University Hospital (SQUH), aged between 22.5 and 69 years, were HLA genotyped using SSP-PCR technique. The frequencies of HLA alleles were compared between AIDS patients and the healthy individuals as well as between “good” and “poor” immunological responders to HAART. Viral load measurement and CD4 cells counts for AIDS patients were performed according to standard techniques. The Statistical Package for Social Sciences (SPSS version 19) was used for data processing and analysis.
Results & Conclusion: Only two alleles, HLA-A68 and HLA-B15, were found to be significantly responsible for more than 50% of the poor response to HAART. Both alleles belong to the HLA class I and none of them were encountered among the prevalent HLA alleles among
Omani healthy individuals.

P4.03.04
HIV infection is associated with altered monocyte subset proportion and responsiveness to LPS stimulation

***T. A. Angelovich**[1,2], A. Maisa[1], J. Zhou[1], S. M. Crowe[1,3], P. M. Smooker[2], A. C. Hearps[1,3], A. Jaworowski[1,3];*
[1]Burnet Institute, Melbourne, Australia, [2]RMIT University, Melbourne, Australia, [3]Monash University, Melbourne, Australia.

Introduction: HIV+ individuals are at increased risk of inflammatory age-related disease despite effective suppression of viremia with combination antiretroviral therapy (cART). While monocyte subsets play individual roles in responding to inflammatory stimuli, the effect of therapy on their function and potential to contribute to chronic inflammation is not well defined.
Methods: We evaluated the inflammatory state of the three monocyte subsets (classical, intermediate and non-classical) from cART naïve, viremic and virologically supressed (VS) HIV+ donors by measuring basal and LPS-induced (10 ng/mL, 4 h) levels of IL-6 and TNF by whole blood intracellular cytokine staining via flow cytometry and compared results to age-matched HIV- controls. Soluble signalling components (LPS, LBP, sCD14), inflammatory markers (Neopterin, CXCL-10) and surface TLR-4 were also measured.
Results: All three subsets from HIV+ donors (viremic and VS) showed increased basal and LPS-induced IL-6 and TNF levels in comparison to uninfected donors ($p<0.05$ for all). Viremic HIV+ donors also displayed an increased proportion of inflammatory intermediate and non-classical monocytes in comparison to controls ($p<0.01$ for both); however this was attenuated with therapy. Plasma neopterin, LPS, LBP, sCD14 and CXCL-10 were all elevated in HIV+ groups ($p<0.05$) with a positive association between intermediate monocytes and plasma levels of CXCL-10 observed in viremic donors ($p=0.06$). Surface TLR-4 expression was also increased on intermediate monocytes of both HIV+ groups ($p<0.01$).
Conclusions: Monocytes from HIV+ donors show increased basal intracellular IL-6 and TNF levels and a heightened response to LPS, which may contribute to chronic inflammation and related inflammatory diseases,.

P4.03.05
Poor handling of bacterial antigens relate to functionally defective myeloid dendritic cells in advanced stage of HIV infection

***S. K. Arora**, M. Sachdeva, A. Sharma;*
PGIMER, Chandigarh, India.

HIV-1 infection is associated with functional impairement of dendritic cells. The exact mechanism has not been elucidated so far. We aim to study the role of some negative regulatory factors, during HIV1 infection.
Dendritic cells in the whole Blood from therapy naïve, on ART and healthy subjects, were immunophenotyped for maturation and activation markers at baseline and after *ex vivo* stimulation with LPS. Monocytes derived DC stimulated with either LPS or HIVgp120. The expression of SOCS1 & HO1 was measured by qPCR. The culture supernatants were analyzed for cytokines.
The baseline levels of DCs ($CD11c^{+}HLA^{-}DR^{+}$) expressing CD83, CD80 and CD86 was similar in all the groups. The treatment naïve patients with advanced disease had significantly lower percentage of cells expressing CD83, CD80, CD86 and did not present the antigen well as compared to early stage patients & healthy controls upon stimulation with LPS. The DCs from ART treated patients depicted functional reconstitution. HIV-1 antigen induced an increased expression of SOCS1 & HO1 genes in moDC from healthy donors. The gp120 stimulated cultures had suppression of all the cytokines IL12p70, IL10, IL1β, IL6, IL8, and TNFα.
The results indicate a maturation defect in dendritic cells of HIV1 infected ART naïve patients in advanced stage of disease. Upon ART initiation, there was functional reconstitution. Virus triggered increased expression of SOCS1 & HO1 could be responsible for the functional impairment of these cells during HIV1 infection. Further studies evaluating expression profile of more regulatory genes in patients will elucidate the mechanisms involved.

No association between TNF-α genetic variants and lipodystrophy in a population of HIV-infected patients from South of Spain

M. J. Bravo[1]*, J. D. Colmenero*[2]*, M. Delgado*[2]*, F. Orihuela*[2]*, P. Morata*[3]*, A. Alonso*[4]*, A. Caballero*[4]*, N. Fernández*[4]*;*
[1]*Biochemistry and Molecular Biology Department, Faculty of Medicine, University of Malaga, Málaga, Spain,* [2]*Infectious diseases Service, Carlos Haya University Hospital, Málaga, Spain,* [3]*1Biochemistry and Molecular Biology Department, Faculty of Medicine, University of Malaga, Málaga, Spain,* [4]*Inmunology Service, Carlos Haya University Hospital, Málaga, Spain.*

Introduction: Some HIV-infected patients undergoing highly active antirretroviral therapy develop adipose tissue redistribution and metabolic abnormalities called lipodystrophy syndrome. The frecuency of lipodystrophy is approximately between 35-50% and host genetic factors might confer particulary susceptibility. Tumor necrosis factor alpha (TNF-α) is thought to be involved in the pathogenic and metabolic events associated with HIV-1 infection. We assessed whether carriage of the TNF-α gene promoter single nucleotide polymorphism (SNP) is associated with lipodystrophy and metabolic derangements in HIV-1-infected patients.
Material and methods: A case-control study was conducted for HIV-patients. Clinical assessments for lipodystrophy by phisical examination and DEXA were obtained. The patients were classified into 2 groups: patients with lipodystrophy and patients without lipodystrophy (control group). We compared the allelic frequency between the case and the control group to determine the possible association of TNF-α associates lipodystrophy.
We studied 277 patients with HIV infection. 186 had lipodystrophy and 91 without LD that were considered as controls. DNA was isolated from anticoagulated peripheral blood mononuclear cells using standard techniques. The data were analyzed using the chi-square test or Fisher exact test, the magnitude of associations was estimated by odds ratio by the Woolf-Haldane method.
Results: Distribution analysis of the alleles at the TNF-α -308 and -238 variants showed no statistically significant between both groups of patients with LD compared to those with no LD.
Conclusion: Although greater numbers of patients are needed the TNF-α variants seems no confer susceptibility for lipodystrophy in patients with HIV in a population from south of Spain.

P4.03.07

Increased immune activation and susceptibility to HIV-1 of $CD4^+$ T cells in children born to HIV-1 infected women

M. J. Bunders[1]*, J. L. van Hamme*[1]*, M. H. Jansen*[1]*, K. Boer*[2]*, N. A. Kootstra*[3]*, T. W. Kuijpers*[1]*;*
[1]*Department of Pediatric Hematology, Immunology and Infectious Diseases, Emma Children's Hospital, AMC, Amsterdam, Netherlands,* [2]*Department of Obstetrics, AMC, Amsterdam, Netherlands,* [3]*Department of Experimental Immunology, AMC, Amsterdam, Netherlands.*

Uninfected infants born to HIV-1-infected women have lower counts of $CD4^+$ T cells in infancy than those born to uninfected mothers. Although the exact mechanisms are unknown *in-utero* exposure to maternal HIV-1-infection could shape $CD4^+$ T cell responses and chemokine receptor expression affecting T cell homing and numbers in the circulation. We assessed chemokine receptor expression on cord blood $CD4^+$ T cells of HIV-1-exposed and healthy infants. $CD4^+$ T cells derived from cord blood had a naive phenotype and chemokine receptors associated with inflammatory responses (i.e. CCR3, CXCR6, CCR5) were virtually absent in healthy controls and HIV-1-exposed infants. *In-vitro* culture of cord blood $CD4^+$ T cells with i.e. IL1[[Unsupported Character - Symbol Font ]] or IL-2, IL-7 or IL-15 increased expression of inflammatory response-associated chemokine receptors. $CD4^+$ T cells from HIV-1-exposed infants had an increased expression of inflammatory response-associated chemokine receptors compared to healthy controls (CCR3 $P<0.01$, CCR8 $P=0.03$), whereas CCR7, largely expressed by naïve cells, was lower than in controls ($P=0.01$). Furthermore, $CD4^+$ T cells of HIV-1-exposed infants were significantly more susceptible to in-vitro infection with a R5 HIV-1 strain after prestimulation for 4 days with cytokines.
In sum, $CD4^+$ T cells of HIV-1-infants have an enhanced state of activation, with an increased expression of inflammatory response-associated chemokine receptors, likely affecting the homing of $CD4^+$ T cells. One of the additional clinical implications of the primed immune system in children born to HIV-1 infected women is an increased susceptibility to HIV-1 postnatally, i.e. via breastfeeding.

P4.03.08

Phenotypic and functional characterization of CD4 stem-cell like memory cells in rhesus macaques

E. Cartwright[1]*, C. McGary*[1]*, M. Paiardini*[1]*, A. Chahroudi*[2]*, G. Silvestri*[1]*;*
[1]*Yerkes National Primate Center, Emory University, Atlanta, GA, United States,* [2]*Emory University School of Medicine, Pediatrics, Atlanta, GA, United States.*

The progressive depletion of central-memory CD4 T cells (CD4+ TCM) is a key pathogenic event during HIV infection, and differentiates pathogenic from non-pathogenic SIV infections, in which CD4+ TCM are relatively resistant from direct virus infection. Recently, several studies have identified a novel subset of memory T-cells with stem cell-like properties (TSCM). These cells are the least differentiated subset of memory T-cells and exhibit increased longevity and proliferative potential when compared to other T-cell memory subsets. Currently, little is known about CD4+ TSCM in rhesus macaques (RM).
In this study, we used multi-parametric flow cytometry and applied an established set of phenotypic markers (i.e., CD45RA, CCR7, CD28, CD27, CD122, LFA-1, CXCR3, and CD95) to identify and characterize CD4+ TSCM both in healthy and SIV-infected RM. CD4+ TSCM can be readily identified in the blood and lymphoid organs of rhesus macaques, while they are rare in mucosal tissues. These cells express variable levels of the SIV co-receptor CCR5, the proliferation marker Ki-67, and the co-inhibitory molecule PD-1. When we monitored the frequency of CD4+ TSCM cells during SIV infection we observed that their level does not decrease and that they maintain a normal proliferative potential. In addition, we observed a significant inverse correlation between total CD4 T cells and the percentage of CD4+ TSCM cells. The persistence of proliferating CD4+ TSCM during chronic HIV and SIV infection suggests that these cells may be involved in the preservation of reservoir of latently infected cells, which represents a key barrier to HIV eradication.

P4.03.09

Association of DC-SIGNR genotypes with dendritic cells in HIV-1 infection

O. Chaudhary[1]*, M. Bala*[2]*, J. Singh*[3]*, A. Hazarika*[4]*, R. Kumar*[5]*, K. Luthra*[6]*;*
[1]*All India Institute of Medical Sciences, New Delhi, India,* [2]*Regional STD Teaching, Training & Research Centre, Safdarjung Hospital, New Delhi, India,* [3]*Deptt. of Biochemistry, Kurukshetra University, Kurukshetra, India,* [4]*Blood Transfusion Services, Cardiothoracic and Neurosciences Center, All India Institute of Medical Sciences, New Delhi, India,* [5]*Society for Promotion of Youth and Masses center, New Delhi, India,* [6]*Deptt. of Biochemistry, All India Institute of Medical Sciences, New Delhi, India.*

Objectives: - Dendritic Cell-specific intracellular adhesion molecule 3 grabbing non-integrin related (DC-SIGNR) is a C-type lectin receptor and variation in its repeat region may affect HIV-1 transmission. The aim of this study was to assess peripheral blood dendritic cell (DC) frequencies and (DC-SIGNR) genotyping in healthy individuals and HIV-1 infected individuals and correlate with different clinical parameters from north India.
Methods: Blood from 30 seronegative healthy individuals and 30 patients infected with HIV-1 from North India were collected. Peripheral blood DC frequencies were determined by flow cytometer and repeat region polymorphism in DC-SIGNR was performed by PCR.
Results: There was a significantly lower number of DCs and their subsets in patients infected with HIV-1 compared to healthy individuals. A significant positive correlation of DCs and their subsets with CD4+ T cells and negative correlation with HIV-1 viral load was

found. A salient finding of this study was the association of the heterozygous 7/5 DC-SIGNR genotypes with higher percentage of DCs and their subsets and higher CD4+ T cell counts and lower viral load compared to the homozygous 7/7 DC-SIGNR genotypes in patients infected with HIV-1.
Conclusions: This is the first study to assess the DC subsets and its association with DC-SIGNR polymorphism in healthy individuals and HIV-1 infected patients and suggests the protective role of 7/5 DC-SIGNR genotypes in HIV-1 infection.

P4.03.11
Antiphospholipid antibodies in perinatally HIV infected children

L. Chernyshova[1], *Y. Stepanovskiy*[1], *B. Dons'koi*[2], *V. Chernyshov*[2];
[1]*National Medical Academy for Post-graduate Education, Kiev, Ukraine,* [2]*Institute of Pediatrics, Obstetrics and Gynecology, Kiev, Ukraine.*

Search for predictors of fast progressing of HIV infection continues. Objectives are to evaluate clinical importance of measuring levels of antiphospholipid antibodies (APA) in serum of HIV-infected children. Materials and methods. 73 children born from HIV-infected mothers were included into study. Mean age of children in study was 2.5 years. Information contents for using of study results were received from parents. Measuring of cofactor-independent IgG anti-cardiolipin APA (Cf-I-APA) was made by ELISA. Results. In clinical stages I or II of disease APA levels were lower than in stages III-IV but remained significantly higher in comparison with HIV non-infected children (12.3+2.3 U/mL; 31.2+14.2 U/mL; 3.5+1.0 U/mL, respectively, p<0.002).During the course of ART, APA levels normalized, but this was not observed in children with stages I-II of diseases which did not received ART (8.2+1.8 U/mL and 17.2+1.8 U/mL respectively, p<0.07). APA levels increased significantly before diminishing of CD4 lymphocytes. During viral load APA levels became higher. Conclusions. Increase of Cf-I-APA levels appears before clinical signs of HIV-infection and diminishing of CD4 level. Measuring of these levels may serve as additional criterion for optimal choice of time for ART beginning. Increased Cf-I-APA levels become lower while clinical state becomes better but even when CD4 levels normalize after administration of ART they are detectable, that's why APA levels may be considered as additional criterion of effectiveness of ART. Measuring of Cf-I-APA levels may be used in health care as sign of fast progression of HIV infection in perinatally infected children.

P4.03.12
Mother-to-child anti-Nef antibody passage may protect HIV-1 vertically-infected children from AIDS disease

G. Corró[1], *S. A. Marino*[2], *C. A. Rocco*[2];
[1]*Immunology Chair, Pharmacy and Biochemistry School, University of Buenos Aires, Buenos Aires, Argentina,* [2]*Lab. de Biología Celular y Retrovirus, Hospital de Pediatría Garrahan, Buenos Aires, Argentina.*

HIV-1 Nef protein has been strongly associated with uninfected T-cell death (bystander effect). This protein exerts a cytotoxic effect upon CD4+ cells though some authors found no correlation between Nef concentration in plasma and T-cell counts. On the other hand, we have previously observed that high titers of anti-Nef antibodies were found in plasmas of long-term non-progressor children but not in typical or rapid-progressors. The aim of this preliminary study was to evaluate the protective effect that may have the pre-existent anti-Nef antibodies at acute or primary infection. Twelve children who had been clinically assisted in the Garrahan Hospital from Buenos Aires were retrospectively included in the study. Plasma samples at 1-3 months post-birth were evaluated for anti-Nef IgG. The children were then classified into 3 groups according to the anti-Nef antibody levels: IgG- (anti-Nef-IgG titer <50) n=2, IgG+ (anti-Nef-IgG titer range 200-7500) n=7 and LTNPsimil (anti-Nef-IgG >11000) n=3. We observed that the children of the last group remained AIDS-free for more than 10 years while the children that had low titers or no anti-Nef Antibodies progressed to AIDS within 2 years post-birth. Our preliminary data and results suggest that pre-existent anti-Nef antibodies may have a protective effect, preventing AIDS disease progression in HIV-1 vertically infected children. Although this is a preliminary study, our observations would be of great interest for a therapeutic vaccine design as well as alternative therapies development.

P4.03.13
Inflammatory status in residual immunodeficiency under cART in HIV-infected patients

R. S. de Pablo-Bernal[1], *E. Ruiz-Mateos*[1], *J. Delgado*[2], *R. de la Rosa*[2], *M. Leal*[1], *S. Ferrando-Martinez*[1,3];
[1]*Laboratory of Immunovirology, Institute of Biomedicine of Sevilla, Sevilla, Spain,* [2]*Hospital San Juan de Dios del Aljarafe, Bormujos, Spain,* [3]*Laboratory of Molecular Immuno-Biology, Hospital General Universitario Gregorio Marañón, Madrid, Spain.*

Current combined antiretroviral treatments (cART) for HIV infection, indefinitely maintaining undetectable viral loads in most patients, have successfully decreased AIDS-related diseases and mortality. However, a higher prevalence of age- but non-AIDS-related diseases has been revealed as a new clinical outcome in the HIV infection management. High levels of systemic inflammation, usually accompanying age-related morbidities, have been reported in viremic HIV-infected patients. However, the effect of a long-term suppressive cART remains still unknown. In this study, we have analyzed systemic inflammatory levels (sCD40L, IFNγ, TNFα, IL1α, IL1β, IL6, IL8 and IL17) in a cohort of viremic HIV regarding 1) age-matched, 2) elderly and 3) elderly at risk of death uninfected healthy controls. Besides, we have longitudinally analyzed the effect of a suppressive cART on these inflammatory markers. Our results showed that, while IL6 and IL8 levels were similar in HIV-infected patients and healthy elderly individuals, most of the analyzed markers showed a worse profile in HIV-infected patients than elderly subjects at risk of death. In addition, at least 96 weeks of suppressive cART are needed to normalize some of these markers (IL6, IL8 or IFNγ) while sCD40L, TNFα or IL1α remained altered even after two years of suppressive cART. Altogether our results show that systemic inflammation in HIV-infected patients remains altered even under long-term suppressive cART. Moreover, inflammation patterns are different to those observed in uninfected elderly individuals, suggesting that immune alterations of HIV-infected patients should not be considered strictly as premature immunosenescence but residual immunodeficiency under cART (RIA).

P4.03.14
Evaluation of Monocytes and Natural Killer cells activation, inflammatory parameters in Virologically Suppressed HIV infected Maraviroc treated patients

Background: Monocytes and Natural Killer (NK) cell activation contribute to complications on HIV infection. The effect of maraviroc (MVC, antiretroviral drug) on immune activation in virological suppressed HIV-infected patients (pts) needs to be further characterized.
Methods: In a multicenter cross-sectional study were enrolled HIV infected pts receiving antiretroviral therapy (ART)≥ 6 months with or without MVC, defined respectively MVC group and not MVC group. Peripheral blood NK and monocyte phenotype and activation were studied by flow cytometry and correlated with inflammatory and metabolic parameters.
Results: Overall, 68 pts with HIV-RNA ≤50 copies/ml were included, 43 in MVC group (63%) and 25 in not MVC group (37%). In a univariate analysis in MVC group CD38+ mean fluorescence intensity (MFI) were reduced and PDL1 MFI increased on inflammatory

monocytes (iM) (p=0.0032 and p=0.0447). BMI was positively correlated with iM percentage (%) (p=0.034), Total cholesterol was negatively correlated with NK HLA-DR frequency (p=0.034); d-dimer was positively correlated with HLA-DR MFI on iM and pM (p=0.05 and 0.04). CD38 and PDL1 MFI on iM were negatively correlated (p=0.0001). Only in not MVC group, we found a positive correlation between PCR and %NK CD69+(p=0.032), d-dimer and %NK HLA-DR (p=0.05). In a multivariate analysis minimum arterial pressure, HCV-RNA and %TCD4 correlated with MVC use (p=0.004, p=0.016 and p=0.026).
Conclusion: Monocytes and NK activation persists in virologically suppressed HIV infected individuals. Reduction of iM activation might impact on atherosclerotic plaque formation/remodelling. Modulation of persistent immune-inflammation in HIV-infected pts is feasible using different treatment.

P4.03.15
Analysis of NKG2D ligand expression and release during HIV-1 infection: implication for NKG2D-mediated immunosurveillance

*G. Matusali, L. Vassena, E. Giuliani, **M. Doria**;*
Bambino Gesù Children's Hospital, Rome, Italy.

Human cells may respond to viral infection, tumor transformation or other stress by expressing on their membrane ligands for activating receptors present on cytotoxic NK and T cells, thus eliciting recognition and elimination by the immune system. Work from our and other laboratories has shown that, upon infection with HIV-1, CD4+ T cells express ligands for the NKG2D activating receptor, becoming susceptible to lysis mediated by NK cells that are all NKG2D+. However, some viral proteins (Nef, Vpu, Vif) contrast the cell surface expression of NKG2D ligands, hence protecting infected cells from NKG2D-mediated cytotoxic responses. Here we investigated whether HIV-1 infection also causes the release of soluble NKG2D ligands (sNKG2DLs) in the extracellular environment. In vitro experiments show that HIV-1 induces the release of soluble NKG2D ligands in a manner that relies on the activity of cellular matrix metalloproteinases (MMP). Moreover, we found that naïve HIV-infected patients displayed increased plasma levels of sNKG2DLs and reduced NKG2D expression on NK and CD8+ T cells. In individual patients, uptake of antiretroviral therapy (ART) resulted in the drop of sNKG2DLs and recovery of NKG2D expression. Of note, sNKG2DLs in patients' plasma down-regulated NKG2D on NK and CD8+ T cells and impaired NKG2D-mediated cytotoxicity of NK cells. Thus, NKG2D detuning by its soluble ligands may promote HIV-1 immune evasion and compromise host resistance to opportunistic infection but ART and, possibly, MMP inhibitors, have the potential to avoid such immune dysfunction. This work was supported by grants from Italian Ministry of Health and Bristol-Myers Squibb.

P4.03.16
Presence of HIV-1 broadly neutralizing antibodies during pregnancy in relation to mother-to-child transmission blocking

***S. Dzoro**[1], K. Bedi[1], S. Mpoloka[2], A. Chaillon[3], R. Musonda[1], S. Gaseitsiwe[1], V. Novitsky[4], M. Essex[4], F. Barin[3], T. Mduluza[1];*
[1]Botswana-Harvard HIV Research Laboratory, Gaborone, Botswana, [2]Biological Sciences, Faculty of Sciences, University of Botswana, Gaborone, Botswana, [3]Laboratoire de Virologie CHU Bretonneau, University of Tours, Tours, France, [4]Harvard School of Public Health, Boston, MA, United States.

Introduction: HIV vaccine research is shifting towards the need to generate high titer antibodies capable of neutralizing primary isolates of multiple HIV-1 clades and conferring sterilizing immunity. There are strong arguments in favor of a beneficial role of broadly neutralizing antibodies in prevention of HIV infection if these antibodies exist prior to exposure.
Methods: Archived plasma samples obtained from HIV1-C infected mothers recruited into a Prevention of Mother to Child Transmission study, conducted in Botswana were used in the assays. Plasma collected at screening, recruitment and delivery, was analyzed for HIV-1 broadly neutralizing antibodies and the responses were related to mother-to-child transmission at delivery. Panels of well-characterized HIV reference strains were used to assess plasma ability of HIV-1 neutralization using TZM-bl cells with a tat regulated luciferase reporter gene. Results were expressed as fifty or ninety percent inhibitory dose, defined as the highest plasma dilution causing fifty or ninety percent reduction in relative luminescence compared to virus control wells after subtraction of background luminescence.
Results: Both transmitters and non-transmitters show presence of broadly neutralizing antibodies at fifty percent HIV-1 infection inhibition, but moderately on the HIV-1C subtypes. However, non-transmitting mothers show significantly higher neutralization at ninety percent virus inhibition, across different HIV-1 clades at delivery, compared to the transmitting mothers.
Conclusion: Broadly neutralizing antibodies are present during pregnancy and there is potential of their role in reducing transmission at delivery. However, there is need to understand further the immunological environments that support viral neutralization and their dominant effect.

P4.03.17
A more pro-inflammatory environment is generated in nervous cells cultures in the simultaneous presence of HIV-1 and Toxoplasma gondii, even with lower parasite replication

***E. E. Escobar**[1,2], M. A. Alfonzo[2];*
[1]Instituto Venezolano de Investigaciones Científicas, Caracas, Venezuela, [2]Universidad Central de Venezuela, Caracas, Venezuela.

Background: HIV-1 and *Toxoplasma gondii* (*Tx*) can invade central nervous system (*CNS*) and affect its function. To study CNS's pro-inflammatory/neurotoxic response, we evaluate production of cytokines and nitric oxide (*NO*) in primary cultures of nervous cells in the simultaneous presence of HIV-1/*Tx*.
Methods: We used primary cultures of *Sprague-Dawley* rat-fetal brain cells, cultured in 24 wells plaques ($2.5x10^5$ cells/well), in RPMI-10%FCS (Group A-*Control*), or in the presence of $1.9x10^9$ copies/ml of $HIV\text{-}1_{IIIB}$ (Group B-*HIV*), of 1.000 viable tachyzoites/well of *Tx*-RH strain (Group C-*Tx*) or in the simultaneous presence of HIV/*Tx* (Group D-*HIV/Tx*), for 3, 5 and 7 days. IL-1α, IL-6, IL-10, TNF-α and *NO* levels were determined in culture supernatants; nervous cells and free tachyzoites were counted after trypsin treatment. ANOVA or Kruskal-Wallis tests were used, as appropriate.
Results: The presences of only HIV-1 or *Tx* were associated with significantly lower nervous cell counts (Groups B and C vs. A). Significantly higher levels of IL-1α, IL-6, IL-10, TNF-α and *NO* were associated with HIV-1-stimulation (Group B vs. A). *Tx*-infection alone (Group C) didn't induce significant production of any cytokine or *NO*. But when HIV/*Tx* were co-culture, production of IL-1α was significantly enhanced, IL-10 and TNF-α were significantly lower (Group D vs. B), while nervous cells and free tachyzoites counts were significantly lower (Group D vs. B and C).
Conclusion: Simultaneous presence of HIV/*Tx* was associated with a more pro-inflammatory environment and more nervous cell destruction, suggesting enhancement of neurotoxicity (as could be in co-infected patients), even with lower parasite replication.

P4.03.18
Enhancement of NK polyfunctional cells upon TLR-7/8 activation is dependent of CD62L expression in HIV-1 exposed non-infected individuals

***J. Feitosa Lima**, L. Mara Silva Oliveira, G. Eimi Mitsunari, A. José Silva Duarte, M. Notomi Sato;*
School of Medicine - USP, São Paulo, Brazil.

Introduction. Natural killer cells (NK) exert a crucial role in the immune response to certain infections and transformed cells. In humans, two subtypes of NK cells are described, CD56brigth and CD56dim. Moreover, NK cells express Toll-like receptors (TLR) that help in the pathogen recognition stimulating cytokine production and cytotoxic pathways. The NK cell has been related as protection in exposed-uninfected individuals (ENI). To better understand the role of NK cells, is important to evaluate their ability to secrete several factors followed TLR-7/TLR-8 stimulation. Aim. To determine the polyfunctional NK profile by TLR-7/8 stimulation in ENI and HIV-1-

infected partner. Methods. ENI and HIV-1-infected (INF) partner (n=10/each) were from Instituto de Infectologia Emilio Ribas of São Paulo-Brazil. Peripheral blood mononuclear cells were stimulated for 6 hours with agonist CL097 (TLR-7/8 - 10 µg/mL) or PMA (30 ηg/mL) + ionomycin (0.3 µg/mL) and NK subtypes were assessed by flow cytometry. Results. Increased polyfunctional (CD107a, IFN-γ, TNF-α, IL-10) response in CD56brigth and CD56dim cells upon CL097 stimulation were observed in ENI when compared to healthy controls group (HC). It was also observed that polyfunctional profile of these cells was dependent on the expression of CD62L. Conclusion. These data suggest that high polyfunctional NK responsiveness for TLR-7/8 activation in exposed-uninfected individuals may represent an important mechanism of resistance for HIV-1 infection.

P4.03.19
Diminished immune response of M1 and M2 macrophages derived from HIV+ patients

*L. J. Galvão-Lima[1], M. S. Espindola[1], L. S. Soares[1], M. C. Cacemiro[1], F. A. Zambuzi[1], C. Fontanari[1], S. K. Haddad[2], V. R. Bollela[2], **F. G. Frantz**[1];*
[1]University of São Paulo, FCFRP, Ribeirao Preto, Brazil, [2]University of São Paulo, FMRP, Ribeirao Preto, Brazil.

Even 30 years past from the recognition of AIDS as a worldwide epidemic caused by HIV, many questions remain unanswered. Besides of huge CD4+ T cells commitment, classical (M1) or alternatively activated (M2) macrophages derived from HIV+ patients exhibit phenotypic changes, what can be associated with the immune impairment. Our aim was to evaluate the immune response against different PAMPs, developed by macrophages obtained from HIV+ patients.
This project was approved by ethical committee from FMRP-USP. All clinical samples were obtained from HIV+ treatment-naive patients, assisted at HC-FMRP-USP. Control group was recruited from volunteer blood-donors of Blood Bank of Ribeirão Preto - FMRP-USP. Mononuclear CD14+ cells were isolated from peripheral blood samples and plated using M1 or M2 driven medium. After six days, LPS or β-Glucan were added to cells during 24 hours and the supernatant was collected. Cytokines and chemokines from cells culture and plasma samples were quantified. Analysis of mRNA expression was performed to confirm cell phenotype.
The purity of cells in the culture was upper than 93%. Our preliminary data have shown higher levels of inflammatory chemokines on plasma and M1 supernatant samples from HIV+ patients. The CCL3 expression seems to be better indicator of cell classical activation under M1 conditions.
Taken together, our results indicated an inflammatory disorder caused by HIV infection, which may be associated with prolonged macrophage activation on M1 pattern, resulting on exhaustion of the immune response against pathogens and allowing the occurrence of opportunistic infections.

P4.03.20
NetFCM: A tool for Automated Flow Cytometric Data Analysis

***J. Frederiksen**[1], M. Buggert[2], J. Tauriainen[2], A. Karlsson[2], O. Lund[1];*
[1]Center for Biological Sequence Analysis, Technical University of Denmark, Lyngby, Denmark, [2]Division of Clinical Microbiology, F68, Karolinska Institutet, Stockholm, Sweden.

Multiplexed methods such as multiparametric flow cytometry (FCM) are important to elucidate the comprehensive pattern of a healthy and perturbed immune system. Advances in the field of FCM allows for the detection of up to 18 parameters on individual cells, yielding output data of increased dimensionality and complexity.
To tackle the problem of increased complexity, we developed NetFCM, an automated method driven by machine learning methods to analyse multiparametric flow cytometric data. The tool uses information from multidimensional datasets to classify and cluster the samples into populations.
The framework of the data analysis is divided into phenotypic characterisation of the cells and functional characterisation of the samples. The phenotypic characterisation is based on an automated classification of the cells based on a flexible sequence of algorithms. The functional characterisation of the samples is an unbiased statistical classification and clustering of the datasets based on the expression of a chosen set of markers on the cells within the individual datasets.
To test the validity of NetFCM, peripheral blood mononuclear cells collected from 23 HIV infected individuals were stimulated with saline solution, overlapping HIV Gag-p55 peptides and overlapping CMV-pp65 peptides. The FCM data was then analysed using NetFCM with the goal of collecting pure CD4+ and CD8+ T-cell populations as well as identifying IFNγ and TNF responses. The method was able to classify cells, identify positive antigen-specific responses and categorise the datasets into meaningful clusters in similarity to manual gating strategies.

P4.03.21
Divergent immunological and virological profile between HCV viremic HIV-1-infected injection drug users and former blood donors in China

***W. Geng**, H. Cui, H. Sun, H. Shang;*
Key Laboratory of AIDS Immunology, Ministry of Health, First Hospital of China Medical University, Shenyang, China.

Background−Whether HIV-1/HCV-coinfected injection drug users (IDUs) and former blood donors (FBDs) in China present different immunological and virological characteristics has never been described.
Methods− HCV detectable HIV-1-infected Chinese, 61 IDUs and 87 FBDs, were recruited from a chronic HIV-1-infection cohort. The levels of $CD4^+$T cells, HIV-1 and HCV RNA load, immune activation, and CCR5/CXCR4 expression on T cells and their ligands in blood were detected using flow cytometry and molecular methods.
Results− Significantly higher HIV-1 and HCV plasma load and HLA-DR expression on T cells were observed in coinfected-IDUs compared with coinfected-FBDs after adjustment of age, sex, $CD4^+$T cell counts. The percentages of $HLA\text{-}DR^+CD4^+$T cells and $CD38^+CD8^+$T cells were associated independently and negatively with $CD4^+$T cell counts, while the frequencies of $CD38^+CD4^+$T cells were associated independently with HIV-1 load in HIV-1/HCV-coinfected subjects after adjustment for age, gender and serum aminotransferase. Furthermore, significantly lower frequency of $CCR5^+CD4^+$T cells, higher level of RANTES and lower level of SDF-1 in serum were found in coinfected-IDUs in comparions with coinfected-FBDs. The frequency of $CXCR4^+CD4^+$T cells was similar in coinfected IDUs and FBDs although the two groups showed higher level than that of NCs. In addition, injection drug use was associated independently with high levels of HIV-1 and HCV load in HIV-1/HCV-coinfected subjects with HCV viremia.
Conclusion− Our findings in Chinese HIV-1/HCV-coinfected IDUs and FBDs underline the urgency of helping coinfected injection drug users to cease drug use and the potential benefits to reduce T cell activation during antiretroviral therapy.

P4.03.22
Immunomodulatory effects of HIV-1 gp120 on human dendritic cells: role of STAT3/IL-6 axis

*M. Del Cornò[1], G. Donninelli[1], B. Varano[1], A. Masotti[2], L. Da Sacco[2], **S. Gessani**[1];*
[1]Istituto Superiore di Sanità, Rome, Italy, [2]Bambino Gesù Children's Hospital, Rome, Italy.

The ability of HIV-1 to exploit the host immune responses to its own advantage is critical in the pathogenesis of AIDS. Since dendritic cells (DCs) are key players in the induction of immune responses, the modulation of their functional activities represents a strategic mechanism for HIV-1 to evade immune surveillance. In this study, we report that exposure of immature monocyte-derived DCs (MDDCs) to recombinant gp120 transcriptionally activates IL-6 expression and promotes its secretion in a concentration and time-dependent manner. Activation of MAPK p38 is involved in gp120 triggered IL-6 over-expression as p38 specific inhibitors markedly reduced IL-6 secretion. IL-6 over-expression induces at later time points accumulation of the tyrosine phosphorylated form of STAT3. Blocking IL-6 biological activity resulted in a dramatic reduction of STAT3

activation suggesting that gp120 might interfere with the STAT3/IL-6 axis. Consistently with this hypothesis, blocking STAT3 activation markedly decreases IL-6 secretion. Reconstruction of the signaling pathway triggered by gp120 in MDDCs unraveled a biphasic activation of STAT3, triggered early on by gp120 and leading to IL-6 secretion which, at later time points, induces a second round of STAT3 activation. Moreover, the possible involvement of cellular microRNAs in the regulation of this process will be discussed. Overall, these results indicate that DCs may contribute to the up-modulation of IL-6 found in HIV infected individuals. Furthermore, chronic activation of STAT3 in DCs may provide an explanation for the impairment of DC functions.

P4.03.23
Early appearance of an age-related, activated monocyte phenotype in young HIV+ individuals

A. C. Hearps[1,2]*, T. A. Angelovich*[1]*, A. Maisa*[1]*, G. F. Lichtfuss*[1,2]*, C. Palmer*[1]*, A. L. Landay*[3]*, A. Jaworowski*[1,2]*, S. M. Crowe*[1,2]*;*
[1]Burnet Institute, Melbourne, Australia, [2]Monash University, Melbourne, Australia, [3]Rush University Medical Center, Chicago, IL, United States.

Background: Despite effective combination antiretroviral therapy (cART), HIV^+ individuals display chronic inflammation and an increased risk of inflammatory, age-related conditions such as cardiovascular disease, frailty and dementia. Monocytes are critical regulators of inflammation but the effect of chronic HIV infection on their activation and function remains unclear.
Methods: Monocyte phenotype and function was determined in fresh whole blood via a cross-sectional study of young (median age [range] 30 [19-45]) HIV^+ males and young (median age 28 [20-45]) and elderly (median age 72 [65-84]) uninfected males. Plasma markers of innate immune activation were measured in samples from an expanded cohort of HIV^+ and seronegative individuals (n=188).
Results: We have previously characterised age-related changes to monocytes; here we show that many of these changes occur prematurely in young, viremic HIV^+ individuals including an increased proportion of inflammatory $CD16^+$ monocytes (p=0.004), altered monocyte phenotype (altered expression of CD11b, CD115 and CD62L, p<0.05 for all), impaired monocyte phagocytosis (p=0.005), shortened telomeres (p=0.05) and increased concentrations of innate immune activation markers CXCL10, sCD163 and neopterin (p<0.0001 for all). Importantly, many of these changes persisted in virologically suppressed HIV^+ individuals receiving cART. Regression analysis revealed that HIV^+ individuals exhibit levels of CXCL10, sCD163 and $CD16^+$ monocytes similar to those in uninfected individuals aged between 5-7 years older.
Conclusions: Age-related changes to monocytes may occur up to 7 years earlier in HIV^+ individuals. These findings may help identify the mechanisms driving the premature development of inflammatory, age-related diseases in the HIV^+ population.

P4.03.24
Lymphocytes TCD4+ and viral load in patient with premiere of aids that receive antirretroviral treatment

D. D. Hernandez Requejo*, J. J. Perez Avila;*
Instituto de Medicina tropical Pedro Kouri, Habana, Cuba.

Introduction: The infection for HIV is a health problem; 40 million people are infected in the world. The AIDS premiere is a form of presentation of the illness in which the clinical manifestations of aids are presented as the beginning of the infection, in people without previous serology HIV; it is characterized by waste syndrome, opportunists infections, neoplasy and neurological alterations.
Objectives: The behaviour of the lymphocytes values T CD4+ was studied and of viral load in patient with aids premiere and therapy antirretroviral, to the beginning and one year after the antirretroviral treatment with Cuban generic. Results: 55 patients those were studied which had to the beginning of the treatment lymphocytes values inferior T CD4+ to 200 cell/µL and viral load bigger than 55 000 cp/µL after a year of therapy, the values of cells T CD4+ increased more than 262 cell/µL and the viral load diminished at levels non detectable in the evaluated patients. The lymphocytes values T CD4+ first floor and the high viral load associated with opportunists illnesses, being the most frequent the Neurotoxoplasmosis and the pneumonia for Pneumocystis jirovecii. The mortality associated to the aids in those bigger than 50 years was bigger in people than they presented more than an illness opportunist. Conclusions: People with aids premiere one year after initiate the antirretroviral treatment presented increase of the lymphocytes T CD4+ and decrease of the values of viral load what evidences the benefits of the antirretroviral treatment with Cuban generic.

P4.03.25
Expression of CX3CR1 drives pro-inflammatory M-DC8+ ("slan-DC") monocyte and NK cell accumulation into HIV-1-infected patient spleens

S. Degrelle[1]*, C. Dutertre*[1]*, S. Amraoui*[1]*, J. Jourdain*[1]*, K. Schaekel*[2]*, B. Fabiani*[3]*, L. Garderet*[3]*, R. Cheynier*[1]*, Y. RIchard*[1]*,* ***A. Hosmalin***[1]*;*
[1]Institut Cochin, Paris, France, [2]University of Heidelberg, Heidelberg, Germany, [3]Université Pierre et Marie Curie, Paris, France.

$M\text{-}DC8^+$ or slan (6-sulfo Lac NAc glysosylation of PSGL1) monocytes are known to be present in active lesions from patients suffering from evolutive Crohn´s disease or psoriasis. In the peripheral blood mononuclear cells from viremic HIV-1 infected patients, we had found an accumulation of these inflammatory monocytes, which were mostly responsible for the hyper-responsiveness to LPS of the PBMC from viremic HIV-1 infected patients (Dutertre Blood 2012). We addressed whether these cells were also in high numbers in the lymphoid organs from HIV-infected patients.We studied mononuclear spleen cells from 10 patients (6 HIV^+ with idiopathic thrombocytopenic purpura, 4 HIV^-) and spleen cryosections from 17 patients (9 HIV^+ including 4 untreated by antiretrovirals, 8 HIV^-). We quantified and localized monocytes, NK cells and TNFα by 12-color flow cytometry and immunohistofluorescence, and performed mRNA microarray analysis.
$M\text{-}DC8^+$ ($DD2^+$) and $CD16^+$ NK cells were in higher numbers in HIV-infected than in uninfected patients. They expressed the CX3CR1 chemokine receptor, and fractalkine mRNA was overexpressed in spleens from HIV-infected compared to uninfected patients.
Following HIV chronic infection and destruction of $CD4^+$ T lymphocytes beneath the intestinal epithelial barrier, which becomes permeable to bacterial products, induced cytokines stimulate $MDC8^+$ monocyte differentiation, and chemokines attract them to lymphoid organs, where circulating bacterial products stimulate TNF-α secretion, hence immune system activation, further $CD4^+$ T cell activation and infection, direct intestinal epithelial damage. Therefore, $M\text{-}DC8^+$ monocyte depletion might interrupt this vicious cycle and restore homeostasis and viral control.

P4.03.26
Change of cellular immunity in patients with HIV infection and tuberculosis.

S. H. Ibrahimova*;*
Azerbaycan Medical University, Immunology department, Baku, Azerbaijan.

Introduction. Tuberculosis and HIV infection - diseases that are mutually aggravate each other. Clinical presentation and course of tuberculosis in patients with HIV infection depends on its stage and determines the depth of the T-cell immunodeficiency.
Objective of the study is to determine the changes of cellular immunity in patients with HIVinfection, combined with tuberculosis.
Methods. We examined 37 adult patients aged 24 to 50 with HIV infection in the third and fourth stages, combined with tuberculosis. Determined absolute numbers and percentages of white blood cells, lymphocytes, CD3+, CD4+, CD8+ lymphocyte populations, the ratio of CD4/CD8 by flow cytometry.
Result. In the HIV - infected patients with tuberculosis were found significantly reduced the percentage and absolute number of lymphocytes, the absolute number of CD3 + lymphocytes compared with the control group (p <0.001). Especially significant changes

showed the reduction of lymphocyte phenotype CD4 + (p <0.001). But opposite changes of the relative and absolute CD8+ T cells in HIV-infected patients in combination with tuberculosis were found. Indicators of the relative amount of CD8+ T cells were significantly higher, and rates of the absolute number of CD8 + T cells were significantly lower than the control group (p <0.001). CD4/CD8 level was 4 times low compared with the control group, which was the most reliable indicator of immunodeficiency and imbalance lymphocyte subpopulations.
Conclusions. Revealed violations of cellular immunity in HIV-infected patients in combination with tuberculosis may condition the activation of tuberculosis and burdening the course of HIV infection.

P4.03.27
Interleukin-7 facilitates HIV-1 transmission to cervico-vaginal tissue ex vivo

***A. Introini**, C. Vanpouille, A. Lisco, J. Grivel, L. Margolis;*
NICHD/NIH, Bethesda, MD, United States.

Background: Interleukin (IL)-7 is one of the most prominent cytokines in semen of healthy fertile men and its concentration is increased in semen of HIV-1-infected individuals. IL-7 plays a central role in T cell development and homeostasis, however, despite evidence of elevated IL-7 levels in semen, little is known on its role in HIV-1 transmission.
Methods: Human cervico-vaginal and lymphoid (tonsillar) tissues were infected ex vivo using 2 laboratory-adapted or 4 primary isolated HIV-1 variants and cultured in the presence of IL-7 5 or 25 ng/mL. We evaluated HIV-1 replication by measuring HIV-1 p24gag released into culture medium. We assessed CD4+ T cell death by measuring cell depletion, and we evaluated apoptosis by measuring the expression of the apoptotic marker APO2.7 and of the anti-apoptotic factor Bcl-2. Finally, we evaluated cell proliferation by measuring the expression of Ki-67.
Results: Compared with untreated tissues, tissues treated with IL-7 showed: (I) enhanced replication of HIV-1 in a dose and time dependent manner; (II) higher number of HIV-1-infected CD4+ T cells; (III) increase in Bcl-2 expression; (IV) decrease in the fraction of CD4+ T cells expressing APO2.7; (V) reduction in CD4+ T cell depletion; (VI) increase in the fraction of CD4+ T cells expressing Ki-67. Conclusion: IL-7 exerts a protective effect on HIV-1-infected and uninfected CD4+ T cells in the early stages of infection by preventing their death and inducing their proliferation. In vivo an elevated concentration of IL-7 in semen may increase the efficiency of HIV-1 transmission to the female genital mucosa.

P4.03.28
Cytokines found to be elevated in HIV elite controllers reduce HIV replication in vitro

***E. S. Jacobs**[1], S. M. Keating[1], K. Anastos[2], H. Crystal[3], R. M. Greenblatt[4], A. L. Landay[5], E. T. Golub[6], J. N. Martin[7], S. Deeks[7], P. J. Norris[1,7];*
[1]Blood Systems Research Institute, San Francisco, CA, United States, [2]Albert Einstein College of Medicine, Bronx, NY, United States, [3]SUNY Downstate Medical Center, Brooklyn, NY, United States, [4]University of California San Francisco, School of Pharmacy, San Francisco, CA, United States, [5]Rush University Medical Center, Chicago, IL, United States, [6]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [7]University of California San Francisco, School of Medicine, San Francisco, CA, United States.

Background: Soluble mediators are a major form of communication for the immune system, and HIV infection causes changes in a number of soluble biomarkers. Inflammatory cytokine responses are seen in individuals with uncontrolled viremia and are ameliorated by natural control of the virus or by reduction in viremia after HAART treatment.
Methods: Multiplex assays were used to measure 73 cytokines, chemokines, and growth factors in samples from elite controllers (EC), HAART responders (HAART), untreated HIV non-controllers (NC), and HIV-uninfected (NEG) subjects from the WIHS and SCOPE cohorts. For infectivity studies CD8-depleted PBMC were infected in the presence or absence of cytokines at 0.5µg/mL (50ng/mL for IL-21) individually or in combination, cultured for 6 days and measured for p24. Infections were controlled for cell number and MOI. Significant differences were interpreted as p<0.05 and FDR<0.1.
Results: IL-21, SDF-1, CCL21, XCL-2, CCL27 and HCC-1 were significantly elevated in the serum of EC compared to NEG or HAART and not in NC. Infections with 81-A in the presence of SDF-1, HCC-1, CCL27 and combination of all six elevated cytokines showed significant suppression of virus replication (42%, 73%,66%, 85% respectively, p<0.05). Infections with NL4-3 in the presence of SDF-1, CCL21, HCC-1, and combination also showed suppression of replication (69%, 36%, 54%, 97%, respectively, p<0.05). Cell viability was not affected by cytokine concentration.
Conclusions: These cytokines may be critical in creating the immune environment responsible for elite control of HIV. They illustrate an effective cytokine profile that may help inform future immunotherapy for HIV infection.

P4.03.29
DRB1*01:01 gene mutation study in the second exon in patients with HIV/AIDS

***D. Kasjko**[1], V. Jasinskis[1], J. Eglite[1], E. Dobele[1], L. Kovalchuka[1], G. Sture[2,3], L. Viksna[2], A. Sochnevs[1];*
[1]Riga Stradiņš University, Clinical Immunology and Immunogenetic Laboratory, Riga, Latvia, [2]Riga Stradiņš University, Infectology and Dermatology department, Riga, Latvia, [3]Riga Eastern Clinical University Hospital, "Infectology Center of Latvia", Riga, Latvia.

Introduction. Many studies related to HIV/AIDS cases demonstrate the protective activity of the DRB1*01:01 allele, namely, AIDS-related complex developed more slowly in patients with this gene in comparison to the patients in which this allele was not detected. With the recent developments, individuals who would have needed more time to develop AIDS, it developed in less than 6 years. The second exon forms the binding site for the HLA class II to the peptide and presents it to the immune system. The aim of the study. Find out whether DRB1*01:01 ongoing point mutations in the second exon affect the operation of this protective alleles in HIV patients. Methods. A study of 200 HIV patients. DNA was isolated using the Qiagen QIAamp DNA kit, second exon nucleotide sequence was determined by "Big Dye Terminator mix". Statistical analysis was performed by using MS excel, *StatCalc* programs (p≤0.05). The OR was calculated - Wolf's method. Results. The incidence of nucleotide polymorphism in the DRB1*0101 gene of the second exon, the missense mutations of this exon were found in 200 patients: in the 9th codon - 27% of cases, 14th codon - 36%; 87th codon - 28% (p <0.001). In one sample a STOP-codon was found (13th codon). Balanced relationships between nucleotide transversions and transitions have been detected (OR 0.05, 95% CI0.00-0.053). Conclusions. After the assessment of the risk and ratio of the protective alleles, it could be possible to determine for each individual which patient is predisposed to faster development of AIDS.

P4.03.30
Effect of HAART on reconstitution of memory versus naive T cells during tuberculosis treatment in HIV/active pulmonary tuberculosis individuals

***S. N. Kiyingi**;*
Joint Clinical Research Centre, Kampala, Uganda.

Although HAART has improved survival of HIV-infected patients, it can lead to acute and progressive side effects and high costs can limit affordability of these drugs. Therefore, stopping of HAART in HIV/TB patients for some time can reduce the above hindrances. It is not clear how the interruption of HAART would affect reconstitution of naive and specific memory T cell populations in these patients.
Participants were randomised to receive HAART/TB treatment (intervention arm n =39) or tuberculosis treatment (control arm n =37). CD45RO and CD62L cellular markers were used to differentiate naive from memory T cells on CD4 and CD8 T cells. Plasma HIV-RNA copy levels were measured using Amplicor quantitative

restriction transcriptase polymerase chain reaction assay (PCR). Samples were analysed at baseline, 3, 6 and 12 months time points.
HAART concurrently with TB treatment caused significant changes in CD8+ naive and memory T cells unlike TB treatment alone. These observations were supported by positive correlation between viral load and CD4+ naive plus the negative correlation between viral load and CD8+ naive T cells under HAART/TB treatment. Overall, HAART caused relative decrease in naive and an increase in memory CD4+ T cells.
Concurrent HAART and tuberculosis treatment gradually restores CD8+ naive T cells in adults HIV-1 co-infected with TB with CD4+ T cell counts >350 cells/mm^3. For better recovery of naive and memory CD4+ and CD8+ T cell populations both HAART and anti-tuberculosis treatment should administered to HIV patients co-infected with tuberculosis without interruption.

P4.03.31
The Human Leukocyte Antigen-G 3'UTR 14-bp deletion is associated with increased CD4 T-cell recovery during HAART in European HIV-infected women

M. H. Larsen[1], *L. W. Thørner*[1], *C. Erikstrup*[2], *L. H. Harritshøj*[1], *G. Kronborg*[3], *C. Pedersen*[4], *C. S. Larsen*[2], *G. Pedersen*[5], *J. Gerstoft*[1], *N. Obel*[1];
[1]*Copenhagen University Hospital, Copenhagen, Denmark,* [2]*Aarhus University Hospital, Aarhus, Denmark,* [3]*Copenhagen University Hospital, Hvidovre, Denmark,* [4]*Odense University Hospital, Odense, Denmark,* [5]*Aarhus University Hospital, Aalborg, Denmark.*

Background: Human leukocyte antigen G (HLA-G) is involved in the modulation of immunological responses and might therefore assist viruses in escaping the host immune response to HIV. Homozygous carriers of the 14-bp deletion (-14) polymorphism (rs16375) in *HLA-G* have significantly higher soluble HLA-G protein expression (sHLA-G). Further, substantial gender difference in sHLA-G levels has been found in an earlier experiment. We aimed to determine the influence of rs16375 on HIV-RNA in treatment-naïve individuals and on CD4 T-cell recovery during highly active antiretroviral treatment (HAART).
Methods: The Danish HIV Cohort Study is a prospective, nationwide, population-based study of 6000 HIV-infected individuals in Denmark. From this cohort we genotyped 1363 Caucasian individuals (1178 men and 185 women) for rs16375 using a competitive allele-specific PCR system. Log-transformed mean HIV-RNA in treatment-naïve individuals and CD4 cell recovery during HAART were compared between carriers of the +14-bp allele and homozygous carriers of the -14-bp deletion by a general linear model analysis with adjustment for age, calendar period, and CD4 T-cell concentration at start of HAART (where appropriate). Analysis was stratified on sex.
Results: Among women the homozygous *HLA-G* -14-bp genotype was associated with increased CD4 T-cell recovery during HAART as compared with +14-bp allele carriers (P = 0.017). We found no significant associations with mean HIV-RNA for the rs16375. No significant associations were seen among HIV-infected men.
Conclusions: These results suggest that the homozygous *HLA-G* -14-bp genotype in women is associated with increased CD4 T-cell recovery during HAART, but not associated with viral load.

P4.03.32
Incomplete immune recovery of naïve CD4 T-cell subsets after antiretroviral treatment in HIV-1 infection

I. Lu[1,2], *F. Ahmad*[1,2], *N. T. Baerlecken*[2], *R. Jacobs*[1,2], *R. E. Schmidt*[1,2], *D. Meyer-Olson*[1,2];
[1]*Hanover Biomedical Research School, Hannover, Germany,* [2]*Institute of Clinical Immunology and Rheumatology, Hannover, Germany.*

Purpose/Objective: Our goal was to investigate how HIV-1 infection affects phenotype and function of different naïve CD4+ T-cell subsets and the role of ART in immune reconstitution.
Materials and Methods: We performed phenotypic analysis of CD4+ recent thymic immigrants (RTE) and CD4+ central naïve T cells (CN) from PBMCs in 25 HIV-1 healthy controls (HC), 18 untreated HIV-1+ viremic progressors (VP), 10 untreated HIV-1+ viral controllers (VC) and 18 ART-treated HIV-1+ individuals (10 of whom were longitudinally followed). T-cell proliferation was assessed using CFSE proliferation assays; apoptosis was assessed using 7-AAD viability staining. Statistical Analysis included paired t-test and one-way ANOVA.
Results: Identifying CD3+ CD4+ CD45RO- CCR7+ CD31+ T-cell as RTE and CD3+ CD4+ CD45RO- CCR7+ CD31- T-cell as CN, we found that the correlations between age and these subsets were disrupted in HIV-1 infection and could not be restored after ART. Cross-sectional and longitudinal analysis of our age-matched cohort revealed increased expression of the immune activation marker CD95, increased cell turnover-rate (identified by Ki-67+ expression), and increased proliferative senescence (identified by CD57+ expression) on both subsets in HIV-1 infection which could not be restored after initiation of ART. Despite remaining impaired proliferative function in response to IL-7, ART reduced apoptosis of RTE and CN, which might account for the restoration of cell numbers of RTE and CN in HIV-1 infection following ART.
Conclusions: Our data indicate an incomplete immune recovery of RTE and CN after ART in HIV-1 infection.

P4.03.33
Dissociation of the nuclear pore complex during viral infection

K. Maeda[1], *S. A. Almofty*[2], *S. K. Singh*[2], *M. M. A. Eid*[2], *M. Shimoda*[2], *N. Sakaguchi*[1];
[1]*Department of Immunology, Graduate School of Medical Sciences, Kumamoto University, Kumamoto City, Japan,* [2]*Department of Immunology, Faculty of Life Sciences, Kumamoto University, Kumamoto City, Japan.*

HIV-1 infection induces changes in assembly of various cellular organelles, which causes translocation of cellular components into virions. The nuclear pore complex (NPC) is targeted during traverse of reverse transcribed viral cDNA through the nuclear envelope (NE). Here we investigate the change of GANP, a component of mammalian transcription-export 2 complex, in HIV-1 infection. GANP is associated with various nucleoporins (Nups) and is co-localized at the NE. HIV-1 infection altered the localization of GANP from other Nups. Knockdown of Nups causes the reduction of GANP expression, suggesting functional interaction of GANP with NPC composition. HIV-1 infectivity was increased by knockdown of GANP, presumably by the failure to regulate the HIV-1 mRNA export in a Rev-dependent mechanism. Importantly, GANP overexpression significantly augments virus production in addition to the increased Rev-dependent HIV-1 mRNA export while it does not alter HIV-1 transcription. These data suggest that HIV-1 virus causes disassembly of the host factor GANP from the NPC assembly and hijacks its mRNA export function for production of virions in the infected cells.

P4.03.34
The origin of emerged HIV after terminating anti-retroviral therapy (ART)

J. Matsumura[1], *M. Shimizu*[1], *E. Shinya*[1], *S. Oka*[2], *H. Takahashi*[1];
[1]*Department of Microbiology and Immunology, Nippon Medical School, Tokyo, Japan,* [2]*AIDS Clinical Center, National Center for Global Health and Medicine, Tokyo, Japan.*

Even if HIV successfully disappears in the blood by ART, it immediately emerges after interruption of ART. Comparing the third variable region of envelope protein (V3 loop)-sequence of HIV-1, we confirmed that CD4+ PBMC was not the origin of emerged HIV after interruption of ART. Next, we thought that the gut was a candidate for the origin of emerged HIV, we performed endoscopic biopsies for ART-patients to obtain ileum samples and analyzed whether there were some HIV-replicating infected cells by flow-cytometry and determined the HIV-1-V3 sequences from extracted nucleic acid if the samples were positive for HIV-1 p24 antigen by flow-cytometry analysis. To our surprise, even if viral load in the blood was undetectable level and p24 antigen was not observed among PBMCs by ART, proviral DNA as well as p24 antigen could be detected in the ileum samples from the same patient. It should be noted that among HIV-1-infected CD4+ cells, Vα24+ NKT cells and CD11c DCs also

seem to be the major population for p24-positive cells involved. Moreover, we transmitted HIV to NKT cell line and CD4+ conventional T cell line in the culture medium containing the anti-HIV drug in vitro. After washing the drug, we confirmed that HIV emerged more immediately from NKT cells than from CD4+ conventional T cells. These result suggested that NKT cells in the ileum was the most likely candidate of the origin of emerged HIV.

P4.03.35
Viral load impact in HIV cellular immune response from children and adolescents

***T. N. Mazzola**, J. Bernachi, E. Anjos, A. Longhini, R. Lemos, S. Saad, S. Costa, M. Da Silva, M. Vilela;*
UNICAMP, Campinas, Brazil.

Objective: To evaluate cell-mediated immune response to Human Immunodeficiency Virus (HIV) in 33 infected children and adolescents in long term antiretroviral therapy. Design: Cross-sectional study. Methods: HIV-infected children and adolescents were recruited at Pediatrics Out-Patients Unit of Hospital de Clinicas in UNICAMP, Sao Paulo, Brazil and separated in two groups: 20 patients with controlled HIV viral load (VL < 50 RNA copies/mL) and 13 viremic patients (VL > 1,000 RNA copies/mL). Patients with clinical or laboratorial signs of infections of TB, CMV, hepatitis B and C, syphilis or toxoplasmosis were excluded. Aldrithiol inactivated HIV-1-specific lymphoproliferation by flow cytometry, IL-2, IL-4, IL-5, IL-10, IFN-γ and TNF-α concentration by CBA and TGF-β1 concentration by ELISA were performed on PBMC cultures. Nonparametric tests were used ($p < 0.05$). Results: Cell proliferation and was not different between patients groups, neither for HIV ($p = 0.161$) nor for PHA-stimulated cultures ($p = 0.439$). There was lower IL-2 secretion in cultures with HIV from patients with VL > 1,000 RNA copies/mL (medians 33.42 and 4.82 pg/mL for controlled and viremic patients, respectively, $p = 0.001$). IFN-γ concentration correlated to proliferation and to IL-2, IL-10 and TNF-α production in HIV-stimulated PBMC cultures from patients. Age had no association to HIV-specific proliferation or cytokine production. Conclusions: Although HIV-1 lymphoproliferation was not different between groups, there was a reduction in IL-2 production to HIV in viremic patients, showing reduced functional activity to HIV in these patients. Financial support: FAPESP (process: 2010/16513-9) and CNPQ.

P4.03.36
CCR5 expression reduces T-tropic HIV-1 strain infection by forming CD4/CXCR4/CCR5 oligomers

*L. Martínez-Muñoz[1], R. Barroso[1], S. Y. Dyrhaug[1], G. Navarro[2], B. Vega[1], P. Lucas[1], S. F. Soriano[3], J. Rodríguez-Frade[1], R. Franco[2], **M. Mellado**[1];*
[1]Centro Nacional de Biotecnología/CSIC, Madrid, Spain, [2]Universidad de Barcelona, Barcelona, Spain, [3]Hospital General Universitario Gregorio Marañón, Madrid, Spain.

The HIV-1 envelope glycoprotein gp120 regulates the initial attachment of viral particles to target cells through its association with CD4 and the chemokine receptors CXCR4 or CCR5. Using several resonance energy transfer techniques, we detected that CD4, CXCR4 and CCR5 form homo- and heterodimers as well as CD4/CXCR4/CCR5 hetero-oligomers. We report that the oligomerization between CD4 and these coreceptors reduces T-tropic HIV1 infection. FRET and BRET experiments showed that CCR5 coexpression in CD4/CXCR4 cells altered CXCR4 homodimer and CD4/CXCR4 heterodimer conformation. As a result, $gp120_{IIIB}$-induced viral fusion to host cell membranes was reduced in CD4/CXCR4/CCR5 cells, as was infection by the X4 T-tropic HIV-$1_{NL4.3}$ strain in human CCR5-expressing $CD4^+$ T cells. When coexpressed in these oligomers, CCR5 blocked $gp120_{IIIB}$ binding to CD4/CXCR4 cells and consequently abrogated actin cytoskeleton rearrangement promoted by $gp120_{IIIB}$, indicating a mechanism that prevents Ttropic HIV infection. Receptor oligomerization is a dynamic process controlled by receptor expression levels that influence the first step in HIV-1 infection, and might be a target for new therapeutic approaches for AIDS intervention.

P4.03.37
T-lymphocyte/macrophage activation and HIV production upon toll-like receptor (TLRs) stimulation in naive and HAART-treated HIV+ patients according to CD4 lymphopenia

***E. Merlini**, C. Tincati, G. M. Bellistri, J. Sanchez-Martinez, G. Ancona, A. d'Arminio Monforte, G. Marchetti;*
University of Milan - San Paolo Hospital, Milan, Italy.

Background: Chronic exposure to gut-derived microbial components represents a driver of immune activation and affects both HIV/AIDS pathogenesis and HAART response. We evaluated the role of *in vitro* TLR stimulation in inducing macrophage/T-cell activation and HIV production in untreated and treated HIV+ patients with different CD4 count.
Methods: PBMCs from HIV+naive (NA; 12 with High Counts, HC: CD4>500; 11 with Low Counts, LC; CD4≤500) and HAART-treated (HT; HIV-RNA <40cp/mL; 20 Full Responders, FRs: CD4≥350; 16 Immunological Non Responders, INRs: CD4<350) were matured into Monocyte-Derived Macrophages (MDMs). PBMCs/MDMs were cultured with CD3/CD28, LPS, LTA, PGN, ssRNA, IFNg. HLA-DR/CD38 on CD8/CD4 and HLA-DR/CD69 on CD14+MDMs were analyzed (flow cytometry). HIV-1 p24 and sCD14 were measured in supernatants (ELISA).
Results: TLR stimulation did not result in cellular activation and HIV production changes in HIV+ naive patients.
Interestingly, among HT, while INRs showed significant increase in CD38+CD8+ following TLR stimulation (LPS p=.0008; LTA p=.009; PGN p=.037; ssRNA p=.0003; IFNg p=.004; CD3/CD28 p=.0004), FRs increased CD38+CD8+ after ssRNA (p=.0006) and CD3/CD28 (p=.0005) exposure. Only ssRNA stimulation accounted for a significant rise in CD69+MDMs in INRs (p=.02) and FRs (p=<.01) and p24 release, resulting significant from PBMCs in INRs (p<.01) and FRs (p=.03) and from MDMs in FRs (p=.01).
Conclusion: TLR stimulation accounts for T-lymphocyte activation in INRs, whereas viral challenge alone seems to potently activate MDMs in HAART patients irrespective of CD4 reconstitution. Our data confirm the central role of TLR stimulation by microbial-derived bioproducts in sustaining T-cell activation, with partial impact on HIV production.

P4.03.38
Platelet activation and activation of cell death pathways in platelets isolated from HIV/AIDS patients

***E. C. Mesquita**, E. D. Hottz, R. T. Amâncio, A. M. Japiassú, D. M. Medeiros, B. G. J. Grinsztejn, P. T. Bozza, F. A. Bozza;*
FIOCRUZ, Rio de Janeiro, Brazil.

The acquired immunodeficiency syndrome (AIDS) is a pandemic threat. Around 1.700.000 deaths globally were registered only in 2012, accordingly with the Joint United Nations Programme on HIV/AIDS (UNAIDS). New clinical data emphasizes long term complications of HIV infection such as cardiovascular disease and thrombotic events. Platelets have a paramount role on thrombus formation and the mechanisms behind HIV-1 induced platelet abnormities are still elusive. The aim of this work is to build up this literature by characterizing platelet activation and cell death pathways in platelets isolated from HIV/AIDS patients. Platelets were isolated from platelets-rich-plasma (PRP) of 18 HIV/AIDS patients and 30 healthy volunteers. P-selectin (CD62) was analyzed by flow cytometry (BD FACScan Excalibur) as a marker of platelet activation and degranulation. Mitochondrial dysfunction and cell death pathways were analyzed by mitochondrial membrane potential, caspase-9 activity, phosphatidylserine exposure and reactive oxygen species production. We observed that, despite virological suppression achieved by HAART, platelets derived from HIV/AIDS patients exhibited marked signs of intrinsic apoptotic pathway activation (decreased mitochondrial membrane potential, increased phosphatidylserine exposure, increased reactive oxygen species production and increased caspase-9 activation). Moreover, we demonstrated that platelets isolated from HIV/AIDS patients are less responsive to thrombin stimulus (P-selectin expression and RANTES production) than control platelets. Our results suggest that platelet activation in HIV infection initiate cell death pathways in platelets, which might be an important mechanism of HIV-associated thrombocytopenia. Moreover, platelet dysfunction might correlate with HIV infection towards AIDS.

P4.03.39
Differential capacity of CCR5- and CXCR4-dependent HIV-1 strains to replicate in primary cord blood CD4+ T cells. A transcriptome analysis

M. Moni[1], *S. Mariani*[2], *E. Vicenzi*[3], *G. Poli*[2,3,4], *P. Liò*[1];
[1]*Computer Laboratory, University of Cambridge, Cambridge, United Kingdom,* [2]*Viral Pathogens and Biosafety, Division of Immunology, Transplantation and Infectious Diseases, San Raffaele Scientific Institute, Milano, Italy,* [3]*AIDS Immunopathogenesis Units, Division of Immunology, Transplantation and Infectious Diseases, San Raffaele Scientific Institute, Milano, Italy,* [4]*Università Vita-Salute San Raffaele, School of Medicine, Milano, Italy.*

HIV-1, the causative agent of the acquired immunodeficiency syndrome (AIDS), infects $CD4^+$ cells via interaction with CD4 and either CCR5 or CXCR4 coreceptors, but only the former has pandemic proportions and is efficiently transmitted among individuals, either sexually or mother to child, whereas the latter emerges only in the late phase of the infection in association with an advanced state of immunodeficiency. On the basis of a model system in which only CCR5-dependent (R5), but not CXCR4-dependent (X4) virus efficiently replicates in cord blood derived $CD4^+$ T cell lines, we searched for gene expression profiles and differences among Mock (Control), R5 and X4 phenotype experimental groups. The transcriptome of cord blood $CD4^+$ T cells established from 6 independent donors was examined at different time points (8, 24, 48, 72 h) after infection by isogenic NL4-3 (X4) and NL-AD8 (R5) viral strains. To detect differentially expressed genes profiles involved in entry of R5 and X4 phenotype viral into T cells, we performed statistical analysis of multi-series time-course gene expression data. Approximately 6 and 73 genes were selectively mobilized by R5 and X4 HIV-1 infection respectively, while 21 genes were modulated by both strains vs. control. Most genes were regulated in the same manner by both strains vs. the Mock condition, suggesting that the asymmetric replication profiles of the two viruses might not be due to a differential capacity of the two viruses to mobilize discrete sets of genes, but by other post-transcriptional mechanisms.

P4.03.40
Adaptation of Simian/Human Immunodeficiency Chimeric Virus (SHIV89.6p) replication in Baboon by in vivo serial viral passage; a preclinical disease model

S. P. M. Mutuiri[1], *P. M. Mwethera*[1], *G. Chege*[2], *E. W. Munene*[1], *M. Ngotho*[1], *M. Akinyi*[3], *D. Odoyo*[1], *M. Kiio*[1], *M. Ndung'u*[1], *T. M. Kariuki*[1];
[1]*Institute of Primate Research, Nairobi, Kenya,* [2]*University of Cape Town, Cape Town, South Africa,* [3]*Duke University, Durham, NC, United States.*

Background: Simian-human immunodeficiency virus (SHIV) is widely used in HIV research to assess the efficacy of AIDS vaccines and anti-HIV microbicides using the macaque animal model. The objective of this study was to generate a baboon-adapted SHIV to allow similar studies to be conducted in the baboon, which is already a well-characterised model at IPR for human diseases.
Objectives: To ensure pathogenicity and increase the virulence of stock SHIV89.6P through in vivo serial passage.
Methods: To achieve this, SHIV89.6P, a macaque-adapted lentivirus, was serially passaged in vivo in three juvenile baboons via direct intravenous (I.V.) injection of undiluted cell culture supernatant in the 1st baboon and i.v inoculation of heparinised whole blood and bone marrow (BM) from SHIV-inoculated baboon into subsequent baboons.
Results: SHIV was recovered from all the three animals through co-culturing blood and BM mononuclear cells with CEMX174 and HUT78 cell lines. In addition, viral antigens were readily detected in the plasma obtained at day 14 post-inoculation (75, 172 and 2,287 pg/ml for the 1st, 2nd, and 3rd passages respectively). Titration of the inoculum in CEM X174 cells yielded higher viral titres, ranging from 10-6 to 10-6.5 tissue culture infectious doses at 50% (TCID-50), compared to the original inoculum at 10-2.5 TCID-50. Measurement of the viral Gag (SIVp27) contents in these inocula confirmed that the baboon-generated SHIV inoculum was several-fold higher (>10 µg/ml) than the initial virus stock (0.03 µg/ml).
Conclusions: These observations indicate a baboon-adapted SHIV89.6P. This can thus be utilized for future studies using the model.

P4.03.41
Chemokine and chemokine receptor expression in HIV-infected individuals with tuberculosis on ATT and ART

K. Nayak[1,2], *L. Hanna*[3], *S. Subramanyam*[3], *S. Anbalagan*[3], *S. Swaminathan*[3];
[1]*The Joint ICGEB-Emory Vaccine Centre, International Centre for Genetic Engineering and Biotechnology, New Delhi, India,* [2]*Formally at National Institute for Reserach in Tuberculosis, Chennai, India,* [3]*National Institute for Research In Tuberculosis (Indian Council of Medical Research), Chennai, India.*

Background: HIV-infected individuals with pulmonary tuberculosis (HIV+TB+) on ATT and ART frequently experience deterioration despite improvement in CD4 counts and viral suppression. The pathogenesis of such phenomenon indicative of IRIS is speculative.
Aim: To characterize chemokine and chemokine receptors expression associated with combined administration of ATT and ART.
Methodology Thirtyone HIV+TB+ patients initiated on treatment were studied at three time points (baseline, 2 months of ATT and 1 month of ART). Twenty normal healthy individuals (HIV-TB-) were recruited as controls. Expression of CD38, CXCR4 & CCR5 positive T cells along with plasma and antigen stimulated (p24 & PPD) chemokine production (MIP-1a, MIP-1β and RANTES) were investigated.
Results: HIV+TB+ patients had significantly reduced expression of CXCR4(21.1$\pm$ 1.7 vs 36.2$\pm$ 1.5; 12.6$\pm$1.5vs34.2$\pm$1.4) and CCR5(5.5$\pm$0.7vs12.0$\pm$0.9 ;11.7$\pm$1.6vs18.0$\pm$1.3) expressing CD4 and CD8 T cells compared to controls. The plasma levels of all the three chemokine were higher in patients, MIP-1α (58$\pm$13vs12.7$\pm$6.7pg/ml), MIP1-β(201.6$\pm$21.2vs44.3$\pm$18.3pg/ml) and RANTES(4909.6$\pm$444.3 vs 2454.6$\pm$324.5 pg/ml). After 1 month of ART, 58% patients had viral suppression. Two months of intensive ATT significantly reduced chemokine levels compared to baseline,MIP-1α (31.4$\pm$4pg/ml) and MIP1-β(186.4$\pm$18.9) but reversed immediately after start of ART, MIP-1(63.6$\pm$10.9) and MIP-1β (228.2$\pm$23.6). The levels of stimulated chemokines followed a similar trend.
Discussion: ART tends to normalize chemokine receptor expression irrespective of complete viral suppression. The knowledge of both chemokine and receptor expression at later time points would provide much clearer information. However the present study demonstrates the relevance of β-chemokine to evaluate the exuberant immunological response indicative of IRIS in this group of individuals.

P4.03.42
DNA sensing and innate immune activation during HIV infection

S. K. Nissen[1], *J. F. Højen*[1], *R. K. Berg*[1], *S. R. Paludan*[2], *M. Tolstrup*[1], *M. R. Jacobsen*[2], *T. H. Mogensen*[1];
[1]*Aarhus University Hospital, Skejby, Aarhus N, Denmark,* [2]*Aarhus University, Aarhus C, Denmark.*

Background: The role of innate immunity during HIV infection remains poorly understood. It is important to understand HIV immunopathogenesis and chronic immune activation. Immune cells express various pattern recognition receptors (PRRs), of which the cytosolic DNA sensors recognize foreign DNA. An important question is whether sensing of proviral HIV-DNA or DNA from opportunistic pathogens is compromised in HIV infection.
Materials and methods: Expression levels of the DNA sensors (IFI16, DDX41, and cGAS) and downstream signaling molecules (STING and IRF-3) were measured by qPCR on whole blood from 20 highly active antiretroviral treatment (HAART) naïve HIV patients, 20 HAART responders, 20 HAART non-responders, and 20 healthy controls. Furthermore HIV-DNA was transfected into PBMCs and levels of the interferon-inducible genes ISG56 and CXCL10 as well as TNF-α were measured by qPCR.
Results: We found significant differences between HIV infected individuals and controls in the response to HIV-DNA as measured by CXCL10 expression. This difference was specific since the NF-κB/TNFα pathway was not differentially induced. Finally, we demonstrated differences between patients and controls in expression of the DNA sensor IFI16, and a significant correlation between HIV viral load and IFI16 mRNA expression was observed in HAART naïve patients.
Conclusion: Our study demonstrates significant differences between HIV-infected individuals and controls in the ability to recognize and respond to DNA and mount an antiviral innate immune response. This

finding may play a role in the immunopathogenesis of HIV infection and may have potential implications for efforts to develop a vaccine or cure for HIV.

P4.03.43
Characterization of HIV-specific lymphocytes as a tool for patient management

V. Orlando[1], *S. Meraviglia*[1], *E. Lo Presti*[1], *P. Di Carlo*[2], *N. Caccamo*[1], *L. Titone*[3], *F. Dieli*[1];
[1]*Dipartimento di Biopatologia e Biotecnologie Mediche e Forensi, University of Palermo, Palermo, Italy,* [2]*Dipartimento di Scienze per la Promozione della Salute G. D'Alessandro, University of Palermo, Palermo, Italy,* [3]*Dipartimento di Scienze per la Promozione della Salute, G. D'Alessandro, University of Palermo, Palermo, Italy.*

HIV infection is known for its heterogeneous manifestation in which the immune system plays a key role in regulating long-term balance between HIV and the host. We have carried out a follow-up study in different groups of HIV-1 infected patients, treated and untreated with antiretroviral therapy, analyzing the functional gag-specific $CD4^+$ and $CD8^+$circulating T-cells stimulated *in vitro*. The results of this study showed that subjects who control chronic infection, with or without antiretroviral therapy (virologic controllers and virologic responders) had higher levels of polyfunctional IFN-γ/IL-2 producers gag-specific CD4 and CD8 T cells, compared to subjects who had a progression of viral infection, treated with or without antiretroviral therapy (virologic non controllers and virologic non responders), that showed a predominance of single IFN-γ producers gag-specific T-cells. Moreover, we analyzed cytokines levels in the sera of HIV patients, by the Luminex platform and we found that all patients showed a state of immune-activation even though non responder patients had higher levels of inflammatory cytokines and low level of IL-10 compared with responders.
Overall, our results suggest that analysis of polyfunctional CD4 and CD8 T cells in different cohorts of HIV-infected individuals, may be of help to find a correlation between immunological and clinical status of these patients and to identify possible markers that help clinicians to predict progression of HIV disease and to define the most opportune time to initiate, modulate or interrupt therapeutic measures.

P4.03.44
Differential regulatory T cell activity in HIV-1-exposed seronegative individuals.

L. Pattacini*, J. Lund;*
Fred Hutchinson Cancer Research Center, Seattle, WA, United States.

The potential role of regulatory T cells (Tregs) in protection from HIV infection remains unclear, although it has been hypothesized that by dampening general T cell activation, Tregs could limit the pool of HIV-susceptible cells but they could also limit the HIV-specific response. To address this question, we analyzed samples from 129 HIV-exposed seronegative individuals (HESN) that are part of a HIV-serodiscordant couples cohort. To assess T cell and Treg function, we measured the proliferation of T cells in response to HIV peptide pools by a CFSE-based proliferation assay. The HIV-specific proliferative response rates were low for both CD4 and CD8 T cells, and surprisingly, the overall CD4 T cell proliferation response rate was not increased when Tregs were removed from cell preparations prior to culture. Of the 20 individuals that had HIV-specific CD4 T cell proliferative responses, 8 of them had Tregs that could functionally suppress this proliferation, whereas 12 of them had Tregs unable to suppress. When subjects were thus identified based on Tregs able to suppress or not suppress CD4 T cell proliferation, we found a correlation between T cell activation and Tregs frequencies. Additionally, subjects with Tregs unable to suppress proliferation had a statistically significant increase in HIV-specific production of MIP1[[Unsupported Character - Symbol Font ]][[Unsupported Character - Symbol Font ]] by CD4+ T cells. Interestingly, CD4+ T cell autocrine production of MIP-1[[Unsupported Character - Symbol Font ]] has been shown to be protective from HIV infection.

P4.03.45
Development of a new multi-epitope HIV-1 tat/env/pol/gag vaccine candidate: a preliminary study on immunogenicity

R. Rahimi[1], *M. Ebtekar*[1], *N. Arabi*[2], *M. Mahdavi*[2];
[1]*Tarbiat Modares University, Tehran, Iran,* [2]*Pasteur Institute of Iran, Tehran, Iran.*

Background: Multi-epitope vaccines may be promising HIV-1. In this study, a multiepitopic recombinant protein containing various HIV-1 antigens was expressed in E. coli BL21D3 and its immunogenicity was evaluated in BALB/c.
Methods: HIVtop4 sequence spanning the junction of six amino acid fragments ($Gag_{158-186}$, $Pol_{150-190}$, $ENV_{296-323}$, $ENV_{577-610}$, Tat_{1-20} and Tat_{44-61}) was designed based on computer analysis. Synthesized nucleotide sequence was cloned into pET23a plasmid and Expressed in BL21 *E. coli* cells by addition of 1 mM IPTG during 3 hrs culture, Then due to C-terminal fusion of 6xHis-tag, was purified by IMAC and confirmed with western-blotting. Groups of BALB/c mice (n=6) were immunized with of 20 µg of candidate vaccine adjuvanted in Complete Freund's adjuvant, Montanide ISI-70 and Alum. Two weeks after last immunization lymphocyte proliferation was measured with Brdu, IL-4 and IFN-γ cytokine with ELISA, total antibody and IgG1, IgG2a isotypes with indirect ELISA methods.
Results: Immunization led to a significant increase in the proliferative responses of lymphocytes, IFN-γ cytokine and total antibody titer with poly-isotypic form in comparison with the control groups. However Vaccine formulation in alum adjuvant resulted in the highest humoral response and formulation in Freund's adjuvant resulted in highest level of lymphocyte proliferation and IFN-γ cytokine release.
Conclusion: In this study we concluded tat, env, pol, gag with adjuvants (Montanide, Alum and CFA) can be considered as a candidate vaccine against the HIV virus.

Sub-optimal CD4 T-cell recovery in HIV-1 subtype C patients on antiretroviral therapy: A search for predictive biomarkers and baseline characteristics

G. Retshabile[1,2], *E. R. Kisanga*[2], *S. Gaseitsiwe*[1], *S. Moyo*[1], *H. Bussmann*[1], *J. Makhema*[1], *M. Essex*[3], *R. Marlink*[3], *R. Musonda*[1];
[1]*Botswana-Harvard AIDS Institute Partnership, Gaborone, Botswana,* [2]*Kilimanjaro Christian Medical University College, Moshi, Tanzania, United Republic of,* [3]*Dept of Immunology and Infectious Diseases, Harvard School of Public Health AIDS Institute, Boston, MA., Boston, MA, United States.*

Background: Despite suppressive antiretroviral therapy (cART) some 15-30% of treated HIV infected patients fail to achieve optimal CD4 T-cell reconstitution. Sub-optimal CD4 recovery has been associated with unfavourable outcomes for patients on cART. We assessed markers of immune activation, microbial translocation and patient baseline characteristics for associations with sub-optimal CD4 T-cell recovery post cART initiation.
Methods: This was a retrospective case control analysis based on the Adult Antiretroviral Treatment and Drug Resistance study, in Botswana. Cases had CD4≤ 200 cells/µl at 12 months post ART initiation and virologic suppression within 6 months. Microbial translocation (sCD14) and immune activation (interferon-gamma) markers were quantified using ELISA assays on a subset of plasma samples (30 cases and 30 controls matched by gender). Analyses of associations with sub-optimal response were based on Mann-Whitney Test, univariate and logistic regression.
Results: 21% virologically suppressed patients had sub-optimal CD4 recovery (51 from 249). Median age was 33.39 years and 69.9% were female. Baseline CD4 count <100cells, haemoglobin and aspartate transaminase were associated with sub-optimal CD4 recovery (adjusted OR (aOR) =3.03 95%CI [1.65, 5.57], p <0.001; aOR=0.81 [0.67, 0.99], p=0.038 and aOR=1.03 [1.00, 1.05], respectively). sCD14 levels were significantly different between cases and controls, p=0.0011, at 12 months.
Conclusion: Low baseline CD4 T-cell count, haemoglobin, aspartate transaminase and sCD14 levels are predictive of suboptimal CD4 T-cell recovery in this HIV-1 subtype C infected cohort. These characteristics are potentially useful in identifying patients who need frequent clinical monitoring to minimise unfavourable outcomes associated with poor CD4 T-cell recovery.

P4.03.47

CD4+ T cells lacking SAMHD1 expression are highly proliferative in vivo and decrease during HIV-1 infection

N. Ruffin[1], *V. Brezar*[1], *D. Ayinde*[2], *O. Schwartz*[2], *J. Lelievre*[1], *Y. Levy*[1], *N. Seddiki*[1];
[1]*INSERM U955, Equipe 16, Créteil, France,* [2]*Institut Pasteur, Paris, France.*

Although it is well established that SAMHD1 is a restriction factor for HIV-1 in macrophages and resting $CD4^+$ T-cells, it needs to be determined whether SAMHD1 levels are modulated during HIV-1 infection.
Here we assessed SAMHD1 expression in $CD4^+$ T-cell subsets from antiretroviral therapy treated and non-treated HIV-1 infected individuals as well as in healthy controls, and addressed whether SAMHD1 expression is modified during T cell activation and proliferation.
Our results revealed that in healthy individuals (n=12) while the vast majority of T-cells express SAMHD1, a small subset of $CD4^+$ cells (11.025.36%) displays lower levels. Phenotypic characterization showed that memory $CD4^+$ T-cells, notably effector/memory $CD45RA^-/RO^+CCR7^-CD27^+CD28^+$ and terminally differentiated $CD45RA^+/RO^-CCR7^-CD27^-CD28^+$ subsets contain higher proportions of $SAMHD1^{low}$ cells (15.227.31% and 23.3610.37% respectively) as compared to naïve cells (7.084.27, $p<0.05$ and $p<0.001$ respectively). Importantly, both ART-treated (n=10) and non-treated (n=8) HIV-1 infected individuals displayed lower frequencies of $SAMHD1^{low}$ cells (5.423.90% and 5.473.09% respectively, $p<0.05$ as compared to controls). Moreover, $SAMHD1^{low}$ $CD4^+$ T-cells exhibit higher proportions of cycling $KI67^+$ cells as compared to $SAMHD1^+$ cells (6.155.24% vs 3.901.36% for treated and 27.7424.18% vs 5.484.46% for non-treated HIV-1 infected individuals; 2.202.24% vs 1.980.76% for controls). We confirmed these results by *in vitro* stimulation (anti-CD3/CD28) where dividing $CD4^+$ T-cells exhibited lower SAMHD1 expression as assessed by both RT-PCR and flow-cytometry.
Our results show that memory/cycling $CD4^+$ T-cells exhibit low levels of SAMHD1 which might explain their preferential productive infection and thus provide new insight in the mechanism of $CD4^+$ T-cell depletion, hallmark of HIV-1 infection.

P4.03.48

The HIV Tat protein favors the activation of CD8 T cells thus contributing to HIV-related immune dysfunctions

F. Sforza[1], *F. Nicoli*[1], *V. Finessi*[1], *E. Gallerani*[1], *A. Caputo*[2], *R. Gavioli*[1];
[1]*University of Ferrara, Ferrara, Italy,* [2]*University of Padova, Padova, Italy.*

Tat is a regulatory protein produced very early after HIV infection, necessary for viral gene expression, cell-to-cell virus transmission and disease progression. Tat can be released extracellularly and, upon release, enter uninfected T cells displaying several functions, only partially characterized. A large number of studies show an immunomodulatory effect of Tat on CD4 T Lymphocytes and professional APCs, demonstrating how Tat increases their activation and the secretion of pro-inflammatory cytokines and proposing a contribution of Tat to the chronic immune activation described during HIV infection.
CD8 T cells from HIV infected subjects are also characterized by several dysfunctions, including an increased activation. However, whether Tat can modulate also the CD8 T cell response is not clear.
To characterize the role of Tat on CD8 T cell activation, PBLs form healthy donors were stimulated with anti-CD3/CD28 in the presence or absence of Tat protein. Both CD4 and CD8 T cells activated in the presence of Tat showed an enhanced pro-inflammatory cytokine production compared to T cells activated without Tat. Furthermore, memory CD8 T cells from EBV positive donors were stimulated with EBV peptides in the presence or absence of Tat. EBV-specific CTLs generated in the presence of Tat exhibited enhanced effector functions compared to CTLs generated without Tat. The same effect was observed on naïve CD8 T cells primed with CD8 peptide epitopes.
Taken together, these results suggest that the Tat protein of HIV enhances the stimulation of CD8 T cells thus contributing to immune activation during the course of HIV.

P4.03.49

HIV-1 Nef downregulates CD1a lipid-antigen presentation in dendritic cells via hemopoietic cell kinase (HCK) and p21 activated kinase 2 (PAK2)

E. Shinya[1], *M. Shimizu*[1], *A. Owaki*[1], *L. Mori*[2], *G. De Libero*[2], *H. Takahashi*[1];
[1]*Nippon Medical School, Tokyo, Japan,* [2]*Basel University Hospital, Basel, Switzerland.*

We previously reported that Nef significantly down-regulated CD1a expression in immature dendritic cells (iDCs). Here we show that Nef down-regulates CD1a lipid-antigen (Ag) presentation, which is due to the association of Nef with p21-activated kinase 2 (PAK2), and that SH3-protein hemopoietic cell kinase (HCK) specifically expressed in immature dendritic cells (iDCs), is crucial in this process, as analyzed using a CD1a antigen presentation assay with a series of mutated *nef genes* using iDCs. The Nef-PAK2 intermolecular interaction was further confirmed by the colocalization of Nef and PAK2 and a protein fragment complementation assay, which revealed that HCK significantly augmented the intermolecular interaction of Nef with PAK2. These results suggest that iDC-specific HCK plays a critical role in the assembly of the Nef/PAK2 complex, which may be another mechanism of immune-evasion by HIV-1, and that HCK may be a therapeutic target to control HIV-1-infected iDCs, one of the possible reservoirs of HIV-1 even after anti-retroviral therapy (ART).

P4.03.50

Correlation between c-reactive protein and CD4+ cell count in HIV-infected and HIV/PTB co-infected patients at the University of Maiduguri Teaching Hospital (UMTH), Maiduguri, Nigeria

A. Tahir[1], *H. Yusuph*[2], *B. Bakki*[2], *Y. B. Jibrin*[1];
[1]*Department of Medicine, Abubakar Tafawa Balewa University Teaching Hospital, Bauchi, Nigeria,* [2]*Department of Medicine, University of Maiduguri, Maiduguri, Nigeria.*

The objective of this study was to determine the correlation between CRP and CD4+ cell count in HIV-infected patients at the University of Maiduguri Teaching Hospital; and to compare with HIV/PTB co-infected patients as well as HIV-seronegative healthy age- and sex-matched controls. A hospital-based cross-sectional comparative study was undertaken. One hundred and twenty consecutive HIV-infected patients comprising 60 HIV+ only and 60 HIV/PTB co-infected patients and 60 apparently healthy HIV-seronegative age- and sex-matched controls were recruited. The Pearson's product moment correlation coefficients (r) for the correlation between CRP and CD4+ cell count were -0.596 (p=0.000) for HIV+, -0.365 (p=0.004) for HIV/PTB patients and +0.147 (p=0.263) for healthy controls. Whereas, *r* for the correlation between CRP and HIV-1 viral load were +0.023 (p=0.859) for HIV+ patients and +0.097 (p=0.463) for HIV/PTB patients. The diagnostic usefulness of the CRP measurement as a surrogate for CD4+ cell count showed sensitivity, specificity and positive predictive values of 80.6%, 72.4% and 75.8% for HIV+ patients and 88.9%, 63.6% and 66.7% for the HIV/PTB patients. This study found a strong linear negative correlation between CRP and CD4+ cell count in HIV-infected patients as well as those with HIV/PTB co-infection. Therefore, serum CRP level of >10mg/L in HIV-infected patients, can be used to predict low CD4+ cell counts in resource-poor locations lacking the facility for measuring CD4+ cells.

P4.03.51

Manipulation of rapid apoptosis for HIV-1 gp160-specific murine CD8+ CTLs by free antigenic peptide in vivo

H. Takahashi, *M. Shimizu, Y. Norose, S. Takaku, M. Takahashi, Y. Nakagawa;*
Department of Microbiology and Immunology, Nippon Medical School, Tokyo, Japan.

We have previously reported that the cytotoxic activity of murine CD8+ CTLs specific for HIV-1 gp160 envelope protein was markedly inhibited in vitro by brief exposure to a free epitope peptide P18-I10 (RGPGRAFVTI) using the epitope-specific CTL line (LINE-IIIB) or a

clone (RT-1) (JEM, 183:879, 1996). We have also shown that recently stimulated P18-I10-specific murine CTLs rapidly fell into apoptosis in vitro after brief exposure to peptide P18-I10 (JI, 169:6588, 2002). Here, we examined whether similar inactivation or apoptosis of recently stimulated CTLs occurred in vivo by exposure to the free epitope peptide using T cell receptor (TCR) transgenic mice (Tg-RT-1) (JEM, 195:991, 2002) expressing αβTCR genes of CTL clone RT-1. When the Tg mice were inoculated with recombinant vaccinia virus expressing HIV-1 IIIB gp160 genes (vSC25) followed by injection of P18-I10 epitope peptide, apparent reduction in the number of CTLs determined by flow cytometry using H-2Dd/P18-I10 pentamer was observed within few hours. Most of the H-2Dd/P18-I10 pentamer-stained cells were positive for Annexin V and apoptosis was confirmed by microscopic analyses. Moreover, when mice were pretreated with immunosuppressive agents, such as cyclosporin A (CsA) or tacrolimus (FK506), induction of apoptosis by P18-I10 was significantly inhibited and CTL cytotoxicity was maintained. These results suggest that the rapid loss of virus-specific CD8+ CTLs might occur in vivo through apoptosis in the early stages of viral infection when activated CTLs may encounter viral epitope(s) released from virus infected cells attacked by CTLs and we can prevent the loss by pretreatment with immunosuppressive agents.

P4.03.52
Immunological, hematological and biochemical parameters are changed in asymptomatic HIV-infected patients, treated or not with antiretroviral drugs

***K. I. Tasca**, C. C. de Camargo, M. Gatto, M. B. Mendes, L. R. de Souza;*
UNESP - FMB, Botucatu, Brazil.

In HIV-infected even during antiretroviral therapy (ART) and absence of symptoms, the imbalance in immunological, hematological and biochemical factors can potentially contribute to progression to AIDS or other comorbidities. We aimed to analyze some of these parameters in 58 asymptomatic HIV-patients: ART-naïve (HIVn, n=18); virologic failure on ART (HIVf, n=18); on ART and complete viral suppression (HIVc, n=22). Quantification of viral load and CD4+ T cells were done by branched-DNA and flow cytometry, respectively. Sandwich immunosorbent assays were performed to quantify cytokines as IFN-g, TNF-a, IL-10 and IL-6. Other results were collected from medical records. Tukey-Kramer test and negative binomial and gamma distributions were calculated ($p<0.05$). Comparing three groups, we found the lowest levels of IL-10 in HIVc. The HIVf presented the lowest concentration of IFN-g and the highest levels of TNF-a and IL-6. To lymphocytes, mainly CD4+ T, HIVf presented lower counts than other groups. Triglycerides, high-density lipoprotein (HDL) and very low-density lipoprotein (VLDL) were higher in treat-patients (HIVc and HIVf) than HIVn. Total cholesterol was elevated in HIVc when was compared to HIVn, without difference to HIVf. An intriguing result was the higher aspartate-aminotransferase(AST) value found in HIVn than HIVc. When we checked the normal references ranges, the most common changes in the studied population were observed to neutrophils, total leukocytes, hematocrit, creatinine and metabolic exams. Thereby, therapeutic advances have contributed to the slower evolution to AIDS, however the laboratory changes observed in HIV+ deserve to be better understood in order to seek a greater -and better- longevity.

P4.03.53
Can cytokine profiles in HIV patients be useful in clinical practice?

***K. I. Tasca**, M. Gatto, C. C. Camargo, S. A. Calvi, A. Sartori, L. R. de Souza;*
UNESP, Botucatu, Brazil.

HIV infection causes an accentuated dysregulation on cytokine production. These changes have been extensively studied in patients on antiretroviral therapy (ART). The aim of this study was to characterize the cytokine profile in 58 asymptomatic HIV-patients, according to different answer to ART. The following groups were enrolled: naïve to ART (HIVn, n=18); on ART but presenting incomplete viral suppression (HIVi, n=18); on ART and presenting complete viral suppression (HIVc, n=22). Quantification of viral load and CD4+ T cells were done by branched-DNA and flow cytometry, respectively. Sandwich immunosorbent assays were performed to quantify cytokines as IFN-g (Th1 profile), TNF-a (Th1 and Th17), IL-6, IL-17 (Th17) and IL-10 (Th2 and Treg). The asymmetric variables were analyzed by negative binomial and gamma distributions ($p<0.05$); normal variables were analyzed by ANOVA followed by Tukey ($p<0.05$). The HIVc group presented the lowest concentrations of IL-10 and IL-17. The HIVi group presented intermediate levels of IL-17, the lowest levels of IFN-g and the highest of IL-6 and TNF-a; a positive correlation between these last two cytokines was observed. HIVn showed the highest level of IL-17. This cytokine was the only one that differentiated the 3 groups (HIVn > HIVi > HIVc). These findings suggest the cytokine profile can be useful in clinical practice to characterize the immunological status of asymptomatic patients.

P4.03.54
Nef-HIV-1 dimerization domain plays a key role in p22-phox association and ROS modulation

***G. Teran-Angel**[1], J. C. Valencia-Molina[1], L. Barboza[1], D. L. Peterson[2], L. Berrueta[1], S. Salmen[1];*
[1]Institute of Clinical Immunology, University of Los Andes, Merida, Venezuela, [2]Department of Biochemistry and Molecular Biology, Virginia Commonwealth University, Richmond, VA, USA, Richmond, VA, United States.

Several mechanisms have been proposed to explain how HIV could modulate ROS generation and some data shows that HIV proteins have been implicated in oxidative stress during infection. HIV-1 Nef is a regulatory protein with pro-oxidant properties, and we recently show a specific association between Nef and p22-phox, a membrane component of the NADPH oxidase complex. In this work we explored which domain is critical to mediate this association. Due to a hypothetical predictive model of protein-protein association between p22-phox and Nef, showed low values of free energy between the molecules, in particular, residues VRGE (126-129) from p22-phox corresponding to an intracellular portion of the protein and residues RRQDI (105-109) from Nef, demonstrated the highest probability of interaction, we decided to map this association by cloning different truncated form of Nef-HIV-1, including membrane-binding, SH3, Pak1, dimerization and Pak2 domains, and perform immunoprecipitation and functional assays. We observed that dimerization domain (which contain the RRQDI sequence) is critical for ROS production (empty vector suspension: 5%±3: Nef-HIV-1 wt: 19,8%±8; truncate which contain dimerization domain: 16,4%±8 SD; $p< 0.05$) and p22-phox association. These results shows that dimerization domain play a key role in modulate ROS production due to their association with p22-phox , and probably is implicated in modulate oxidative stress during HIV infection.

P4.03.55
Genital epithelial cells interferon-alpha production is associated with HIV-1 infection in Beninese female commercial sex workers

***V. Thibodeau**[1], A. Labbé[2], M. Alary[3], J. Poudrier[1], M. Roger[1];*
[1]Research Center of the Hospital Center of the University of Montreal, Montreal, QC, Canada, [2]University of Montreal, Montreal, QC, Canada, [3]Laval University, Québec, QC, Canada.

Interferon-alpha (IFN-α) is an important antiviral molecule of the innate immunity. HIV-1-infected commercial sex workers (CSWs) from Benin had higher levels of IFN-α in the genital mucosa when compared to those found in HIV-uninfected CSWs (p=0,039). Epithelial cells are involved in innate immune responses, by sensing pathogens via Toll-like receptors (TLRs), and are one of the first cells to encounter HIV in the genital tract. Specific aim: To define the role of epithelial cells in the production of IFN-α in the female genital tract during HIV infection. Methodology: Cervico-vaginal lavages (CVLs) and cytobrush samples from cervix of 30 HIV-uninfected and 50 HIV-1-infected CSWs were analysed. TLR7-9, interferon regulatory factor (IRF)-7 and IFN-α proteins expression patterns by genital epithelial and myeloid cells were determined by FACS. TLR7-9, IRF-7 and IFNA-17 gene polymorphisms involved in IFN-α signalling pathway were genotyped by direct DNA sequencing. Results: Genital epithelial cell TLR-7 and IFN-α expressions were higher in the HIV-1-infected

CSWs compared to those in HIV-uninfected CSWs (p=0.029, p=0.032). In contrast, IRF-7 epithelial cell expression was lower in the HIV-1-infected CSWs compared to the HIV-uninfected CSWs (p=0.005). Two IRF-7 linked genetic variants (rs1061502, rs12290989) were (p=0.041) associated with IFN-α genital levels in the HIV-1-infected group and with IFN-α intracellular expression in the HIV-1-infected and HIV-uninfected CSWs, (p=0.022, p=0.053). Conclusion: Epithelial cells are major contributors of IFN-α production in the genital mucosa and its production could be genetically-determined in CSWs from Benin.

P4.03.56
Membrane-binding domain from NEF-HIV-1 increases FOXP3 transcription factor expression on human monocytes

J. C. Valencia-Molina[1], *G. Teran-Angel*[1], *L. Barboza*[1], *L. Berrueta*[1], *D. L. Peterson*[2], *S. Salmen*[1];
[1]*Institute of Clinical Immunology, University of Los Andes, Merida, Venezuela,* [2]*Department of Biochemistry and Molecular Biology, Virginia Commonwealth University, VA, USA, Richmond, VA, United States.*

It has been shown that during human immunodeficiency virus (HIV) several mechanism are involved to evade the immune response, including a promotion of the regulatory immune response by increase regulatory T cells (Treg) development. Foxp3 a transcription factor which is considered the most important Treg marker, are also been detected in monocytes/macrophages, and it is associated with their inhibitory activity. Due to monocytes/macrophages are susceptible to HIV-1 infection and are a major viral reservoirs, we explore if Nef-HIV-1 (complete protein) and four different truncate form including membrane-binding, SH3, Pak1, dimerization and Pak2 domains) could modulate Foxp3 on peripheral blood monocytes. We analyzed Foxp3 expression in monocytes from 10 healthy individuals, in prescence of suspension purified from empty vector transformed bacteria, Nef-HIV-1, and four different truncate form. A curve dosis/time was performed, and samples were analyzed on a flow cytometer. We observe that Nef-HIV-1 and only their membrane-binding domain (250ng/ml during 24h), are responsible to increase Foxp3 expression in human monocytes (empty vector suspension: 12%±3: Nef-HIV-1 wt: 26%±5; Nef-HIV-1 membrane-binding: 18%±2 SD; p< 0.05). Our result suggests that Nef-HIV-1 increase Foxp3 expression in monocytes and membrane-binding domain is important to Foxp3 modulation. These results could be important to try reverse the suppressive microenvironment created by HIV to protect themselves in their viral reservoirs and a possible therapeutic target.

P4.03.57
The role of immunological tolerance in humoral responses to the 2F5 epitope of HIV-1

G. Yang[1], *T. M. Holl*[1], *Y. Liu*[1], *T. Nojima*[1], *L. Verkoczy*[1], *J. L. VandeBerg*[2], *D. Kitamura*[3], *B. Haynes*[1], *G. Kelsoe*[1];
[1]*Duke University, Durham, NC, United States,* [2]*Texas Biomedical Research Institute, San Antonio, TX, United States,* [3]*Research Institute for Biological Sciences (RIBS), Tokyo University of Science, Noda, Japan.*

Accumulating evidence suggests that the generation of neutralizing HIV-1 antibody may be proscribed by immunological tolerance. A majority of monoclonal human antibodies, including 2F5, that neutralize multiple clades of HIV-1 are polyreactive and bind avidly to unknown components of mammalian cells. Knock-in mice expressing the VH and VL regions of 2F5 (2F5 KI) are characterized by a central defect in B-cell development that indicates the presence of a tolerizing autoantigen(s) mimicked by the 2F5 epitope of HIV-1 gp41.
We now demonstrate that the 2F5 antibody and its unmutated ancestor avidly bind human kynureninase (KYNU), a conserved enzyme of tryptophan metabolism, via the H4 domain that shares the 2F5 epitope within HIV-1. In mice that express KYNU, B cells with 2F5-like BCR are lost during maturation in the bone marrow, as determined by binding to the 2F5 epitope. To compare the B cell repertoire of 2F5 KI mice before and after central tolerance, we use a single B-cell culture that permits maturation of autoreactive cells normally deleted in vivo. The pre-tolerance compartment (small pre-B) reacts to HIV-1 gp41 and KYNU, whereas the mature, post-tolerance B cells are purged of gp41- and KYNU-reactivity, and contain extensive light-chain editing. Opossums naturally carry an H4 alteration in KYNU that resulted in a fully active enzyme completely unreactive with the 2F5 antibody. Immunization of opossums with HIV-1 gp140 resulted in extraordinarily high HIV-1 gp41-titers.
Identification of an epitope shared by most mammals and HIV-1 provides direct evidence that immunological tolerance impairs humoral responses to HIV-1.

P4.03.58
Differences in the profile of antiviral response in mothers infected by HIV-1 and newborns

N. Zanete Pereira[1], *E. C. Cardoso*[1], *G. E. Mitsunari*[1], *R. M. S. A. Ruocco*[1], *M. Zugaib*[1], *J. B. Oliveira-Filho*[2], *A. J. S. Duarte*[1], *M. N. Sato*[1];
[1]*Faculdade de Medicina USP, São Paulo, Brazil,* [2]*National Health Institute, Bethesda, MD, United States.*

Introduction: A high percentage (65-80%) of infants from mothers infected by HIV-1 is uninfected even in the absence of antiretroviral therapy. This finding emphasizes the importance of evaluating the immunological characteristics in the maternal-fetal interface, mainly related to the innate immune response. The purpose of this study was to evaluate the RNA and protein expression of antiviral factors in HIV-infected mothers peripheral blood mononuclear cells (PBMC) and umbilical cord blood (CB), compared with uninfected mothers-CB.
Methods and Results: The results show that expression of APOBEC3G and 3F, TRIM-5 and 22, MxA, IFN- and STING were increased in CB and PBMC from infected mothers (n =15) compared to control mothers (n =14). Expression of APOBEC3G, TRIM-22, MxA and tetherin was decreased in newborn compared to the healthy adult, moreover, the expression of these factors in CB from HIV-infected mothers were similar to those found in infected mothers group. In placental tissue it was observed decreased expression of APOBEC3G protein in decidua and TRIM-5 in villi tissue of HIV-infected mothers compared to control mothers, however this difference was not observed in the mRNA expression.
Conclusion: This data shows that HIV infection alters the expression of APOBEC3G and TRIM-5 at the post-translational stage, in placental tissue, contrariwise to the enhanced expression in PBMC from HIV-infected mothers. Despite of the immunological immaturity in the neonatal period, the maternal HIV infection generated a similar profile of antiviral factors expression in newborn, probably due to a complex factor interaction related to the pregnancy and HIV-1 infection.

Mice oral immunization against Vibrio cholera: Zot and Ace recombinant proteins used as a subunit vaccine

S. Anvari[1], *S. Najar Peerayeh*[2], *A. Memarian*[1], *M. Behmanesh*[3], *S. D. Siadat*[4];
[1]*Department of Microbiology, School of medicine ,Golestan University of Medical Sciences, Gorgan, Iran,* [2]*Department of Bacteriology, Faculty of Medical Sciences, Tarbiat Modares University, Tehran, Iran,* [3]*Department of Genetic, Faculty of Basic Science, Tarbiat Modares University, Tehran, Iran,* [4]*Department of Hepatitis and AIDS, Pasteur Institute of Iran, Tehran, Iran.*

Cholera is an acute diarrheal disease which is characterized by discharge of voluminous rice watery diarrhea, caused by toxigenic Vibrio cholerae strains. Accessory Cholera Enterotoxin (Ace) is the third toxin of V.cholerae, increases transcellular ion transport and contributes to diarrhea. The second important toxin of V.cholera, Zonula occludens toxin (Zot), is a single polypeptide chain which binds to a receptor on intestinal epithelial cells and increases mucosal permeability by affecting the structure of epithelial tight junctions. This

property makes Zot as a promising tool for mucosal drug and antigen delivery. Ace & Zot proteins from V. cholerae strain 62013 were cloned, over-expressed and purified in Escherichia coli and their biological activity were determined on rabbit ileal loops. In the current study, we used the combination of these proteins in female BALB/c mice to evaluate the efficacy of oral administration and immunization. Following immunization, antibody responses against Zot and Ace proteins were assessed in serum and feces after 7 days. Mice were also challenged with toxigenic V.cholerae 61013 and its shedding was monitored during two weeks in feces. Immunization with both proteins induced significant Zot & Ace specific IgA responses in feces, but not IgG in serum. Mice were immunized with both of Zot & Ace proteins showed dramatically decreased toxigenic V.cholerea shedding compared to those received single protein or negative control. These results demonstrate the future perspective for the use of these proteins as a new recombinant subunit vaccine to prevent colonization and shedding of toxigenic V.cholera.

P4.04.02
Antibodies against outer membrane proteins of Moraxella catarrhalis and nontypeable Haemophilus influenzae cross-react with various pathogens of human respiratory tract

D. Augustyniak[1]*, J. Bonarowska*[1]*, P. Mackiewicz*[2]*, Z. Drulis-Kawa*[1]*;*
[1]*Department of Pathogen Biology and Immunology, Institute of Genetics and Microbiology, University of Wroclaw, Wroclaw, Poland,*
[2]*Department of Genomics, Faculty of Biotechnology, University of Wroclaw, Wroclaw, Poland, Wroclaw, Poland.*

Outer membrane proteins (OMPs) of bacteria Moraxella catarrhalis and nontypeable Haemophilus influenzae are the most immunogenic antigens of these respiratory tract pathogens. The goal of the study was to quantitatively and qualitatively assess the reactivity of anti-OMPs antibodies against cross-reactive and surface-exposed epitopes of heterologous strains as well as other important pathogens of respiratory tract.
Antisera were obtained from six groups of mice, each immunized with isolated different Moraxella catarrhalis OMPs (anti-OMPMc sera) or nontypeable Haemophilus influenzae OMPs (anti-OMPNTHi sera). The titers of cross-reactive antibodies were measured by whole-cell ELISA whereas their specificities with bacterial OMPs was confirmed by Western-blot. The studied pathogens were: Pseudomonas aeruginosa including cystic fibrosis (CF) and non-cystic fibrosis (non-CF) strains, Burkolderia cepacia (CF, non-CF), Acinetobacter baumannii, Haemophilus parainfluenzae and additionally Candida albicans. The pathogens were chosen on the basis of in silico analysis of their surface-exposed antigen homology.
We found that among analyzed anti-OMPMc and anti-OMPNTHi sera, the several were medium or highly cross-reactive. The cross-reactive titers in anti-OMPMc sera were in the range 1:200 - 1:1500 that was 500 - 1000-fold lower than titers for homologous strains. The cross-reactivity of anti-OMPNTHi sera were in the range 1:2000 - 1:11000 that was 4 - 20-fold lower than for homologous counterparts. The reactivity of some cross-reactive antibodies was confirmed with OMPs of tested strains.These results indicate that IgG antibodies induced against OMPs of M.catarrhalis and H.influenzae recognize cross-reactive surface-exposed epitopes in multiple respiratory pathogens. The biological role of this phenomenom will be confirmed in antibody-dependent assays.

P4.04.03
Functionality of cross-reactive antibodies against Moraxella catarrhalis

D. Augustyniak*, M. Piekut, G. Majkowska-Skrobek;*
Department of Pathogen Biology and Immunology, Institute of Genetics and Microbiology, University of Wroclaw, Wroclaw, Poland.

Antibody-dependent immune response against respiratory human pathogen Moraxella catarrhalis is critical for its effective elimination. The goal of the study was to characterize the broad-spectrum effectiveness of cross-reacting antibodies produced in response to whole cells (Mc) or purified outer membrane proteins (OMPs) of this pathogen.
Antisera were obtained from mice immunized with bacteria (anti-Mc sera) or OMPs (anti-OMPMc sera). The titers of cross-reactive antibodies were measured by whole-cell ELISA whereas their avidities by ELISA elution assay with sodium thiocyanate. The following functional methods were used: (1) the antibody-dependent bactericidal assay, (2) the opsonophagocytic assay with human THP-1 cell line, and (3) the blocking adhesion assay with human A549 epithelial cell line.
There were high titers of cross-reactive antibodies both in anti-Mc and anti-OMPMc sera. The titers of anti-OMPMc sera were higher than that of anti-Mc sera. The cross-reactive IgG produced exclusively to OMPs had stronger avidity comparing to those elicited against Mc. Additionally, these antibodies played a pivotal role in complement-mediated killing of heterologous M. catarrhalis isolates. The positive relationship between the total titer of complement-fixing murine subclasses IgG2a and IgG2b and the bactericidal titer was found for both anti-Mc and anti-OMPMc sera. The opsonophagocytic potency as well as reduction of bacterial attachment to human epithelium was much stronger for cross-reactive anti-OMPMc than cross-reactive anti-Mc antibodies.
The presence of cross-reactive antibodies with bactericidal, opsonophagocytic and bacterial adhesion blocking potency may be additional source to control host-Moraxella catarrhalis interaction especially when the host immune status is prone to a new infection.

P4.04.04
Secondary bacterial pneumonia following flu infection: Pathogenesis and protective immunity

M. E. Bernui*, H. Shen;*
University of Pennsylvania, Phladelphia, PA, United States.

Seasonal and pandemic influenza (IAV) has cost us millions of lives and inestimable amounts of money. Studies now indicate secondary bacterial pneumonia is responsible for most flu-associated fatalities. Nonencapsulated-nontypeable *Haemophilus influenzae* (NTHi) is a growing clinical concern in the context of IAV co-infections due its high antigenic variability, increasing antibiotic resistance, vaccine unavailability, and insufficient knowledge. In this study we have developed a highly susceptible murine model to IAV/NTHi co-infections. Less than 10 CFU of NTHi kill all IAV-infected mice 4 days post-bacterial infection (pbi), due partially to NTHi uncontrolled growth. Over 10^6 CFU are found in lungs of co-infected mice in contrast to the undetectable levels in single infected-mice 4 days pbi. By day 6 pbi, co-infected mice become bacteremic before succumbing to infection. To elucidate this interaction and move towards the discovery of vaccines, we utilized the novel High-throughput Insertion-Tracking by Deep-Sequencing (HITS) assay to identify virulent factors essential during IAV/NTHi co-infections. We validated HITS results *in vivo* and identified one mutant strain, NTgalU, as a potential vaccine candidate. NTgalU-immunized mice are protected against an IAV/NTHi challenge, whereas 100% of NTHi-immunized mice perish after challenge. NTgalU immunization potentiates the cellular immune response both quantitatively and functionally with >20% more $CD4^+$ and $CD8^+$ T cells and about 30% more IFN-g production. Finally, naïve mice receiving memory lymphocytes from NTgalU-vaccinated mice are protected against an IAV/NTHi co-infection. Future studies include the assessment of more virulent factors useful toward vaccine development against other pulmonary bacterial co-infections.

P4.04.05
Induction of Mast Cell Extracellular Traps by intracellular bacteria

M. Campillo-Navarro[1]*, J. Serafín-López*[1]*, I. Estrada-García*[1]*, M. González-jimenez*[2]*, A. Cerbulo-Vazquez*[2]*, K. Leyva-Paredes*[1]*, B. García-Pérez*[1]*, L. Donis-Maturano*[3]*, S. Estrada-Parra*[1]*, R. Chacon-Salinas*[1]*;*
[1]*Escuela Nacional de Ciencias Biologicas, IPN, Mexico city, Mexico,* [2]*INPER, Mexico city, Mexico,* [3]*CINVESTAV, IPN, Mexico city, Mexico.*

Mast cells (MCs) are involved in various immunological phenomena, as allergies and infectious diseases. Extracellular and intracellular bacteria are able to activate MC. A mechanism by which MCs

respond to bacterial infections is by the production of Mast Cell Extracellular Traps (MCETs), which are formed by chromatin covered of granule proteins with antimicrobial activity, in a process dependent on the production of ROS. Although extracellular bacteria induce the production MCETs, it is unknown whether intracellular bacteria induce this process. In the present study we evaluated the production of MCETs by Mycobacterium tuberculosis (Mtb) and Listeria monocytogenes (Lm). MCs were exposed to PMA, Mtb or Lm at different times. MCETs formation was evaluated by fluorescent microscopy. Morphological changes were assessed by transmission electron microscopy and production of ROS was evaluated with the NBT reduction. MCs showed a fast release of DNA when stimulated with PMA or Lm. In contrast, Mtb produced a slower release of DNA. PMA-induced MCETs showed presence of histone and tryptase. Moreover, these cells had changes in the nuclear envelope and the DNA outside the cell nucleus when stimulated with PMA or Lm. Interestingly, the MCETs showed antimicrobial activity against Lm, but not against Mtb. Finally, MCs showed significant production of ROS when challenged with PMA or Lm. Our results suggest that the intracellular bacteria tested are capable to induce the production of MCETs, and have antimicrobial activity against Lm but not Mtb.

P4.04.06
Plasmin Cleaves Human complement C3b and C5 Proteins in the Presence of Leptospira interrogans Proteins: A New Role of LigA and LigB for complement Immune Evasion

M. M. Castiblanco-Valencia[1,2]*, T. R. Fraga*[1,2]*, L. B. Silva*[3,4]*, D. Monaris*[3,4]*, P. A. E. Abreu*[4,4]*, A. S. Barbosa*[4,4]*, L. Isaac*[1,2]*;*
[1]University of São Paulo, São Paulo, Brazil, [2]Institute of Biomedical Sciences, São Paulo, Brazil, [3]Butantan Institute, Laboratory of Bacteriology, Brazil, [4]Butantan Institute, São Paulo, Brazil.

The spirochete Leptospira interrogans is a highly invasive pathogen of worldwide public health importance. The ability of Leptospira to evade the complement system is crucial for a successful infection. An important immune evasion strategy employed by pathogens is the acquisition of plasminogen and its conversion to plasmin, which is able to cleave the complement components C3b and C5 on the pathogen's surface. Leptospiral immunoglobulin-like (Lig) proteins are multifunctional molecules that interact with extracellular matrix components and host complement regulatory proteins. We therefore decided to evaluate the interaction of these proteins with plasminogen as a complement evasion mechanism. Both C- and N-terminal portions of LigA and LigB genes were cloned, expressed and purified as recombinant proteins in E. coli. We demonstrate that the Lig proteins were able to bind plasminogen, which was activated to plasmin by addition of human urokinase type plasminogen activator (uPA). Lig-plasminogen interactions were significantly inhibited by the lysine analog aminocaproic acid, suggesting that the lysine-binding sites of the plasminogen molecule play a role in the binding. We also show that plasminogen bound to Lig proteins was converted to active plasmin and this enzyme was able to degrade fibrinogen, C3b and C5. These cleavages inactivate C3b and C5, preventing progression of the complement cascade and blocking the three complement pathways. The identification of these leptospiral ligands is of great relevance since they may represent targets for immune interference. We conclude that Lig proteins are multifunctional molecules that contribute to leptospiral adhesion and immune evasion.

P4.04.07
A murine air pouch model to study group A streptococcal pathogenesis and protective immunity

N. Chiappini*, A. Seubert, P. Fontani, J. L. Telford, D. Serruto, G. Grandi, I. M. Y Ros, R. Janulczyk;*
Novartis Vaccines, Siena, Italy.

Group A Streptococcus (GAS) is a major human pathogen worldwide, responsible for both local and systemic infections. In this work we apply the air pouch model to study GAS infection, in particular the role of a well-known virulence factor – the chemokine-degrading protease SpyCEP. Dorsolateral air pouches were inflated in CD1 mice by subcutaneous injection of 3 ml air on day 1 and day 4. On day 6, 3348 wild type or 3348*ΔspyCEP* knock out strains were injected into the pouch. At 2, 4 or 24 h after infection an air pouch lavage was performed. Lavage samples were processed for the parallel analysis of bacterial content, cell recruitment and chemokines. Mice infected with 3348Δ*spyCEP* showed a tendency to have more neutrophils and monocytes compared to mice infected with the wild type 3348 strain. Concomitantly, the chemokines KC, LIX, and MIP-2 were drastically increased in mice infected with the SpyCEP knockout strain, and growth of this mutant strain was reduced compared to the wild type. We extended the application of the air pouch model to evaluate protective immunity. Mice were immunized with adjuvant only, M protein, or a combination of GAS antigens (including SpyCEP), and samples were collected and analyzed 24 hours post infection. We observed that vaccinated groups showed significant bacterial growth reduction compared to the group immunized with adjuvant only. Taken together, our data suggest that the air pouch model promises broad application in the study of immune system response after streptococcal infection.

P4.04.08
Investigation of innate immunity genes on the japanese oak silkworm, *Anthereae yamamai*

K. Choi*, S. Kim, S. Kim, S. Kang, T. Goo;*
National Academy of Agricultural Science, Suwon, Republic of Korea.

Japanese oak silkworm, *Antheraea yamamai*, is a large moth in the family and distributed throughout China, Korea, and Japan. Japanese oak silkworms cocoon is superior to that of the domestic silkworm in gloss, durability, and wrinkle. The main targets of our investigation were innate immune-related genes and effect molecules, the key components of humoral defense reaction in the japanese oak silkworm, *A. yamamai.* The expressed sequence tag analysis was used for screening of genes that are induced to injected bacterial lipopolysaccharide(LPS). Analysis of 1180 cDNAs resulted in identification of 31 immune-related genes including pathogen recognition, modulation and putative antimicrobial peptides. In addition, we compared acidic extracted hemolymph protein profiles between control and immune-challenged *A. yamamai* larvae using two-dimensional gel electrophoresis(2-DE). Protein spots showing differential expression were identified by MALDI-TOF and MS/MS spectra. Subsequently, three of them were estimated to be attacin antibacterial peptides with high coverage of sequence. These attacin peptides were intensively induced after an immune-challenge with LPS.

P4.04.09
An inhibitor of sirtuin 1 and sirtuin 2, cambinol, impairs MAPK signaling, inhibits inflammatory and innate immune responses and protects from septic shock

E. Ciarlo*, J. Lugrin, A. Santos, G. Grandmaison, I. Dos Santos Pinheiro, D. Le Roy, T. Roger;*
Infectious Diseases Service, Department of Medicine, Centre Hospitalier Universitaire Vaudois and University of Lausanne, Lausanne, Switzerland.

Background: The histone deacetylase family comprises HDAC1-11 and Sirtuins (SIRT)1-7. SIRTs are involved in the control of metabolism and cell proliferation, and in the development of oncologic, cardiovascular and neurodegenerative diseases. Cambinol was recently identified as a compound inhibiting SIRT1/2 with anti-tumor activity *in vivo*. As HDAC1-1 inhibitors are potent anti-inflammatory drugs, we questioned whether cambinol also modulates inflammatory and innate immune responses *in vitro* and *in vivo*.
Methods: Macrophages, DCs, splenocytes, whole blood and PBMCs were stimulated with LPS, Pam3CSK4, CpG, TSST-1, SEB, *E.coli* and *S.aureus* before measuring activation of NF-kB and MAPK pathways, production of cytokines, NO and CD40, and proliferation. Mice were challenged with lethal doses of LPS or *K.pneumonia*.
Results: Cambinol inhibited the expression of cytokines, NO and CD40 by mouse and humans immune cells. Unexpectedly, selective inhibitors of SIRT1 (EX-527, CHIC-35) and SIRT2 (AGK2, AK7) used alone or in combination had no impact on cytokine production by macrophages, suggesting that cambinol acts by targeting more than just SIRT1/2. Cambinol impaired stimulus-induced phosphorylation of

MEKs and MAPKs. In line with these results, cambinol treatment reduced TNF blood levels (*P* = 0.04) and improved survival to endotoxic shock (from 8% to 46%; P < 0.001) and acute *K.pneumoniae* pneumonia (from 13% to 60%; P = 0.013).
Conclusions: Cambinol has powerful anti-inflammatory activity and protects from septic shock. Pharmacological inhibitors structurally related to cambinol have promising therapeutic potential for the treatment of pathologies characterized by acute and chronic inflammatory responses.

P4.04.10
Study of the impact of Sirtuin 2 knockout on innate immune responses and sepsis

E. Ciarlo[1], *J. Lugrin*[1], *I. Dos Santos Pinheiro*[1], *D. Le Roy*[1], *N. Moulan*[2], *H. Yamamoto*[2], *H. Acha-Orbea*[3], *T. Calandra*[1], *J. Auwerx*[2], *T. Roger*[1];
[1]*Infectious Diseases Service, Department of Medicine, Centre Hospitalier Universitaire Vaudois and University of Lausanne, Lausanne, Switzerland,* [2]*Laboratory for Integrative and Systems Physiology, Ecole Polytechnique Fédérale de Lausanne, Lausanne, Switzerland, Lausanne, Switzerland,* [3]*Department of Biochemistry, University of Lausanne, Epalinges, Switzerland, Lausanne, Switzerland.*

Background: Sirtuins (SIRT1-7) are NAD-dependent histone deacetylases. Sirtuins are the center of great interest due to their role in influencing metabolism, ageing and age-related diseases. The impact of sirtuins on immune responses is poorly described, and nothing is known about the role of SIRT2. The aim of the study was to analyze the influence of SIRT2 knockout on immune parameters in vitro and in vivo.
Methods: Thymic (DN1-4, DP, SP) and splenic (DN, SP, naïve and memory T cells; immature and mature B-cells; cDCs; pDCs) populations were analyzed by FACS. Bone marrow derived macrophages and DCs and splenocytes were stimulated with LPS, Pam3CSK4, CpG, *E.coli*, *S.aureus*, TSST-1, SEB, anti-CD3+CD28 before measuring cytokines, SIRTs, CD40, and proliferation. Mice (n=6-16) were challenged with LPS, TNF/D-gal, *E.coli*, *K.pneumonia*.
Results: SIRT2 is the most expressed sirtuin in myeloid cells. SIRT2-/- mice born at expected Mendelian ratio, develop normally, and express normal proportions and absolute numbers of thymocytes, and splenic T-cells, B-cells, DCs and granulocytes. SIRT2-/- macrophages, DCs and splenocytes express cytokines and CD40 (RNA and protein), and proliferate like SIRT2+/+. SIRT2-/- and SIRT2+/+ mice respond similarly (cytokine levels, bacterial counts and mortality) to non-severe and lethal septic and toxic shock.
Conclusions: SIRT2 knockout has no dramatic impact on the development of immune cells and on innate immune responses *in vitro* and *in vivo*. Considering that SIRT2 may participate to control metabolic homeostasis, we are currently assessing the impact of SIRT2 deficiency on innate immune responses under metabolic stress.

P4.04.11
Immune-response in lesional skin of secondary syphilis

M. Cusini, *V. Merlo, L. Corti, R. Gianotti, L. Venegoni, E. Berti;
Dept. of Dermatology - Fondazione IRCCS Cà Granda - Ospedale Maggiore Policlinico, Milan, Italy.*

Tissue immune response is very important in several bacterial and viral infections determining granulomatous reactions (mycobacteria), local immunodeficiency (HHV8-HIV) or disregulation (HCV-HSV). Few data are known about the cutaneous host immunoresponse during infection by Treponema pallidum (TP), the causative agent of syphilis . In our study, by using several monoclonal antibodies (Mabs) specific for lymphoid subsets, monocytes-macrophages and an anti TP polyclonal antibody, we analyzed the characteristic of the infiltrate of 5 cases of secondary syphilis lesional skin. TP bacteria were mainly localized in the epithelial sheets, even if some TP were also detected in the dermis (perivascular areas). The infiltrate was characterized, as expected, by large number of plasmacytes, as detected by CD138, CD79a and MUM-1. Plasmacytes showed active in situ proliferation, as demonstrated by MIB-1/Ki-67 proliferation marker. An abundant epidermotropic T-lymphocytes infiltrate consisting of the CD8+ subset was easily demonstrated in the superficial dermis, where several macrophages (M1 and M2) were also detected. Unexpectedly the staining of dendritic cells by using anti CD1a Mab evidenced the quite complete absence of Langerhans cells, both in the epidermis and in the dermis. These data suggest the presence of a characteristic immune-disregulation in the skin affected from TP infections (abundant plasmacytes and CD8+ lymphocytes and absence of dendritic Langerhans cells).

P4.04.12
The role of neutrophil extracellular traps (NETs) in the host defense against Gram-negative sepsis (melioidosis)

H. K. de Jong[1], *G. C. K. W. Koh*[2,3,4], *T. A. F. Weehuizen*[1], *A. Achouiti*[1], *F. Stephan*[5,6], *N. P. J. Day*[3,7], *S. J. Peacock*[2,3], *S. Zeerleder*[5,6], *T. van der Poll*[1], *W. J. Wiersinga*[1];
[1]*Center for Infection and Immunity Amsterdam (CINIMA), Center of Experimental and Molecular Medicine (CEMM) and Division of Infectious Diseases, Academic Medical Center, Amsterdam, Netherlands,* [2]*Department of Medicine, Addenbrooke's Hospital, University of Cambridge, Cambridge, United Kingdom,* [3]*Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand,* [4]*Department of Infection and tropical Medicine, Heartlands Hospital, Birmingham, United Kingdom,* [5]*Department of Immunopathology, Sanquin, Amsterdam, Netherlands,* [6]*Department of Haematology, Academic Medical Center, Amsterdam, Netherlands,* [7]*Nuffield Department of Clinical Medicine, Churchill Hospital, University of Oxford, Oxford, United Kingdom.*

Introduction: Neutrophil extracellular traps (NETs) have emerged as a central part of innate host response to bacteria. Neutrophils release extracellular fibers that ensnare bacteria and, ultimately, kill their target. Major components of NETs include extracellular DNA-histone complexes (nucleosomes) and neutrophil-elastase. We studied the role of NETs in *B. pseudomallei* infection (melioidosis), which is an important cause of sepsis in SE-Asia.
Methods: We assessed circulating nucleosomes and neutrophil-elastase (HNE-A1AT) in 43 septic melioidosis patients and 83 controls. Isolated human neutrophils were stimulated *in vitro* with *B. pseudomallei*: NET formation was quantified by measuring nucleosome, HNE-A1AT and cleaved DNA release. NET function was investigated *in vivo* in mice infected with *B. pseudomallei* and treated with DNAse to degrade the DNA backbone of NETs. Mice were sacrificed post infection to assess bacterial loads, inflammation and pathology.
Results: Nucleosome and HNE-A1AT levels were elevated in melioidosis patients, and gradually normalized in those who survived. In line, human neutrophils stimulated with *B. pseudomallei* induced NET formation and showed increased levels of elastase and cleaved DNA. In mice, disruption of intravascular NETs by intravenous DNAse administration resulted in decreased nucleosome plasma levels compared to controls at 24 and 72 hour after infection but no differences were seen on bacterial loads and cytokine release.
Conclusion: *B. pseudomallei* induce NET formation by human neutrophils which is reflected by strongly increased levels of NET related-components in melioidosis patients. Surprisingly, disruption of NET production leads to a decrease in circulating nucleosomes but not to defective clearance of *B. pseudomallei*.

P4.04.13
Protease Activated Receptor 4 contributes to host defense in Streptococcus pneumoniae induced pneumonia

S. F. de Stoppelaar, *C. van 't Veer, F. E. van den Boogaard, R. Nieuwland, A. J. Hoogendijk, O. J. de Boer, J. J. T. H. Roelofs, T. van der Poll;
Academic Medical Center, Amsterdam, Netherlands.*

BACKGROUND: Streptococcus (S.) pneumoniae is a common causative pathogen of pneumonia and sepsis. Pneumonia and sepsis are associated with enhanced activation of coagulation, resulting in the production of several host derived proteases at the primary site of infection and in the circulation. Serine proteases cleave protease activated receptors (PARs), which form a molecular link between

coagulation and inflammation. PAR4 is one of 4 subtypes of PARs and is widely expressed by multiple cell types in the respiratory tract implicated in pulmonary inflammation, by immune cells and by platelets. In mice, PAR4 is the only thrombin receptor expressed by platelets.
AIMS: To determine the contribution of PAR4 to the host response during pneumococcal pneumonia.
METHODS: Pneumonia was induced by intranasal inoculation with S. pneumoniae in PAR4-deficient (par4-/-) and wild-type mice. Mice were sacrificed after 6, 24 or 48 hours. Blood, lungs, liver and spleen were collected for analyses.
RESULTS: After 48 hours of infection, higher bacterial loads were found in the lungs of par4-/- mice ($P < 0.05$), accompanied by higher histopathology scores and increased cytokine levels ($P < 0.05$). At 24 hours post infection par4-/- mice displayed lower plasma and lung thrombin-antithrombin complex (TATc) levels, whereas they showed higher TATc concentrations at 48 hours. Of interest, par4-/- mice displayed a trend towards lower plasma platelet factor 4 levels at this latter time point, indicative of decreased platelet activation in spite of the apparently increased thrombin formation.
CONCLUSION: Our findings suggest that PAR4 contributes to antibacterial defence during murine pneumococcal pneumonia.

P4.04.14
Streptococcus pneumoniae serine protease HtrA, but not SFP or PrtA, is a major virulence factor in pneumonia

S. F. de Stoppelaar[1], *H. Bootsma*[2], *A. Zomer*[2], *J. J. T. H. Roelofs*[1], *P. W. Hermans*[2], *C. van 't Veer*[1], *T. van der Poll*[1];
[1]*Academic Medical Center, Amsterdam, Netherlands,* [2]*Radboud University Medical Center, Nijmegen, Netherlands.*

BACKGROUND: Serine protease orthologs expressed by a variety of bacteria have been found of importance for virulence. Previous studies have identified two serine proteases in S. pneumoniae, HtrA (high-temperature requirement A) and PtrA (cell wall-associated serine protease A), that contributed to virulence in models of pneumonia and intraperitoneal infection respectively.
OBJECTIVE: To identify additional S. pneumoniae serine proteases and determine their role in virulence in vivo.
METHODS: The S. pneumoniae D39 genome was searched for genes encoding putative serine proteases. Mutant D39 strains lacking serine proteases were constructed by in-frame insertion deletion mutagenesis. Pneumonia was induced in C57Bl/6 mice by intranasal infection with wild-type or mutant D39 (50.000 or 500.000 colony forming units); mice were euthanized after 6 or 48 hours and blood and organs were collected for analyses.
RESULTS: The S. pneumoniae D39 genome contains three putative serine proteases: HtrA, Subtilase Family Protein (SFP) and PrtA. After low dose infection, D39ΔHtrA showed reduced virulence, as reflected by a strongly increased bacterial clearance in lungs, distant organs and no detectable bacteria in the blood. Notably, pneumococcal burdens were also modestly but significantly lower in lungs after infection with D39ΔSFP. After high dose infection, reduced virulence only remained for D39ΔHtrA; D39ΔPrtA induced significantly less lung inflammation without influencing bacterial loads.
CONCLUSIONS: These data confirm the important role for HtrA in S. pneumoniae virulence. SFP may facilitate S. pneumoniae growth after low dose infection. In contrast to its reported role in intraperitoneal infection, PrtA does not contribute to virulence in pneumococcal pneumonia.

P4.04.15
Th9 and Th22 cytokines profiles expressed by TCD4+ lymphocytes activated with different Aggregatibacter actinomycetemcomitans-serotypes

J. Díaz-Zúñiga*, S. Melgar-Rodríguez, C. Alvarez, R. Vernal;*
Universidad de Chile, Santiago, Chile.

Objective: Periodontitis represents a heterogenic group of periodontal infections elicited by bacteria residing at the subgingival biofilm. Although bacteria may cause direct tissue destruction, their pathogenicity relies mainly on the activation of Th1 and Th17 lymphocytes. This biofilm is constituted by a broad variety of bacterial species, only a limited number has been associated with the periodontitis aetiology, among them, Aggregatibacter actinomycetemcomitans.
Based on the antigenicity of LPS O-polysaccharide, distinct serotypes have been described. The aim of this study was to determine the Th9 and Th22 master-switch genes and cytokines expression on TCD4+ lymphocytes stimulated with a, b and c A. actinomycetemcomitans serotypes.
Method: Using different multiplicity of infections of a, b and c of A. actinomycetemcomitans serotypes, the mRNA expression and secretion levels for IL-9, IL-17F, IL-22 and expression levels of AHR and SPU-1/PU.1 on stimulated TCD4 lymphocytes were quantified by PCR.
Result: On TCD4 lymphocytes, A. actinomycetemcomitans b serotype induced higher levels of cytokines compared with the other strains. In addition, b serotype induced higher levels of Th9 and lower levels of Th22 cytokines, and at lower MOI than TCD4 lymphocytes stimulated with the other strains.
Conclusion: These results demonstrate a different potential of O-polysaccharide A. actinomycetemcomitans serotypes to induce Th9 or Th22 differentiation on TCD4+ T lymphocytes and a higher capacity of b serotype to trigger Th9 cytokines.

P4.04.16
Undernutrition and birth season influence the antibody response to B. pertussis in children of Northern Senegal

L. Gaayeb*;*
EPLS Biomedical Research Center, Saint-Louis, Senegal.

Background:
While vaccines elicit a protective response in most recipients, studies suggest that environmental and nutritional factors can influence the strength of the individual response to immunization and to subsequent natural infectious challenges.
Methods:
We conducted a longitudinal survey in Senegal to assess the individual response to B. pertussis, a respiratory disease against which Senegalese children are vaccinated before the age of one. A cohort of 203 children aged 1 to 10 from four villages of the Senegal River Valley was followed-up for one year. During that period, four visits have been made to the villages to assess the immunological and the nutritional status of the children and to determine risk factors involved in the modulation of their humoral immune response to B. pertussis toxin.
Results:
A multivariate model has demonstrated that birth season and nutritional status appeared to modulate humoral response to pertussis toxin. Moreover, response to B. pertussis was dependent on age, village and time of visit.
Conclusions:
These results are consistent with the hypothesis that environmental and nutritional factors modulate children's response to pertussis following natural infection or vaccination.

P4.04.17
Immuno-microbiological aspects of chronic apical periodontitis

L. A. Mozgovaya, I. I. Zadorina, L. P. Bykova, ***A. P. Godovalov****;*
Acad. E.A. Wagner Perm State Medical Academy, Perm, Russian Federation.

Microbiological research of 24 root canals discharge at patients with chronic apical periodontitis was conducted. In assessing the persistence of opportunistic microbial species identified a number of cultures of obligate and facultative forms, of which dominated gram-positive species. Thus, in 62.9% of cases identified members of the genus Staphylococcus, including most types of coagulasa-positive met (St. aureus, intermedius et hyicus). In 70.4% of cases were found members of the genus Streptococcus, among which the most met Str. pyogenes and enterococci. Of gram-negative Neisseria species predominated (62.5%), the family Enterobacteriaceae (Proteus mirabilis et Citrobacter diversus) represented 25%. Growth of Lactobacillus sp. detected in 33% of cases, and Corynebacterium sp. - in 11%. Anaerobes (Prevotella, Fusobacterium, Peptococcus etc.)

isolated in 29.6%. At this patients found that the total protein concentration in root canals at maximum value observed in radicular cyst and minimal - in chronic periodontitis. During exacerbation of chronic periodontitis, the total protein concentration in the discharge of the root canal rises slightly, while the number of white blood cells is significantly increased (mainly granulocytes). Thus, it can be assumed that chronic apical periodontitis is caused predominantly by bacteria of the genus Staphylococcus and Streptococcus, and chronic inflammation is supported by the presence of a number of leukocyte that produce massive amounts of protein molecules (globulin).

P4.04.18
Thrombospondin 1 expression in THP-1 cells stimulated with periodontopathic bacteria

M. Gokyu[1]*, H. Kobayashi*[1]*, H. Nanbara*[1]*, Y. Changchang*[1]*, Y. Izumi*[1,2]*;*
[1]Periodontology, Graduate School, Tokyo Medical and Dental University, Tokyo, Japan, [2]Global Center of Excellence Program, International Research Center for Molecular Science in Tooth and Bone Diseases, Tokyo Medical and Dental University, Tokyo, Japan.

Periodontitis is an inflammatory disease infected with periodontopathic bacteria, causing tissue destruction and bone loss around teeth. Recently periodontitis is reported to have a relationship to systemic disease such as cardiovascular disease, diabetes mellitus and preterm birth. Porpyromonas gingivalis (P.gingivalis) is one of major peridontopathic bacteria and is detected in not periodontitis region but a blood vessel. LPS of P.gingivalis was reported to activate THP-1 cells, a human acute monocytic leukemic cell line, through TLR2 and to induce inflammation in periodontitis. To identify P.gingivalis LPS effect in THP-1 cells, DNA array was used. In DNA array analysis, we focused high thrombospondin 1 (TSP-1) expression in THP-1 cells. TSP-1 is a multifunctional extracellular matrix protein and generally elevated in inflammatory processes and modulates the immune response at sites of inflammation. To detect TSP-1 expression in periodontitis, inflammatory granulation tissues were collected from periodontitis region and real time RT-PCR was performed. In these inflammatory periodontal tissues, TSP-1 mRNA were enhanced in comparison to healthy sites. In vitro experiments, P.gingivalis LPS increased TSP-1 mRNA expression in THP-1 cells dose and time dependent manner. Pam2CSK4(TLR2 ligand) and E.coli LPS (TLR4 ligand) also increased TSP-1 mRNA expression in THP-1 cells. These data suggested that P.gingivalis LPS was involved in TSP-1 introduction in inflammatory periodontal region via TLR2 receptor.

P4.04.19
Development of an in vitro infection model for the evaluation of viable, macrophage-engulfed Pseudomonas aeruginosa

L. K. Green*, A. C. La Flamme, D. F. Ackerley;*
Victoria University of Wellington, Wellington, New Zealand.

Pseudomonas aeruginosa, an increasingly multi-drug resistant human pathogen, is now one of the top three causes of opportunistic infection and there is much interest in identifying novel therapeutic targets for treatment. Though both *P. aeruginosa* virulence determinants and the macrophage responses to bacterial pathogens have been well characterised over the last several decades, most recent work acknowledges the complex interaction between the human host and the pathogen as an on-going dialogue of virulence factors adapting to the continuum that is the immune response. Therapeutic target identification is now moving beyond isolated constituent stressor studies to a more complex map of crosstalk between host and pathogen in the presence of naturally produced immune compounds in physiologically correct conditions. To address this, we have developed an *in vitro* infection model for assessing *P. aeruginosa* responses to challenge by immunocompetent murine macrophages. Furthermore, this method was adapted to examine the global transcriptional events taking place during macrophage exposure. This new technique allowed for the evaluation of individual infection parameters side-by-side in a high-throughput fashion and has the potential flexibility to be adapted for evaluation of the *P. aeruginosa* response to challenge by other phagocytic cell types (e.g. neutrophils); as well as to gauge, in tandem, how the eukaryotic host acts in response to the bacteria by employing established immunological assays. The method thus contributes a valuable tool for understanding of the greater biological process encompassing the establishment of disease.

P4.04.20
Protective immunity of intranasally infected mice with Brucella Melitensis

D. Hanot Mambres[1]*, E. Muraille*[2]*, J. Letesson*[1]*;*
[1]Université de Namur (FUNDP), Namur, Belgium, [2]Université libre de Bruxelles (ULB), Bruxelles, Belgium.

The α-proteobacterium Brucella is a gram-negative intracellular bacterium responsible for brucellosis that causes abortion and infertility in animals and undulant fever in humans. If untreated, the human brucellosis can become chronic with severe clinical complications. Although eradicated in most of developed countries, brucellosis remains a worldwide public health problem.
The intraperitoneal inoculation of mice is the most used experimental model to study Brucella infection. However, natural infections are generated by contaminated food intake or aerosol. Bacteria have to cope with effectors of the mucosal immune system, which are bypassed by intraperitoneal inoculation. Thus, we have developed an intranasal infectious model in mice, using a B.melitensis strain expressing the fluorescent mCherry protein.
We have focused our study on the identification of essential signaling pathways and cells controlling the infection. IL-12 dependent IFNγ producing T CD4+ (Th1) lymphocytes played a dominant role during the infection, when compared to CD8+ T cells and B cells. We also characterized, by immuno-histofluorescence, the main alterations due to the infection in lung, spleen and liver.
Finally, we have analyzed the secondary immune response against B. melitensis in intranasally vaccinated mice. In order to determine the importance of specific antibodies, we have compared the ability of vaccinated wild-type and B-lymphocytes deficient mice to control infection. Our preliminary data suggest a major role of circulating antibodies in the control of secondary infection.
Globally, our results in intranasal infectious model could improve our ability to generate a protective vaccine against brucellosis and others infectious pathologies due to intracellular bacteria.

P4.04.21
DAP12 impairs host defense in pneumococcal pneumonia

T. J. Hommes*, A. A. Anas, M. C. Dessing, C. van 't Veer, A. de Vos, T. van der Poll;*
AMC, Amsterdam, Netherlands.

Background: Streptococcus pneumoniae is the most common cause of community-acquired pneumonia. DNAX activation protein of 12 kDa (DAP12) is a transmembrane protein that functions as a signal transduction adaptor molecule that associates with a variety of receptors on NK and myeloid cells. DAP12 can either activate or inhibit immune responses.
Aim: To determine the role of DAP12 in pneumococcal pneumonia.
Methods: Pneumonia was induced in DAP12 knockout (KO) and wild-type (WT) mice by intranasal inoculation with viable S. pneumoniae. Pulmonary DAP12 expression was studied using qRT-PCR. Lungs, spleen, liver and blood were harvested at 6, 24 and 48 hour post-infection for quantitative cultures. Cytokines, chemokines and MPO were measured in lung homogenates. Responsiveness towards S. pneumoniae of DAP12 KO versus WT alveolar macrophages was tested in vitro.
Results: Alveolar macrophages lacking DAP12 produced more TNF-α than WT cells upon stimulation with S. pneumoniae in vitro, suggesting a role for DAP12 in the initiation of innate immunity against this pathogen. WT mice demonstrated enhanced pulmonary DAP12 expression during pneumococcal pneumonia. DAP12 KO mice showed prolonged survival relative to WT mice which was accompanied by decreased bacterial loads in lungs, blood and distant organs at 24 and 48 hours post-infection. In addition, at 24 and 48 hours after infection pulmonary inflammation was decreased in DAP12 KO mice as reflected by lower inflammation scores and reduced chemokine and MPO concentrations.

Conclusion: DAP12 impairs host defense during pneumococcal pneumonia.

P4.04.22
TREM-1 improves host defense in pneumococcal pneumonia

T. J. Hommes[1], *M. C. Dessing*[1], *M. Colonna*[2], *C. van 't Veer*[1], *A. de Vos*[1], *T. van der Poll*[1];
[1]*AMC, Amsterdam, Netherlands,* [2]*BJC Institute of Health at Washington University, St Louis, MO, United States.*

Background: Streptococcus pneumoniae is the most common cause of community-acquired pneumonia. Triggering receptor expressed on myeloid cells 1 (TREM-1) is an activating receptor that is primarily expressed on myeloid cells. Through an unknown ligand TREM-1 enhances Toll- and NOD-like receptor signaling.
Aim: To determine the role of TREM-1 in pneumococcal pneumonia.
Methods: Pneumonia was induced in TREM-1/3 knockout (KO) and wild-type (WT) mice by intranasal inoculation with S. pneumoniae. TREM-1 expression was investigated using qRT-PCR and FACS. Lungs, spleen, liver and blood were harvested at 6, 24 and 48 hour post-infection for quantitative cultures. Cytokines and MPO were measured in lung homogenates. Responsiveness towards S. pneumoniae of TREM-1/3 KO versus WT macrophages and the phagocytic capacity of TREM1/3 KO and WT neutrophils and macrophages were tested in vitro.
Results: WT mice demonstrated enhanced TREM-1 expression during pneumococcal pneumonia. TREM-1/3 KO mice were more susceptible to pneumococcal pneumonia, as reflected by a reduced survival and increased bacterial loads in lungs, blood and distant organs at 24 and 48 hours post infection. At 6 hours post-infection, pulmonary TNF-α, IL-1β and MPO levels were lower in TREM-1/3 KO mice despite equal bacterial loads, pointing to an impaired initiation of the host response. Macrophages lacking TREM-1/3 produced less TNF-α and KC than WT cells upon stimulation with S. pneumoniae and showed impaired phagocytosis in vitro. TREM-1/3 KO neutrophils showed no defect in their capacity to phagocytose S. pneumoniae.
Conclusion: TREM-1 contributes to protective immunity during pneumococcal pneumonia most likely through its expression on macrophages.

P4.04.23
Immune Evasion by Staphylococcal Superantigen-Like Protein 10

W. Hou[1], *D. Patel*[2], *R. J. Langley*[1], *J. D. Fraser*[1];
[1]*The University of Auckland, Auckland, New Zealand,* [2]*Formerly The University of Auckland, Auckland, New Zealand.*

Staphylococcus aureus is a versatile pathogen that remains the most common cause of hospital acquired infections world-wide. The rapid spread of antibiotic resistant *S. aureus* strains through human communities calls for a better understanding of its pathogenicity.
Staphylococcal superantigen like protein 10 (SSL10) is a highly conserved 26 kD protein that acts as an immune evasion molecule targeting multiple aspects of the host immune system. A strong affinity to immunoglobulin G (IgG) has been observed. In contrast to protein A and Sbi (Staphylococcus aureus binder of IgG), two other IgG binding proteins produced by *S. aureus*, SSL10 shows a strict specificity to the IgG γ1 subclass (IgG1) and the binding is limited to human and non-human primate species. IgG1 is the most abundant IgG subclass in circulation and is one of the major contributors for complement fixation. Interestingly, the SSL10/IgG1 interaction was shown to involve the Cγ2 domain of IgG1, in proximity to the C1q and Fcγ receptor recognition sites, highlighting the importance of SSL10 in *S. aureus* evasion from IgG-mediated immune attack. We have identified an interface on SSL10 that plays a crucial role in mediating its binding to IgG1. Mutations made to this binding site provide important insight on how SSL10 contributes to bacterial survival, in particular the impact on IgG1-mediated phagocytosis and complement activation.

P4.04.24
State of cellular immunity in children with Recurrent Respiratory Tract Infections before and after vaccination Pneumo23 and Influvac

R. R. Isayeva;
Azerbaijan Medical University, Baku, Azerbaijan.

One of the actual tasks of Pediatrics is still the problem of Recurrent Respiratory Tract Infections in children (RRTİ).Common indicators of impaired immune response in RRTİ in children, is an imbalance of T- and B-cells. The purpose of the study is to investigate the state of cellular immunity CD3; CD4; CD8; CD19; CD16/56; IRI and cytokine system sickly children and selection of appropriate therapies, correcting violations.
We observed 56 children in RRTİ group without clinical manifestations of disease at the time of the study and during the previous month.
Discussion: Results of the study of immune status showed that in the majority of cases (91.7%) in children with RRTI were identified various immunological disorders, worn both alone and combined character. The absolute value of the level of CD4+ in children with RRTI was reduced by approximately 49.6%, compared with healthy children. The absolute value of the level of CD8+ in the examined children was reduced more than 2-fold, the absolute value of CD19+ study group was reduced two times in comparison with the control group. Lymphopenia and reduction of all types of lymphocytes were found in the analysis of cellular immunity in children with RRTI, neutrophils, both in quantitative and functional composition, is not much different from the parameters of healthy children. The immune status of sickly children, characterized by suppression of specific cellular immunity parameters in combination with the increased expression of activation markers and concentration of CD16/56+, which, should be regarded as triggering compensatory mechanisms regulating immunological interactions.

P4.04.25
Long-term protective immunity of multi-antigen outer-membrane protein vaccine against Orientia tsutsugamushi

W. Jeung[1], *S. Park*[1,2,3], *H. Chu*[4], *I. Cheon*[1,5], *B. Shim*[5], *S. Han*[6], *C. Yun*[1,2,3];
[1]*Department of Agricultural Biotechnology and Research Institute for Agriculture and Life Sciences, Seoul National University, Seoul, Republic of Korea,* [2]*World Class University Biomodulation Program, Seoul National University, Seoul, Republic of Korea,* [3]*Center for Food and Bioconvergence, Seoul National University, Seoul, Republic of Korea,* [4]*Korea National Institute of Health, Osong, Republic of Korea,* [5]*Laboratory Science Division, International Vaccine Institute, Seoul, Republic of Korea,* [6]*Department of Oral Microbiology & Immunology, Dental Research Institute, and BK21 Program, School of Dentistry, Seoul National University, Seoul, Republic of Korea.*

Scrub typhus is an acute, febrile, mite-borne infection in humans caused by Orientia tsutsugamushi. Since no vaccine is available at present, development of the vaccine is an urgent issue. In the current study, we identified the effectiveness of the combination of three outer-membrane proteins (22, 47 and 56 kDa) of Orientia tsutsugamushi on enhancing the protective immunity by using single, double or triple antigenic proteins. BALB/c mice were immunized intranasally three times with two-week interval. Humoral and cellular responses were performed one week after the last immunization. The production of TNF-α, IFN-γ, IL-17, and IL-2 in CD4+ T cells, and antigen-specific antibody increased in all immunized groups. Challenge was performed with lethal dose of Orientia tsutsugamushi via intraperitoneal route, four (early) and twenty four (long-term) weeks after the last immunization. In early challenge experiment, all immunized mice survived but the control and adjuvant only group all died by day 7. In the long-term challenge experiment, PBS and adjuvant-treated groups had the survival rate of 0% and 25%, respectively, while 100% survived in all three groups treated with single antigenic protein 22, 47, or 56kDa. Double antigen-immunization groups using the combination of 22/47 kDa, 22/56 kDa, and 47/56 kDa, and the triple antigen-immunization group, 22/47/56 kDa had the survival rate of 87.5%, 100%, 62.5%, and 100%, respectively. In summary, the current study shows that the vaccine strategy using the combination of double and triple antigen enhanced

the survival rate, vaccine efficacy, and also highly-effective long-term protective immunity against Orientia tsutsugamushi infection.

P4.04.26
Evaluation of antimicrobial effects of Silver, Zinc and Copper nanoparticles on different Bacillus species spores and vegetative cells

***R. Khosravi Eghbal**, A. Khanafari, A. Akhavan Sepahy*;*
Department of Microbiological Sciences,Islamic Azad University, North Branch of Tehran, Tehran, Iran.

Antimicrobial features of three metal nanoparticles were investigated on four species of Bacillus inclusive: B.cereus PTCC(1247),B.subtilis PTCC (6633), B.polymyxa PTCC(1020), B.stearothermophilus ATCC(7953). The average size of these nanoparticles was between 10-40 nm and in general they had a circular shape. The germicidal effect of nanoparticles were accomplished anchored in the test disc diffusion and review of sensitive region and the minimum inhibitory concentrations (MIC) and minimum bactericidal concentrations (MBC) for vegetative cells then observed that Bacillus species spores and vegetative cells were more sensitive than silver nanoparticles. As ascertained frae scanning electron microscopy. The study also revealed that the B.subtilis greatest sensitivity to these nanoparticles are measured up to other Bacillus. So that the MIC of B.subtilis on the silver, zinc and copper nanoparticles was measured 5 ppm, 750 ppm and 40 ppm, respectively. These bacteria spores are inhibited at 350 µg/ml concentration vicinity of silver nanoparticles and the time of zero. However, the nanozinc and nanocopper had no effect on Bacillus spores and all of them have been able to grow at the highest concentration of nanozinc.

P4.04.27
Differential immune cell responses of infected lung tissues in mice strains with different susceptibility to *Legionella pneumophila*

***S. Kim**[1], Y. Yoon[2], J. Sohn[2], M. Kim[2,3];*
[1]Korea University College of Medicine, Seoul, Republic of Korea, [2]Division of Infectious Diseases, Korea University Medical Center, Seoul, Republic of Korea, [3]Institute of Emerging Infectious Diseases, Korea University, Seoul, Republic of Korea.

Legionella pneumophila is an intracellular bacterium of host phagocytic cells that causes a severe pneumonia. *Naip5* gene was previously reported to be associated with susceptibility to *L. pneumophila* infection. To investigate difference in innate immune responses between the susceptible A/J and the resistant BALB/c mice, dynamics of immune cells and gene expression patterns of lung tissues were examined at 4, 8, 24, 48hr postinfection (pi) to *L. pneumophila* by flow cytometry and microarrays, respectively.
On FACS analyses, A/J mice showed a marked influx in neutrophils and a remarkable decrease in alveolar macrophages ($CD11b^-$ $CD11c^+$) at 4hpi, followed by influx of dendritic cells and $CD11b^+CD11c^-$ macrophages at 24 hpi. BALB/c mice showed similar, but lesser degree of cellular influx. In apoptosis assays using annexin V, A/J mice showed significantly increase of apoptotic alveolar macrophages (49% vs 13.5%) and dendritic cells (50.2% vs 25.4%) at 4hpi compared to BALB/c mice. The transcriptional profiling of the apoptosis-related genes showed the genes encoding Tnfsf13b, Casp1 and Bak1 were significantly induced only in A/J mice, whereas the genes encoding Tnfrsf12a, Tnf, Birc5 and Casp4 were more up-regulated in A/J than BALB/c mice. Particularly, the induction of genes involved in macrophage apoptosis namely CCL5 and CCR5 was significantly expressed only in A/J mice.
In conclusions, this study indicates that apoptosis of alveolar macrophages and dendritic cells, as well as influx of immune cells differ between A/J and BALB/c mice, as an important host defense mechanism at the early stage of *Legionella* infection.

P4.04.28
Poly(I:C) sensitization induces a cytokine imprinting mechanism in dendritic cells and aggravates septic peritonitis

***M. Kocur**, J. Bauer, S. Kropp, S. Scheu;*
Institute of Medical Microbiology and Hospital Hygiene, Duesseldorf, Germany.

Viral infections inducing Type I IFN were shown to be detrimental, while IL-12p40 mediated protective effects in mouse models of polymicrobial peritonitis. However, the specific contribution of IFNβ which is the first Type I IFN expressed after pathogen recognition remains unknown. Therefore we analyzed the influence of a virus infection mimicked by poly(I:C) stimulation on the disease outcome in WT, IFNβ-/- and IFNAR-/- mice.
IFNAR-/- mice showed significantly increased resistance compared to WT mice while IFNβ-/- mice exhibited intermediate resistance in the colon ascendens stent peritonitis (CASP) model. Poly(I:C) prestimulation did not change the outcome in IFNAR-/- or IFNβ-/- mice but sensitized WT mice to CASP which was associated with a dysregulated cytokine profile and reduced peritoneal granulocyte numbers. Using the IFNβ/YFPxIL-12p40/GFP double reporter mouse model we showed that conventional DCs are responsible for the production of IFNβ and IL-12p40 after CASP surgery with or without poly(I:C) pretreatment.
We recapitulated the viral followed by bacterial challenge in vitro and sorted poly(I:C) stimulated GM-CSF BM-DCs according to their reporter allele expression and restimulated with different TLR ligands. Poly(I:C) restimulated cells exhibited a fixed phenotype only expressing the cytokine they were sorted for initially, while CpG and LPS restimulated cells showed more plasticity. This fixed cytokine expression phenotype was confirmed in vivo by transferring sorted poly(I:C) stimulated cells into mice followed by CASP surgery. This study reveals a functional imprinting in DC cytokine expression after primary poly(I:C) stimulation interfering with the generation of optimally adapted immune responses to secondary bacterial challenge.

P4.04.29
Cathepsin X inhibitor decrease the production of cytokines and monocyte microparticles on THP-1 macrophage-like cells stimulated with *Helicobacter pylori*

***A. N. Kopitar**[1], S. Jeverica[1], J. Kos[2], A. Ihan[1];*
[1]University of Ljubljana, Medical Faculty Ljubljana, Institute of Microbiology and Immunology, Ljubljana, Slovenia, [2]University of Ljubljana, Faculty of Pharmacy, Department of Pharmaceutical Biology, Ljubljana, Slovenia.

The infection with *H. pylori* induces higher levels of cathepsin X in macrophages of the gastric mucosa. Active cathepsin X has been shown to regulate β-2 integrin-dependent adhesion and phagocytosis, which is crucial for effective antigen presentation and initiation of T cell dependent immune response. Microparticles have been considered as cellular debris for a long time. However recent findings associate them with cellular stimulation, activation, and apoptosis. Our hypothesis suggests that cathepsin X inhibitor could suppress microvesiculation and activation of macrophages. This process could result in the insufficient immune response to the infection with *H. pylori*. Macrophages like cells were differentiated from THP-1 cell line treated with PHA for 24h. The cells were than stimulated with *H. pylori* strains***, isolated from 20*** dyspeptic patients. The *in vitro* secretion of IL-1b, IL-6, IL-8, IL-10, IL-12, TNF and concentration of microparticles were measured with flow cytometry. Higher concentration of microparticles were observed in the cases of THP-1 macrophage like cells, which were treated with *H. pylori* alone than in the cases of the untreated cells ($p<0.01$). Cathepsin X inhibitor decreased the amount of microparticles compared to THP-1 cells stimulated with *H. pylori* alone ($p<0.05$). The *H. pylori* stimulation alone as well as the stimulation in combination of cathepsin X inhibitor increased the production of IL-8, IL-6, IL-10, TNF, IL-12 compared to the negative control. However, we observed lower production of IL-1β and IL-6 by the THP-1 cells stimulated with *H. pylori* in combination with cathepsin X inhibitor ($p<0.01$).

P4.04.30
Mechanisms underlying bacteria-infected macrophage cell death-mediated IFN-γ production by innate lymphocytes

***K. Kubota**;*
Kitasato University School of Medicine, Sagamihara, Japan.

We have previously reported that the B6HO3 T-cell hybrdioma with a CD244+CD11c+ phenotype and subsets of innate lymphocytes respond to dying macrophages infected with bacteria by producing IFN-γ in both IL-12p70-dependent and independent manners and that approximately 50% of the IFN-γ-producing innate lymphocyte expressed the adhesion molecule CD11c (J. Immunol. 176:7576,2006; Scan. J. Immunol. 71:199,2010; Front. Immunol. 2:26,2011). We refer to this phenomenon as bacteria-infected macrophage cell death (BIMD)-mediated IFN-γ production, and here we explore the mechanisms underlying this phenomenon. We found that cellular conjugate formation between B6HO3 cells and bacterial infected macrophages allows the low amounts of IL-18 secreted by the infected macrophages to exert its influence on the interface of the conjugates, thereby inducing BIMD-mediated IFN-γ production by B6HO3 cells. Similarly, the innate lymphocytes that were able to adhere to macrophages and hence included abundant CD11c-positive NK, αβ T, and γδ T cells, had greater capability to exhibit BIMD-mediated IFN-γ production than non-adherent lymphocytes. Innate lymphocytes from C57BL/6 mice, which are prone to be biased towards Th1 responses, exhibited stronger BIMD-mediated IFN-γ production than those from BALB/c and DBA mice. Macrophages that were activated by IFN-γ beforehand and then infected with bacteria produced soluble factors that could inhibit BIMD-mediated IFN-γ production. Taken together, we propose that specific subsets of innate lymphocytes may form cell conjugates with resident tissue macrophages to monitor macrophage cell 'danger' caused by bacteria, thus protecting an individual from bacterial infection through the macrophage activation by BIMD-mediated IFN-γ production at early stages of infection.

P4.04.31
Mechanisms of NK cell-macrophage Bacillus anthracis crosstalk: a balance between stimulation by spores and differential disruption by toxins

***M. Le Gars**[1], M. Klezovich-Bénard[1], J. Corre[1], H. Jusforgues-Salkani[1], D. Fiole[2], N. Burjek[1], J. Tournier[2], P. Goossens[1];*
[1]Institut Pasteur, Paris, France, [2]Institut de Recherche Biomédicale des Armées, La Tronche, France.

Bacillus anthracis, the etiological agent of anthrax, is a spore-forming bacterium that kills through a combination of acute bacterial infection and toxemia.
We evaluated how B. anthracis spores are recognized by the innate immune system and we determine strategies that are employed by bacteria to subvert and evade this response.
We demonstrated that IFN-γ production by NK cells in response to B. anthracis spores is dependent on macrophages, contact-dependent and IL-12, IL-18 and IL-15-dependent, where IL-12 regulates both NK cells and macrophages activation.
B. anthracis toxins similarly disrupted IFN-γ production by spore-stimulated splenocytes, but the mechanism of inhibition was different for each toxin. LT acted at the macrophage and NK cell levels, whereas ET acted at the macrophage level. Both ET and LT directly altered the innate ability of NK cells to exert their natural cytotoxicity function in vitro and in vivo. Thus, ET subverting action leads to dissociation in NK cell function.
Our in vivo data indicate that non-toxigenic capsulated B. anthracis, administrated subcutaneously, induced recruitment of NK cells and macrophages into the lymph node draining site of infection, where interaction between these cells occurs, probably allowing performing their surveillance function in containing infection at an early stage. Additionally, capsulated strain of B. anthracis producing only one toxin, ET or LT, impaired the NK cell and macrophage recruitment into the lymph node draining site of infection.
Our findings are important for understanding the initial host control mechanisms of anthrax and the bacterial evasion strategies to overcome innate host defences.

P4.04.32
Autophagy and cell death pathways in Shigella-infected MoDCs: a difficult choice

***L. Lembo Fazio**[1], A. Hermansson[1], V. Ciancarella[1], E. Mileti[2], G. Fimia[3], M. Rescigno[2], M. Bernardini[1];*
[1]Sapienza-University of Rome, Rome, Italy, [2]IFOM-IEO Milan, Milan, Italy, [3]National Institute for Infectious Diseases IRCCS 'L. Spallanzani', Rome, Rome, Italy.

The immune system responds to infection in a variety of ways, including activation of pathways that promote survival to eliciting programmed cell death. The initial response to infection is geared toward eradicating or containing the infection; this can be achieved by activation of inflammatory pathway, recruitment of immune cells to the site of infection, production of antimicrobial peptides and cytokines. If the condition is unresolved, cell death signaling pathways are engaged to eliminate the infected cells from the organism. These mechanisms might not be mutually exclusive. This complexity of regulatory mechanisms is observed in the invasive process of *Shigella* spp., an enteric pathogen that causes bacillary dysentery in humans. In epithelial cells, *Shigella* triggers NF-κB via peptidoglycan sensing by the PRR Nod1, thereby inducing the secretion of CXCL8. This pathogen is equally able to induce various types of cell death in different cell populations. Apoptosis, necrosis and pyroptosis constitute the principal mechanisms by which programmed host cell death occurs.
Here, we have investigated on the molecular mechanisms and cell effectors governing the balance between survival and cell death in monocyte-derived dendritic cells (MoDCs) infected with *Shigella.* Our results show that *Shigella* induces a rapid cell death of MoDCs, with hallmarks of both necrosis and apoptosis. We also demonstrate that autophagic pathway is engaged by infected-MoDCs, *via* LC3 lipidation. By chemically blocking the autophagic process, the rate of cell death of *Shigella*-infected MoDCs increased. Put together, our data highlight that MoDCs respond to *Shigella* infection by modulating cell death and autophagy.

P4.04.33
Group B Streptococcus and Streptococcus suis differently modulate bacterial interactions with dendritic cells and natural killer cells.

***P. Lemire**, D. Roy, M. Segura;*
University of Montreal, St-Hyacinthe, QC, Canada.

Presently, the mechanisms underlying innate and adaptive immune responses to encapsulated bacteria have not been fully elucidated. Group B Streptococcus (GBS) and Streptococcus suis are well encapsulated streptococci that can cause meningitis and septicemia. Their capsular polysaccharide (CPS) is considered the major virulence factor and previous data suggest that they selectively modulate the functions of dendritic cells (DCs). However, neither the role of Natural Killer cells (NKs) nor the effects of DCs on NK activation is clearly defined in the context of infection by streptococcal species. Here, we infected single or co-cultures of mouse bone marrow-derived DCs and splenic NKs with GBS or S. suis. The role of CPS was evaluated by using non-encapsulated mutants. We observed that NKs alone failed to directly respond to bacterial infection and that DCs are required for NK activation. Under co-culture conditions, copious amounts of IFN-γ are produced by NKs during GBS infection. The production of IL-12p70, CXCL9 and CXCL10 are significantly increased in presence of NKs compared to DCs alone. Interestingly, S. suis-infected co-cultures produced higher levels of IFN-γ, with no change in IL-12p70 production and a decrease in CXC10 release. Transwell insert experiments showed that cytokine production by DCs and NK cells depends on both direct contact and soluble factors. The CPS does not seem to play a major role in these interactions. Together, these results demonstrate that GBS and S. suis modulate DC-NK crosstalk functions differently which may have important consequences in the development of adaptive immune response against these pathogens.

P4.04.34
Immunoregulative mechanism of the Leydig cell in the infection by expression of IL-1, IL-6, TGF-β, Fas and FasL mRNA

***W. Li**, Y. XI, G. Chen;*
Shanghai Jiaotong University School of Medicine, Shanghai, China.

To investigate the immune regulative mechanism of Leydig cells in the local infection of rat's testis. Methods: Ureaplasma Urealyticum(UU) was injected into rat's bladder, which mimicked an ascending infectious way, and at the same time culture medium was injected into rat's bladder as control. The rats were sacrificed at at the first, second and third week after injection respectively. Then pathological changes of in testis were analyzed by histological examination. At the same time Leydig cells were separated from rat's testis. The comparison of levels of IL-1, IL-6, TGF-**β**, Fas and FasL mRNA expression among the three groups was made by RT-PCR. Results: As compared with control group, the levels of IL-1, IL-6, TGF-**β** mRNA expression for UU supernatant and living UU groups increased; and levels of Fas and FasL mRNA expression decreased and increased respectively after UU infection. Conclusion: During anti-infective immunity, rat's Leydig cells may regulate immune function of the testis by changing the levels of IL-1, IL-6, TGF-**β**, Fas and FasL mRNA expression and may contribute to maintain immune privilege of the testis.

P4.04.35
Differential inflammasome activation in human macrophages between Salmonella Typhimurium and Salmonella Typhi

***H. Lin**[1,2], C. Chiu[1,2];*
[1]Molecular Infectious Diseases Research Center, Chang Gung Memorial Hospital, Taiwan, Taoyuan,, Taiwan, [2]Graduate Institute of Biomedical Sciences, Chang Gung University College of Medicine, Taoyuan, Taiwan.

Salmonella Typhi caused Typhoid fever, a systemic inflammatory response syndrome (SIRS) in humans but S. Typhimurium causes only gastroenteritis. When infecting humans, S. Typhi uses Vi capsule to evade host immune system and survive in macrophages to circulate in bloodstream. After proliferating in bone marrow, liver, and spleen, S. Typhi reenters into bloodstream, causing SIRS, and intestine, causing hemorrhage and perforation. S. Macrophages are the important reservoir for S. Typhi during the infection. The interaction of macrophages with S. Typhi and S. Typhmurium was studied. S. Typhi, rather than S. Typhimurium, induced less inflammation when infecting epithelial cells by virtue of Vi. But when infecting THP-1 macrophages in MOI=100, we found that within an hour S. Typhi with or without Vi caused more cell death than S. Typhimurium. It was confirned to be caspase-1-mediated pyroptosis. The IL-1β secretion induced by S. Typhi was also significantly higher than S. Typhimurium. We constructed a mutant library of S. Typhi to search early cell death related genes. We found that SPI-1 mutants induced less cell death as well as caspase-1 activation than the parent strain. Because S. Typhi existed in liver before reentering into intestine, we also determined the growth of the two serotypes in LB with or without bile, and found that the growth of S. Typhi was more rapid than S. Typhimurium in LB with bile. We concluded that S. Typhi is more adapted to bile environment than S. Tyhpimurium to induce caspase-1-mediated pyroptosis in macrophages, presumably by hyper-expressing SPI-1 genes.

P4.04.36
Oral infection with *Brucella abortus* 2308 induces systemic activation of B cells, but a downregulation of CD86 in intestine B cells

*K. E. Pineda-Benito, O. Rodríguez-Cortés, A. Gutiérrez-Hoya, D. Sandoval-Borrego, **R. López-Santiago**;*
Escuela Nacional de Ciencias Biologicas-IPN, Mexico DF, Mexico.

B-cell activation induces the transcription of MHC II genes, the expression of receptors for cytokines, and the expression of costimulatory molecules such as CD40, CD69, CD80 and CD86. Since the 1970's it was reported the interaction of B cells with *Brucella* spp., and it was used for diagnosis of some B-cell malignancies. Recently, it was reported the probable regulation of the immunity anti *Brucella* through the production of TGF- and IL-10 by splenic B cells. The objective of the work here reported is to analyze the activation of B cells in the intestine of mice orally infected with *B. abortus*, since this is the natural route of infection in humans. BALB/c mice were orally infected with *B. abortus* 2308-GFP. At different time points, a group of mice were euthanized and the cells from Peyer's patches and mesenteric lymph node were stained with antibodies to costimulatory molecules coupled to fluorochromes. Mice inoculated with PBS were included as controls. Cells were analyzed by flow cytometry. CD40 and CD80 were expressed at one hour p.i. and peaked at 24 h p.i. At this time 24% of B cells were infected con *B. abortus*. The percentage of responder cells was higher than the apparently infected ones; this result suggests that the B cells are getting infected with a very low number of bacteria, however enough to activate them or some B cells may be activated by neighboring infected cells, such as dendritic cells.

The mechanism behind insufficient Streptococcus pyogenes clearance by autophagy in endothelial cells compared to epithelial cells

***S. Lu**[1,2], Y. Lin[3], T. Yoshimori[4,5];*
[1]Graduate school of Frontier Biosciences, NCKU, Tainan, Taiwan; Osaka University, Osaka, Japan, [2]Institute of Basic Medical Sciences, National Cheng Kung University, Tainan, Taiwan, [3]Department of Microbiology and Immunology, National Cheng Kung University, Tainan, Taiwan, [4]Graduate school of Frontier Biosciences, Osaka University, Osaka, Japan, [5]Department of Genetics, Graduate School of Medicine, Osaka University, Osaka, Japan.

Streptococcus pyogenes (Group A *Streptococcus*, GAS) is an important human pathogen and its interaction with blood vessels is critically important with respect to serious diseases such as bacteremia or multi-organ failure. Although GAS internalizes into non-phagocytic cells to escape immune surveillance and get nutrients, our previous reports show that invading GAS induces autophagy and is efficiently killed within lysosome-fused autophagosomes in epithelial cells. In the present study, we found that GAS can survive and multiply in endothelial cells, including human microvascular endothelial cells (HMEC-1) and human umbilical vein endothelial cells (HUVEC). Since we found that canonical starvation-induced autophagy is normal in endothelial cells, we examined selective autophagy and the formation of autophagosomes specific to GAS. As results, we found that the recruitments of ubiquitin and several core Atg proteins essential to autophagosome formation against GAS are significantly reduced in these cells compared with epithelial cells. Furthermore, we observed reduced autophagosome formation surrounding GAS in endothelial cells. In contrast, while in epithelial cells autophagosomes could directly surround GAS-containing damaged endosomes prior to GAS escape into the cytoplasm. Our data suggest that the high efficient clearance of GAS is achieved by selective-autophagy targeting to GAS-containing damaged endosomes and cytoplasmic GAS in epithelial cells, but that the deficiency in the selective targeting machinery of autophagosome formation in endothelial cells results in GAS multiplication and persistence within this cell type.

P4.04.38
Detailed antibody-profile of Helicobacter pylori infected individuals revealed by peptide array screening

***S. B. Lundin**[1], K. Thorell[1], I. Nookaew[2], T. Perkins[3];*
[1]Inst. of Biomedicine, Gothenburg, Sweden, [2]Chalmers University of Technology, Gothenburg, Sweden, [3]University of Western Australia, Perth, Australia.

Helicobacter pylori infection is a cause of gastric ulcer and gastric cancer. A number of virulence factors are associated with risk of gastric cancer, including cagA, vacA and babA.
We used a peptide array screen to investigate the detailed pattern of antibody-responses to H. pylori proteins. Antigens were selected

based on a surface proteomic screen, in addition to antigens previously shown to be relevant based on different proteomic methods. Thus, 330 antigens were selected, and arrays of 10-mer peptides with a sequential 5 amino acid overlap covering this entire proteome were printed using the PepPERPrint technology. The arrays were incubated with sera from uninfected individuals as well as with sera from patients infected with H. pylori. The detailed pattern of antibody responses were detected using Cy3-conjugated anti-Ig antibodies.
The results showed that out of the 330 antigens tested, there were peptide domains with a strong differential antibody response in the H. pylori infected subjects in 125 antigens. Thus, in these 125 antigens there were a stretch of at least 3 consecutive peptides with a response higher in Hp+ vs Hp- individuals (f-test, cut-off $p < 0.00001$). The antigen with the strongest differential response in Hp+ indiviudals was cagA.
In conclusion, a screen using peptide arrays with consecutive overlapping peptides allowed detailed identification of the antibody response to H. pylori antigens. This analysis confirmed that cagA is a very strong immunogen, and showed that there is a strong antibody response to a large variety of different surface-associated H. pylori antigens.

P4.04.39
Mechanism of interleukin (IL)-17A-mediated enhancement of protective immunity against *Listeria monocytogenes* infection

***G. Matsuzaki**, Y. Okita, T. Shiono, S. Hamada, M. Umemura;*
TBRC, Univ. Ryukyus, Nishihara, Okinawa, Japan.

IL-17A participates in protective immunity against *Listeria monocytogenes* (Lm) infection and the major IL-17A-producing cells were T cell receptor (TCR) γδ T cells rather than Lm-specific Th17 cells. Mechanism of the IL-17A-dependent protection against Lm infection was addressed in the present report. On day 9 of Lm infection, IL-17A-deficient (Il17a-/-) mice showed impaired protection although Lm-specific protective Th1 and Tc1 cells were normally induced. Interestingly, naïve Il17a-/- mice adoptively transfer with primed CD4+ T cells from Lm-infected WT mice showed higher bacterial burden in the spleen and liver when compared to naive WT mice transfer with the primed CD4+ cells. Therefore, it is possible that IL-17A produced by TCRγδ T cells co-operate with antigen-specific Th1 cells to mount optimum protective immunity. However, IL-17A did not show any cooperative effect with IFN-γ when Lm-infected macrophages were cultured with the cytokines. In contrast, IL-17A induced expression of IL-22 in the infected liver, and IL-17A suppressed bacterial burden of Lm-infected hepatocyte line in combination with IL-22. The results suggest that IL-17A enhances protective immunity through induction of IL-22 and enhancement of protective innate response of non-hematopoietic cells.

P4.04.40
PKF, a secreted serine protease, allows Acinetobacter baumannii to evade innate immune responses

***L. S. McDaniel**, L. B. King;*
University of Mississippi Medical Center, Jackson, MS, United States.

Acinetobacter baumannii has emerged as a hospital adapted multidrug-resistant pathogen. We previously have identified a serine Protease required for resistance to complement Killing and suppression of biofilm Formation (PKF). We wanted to determine if PKF affects the survival of *A. baumannii* within the host and if expression of PKF is regulated. We used a mouse model of lung infection to examine the survival of a PKF mutant during infection. A quantitative biofilm assay was used to examine biofilm formation at different temperatures. Real-time PCR was used to assess PKF expression at different temperatures. Additionally, recombinant exogenous PKF was used to examine biofilm formation. We recovered significantly higher numbers of an *A. baumannii* PKF mutant at 24 hours from the lungs of infected mice as compared to the wild-type. At 37^0C there was a six-fold increase in the level of *pkf* transcription compared to bacteria grown at 26^0C. Biofilm formation was significantly increased at growth temperatures ranging from 25^0C to 33^0C as compared to 37^0C. Recombinant PKF failed to disperse biofilm once it had formed, but significantly suppressed biofilm formation. Also, recombinant PKF degraded complement components resulting in increased survival of *A. baumannii* in human serum. Bacteria can sense their environment and respond by regulating gene expression. As a result, *A. baumannii* can form biofilm at room temperature which may aid in the environmental persistence of the bacterium. Once in the host, increased expression of PKF appears to protect *A. baumannii* from the innate immune response.

P4.04.41
Effect of the stimulation with different serotypes Aggregatibacter actinomycetemcomitans in the activity of the lymphocytes TCD4+

***S. Melgar-Rodríguez**, J. Díaz-Zúñiga, C. Álvarez, R. Vernal;*
Universidad de Chile, Santiago, Chile.

Objective: In *Aggregatibacter actinomycetemcomitans*, six serotypes have been described based on O-polysaccharide-LPS immunogenicity: a-f. These different serotypes induce distinct dendritic cell and T-cell responses. In particular, b serotype of *A. actinomycetemcomitans* induce a Th1- and Th17-type phenotype and immune response. The aim of this study was to determine the frequency of cellular proliferation either periodontal disease or health.
Methods: $CD4^+$T lymphocytes were isolated from chronic periodontitis patients and healthy subjects. T cells were activated with autologous dendritic cells primed with different *A. actinomycetemcomitans* serotypes at different multiplicity of infection. To determine the frequency of $CD4^+$T lymphocytes activated in response to the different bacterial serotypes, limiting dilution analysis was performed and cell proliferation was quantified. T lymphocytes exposed to non-induced dendritic cells were used as control. Statistical analyzed was performed by assuming a Poisson single-hit model.
Results: Lower frequencies of T lymphocytes able to respond to a and c serotypes were detected on periodontitis patients as compared with healthy individuals. The frequencies of T lymphocytes able to respond to b serotypes were higher on periodontitis patients than controls.
Conclusion: Serotype b of *A. actinomycetemcomitans* is associated with the host immune response induced during chronic periodontitis.

P4.04.42
A neutrophil elastase inhibitor improves LPS-induced acute lung injury in burn-injured mice

***H. Miyazaki**[1], S. Ono[1], M. Kinoshita[2], R. Takahata[3], A. Kimura[3], D. Saitoh[1];*
[1]Division of Traumatology, National Defense Medical College Research Institute, Tokorozawa, Japan, [2]Department of Immunology and Microbiology, National Defense Medical College, Tokorozawa, Japan, [3]Department of Surgery, National Defense Medical College, Tokorozawa, Japan.

Neutrophil elastase derived from activated neutrophils is well known to cause acute lung injury (ALI), particularly in septic patients. Complications of septic ALI severely worsen the prognoses of burn-injured patients; therefore, treatment is crucial in order to improve the typical poor outcomes. We herein investigated the efficacy of a neutrophil elastase inhibitor in treating pulmonary dysfunction following LPS-induced ALI in burn-injured mice. The mice received 20% full-thickness burn injuries and were challenged three days later with LPS. The mice were treated with sivelestat, a neutrophil elastase inhibitor, one hour before and six hours after the LPS challenge. The control mice were treated with saline instead of sivelestat. Although the burn injuries severely decreased survival following the LPS challenge, treatment with sivelestat remarkably increased survival. The burn injuries markedly enhanced pulmonary microvascular permeability, the MIP-2 levels in the pulmonary tissue and plasma and neutrophil pulmonary accumulation following the LPS challenge, resulting in deterioration of ALI. Notably, treatment with sivelestat suppressed the LPS-induced increases in vascular permeability, the MIP-2 levels and neutrophil accumulation in the lungs, thereby potently improving LPS-induced ALI following burn injury. Burn injuries can induce LPS hypersensitivity via augmentation of MIP-2 production, neutrophil accumulation in the lungs and pulmonary

microvascular permeability, thereby leading to the development of ALI and worsening the outcome. Sivelestat is effective for improving pulmonary dysfunction and survival following LPS challenges in burn-injured mice, suggesting its role as an effective therapeutic tool against the development of ALI following burn injury.

P4.04.43
Citrullination and proteolytic processing of chemokines by Porphyromonas gingivalis

E. A. V. Moelants[1], *G. Loozen*[2], *A. Mortier*[1], *J. Van Damme*[1], *W. Teughels*[2], *P. Proost*[1];
[1]*Rega Institute, Leuven, Belgium,* [2]*Department of Periodontology, Leuven, Belgium.*

Chemokine activity is regulated at multiple levels including posttranslational modification (PTM), including proteolytic processing and citrullination. Oral infection with the bacterium *Porphyromonas gingivalis* can lead to a group of inflammatory disorders of the periodontal pocket, called periodontitis, characterized by periodontal tissue destruction, loss of alveolar bone and eventually tooth loss. *P. gingivalis* peptidylarginine deiminase (PPAD), an enzyme responsible for modification of arginine to citrulline, and bacterial proteases belonging to the gingipains are considered to be potential virulence factors. Since chemokine processing may be particularly important in microbial defense mechanisms, we investigated whether PTM of chemokines by these enzymes represents a way by which *P. gingivalis* regulates the host's inflammatory response. Therefore, different *P. gingivalis* strains were incubated with the chemokines CXCL8 or CXCL10 and PTM of these chemokines was investigated by ELISA and Edman degradation. For multiple strains, CXCL8 could be recovered after incubation, however, no significant citrullination of CXCL8 by PPAD could be detected for any of the tested strains. Some strains, i.e. Pg1, Pg2 and K14, were more efficient in degrading CXCL8. In contrast to the difference in cleavage efficiency measured for CXCL8 incubated with *P. gingivalis* strains, no difference in processing of CXCL8 for the strains supernatants could be seen. Sequencing of the CXCL8 incubated with supernatant or bacteria showed that CXCL8 is processed into its more potent 5-77 and 9-77 forms. In conclusion, this study demonstrates PTM of CXCL8 by gingipains of *P. gingivalis* and strains differences particularly affect the activity of the bacterial membrane-associated proteases.

P4.04.44
Intracellular crosstalk in Wnt5a expression by LPS

H. Nanbara[1], *Y. Yoshida*[2], *N. Wara-aswapati*[3], *T. Nagasawa*[4], *H. Kobayashi*[1], *Y. Izumi*[1,5];
[1]*Department of Periodontology, Graduate School, Tokyo Medical and Dental University, Tokyo, Japan,* [2]*Department of Immunology, School of Medicine, University of Occupational and Environmental Health, Fukuoka, Japan,* [3]*Department of Periodontology, Faculty of Dentistry, Khon Kaen University, Khon Kaen, Thailand,* [4]*Department of Periodontology and Endodontology, Health Science University of Hokkaido, Hokkaido, Japan,* [5]*Global Center of Excellence Program, International Research Center for Molecular Science in Tooth and Bone Diseases, Tokyo Medical and Dental University, Tokyo, Japan.*

Objectives: Periodontal diseases are infections that are caused by specific gram negative micro-organisms that eventually lead to loss of supporting structures of teeth, including resorption of the alveolar bone. Wnt signaling molecules play important roles in bone biology, apoptosis and chronic inflammation. Recent studies have suggested an association of these molecules with various disorders including cardiovascular diseases, rheumatoid arthritis and osteoarthritis. We previously reported that Wnt5a mRNA expression was up-regulated in chronic periodontitis tissue. In addition, we demonstrated that the expression of Wnt5a mRNA induced by LPS of P.gingivalis, an important member of the periodontopathic bacteria, was higher than the expression induced by E.coli LPS. In this study, we investigated the intracellular cross talk in Wnt5a mRNA expression by LPS from E.coli or P.gingivalis .
Methods: Human monocytic cell line THP-1 cells were stimulated with LPS from E.coli (TLR4 ligand) or P.gingivalis (TLR2 ligand). To identify the involvement of NF-κB or PI3K/Akt/mTOR signaling pathway in Wnt5a mRNA expression following stimulation with LPS, inhibition assay, luciferase reporter assay and western blot were performed.
Results and Conclusion: The expression of Wnt5a mRNA induced by P.gingivalis LPS was higher than the expression induced by E.coli LPS. The activated proteins of the NF-κB signaling are different between the stimulation by E.coli LPS and P.gingivalis LPS. The inhibition assay and luciferase assay showed crosstalk of NF-κB and PI3K/Akt/mTOR. Our study suggests that induction of Wnt5a by P gingivalis is regulated by crosstalk signaling between NF-κB and PI3K/Akt/mTOR.

P4.04.45
The transformation of subpopulations CD64+CD16-CD32+CD11b+, CD64+CD16+CD32+CD11b+, CD64-CD16+ CD32+CD11b+ of monocytes in premature newborn with congenital pneumonia

I. V. Nesterova[1], *G. A. Chudilova*[2], *L. V. Lomtatidze*[2], *O. Sapun*[2], *R. I. Sepiashvili*[3];
[1]*Russian University of Friendship of People, Kuban State Medical University, Moscow, Krasnodar, Russian Federation,* [2]*Kuban State Medical University, Krasnodar, Russian Federation,* [3]*Russian University of Friendship of People, Moscow, Russian Federation.*

Monocytes (MON) of different subpopulations, expressing or not expressing CD64 and/or CD16, differ in their phagocytic activity and the ability to generate reactive oxygen species ROS (E.Grade-Griebenow et al.,2000). We had studied 3 subpopulations of Mon in very preterm infants with congenital pneumonia associated with respiratory distress syndrome(RDS). Clinical-immunological study was carried out on 1-2 days of life of those patients. One-moment expression of surface molecules of membrane MON, - CD64, CD32, CD16, CD11b,- by flow cytometry, the level of the density of molecules expression by measure of the MFI had detected. We observed 11 deeply premature infants , control group-10 healthy full-term newborn. Patients were randomized into 2 groups: group 1-with severe congenital pneumonia, group 2- with very severe congenital pneumonia. We had shown for the first time the presence of subpopulations CD64+CD16-CD32+CD11b+, CD64+CD16+CD32+ CD11b+, CD64-CD16+CD32+CD11b+ MON in full-term newborns and the different transformation of the phenotype of these subpopulations in both groups of deeply premature neonates with congenital pneumonia associated with RDS. We detected some inadequate response to bacterial invasion in patients of group1, and mark transformation of different subpopulations MON associated with greatly aggravates the manifestation of the disease in group2. The detection of the subpopulation CD64-CD16+CD32+CD11b+ MON with measure of receptors density may be useful as diagnostic marker of severity of the inflammatory process in deep preterm infants.

P4.04.46
Gestational hypothyroidism and its effects on the offspring immune response against infection: Evaluation in a murine model of pneumococcal pneumonia

P. A. Nieto[1,2], *F. J. Salazar*[1,2], *H. F. Peñaloza*[1,2], *B. M. Schultz*[1,2], *A. M. Kalergis*[1,2], *C. A. Riedel*[3,2], *S. M. Bueno*[1,2];
[1]*Departamento de Genética Molecular y Microbiología, Facultad de Ciencias Biológicas, Pontificia Universidad Católica de Chile, Santiago, Chile,* [2]*Millennium Institute on Immunology and Immunotherapy, Santiago, Chile,* [3]*Facultad de Ciencias Biológicas y Facultad de Medicina, Universidad Andrés Bello, Santiago, Chile.*

Gestational hypothyroidism affects fetus neurodevelopment and leads to cognitive deficiencies. In rodents, this condition also affects lung development and produces differences in the amount and type of immune cells present in the spleen. Preliminary data from our laboratory showed that gestational hypothyroidism increases the intensity of an autoimmune disease at the central nervous system of the progeny. We think that the offspring gestated under hypothyroidism will have alterations in the performance and/or activation state of the immune cells during an infection. To evaluate

this, we have chosen to study the immune response against the pathogen *Streptococcus pneumoniae* in mice gestated in hypothyroid mothers (MMIo mice) or in control mothers. Mice were infected intranasally to cause pneumonia and the bacterial loads in lungs and brain, the immune populations present in lungs and bronchoalveolar lavage, the cytokine profiles, and lung histopathology were analyzed. We have found that both groups of mice showed a similar response against the infection, with MMIo mice displaying a tendency to be more resistant. Interestingly, all infected mice showed a marked decrease of the resident lung T- and B-cell populations. Our work explores for the first time the correlation between gestational hypothyroidism and the functionality of the offspring immune cells during infection. Grant Support: Fondecyt 1110604, Fondecyt 1100926 and Millennium Institute on Immunology and Immunotherapy P09/016-F.

P4.04.47

Specific pulse-width mild electrical stimulation induces p53 activation via p38 MAPK and ameliorates LPS-induced inflammatory cytokine response

*R. Fukuda[1], **K. Omachi**[1], M. A. Suico[1], K. Koyama[1], Y. Kai[1], S. Matsuyama[1], K. Mitsutake[2], S. Morino-Koga[1], T. Shuto[1], H. Kai[1]; [1]Dept. of Molecular medicine, graduate school of pharmaceutical science, Kumamoto Uiniversity, Kumamoto-si, Japan, [2]Graduate school of Science of Technology, Kumamoto Uiniversity, Kumamoto-si, Japan.*

p53 is activated by diverse cell stresses such as DNA damage, oncogene activation and heat stress. Studies have shown that p53 works as a suppressor of inflammatory responses in virus or bacteria infected cells. Hence, functional activation of p53 could be beneficial for treatment of inflammatory diseases. p53 activation methods such as irradiation, hyperthermia and DNA-damaging reagents have the risk of cell damage. Therefore, a novel method of p53 activation without cell damage would be advantageous. In this study, we focused on mild electrical stimulation (MES) as a p53 activator, and determined whether MES can potentiate p53 function. HCT116 cells were treated with MES using electrical stimulation generator (Duration: 0.01~10 msec, Voltage: 1 V/cm, Pulse number: 55 pulse per sec). Protein extracts or RNA were analyzed for phospho-p53 and p53 target genes expression after MES treatment. p53 binding to p21 promoter was assessed by ChIP assay. MAPKs inhibitors were used to clarify the MES-induced p53 phosphorylation pathway. Peripheral macrophages (pMφ) from p53+/+ or p53-/- mice pre-treated with MES and LPS-induced inflammatory cytokines expression were assessed by quantitative-RT-PCR. Our results show that specific MES conditions can phosphorylate p53 and potentiate transcriptional function via activation of p38 pathway. Furthermore, MES treatment ameliorated LPS-induced upregulation of inflammatory cytokines such as IL-6, IL-1βand TNFαin p53+/+ mouse-derived pMφ but not in p53-/- pMφ. Our findings suggest that MES is a novel p53 physiological activator and MES might be a new therapeutic strategy for inflammatory diseases.

P4.04.48

***Legionella pneumophila* thymidine auxotroph mutant promote a protective immunity dependent on the bacterial Dot/Icm secretion system and Myd88 signaling pathway against Legionella pneumophila *flaA*$^-$**

***M. Pereira**, D. S. Zamboni;*
FMRP-USP, Ribeirão Preto, Brazil.

The importance of the priming of the lung environment by past infections is being increasingly recognized. Exposure to any given antigen can either improve or worsen the outcome of subsequent lung infections, depending on the immunological history of the host can provide an important novel therapy for emerging infectious diseases. To gain insight in the molecular mechanisms related to protection during previous bacterial infection we used a mouse model of *Legionella pneumophila* (*L.p.*). Mouse were infected via intranasal (i.n) with thymidine auxotroph mutants of *L.p.* (*thyA*$^-$, which fail to replicate *in vivo*) for 10 days (day -10) before challenge with virulent bacteria (*L.p flaA*$^-$). At day 0 mice were infected with *L.p. flaA*$^-$ (i.n), after 2 or 4 days, lungs were harvest, crushed and plated on CYE and CFU were evaluated. We show that C57BL/6 pre-stimulated mice became significantly resistant to infection. Additionally we evaluated TLRs-/- as well as IL-1R-/- and these mice were also protected. Moreover this protection required T4SS and MyD88 signaling. To evaluate if this protection requires neutrophils C57BL/6 mice were depleted with anti-Ly6G. We found that anti-Ly6G depletion at day 0 promoted a partially reduction on protection. Additionally, we observed a partially involvement of $CD4^+$ T cells to due a deficient bacterial clearance $MHCII^{-/-}$ mice. We concluded mice pre-exposed to bacteria became more resistant for re-infection. This process requires bacterial virulence (T4SS), MyD88 signaling, neutrophils and $CD4^+$ T cells, which leads to generation of a strong and durable response. Financial support: CAPES, INCTV, CNPq and FAPESP.

P4.04.49

A critical role for Interferon-gamma but not IL-17 in staphylococcal superantigen-mediated toxic shock syndrome

*A. Scheid, A. Tilahun, V. Chowdhary, **G. Rajagopalan**;*
Mayo Clinic, Rochester, MN, United States.

Superantigens (SAg) elaborated by Staphylococcus aureus cause a robust immune activation resulting in profound elevation in systemic levels of various cytokines. This leads to multi organ failure and death. However, the precise roles of the two major pro-inflammatory cytokines IFN-γ and IL-17, in the pathogenesis of toxic shock syndrome are not known. As HLA-DR3 transgenic mice mount a superior response to SAg compared to conventional mice, IFN-γ-sufficient (DR3.IFN-γ+/+) and -deficient (DR3.IFN-γ-/-) mice were challenged intraperitoneally with 50 µg of staphylococcal enterotoxin B (SEB). Mice were treated with 100 µg of isotype control or neutralizing αIL-17 antibodies (R&D systems). Sera were collected at 3, 6, 12, 24, 48 and 72 hours for 23-plex cytokine/chemokine assay (Bio-Rad). Animals were killed at 24, 48 and 72 hrs for experimental analyses.
SEB-challenged, isotype control DR3.IFN-γ+/+ mice had significantly elevated serum IL-17 and IFN-γ along with marked inflammation in lung, liver, kidney, heart and small intestines. SEB-challenged, αIL-17 treated DR3.IFN-γ+/+ mice had little IL-17, but significantly elevated IFN-γ in serum. Multi organ inflammation was not mitigated. SEB-challenged isotype control DR3.IFN-γ-/- mice had significantly elevated IL-17. Lung, liver, kidney and heart displayed marked inflammation. However, the small intestines were devoid of inflammation. αIL-17-treated, SEB-challenged DR3.IFN-γ-/- mice had significantly lower IL-17. They still had marked inflammation in lung, liver, kidney and heart but not in the small intestines. In conclusion, our study suggests that IFN-γ but not IL-17, plays an important role in pathogenesis of TSS. Therapeutic approaches targeting IFN-γ should be explored in treatment of TSS.

P4.04.50

Evaluation of the immune response against *Brucella abortus* in splenectomized mice

***A. B. Rezende**, N. N. Neto, O. H. M. Assis, C. S. Miranda, M. Mota, G. C. Macedo, H. C. Teixeira;*
Federal University of Juiz de Fora, Juiz de Fora, Brazil.

Introduction: The influence of the spleen in control of intracellular bacterial infections remains unclear. Brucellosis is a zoonosis caused by the facultative intracellular bacteria of the genus *Brucella*. Thousands of new cases of human brucellosis are diagnosed each year worldwide. In Brazil, bovine brucellosis is endemic throughout the country, compromising the quality of cattle. *Brucella abortus* has a tropism for the spleen and induces an immune response mediated by cytokines such as IFN-γ and TNF-α. The objective of this work was to investigate the immune response against *Brucella abortus* in splenectomized mice.
Methods and Results: C57Bl/6 mice were divided into a sham-operated control group (SH) and splenectomized group (SP). Thirty days after surgery, animals were intraperitoneally infected with 10^6 bacteria/mouse of *Brucella abortus* (S2308). Twenty one days after infection, *B. abortus* colony-forming units (CFU) were evaluated in macerated liver. Cytokine production (IFN-γ, IL-12, TNF-α, IL-6, IL-

10) was analyzed in liver (ELISA). A higher number of *B. abortus* CFU was observed in liver of splenectomized mice (Ln = 3.8 ± 0.1) in comparison to the sham-operated group (Ln = 3.4 ± 0.1). IFN-γ and IL-12 production was lower in liver of SP mice (600.3 ± 75.9 and 1303 ± 99.3 pg/ml, respectively). In addition, SH animals presented a greater production of TNF-α, IL-6 and IL-10 in liver in comparison to the splenectomized group ($p<0.05$).
Conclusion: Splenectomy reduces the capacity of C57Bl/6 mice to control *B.abortus* infection which correlates with a lower cytokine production in splenectomized mice.

P4.04.51
Physiological significance of the sodium/proline transporter putP of Helicobacter pylori

***A. Rivera-Ordaz**, S. Imrich, H. Jung;*
Ludwig-Maximilians Universität München, Martinsried, Germany.

Helicobacter pylori is recognized as one of the most prevalent human pathogens. It is the causative agent of type B gastritis and gastric carcinoma. It uses several mechanisms to manipulate the immune system to persist long-term within the gastric niche manipulating phagocytosis and the subsequent oxidative burst. A genome wide search predicted that the genes encoding L-proline transport (putP) and metabolizing proteins (putA) were essential for gastric colonization (Kavermann H, et al. in 2003). Furthermore L-proline is present in high amounts in humans infected with H. pylori, can be used as energy source and is recognized as scavenger of reactive oxygen species (Nagata et al., 2003). This research focuses on the physiological role of L-proline and L-proline-specific systems for H. pylori. First characterization of the putative proline transporter in H. pylori was performed. The gene HpputP from strain P12 complemented an E. coli putP mutant. Functional analyses with HpPutP reconstituted in proteoliposomes demonstrated that transport activity depends on an electrochemical sodium gradient. Analysis of proline transport in H. pylori wild type showed accumulation of extracellularly applied L-proline and deletion of the putative transporter gene inhibited transport completely. Kinetic parameters were similar to those of EcPutP and complemented mutants were able to restore transport. The mutants had an altered energy status; flaA gene expression was impaired and phenotypic characterization demostrated the absence of flagella. Therefore proline availability could have very important implications during infection, and HpputP may represent a new drug target

P4.04.52
Protection from severe bacterial infection by injections of cytokine-gene transfected cells

***T. Saito-Taki**[1], T. Onogawa[2], H. Kitasato[1];*
[1]Microbiology, Kitasato Univ. Sch. Allied Health Sciences, Sagamihara, Japan, [2]Med. Tech. duc. Unit, Kyourin Univ. Fac. Health Sciences, Hachioji, Japan.

In hospital-aquired infections in immunocompromized hosts by multiple-drug resistant *Staphylococcus aureus* (MRSA) or *Pseudomonas aeruginosa,* recovery from infection by chemotherapeutics treatment are very difficult. Since these microorganisms are weak pathogenicities, encouragement of immune responses to normal level in these hosts is important therapeutic strategy. One of procedures to improve host resistancy against bacterial infection, injections of immunostimulating cytokines will be effective. Several reports showed some cytokine induced anti-bacterial effects, but high concentration of cytokines and maintenance of long period were required to exert these effects.
In this study, we prepared specific cells which harboring cytokine genes, such as IL-2, IL-6 or IL-12 and secret cytokines. These cells will produce cytokines constantly *in vivo* and enhance macrophage activity, humoral immunity and cellular immunity. After inoculations of these bacteria in *beige* mice, model mice of Chediak-Higashi syndrome, cytokine-secreting cells were injected in mice, survival period and growth of bqacteria at injected region were traces. In this paper, we will summarize our experimental results.

P4.04.53
The scavenger receptor CD36 downmodulates the early inflammatory response while enhancing bacterial phagocytosis during pneumococcal pneumonia

***S. Saluzzo**[1,2], O. Sharif[1,2], U. Matt[1,2], K. Lakovitz[1,2], S. Knapp[1,2];*
[1]Center for Molecular Medicine (Ce-M-M-) of the Austrian Academy of Sciences, Vienna, Austria, [2]Department of Medicine I, Laboratory of Infection Biology, Medical University Vienna, Vienna, Austria.

CD36 is a scavenger receptor which exhibits pleiotropic functions including: adhesion to thrombospondin, inhibition of angiogenesis, transport of long chain fatty acids and clearance of apoptotic cells. Additionally, it has been implicated in the host immune response since it acts as a co-receptor for Toll like receptor 2 (TLR2) and plays a role in *Staphylococcus aureus* infection. However, its role in other Gram positive bacterial infections is unclear. Here using mice deficient in CD36 we sought to examine the role of CD36 in pneumococcal pneumonia, a major cause of morbidity and mortality worldwide. We show that CD36 is expressed on both alveolar macrophages and respiratory epithelial cells. Early in infection $CD36^{-/-}$ mice have an exaggerated inflammatory response compared to WT littermate controls. *In vitro* studies utilizing $CD36^{-/-}$ primary cells confirm the enhanced early inflammation in response to *S. pneumoniae* and its LTA, demonstrate that *S. pneumoniae* binds to cells via its phosphocholine residues and suggest a role for CD36 in reducing inflammation induced by the phosphocholine residues of pneumococcal LTA. Later in infection, although $CD36^{-/-}$ mice exhibit impaired bacterial clearance, due to a decreased capacity of $CD36^{-/-}$ macrophages to phagocytose *S. pneumoniae*, there are minor effects on mortality compared to WT littermate control mice. These data show that CD36 contributes to the pulmonary host response during S. *pneumoniae* infection by virtue of its ability to act as a phagocytic receptor and as a modulator of the early innate immune response.

P4.04.54
Identification of functional polymorphisms of the macrophage migration inhibitory factor (MIF) gene associated with morbidity and mortality in pneumococcal meningitis and sepsis

***A. Savva**[1], M. C. Brouwer[2], T. Roger[1], P. Bochud[1], D. Le Roy[1], A. van der Ende[2], D. van de Beek[2], T. Calandra[1];*
[1]Infectious Diseases Service, Centre Hospitalier Universitaire Vaudois and University of Lausanne, Lausanne, Switzerland, [2]Department of Neurology and Netherlands Reference Laboratory for Bacterial Meningitis, Academic Medical Center, Amsterdam, Netherlands.

Background: The cytokine MIF is an important regulator of innate immune responses. Elevated MIF levels in septic patients correlate with disease severity and outcome. We examined whether functional MIF polymorphisms (-794 CATT-5/8 microsatellite and -173*G/C SNP) were associated with morbidity and mortality in patients with pneumococcal meningitis, and assessed the impact of anti-MIF therapy in a mouse model of streptococcal sepsis.
Methods: MIF polymorphisms were genotyped in 404 patients with community-acquired pneumococcal meningitis and 329 non-related proxies. MIF levels were measured in CSF of 426 patients and in human whole blood stimulated with *S.pneumoniae*. The effect of anti-MIF IgG was assessed in a mouse model of *S.pneumoniae* pneumonia.
Results: Frequencies of CATT-5/8 and -173*G/C alleles were similar in patients and controls. In patients with pneumococcal meningitis, carriage of the CATT-7 and -173*C high MIF expression alleles was associated with sepsis biomarkers, unfavourable outcome (P=0.005 and P=0.003) and death (OR 2.27 and 2.6, P=0.03 and P=0.01). CSF MIF levels were 2-fold higher in non-survivors than in survivors ($P<0.001$). MIF concentrations increased 7.5-fold in *S.pneumoniae* stimulated whole blood (P=0.001). In mice with pneumococcal sepsis, anti-MIF antibodies reduced bacterial counts, TNF and IL-6 concentrations in blood and BAL, and mortality (from 75% to 46%, P=0.03).
Conclusions: Functional MIF polymorphisms affecting MIF expression and CSF levels are associated with severity and outcome in adult patients with pneumococcal meningitis. Conducted in a homogenous population of septic patients, this study shows that genotyping may help identifying patients who could benefit from mediator targeted treatment strategies.

P4.04.55
Phagocytic activity in antibiotic and bacteriophage therapy of peritonitis caused by Escherichia coli

***G. Siritsa**, O. Kosilova, H. Khidwrbagi;*
Kharkov National Medical University, Kharkov, Ukraine.

Worldwide spread of polyresistant pathogenic bacteria has become a global medical problem. Phage therapy is one of alternative ways of antimicrobial treatment. Bacteriophages provide elimination of bacteria in vivo by both direct bactericidal activity and activation of phagocytosis.
Objective: Assessment of phagocytic activity in antibiotic and bacteriophage treatment of peritonitis caused by Escherichia coli in mice.
Material and methods: Eight groups of mice took part in the experiment. Each group included 10 animals. Healthy mice comprised the control group. The remaining animals had peritonitis caused by intraperitoneal injection of Escherichia coli. Gatifloxacin (G), amikacin (A) and bacteriophagum coliproteicum (BCP) were used for antimicrobial treatment. Mono (G, A and BCP) and combined (G+A, G+BCP, A+BCP and G+A+BCP) therapies were used. Sick animals received the medicines intraperitoneally in daily doses during 5 days. Phagocytosis was assessed by rate of activation, phagocytic index and completeness of phagocytosis on the 1st, 3rd and 5th days of the therapy.
Results and discussion: Parameters of phagocytosis in both monotherapy with G and A, and combined therapy with G+A and G+A+BCP were below the control values during the whole period of treatment ($p \leq 0.05$). The animals receiving BCP therapy revealed high phagocytic activity exceeding the control values ($p > 0.05$). Parameters of phagocytosis in combined therapy with G+BCP and A+BCP were equal to the control values.
These results prove bacteriophage to activate phagocytosis. Combinations of G with BCP and A with BCP can be recommended for treatment of peritonitis caused by Escherichia coli.

P4.04.56
Infection with invasive bacterial pathogens triggers distinct Nod-dependent autophagy and cytokine responses

***M. Sorbara**, S. Girardin, D. Philpott;*
University of Toronto, Toronto, ON, Canada.

Autophagy plays a critical role in cellular metabolism as a starvation response but is also activated during infection as an intracellular defense mechanism. Indeed, these two roles for autophagy are linked, since infection with the invasive bacteria *Shigella flexneri* or *Salmonella typhimurium* triggers amino acid starvation, which contributes to autophagy activation. Nod1/2 are intracellular sensors of peptidoglycan fragments that drive cytokine responses. In addition, Nod1/2 promote autophagy of both *Shigella* and *Salmonella* through their interaction with the autophagy protein, ATG16L1, and ability to activate p38 MAPK signaling. Here, we examined the role of Nod1/2 in the autophagy response to *Shigella* and *Salmonella* and demonstrate that they play distinct roles during infection with these pathogens. We demonstrate that anti-*Shigella* autophagy occurs in two distinct and separable phases comprised of induction and targeting, with Nod1/2-dependent recruitment of ATG16L1 helping to overcome *Shigella's* evasion of the targeting machinery. In contrast, Nod1/2 contribute to the induction of autophagy through downstream signaling during *Salmonella* infection but are dispensable for targeting, as a result of *Salomonella*'s replication in a membrane-damaged vacuole that drives targeting through complementary mechanisms. Finally, during infection with cyto-invasive bacteria, the interaction of ATG16L1 with Nod1/2 functions to negatively regulate the pro-inflammatory cytokine response. Therefore, there is a complex interaction that occurs between Nod1/2, the autophagy system and ATG16L1 to promote autophagy of intracellullar bacteria and modulate levels of pro-inflammatory cytokines. Since Nod2 and ATG16L1 are strongly linked to Crohn's disease, understanding the interplay between these proteins may provide insight into disease pathogenesis.

P4.04.57
Selective criteria and important features of protective monoclonal antibodies to tetanus toxin

***I. D. Stojicevic**, E. M. Marinkovic, I. P. Zivkovic, V. Z. Petrusic, L. A. Dimitrijevic, M. M. Stojanovic;*
Institute of Virology, Vaccines and Sera Torlak, Belgrade, Serbia.

Completely characterized, high specific monoclonal antibodies (MoAbs) with proven protective capacity could be used as the effective therapy of tetanus. The aim of our study was to elucidate the relationship between binding characteristics of MoAb and protectiveness it provides. Five MoAbs specific for tetanus toxin (TeNT) were evaluated for its fine epitop specificity, affinities of interaction with TeNT and capability to ensure protection in vivo.
Among selected antibodies, MoAb51 and MoAb62 recognize TeNT with the highest affinity (Ka>1010M-1). Bindings of MoAb26, MoAb41 and MoAb71 to TeNT are significantly weaker Ka<109M-1. Target epitopes of MoAb26, MoAb41, MoAb51 and MoAb71 are found to be in ganglioside-binding site or in its close proximity. Recognition of TeNT by MoAb62 is not influenced by TeNT-gangliosides interaction. In mice treated by tetanus toxin pre-incubated with MoAb51 slight transitional clinical symptoms of tetanus are marked, but at the end of follow up period survival was 100% without any signs of tetanus. In addition, MoAb51 confers full protection against tetanus, even administrated 2 or 6 hours after TeNT injection. Protection by MoAb26, MoAb41 and MoAb71, was partial, while MoAb62 does not provide any protection.
Since binding of TeNT to gangliosides on neuronal cells is crucial step for further intoxication, binding of MoAbs to ganglioside-binding site or some close epitops on TeNT is assumed to be critical for protection. Our results are in accordance with this assumption but also provide clear evidence that only MoAbs that recognize TeNT with high affinity (Ka>1x1010M-1) could provide full protection against tetanus.

P4.04.58
Th1-Th17 cells mediate pelvic pain induced by uropathogenic Escherichia coli

***P. Thumbikat**, L. Wong, M. Quick, J. D. Done, A. J. Schaeffer;*
Northwestern University, Chicago, IL, United States.

Chronic prostatitis/chronic pelvic pain syndrome (CP/CPPS) is characterized by pelvic pain in men and has an etiology that is not known but may involve microbes and autoimmune mechanisms. We developed an infection model of chronic pelvic pain in NOD/ShiLtJ (NOD) mice with a clinical Escherichia coli isolate (CP-1) from a patient with chronic pelvic pain. We investigated pain mechanisms in NOD mice and compared it to C57BL/6 (B6) mice, a strain resistant to CP-1-induced pain. Adoptive transfer of CD4+ T cells, but not serum, from CP-1-infected NOD mice was sufficient to induce chronic pelvic pain. CD4+ T cells in CP-1-infected NOD mice expressed IFN-γ and IL-17A but not IL-4. Adoptive transfer of ex-vivo expanded IFN-γ or IL-17A-expressing cells was sufficient to induce pelvic pain in naïve NOD recipients. Pelvic pain was not abolished in NOD-IFN-γ-KO mice but was associated with an enhanced IL-17A immune response to CP1 infection. Furthermore, we show that regulatory Foxp3+ T cells (Treg) cells are necessary for the fateful development of pain in mice with prostatitis. In agreement with these animal model studies, clinical samples isolated from patients with CP/CPPS show higher levels of IL-17 compared to control patients. Taken together, our data demonstrate that Th1, Th17, and Treg cells play a vital role in the development of pain in chronic prostatitis.

P4.04.59
Anti-alpha toxin mAb promotes both innate and adaptive immune response in a CA-MRSA USA300 mouse dermonecrosis model

***C. Tkaczyk**, X. P. Yang, M. Hamilton, V. Datta, J. Suzich, C. K. Stover, B. R. Sellman;*
Medimmune, LLC, Gaithersburg, MD, United States.

During a S. aureus skin and soft tissue infections (SSTI), an effective host response is initially orchestrated by IL-1β and IL-17 resulting in neutrophilic abscess formation and bacterial clearance. Recent studies have shown γδ T cells along with Th1 and Th17 cells play an important role in mounting this response. Alpha toxin (AT), a key virulence determinant in *S.aureus* SSTI, plays a role in tissue damage, but its effect on the immune system is unknown. We previously described that prophylactic administration with 2A3, an AT neutralizing human monoclonal antibody, resulted in significant reduction in disease severity in a CA-MRSA mouse dermonecrosis model. Reduction in disease severity in mice that received 2A3 correlated with increased proinflammatory cytokine (e.g. IL-1β, IL-17, IFN-γ) and chemokine levels leading to neutrophil influx and abscess formation not seen in animals that received an irrelevant control IgG, R347. To understand how AT modulates the T cell responses, intra-cellular IFN-γ and IL-17 were measured in different T cell populations. Single cell suspensions, in presence of 2A3 or R347, were analyzed from skin lesions 3 and 7 days post infection. At day 3 post challenge, 2A3 prophylaxis increased IL-17$^+$ γδ T cell numbers. After 7 days infection, IL-17$^+$ γδ T cells as well as Th17 and Th1 cell numbers were significantly higher in presence of 2A3 (respectively p= 0.003 ; 0.029; 0.0096).
Together, these results suggest AT neutralization with 2A3 promotes an early innate immune response through IL-17$^+$γδT cells, and later an adaptive Th1 / Th17 response.

P4.04.60
A novel polarized ex-vivo organ culture model to study gut inflammation and response to probiotics

***A. Tsilingiri**, M. Rescigno;*
European Institute of Oncology, Milano, Italy.

In recent years, the importance of a properly balanced gut flora for homeostasis and wellbeing has been greatly highlighted by many reports. In the light of recent findings, the use of probiotic strains as nutritional supplements has been exceedingly gaining ground in the last decade. As the mechanisms with which probiotics modulate innate and adaptive immunity start to become clearer, these have repeatedly been suggested as potential treatment for a wide variety of diseases, especially inflammatory bowel disease (IBD). However, even though the benefits of probiotic treatment for conditions like atopic dermatitis are well established, very limited clinical benefit has been obtained on IBD treatment. This could because of the lack of suitable models on which to obtain valid pre-clinical data, as it has been reported that although many treatments seem promising when tested on mouse or rat models of colitis, only a very small percentage of these translate to significant clinical benefit.
We recently described a newly developed model for the culture and apical stimulation of whole human intestinal mucosal explants. Polarized stimulation proved to be important for obtaining valid data, and we showed that the tissue was only viable if incubated in an O_2 chamber and that it did not survive culture if a thick layer of medium on the apical side prevented gas exchange. We used the new set-up to test three different Lactobacilli strains, none of which appeared to be benign on inflamed IBD mucosa.

P4.04.61
Study of the development of actinomycetoma during Nocardia brasiliensis infection in mice with partial genetic blockade of eNOS

***A. Vázquez-Marmolejo**, M. Salinas-Carmona, L. Pérez-Rivera, A. Atilano-Díaz, D. Domínguez-Armendariz, H. Garza-Esquivel, J. López-Ulloa, L. Fernández-Carrizales;*
Inmunology Department, Faculty of Medicine UANL, Monterrey, Nuevo Leon, Mexico.

Introduction: Nocardia brasiliensis infection, is the primary cause of Actinomycetoma in Mexico. This disease is characterized by the development of chronic granulomatous lesions containing numerous foam cells, which act as reservoirs for bacteria. Nitric oxide (NO) plays an important role in regulating blood pressure and in the process of angiogenesis as well as in anti-infectious immune response.
Objective: Study the development of actinomycetoma during Nocardia brasiliensis infection in mice with partial genetic blockade of endothelial nitric oxide synthase (eNOS).
Methodology: We compared BALB/c and C57BL6 wild type (WT) mice, with the C57BL6 heterozygous for eNOS -/+ mice. The mice were inoculated with N. brasiliensis (0.1ml 1x106 bacteria) in the footpad. They were followed up for 250 days during infection, serum was obtained for measurement of the production of IgG antibodies against N. brasiliensis and the bacterial burden was determined in blood.
Results: By the 10th day, all the mice presented the acute inflammation. On the day 30, the WT and BALB/c started developing the actinomycetoma until their sacrifice; in none of the mice with incomplete genetic blockade for eNOS, the actinomycetoma had developed until the time of their sacrifice. Even though they showed similar antibody levels to WT and BALB/c, the bacterial burden in blood was negative for all mice.
Conclusion: The incomplete genetic blockade of endothelial NO synthase (eNOS) protects mice against the development of actinomycetoma caused by Nocardia brasiliensis infection.

P4.04.62
Neutrophilic granulocyte subtype recruitment in human peritonitis

***S. von Vietinghoff**, L. Wang, S. Ge, M. Hiss, H. Haller;*
Hannover Medical School, Hannover, Germany.

Background: Human neutrophilic granulocytes (PMN) are distinguished into two subpopulations by the NB1 molecule (CD177). NB1 presents the serine protease Proteinase 3 on the PMN surface. Recent in vitro data have suggested a role of the NB1/PR3 complex in cell migration. We here studied neutrophil subtype recruitment in acute peritonitis in humans in vivo.
Methods: Blood and peritoneal fluid from patients treated with peritoneal dialysis presenting with acute peritonitis was analyzed by immunofluorescence and flow cytometry for NB1 and integrin expression at presentation and during follow-up. Patients without evidence of infection served as controls.
Results: NB1 was up-regulated on migrated NB1+ neutrophils. However, the proportion of NB1/CD177+PMN was very similar in every patient in blood and peritoneal fluid in patients with acute peritonitis and controls. There was no evidence of transfer of NB1 to NB1- cells. Differential cell death might obscure a migration advantage of either PMN type. However, in acute peritonitis, no significant difference in the proportion of dead cells among NB1+ and NB1-PMN was observed. Also, re-assessment of blood and peritoneal PMN after treatment again revealed very similar proportions of NB1+ among peritoneal and blood PMN.
Conclusion: Our results argue against a cell specific role for NB1/CD177 in inflammatory neutrophil recruitment in vivo.

P4.04.63
Suppression of IFN-γ signaling by Src homology-2 domain-containing phosphatase 2 during Helicobacter pylori infection

***Y. Wang**, C. Lin;*
The Institute of Clinical Medicine, Tainan, Taiwan.

Helicobacter pylori (*H. pylori*), a gram-negative spiral bacteria, infection not only induces gastric inflammation but also increase the risk of gastric tumorigenesis. Interferon (IFN)-γ has antimicrobial effects; however, *H. pylori* infection elevates IFN-γ-mediated gastric inflammation and may suppress IFN-γ signaling as a strategy to avoid immune destruction through an as-yet unknown mechanism. This study was aimed at investigating the mechanism of *H. pylori*-induced IFN-γ resistance. Post-infection viable clinical isolates of wild-type *H. pylori* strain HP238 decreased IFN-γ-activated signal transducers and activators of transcription 1 and IFN-regulatory factor 1. HP238 caused an increase in the C-terminal tyrosine phosphorylation of Src homology-2 domain-containing phosphatase (SHP) 2. Pharmacologically and genetically inhibiting SHP2 reversed HP238-induced IFN-γ resistance. The cytotoxin-associated gene A (*CagA)* isogenic mutant strain $HP238^{CagAm}$ failed to induce IFN-γ resistance, indicating that CagA regulates this effect. Notably, HP238 and $HP238^{CagAm}$ both caused SHP2 phosphorylation; however, imaging and biochemical analyses demonstrated CagA-mediated membrane-associated binding with phosphorylated SHP2. CagA-independent generation of reactive oxygen species (ROS) contributed to *H. pylori*-induced SHP2 phosphorylation and IFN-γ resistance when CagA was concurrently present. This finding not only provides an alternative mechanism for how CagA and ROS co-regulate SHP2 activation but may also explain their roles in *H. pylori*-induced IFN-γ resistance.

P4.04.64
Protective immunity against invasive *Streptococcus pneumoniae* infections by tissue-specific memory Th17 cells

***Y. Wang**, B. Jiang, J. N. Weiser, H. Shen;*
Department of Microbiology, University of Pennsylvania School of Medicine, Philadelphia, PA, United States.

Pneumonia caused by *Streptococcus pneumoniae* (Sp) remains a leading cause of serious illness and death in children and elderly worldwide. Current vaccine is highly effective in preventing colonization by inducing serotype-specific antibodies. However, there is an increasing prevalence of infection by serotype strains not included in the vaccine; this highlights the need for a universal vaccine that protects against all serotypes. The first step in developing a universal vaccine is to elucidate the immune mechanism that can provide broad protection against different serotype of Sp strains. We found that intranasal immunization of mice with Sp resulted in a strong CD4+T cell response in the lung that consisted of mostly Th17 cells but also IFN-gamma producing Th1 cells. These immunized mice were protected against lethal challenge with a different serotype strain of Sp and cleared bacteria from the lung by day 2 post-challenge. Adoptive transfer of T cells from immunized mice also provided protection against a heterologous challenge, with a dominant Th17 recall response in the lung from donor memory T cells. Furthermore, immunization of mice with *Listeria monocytogenes* (LM) provided protection against a recombinant Sp strain expressing a CD4 epitope from LM (LLO190), as shown by decreased CFU in the lung, and elevated LLO190-specific Th17 response. Our results suggest that memory Th17 cells may play a key role in providing broad protective immunity against invasive Sp infection in a serotype independent manner.

P4.04.65
Differential inflammasome activation by Salmonella strains expressing mutant forms of the NLRC4 ligands FliC and PrgJ

***J. A. Wright**, S. Man, G. Frazer, C. E. Bryant;*
University of Cambridge, Cambridge, United Kingdom.

The Nod-like receptor NLRC4 is activated in response to *Salmonella* infection and, in combination with the adaptor protein ASC, recruits caspase-1 to form an inflammasome complex. Inflammasome assembly leads to secretion of active IL-1 and IL-18 and drives pyroptotic macrophage cell death. NLRC4 recognises FliC, the major flagellin subunit of *Salmonella*, in combination with NAIP5 and NAIP6 and also PrgJ, the rod protein of the SPI-1 type three secretion system (T3SS), in combination with NAIP2. Conserved residues at the C-termini of these bacterial proteins are required for their recognition by NLRC4. However, it is not known whether these residues are critical for function, or whether they can be mutated to abolish NLRC4 activation whilst retaining bacterial motility and SPI-1 T3SS activity. We have generated Salmonella strains lacking the *fliC*, *prgJ* and minor flagellin *fljB* genes, either alone or in combination. Constructs have been produced to express mutant forms of FliC and PrgJ in appropriate mutant backgrounds. The effect of these mutations is currently being assessed in bacterial motility and protein secretion assays, and in macrophage infection experiments to measure host cell death and cytokine secretion. This study will provide further insight into the structure-function relationship of NLRC4 ligands.

P4.04.66
The effect of dietary oils on *citrobacter rodentium* induced colitis

***X. Wu**[1], A. Hekmatdoost[2], V. Morampudi[1], S. M. Innis[1], K. Jacosbon[1];*
[1]University of British Columbia, Vancouver, BC, Canada, [2]Shahid Beheshti University of Medical Sciences, Tehran, Iran.

BACKGROUND/AIM: Increasing evidence suggests that high dietary intake of n-3 fatty acids attenuates inflammation in chemically induced colitis, but data evaluating the effect of dietary oils on bacterial-induced colitis is lacking. The aim of this study was to determine the effect of fish oil, canola oil, and safflower oil on *C. rodentium*- induced colitis.
METHODS: Female 6-8 week-old C57BL/6 mice were fed diets varying only in fat composition with % energy from fat, 20% safflower oil (SO), 20% canola oil (CO), or 18% fish oil plus 2% safflower oil (FO) for three weeks before and 10 days after *C. rodentium* inoculation. The distal colon was assessed for histological damage score, bacterial count, macrophage and neutrophil recruitment evaluated by immunohistochemistry and levels of chemokines and cytokines assessed by real-time PCR and ELISA.
RESULTS: While bacterial burdens were similar between groups after infection, the FO group was the least susceptible to *C. rodentium*-induced colitis; histological damage score was lowest in the FO group (2.6 ±0.8) followed by CO (5.0 ±1.1) and SO (6.6 ±0.8). Moreover, the FO group demonstrated a significantly reduced inflammatory cell infiltration. Cytokines measurement indicated that the FO diet reduced critical chemokines (MCP1, MIP2 and KC) and cytokines (IL-6, IFNγ, IL-17A) and increased IL10 mRNA level compared to all other groups.
CONCLUSION: Our results indicate that in *C. rodentium*-induced colitis, the intake of fish oil was associated with a modulating effect on the host mucosal immune response in the absence of an effect on initial bacterial colonization.

P4.04.67
A mouse model of shigellosis by intraperitoneal infection

***J. Yang**, S. Lee, M. Kweon;*
International Vaccine Institute, Seoul, Republic of Korea.

While *Shigella spp.* causes bacillary dysentery by invading colon epithelium and promoting a strong inflammatory response in humans and non-human primates, adult mice are resistant to oral *Shigella* infection.
In this study, we found that intraperitoneal (i.p.) challenge with virulent *Shigella (S.) flexneri* 2a (YSH6000) resulted in diarrhea and severe body weight loss in adult B6 mice. Of note, virulent *S. flexneri* 2a could invade and colonize not only systemic tissues but also the serosa and lamina propria region of the large intestine. In addition, severe host cell death, epithelium shedding, barrier integrity and goblet cell hyperplasia were also found in the large intestine around 24 hours post i.p. *Shigella* infection. Microarray analysis showed that expression levels of chemokines (i.e., CCL4, CCL7, CXCL1, and CXCL10) and proinflammatory cytokines (i.e., TNF-α, IFN-γ, IL-1α

and IL-6) were dramatically increased in the large intestine post i.p. challenge. Furthermore, it was found that monocytes play a critical role in attenuating diarrhea and providing protective efficacy against *Shigella* i.p. infection. Most importantly, mice pre-vaccinated with avirulent *S. flexneri* 2a (SC602) showed effective protection against i.p. challenge with YSH6000. Taken together, i.p. challenge with virulent *S. flexneri* 2a can provoke bacillary dysentery and severe pathogenesis in adult mice, which could be applicable for understanding the induction mechanism of bacillary dysentery and for evaluating *Shigella* vaccine candidates.

P4.04.68
Production and characterization of neutralizing monoclonal antibodies directed against tetanus toxin fragment C

M. Yousefi[1,2], F. Tahmasebi[1], V. Younesi[1], A. Razavi[1], J. Khoshnoodi[1], A. Bayat[3], E. Abbasi[4], H. Rabbani[3], M. Jeddi-Tehrani[3], F. Shokri[1,3];
[1]*Department of Immunology, School of Public Health, Tehran University of Medical Sciences, Tehran, Iran,* [2]*Department of Immunology, Faculty of medicine, Tabriz University of Medical Sciences, Tabriz, Iran,* [3]*Monoclonal Antibody Research Center, Avicenna Research Institute, ACECR, Tehran, Iran,* [4]*Department of Bacterial Vaccines, Razi Vaccine and Serum Research Institute, Karaj , Iran, Tehran, Iran.*

Clostridium tetani causes life threatening infectious disease by production of tetanus toxin. Tetanus toxin (TeNT) is composed of light (LC) and heavy chain (HC) polypeptides with a molecular weight of 150 kDa. The TeNT HC is constituted of an N-terminal domain which is important for LC translocation and a C-terminal toxin receptor binding domain, also known as fragment C. Despite extensive investigations on epitope specificity of tetanus toxin antibodies, the immunodominant neutralizing epitopes of the toxin are poorly defined. Here, we describe the generation and characterization of four monoclonal antibodies (MAbs) specific for TeNT. Our data demonstrated that all MAbs bind to tetanus toxin and toxoid. Subfragments binding analysis showed that 2 MAbs react with fragment C, one with both fragment C and LC and one with LC, of which the former two MAbs were able to neutralize toxin activity in vitro. Sequencing of the immunoglobulin heavy chain variable region genes revealed rearrangement of various gene segments in all hybridoma clones. Individually of the clones was also confirmed by a competition assay which showed recognition of distinct epitopes by these MAbs. Our results suggest the importance of TeNT fragment C in terms of immunogenicity and toxin neutralization activity.
Key words: Tetanus toxin, Monoclonal antibody, Fragment C, Toxin neutralization

P4.04.69
Ephedrine hydrochloride inhibits PGN-induced inflammatory responses by promoting IL-10 production via PI3K/Akt/GSK3β pathway

Y. Zheng[1,2], Y. Yang[2], Y. Li[1], L. Xu[2], Y. Wang[1], H. Song[3], G. Ji[3], Y. Yu[2];
[1]*Department of Immunology and Microbiology, Shanghai University of Traditional Chinese Medicine, Shanghai, China,* [2]*National Key Laboratory of Medical Immunology & Institute of Immunology, Second Military Medical University, Shanghai, China,* [3]*Institute of Digestive Disease, Longhua Hospital, Shanghai University of Traditional Chinese Medicine, Shanghai, China.*

The approaches to control the inflammatory responses and reduce the mortality rate of sepsis are still not very effective in clinics and new potential drugs are needed to be confirmed to be useful in the induction of anti-inflammatory response. Ephedrine hydrochloride (EH) is a compound widely used for cardiovascular diseases, especially to treat hypotension caused by anesthesia or overdose of antihypertensive drugs. In this study, we reported that EH also plays an important role in the control of inflammatory response. It increases interleukin 10 (IL-10) and decreases proinflammatory cytokine (IL-6, TNF-α, IL-12, and IL-1b) expression in response to gram-positive cell wall component peptidoglycan (PGN) in primary peritoneal macrophages and Raw264.7 cells. The anti-inflammatory role of EH was also observed in experimental peritonitis mouse model induced by intraperitoneally PGN injection. Phosphatidylinositol 3-kinase (PI3K)/Akt pathway was found to be responsible for EH-enhanced IL-10 production and EH-decreased IL-6 expression. Therefore, our results illustrated that EH can help to maintain immune equilibrium and diminish host damage by balancing the production of proinflammatory cytokines and anti-inflammatory cytokine after PGN challenge. EH may be a new potential anti-inflammatory drug in treatment of severe invasive gram-positive bacterial infection.

P4.04.70
Anaphylatoxin C5a promotes kidney infection caused by uropathogenic E. coli

K. Li[1], *N. Choudhry*[2], *Q. Peng*[2], *N. Wang*[1], *B. Lu*[3], *S. Sacks*[2], ***W. Zhou***[2];
[1]*Xi'an Jiaotong University, Xi'an, China,* [2]*King's College London, London, United Kingdom,* [3]*Harvard Medical School, Boston, MA, United States.*

Previous studies have shown that most uropathogenic E coli strains are complement resistance, and complement depletion and deficiency of C3 protected mice from urinary tract infection (UTI). However, the mechanisms by which complement contributing to UTI remain to be elucidated. In this study, we tested a hypothesis that excessive C5a generated during infection contributes to the pathogenesis of UTI.
Using a well-established murine model of ascending UTI leading to kidney infection, we found that deficiency of C5aR or blocking C5aR significantly protected mice from kidney infection at 6h -72h after bladder inoculation of E. coli. Compared with wild type mice, C5aR-/- mice exhibited a lower rate of kidney infection (31% vs 79%), reduced bacterial load in the infected kidney and tissue damage, and lowered cytokine/chemokine production in kidney tissue. C5aR antagonist treatment protected mice from the kidney infection with a similar protection level as that observed in C5aR-/- mice. Chimera studies showed that the absence of C5aR on renal or circulating cells attenuated kidney infection, suggesting that C5aR on both renal and circulating cells contribute to the infection. *In vitro*, C5a stimulation significantly increased cytokine/chemokine production by macrophages and renal tubular cells, and impaired neutrophils functions (uptake, reactive oxygen species activity), in the presence of LPS or E coli.
These data demonstrate that C5a/C5aR signaling is a critical pathogenic factor in the ascending kidney infection. Mechanistic studies suggest that C5aR mediated macrophage and renal tubular cell activation/inflammation, and neutrophil functional impairment contribute to the pathogenesis of the infection.

Mycobacterium tuberculosis secretory protein MPT 70 induces production of pro-inflammatory cytokines and nitric oxide in macrophages

R. Agarwal[1,2], J. A. Khan[1], P. Kumar[1], H. Vora[1], A. Kumar[1], P. Sharma[1,3];
[1]*International Center for Genetic Engineering and Biotechnology, New Delhi, India,* [2]*Ramlal Anand College, University of Delhi, New Delhi, India,* [3]*NER-BPMC, DBT, Government of India, New Delhi, India.*

Secretory proteins of Mycobacterium tuberculosis play important role in pathogenesis as well as in immunity against the pathogen rendering them as promising candidates for development of vaccines and diagnostics. In the present study, we show that M. tuberculosis secretory protein MPT 70 binds to the surface of murine macrophages and stimulate secretion of proinflammatory cytokines IL-12p40, TNFα, IL-6, IL-1β but not anti-inflammatory cytokine IL-10. Pre-treatment of macrophages with MPT 70 resulted in increased NO release upon subsequent exposure to M. tuberculosis whole cell lysate or LPS, a potent inducible NO synthase (iNOS) activator thereby sensitizing macrophages for LPS-induced NO production.

MPT 70 also synergized with IFN-γ for NO production in a dose dependent manner suggesting that MPT 70 may have a pro-inflammatory function. MPT 70 was found to mediate these effects through ERK1/2 and p38 MAPK signaling pathways as TNFα released by MPT 70 and MPT 70- IFN-γ- stimulated macrophages as well as NO induced by pre- MPT 70- LPS- stimulated and MPT 70- IFN-γ- stimulated macrophages, are partially dependent on both p38 and ERK1/2 pathways as revealed by specific kinase inhibitors. MPT 70 increased p-ERK1/2 and p-p38 expression in macrophages. Also, pre-treatment with MPT 70 further heightened LPS- induced ERK1/2 and p38 phosphorylation and thus magnifies LPS effects. The study suggests that MPT 70 might play a protective role against M.tb infection by tilting the macrophage effector functions towards pro-inflammatory response and can have crucial implications in providing protection against tuberculosis.

P4.05.02
Regulation of granuloma formation in response to infection with Mycobacterium tuberculosis

***N. Agrawal**, U. Ullah, K. V. S. Rao;*
Intenational Centre for Genetic Engineering and Biotechnology, New Delhi, India.

A scourge of human kind throughout the recorded history, tuberculosis (TB) continues to be a leading cause of death across the globe. Major challenges in TB control are to understand the biology of latent TB, and to identify the very early sequence of events after bacilli gains access to the lungs. In lieu of this, we chose to study the immune responses generated against Mycobacterium tuberculosis in in vitro granuloma model. Our initial studies have reflected the differences in individual manifestation of the disease in terms of resistance or susceptibility against H37Rv. Low MOIs lead to the development of granuloma-like structures which are dynamic and could be maintained for several days. We observed the differences among individuals in terms of the ability to clear infection, extent of granuloma formation and foamy macrophage appearance, and also, in the levels of many Th1/Th2 cytokines and chemokines.
A multivariate regression analysis showed some positive and negative cytokine correlates of granuloma formation, and/or resistance and susceptibility for TB. Supporting the redundancy of human system, we have found some groups of different patterns of immune responses against the pathogen. In other words, there appears to be multiple signatures for different groups of people. The next question we are addressing is whether these signatures could be of any use to diagnostics or personalized medicines. Since many meta-analysis studies have already shown polymorphism linkage to the TB susceptibility, currently, we are investigating whether these patterns are governed at genetic level or not.

P4.05.03
Role of Oxidative stress associated anemic prevalence among Leprosy Patients.

***A. M. Ahamed**, A. M. Pradeep, N. Vetrivel;*
The American College, Madurai, India.

Introduction: Leprosy is a chronic disease. A constellation of reactive oxygen species (ROS) capable of damaging cellular constituents generated in excess during the chronic, inflammatory, neurodegenerative disease process of leprosy due to prooxidant shift results from changes in cellular metabolism (especially energy metabolism), higher flux rates in catecholamine metabolism and permanent leukocyte activation. The purpose of this study was to investigate the role of oxidative stress associated anemic prevalence among Leprosy patients.
Methodology: The study involves fifty Leprosy patients who are the inmate of Government Rehabilitation Centre for Leprosy, Pudhupatti, Madurai. The samples were collected at the informed consent of the patients. Serum sample were collected and Reactive Oxygen Species (ROS) was quantified using Nitro Blue Tetrazollium (NBT) reduction assay. Result: Study Involves Gaussian distribution and statistical analysis confirms the existence of the extreme significance of oxidative stress among the study population ($p<0.0001$) one way variance analysis (ANOVA). Study document existence of Correlation between increased oxidative stress with anemic prevalence.
Conclusion: The excess production of ROS evidenced in leprosy patients leads to oxidative damage of the erythroid cells which plays a crucial role in hemolysis due to ineffective erythropoiesis in the bone marrow and short survival of red blood cells (RBC) in the circulation leads to anemia . Intervention with antioxidant supplementation like vitamin E prevents oxidative stress mediated through ROS and activates the net antioxidant status thereby minimizing the risk of anemic associated complication among leprosy patients

P4.05.04
Immunotherapeutic effects of recombinant adenovirus encoding granulocyte-macrophage stimulating-colony factor in experimental pulmonary tuberculosis

***F. Alejandro**[1], M. Dulce[2], X. Zhou[3], H. Rogelio[4];*
[1]National School of Biological Sciences; National Polytechnic Institute, Mexico, Mexico, [2]National Institute of Medical Sciences and Nutrition, Mexico, Mexico, [3]McMaster University, Canada, ON, Canada, [4]National Institute of Medical Sciences and Nutrition "Salvador Zubirán", Mexico, Mexico.

BALB/c mice with pulmonary tuberculosis (TB) develop a T helper cell type 1 that temporarily controls bacterial growth. Bacterial proliferation increases accompanied by decreasing expression of interferon (IFN)-γ, tumor necrosis factor (TNF)-α, and inducible nitric oxide synthase (iNOS). Activation of dendritic cells (DCs) is delayed. Intratracheal administration of only one dose of recombinant adenoviruses encoding granulocyte-macrophage stimulating-colony factor (AdGM-CSF) one day before *M. tuberculosis* (Mtb) infection produced significant decrease of pulmonary bacterial loads, higher activated DCs and increased expression of TNF-α, IFN-γ, and iNOS. When AdGM-CSF was given in female mice B6D2F1 (C57BL/6J X DBA/2J) infected with low Mtb dose to induce chronic infection similar to latent infection and used corticosterone to induce reactivation, a very low bacilli burden in lungs was detected and the same effect was observed in healthy mice cohoused with mice infected with mild and highly virulent bacteria in a model of transmissibility. Thus, GM-CSF is a significant cytokine in the immune protection against Mtb and gene therapy with AdGM-CSF increased protective immunity when administered in a single dose one day before Mtb infection in a model of progressive disease, and when used to prevent reactivation of latent infection or transmission.

P4.05.05
Clinical isolates of Mycobacterium tuberculosis in Argentina differentially induces respiratory burst via TLR2 and dectin-1 in neutrophils as possible mechanism of immune escape

*M. Romero[1], J. I. Basile[1], B. Lopez[2], V. Ritacco[2], L. Barrera[2], M. C. Sasiain[1], **M. Aleman**[1];*
[1]IMEX-CONICET-ANM, Buenos Aires, Argentina, [2]Servicio de Micobacterias, Hospital Malbrán, Buenos Aires, Argentina.

Some years ago it was thought that both illness and latency of Tuberculosis (TB) were primary related by host factors. Nonetheless, it becomes evident that there are also factors from the bacteria which participate. The goal of this study was to characterize the immune response of multidrug-resistant clinical isolates representative of the most successful families in South America (LAM and Haarlem). We observed that Ra from LAM family, induce high levels of apoptosis, dependent on ROS generation and mediated by dectin-1 and TLR2, with subsequent activation of the Syk and p38 pathways. In this process, lipid rafts coalescence is a key step for assembly of the NADPH oxidase. We propose the α-glucan of the mycobacterial capsule as potential ligands *Mtb* dectin-1, triggering ROS generation, via Syk activation in PMN. Particularly, the clinical isolate M, does not induce apoptosis as a result of poor induction of ROS, associated with a deficient lipid rafts formation and no or faulty interaction with dectin-1. These observed differences among clinical isolates of *Mtb* may be associated with structural and / or spatial variations of the cell wall, which condition their interaction with the target cell. Thus, we postulate that differences in composition of the cell wall at the level of α-glucans and ligands for TLR2, allow some bacteria to hide from the immune system, acting as a potential evasion mechanism, permitting perpetuation.

P4.05.06
P2X7 receptor activation by ATP released from necrotic cells is crucial to severity of tuberculosis caused by hypervirulent mycobacteria

E. P. Amaral[1], *M. R. M. Andrade*[2], *S. C. M. Ribeiro*[2], *V. R. Lanes*[2], *F. M. Almeida*[2], *E. M. Salles*[1], *K. R. Bortoluci*[3], *J. M. M. Alvarez*[1], *E. Lasunskaia*[2], *M. R. D'Império-Lima*[1];
[1]*University of São Paulo, Sao Paulo, Brazil,* [2]*State University of North Fluminense, Campos dos Goytacazes, Rio de Janeiro, Brazil,*
[3]*Federal University of São Paulo, Sao Paulo, Brazil.*

Progressive Primary Tuberculosis (PPT) is an aggressive form of severe tuberculosis, which is characterized by lung necrosis, pneumonia and bacillus dissemination. To determine the major features of the bacillus-host interaction that are responsible for the development of severe tuberculosis, we infected C57BL/6 mice via intratracheal injection with ~100 bacilli from phylogenetically distant and highly virulent mycobacterial strains (*Mycobacterium tuberculosis* (Beijing 1471) and *Mycobacterium bovis* (MP287/03)). We observed extensive areas of pulmonary inflammation and necrosis that culminated in bacillus dissemination, at the 28 days post-infection, and death of mice groups around 40 days post-infection. We wondered whether the recognition of damage signals released from necrotic cells by innate immune cells could aggravate the disease. The purinergic P2X7 receptor (P2X7R) is a sensor of extracellular ATP, a damage-associated molecular pattern that is released from necrotic cells and induces pro-inflammatory cytokine production and cell death. Our data show that both hypervirulent mycobacterial strains grew rapidly inside macrophages and induced death by a P2X7R-dependent mechanism facilitating the spread of bacilli. Moreover, the disease caused by these strains was attenuated in mice that lacked the P2X7R, as determined by lung bacterial burdens, pneumonia and bacillus dissemination without evidence of necrotic lesions. ATP release triggers a vicious cycle in which extracellular ATP exacerbates the pulmonary recruitment of inflammatory cells and results in further cell destruction through the activation of the P2X7R. These findings suggest the use of drugs designed to inhibit the P2X7R as a new therapeutic approach to treat the aggressive forms of tuberculosis.

P4.05.07
Mixed DC /macrophage lineage phenotypes in activated lepromatous lesions during reverse reaction

P. R. Andrade, *T. P. Amadeu, A. Miranda, R. O. Pinheiro, J. Nery, E. N. Sarno;*
Oswaldo Cruz Foundation, Rio de Janeiro, Brazil.

Reverse Reaction (RR) in leprosy is a phenomenon incited by the rearrangement of the immune response with new waves of cellular activation and the disruption of the tolerance established by immunosuppression mechanisms. We hypothesized that in the cutaneous environment, these waves of migratory cells might affect different cellular populations in diverse stages of maturation, such as macrophages and dendritic cells. Our aim is to characterize the populations constituting the RR skin lesion and to determine the set of molecules involved in the onset of the episode. The immunohistochemical (IH) analysis showed in BL/LL, as well as RR skin lesions, the presence of specific markers of macrophage and dendritic cell populations, indicating the higher concentration of CD123. Immunofluorescence analysis showed that the dermal $CD123^+$ cell also exhibited expression of CD68, CD163, CD11c, CD86, CD14, HLADR, CD1a, CD1b, BDCA2 and BDCA4, without notable difference between the groups. In the RR group the gene expression of M-CSF (p=0.0077), GM-CSF (p=0.0033), TNF (p=0.0041) and IFN-γ (p=0.0312) was increased in comparison with the non-reactional group. CD123 gene expression was augmented in the RR patients when compared with the BL/LL group (p=0.0381), corroborating the IH analysis. The same was observed for the gene expression of CD209 (p=0.0394) and defensin 2 (p=0.0317). The expression of IDO (p=0.3148) was detected in BL/LL and RR lesions and although it seemed higher in the RR group, there was no statistical significance. The expression of IL-23 (p=0.0317) and IL-17 (p=0.0120) were also higher in the RR group in comparison to BL/LL.

P4.05.08
In vitro TLR2 and CD14 gene silencing effect in the control of Mycobacterium tuberculosis infection

A. Y. Arce-Mendoza, *F. Hernandez-Cabrera, A. G. Rosas-Taraco;*
Universidad Autonoma de Nuevo Leon, Monterrey, Mexico.

Introduction: TLR2 and CD14 are considered as key receptors for the penetration of Mycobacterium tuberculosis in macrophages. The increased expression of TLR2 enhances bacterial survival, proliferation and produces a large activation in infected macrophages, but little is known about the absence of TLR2 and CD14 in human macrophages. This work studied TLR2 and CD14 silencing and its effect on death or survival of intracellular Mycobacterium tuberculosis. Methodology: We designed siRNA and transfected human macrophage cell line THP1 and the percentage of silencing was measured by RT-PCR and flow-cytometry. Once silenced receptors proceeded to infect them with M. tuberculosis strain H37Rv. Macrophage CD14 and TLR2 KD were infected with Mycobacterium tuberculosis and Mycobacterium bovis (BCG). At 48 hrs. after infection of macrophages part lysed and intracellular bacteria were cultured in Middlebrook 7H10 to evaluate the UFC. We analyzed the expression of mRNA of cytokines (IL-12, IFN-γ, TNF-α, TGF-β and IL-10), nitric oxide synthase (iNOS) as well as the quantification of cytokines by ELISA and concentration of nitrite with the Griess reagent. Results. TLR2 receptor silencing reflected an increase in expression of IL-12, TNF-α, IFN-γ as well as the iNOS mRNA, nitric oxide production. There was a decrease of 95% over the CFU(p <0.001) compared to control infection. Conclusion: These results suggest that the silencing of TLR2 and CD14 activates microbicidal mechanisms providing an environment able to kill bacteria, this is proposed as a new strategy of molecular treatments, silencing genes temporarily promoting an effective immune response to the M. tuberculosis infection.

P4.05.09
Pilot study: cytokine pattern in children under eight years with pulmonary tuberculosis

M. Asturizaga Mallea[1], *D. Correa*[2], *A. Escobar-Gutiérrez*[3], *Y. Flores-García*[2], *L. Pérez-Fernández*[2], *F. Cuevas-Schacht*[2];
[1]*Posgr. C Médicas, Fac Med. UNAM-Instituto Nacional de Pediatria, Mexico, Mexico,* [2]*Instituto Nacional de Pediatria, Mexico, Mexico,*
[3]*Instituto de Diagnóstico y Referencia Epidemiológicos, Mexico, Mexico.*

The IFN-γ assays can help diagnose active tuberculosis in adults, but due to the immunological and clinical characteristics, it may not be as useful in children. Therefore, we decided to assess other cutoff points in the assay as well as other cytokines in patients under eight years, classified in three groups on the basis of culture result, clinical, epidemiological and radiological criteria: chronic lung disease (n=6), confirmed (n=3) and probable (n=9) pulmonary tuberculosis. IFN-γ, TNF-α, IL-10, IL-5, IL-4 and IL-2 were measured in the supernatant of PBMC stimulated with a mixture of early secretory antigenic target-6, culture filtrate protein-10 and tuberculosis 7.7 (QTF-TB Gold Tubes) by the flow cytometry bead array. When the IFN-γ values were interpreted according to Quantiferon-TB Gold, cero confirmed cases and three with probable tuberculosis were positive. No case of the chronic lung disease group responded. When a lower cut off was used, IFN-γ response was positive in one of the confirmed and seven of the probable cases, with no reaction among the control group. The response with other cytokines was heterogeneous in the confirmed and probable tuberculosis groups, although IL-5 and IL-2 were commonly positive. Low or null IL-4 response was observed in most tuberculosis cases. No relation between disease activity and TNF-α or IL-2 levels was found. It is concluded that lowering the Quantiferon-TB Gold assay cutoff point or testing other cytokines may improve immunodiagnostic of tuberculosis in children.

P4.05.10
Dynamics of the immune response to DosR and Rpf antigens of *Mycobacterium tuberculosis* in house hold contacts of tuberculosis patients

*L. Arroyo[1,2], B. Ortiz[1,2], M. Rojas[1,3], L. F. García[1,3], T. Ottenhoff[4], **L. F. Barrera**[1,3];*
[1]Universidad de Antioquia, Medellin, Colombia, [2]Grupo de Inmunología Celular e Inmunogenética, Universidad de Antioquia, Medellin, Colombia, [3]Grupo de Inmunología Celular e Inmunogenética, Instituto de Investigaciones Médicas, Universidad de Antioquia, Medellin, Colombia, [4]Department of Infectious Diseases, Leiden University Medical Center, Leiden University, Medellin, Netherlands.

Previously, we found a predominance of T $CD4^+$ response with a T_{CM} phenotype to selected DosR and Rpf antigens of *M. tuberculosis* (*Mtb*) in LTBI subjects (> 3 years), suggesting that this response may be important to maintain latent infection. To better understand the development of this response, we followed-up for one year the T CD4 and T CD8 expressing iIFNγ, the memory phenotype, and cytokine production in HHC of recently diagnosed TB patients. PBMCs from HHC were cultured for 7 days in presence/absence of DosR (Rv1737c, Rv2029c and Rv2628), Rpf (Rv0867c and Rv2389c), and control ESAT6-CFP10 (E6-C10) and PPD antigens. The frequency of T $CD4^+IFNγ^+$, T $CD8^+IFNγ^+$, and memory phenotype (CD45RO and CD27) was established by flow cytometry. The cytokine production (IL-2, IL-4, IL-5, IL-10, IL-13, IL-15, IL-17, IFNγ and MIP-1α) was determined by the Luminex technology. A significant decrease in the frequency of T $CD4^+IFNγ^+$ cells after 12 months in response to Rv1737c and Rv2029c, and E6-C10 was observed, concomitant with an increase in the frequency of $CD4^+IFNγ^+$ T cells with a T_{CM} phenotype. The levels of IFNγ, IL-10, IL-17, and TNFα in response to both DosR and Rpf antigens decreased significantly after 12 months of the follow-up. **Conclusions.** The decreased frequency of $CD4^+IFNγ^+$ T cells and cytokine production may be an indication of an attenuated inflammatory response to *Mtb* infection. The increased frequency of $CD4^+IFNγ^+$ with a T_{CM} phenotype could be crucial to the control of *Mtb* infection and TB reactivation.

P4.05.11
Functional modulation by Cortisol and/or Dehydroepiandrosterone on THP1-derived macrophages infected with *Mycobacterium tuberculosis*

*B. Bongiovanni[1], D. Mata Espinosa[2], R. Marquez Velasco[3], O. A. Bottasso[1], R. Hernandez Pando[2], **M. L. Bay**[1];*
[1]Institute of Immunology, School of Medical Sciences, National University of Rosario, Rosario, Argentina, [2]Departament of Experimental Pathology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico, Mexico, [3]Department of Immunology, Instituto Nacional de Cardiología Ignacio Chávez, Mexico, Mexico.

Tuberculosis (TB) is an ancient disease caused by the intracellular pathogen *Mycobacterium tuberculosis* (Mtb). Partly because macrophages play a central role in the response against Mtb and our previous work indicating an unbalanced immune-endocrine response in TB patients, we have now studied whether cortisol and dehydroepiandrosterone (DHEA) were likely to modify the macrophage response upon infection with Mtb. Macrophages derived from THP-1 monocytic cell line were exposed to live Mtb strain H37Rv (MOI 5:1) during 3 hours in the presence or absence of cortisol (1 μM) and/or DHEA (1 and 0.1μM). Upon washing, cells were cultured for 1 (T0), 24 (T1) and 96 hours (T2) in the same media with or without hormones. End points included: phagocytic capacity (T0); cytokine levels in macrophage culture supernatants (TNF-α, IL-1β, IL-6, TGF-β and IL-10, T1), and number of CFU in agar-Middlebrook media exposed to lysed macrophages which had been cultured as mentioned (T0, T1 and T2).
Single cortisol-treated cultures had a decreased Mtb phagocytosis respect to untreated counterparts ($p<0.05$). Cortisol, alone or combined with DHEA, inhibited the Mtb-induced production of TNF-α, IL-1β and IL-10 ($p<0.05$). A time-related rise in CFU was seen in control cultures ($p<0.05$) whereas treatment with cortisol and DHEA resulted in an inverse trend ($p<0.05$). Combined treatment with cortisol and DHEA seems to favor the macrophage effector response, in the sense of bacillary growth control, apparently in no close correspondence with the profile of cytokines involved in such regard.

P4.05.12
Assessment the activity of blood phagocytes at tuberculosis of lungs

***O. V. Berdugina**[1], S. N. Skornyakov[1], I. D. Medvinsky[1], A. V. Ershova[1], K. A. Berdugin[2];*
[1]Ural scietyphic research institute of physiopulmonology, Ekaterinburg, Russian Federation, [2]Ural scietyphic research institute of traumatology and orthopedics, Ekaterinburg, Russian Federation.

Phagocitosis is a key element in protection of an organism against tuberculosis mikobakteriya. Studying of possibilities of a flowing cytofluorimetry in an assessment of activity of blood phagocytes of cages at tuberculosis of lungs became the purpose of work. Surveyed 39 people: 14-with an infiltrative form of tuberculosis, 15 - from tuberkuloma, 10 almost healthy people. In work used the CoulterEpicsXL device, Phagotest reagents (Orpegen Pharma), BurstTestKit (Glycotope Biotechnology) and monoclonal antibodies for definition of subpopulations of lymphocytes. Statistical processing is carried out with Statistica program use. It is established that the assessment activity of blood phagocytes is important criterion of determination of activity of tuberculosis of lungs at early stages of supervision and in the course of treatment, the flowing cytofluorimetry allows quickly, precisely and objectively to estimate activity of blood phagocytes. Tuberculosis of the lungs, being accompanied formation tuberkuloma, is characterized by considerable decrease in number and functional and metabolic activity of neutrophil phagocytes and the monocytes, the expressed reduction of number of T - and B - cells, increase in TNK cells. Infiltrative form of tuberculosis within one share of lungs is accompanied by considerable inflammatory reaction (leycocytosis), decrease in number of T - and B - cells, prevalence of cells with index early activation (CD25+), increase is functional - metabolic activity of neutrophil phagocytes. Markers of early activation of a cage can reflect activity of pathological process and be used for forecasting of a course of tuberculosis of lungs.

P4.05.13
Immunological assessment of inflammatory reaction at patients with different forms of tuberculosis of lungs

***O. V. Berdugina**[1], S. N. Skornyakov[1], I. D. Medvinsky[1], A. V. Ershova[1], K. A. Berdugin[2];*
[1]Ural scietyphic research institute of physiopulmonology, Ekaterinburg, Russian Federation, [2]Ural scietyphic research institute of traumatology and orthopedics, Ekaterinburg, Russian Federation.

Studying of biology of a mikobakteriya of tuberculosis in a separation from research of response of an organism on presence of a pathogen is wrong approach to a solution of the problem of treatment of patients. The susceptibility or resistance to this disease, and also dynamics of treatment in many respects is defined by macroorganism response. Inflammatory reaction which develops in the course of supervision becomes one of manifestations of protective reactions. Clarification of conditions of its formation and current is one of problems of the conducted research. 50 patients with various clinical forms of tuberculosis of lungs, and also group of healthy patients are surveyed and treated. Studied clinic - radiological research, the main biochemical indicators, and also definition of immunological indicators of existence of inflammatory reaction. Defined as soluble mediators of an inflammation (a complex interleukins, reagents Bender MedSystems eBioscience, GmbH, and estimated cellular reactions (phagocytosis micro and macro - phagocytes, used reagents of Phagotest reagents firm (Orpegen Pharma) and BurstTestKit (Glycotope Biotechnology). It is established that the indicators characterizing oxidizing explosion are sharply raised in neutrophils at infiltrative tuberculosis. In monocytes at all studied forms of tuberculosis they are a little lowered. Level of interleukin-4 and a factor of a necrosis of tumors in the majority of samples appeared below level of sensitivity of test system. But at patients tuberkuloma level of interleukins-4 made from 5,17 to 8,58 pg/ml. Concentration of TNF was in the range of 24,6 - 39,9 pg/ml of four serum samples.

P4.05.14
Mycobacterium tuberculosis antigen-specific immune responses among tuberculosis lymphadenitis patients

***K. Bobosha**, L. Wassie, M. Habtamu, M. Zewdie, J. Hussien, L. Yamuah, A. Aseffa;*
AHRI, Addis Ababa, Ethiopia.

The reporting rate of extra-pulmonary TB (EPTB) has increased in most high TB burden countries in recent years. Tuberculosis lymphadenitis (TBLN) is one of the most common forms of EPTB and is considered as a local manifestation of a systemic infection. Evaluating the immune responses of TBLN patients to *M. tuberculosis (*MTB*)* specific antigens will provide important inputs to efforts being made towards developing efficient TB diagnostic tools and vaccines. In this study, peripheral blood mononuclear cells (PBMCs), from non-pulmonary TB but clinically, cytologically and/or culture and PCR confirmed TBLN patients (n=48) and healthy controls (n=23) were isolated and frequencies of antigen-specific (ESAT-6, CFP-10, RV2031c (ACR), Ag85B, TB10.4 and PPD) IFN-γ producing T-cells (spot forming units/10^6 PBMCs) were measured using ELISpot assay. Considering PHA as negative and media alone as negative control, the median frequencies of CFP-10- and TB10.4-specific IFN-γ producing T-cells were significantly higher in TBLN patients compared to healthy controls ($p < 0.001$). Both groups showed poor responses to Ag85B. Strong responses to some of the selected TB antigens could demonstrate the role of the antigens in the identification of TBLN cases; however, more detailed analyses are warranted to satisfy the need for specific diagnosis of extra-pulmonary TB cases.

P4.05.15
Integrin alpha2 beta1 modulates MMP-1 expression in Tuberculosis

***S. Brilha**[1], J. C. Porter[2], H. Zecchini[3], J. S. Friedland[1];*
[1]Imperial College London, London, United Kingdom, [2]University College London, London, United Kingdom, [3]Cancer Research UK, Cambridge, United Kingdom.

In tuberculosis (TB) Matrix Metalloproteinase-1 (MMP-1), a collagenase, has a major role in tissue destruction and cavitation. MMP-1 secretion is amplified by networks such as those between monocytes and respiratory epithelial cells. Cell adhesion to the extracellular matrix is mediated by integrins, which can coordinate rapid responses to airway injuries. We hypothesised that adhesion to collagen I modulates MMP-1 secretion in primary Human Bronchial Epithelial cells (NHBEs) in TB.
NHBEs were stimulated with conditioned medium from Mtb-infected monocytes (CoMtb) or control medium, in the presence or absence of coated or free human collagen I. Integrin engagement was studied by neutralising anti-integrin alpha2 and alpha3 antibodies (mAbs), confocal microscopy and laser scanning cytometry. MMP-1 gene expression and secretion was measured by ELISA, Luminex, real-time PCR and functional DQ collagenase assay.

CoMtb stimulated NHBEs, adherent to 100µg/ml coated collagen decreased MMP-1 secretion from 1647±65pg/mL to 1127±91pg/mL (32%). In contrast, free collagen upregulated MMP-1 by 23%. Gene expression was consistent with secretion. Collagenolytic activity was 3-fold higher in absence of collagen than with coated collagen and 5-fold higher in the presence of free collagen ($p<0.05$). MMP-1 suppression with coated collagen was abolished by 2mM EDTA ($p>0.05$). Adhesion to coated anti-alpha2 mAbs reduced MMP-1 secretion by 30% ($p<0.01$). Confocal microscopy showed integrin alpha2 beta1 polarization on coated collagen while free collagen I caused integrin alpha2 beta1 microclustering.
In summary, MMP-1 activity, gene expression and secretion is regulated by collagen-cell interactions and integrins are potentially crucial in the control of inflammatory tissue destruction in TB.

P4.05.16
Degradation of cholesterol is essential for the pathogenicity of _Mycobacterium tuberculosis_

***M. Brzezinska**, I. Szulc, M. Klink, A. Brzostek, M. Kielbik, Z. Sulowska, J. Dziadek;*
Institute of Medical Biology, Polish Academy of Sciences, Lodz, Poland.

Objective: *Mycobacterium tuberculosis* (Mtb) cholesterol oxidase (ChoD) and ketosteroid dehydrogenase (KstD) enzymes are involved in cholesterol degradation but its role in the infection of human macrophages is not preciously defined. Methods: Using the technique of gene replacement based on the process of homologous recombination we obtained MtbH37Rv mutants lacking functional copy of ChoD (Δ*choD)* or KstD (Δ*kstD*) as well as complemented strains obtained by insert intact *choD* or *kstD* genes. The ability of MtbH37Rv and its mutants to replicate in human resting macrophages and their impact on the macrophages functional response was evaluated. We also assessed the TLR2 involvement in the activation of bactericidal activity of macrophages. Results: Δ*choD* and Δ*kstD* mutants grew weaker in macrophages in comparison to wild-type and complemented strains. Blocking of TLR2-signalling pathway significantly increased the survival of both mutants in contrast to wild-type strain. Only mutants stimulated macrophages to NO production that was blocked in the presence of TLR2-signalling pathway inhibitor. In turn, ROS production was significantly less inhibited by mutants than by wild type and complemented strains. Wild-type and complemented strains contributed to significantly higher production of IL-10 by macrophages than Δ*choD* strain. Conclusion: We indicate a relationship between degradation of cholesterol by Mtb, Mtb intracellular survival and functional responses of macrophages. Cholesterol metabolism by Mtb may contribute to the production of specific virulence factors that affect NO/ROS production and disrupt the host cell TLR2-signalling pathway.

P4.05.17
Granzyme A is an additional marker for tuberculosis (TB) to discriminate between patients with active disease and subjects with latent infection

***N. Caccamo**[1], V. Orlando[1], M. La Manna[1], D. Di Liberto[1], S. Cutrera[1], F. Dieli[1], V. Vanini[2], E. Petruccioli[2], D. Goletti[2];*
[1]Department of Biopathology, Palermo, Italy, [2]Translational Research Unit, Department of Epidemiology and Preclinical Research, INMI, Roma, Italy.

Tuberculosis is a major global health problem, with an estimated 8.7 million cases and 1.4 million deaths in 2011. Cytotoxic molecules such as granulysin, perforin and granzymes produced by cytolytic T cells directly contributes to immune defense against tuberculosis (TB). It is still difficult to discriminate active disease, latent infection (LTBI), past TB patients subjects based on Quantiferon TB-Gold in tube (QFT-IT) response; therefore the aim of this study was to evaluate if the responses to granzyme A-could help to discriminate between the different TB stages. We compared the release of granzyme A in whole blood cells stimulated with QFT-IT. We found significant higher level of this cytototoxic molecule in LTBI and past TB subjects compared to the level found in patients with active disease (at least $p<0.001$).
These results suggest that the evaluation of the level of cytotoxic molecules such as granzyme A could be considered as a biomarker of TB to better discriminate among LTBI, active disease, past TB.

Mycobacterium tuberculosis Beijing induces a tolerogenic phenotype in dendritic cells

*J. Reyes-Martínez[1], **A. Chávez-Blanco**[2], T. Santos-Mendoza[3], J. Serafín-López[1], C. Sandoval-Montes[1], L. Flores-Romo[3], S. Estrada-Parra[1], I. Estrada-García[1], R. Chacón-Salinas[1];*
[1]ENCB, IPN, Mexico City, Mexico, [2]INCAN, SS, Mexico City, Mexico, [3]CINVESTAV, IPN, Mexico City, Mexico.

Dendritic cells (DC) play a pivotal role during the immune response to Mycobacterium tuberculosis (Mtb). Different works have demonstrated that Mtb inhibits several functions of DC in order to delay and modify T cell responses. Furthermore, there is increasing evidence about the genetic diversity of Mtb strains and how these affect their interaction with the immune system. Beijing genotype has attracted attention because of their high prevalence and multi-drug resistance. Although it is known that this genotype is particularly hypervirulent and activates differentially macrophages when compared to other genotypes, little is known about its interaction with dendritic cells. In order to address this issue, bone marrow derived DC (BMDC) were stimulated with protein extracts from BCG, H37Rv, Canetti and Beijing genotypes. We observed that Beijing was unable to induce maturation of DC as assessed by MHC-II molecule expression, contrasting with other mycobacteria. Moreover DC stimulated with Beijing failed to produce IL-12 and TNF-α, but was the only mycobacteria able to induce IL-10 in BMDC. Interestingly, Beijing induced CCR7 and PDL-1 on BMDC, but was unsuccessful to induce CD86. These results points that Beijing is able to modulate DC functions that could be related to the pathogenesis induced by this genotype.

P4.05.19
Macrophage exposure to crystalline silica promotes growth of Mycobacterium tuberculosis by deregulating cell death pathways

***L. Chávez-Galán**, L. Torre-Bouscoulet, R. Pérez-Padilla, A. Ramírez-Venegas, I. Sada-Ovalle;*
National Institute of Respiratory Diseases, Distrito Federal, Mexico.

Background: Inhalation of crystalline silica (CS) particles increases the risk for pulmonary tuberculosis. The exact immune mechanism through which CS exposure is associated with *Mycobacterium tuberculosis* (Mtb) infection is unclear. The oxidative stress theory turns on cell death and interferes with the ability of phagocytic cells to eliminate pathogens, which might contribute to spread the infection. We speculate that deregulation of apoptosis *vs.* necrosis could explain the association between exposure to CS and tuberculosis. Methods: THP-macrophages were exposed to CS and infected with Mtb. Expression of surface markers was analyzed by flow cytometry. Cell death was assed by TUNEL. Intracellular expression of JNK1/2, ASK1, caspase 9, P-p38, Bcl-2 and Mcl-1 was analyzed by Western blott and cytokines by ELISA. Results: Pre-exposure to CS limits the control of Mtb growth. Reduced expression of TLR2, Bcl-2 and Mcl-1 and increased the expression of JNK1 and ASK1 molecules, was observed after macrophage exposure to CS. We identified that priming uninfected macrophages with CS increased DNA fragmentation but not in Mtb-infected macrophages. Finally, when pre-exposed macrophages were infected with Mtb the concentration of TNF-alpha, IL-1beta and caspase-9 expression increased. This pro-inflammatory profile of the macrophage unbalanced the apoptosis/necrosis pathway. Conclusions: CS exposure sensitizes macrophages to present cell death by inducing activation of the MAPK intracellular pathway. Secretion of TNF-alpha and IL-1beta by M.tb-infected macrophages promotes necrosis. Deregulation of cell death pathways may be detrimental to the host defenses because it favors the release of viable bacilli and; therefore of tuberculosis.

P4.05.20
Mycobacterium tuberculosis impairs autophagic flux in human dendritic cells by ESX-1

*M. Etna[1], A. Romagnoli[2], E. Giacomini[1], M. Pardini[1], M. Corazzari[2], R. Simeone[3], R. Brosch[3], G. Fimia[2], **E. M. Coccia**[1];*
[1]Istituto Superiore di Sanità, Roma, Italy, [2]National Institute for Infectious Diseases "L. Spallanzani", Roma, Italy, [3]Institut Pasteur, Paris, France.

The autophagic process has been investigated in human primary dendritic cells (DC) to optimize Mycobacterium tuberculosis (Mtb) vaccine strategies. Indeed, given the importance of autophagy in different facets of antigen presentation, we studied this process in DC, which represent key effectors of the immune response against Mtb.
We have observed that Mtb, but not the avirulent BCG, inhibits the late steps of autophagy and that a functional ESX-1 secretion system is required for this block. Infecting DC with recombinant BCG and H37Ra Mtb strains expressing the RD1 region, BCG::RD1, or the trascriptional factor phoP, (H37Ra::phoP) involved in the expression of the ESAT-6 molecule, we observed a restored capacity of these strains to induce autophagy blockage.
In addition, treatment with rapamycin (a pharmacological inducer of autophagy) restores autophagy in Mtb-infected DC and enables DC to prime a robust Th1 response. These findings underscore a previously unrecognized link between Mtb virulence and autophagy inhibition and, together with the findings on maturation and cytokine expression, indicate that Mtb may control DC immunoregulatory functions through ESX-1.

P4.05.21
Virulence, immunopathology and transmissibility of selected strains of M. tuberculosis from epidemiological studies in Colombia evaluated in a murine model

***M. F. Cornejo**[1], J. Robledo[2], D. Mata[1], B. Marquina[1], J. Barrios[1], L. F. García[3];*
[1]Section of Experimental Pathology, Department of Pathology, National Institute of Medical Sciences and Nutrition Salvador Zubirán, Mexico City, Mexico, [2]School of Health Sciences, Universidad Pontificia Bolivariana, Medellín, Colombia, [3]Instituto de Investigaciones Médicas and Sede de Investigación Universitaria, Universidad de Antioquía, Medellín, Colombia.

Until recently the M. tuberculosis (Mtb) complex was considered genetically a highly conserved group of bacteria, however, over the last decade, a wide variety of genotypes have been discovered among Mtb strains. Also, epidemiological data has shown that differences in transmissibility and virulence could be related to the genetic background of the organism.
Six Mtb strains were selected based on relevant clinical/epidemiological patterns from pulmonary tuberculosis patients from Colombia and tested in a well-characterized BALB/c mouse model of progressive pulmonary tuberculosis to examine the course of infection in terms of strain virulence (mouse survival, lung bacillary loads, histopathology) and immunological response (cytokine expression). Also, a mouse model of transmissibility consisting of prolonged cohousing of infected and naïve animals was tested.
We observed that particular outbreak strains caused distinct disease patterns, regardless having the same genotype (LAM): 1) two of the strains showed high bacterial loads and more tissue damage including necrosis towards the 3rd week; 2) in contrast, the rest of the isolates showed lower bacterial loads and formation of granulomas and pneumonia around the 3rd week ; 3) all six strains could be transmitted to nïve animals.
According with epidemiological data, the two more virulent strains were isolated from females while the rest were obtained from men.
In conclusion, genetically different Mtb strains may affect the progression of the disease, and establishing the link between virulence and transmission is important to reach the goal for Tb control.

P4.05.22
Induction of Transcription Factors involved in T lymphocyte differentiation in BCG vaccinated subjects and pulmonary Tuberculosis patients with antituberculosis therapy

***N. E. Corral-Fernandez**, N. Cortez-Espinosa, M. Salgado-Bustamante, S. Romano-Moreno, S. E. Medellín-Garibay, B. Hernández-Castro, J. J. Macias-Mendoza, R. González-Amaro, D. P. Portales-Perez;*
UASLP, San Luis Potosí, Mexico.

Tuberculosis is still a leading cause of death in the world, by the intracellular pathogen Mycobacterium tuberculosis. One of the many strategies to evade the dissemination of the pathogen is through BCG vaccination. Acquired immune response mediated by subpopulations of T cells, like Th1 (TBET), Th2 (GATA3), Th17 (RORC2) and Treg (FOXP3) have been described. However, it remains unknown the precise role of Th cells after the antituberculosis therapy and after BCG vaccination. The aim is to evaluate the expression of transcription factors in peripheral blood mononuclear cells from patients with pulmonary tuberculosis after antituberculosis therapy and in subjects who received the BCG vaccine. Blood samples were obtained from healthy subjects and patients at times 0, 2 and 6 months after BCG vaccine or antituberculosis therapy. Mononuclear cells were cultivated for 48 hours in the presence of ESAT-6 10 µg/ml and CFP-10 10 µg/ml and the transcription factors were measured using Real-Time PCR. We found in BCG vaccinated subjects, a decrease in the expression of FOXP3 after 2 months of having received the vaccine, and an increase in the expression of RORC2 after 6 months. For tuberculosis patients, high levels of FOXP3 and low levels of RORC2 were observed. In contrast, after 2 months of therapy, the expression of TBET and FOXP3 were decreased and GATA and RORC2 were increased. In conclusion, the BCG vaccine induces Th17 cells and it may contribute to protected immune response and the 2 months-antituberculosis therapy induces Th17 and Th2 cells in tuberculosis patients.

P4.05.23
A partly normalization in the immune-endocrine circulating profile of tuberculosis patients undergoing specific treatment

*A. Diaz[1], B. Bongiovanni[1], L. D'Attilio[1], N. Santucci[1], G. Dídoli[1], S. Radcliffe[2], N. Brandan[3], L. Nannini[3], O. A. Bottasso[1], **M. L. Bay**[1];*
[1]Institute of Immunology, School of Medical Sciences, National University of Rosario, Rosario, Argentina, [2]Clinical Laboratory, Provincial Hospital of the Centenary, Rosario, Argentina, [3]Respiratory Diseases, Eva Perón School Hospital, Granadero Baigorria, Argentina.

Tuberculosis (TB) continues to be a global health problem. Extending our earlier findings in which untreated TB patients revealed imbalanced immune-endocrine responses, we have now analyzed the immune-endocrine profile throughout the 6-month course of specific treatment and 3 month following its completion. Twenty healthy controls (HCo) and 19 age- and sex-matched TB -HIV negative-patients were bled at diagnosis (T0), two (T2), four (T4) and 6 months (T6) of treatment as well as 3 months later (T9). At diagnosis patients showed a low BMI ($p<0.001$) and lymphoproliferative response ($p<0.05$), without no major changes in clinical laboratory tests; respect to HCo. The two former ones increased during treatment. Lymphoproliferation reached values similar to HCo at T9, whereas BMI showed a partial recovery remaining below the values seen in HCo. Analysis of plasma endocrine compounds (Cortisol and dehydroepiandrosterone -DHEA), cytokines (IFN-γ, IL-6, TGF-β, IL-4, IL-17), C reactive protein and peripheral T regulatory cells were carried out at the same time-points. Pro-inflammatory mediators were increased at T0, as was the Cortisol/DHEA ratio ($p<0.01$ vs. HCo, all cases). Such an increase coexisted with a high percentage of T regulatory cells, augmenting even further at T2 ($p<0.05$); the time when inflammatory compounds decreased. Throughout treatment Cortisol remained a little but significantly increased, whereas DHEA levels reached the values seen in HCo, collectively resulting in a restored Cortisol/DHEA ratio. While the clinical improvement resulting from antituberculosis treatment coincided with a decreased inflammatory pattern, the activity of the hypothalamic-pituitary-adrenal axis remained somewhat disturbed.

P4.05.24
Mycobacterium bovis culture filtrate proteins induces expression of autocrine prolactin loop enhancing inflammatory response in monocytes THP1

***C. Estrada**[1], G. López[1], A. Pereira[2];*
[1]Centro de Investigación y Asistencia en Tecnología y Diseño del Estado de Jalisco, A.C., Guadalajara, Mexico, [2]Universidad de Guadalajara, Guadalajara, Mexico.

Prolactin (PRL) of pituitary origin is known to regulate many physiological functions such as proliferation, differentiation and cell survival. Also, its purpose is to act as an immunomodulator, which can interfere with lymphocyte activation and cytokine production. It has recently been associated with carcinogenesis and exacerbation of autoimmune diseases. The Tuberculosis in humans induces increased physiological levels of PRL, however, their involvement in disease progression has not been determined. The aim of this work was to investigate whether PRL autocrine modulates the proinflammatory response in THP1 monocytic cells incubated with Mycobacterium bovis culture filtrate proteins (CFP). The monocytes stimulated with CFP-M.bovis express autocrine Big PRL 60-80 kDa and short isoforms of PRLr 40 and 50 kDa. RT-PCR showed an increase mRNA of PRL and PRLr vs untreated cells $P<0.001$. For immunocytochemistry the PRLr and PRL were observed in medium, membrane and nucleus. As expected, M.bovis induced high concentrations of nitric oxide, IL1-β, (681.5 pg/mL) and IL-6 (600.4 pg/mL), and TNF-α (28.7 pg/mL). The levels were measured by the Greiss reaction and ELISA. However proinflammatory cytokines IL1-β, (100 pg/mL) and IL-6 (110.5 pg/mL), and TNF-α (16.4 pg/mL) significantly decrease secretion levels by inhibition of the PRLr. In summary, our results suggest the CFP-M.bovis induces overexpression of short isoforms of PRLr and autocrine synthesis of Big PRL in myeloid cells. This autocrine mechanism suggesting a primary pro-inflamatory role of this hormone and these results suggest the PRL autocrine might have a crucial role in resolving inflammation.

P4.05.25
Immunogenicity assessment of live TB vaccine candidates in human primary dendritic cells

***M. P. Etna**[1], E. Giacomini[1], M. Pardini[1], M. Severa[1], D. Bottai[2], R. Brosch[3], E. M. Coccia[1];*
[1]Istituto Superiore di Sanità, Roma, Italy, [2]Università di Pisa, Pisa, Italy, [3]Institute Pasteur, Paris, France.

Vaccination strategies against Tuberculosis (TB) by engineering new mycobacterial strains are based on either on improvement of BCG (Bacillus Calmette-Guerin) vaccine through addition of relevant genes or attenuation of Mycobacterium tuberculosis (Mtb) through deletion of virulence genes.
Several live vaccine candidates have been tested for safety, immunogenicity and protection in pre-clinical studies in animal models. However, due to the different outcome of Mtb infection in animals versus man, it would be critical to test live vaccine in a human experimental setting composed by primary dendritic cells (DC), key effectors of the immune response against Mtb.
To this aim, we are investigating DC response to infection with BCG and Mtb strains mutated in ESAT-6 and CFP10 complex, whose virulence attenuation was previously characterized in mice. By a comparative analysis of DC phenotype, pro-inflammatory and regulatory cytokine production profile and the capacity to promote T cell response, differences were observed in immunogenic potential of the recombinant BCG and Mtb clones.
Collectively, our data indicate that a model based on human DC could be used to select the most immunogenic vaccine candidate among the available recombinant strains displaying a similar attenuated phenotype. In addition a deeper understanding of host-pathogen interaction will improve our knowledge on human vaccinology and for designing of vaccination strategies against Mtb.

P4.05.26
B cells are important to modulate the immune response against Mycobacterium tuberculosis (Mtb) in mice

***I. C. Fontoura**, A. Gembre, É. Padilha, T. Malardo, A. A. M. Coelho-Castelo;*
University of São Paulo, Department of Immunology, Ribeirão Preto, Brazil.

Tuberculosis is the second cause of death by infectious disease in the world. The unique vaccine certified nowadays is BCG. However, the role of B cells in BCG immunization and tuberculosis infection is poorly understood. We want to investigate the role of B cells in tuberculosis progression in mice. C57BL/6 and Bko mice were immunized with BCG and 30 days after immunization, mice were infected with Mtb H37Rv. After 10, 30 or 60 days post infection, the percentage of B cells and T memory cells were determined by flow citometry in lungs. In parallel the bacilli charge was determined in the lungs and the inflammatory infiltrate was shown by histological analyses using HE. Adittionally, mRNA of INF-γ, IL-6, IL-17 and TGF-β were quantified using RT PCR. Results shown that in animals only infected with Mtb, lack of B cells caused an exacerbation of lungs pathology by promote an increase of inflammation and migration of memory T cells, although didn't not affected the number of CFU. Even in lung of animals previously immunized, BCG couldn't be able to promote protection in Bko mice, because this immunization did not caused a significant reduction of inflammation and CFU as seen in WT mice. Additionally, lack of B cells induced a drastic decrease in expression of IFN-γ mRNA and increase expression of IL-6, TGF-β and IL-17 mRNA in lungs of Bko. B cells seem to be important to control tuberculosis immunopathology and bacterial growth, beyond to promote the optimal efficacy of BCG immunization.

P4.05.27
***Mycobacterium leprae* DNA and cytokine profile of household contacts resident in Governador Valadares, MG, Brazil.**

*R. S. Gama[1], P. Marçal[1], R. Cypriano[2], A. Castelo Branco[2], E. N. Sarno[3], M. O. Moraes[3], **L. A. O. Fraga**[1];*
[1]Universidade Vale do Rio Doce, Governador Valadares , Minas Gerais, Brazil, [2]CREDEN-PES, Governador Valadares , Minas Gerais, Brazil, [3]FIOCRUZ, Rio de Janeiro, Brazil.

Hansen's disease has a long incubation period and essentially clinical diagnosis. Household contacts, which live with patients, may be infected and asymptomatic. Therefore, the validation of a diagnostic method to identify infection earlier is required. We evaluated the qPCR as a tool to identify DNA of ML in samples of dermal scrapings of patients and their household contacts, and also the cytokine profile of those individuals to indicate the possibility of existing subclinical infection. We had 156 individuals, 43 index cases and 113 household contacts. The qPCR was performed to amplify 16S rRNA fragment, specific for ML and was positive in 48.8% of 43 patients with leprosy while the BAAR was positive in only 30.2% of the total. For household contacts 23.9% of 113 subjects showed bacterial DNA. The intracellular cytokine pattern was evaluated following antigen stimulation. Patients classified as PB showed high frequency of IL-10 high producer cells. However, it was observed a higher frequency of IFN-γ high producer cells in these individuals when compared to MB patients. On the other hand, MB patients showed a higher frequency of IL-4 and IL-10 high producer cells than PB. The cytokine profile of household contacts, showed a higher frequency of IFN-γ high producer cells among PB household contacts, in contrast, higher frequency of IL-4 high producer cells among MB household contacts. These data reinforce the relevance of monitoring household contacts that showed qPCR positive for ML and higher frequency of T cells producing IL-4 and IL-10 cytokines. Financial support: CNPQ/FAPEMIG/FIOCRUZ/UNIVALE/CREDEN-PES.

P4.05.28
Apoptotic body like liposomes carrying phosphatidic acid enhance antimicrobial and anti-inflammatory innate immune response

*E. Greco[1], M. B. Santucci[1], F. Taus[1], A. Serafino[2], A. Ciccaglione[3], N. Caccamo[4], R. Nisini[3], F. Dieli[4], T. H. Ottenhoff[5], **M. Fraziano**[1];*
[1]Department of Biology, University of Rome "Tor Vergata", Rome, Italy, [2]Institute of Translational Pharmacology, National Research Council, Rome, Italy, [3]Department of Infectious, Parasitic and Immunomediated Diseases, Istituto Superiore di Sanità, Rome, Italy, [4]Department of Biopathology and Medical and Forensis Biotechnologies, University of Palermo, Palermo, Italy, [5]Department of Infectious Diseases, Leiden University Medical Center, Leiden, Netherlands.

We have generated novel asymmetric liposomes with phosphatidylserine (PS) distributed at the outer membrane surface, to resemble apoptotic bodies, and phosphatidic acid at the inner layer, to promote phagolysosome maturation, as a strategy to enhance innate anti-mycobacterial activity in phagocytes while limiting the inflammatory response. Our results show that the stimulation of human macrophages with apoptotic body-like liposomes carrying phosphatidic acid (ABL/PA) i) promote maturation of phagolysosomes containing *Mycobacterium tuberculosis* (MTB); ii) enhance intracellular MTB killing in infected type-1 and -2 macrophages; iii) induce intracellular killing of endogenous pathogens in bronchoalveolar lavage cells from 4 patients with active pulmonary tuberculosis and 1 patient with Klebsiella pneumonitis. Moreover, the intranasal administration of ABL/PA in MTB infected mice dramatically reduced pulmonary mycobacterial burden, with a concomitant 10 fold reduction of serum TNF-α, IL-1β, and IFN-γ in comparison with untreated mice. Furthermore, ABL/PA stimulated macrophages down-regulate Tumor Necrosis Factor (TNF)-α, Interleukin (IL)-12, IL-1β, IL-18 and IL-23 and up-regulate Transforming Growth Factor (TGF)-β without altering IL-10, IL-27 and IL-6 mRNA expression. Finally, when ABL/PA stimulated macrophages were used as target cells and allogeneic purified naïve CD4+ T cells were used as responder cells, in a mixed lymphocyte reaction model, a dramatic inhibition of alloreactive CD4+ T cell proliferation was observed. Altogether, these results suggest that apoptotic body-like liposomes may be used as a Janus-faced immunotherapeutic platform to deliver polar secondary lipid messengers, such as PA, into phagocytes to improve and recover phagolysosome biogenesis and intracellular pathogen killing while limiting the potentially pathogenetic inflammatory response.

P4.05.29
Proteomics reveals dynamic phagosomal environment during *Mycobacterium* -HIV co-infection

***R. Ganji**[1], S. Dhali[2], A. Rizvi[1], S. Rapole[2], S. Banerjee[1];*
[1]University of Hyderabad, Hyderabad, India, [2]National centre for cell science, Pune, India.

Mycobacterial infection is a major cause for increased mortality in HIV infected patients. In order to understand the coalition between Mycobacteria and HIV that makes these diseases more destructive when confronted together, we undertook a proteomics approach to identify differentially regulated proteins during intra-phagosomal phase of infection in macrophages under mycobacteria-HIV co-infection. A comparative protein expression pattern of host proteins during mycobacterial and mycobacteria-HIV co-infection of macrophages revealed 95 phagosomal and 70 mitochondrial proteins differentially regulated. An extreme cytoskeletal rearrangement was observed with categorical up-regulation of energy metabolism proteins during co-infection. Purinergic receptors, which are capable of adjusting cellular metabolic needs and also help HIV entry, were observed to be upregulated during co-infection. Interestingly, co-infected host cells mounted augmented inflammatory response, as evident from increased manganese superoxide dismutase and intracellular ROS levels. 94 mycobacterial proteins were differentially regulated upon co-infection, majority of which belonged to intermediary metabolism, respiration, cell wall synthesis and information pathways. During co-infection, Mycobacteria showed increased expression of proteins of ESX secretion systems that are instrumental in secretion of virulent proteins. An increased expression of cAMP dependent regulator (Rv2565), Rv1265 (regulated by cAMP

dependent regulator) and RecF (DNA repair protein) upon co-infection may protect mycobacteria from increased host ROS levels. Altered expression of toxin-antitoxin family of proteins during mono- and co-infection suggested regulated mycobacterial stress response that may influence programmed cell death. Conclusively, proteomics data suggested a dynamic host-pathogen environment during co-infection leading to identification of critical factors that explained the coalition between HIV and mycobacteria.

P4.05.30
Diagnosis of latent tuberculosis in immunosupressed patients with inflammatory bowel diseases

M. Ghermi[1,2]*, M. Kallel-Sellami*[2]*, L. Kallel*[3]*, L. Laadhar*[2]*, A. Filali*[3]*, S. Makni*[2]*;*
[1]*University of Sidi Bel Abbes, Sidi Bel Abbes, Algeria,* [2]*Laboratory of immunology, La Rabta Hospital, Tunis, Tunisia,* [3]*Service Gastroentérologie A, Hôpital La Rabta, Tunis, Tunisia.*

Objective: This study was conducted in patients with inflammatory bowel diseases to evaluate the performance of Mycobacterium tuberculosis antigen-specific interferon-γ releasing assay (QuantiFERON®-TB Gold In-Tube) for the diagnosis of latent tuberculosis infection (LTBI) comparing to TST, to assess the impact of immunomodulator (IM) treatment in their performances and to analyze whether IGRA positivity is related to genetic susceptibility by screening for INFG+874T→A SNP.
Material and methods: TST by Mantoux method and QuantiFERON®-TB Gold In-Tube (QFT-GIT) in accordance with manufacturer's instructions, were prospectively performed in 100 consecutive IBD patients and 54 healthy individuals. The SNP genotyping was done by an ARMS-PCR technique.
Results: A better agreement was observed between test's results in controls (κ=0.40) than in patients (κ=0.16). Although QFT-GIT results were unaffected by IM therapy, the mean mitogen response was reduced in immunosuppressed patients (8.06 UI/ml) when compared to the rest of patients and controls (12.70 UI/ml). Similarly, lesser TST positivity was observed in those under IM (9.8%vs20.5%). Among the 12 QFT+ subjects, 10(88.3%) had the susceptibility allele (A). Additionally, 6 of them were homozygote for this allele (AA).
Conclusion: Although IM weakens the immunity strength, QFT-GIT seems to be,as previously described, more accurate for detecting LTBI's cases that would otherwise be missed using solely TST. In a large vaccinated population, QFT-GIT appears more reliable for excluding a false positive TST. Even though, the (INFG +874TA) SNP has been frequently associated with active tuberculosis, it seems that this SNP can also be associated with the latent form.

P4.05.31
CD4+ and CD8+ T cells producing IL-17 specific-ESAT-6 or CFP10 M.tuberculosis antigens correlate with therapy successful in MDR-TB patients

Y. Gonzalez*, M. A. Vega Popotla, M. Muñoz-Torrico, M. Salazar Lezama, M. Torres;*
National Instituto of Respiratory Diseases, Mexico City, Mexico.

Multidrug-resistant tuberculosis (MDR-TB) is a disease caused by Mycobacterium tuberculosis (*M. tuberculosis*) strains that are resistant at rifampicin and isoniazid the most effective anti-TB drugs, entails extended treatment and expensive and toxic regimens, higher rates of treatment failure and death. With the aim of assessing immunological biomarkers that can aid with MDR-TB treatment efficacy, we enrolled six MDR-TB patients and followed during drug therapy under program Directly Observed Therapy (DOT). Blood samples were obtained before and monthly trough 2 year of treatment. Then peripheral mononuclear cells (PBMC) were isolated and the frequency of IFN-g producing cells and CD4+ and CD8+ T cells producing IFN-γ, IL-2, IL-4 and IL17 in response to the *M. tuberculosis* antigens ESAT-6 and CFP10 or PPD were assessed by ELISpot and FACS assays respectively. The overall rate cure was of 100%. The successful of MDR-TB treatment was accompanied by a significant reduction of CD4+T and CD8+ T cells producing IL-17 in response to ESAT-6 and CFP-10 (P≥0.05). An inverse response was observed on CD8+ T cells producing IL-17 in response to PPD (P=0.05). We did not find correlation in the CD4+ or CD8+ T cells producing IFN-γ, IL-4, IL-2 or IFN-γ with successful therapy. These findings suggest a correlation of CD4+ and CD8+ specific T cell producing IL-17 with mycobacterial load, which also decrease during successful therapy and suggest that CD4 and CD8 T cell producing IL-17 could represent a potentially useful parameter in the treatment of MDR-TB.

P4.05.32
Attenuation of BCG Delays Cell-to-Cell Spread in the Lung and Promotes its Clearance by T cells

P. Grace*, J. Ernst;*
New York University School of Medicine, New York, NY, United States.

To identify differences between persistent and resolving mycobacterial infection, we compared the course of infection with *M. bovis* BCG Pasteur or *M. tuberculosis* H37Rv in WT and TCRβ/δ$^{-/-}$ mice. *M. tb*-infected TCRβ/δ$^{-/-}$ mice die ~42 d post infection (p.i.), while BCG-infected TCRβ/δ$^{-/-}$ and WT mice both survived >150 days p.i. TCRβ/δ$^{-/-}$ mice infected with 3x10^3 BCG had 10^5 bacteria in lungs 100 days p.i., while WT mice had no detectable CFU at that time, indicating that T cells promote elimination of BCG. We then compared the distribution of bacteria in subsets of lung myeloid cells. 14 d p.i., only 12% of Rv-infected cells were AM, indicating that Rv spreads rapidly to other lung phagocytes. At the same time point, 40% and 82% of BCG-infected cells are AM in WT and TCR β/δ$^{-/-}$ mice, respectively, implying that BCG does not spread efficiently beyond AM, and that T cells prevent spread of BCG beyond AM. 150 days p.i. in TCR β/δ$^{-/-}$ mice, BCG spreads beyond AM and the cellular distribution resembles that of *M. tb*. We conclude that the attenuation of BCG delays cell-to-cell spread in the lung; T cells prevent the further spread of BCG and eliminate the infection.

P4.05.33
IFN-α adjuvant effect in BCG-vaccinated mice against mycobacterial infections

M. Godinez Flores[1]*, O. Rojas-Espinoza*[2]*, S. Giovana*[3]*, R. Hernandez Pando*[4]*, L. Gabriele*[5]*,* ***G. G. Guerrero***[6]*;*
[1]*Instituto Nacional de Cancerologia (INCAN), Distrito Federal, Mexico,* [2]*Laboratorio de Inmunobiologia. ENCB-IPN, Distrito Federal, Mexico,* [3]*Immunotherapy Experimental lab. INCMNSZ, Distrito Federal, Mexico,* [5]*Experimental Immunotherapy lab. Department of Hematology, Oncology and Molecular Medicine, Rome, Italy,* [6]*Unidad Academica de Ciencias Biologicas, Zacatecas, Mexico.*

Tuberculosis is still a global health problem. The current vaccine BCG, is the only prophylatic measure for *M. tuberculosis* (*MTb)*, however, it fails to protect adults from pulmonary Tb. Heterologous prime-boost protocols have been demonstrated to promote long-term memory responses. T cellular responses play a key role in the defense against *MTb*. Type I interferons (IFN-I) (α/β) are cytokines that exerts profounds effects in DCs function as well as in T cellular responses. There is a controversial issue on *in vivo* effects of type Í IFNs on mycobacterial infections. In a preliminary study, we have found that IFN-α exerts mostly a systemic immune protection (reduction of CFUs in spleen). However, the precise role of IFN-α in mediating an adjuvant effect able to improve BCG or other Ag-based vaccines *in vivo* has to be assessed. Thus, the objective of this study was to investigate at different intervals of IFN-α boosting of BCG primed BALB/c adult mice, the IFN-α role in augmenting BCG immunogenicity *in vivo*. Here, we found that intramuscular administration of IFN-α specifically associated to BCG vaccine, exerted a mostly protector effect when the BCG primed mice received a very small concentration of IFN-α at successive days (two weeks after BCG priming) than at intervals of two weeks. Preliminary results using electronic microscopy suggest that IFN-α might promote germinal centers in spleen. Overall our findings provide evidence of the positive role of IFN-α as a potential candidate to be used in BCG-based vaccines against mycobacterial infections.

P4.05.34
Analysis of polymorphisms in TLRs and FcgRs in susceptibility to tuberculosis in a Mexican population

S. Hernández Bazán[1], *B. Sánchez*[2], *E. Ortega*[1];
[1]*Instituto de Investigaciones Biomédicas, UNAM, D. F., Mexico,*
[2]*Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, D. F., Mexico.*

Tuberculosis is an infectious disease caused by *Mycobacterium tuberculosis*. In México, specifically in the state of Veracruz, there´s a relative high prevalence, so it´s important to identify factors which affect the susceptibility to TB in this population. To investigate the influence of genetic variants in TLRs and FcγRs in TB, we conducted a case-control study for the polymorphisms: *TLR1* (p.N248S), *TLR4* (p.D299G; p.T399I), *TLR6* (p.S249P), *TLR10* (p.A163S; p.V298A), *FCGRIIA* (p.R131H) and *FCGRIIIA* (p.V158F).
In a total of 125 cases and 272 controls, we found a protective association to the *TLR4* 299G and 399I variants (OR=0.268 and OR=0.179 respectively) when comparing between alleles. Although the association didn´t reach statistical significance (p=0.062 and p=0.063). A similar association (OR=0.299, p=0.236) was found when comparing genotypes 399TT versus 399TI.
The variant 131H of *FCGRIIA* was found associated with susceptibility to TB when comparing between alleles and homozygotes (OR=1.586, p=0.106 and OR=1.301, p=0.087 respectively), which were not statistically significant.
For *TLR4* SNPs, the haplotype G-I was more frequent in controls than in cases (2% and 0.4%, p=0.085) and the D-T haplotype was more frequent in cases than in controls (99.2% and 96.9%, p=0.049). The analysis of linkage disequilibrium (LD) indicated that *TLR4 (chr:9, r^2=0.6)* and *TLR10 (chr:4, r^2=0.85)* polymorphisms were in LD.
Our results so far indicate that none of the SNPs analyzed were statistically associated with TB in our population. However we found several correlations with other studies in different populations.

Cathepsin S at the crossroads between innate and adaptive immunity to TB infection

A. Lau, V. Singh, A. Talal, ***Z. Hmama****;*
University of British Columbia, Department of Medicine, Vancouver, BC, Canada.

Although the TB vaccine (derived from the non-pathogenic mycobacterium M. bovis bacillus Calmette-Guérin, or BCG) is generally safe and rarely induces disease in human, it appears to mimic virulent M. tuberculosis (Mtb) strains in their capacity to inhibit macrophage (MØ) functions that initiate adaptive immune response. Our investigations have revealed that MØ infection with conventional BCG down-modulates surface expression of mature MHC class II molecules by mechanisms that are in part dependent on the inhibition of Cathepsin S (CatS) expression. Normal phagosome biogenesis, which is a prerequisite for optimal Ag presentation, is prevented by pathogenic Mtb, and also significantly blocked by BCG. Therefore these inhibitory effects of the current BCG vaccine on MØ functions may, at least partially, explain its failure to induce efficient immunity to TB.
CatS is a cysteine protease required for normal processing and maturation of MHC class II molecules in MØ. Therefore, we generated a recombinant BCG strain secreting human active CatS (BCG-CatS) and demonstrated that infection with BCG-CatS (i) restores normal levels of MØ CatS, (ii) induces phagosome-lysosome fusion and apoptosis and (iii) restores the expression of mature class II molecules as well as their capacity to present mycobacterial Ag to specific CD4 T cells. On the other hand, preliminary animal experiments showed a significant decrease in the number of virulent Mtb in the lung of mice vaccinated with BCG-CatS. Such findings were consistent with concomitant observations that CatS also stimulates the MHC class I pathway in cells infected with mycobacteria.

P4.05.36
Prime-boost Mycobacterium smegmatis recombinant vaccination improves protection in mice infected with Mycobacterium tuberculosis by enhancing humoral and cellular specific immune responses

A. Junqueira-Kipnis*, F. M. Oliveira, M. M. Trentini, J. A. de Araújo Fliho, A. Kipnis;*
Universidade Federal de Goias, Goiania, Brazil.

Tuberculosis (TB) presents one of the main causes of death by infectious agents. BCG, the available vaccine for TB, although safe, does not protect against TB in adults. Several proteins from M. tuberculosis (Mtb) were tested as subunit vaccines or in recombinant vectors and, the vaccines composed by more than one protein/antigen showed a good potential to proceed to clinical assays. A fusion protein construction (CMX) containing epitopes from Ag85C, MPT-51 and HSP-X from Mtb were immunogenic in both mice and in individuals with active TB, thus presenting a potential use as vaccine for TB. M. smegmatis (MC2) was used as a vector for a new CMX vaccine. The specific immune response to CMX was evaluated after CMX-MC2 vaccination and challenge with Mtb. IgG1 and IgG2a to CMX were induced, as well also specific CD4+IFN-γ and CD8+IFN-γ cells responses. It was observed higher induction of CMX specific TCD4+IL-17+ cells in the lungs. After Mtb infection, a substantial increase in the CD4+IFN-γ+ cells were observed in the spleen and lungs. The CMX-MC2 vaccine reduced at least to half of the amount of bacteria recovered from the lungs of infected animals. In conclusion a CMX-MC2 vaccine increased protection to mice infected with Mtb by inducing both humoral and cellular immune response to CMX.

P4.05.37
Blockade of PD-1 signal pathway causes exacerbation of Mycobacterium tuberculosis infection via excessive IFN-γ production by antigen-specific Th1 type CD4+ T cells

I. Kawamura*, M. Mitsuyama;*
Kyoto University Graduate School of Medicine, Kyoto, Japan.

$CD4^+$ T cell-mediated acquired immunity is essential for the control of *Mycobacterium tuberculosis* (Mtb) infection. However, the immune response is also responsible for the pathological outcome in lung. Therefore, appropriate regulation of antigen-specific $CD4^+$ T cell response is required to prevent bacterial replication and lung tissue damage. Recent studies of the programmed cell death 1 (PD-1) have revealed the important role in the regulation of T cell response in a wide rage of infections with viruses and bacteria. In this study, therefore, we infected wild type and PD-1 knockout (KO) mice with Mtb to clarify the role of PD-1 in Mtb infection. PD-1 KO mice were highly susceptible to Mtb infection. We observed higher bacterial burden and severe tissue damage in lungs of PD-1 KO mice in the early phase of infection. In addition, the production of inflammatory cytokines and chemokines were markedly increased in the lung. Adoptive transfer study showed that $CD4^+$ T cells of PD-1 KO mice could not confer protection on recipient RAG2 KO mice. Furthermore, administration of anti-IFN-gamma IgG ameliorated severe tissue damage and excessive inflammation in lungs of Mtb-infected PD-1 KO mice. These data indicate that Mtb-induced severe inflammation in lungs of PD-1 KO mice was mainly caused by an enormous amount of IFN-gamma produced by Th1 cells and PD-1 signal is essential to have control over a magnitude of Th1 response to Mtb in the early phase of infection.

P4.05.38
Anti-Interferon-Gamma Autoantibodies in Adults with Disseminated Nontuberculous Mycobacterial Infections are Associated with HLA-DRB1*16:02 and DQB1*05:02 and the Reactivation of Latent Varicella-Zoster Virus Infection

C. Chi[1], *C. Chu*[2], *C. Lin*[3], *J. Liu*[3], ***C. L. Ku***[3];
[1]*China Medical University, Taichuang, Taiwan,* [2]*Mackay Memorial Hospital, Taipei, Taiwan,* [3]*Chang Gung University, Taoyuan, Taiwan.*

Adult patients with disseminated nontuberculous mycobacterial (dNTM) infections usually have severe immune system defects. Recently, several reports have shown that anti-IFN- gamma

autoantibodies may play an important role in the pathogenicity of dNTM infections. A considerable proportion of reported cases of anti-IFN-gamma autoantibodies show either clinical or laboratory evidence of autoimmune disease. In this study, we identified 19 formerly healthy adults who later developed dNTM infections, and 17 were further investigated immunologically. High-titer anti-IFN-gamma autoantibodies capable of inhibiting IL-12 production in vitro were found in the plasma of all of these patients. In addition to dNTM infection, 35% and 71% of our patients also suffered from salmonellosis and herpes zoster, respectively. This observation suggests that IFN-gamma may be crucial in controlling salmonella infection and reactivating latent varicella-zoster virus (VZV) infection in humans. Two HLA alleles, DRB1*16:02 DQB1*05:02 (odds ratios 8.68, 95% CI: 3.47-21.90, P=1.1×10-6, Pc=3.08×10-5 and 7.16, 95% CI: 3.02-17.05, P=1×10-7, Pc=1.4×10-6, respectively), were found in 82% (14/17) of our patients. In conclusion, our data suggest that anti-IFN-gamma autoantibodies may play a critical role in the pathogenesis of dNTM infections and reactivation of latent VZV infection and are associated with HLA-DRB1*16:02 and DQB1*05:02.

Mycobacterium tuberculosis Dos Regulon Gene Rv0079 Encodes a Putative, 'Dormancy Associated Translation Inhibitor (DATIN)' and Induce Proinflammatory Responses

A. Kumar[1], *M. Majid*[1], *A. Lewin*[2], *I. A. Qureshi*[3], *N. Ahmed*[1];
[1]*Pathogen Biology Laboratory, University of Hyderabad, Hyderabad, India,* [2]*Robert Koch Institute, Berlin, Germany,* [3]*Department of Biotechnology, University of Hyderabad, Hyderabad, India.*

Tuberculosis is a human disease which is caused by Mycobacterium tuberculosis. Mtb present in one third of the world population under dormant condition. DosR regulon is mainly responsible for dormancy of mycobacteria. At the time of dormancy Mycobacteria live in the environment which is unfavourable like fewer nutrients, less oxygen condition and more nitric oxide condition. In such unfavourable condition bacteria should slow down its metabolic activity to remain live. Here we discuss the systematic characterization of Rv0079 and shown that it is important in the persistent of Mycobacteria and maintenance of granuloma. Rv0079 is involved in stabilization of ribosome and growth arrest of Mycobacteria during dormancy. This protein is also having antigenic peptides which make it immunomodulatorry protein. Rv0079 interact with TLR2 and induces proinflammatory cytokines in macrophages which are important for granuloma maintenance during dormancy. All the experiments were done with recombinant protein (rRv0079) and Mycobacterium bovis BCG overexpressing Rv0079. TRL interaction and cytokines induction study was done in engineered HEK293, THP-1cell line and PBMCs isolated from human patients blood.

P4.05.40
Protection evaluation following vaccination with a Mycobacterium abscessus virulence factor in a pulmonary infection cftr-/- mice model

V. Le Moigne[1], *C. Goulard*[1], *B. Barteau*[2], *M. Rottman*[1], *A. Roux*[1], *B. Pitard*[1], *J. Herrmann*[1], *J. Gaillard*[1];
[1]*Versailles University, Montigny-le-Bretonneux, France,* [2]*UMR 915/INSERM, Nantes, France.*

Cystic fibrosis (CF) is a disease caused by a mutation in the CFTR gene encoding a transmembrane regulator functioning as a Cl channel within the epithelial membrane. The main mutation is linked to the loss by deletion of a Phe in position 508 (ΔF508). Among the CF pathogens, Mycobacterium abscessus (Mabs), a rapid-growing mycobacterium (RGM), is responsible for severe respiratory infections in CF patients.
The specific objective of our project was to evaluate the protection induced by a Mabs virulence factor, the phospholipase C (PLC) (MAB_0555), administered under the form of a nanovectorized recombinant DNA in a model of systemic infection (intravenously) and a model of pulmonary (aerosol route) infection using as mouse model the ΔF508 CFTR mice ("CF" mice) and their wild-type counterpart (FVB genetic background
Protection was evaluated by CFU counts in the spleen, liver and lungs of animals at day 1, 7, 14 and 21 for the aerosol challenge and day 1, 14 and 45 for the IV challenge.
We only observed a protective effect after the aerosol challenge. After the aerosol challenge of FVB wild-type mice, no protective provided by immunization with the nanovectorized PLC gene effect was observed. However, a protective effect was observed in homozygous ΔF508 CFTR mice. A difference was observed at D7, which was confirmed at D21 ($p = 0.038$).
In conclusion, the use of a nanovectorized gene coding for a virulence factor is able to provide local protection and accelerated clearance of M. abscessus in the lungs of "CF" mice.

P4.05.41
Association between DC-SIGN genetic variants and pulmonary tuberculosis in Chinese Uighurs

D. Liu[1,2], *L. Zhang*[3], *C. Peng*[1], *Y. Min*[1], *H. Wang*[1], *H. Wang*[1];
[1]*State Key Laboratory of Genetic Engineering, Institute of Genetics, School of Life Sciences, Fudan University, PRC., Shanghai, China,* [2]*Department of Immunology and pathogen Biology, Shanghai University of Traditional Chinese Medicine, Shanghai, China,* [3]*State Key Laboratory of Genetic Engineering, Institute of Genetics, School of Life Sciences, Fudan University, PRC, Shanghai, China.*

DC-SIGN and TLR2 on Dentritic cells and macrophages involve in the recognition of *Mycobacterium tuberculosis (MTb)* and play essential roles in the initiation of the immune response against *MTb*. Genetic studies show that these two pathway genes, DC-SIGN, TLR2 and TIRAP, contribute susceptibility to pulmonary tuberculosis in some populations, while no strudies were perforned in Chniese Uighurs. In this study, 15 SNPs in three candidate genes were genotyped in 200 cases suffering active pulmonary tuberculosis and 154 matched controls of Chinese Uygurs by using SnaPshot, including 11 tagSNPs in promotor or 3`UTR of DC-SIGN,rs5743708 and rs121917864 in exon of TLR2, rs8177374 and rs7932766 in TIRAP. We also screened the promotor and 3` UTR of DC-SIGN in 32 control samples by direct sequencing of genomic DNA. The increased risk of variants of -871GG in promotor and *443AA in 3`UTR of DC-SIGN on the occurance of tuberculosis were confirmed, especially in populations never inoculated with BCG or contacted with patients closely, and the epidemiology analysis showed that age, sex, BCG, contact and smoking were all essential factors associated with tuberculosis. The further dual-luciferase assay showed -871GG variant can not promote the transcription of DC-SIGN *in vitro*, but a -336 varient reported before can. No variant was found in rs121917864 of TLR2, and other 3 SNPs in TLR2 and TIRAP did not show significant difference between cases and controls. The presented evidence suggests variants of -871GG and *443AA in DC-SIGN increased the pulmonary tuberculosis risk in Uighur population.

P4.05.42
Mycobacterium bovis culture filtrate proteins induces expression of autocrine prolactin loop enhancing inflammatory response in monocytes THP1

G. López[1], *C. Estrada*[1], *A. Pereira*[2];
[1]*Centro de Investigación y Asistencia en Tecnología y Diseño del Estado de Jalisco, A.C., Guadalajara, Mexico,* [2]*Universidad de Guadalajara, Guadalajara, Mexico.*

Prolactin (PRL) of pituitary origin is known to regulate many physiological functions such as proliferation, differentiation and cell survival. Also, its purpose is to act as an immunomodulator, which can interfere with lymphocyte activation and cytokine production. It has recently been associated with carcinogenesis and exacerbation of autoimmune diseases. The Tuberculosis in humans induces increased physiological levels of PRL, however, their involvement in disease progression has not been determined. The aim of this work was to investigate whether PRL autocrine modulates the proinflammatory response in THP1 monocytic cells incubated with Mycobacterium bovis culture filtrate proteins (CFP). The monocytes stimulated with CFP-M.bovis express autocrine Big PRL 60-80 kDa

and short isoforms of PRLr 40 and 50 kDa. RT-PCR showed an increase mRNA of PRL and PRLr vs untreated cells P<0.001. For immunocytochemistry the PRLr and PRL were observed in medium, membrane and nucleus. As expected, M.bovis induced high concentrations of nitric oxide, IL1-β, (681.5 pg/mL) and IL-6 (600.4 pg/mL), and TNF-α (28.7 pg/mL). The levels were measured by the Greiss reaction and ELISA. However proinflammatory cytokines IL1-β, (100 pg/mL) and IL-6 (110.5 pg/mL), and TNF-α (16.4 pg/mL) significantly decrease secretion levels by inhibition of the PRLr. In summary, our results suggest the CFP-M.bovis induces overexpression of short isoforms of PRLr and autocrine synthesis of Big PRL in myeloid cells. This autocrine mechanism suggesting a primary pro-inflamatory role of this hormone and these results suggest the PRL autocrine might have a crucial role in resolving inflammation.

P4.05.43
Suppression of immune regulation in a murine model of progressive pulmonary tuberculosis

V. Lozano Ordaz[1,2]*, M. M. B. Moreno Altamirano*[3]*, R. Hernandez Pando*[1]*;*
[1]*Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, México,DF, Mexico,* [2]*Instituto Politecnico Nacional, México, DF, Mexico,* [3]*Instituto Politecnico Nacional, México,DF, Mexico.*

Mycobacterium tuberculosis (Mtb) is the etiologic agent of tuberculosis (TB). Many aspects of TB are not completely elucidated, such as the complex process of immunoregulation mediated by T regulatory cells (Treg) and the enzymes hemoxygenase 1 (HO-1) and indoleamine 2,3-dioxygenase (IDO). When BALB/c mice are infected with Mtb strain H37Rv by the intratracheal route a rapid progressive disease is developed. This model has two phases, the early phase with an efficient control of bacilli growth mediated by activation of the innate and acquired (Th-1) immunity, and the progressive phase characterized by a high production of anti-inflammatory Th-2 cytokines. High bacilli loads and tissue damage causes death. We studied the kinetics of T-reg cells, HO-1 and IDO along the infection. In the lungs of tuberculous animals during the progressive phase there was high gene expression and production of HO-1 and IDO, and a highest amount of T-reg cells. In order to study this, T reg cells were eliminated during progressive disease by the administration of specific monoclonal cytolitic antibodies (clone PC61). In separate experiments the activity of HO-1 and IDO was inhibited using the specific inhibitors zinc protoporphyrin-9 (ZnPP9) to suppress HO-1 and 1-methyl-DL-tryptophan (1-MT) to block IDO. In comparison with control animals, mice treated with any of these molecules showed a significant decrease of bacilli loads improving survival but they developed higher lung inflammation. Thus, immune-regulation mediated by T-reg cells, HO-1 and IDO is important to control excessive inflammation, permitting bacilli proliferation and disease progression.

P4.05.44
Reduced frequency of BCG-specific IFN-γ Producing T Cells in Ugandan infants when Bacillus Calmette-Guerin vaccination is delayed from birth to 6 Weeks Of Age

F. Lutwama[1,2]*, B. M. Kagina*[1]*, C. Day*[3]*, A. Wajja*[2]*, S. Kirimunda*[2]*, M. Joloba*[2]*, P. Musoke*[2]*, T. Scriba*[1]*, H. Mayanja-Kizza*[2]*, W. Hanekom*[1]*;*
[1]*South African Tuberculosis Vaccine Initiative, University of Cape Town, Cape Town, South Africa,* [2]*Infectious Diseases Institute, Makerere University College of Health Sciences., Kampala, Uganda,* [3]*Emory vaccine Center, Emory University, Atalanta, GA, United States.*

Background: In Uganda, Bacillus Calmette-Guerin (BCG) is administered at birth within a health facility. However, homebirths are prevalent therefore some newborns receive BCG later. We compared BCG-specific $CD4^+$ and $CD8^+$ T cell response in infants who received BCG at birth or at 6 weeks of age. We hypothesised that infants vaccinated at birth would show lower frequencies of BCG-specific $CD4^+$ and $CD8^+$ T cells compared with infants vaccinated at 6 weeks of age.
Methods: Nine months-old infants who received BCG at birth or at 6 weeks of age were enrolled. Blood was drawn from each infant and left unstimulated or stimulated with BCG in a short-term whole blood assay. Plasma was harvested after 7 hours for soluble cytokine levels by luminex. After 12 hours, cells were fixed, harvested and cryopreserved for later intracellular cytokine staining and flow cytometry.
Results: We enrolled 50 infants vaccinated with BCG at birth while 42 were vaccinated at 6 weeks of age. All infants showed a robust BCG-specific IL-2, IFN-γ and TNF-α, IL-17 and perforin $CD4^+$ and $CD8^+$ T cells response. Birth vaccinated infants showed a higher frequency of $CD4^+$ and $CD8^+$ T cells producing IFN-γ and lower levels of BCG-specific soluble IL-10 than six weeks old BCG vaccinated infants.
Conclusions: The higher social economic levels in birth than delayed vaccinated infants may partly explain the observed differential specific T cell responses in the two groups. Our findings prompt follow up studies that will give more insight into clinical relevance of these findings.

P4.05.45
Effects of multi-drug therapy (MDT) on cellular immunity in patients with leprosy

P. Marcinek*, T. Engleitner, V. Thirumalaisamy Palanichamy; Institut für Tropenmedizin Tübingen, Tübingen, Germany.*

Leprosy is one of the most neglected infectious tropical diseases of the skin and the nerves caused by the intracellular pathogen *Mycobacterium leprae*. Despite eradication programs, the annual new case and prevalence rate remain consistent in affected countries, especially in India, here with a WHO estimate of 127,000 newly infected individuals per year. Multi drug therapy (MDT) has been established for different disease presentations, such as multibacillary (MB) and paucibacillary (PB) infections. However, the response to these treatment regimens remains diverse across individuals. Protection against intracellular pathogens such as *M. leprae* is critically dependent on the function of NK cells at early stages of the immune response.
Natural killer cells (NK) can interact with macrophages, the preferred host cell for mycobacterium, and this interaction will trigger an adaptive or antigenic-specific immune response. We investigated the transcriptome profile of NK cells in paucibacillary and multibacillary patients who responded to MDT, and in MDT non-responders. We observed a marked differential upregulation of gene-products active in inflammation and cellular defence via mass array studies.
Additionally, we also discovered specific genotypes within the TAP1, TAP2, NOD2, LRRK2, and RIPK2 genes that are associated to disease outcome. These differential signatures and knowledge on differential regulatory pathways during the disease onset and treatment will lead to important repercussions in understanding how NK cells and *Mycobacterium leprae* interact. This may guide us to a supportive treatment by activating innate immunity in general or NK cells in particular via a supplementary supportive treatment of leprosy.

P4.05.46
The role of CD137 ligand (CD137L) signaling pathway during M. tuberculosis infection

J. M. Martinez Gomez[1,2]*, V. Koh*[1]*, W. Lin*[1]*, M. Ang*[1]*, Z. Zainul Rahim*[1]*, H. Schwarz*[1]*, S. Alonso*[1]*;*
[1]*National University of Singapore, Singapore, Singapore,* [2]*Immunology Program, Singapore, Singapore.*

The role of the CD137-CD137 ligand (CD137L) signaling pathway in T cell co-stimulation has been well established. Dysregulated CD137 or CD137L stimulation leads to pathological conditions such as inflammatory diseases and cancer. However, the contribution of the CD137-CD137L interactions in the control of infectious diseases has not been extensively studied, with the few available reports focusing mainly on viral infections. Here we investigated the role of the CD137-CD137L interactions during Mycobacterium tuberculosis infection. Using CD137L deficient mice, we found that the absence of CD137L resulted in impaired priming of T cells by dendritic cells in vitro and a delayed CD4+ T cell activation in vivo. We found increased cellular

infiltrates in the lungs of CD137L deficient mice and reduced production of key cytokines such as TNF-α and IL-12 but similar levels of IFN-γ in the broncho-alveoar lavage fluid. However, these disorders translated only into a modest transient increase in the bacterial loads and granulomatous lesions in the lungs of the CD137L deficient infected mice. Our data thus suggests that compensatory mechanisms exist in these mice.

P4.05.47

Prolactin modulate proinflammatory inmune response induced by culture filtrate protein from Mycobacterium bovis in THP1 cells through different signaling pathways.

P. A. Martinez-Neri[1], *G. Lopez-Rincon*[2], *J. F. Muñoz-Valle*[1], *E. I. Lopez-Pulido*[1], *C. Estrada-Chavez*[2], *A. L. Pereira-Suarez*[1];
[1]*Universidad de Guadalajara, Guadalajara, Mexico,* [2]*Centro de Investigación y Asistencia en Tecnología y Diseño del Estado de Jalisco, Guadalajara, Mexico.*

Prolactin (PRL) has been implicates as a modulator of immune function and some of its actions may be linked with nitric oxide (NO) and cytokines synthesis. Several reports show evidence of a protective role of PRL during different infectious diseases caused by bacteria, fungi and protozoa. Significant increase of prolactin plasma levels was observed in patients with advanced tuberculosis. Monocytes/macrophages play an essential role in innate defense against microbial infection. The aim of this work was determine if PRL module a proinflamatory immune response in THP-1 cell stimulated with *Mycobacterium bovis* culture filtrate proteins (CFP) and its signaling pathway associated. The THP-1 cells were stimulated by PRL, *M. bovis* CFP and both. The levels of IL1-β, IL-6, TNF-α, IL-10 and the oxidation products of NO in THP1 cells were measure by ELISA and the Griess reaction respectively. Activation of STAT3, ERK1/2 and Akt were evaluated by western blot. As expected, *M. bovis* CFP induced high concentrations of NO also IL1-β, IL-6, and TNF-α in THP-1 monocytes. PRL (20 ng/ml) treatment considerably decreases IL1-β, IL-6, TNF-α secretion and NO concentration in THP-1 cell stimulated by *M. bovis* CFP, however increased IL-10 production. The effect of PRL was corroborated by inhibition of their receptor binding. Significantly enhanced expression p-STAT-3 and p-ERK 1/2 with PRL, and with *M. bovis* CFP treatments was observed, however with both treatments was diminished. PRL could be mediating an anti-inflammatory response during a mycobacterial infection and may be, in turn, regulated by the JAK/STAT-3 pathway.

P4.05.48

Human memory T cells in latent *Mycobacterium tuberculosis* infection are directed against three antigenic islands and are found in a CXCR3$^+$CCR6$^+$ Th1 subset

F. Mele[1,2], *C. Lindestam Arlehamn*[3], *B. Peters*[3], *A. Lanzavecchia*[1,4], *A. Sette*[3], *F. Sallusto*[1];
[1]*Institue for Research in Biomedicine, Bellinzona, Switzerland,* [2]*Graduate School for Cellular and Biomedical Sciences, University of Bern, Bern, Switzerland,* [3]*Institute for Allergy and Immunology, La Jolla, CA, United States,* [4]*ETH Zurich, Switzerland, Switzerland.*

In this study we performed a systematic analysis of the specificity and functional properties of memory T cells in individuals with latent tuberculosis by combining a genome-wide library of *Mycobacterium tuberculosis* (MTB)-derived predicted HLA class II epitopes with a high throughput cellular screening method. We found that natural immunity to MTB is directed against multiple epitopes and antigens, with more than 80 antigens necessary to capture 80% of the response. As a result of this analysis, 34 novel antigens and 3 broadly immunodominant antigenic islands were defined. The majority of the novel antigens identified are associated (contained within or in close proximity of) with these antigenic islands, which all contain Esx protein pairs and PE/PPE proteins, and are part of a putative secretory system. We also found that the response to MTB is virtually confined to a CCR6$^+$CXCR3$^+$ memory Th1 cell subset, with a minority of MTB-specific cells displaying a CCR6$^+$CXCR3$^-$ Th1/Th17 phenotype. The origin and lineage relationship of CXCR3$^+$ and CXCR3$^-$ MTB-specific T cells remain to be defined: while it is possible that they represent separate lineages (Th1 and Th1/Th17, respectively), they may also represent two differentiation stages within the same lineage. TCR deep sequencing experiments are ongoing to determine the T cell repertoires in the two T cell subsets. This study demonstrates the power of genome-wide, high throughput cellular screenings to analyze the human immune response to complex pathogens.

P4.05.49

Plasma cytokines and chemokines differentiate between active disease and non-active tuberculosis infection

A. Mihret[1], *Y. Bekele*[1], *K. Bobosha*[1], *M. Kidd*[2], *A. Aseffa*[1], *R. Howe*[1], *G. Walzl*[2];
[1]*Armauer Hansen Research Institute, Addis Ababa, Ethiopia,* [2]*Stellenbosch University, Faculty of Medicine and Health Sciences, Cape Town, South Africa.*

To analyse cytokines and chemokines from unstimulated plasma samples for detection of active TB disease, latent TB, discriminating active TB cases from latently infected contacts and for monitoring anti TB treatment. We analysed ex vivo plasma samples from 33 TB patients (17 HIV negative and 16 HIV positive) and 30 healthy household contacts with Luminex. We found statistically significant differences ($p < 0.05$) in median plasma concentrations of EGF, fractalkine, IFN-γ, IL-4, MCP-3 and IP-10 between contacts and TB patients. Single cytokines or chemokines predict with an area under the Receiver Operating Characteristic (ROC) curve of 0.59 for VEGF to 0.98 for IP 10 while a combination of fractalkine, IFN-g, IL-4, IP-10 and TNF identified 96.87% of TB cases and 100% of household contacts. However, none of the cytokines were significantly different in QFT positive and QFT negative contacts ($p > 0.05$). HIV does not affect the median plasma level of any of the cytokines or chemokines and there was not significant difference between HIV positive and HIV negative TB patients ($p > 0.05$) in any of the cytokines or chemokines. The median plasma concentrations of IFN-γ, IL-4, MCP-3, MIP-1β and IP-10 were significantly different ($p < 0.05$) before treatment and after treatment. Plasma cytokines and chemokines could be used as immunological markers for diagnosing active TB disease and for monitoring effective antituberculosis therapy.

P4.05.50

Knockdown of suppressor of cytokine signalling 3 mediates killing of Mycobacterium tuberculosis in THP1 derived macrophages

M. Mohan, *A. Misra;*
CSIR Central Drug Research Institute, Lucknow, India.

Mycobacterium tuberculosis (M.tb) is the etiological agent of tuberculosis (TB), which initiates with pulmonary manifestations. M.tb resides in alveolar macrophages of the host, the very cell type that has evolved to phagocytose and destroy microbes entering the lungs. M.tb inhibits phagosome maturation and phagolysosome fusion. It induces alternative activation of the host macrophage and perturbs cytokine signalling. Genome-wide transcription analysis in our lab has identified upregulation of the human suppressor of cytokine signalling 3 (SOCS3) as a consequence of colonization of macrophages by M.tb. SOCS-3 is a negative regulator of cytokine signalling working by inhibiting Janus kinase (JAK). SOCS3 thus inhibits cytokine signalling from γ-interferon (IFN-γ) which is a potent proinflamatory cytokine. This report describes knock-down of SOCS3 siRNA using morpholino oligonucleotides chemically conjugated to a dendrimer. Upregulation of SOCS3 RNA by 127-fold was observed in M.tb infected THP1 derived macrophages. Knockdown of of SOCS3 resulted in significant reduction of intracellular M.tb survival. The colony count of M.tb recovered from THP-1 cells infected with Mtb but treated with a scrambled morpholino-oligonucleotide sequence was 5.73 log/ml, while parallel wells subjected to SOCS3 knockdown with 1 and 0.1 µM of siRNA had 5.64 and 5.63 log units of surviving bacteria. It was concluded that restoration of cytokine signalling is sufficient to induce bactericidal activation of macrophages infected with M.tb.

P4.05.51

Association of SLC11A1 gene polymorphisms with susceptibility to Lepromatous Leprosy

M. Montoya-Buelna[1,2]*, J. Becerra-Contreras*[3]*, M. Fafutis-Morris*[1,2]*, E. Ochoa-Martínez*[3]*, T. Reddy*[1]*, L. Sandoval-Ramírez*[4]*;*
[1]Centro Universitario de Ciencias de la Salud, Universidad de Guadalajara, Guadalajara, Mexico, [2]Centro de Investigación en Inmunología y Dermatología, Guadalajara, Mexico, [3]Centro Universitario de Ciencias Biológicas y Agropecuarias, Guadalajara, Mexico, [4]Centro de Investigación Biomédica de Occidente, IMSS, Guadalajara, Mexico.

Leprosy is a debilitating infectious disease of human skin and nerves caused by Mycobacterium leprae. The range of clinical forms varies from tuberculoid (TT) to lepromatous leprosy (LL) based in immune response variations to M. leprae. Human SLC11A1 gene is a key candidate to host resistance and susceptibility to certain pathogens. The study aimed to evaluate the association of SLC11A1 gene polymorphism with resistance, susceptibility or clinical forms of leprosy in Mexican patients. Methods: We enrolled 80 LL, 8 TT patients and 148 healthy subjects (HS), which polymorphisms were studied simultaneously. By polymerase chain reaction amplification of genomic DNA followed by restriction fragment length polymorphism analysis, we evaluated the polymorphisms of SLC11A1 gene at INT4 (469 + 14G/C), D543N (codon 543, Asp to Asn) and 5´promoter (GT)n microsatellite. Results: C/C genotype and C allele frequencies in INT4, were significantly associated with susceptibility to LL (p=0.005, OR: 0.4211 [IC 95%, 0.16-1.11]; and p=0.002, OR: 0.33 [IC 95%, 0.52-0.80] respectively). However, variants analyses of D543 and (GT)n loci from LL and TT patients did not reveal any statistical significance versus controls. Conclusions: Our data support the association between the C/C genotype and C allele in INT4 of SCL11A1 gene, which increases the risk to develop LL in Mexican patients.

***Mycobacterium tuberculosis P27* protein targets host cell mitochondria**

M. M. B. Moreno-Altamirano[1]*, C. Espitia*[2]*, I. Paredes-Gonzalez*[1]*;*
[1]Departamento de Inmunología.Escuela Nacional de Ciencias Biológicas IPN, Mexico, City, Mexico, [2]Instituto de Investigaciones Biomedicas- UNAM, Mexico, City, Mexico.

Tuberculosis (TB) is a major health problem worldwide, the selection and spread of multidrug–resistant (MDR) *M. tuberculosis* strains worsens the scenario. A precise knowledge on mycobacteria–host cell interactions is required for successful control of TB. Mycobacterial infection affects mitochondrial function in host cells. However, the identity of the molecules responsible for such effect has not clearly defined. The AIM of this work was to identify M. tuberculosis proteins that target mitochondria and identify its protein targets within mitochondria. Material and Methods: *M. tuberculosis* protein sequences were analyzed by bioinformatic tools such as MitoProt II–v1.101. PSORT II. *M. tuberculosis* Rv1411c (p27) protein was selected as a candidate and experimentally tested on J774.A1 murine macrophages, cells were incubated in the presence of *M. tuberculosis* His-tagged p27 recombinant proteins (p27), or α–crystalline, as negative control, cells were then labelled with MitoTracker red CMXRos (mitochondria), and FITC–labeled anti–His antibody (recombinant protein) and observed by confocal microscope. Results: Bioinformatic analysis singled out 19 proteins as mitochondria-targeting candidates, p27 experimentally targeted mitochondria, and 3 mitochondrial proteins have been shown as likely targets for p27.

Relationship between host Mycobacterium tuberculosis-specific CD4 T cell responses and sputum bacillary clearance during early anti-tuberculosis treatment

D. Mzinza[1]*, D. Sloan*[1,2]*, K. Wilkinson*[3]*, R. Wilkinson*[3]*, G. Davies*[1,2]*, R. Heyderman*[1]*, H. Mwandumba*[1,2]*;*
[1]Malawi Liverpool Wellcome Trust Clinical Research Programme, Blantyre, Malawi, [2]University of Liverpool, Liverpool, United Kingdom, [3]University of Cape Town, Cape Town, South Africa.

Tuberculosis treatment is associated with changes in host Mycobacterium tuberculosis (Mtb) antigen-specific T cell responses. It is unclear how these changes relate to treatment outcomes. We investigated the relationship between Mtb-specific immune response, quantitative bacteriology and clinical outcomes of treatment in sputum smear-positive adult TB patients receiving anti-TB treatment at Queen Elizabeth Central Hospital, Malawi. Peripheral blood and sputum samples for PBMC isolation and serial mycobacterial culture respectively were collected from 45 patients irrespective of their HIV status before and after 56 days of treatment. Mtb-specific immune responses were assessed by quantification of IFN-γ secreting T cells in response to CFP-10 and ESAT-6 using an ELISPOT assay. Mtb clearance from sputum was evaluated by mycobacteria growth indicator tube culture system. Results are given as median and differences were considered statistically significant if $p<0.05$. Preliminary results show a difference in the rate of bacillary clearance and host responses with respect to HIV. 71% of HIV-uninfected and 50% of HIV-infected patients were culture negative by 2 months of treatment. Similarly, the number of IFN-γ secreting T cells reduced during treatment in HIV-uninfected patients (median change -60 SFU/106 PBMC, IQR 4-204), while there was a smaller reduction in HIV-infected patients (median change -14 SFU/106 PBMC, IQR 0-51) (Mann-Whitney U-test p = 0.085). Preliminary findings suggest an association between magnitude of host Mtb-specific T cell responses and mycobacterial load. We plan to analyze the data further by doing regression modeling to investigate the relationship between immunological parameters, HIV status and bacillary clearance.

P4.05.54

The accumulation of highly differentiated Mtb-specific CD4 T cells is associated with lung tissue destruction during pulmonary tuberculosis

I. Y. Nikitina[1]*, A. V. Panteleev*[1]*, R. B. Amansahedov*[1]*, V. V. Ganusov*[2,3]*, I. A. Vasilyeva*[1]*, I. V. Lyadova*[1]*;*
[1]Central Tunerculosis Research Institute, Moscow, Russian Federation, [2]Department of Microbiology, University of Tennessee, Knoxville, TN, United States, [3]National Institute for Mathematical and Biological Synthesis, Knoxville, TN, United States.

Immunological methods are widely used for the diagnostics of *M. tuberculosis* (*Mtb*) infection. In this study we show that these methods can also be used as a means to evaluate and monitor the degree of lung tissue destruction caused by *Mtb*. Lung destruction is a characteristic trait of pulmonary tuberculosis (TB). It underlies disease severity, causes dissemination of the pathogen and needs to be carefully evaluated. Our earlier studies in mice have demonstrated that *Mtb* infection induces the differentiation of effector CD4 T cells into highly differentiated $CD4^+CD27^-$ lymphocytes and that this differentiation takes place in the lungs. We hypothesized therefore that the accumulation of $CD4^+CD27^-$ cells should mirror tuberculosis activity. In this study, we evaluated the percent of $CD27^-$ cells within the population of *Mtb*-reactive CD4 T cells ("Mtb^+CD27^-" cells) in the blood of TB patients. Compared to healthy donors, TB patients had significantly higher percent of Mtb^+CD27^- cells ($p<0.0001$). Within the group of TB patients, the percent of Mtb^+CD27^- cells varied. Among different characteristics of TB disease (i.e., pulmonary destruction, disease duration, et al.), high degree of pulmonary destruction was the main factor associated with high percent of Mtb^+CD27^- cells ($p<0.0001$). ROC-curve analysis revealed that evaluation of Mtb^+CD27^- cells allows assessing pulmonary destruction (sensitivity, 89%; specificity, 74%). During the treatment, a decrease in the percent of Mtb^+CD27^- cells was indicative on the repair of lung destruction ($p<0.01$).
The determination of the percent of Mtb^+CD27^- cells allows assessing pulmonary destruction and its repair following TB therapy.

P4.05.55
Mycobacterium tuberculosis adapts its immune-evasion mechanisms in dependence of the antigen presenting cell and shifting to dormancy.

R. Nisini[1], *M. Pardini*[1], *M. Gagliardi*[1], *F. Giannoni*[1], *F. Lozupone*[1], *R. Teloni*[1], *M. Fraziano*[2], *S. Meschini*[1], *S. Mariotti*[1];
[1]*Istituto Superiore di Sanita', Roma, Italy,* [2]*Università Tor Vergata, Roma, Italy.*

Immune responses to Mycobacterium tuberculosis (Mtb) drive the bacteria into a dormant state, but rarely eliminate them. The latent state of Mtb is reversible and upon reactivation Mtb causes post-primary tuberculosis (TB). Dormant (D-) Mtb determines latent TB infection (LTBI), but it was also observed in sputa of patients with active TB. However, little is known on the capacity of the immune system to recognize D-Mtb.
We observed that human CD4+ T cell clones specific for mycobacterial antigens recognize more efficiently D- than replicating (R)-Mtb. The increased presentation of D-Mtb was observed using both professional, macrophage or DC, and non professional APC, such as fibroblasts. The difference was not dependent on a different capacity of the two forms of Mtb to infect APC or to induce different APC activation. In fact, APC were induced to secrete cytokines and to express MHC class I and II molecules and activation markers at the same levels. However, D- but not R-Mtb co-localized with mature phagolysosome markers Lamp-1 and vATPase in infected macrophages. In addition, R- but not D-Mtb increased the phagosome pH and inhibited the proteolytic efficiency of macrophages. Mice infected with D-Mtb developed a specific immune response earlier than mice infected with R-Mtb. Together, data indicate that D-Mtb does not block phagosome maturation and antigen processing capacity of APC.
Our results suggest that the capacity of Mtb to switch to dormancy may represent a mechanism of survival in LTBI, but also a strategy to modulate the host adaptive immune system in active TB.

Purpose and Methods. Multi-drug resistant (MDR) Mycobacterium tuberculosis (TB) is a big problem in the world. We have developed novel TB vaccines [HVJ-Envelope/HSP65 DNA +IL-12 DNA vaccine, granulysin vaccine and killer specific secretory protein of 37kDa (Ksp37) vaccine] using Hemagglutinating virus of Japan (HVJ)-envelope. Induction of CTL by these vaccines was investigated. Results. HSP65+IL-12DNA vaccine provided remarkable protective efficacy in mouse and monkey models compared to BCG. This vaccine induced strong CTL differentiation against TB, while BCG vaccine induced little CTL. The vaccine also provided strong therapeutic efficacy against MDR-TB and XDR-TB in murine model. Furthermore, the synergistic therapeutic effect of this vaccine in the combination of first line chemotherapy Isoniazid (INH) was observed. The vaccine exerted therapeutic effect on TB-infected monkeys via the augmentation of IL-2 production. On the other hand, granulysin is an important defensive molecule expressed by human T cells. We found granulysin induced the differentiation of in vitro and in vivo CTL. Granulysin vaccine exerted therapeutic efficacy against TB in monkeys and mice. Ksp37 vaccine also augmented in vivo and in vitro differentiation of CTL. The combination of HSP65 vaccine and granulysin vaccine exerted synergistic therapeutic efficacy against TB. Recently, we first established granulysin transgenic mice and Ksp37 transgenic mice, showing strong in vivo anti-TB activity. Conclusions. These data indicate that additive therapy of HSP65-, granulysin- and Ksp37-vaccines to first line chemotherapy might provide very strong therapeutic strategy against MDR-TB. These also indicate that our vaccines provide efficacy against TB via the induction of CTL.

P4.05.57
Role of $CD8^+$ T cells in triggering reversal reaction in HIV/leprosy patients

A. L. Oliveira*, T. P. Amadeu, A. C. d. Gomes, V. M. Menezes, J. A. d. Nery, R. O. Pinheiro, E. N. Sarno;*
FIOCRUZ, Rio de Janeiro, Brazil.

It has been reported that the initiation of HAART is associated with the development of reversal reaction (RR) in co-infected HIV / leprosy patients. Nevertheless, the impact of HIV and HAART therapy on the cellular immune response to *M. leprae* (ML) remains unknown. In the present study, we observed that *ex vivo* PBMCs of both RR and RR/HIV patients presented increased percentages of activated $CD4^+$T cells when compared with the HC group. The frequency of $CD8^+CD38^+$ cells increased in the PBMCs of RR / HIV but not in RR patients when compared with the HC group. RR and RR/HIV skin lesion cells presented similar percentages of activated $CD4^+$ cells, but the numbers of activated $CD8^+$ cells were higher in RR/HIV in comparison to the RR group. The frequency of IFN-γ-producing cells was high in response to ML regardless of HIV co-infection. In ML-stimulated cells, there was an increase in TCM $CD4^+$ T cell frequencies in the RR and RR/HIV groups, but an increase in TCM $CD8^+$ T cell frequency was only observed in the RR/HIV group. ML increased granzyme B^+ TEM $CD8^+$ T cell frequencies in the RR/HIV PBMCs, but not in the HC and RR groups. Our data suggest that the increased expression of TEM $CD8^+$ T cells together with greater perforin/granzyme B production could be an additional mechanism leading to the advent of RR in co-infected patients. Moreoever, this increased expression may explain the severity of RR occurring in these patients.

P4.05.58
Mycobacterial Immune response in tuberculous meningitis is influenced by HIV infection

S. A. Patil*;*
National Institute of Mental Health and Neurosciences, Bangalore, India.

Tuberculous meningitis (TBM) is one of the common and serious forms of extrapulmonary tuberculosis prevlent in many developing countries. The laboratory diagnosis of the disease is always difficult and delay in accurate treatment leads to serious consequences.The mortality due to TBM in children is high and can leave serious sequalae.
The present study comprises 27 autopsy proven TBM cases with and without HIV infection. Paired samples of CSF (lumbar, ventric) and serum samples collected were subjected for anti-TB antibody response, western blotting, Immune complexes and cytokine analysis. Non-neurological samples (LP-CSF) were used as controls in the study.
The anti-mycobacterial antibody response in LP-CSF was up to 60% in TBM cases which was higher than in serum samples highlighting in-situ synthesis antibodies in the CSF compartment. Pro-and anti-inflammatory cytokines were quite varied in these cases. IL-4 and TNF signals were noticed to be weak whereas, the signals for IFN-gamma and IL-6 were exaggerated. The IFN response in HIV positive cases was relatively low. Further, wherever individuals were negative for acid fast bacilli in the CSF the gamma interferon response was poor. It thus appears that the HIV infection abrogates the immune response in TBM cases.

M2-like polarization of Mycobacterium tuberculosis infected human macrophages by extracellular AMP

L. Petit-Jentreau*[1,2], *N. Dubois-Colas**[1,2], *L. B. Barreiro*[3], *S. Durand*[4], *G. Soubigou*[5], *K. Rezai*[4], *F. Lokiec*[4], *J. Coppée*[5], *B. Gicquel*[1], *L. Tailleux*[1];*

[1]Institut Pasteur, Unité de Génétique Mycobactérienne, département Génomes et Génétique, rue du Dr. Roux, Paris, France, [2]Université Paris Diderot, Sorbonne Paris Cité, Cellule Pasteur, rue du Dr Roux, Paris, France, [3]Sainte-Justine Hospital Research Centre, Department of Pedriatics, Faculty of Medicine, University of Montreal, Montreal, QC, Canada, [4]Institut curie-Hôpital René Huguenin, département de Radio-Pharmacologie, Saint Cloud, France, [5]Institut Pasteur, Plate-forme Transcriptome et Epigénome, Département Génomes et Génétique, Paris, France.

Tuberculosis (TB) is a major infectious disease spread worldwide. Mycobacterium tuberculosis-containing droplets are inhaled into the pulmonary alveoli. Following encounter with the bacillus, alveolar macrophages (Mϕ) allow the recruitment and activation of immune cells, leading to the formation of granuloma. As the host fails to control mycobacterial infection, the center of granulomas exhibits necrosis as a result of the dying infected Mϕ and the release of cell content. How Mϕ will respond then to the M. tuberculosis infection in this new environment is poorly understood.
Here, we show that extracellular ATP, an endogenous danger signal released upon cell death modulates human Mϕ response to M. tuberculosis infection. Using a transcriptomic approach, we found that eATP dampens the inflammatory response of M. tuberculosis infected MΦ and contributes to tissue repair. This gene profile is in accordance with a polarization of the infected cells toward an M2-like phenotype. Alternative activation of MΦ was dependent of ATP degradation by the ectonucleotidase CD39. We provide strong evidence that adenosine monophosphate (AMP) mediated the observed effect through the stimulation of the adenosine A2A receptor. These data point to an unrecognized role of extracellular AMP in host response against M. tuberculosis limiting tissue damage but it may also favor bacterial immune escape.

P4.05.60

Differences in the levels of host markers detected in saliva and serum and their potential for diagnosing TB disease

K. G. Phalane*, M. Kriel, A. G. Loxton, A. Menezes, K. Stanley, G. D. van der Spuy, G. Walzl, N. N. Chegou;*
University of Stellenbosch, Cape Town, South Africa.

Despite the recent introduction of molecular beacon assays into clinical practice, the diagnosis of tuberculosis (TB) disease remains challenging in individuals with difficulty in providing good quality sputum. Host biosignatures of inflammatory markers could be valuable in such cases, especially if they are based on more easily obtainable samples such as saliva, and are developed into rapid, point-of-care tests. This study aimed to compare the levels of host markers detectable in the saliva and serum of patients with possible pulmonary TB, and to assess the diagnostic utility of these markers for TB disease.
Methods: Saliva and serum samples were collected from 38 TB suspects,recruited from a community health centre in Cape Town, 33 host markers were evaluated in the samples using the Luminex platform.
Results: ActiveTB disease was confirmed in 11(28.9%) by sputum culture. The levels of most markers were above the minimum detectable limit in both sample types.The levels of fractalkine, IL-17, IL-6, IL-9, MIP-1β, CRP, VEGF and IL-5 in saliva, and those of IL-6, IL-2, SAP and SAA in serum, were significantly higher in TB patients, in comparison to the levels obtained in those without active TB ($p<0.05$). The area under the ROC curve was ≥ 0.70 for most of these markers, thereby confirming their diagnostic potential for TB disease.
Conclusions: There were vast differences in the levels of host markers expressed in saliva in comparison to serum and some markers in both sample types have potential in the diagnosis of TB disease.

P4.05.61

Different immunosuppressive mechanisms in multi-drug-resistant tuberculosis and non-tuberculous mycobacteria patients

R. O. Pinheiro*[1], *E. B. Oliveira*[1], *G. dos Santos*[1], *G. M. Sperandio da Silva*[1], *B. J. A. Silva*[1], *A. Milagres*[2], *E. N. Sarno*[1], *M. P. Dalcolmo*[1], *E. P. Sampaio*[1,3];*

[1]Oswaldo Cruz Foundation, Rio de Janeiro, Brazil, [2]District Hospital Raphael de Paula Souza, Rio de Janeiro, Brazil, [3]National Institutes of Health, Bethesda, WA, United States.

Previous studies have demonstrated that cells from both multi-drug-resistant tuberculosis (MDR-TB) and non-tuberculous mycobacteria (NTM) patients respond poorly to mycobacterial antigens in vitro. In the present study, we compared the in vitro response of cells isolated from sensitive TB (NR-TB)-, MDR-TB- and NTM-infected patients. Analysis of T cell phenotype ex vivo revealed that both MDR-TB and NTM patients present an increased percentage of CD4+ CD25+ FoxP3+ and CD4+ CD25+ CD127- Treg cells when compared to NR-TB. Increased numbers of Treg cells and interleukin (IL)-10 serum levels were detected in MDR-TB, whereas elevated serum transforming growth factor (TGF)-β was found in the NTM group. Cells of MDR-TB patients stimulated with early secretory antigenic target (ESAT)-6, but not purified protein derivative (PPD), showed a lower frequency of CD4+ /interferon (IFN)-γ+ T cells and enhanced CD4+ CD25+ FoxP3+, CD4+ CD25+ CD127- and CD4+ CD25+ IL-10+ T cell population. In addition, increased IL-10 secretion was observed in cultured MDR-TB cells following ESAT-6 stimulation, but not in NR-TB or NTM patients. In vitro blockade of IL-10 or IL-10Rα decreased the CD4+ CD25+ FoxP3+ frequencies induced by ESAT-6 in MDR-TB, suggesting a role of IL-10 on impaired IFN-γ responses seen in MDR-TB. Depletion of CD4+ CD25+ T lymphocytes restored the capacity of MDR-TB T cells to respond to ESAT-6 in vitro, which suggests a potential role for Treg / T regulatory 1 cells in the pathogenesis of MDR-TB. Together, our results indicate that although the similarities in chronicity, NTM- and MDR-TB-impaired antigenic responses involve different mechanisms.

Increase of Reactive Oxygen Species in Natural Killer cells from Pulmonary Tuberculosis patients

D. Silva[1], *M. Abreu*[1], *M. Ferreira-Teixeira*[1,2], *P. Couceiro*[2], *I. Ladeira*[3], *F. Viveiros*[3], *R. Duarte*[3], *H. Sá*[1], ***P. Rodrigues-Santos***[1,2];*

[1]Inst Imunologia, Fac Medicina Univ Coimbra, Coimbra, Portugal, [2]Immunology and Oncology Lab, Center for Neurosciences and Cell Biology, Univ Coimbra, Coimbra, Portugal, [3]Centro Diagnóstico Pneumológico of Vila Nova de Gaia, Gaia, Portugal.

Tuberculosis (TB) remains today a threat for public health and one third of the world population is infected. Although the role of Natural Killer (NK) cells in vivo was never fully understood, their capacity to lyse not only infected macrophages, but also directly M. tuberculosis demonstrates their possible role in the immune response in addition to their regulatory function over other immune cells and their presence inside granulomas. However, their number is decreased and with impaired function in TB patients. Reactive oxygen species (ROS) produced by tissue-specific cells, mainly alveolar macrophages can be responsible for their suppressive state as happens in other diseases. In this work, we intended to demonstrate the increase of ROS in NK cells of patients with pulmonary tuberculosis.
We analyzed by flow cytometry the levels of oxidative stress in cells from peripheral blood of 14 TB patients with main focus in NK cells.
In our work we demonstrated that not only phagocytic cells with active NADPH oxidase have an increase of ROS, but also NK cells and NKT cells. We did not find any difference in ROS-producing CD8+ T cells comparing with healthy controls. Beyond expected decrease of total NK cell number and mainly CD56dim CD16+ subset, we found that almost CD56dim are CD16- corresponding these cells to an increase of oxidative stress. We also demonstrated that contrary to granulocytes and monocytes, in multi-drug resistant (MDR) TB patients the levels of oxidative stress in NK cells are equally higher to TB.

P4.05.63

Fatty acid, cytokines and chemokines profile in exhaled breath condensates (EBCs) of patients with Tuberculosis

*S. Mosquera-Restrepo, A. Caro-Zapata, C. Peláez-Jaramillo, **M. Rojas-Lopez**;*
Universidad de Antioquia, Medellín, Colombia.

Introduction. *Mycobacterium tuberculosis* (*Mtb*) affects host lipid metabolism; differences in the fatty acid profile and inflammatory products from mononuclear phagocytes from TB patients and controls have been reported. These mediators are differentially produced depending upon the clinical TB and should be useful to understand pathology of paucibacillary individuals. *Objective.* To analyze the profile of fatty acid derivatives, cytokines and chemokines in EBC of healthy, asmatic and tuberculosis children (6-12 years) and healthy, smear-positive and paucibacillary (12 years and older). *Methods.* EBCs were collected by capture R-tubes, condensed and some of them used to detect cytokines and chemokines by LUMINEX. Other EBCs were freeze-dried and used to detect fatty acid derivatives by gas chromatography. *Results.* Saturated fatty acids were lower in paucibacillary due to the higher relative amounts of oleate and linoleate and lower proportions of stearate and myristate compared with healthy adults and smear-positive patients. These fatty acids were also present in cells from bronchoalveolar lavages isolated from paucibacillary patients. After six months of treatment, EBC from paucibacillary patients did not differ from healthy controls. EBC from TB children presented higher relative amounts of palmitate, oleate and linoleate and lower amounts of stearate compared with non TB children. *Conclusion.* A combination of different EBCs fatty acids, cytokines and chemokines will allow distinguishing different groups of TB with diverse clinical manifestations, and these will provide insights to understand the mechanisms leading to better understand TB immunopathogenesis. *Funding resources* COLCIENCIAS 1115-4592-1439.

P4.05.64

Profiles of fatty acids released during the differentiation of mononuclear phagocytes in the presence of mycobacterium tuberculosis - stearic acid effect on Differentiation

*A. Caro-Zapata, S. Mosquera-Restrepo, C. Pelaez-Jaramillo, **M. Rojas-Lopez**;*
Universidad de Antioquia, Medellín, Colombia.

Introduction. Our previous results support the idea that fatty acid profile provides a valuable tool to correlate differentiation of mononuclear phagocytes with effector mechanisms. Differentiation into macrophages correlated with increased ratios of saturation mainly due decreased oleate. Laurate correlated with the presence of mycobacteria and arachidonate and linolenate with necrosis in less differentiated cells. Objective. Evaluate which fatty acids are released into the extracellular medium and its possible effect on the differentiation of mononuclear phagocytes. Methods. Human monocytes were isolated from PBMC from healthy donors; cells were infected or not with M. tuberculosis or treated with PPD, and differentiated 120 hours. Supernatants were esterified and analyzed by gas chromatography. Differentiation was also studied in the presence of stearic acid, the highest derivative found in supernatants from cells differentiated in the presence of M. tuberculosis; differentiation markers, cytokines and mycobacterial control were studied. Results. A stearic acid derivative was the only one significantly higher in supernatants from cells differentiated in the presence M. tuberculosis and PPD, compared with untreated cells. Monocyte differentiation in the presence of stearic into macrophages improved effector mechanisms against mycobacteria. Stearic acid increased HLA-DR, CD64, cytokines such as IL-12, TNF-alpha and IL-6 and chemokines as MIP-1 alpha and beta, and this treatment also reduced the bacterial burdens. Conclusion. Our data suggest that during the differentiation process that the cells release a derivative of stearate which favors the control of mycobacteria, the relevance of this finding still requires additional evidence. Funding resources COLCIENCIAS 1115-4592-1439.

Background: Diagnosis of active tuberculosis disease (TB) from latent Mycobacterium tuberculosis (Mtb) infection (LTBI) remains complex and requires several clinical, radiological, histo-pathological, bacteriological and molecular parameters. However, we recently showed that the dominant cytokine profile (i.e. TNFα+/IFNγ-/IL2-) of Mtb-specific CD4 T-cells from TB patients could be used as a diagnosis tool. Furthermore, Mtb-specific CD8 T-cell responses were more frequently detected in TB patients than in LTBI subjects.
Methods: We combined the detection of Mtb-specific CD8 T-cell responses to the analysis of the cytokine profile of Mtb-specific CD4 T-cells in 178 TB and LTBI subjects and determined the performances of the combination of both parameters as diagnosis assay (called SCORE).
Results: The performances of the combined diagnosis assay merging both parameters (cytokine profile of CD4 T cells and detection of CD8 T cells) were significantly (AUC: 0.94; P<0.008) improved as compared to each single parameter. On the basis of the logistic regression analysis, an optimal cutoff of SCORE of 4 was determined (OR=58; specificity=83.5%; sensitivity=92%; PPV=60% and NPV=97.5).
Conclusions: The activity of Mtb infection (i.e. latent versus active) is associated to distinct profiles of Mtb-specific CD4 and CD8 T-cell responses. These parameters can be combined within the same flow-cytometry assay and can be accurately used for the timely diagnosis of TB.

P4.05.66

Functional and phenotypic characterization of Mycobacterium tuberculosis specific CD4+T cells in peripheral blood and at the site of infection

K. Sahmoudi[1,2], *P. Ndishimye*[1,3], *M. Chair*[2], *A. El Habazi*[2], *J. Benamour*[4], *J. Bourkadi*[4], *K. Sadki*[3], *O. Lahlou*[5], *F. Seghrouchni*[1], *R. El Aouad*[1];
[1]*Laboratory of Cellular Immunology, the National Institute of Hygiene, Rabat, Morocco,* [2]*Faculty of Sciences,Université Chouaib Doukkali., El Jadida, Morocco,* [3]*Faculty of Sciences, University MohammedV., Rabat, Morocco,* [4]*University Hospital Moulay Youssef, Rabat, Morocco,* [5]*The reference laboratory of mycobacteriology, the National Institute of Hygiene, Rabat, Morocco.*

Tuberculosis (TB) is a worldwide public health problem. *Mycobacterium tuberculosis* (Mtb) specific CD4+T cells have an efficient role in the immune response against TB since more than 90% of subject infected with *Mtb* do not developing active TB (ATB). However, during ATB, these cells seem have crucial role close to the site of infection. Characterization of these cells could provide biomarker candidates that still represent a real challenge in diagnostic and vaccine research on TB.
In this study, we used surface and intracellular staining flow cytometry methods to determine the memory phenotypes and the functional profiles of *Mtb*-specific CD4+T cells within 12 patients with pleural TB and 16 healthy subjects with latent Mtb infection (LTBI).
Our results showed that the rate of *Mtb*-specific CD4+ T cells simultaneously producing IFN-γ, TNF-α and IL2 cytokines is significantly higher in the peripheral blood (PB) within LTBI subjects compared to patients with pleural TB. Furthermore, these multifunctional cells are highly represented in the pleural fluid compared to the autologous PB within patients.

Analysis of the memory phenotype of Mtb-specific CD4+ T cells showed that the percentage of effector memory (EM) sub-population (CD45RA-/CCR7-) is also increased in the PB of LTBI subjects and in the pleural fluid of patients. Nevertheless, we showed that this repartition involve EM CD4+T cells obligatory producing IFN-γ.
These findings indicate that the characterization of the EM and polyfunctional Mtb-specific CD4+T cells in the PB and in the site of infection may help as a correlate of protection.

P4.05.67
NOD2 triggers an IL-32 dependent human dendritic cell program in leprosy

***M. Schenk**, R. L. Modlin;*
UCLA, Los Angeles, CA, United States.

It is unclear whether the ability of the innate immune system to recognize distinct ligands from a single microbial pathogen via multiple pattern recognition receptors (PRRs) triggers common pathways or differentially triggers specific host responses. In the human mycobacterial infection leprosy, we found that activation of monocytes via NOD2, by its ligand muramyl dipeptide, vs. TLR2/1, by triacylated lipopeptide, preferentially induced differentiation into dendritic cells (DC), dependent upon a novel IL-32-dependent mechanism. IL-32 was sufficient to induce monocytes to rapidly differentiate into DC. Although IL-32 or GM-CSF derived DC efficiently process and present antigen via MHC class II to CD4+ T cells, IL-32 derived DC were more efficient in presenting antigen to MHC class I-restricted CD8+ T cells. Importantly, IL-32 induced DC showed the capacity to cross-present antigen, allowing MHC class I molecules to present peptides derived from exogenous antigens taken up by the endocytic pathway. Our finding that the NOD2 IL-32 dependent DC pathway of cross-presentation is present at the site of disease in tuberculoid leprosy suggests the hypothesis that IL-32 induction of cross-presentation of mLEP antigens results in activation of CD8+ T cells and is important for host defense.

P4.05.68
The role of follicular helper T cells in mycobacterial infection

***Y. Shimohakamada**[1,2], T. Tamura[1], M. Makino[1], S. L. Nutt[3];*
[1]National Institute of Infectious Disease, Higashimurayamashi, Japan, [2]National Sanatorium Tama-Zensyouen, Higashimurayamashi, Japan, [3]The Walter and Eliza Hall Institute of Medical Research, Parkville, Australia.

Immunological protection against Mycobacterial infection requires the activation of the cellular arm of the immune response. However, the role of humoral immunity against Mycobacterial infection is not well understood until now. Follicular helper T (Tfh) cells are one of CD4+ helper T cell subsets that regulate humoral immunity through B cell mediated antibody secretion. IL-21 secreted by Tfh cells plays an important role of induction of the humoral immunity. It is however less clear whether Tfh cells participate cellular immunity. To investigate the role of Tfh cells in mycobacterial infection, we focused on the induction and differentiation of Tfh cells. We used Mycobacterium bovis BCG (Bacille de Calmette et Guérin) that is a popular vaccine against Mycobacterial tuberculosis. Using our recently reported IL-21-GFP reporter mouse, we have compared the frequency, phenotype and capacity to produce IL-21 from Tfh cells in both lymphoid and non-lymphoid organs following BCG and influenza virus infection.

P4.05.69
Specific TCD8+IL-10+ and TCD8+TGF-beta+ cells in active tuberculosis patients

***B. S. Silva**, M. M. Trentini, A. C. Costa, A. O. Costa-Júnior, A. Kipnis, A. Junqueira-Kipnis;*
Universidade Federal de Goiás, Goiânia, Brazil.

Tuberculosis (TB) is responsible for causing over 1.5 million deaths each year. TCD4+ together with TCD8+ cells and their cytokines are important for protective immune response to TB. Although TCD8+ cells have been studied in TB, several aspects are not yet clarified. In the absence of TCD4+ cells, TCD8+ cells increase their cytotoxic function and production of different cytokines in order to respond to Mycobacterium tuberculosis (Mtb) infection. To understand the role of TCD8+ cells as regulatory cytokine producers in TB, peripheral blood TCD8+ cells were characterized and compared their profile with healthy controls (TST-). PBMC from 15 patients with active pulmonary TB (mean age = 40.5) and 15 healthy controls TST-, matched by sex and age to TB patients, were cultivated for 96 hours with Mtb recombinant antigen (rMPT-51). TCD8+ cell subsets were analyzed by flow cytometry. TB patients presented higher levels of TCD8+IL-10+ (medium=1.2±0.9; PHA=12.8±1.5; rMPT-51=5.0±1.4) and TCD8+TGF-beta+ (medium=1.6±1.3; PHA=14.1±1.7; rMPT-51=8.0±1.1) in response to rMPT-51 than TST- individuals (TCD8+IL-10+: medium=1.3±1.1; PHA=11.9±1.7; rMPT-51=3.0±1.5); (TCD8+TGF-beta+: medium=2.4±0.8; PHA=13.6±2.3; rMPT-51=2.8±1.2). The cytotoxic markers of TCD8+ cell such as Perforin and Granzime-B are independent of the rMPT-51 stimulus, and TB patients had lower percentage of triple positive cells than the healthy controls (TST-=21.7±2.8; TB=9.1±1.3). Conclusions: Patients with TB presented Mtb specific TCD8+ cells positive for IL-10 and TGF-beta, whereas presented lower cytotoxic markers. These results suggest that TCD8+ cells can contribute to the regulatory immune response in active tuberculosis.

P4.05.70
Deciphering Dendritic Cell Function during Mycobacterium tuberculosis Infection by RNA Interference

***J. Singhal**, K. Natarajan;*
Dr. B. R. Ambedkar Center for Biomedical Research, University of Delhi, Delhi, India.

With rising incidence of acquired drug resistance amongst life-threatening pathogens, alternative approaches to improve therapy and vaccination have taken centre stage. To this end genome wide and pathway specific siRNA libraries are being increasingly employed to identify genes that regulate immune responses against a number of pathogens. In this study using calcium and cysteine protease pathway specific siRNA libraries we identified genes that play critical roles in modulating diverse functions of dendritic cells (DCs) during Mycobacterium tuberculosis (M. tb) infection. Knockdown of many of these genes in the two pathways resulted in reduced bacterial burden within DCs. These included genes that regulated activation of transcription factors, ubiquitin specific peptidases, and genes that are involved in autophagy and neddylation. Knockdown of certain genes increased the expression of IL-12p40 and surface densities of costimulatory molecules in an antigen and receptor specific manner. Increased IL-12p40 and costimulatory molecules on DCs also promoted the development of Th1 responses from a Th2 inducing antigen. Further, modulation of autophagy and oxidative burst appeared to be one of the mechanisms by which these genes regulated survival of M. tb within DCs. While some genes regulated specific responses, others regulated multiple responses that included IL-12 production, T cell priming as well as intracellular survival of M. tb. Further dissection of the mechanisms such as neddylation, by which these genes regulate immune responses, would improve our understanding of host parameters that are modulated during M. tb infection.

P4.05.71
Clinical isolates of Mycobacterium tuberculosis exacerbate pulmonary inflammation in mice

***E. M. Soares**[1], A. Secatto[1], C. Peres-Buzalaf[2], E. G. Soares[1], M. Palaci[3], C. L. Silva[1], L. H. Faccioli[1];*
[1]Universidade de São Paulo, Ribeirão Preto, Brazil, [2]Universidade de São Paulo, Bauru, Brazil, [3]Universidade do Espírito Santo, Vitória, Brazil.

***Background:** Mycobacterium tuberculosis (Mtb)* is a virulent intracellular pathogen that infects and persists in host macrophages, resulting in granuloma formation and collagen deposition in the lung. The mechanisms that confer resistance to *Mtb* or result in establishment of disease are poorly understood. Data from the

literature suggest that differences in *Mtb* virulence contribute to the development of disease. ***Objective:*** Our purpose was to investigate lung inflammatory reactions in mice induced by three isolates of *Mtb.* These isolates were recovered from patients with non-cavitary (SV009), cavitary (SV038) and extra-pulmonary (SV068) active tuberculosis and compared to H37Ra (avirulent) and H37Rv (virulent) *Mtb* strains. ***Methods:*** Female Balb/c mice were inoculated intratracheally (i.t) with $1x10^5$ CFU of *Mtb* or 100 µL PBS. Neutrophil and mononuclear cell recruitment to the lung was assessed by bronchoalveolar lavage (BALF). Mouse survival, colony formatting units (CFU), lung histology, and cytokines were evaluated. ***Results:*** Mice infected with SV009, SV038 and SV068 presented with more robust cellular recruitment into BALF at 30 and 60 days post infection (p.i.) and survival was reduced compared to H37Rv/a. Spleen CFU recovered 90 days p.i. was higher in mice infected with SV009 strain. Lung histology demonstrated that SV068 infected mice had greater numbers of foamy macrophages containing *Mtb* and intense perivascular and perialveolar infiltration of neutrophils, mainly at 60 days p.i. Cytokine production was variable among the groups, especially IFN-γ, TNF-α, IL-6 and IL-10. ***Preliminary Conclusion:*** Our findings suggest that SV009, SV038 and SV068 are more virulent than H37Rv/a *Mtb* strains.

P4.05.72
Role of Slc11a1 gene in macrophage activation during BCG infection

*P. Aguilar-Ramirez[1], W. H. K. Cabrera[1], J. R. Jensen[1], D. Rodriguez[2], L. C. C. Leite[2], O. G. Ribeiro[1], M. De Franco[1], O. C. M. Ibañez[1], **N. Starobinas**[1];*
[1]Laboratory of Immunogenetics - Instituto Butantan, São Paulo, Brazil, [2]Centro de Biotecnologia - Instituto Butantan, São Paulo, Brazil.

The *Slc11a1* gene regulates resistance against *S. enterica* Typhimurium, *L. donovani* and *M. tuberculosis*. AIRmax and AIRmin mouse sublines, homozygous for *Slc11a1* R and S alleles ($AIRmax^{RR}$, $AIRmax^{SS}$, $AIRmin^{RR}$ and $AIRmin^{SS}$) were produced in our Lab to study the effect of this gene in the inflammation background. The aim of this work is to evaluate the effect of this gene in peritoneal macrophage (MΦ) activation during *M. bovis* BCG infection. Mice were inoculated ip with BCG (14 days) or PBS (control). The peritoneal cells were collected and placed in culture, the adherent MΦ stimulated or not with LPS were used in all experiments. Spleens were homogenized and cultured in MB7H10 medium and the bacterial colonies were counted. Production of NO, H_2O_2 and cytokine were determined in culture supernatants. In BCG infection only $AIRmax^{RR}$ mice were capable of controlling bacterial proliferation, which was accompanied with high levels of IL-1β, IL-12, TNF alfa and IL-6 produced by activated macrophages. On the other hand, susceptible $AIRmin^{SS}$ mice produced higher amounts of NO, H_2O_2 and IL-10 suggesting that both inflammatory background and *Slc11a1* alleles interfere on resistance to BCG infection. Thus, we conclude that the high inflammatory response associated to *Slc11a1* R alleles (in $AIRmax^{RR}$ mice) are mechanisms for efficient bacterial killing, through production of cytokines by MΦ which activates the immune response.

P4.05.73
Development of a new point-of-care test for leprosy

*L. P. V. Cardoso[1], A. A. Freitas[1], E. M. Hungria[1], R. M. Oliveira[1], R. F. Dias[2], M. Collovati[2], S. G. Reed[3], M. S. Duthie[3], **M. M. Stefani**[1];*
[1]Tropical Pathology and Public Health Institute, Goiania, Brazil, [2]Orangelife® Company, Rio de Janeiro, Brazil, [3]Infectious Disease Research Institute, Seattle, WA, United States.

Leprosy is a dermato-neurological disease that remains an important public health problem in many endemic countries. Leprosy presents as a spectrum and no laboratory test is commercially available for its diagnosis/prognosis. Here we report the development of a new point-of-care (POC) test for leprosy using LID-1 fusion-protein and phenolic glycolipid-I (PGL-I) (NDO-LID,Orangelife®/Brazil). A new rapid-test reader platform integrated in a cell phone was also used (Smart Reader application-SR®). NDO-LID® tests were evaluated among newly diagnosed untreated multibacillary (MB=108) and paucibacillary (PB=104) leprosy patients, (Ridley & Jopling classification); leprosy household contacts (HHC=75); pulmonary tuberculosis patients (sputum positive/HIV negative;TB=53) and healthy endemic controls (EC=101) recruited in central-western Brazil. NDO-LID® anti IgM/IgG reactivity (SR®:cut-off=10) was compared to anti PGL-I IgM ELISA (cut-off:optical density=0.250). Across the spectrum of leprosy forms (from lepromatous/LL to tuberculoid/TT pole) a gradual decrease in the seropositivity to NDO-LID® test was observed: 97.4% for LL, 83.7% for borderline lepromatous/BL, 76.9% for borderline borderline/BB patients; 26.2% for borderline tuberculoid/BT and 14% for TT patients. Seropositivity among HHC was 5.3%, 5.7% for TB and 3% among EC. The estimated sensitivity of NDO-LID® test was 87% and the specificity was 96.1%. The new NDO-LID® POC test represents a useful tool for MB leprosy detection/diagnosis and treatment and can also contribute to monitor treatment by leprosy controls programs. MB patient are important *Mycobacterium leprae* disseminators and are at increased risk of complications such as reactional episodes. The digital and automated rapid test SR®-app also represents an improvement towards more accurate results.

P4.05.74
The involvement of proteins of DNA double-strand breaks repair systems of *Mycobacterium tuberculosis* in the infection of human macrophages

***I. Szulc**, M. Brzezinska, M. Klink, A. Brzostek, M. Kielbik, Z. Sulowska, J. Dziadek;*
Institute of Medical Biology, Polish Academy of Sciences, Lodz, Poland.

Objectives: Double-strand breaks repair systems as non-homologous end-joining (NHEJ) and homologous recombination (HR) are important for the *Mycobacterium tuberculosis* (Mtb) survival *in vitro*. We determine the involvement of proteins Ku, ligase D (crucial for NHEJ system) and RecA (major for HR) in the Mtb intracellular survival. Methods: MtbH37Rv mutants with inactivated genes: *ku, ligD* (Δ*ku/ligD*), *recA* (Δ*recA*) or *ku, ligD, recA* (Δ*ku/ligD/recA*) were obtained using the technique of gene replacement based on the process of homologous recombination. Intracellular growth of bacteria and antimicrobial activities of macrophages: nitric oxide (NO) and reactive oxygen species (ROS) production were examined. The involvement of EKR1/2 signalling pathway in the response of macrophages to Mtb infection was assessed. Results: We found that Δ*ku/ligD/recA* mutant grew significantly weaker inside the macrophages than wild-type and the rest of mutants. Inhibition of ERK1/2 pathway in macrophages caused the increased intracellular growth of Δ*ku/ligD/recA*. Δ*ku/ligD/recA* and Δ*recA* mutants, but not wild-type or Δ*ku/ligD*, stimulated NO and ROS production. Nevertheless, inhibition of ERK1/2 signalling pathway blocked NO and ROS production by macrophages infected with Δ*ku/ligD/recA* or Δ*recA*. Only the triple mutant did not disturb the phosphorylation of ERK1/2 proteins induced by phorbol ester. Conclusion: Both NHEJ and HR systems are important for the survival of Mtb inside human resting macrophages. The RecA protein affect the bactericidal activity of macrophages. We suggest that HR repairing pathway can be one of the virulence factor of Mtb.

P4.05.75
The role of Mycobacterium tuberculosis secreted protein in the induction of Th1 immune response

***T. Tamura**[1], Y. Shimohakamada[1,2], M. Makino[1];*
[1]National Institute of Infectious Diseases, Higashimurayama, Japan, [2]National Sanatorium Tama-Zensyouen, Higashimurayama, Japan.

Peptide-25 is the major T cell epitope for Ag85B of Mycobacterium tuberculosis and induces Th1 differentiation in vivo. Using transgenic

mice expressing a T cell receptor specific for Peptide-25, we demonstrated that Peptide-25 induced transient expression of T-bet, and as a result induced Th1 differentiation in the absence of IFN-γ and IL-12. In this study, we examined the role of T-bet in Peptide-25 induced Th1 differentiation. Using T-bet-/- P25 TCR-Tg mice, we demonstrated that Peptide-25 induced Th1 differentiation even in the absence of T-bet, indicating that Peptide-25 induces the expression of transcription factors that induce the chromatin remodeling of ifn-γ gene in a T-bet independent manner. To identify the transcription factors, we analyzed gene expression profile in CD4+ T cells after Peptide-25 stimulation by using Affymetrix GeneChip. Our criterion for the selection of genes induced by Peptide-25 stimulation was that their expressions are more than two-fold changed compared to unstimulated cells and they possess the transcription activity. As a result, we identified 53 genes as a transcription factor induced by Peptide-25 stimulation in the CD4+ T cells from both T-bet-/- and WT P25 TCR-Tg mice.
We are now confirming whether these candidate genes can induce the chromatin remodeling of ifn-γ gene by using retroviral expression system.

P4.05.76
Anti-tuberculosis chemotherapy reveals differences in host immunity to *Mycobacterium africanum* and *Mycobacterium tuberculosis* infection

L. Tientcheu Djomkam[1,2]*, J. S. Sutherland*[1]*, M. C. Haks*[3]*, D. J. Jefferies*[1]*, T. H. M. Ottenhoff*[3]*, H. M. Dockrell*[2]*, M. M. Ota*[4]*;*
[1]Medical Research Council (UK) The Gambia, Banjul, Gambia, [2]London School of Hygiene & Tropical Medicine, London, United Kingdom, [3]Leiden University Medical Center, Leiden, Netherlands, [4]World Health Organization Regional Office for Africa, Brazzaville, Congo, Republic of the.

Mycobacterium tuberculosis (*Mtb*) and *Mycobacterium africanum* (*Maf*) are the two main strains causing tuberculosis (TB) in The Gambia. *Maf* is more likely to affect immune-compromised individuals, implying that it is less virulent than *Mtb*. This study aimed to evaluate differences between the host immune response to both pathogens.
HIV-negative TB patients were classified as *Maf* (n=26) or *Mtb* (n=49) infected based on spoligotyping of sputum isolates. Clinical and immunological evaluation was performed before, and after 2 and 6 months treatment. Undiluted whole blood was stimulated overnight with mycobacterial antigens and controls, multiple cytokines in culture supernatants were measured using the Bio-Plex assay and mRNA expression levels of 85 innate and adaptive immune markers were assessed by dual-colour RT-MLPA assay.
Before treatment, IL-9 secretion and expression was significantly higher in *Maf* than *Mtb*-infected patients in response to PPD and live-*Maf* respectively. Following treatment, IFN-γ, IL-4, IL-13, IL-9 and CCL11 secretion as well as CCL4, Granzyme B and autoimmune regulator (AIRE) expression significantly increased and were higher in *Mtb* than *Maf*-infected patients after treatment in response to ESAT-6/CFP-10, live-*Mtb* and live-*Maf*. There was greater improvement in body mass index and chest X-ray presentation in *Mtb* than *Maf*-infected patients after treatment.
Mtb may have the ability to suppress an immune-competent host response, which is restored following treatment. *Maf*-infected patients may have an intrinsic weaker immunity with high IL-9 production or may require a modified treatment regimen. These data provide an important addition to our understanding of pathogenesis of TB with public health implications.

P4.05.77
The interaction of CD43 with Mycobacterium tuberculosis Cpn60.2 modulates cytokines production

A. Torres Huerta[1]*, C. Espitia*[2]*, M. E. Cruz Muñoz*[1]*, G. Pedraza Alva*[1]*, Y. Rosenstein*[1]*;*
[1]Instituto de Biotecnología, Universidad Nacional Autónoma de México, Cuernavaca, Mexico, [2]Instituto de Investigaciones Biomedicas, Universidad Nacional Autónoma de México, México, DF, Mexico.

The pathology of tuberculosis is considered to begin following the first interactions between *Mycobacterium tuberculosis* (Mtb) and alveolar macrophages through the production of IFN-gamma and TNF-alpha, two essential cytokines for the eradication of the bacteria. Additionally, IL-10 has been found to play an important role in infection and to block Mtb-phagosome maturation. Several molecules such as complement, Fc-gamma and mannose receptors, Scavenger receptors, Sp-A receptors, CD14, TLRs and CD43 participate in these cytokines production. Particularly, CD43KO mice fail to produce TNF-alpha in response to mycobacteria exposure. Given that Cpn60.2 and DnaK, two highly conserved chaperones among mycobacteria (including *Mycobacterium bovis* (BCG)), are presumed ligands for CD43, our aim was to evaluate the role of CD43 in TNF-alpha and IL-10 production in macrophages stimulated with BCG or Cpn60.2 and to elucidate the signaling pathway for the production of these cytokines. We generated clones of THP-1 cells stably transfected with a plasmid that down-regulates the expression of CD43; alternatively we derived BMMs from CD43KO and wild type mice; all cells were stimulated with BCG or Cpn60.2. We found that the lack of expression of CD43 correlated with a down modulation in TNF-alpha production, but surprisingly in enhanced IL-10 secretion. We also found that the CD43-mediated signaling pathway leading to TNF-alpha production depends on PI3K, PLC-gamma and members of the PKC family. All together these data highlights a role for CD43 in regulating the pathology of tuberculosis.

P4.05.78
Combined detection of IFNγ, TGFα and IL-6 can discriminate between active TB disease and latent infection

E. Vasilyeva[1]*, V. Verbov*[1]*, I. Nikitina*[2]*, I. Lyadova*[2]*, A. Totolian*[1]*;*
[1]St. Petersburg Pasteur Institute, Saint-Petersburg, Russian Federation, [2]Central Tuberculosis Research Institute, Moscow, Russian Federation.

Interferon gamma release assays are used for diagnosing Mycobacterium tuberculosis (M.tb.) infection. However these tests fail to differentiate active TB from latent TB infection (LTBI).
Aim: Selection of informative biomarkers for diagnosing M.tb. infection and for discriminating between latent TB infection (LTBI) and active TB disease.
Materials and Methods: We recruited 54 TB patients, 47 TB contacts and 43 healthy donors and performed the “QuantiFERON-TB Gold In-Tube” (“Cellestis”, Australia). Using XMap technology levels of 10 cytokines (EGF, MIP-1β, VEGF, IL-2, IL-4, IL-6, IL-1α, IFN-α2, TGFα, TNFα) as well as sIL-2Rα and sCD40L were evaluated in unstimulated (NIL) and Mycobacterium tuberculosis specific antigen (AG) stimulated plasma. We also determined levels of IP-10 in 48 patients by ELISA.
Results: Six out of 13 biomarkers distinguished active TB from LTBI . As a result of “decision tree” in JMP 9.0 software, we choose three the most informative cytokines. The combination between IFNγ, TGFα and IL-6 may allow to distinguish active TB from latent infection with sensitivity 96,3% and specifity 80,7% (AUC=0,9). We also observed very high levels of IP-10 and IL-2, which correlated with IFNγ levels (r=0,71 and 0,79 respectively).
Conclusion: IL-2 or IP-10 as well as IFNγ, detection could be used as a first step to diagnose (M.tb.) infection. A second step of the test could be performed if positive IL-2 / IP-10 / IFNγ results are obtained to measure three-marker combination of IFNγ, TGFα and IL-6 to differentiate individuals with active TB from LTBI.

P4.05.79
Modelling human granuloma to study the mechanisms by which isoniazid inhibits Mycobacterium tuberculosis growth.

***L. H. Yamashiro**, N. M. de Souza, M. D. Garcia, C. Eto, A. Báfica;*
UFSC, Florianópolis, Brazil.

Tuberculosis (TB), caused by the intracellular pathogen *Mycobacterium tuberculosis* (Mtb), is one of the most devastating infectious diseases worldwide. One of the main anti-TB antibiotic used is isoniazid (INH), which inhibits mycolic acid synthesis, an important bacteria's cell wall component. *In vitro* studies have suggested that INH-dependent bactericidal efficiency requires both a prolonged time of drug exposure as well as elevated concentrations in infected macrophages. In contrast, clinical studies have shown that INH promotes an initial killing of 95% of bacteria during the first 2 days of treatment, pointing to an indirect effect of this drug, which is found at low nM-range concentrations within the granuloma. To investigate the mechanisms by which INH inhibits Mtb survival during cellular infection, we have utilized an *in vitro* model in which these human leukocytes acquire granuloma conformation upon bacteria infection. Interestingly, treatment with INH inhibited Mtb growth in granulomas from PPD negative, but not in PPD positive donnors. Levels of TNF, IL-1beta and IL-6 showed no major diferences in PPD+ versus PPD- granulomas, except for IL-8, which was found to be highly decreased in INH-treated granulomas from PPD+ donnors. These results suggest that INH direct modulates adaptive lymphocyte responses within the granuloma. Experiments to address this hypothesis are in progress.

Aptamer against an immunosuppressive epitope-ManLAM inhibits virulent *Mycobacterium tuberculosis* infection in mice and rhesus monkeys

***X. Zhang**, Q. Wang, Q. Pan, X. Xia, F. Luo;*
Wuhan University School of Medicine, Wuhan, China.

The major surface lipoglycan of *Mycobacterium tuberculosis* (*M. tb*), mannose-capped lipoarabinomannan (ManLAM) is an immunosuppressive epitope of *M. tb*. We used Systematic Evolution of Ligands by EXponential enrichment (SELEX) to generate an aptamer (ZXL1) that specifically bound to ManLAM from the virulent *M. tb* H37Rv strain. Aptamer ZXL1 had the highest binding affinity (equilibrium dissociation constant-[KD] of 8.91 X 10^{-8} M) and competed with the mannose receptor for binding to ManLAM and *M. tb* H37Rv. ZXL1 significantly inhibited the ManLAM-induced immunosuppression of $CD11c^{+}$ dendritic cells (DCs) and enhanced the *M. tb*-antigen-presenting activity of DCs for naïve Th1 $CD4^{+}$ cell activation. More importantly, we demonstrated that a single injection of aptamer ZXL1 significantly reduced the progression of *M. tb* H37Rv infections, bactieral loads in lung and prolonged the survival rates in mice or rhesus monkeys. These results suggest that aptamer ZXL1 is a new potential antimycobacterial agent and TB vaccine immune-adjuvant.

Anti-aspergillus fumigatus IgY antibodies and their protective efficacy in immunocompromised BALB/c mice

*K. Kissoyan, N. Al-Akl, **A. Abdelnoor**;*
American University of Beirut, Beirut, Lebanon.

Earlier the protective and therapeutic effect of immune IgY on normal mice challenged with A. fumigates was established and reported. In the present study immunocompromised, instead of normal mice were used.
Egg laying hens were immunized with a heat-killed suspension of A. fumigatus. IgY- rich extracts were obtained from the yolk of eggs laid post-immunization and pooled. The same was done with eggs laid pre-immunization. The preparations were dialyzed and then lyophilized. The presence of IgY anti-A. fumigatus antibodies in the post-immunization and its absence in pre-immunization extracts was confirmed by ELISA. Pre and post immunization IgY extracts were compared by polyacrylamide gel electrophoresis (PAGE). Groups of BALB/c mice were treated with cyclosporin A for 10 days prior to challenge with viable A. fumigatus, and were given IgY extract either 24hrs before, during, or 24hrs after the A. fumigatus challenge. Survivals were monitored daily and compared to control groups for a period of two weeks.
The post-immunization, but not the pre-immunization extract, protected mice against lethal challenge with A. fumigatus. Protection was observed when the extract was given 24 hours before, simultaneously with, or 24 hours after challenge.
It appears that antibodies produced in egg laying-hens directed against A. fumigatus are protective and therapeutic in the immunocompromised mice when given in proximity of a lethal dose of the fungus. A clinical trial to test their prophylactic/ therapeutic potential in immunocompromised patients might be considered.

P4.06.02
HeNe laser increases the pro-inflammatory cytokines production and the in vitro phagocytosis of P. brasiliensis by macrophages

***T. Alves da Costa**, R. Thomé, R. Di Gangi, C. Francelin, L. Verinaud;*
UNICAMP, Campinas, Brazil.

Cutaneous lesions caused by the fungus *Paracoccidioides brasiliensis* (Pb) lead to painful ulcerative wounds, which are difficult to be cured by conventional treatment with anti-fungal drugs due to their adverse effects and the multidrug resistance that some fungal isolates present. We have previously showed that Helium-Neon (HeNe) laser irradiation of paracoccidioidomycotic lesions in mice accelerates the wound healing as well as the fungal clearance, which is very probably linked to the death of the fungus by macrophages. In this study we evaluated, *in vitro*, whether HeNe laser irradiation was capable of modulating the phenotypic and functional profile of human and murine macrophages. Peritoneal macrophages from BALB/c mice were irradiated with different dosages of HeNe laser (0.836; 1.5 and 3J/cm^2) and cultivated with Pb yeast cells (1:4, macrophage:fungi) for 6 hours. Flow cytometry analysis of macrophages showed that laser irradiation promoted an increase in the expression of TLR-4, which are molecules involved in yeast recognition and internalization, but did not alter other markers, like CD11b, F4/80, MHC-II, for example. Also, co-cultures of irradiated macrophages and Pb showed a higher phagocytic index and a higher pro-inflammatory (IFN-γ, IL-6, TNF-α) cytokines production. Similar results were obtained with a human macrophage cell line (THP1) even under the lowest incidence energy of the laser. Collectively, our results indicate that the accelerated wound healing process, observed after the treatment of paracoccidioidomycotic lesions with the HeNe laser, must be associated with a direct action of irradiation on macrophages.

Cryptococcal infections are caused mainly by two Cryptococcus species; C. neoformans and C. gattii. Unlike C. neoformans that infects primarily the immunocompromised hosts, C. gattii can cause life threating diseases in healthy individual. Accumulating studies suggest that C. gattii infection evades host immune response by preventing leukocyte recruitments into the lungs and inhibiting immune response. However, the underlying mechanisms that immunocompetent host fails to mount effective immune response against C. gattii infection remain unidentified. In this study, we report that C. gattii infection fail to elicit effective Th1 responses. Compared

with C. neoformans-infected mice, mice infected with the high virulent C. gattii strain R265 exhibited reduced recruitments of inflammatory leukocytes and CD4+ T cells in the lungs and developed much fewer antigen-specific IFN-γ-producing T cells. Unexpectedly, this high virulent strain R265 did not impair the development and recruitments of Th17 cells. The failure to mount effective Th1 response in mice infected with C. gattii was further confirmed by the significant reduction of Ifng, but not Il13 or Foxp3 transcripts in their lung compared to in those of C. neoformans-infected mice. Furthermore, we showed that the loss of Th1 response correlated positively with reduced Il12p35 mRNA expression in the lung of mice infected with C. gattii, compared to that of C. neoformans-infected mice. Our data thus suggest that C. gattii is capable of not only inhibiting the recruitments of inflammatory cells, but also dampening protective Th1, but not Th17 responses, possibly by downregulating their Th1-promoting cytokine IL-12 expression in the lung.

P4.06.04
Disentangling immunity and tolerance in candidiasis

***D. Antonella**, A. Carvalho, C. Cunha, G. Giovannini, L. Bartolommei, S. Moretti, C. Massi-Benedetti, M. Puccetti, R. G. Iannitti, L. Romani;*
University, Perugia, Italy.

The ability to tolerate *Candida albicans*, a component of human microbiota, implicates that host defense mechanisms of resistance and tolerance cooperate to limit fungal burden and inflammation at the different body sites. We have disentangled resistance and tolerance components of murine and human *C. albicans* mucosal infection and have introduced the challenging notion of a disease due to a defective tolerance mechanism. While some degree of inflammation is required for protection at mucosal tissues during the transitional response occurring between the rapid innate and slower adaptive responses, progressive inflammation worsens disease and ultimately prevents pathogen Resistance and tolerance mechanisms were both activated in murine intestinal and vaginal candidiasis through the contribution of innate and adaptive immune responses, involving distinct modules of immunity, IL-22 and Th1/Th17 cells for resistance and IL-10-producing regulatory T cells for tolerance., with a major contribution by the enzyme indoleamine 2,3-dioxygenase 1 (IDO1). IDO1 was responsible for the production of tolerogenic kynurenines, such that replacement therapy with kynurenines restored immunoprotection to murine vaginal candidiasis. In humans, two functional genetic variants in *IL22* and *IDO1* genes were found to be associated with heightened resistance to recurrent vulvovaginal candidiasis, a disease of unknown origin, and they correlated with increased local expression of IL-22, IDO1 and kynurenines. Thus, IL-22 and IDO1 are crucial in balancing resistance with tolerance to *Candida*, their deficiencies are risk factors for mucosal infection resulting from transition from symbiont to pathobiont.

P4.06.05
Paracoccidioides brasiliensis* induces neutrophil extracellular traps *in vitro

***T. F. Bachiega**, R. K. Fernandes, D. R. Rodrigues, H. A. Balderramas, L. A. Dias-Melicio, Â. M. V. C. Soares;*
UNESP -Universidade Estadual Paulista, Botucatu, Brazil.

Paracoccidioides brasiliensis is a dimorphic fungus that is the causative agent of paracoccidioidomycosis, a chronic, subacute or acute mycosis, with visceral and cutaneous involvement. Recently, studies have focused on the role of neutrophils that are involved in primary response to the fungus. In addition to their ability to eliminate pathogens by phagocytosis and antimicrobial secretions, it has been shown recently that neutrophils can trap and kill microorganisms by release of extracellular structures composed by DNA and antimicrobial proteins, called neutrophil extracellular traps (NETs).The aim of this study was to demonstrate whether *P. brasiliensis* induces NETs release by human neutrophils activated or not with cytokines that promote fungicidal activity of these cells. Human neutrophils were isolated from peripheral blood of healthy donors and incubated with *P. brasiliensis* for 60, 90, 120 and 150 minutes. Some of these cultures were pré-treated with DNAse (to degrade NETs) or PMA (positive control of NETs release). Samples analyzed by scanning electron microscopy and photomicrographs demonstrated that *P. brasiliensis* induces NETs 60, 90, 120 and 150 minutes after interaction with neutrophils. DNAse treatment degraded these structures, whereas PMA induced their formation. Moreover, by using confocal imunofluorescence microscopy the following NET constituents were identified in activated cells with TNF-α, IFN-γ and GM-CSF: DNA (stained with DAPI, elastase (stained with FITC) and histones (stained with TEXAS RED). Thus, we demonstrated that *Paracoccidioides brasiliensis* is able to induce NETs. FAPESP 2010/17405-5; FAPESP 2010/18957-1.

P4.06.06
Characterization of Regulatory T Cells in Pulmonary Paracoccidioidomycosis Using Foxp3-GFP Transgenic Mice

***S. Bazan**, T. Costa, V. Calich;*
University of São Paulo, Institute of Biomedical Sciences, São Paulo, Brazil.

The involvement of Foxp3-expressing regulatory T (Treg) cells in suppressing immunity against paracoccidioidomycosis, the most prevalent deep mycosis in Latin America, has been previously demonstrated. However, more direct approaches using Foxp3-GFP mice have never been used. In the present study, Foxp3-GFP mice were intratracheally infected with 10^6 yeast cells and examined 2 and 10 weeks post-infection. Flow cytometric analyses showed the expansion of $Foxp3^+$ $CD4^+$ T cells at the site of infection and the up-regulation of diverse cell surface markers, including those associated with the “natural Treg” phenotype at both post-infection periods. In addition, increased expression of Treg-related effector molecules were observed at the chronic phase of *Paracoccidioides brasiliensis* infection. Treg cells were then depleted by administration of anti-CD25 mAb (PC61) at an early phase of infection. Treg ablation led to reduced fungal burden in the lungs as well as virtually no dissemination to liver and spleen both in early and late stages of infection, as shown by a colony forming units assay. Furthermore, PC61-treated mice displayed an increased number of effector T cells and diminished tissue pathology, as revealed by flow cytometry and histopathologic analysis of lung sections, respectively. These data support the deleterious effects exerted by Treg cells on PCM and help to elucidate some of the immunoregulatory phenomena involved in this systemic mycosis.

P4.06.07
Deciphering the class and specificity of the T cell response to C. albicans

***S. Becattini**[1,2], F. Mele[1], G. Gyuelveszi[1], L. Perez[1], A. Sette[3], A. Lanzavecchia[1,2], F. Sallusto[1];*
[1]Institute for Research in Biomedicine, Bellinzona, Switzerland, [2]Institute of Microbiology, ETH, Zurich, Switzerland, [3]La Jolla Institute for Allergy and Immunology, La Jolla, CA, United States.

From the immune system point of view, microbes (pathogens or commensals) are complex antigens that occupy distinct niches and consequently trigger different types of immune responses. The complexity of the microbial proteome, in particular that of bacteria and fungi, represents a considerable challenge to our capacity to analyze the human T cell response. We are using complementary approaches in order to study the human T cell response to Candida albicans and to identify immunodominant and protective antigens. On the one hand, we are performing a wide screening of HLA-binding peptides, identified through bioinformatic analysis, from 80 fungal proteins belonging to different classes for their capacity to be recognized by different memory T cell subsets. On the other hand, we isolate and identify proteins contained in cell wall extracts that are recognized by human IL-17-producing memory T cells (Th17) and induce strong immune responses when used as vaccines in mice. These studies are expected to improve our understanding of the immune response to complex pathogens, to define the correlation between class of antigens and type of T cell response elicited, and, finally, to provide useful information for the design of subunit vaccines against C. albicans.

P4.06.08
Variability in autologous/heterologous binder serum activity anti-Candida albicans and relationship with oral presence of the yeast, in patients with risk factors

D. Brito[1]*, N. Semprún- Hernández1*[2]*, J. Puentes*[1]*, S. Azuero*[1]*;*
[1]Laboratorio de Inmunología, Facultad Experimental de Ciencias, Universidad del Zulia., maracaibo, Venezuela, [2]Proyecto Biología y Química, Programa Educación, Departamento de Ciencias Naturales, UNE. Rafael María Baralt, Cabimas, Venezuela.

Candida albicans is an opportunistic yeast that often causes candidiasis in immunocompromised individuals. Variability in binder serum activity (IgM) autologous/heterologous anti-Candida albicans and oral presence of yeast were determined, in patients with risk (steroids, chemotherapy, HIV + and hemodialysis), without yeast (n = 140). The yeast was isolated and identified by culture in the medium YMAB and Chrom-Agar). The IgM was measured by agglutination plates. The prevalences obtained were 37.14% -13/35, -13/30 43.33%, 40% and 13.33% -12/30 -4/30, in the respective low risk groups. The autologous binder reactivity (self-isolated) was 46.15% (6/13-esteroides), 61.53% (8/13- chemotherapy), 58.33% (7/12-VIH+) and 25% (1/4-hemodialysis), with titers between 1:1-1:32. Frequencies of Heterologous Serum Agglutination (FHSA) most representative corresponded to steroids and hemodialysis: 41.66% and 66.66% of heterologous sera, agglutinated to 91.66% and 100 - 11/12 % -3/3 of heterologous strains respectively. The FHSA were low in chemotherapy and HIV+: only 16.66% and 18.18% of heterologous sera agglutinated to 66.66% or 50% and 100% of the heterologous strains, respectively, indicating low variability in the response. They showed high levels of Heterologous Representativeness Index (HRI) in few strains: 1.0 in steroid therapy (5 strains), 0.92 in chemotherapy, 0.73 and 1.0 in HIV+ in hemodialysis. The prevalence of yeast in the first three groups is higher than that reported in healthy individuals. Autologous serum reactivity tends to be lower, enhancing the risk and requiring prevention. There were no differences (p 0.05) between the prevalence or autologous reactivity and sex. Also among agglutination titers in different Groups.

P4.06.09
Granulomas developed in paracoccidioidomycosis in oral lesions of patients and in experimentally infected mice present similar patterns

E. Burger[1]*, M. Miyazawa*[1]*, D. T. Oliveira*[2]*, A. A. C. Pereira*[1]*, M. L. deCarli*[1]*, I. Felipe*[3]*, J. A. C. Hanemann*[1]*;*
[1]Universidade Federal de Alfenas, Alfenas, Brazil, [2]Universidade de Sao Paulo, Bauru, Brazil, [3]Universidade Estadual de Londrina, Londrina, Brazil.

Severe paracoccidioidomycosis is characterized by the presence of numerous loose granulomas, and mild forms by few compact granulomas. We characterized oral lesions in paracoccidioidomycotic patients, and compared with previously obtained data from experimentally infected susceptible and resistant mice.
We did qualitative microscopical analysis of HE and Grocott-stained slides in 38 paracoccidioidomycosis cases and compared to similar preparations from mice, analyzing architecture of the lesions, presence of morphologically preserved or destroyed fungi and composition of the cellular infiltrate.
In patients (mostly 40-50 years old male adults,) lesions were mainly found in gengiva, hard and soft palate and oral mucosa. Microscopy revealed predominance of loose granulomas with multinucleated giant cells (MGC) of the Langhans type and intense, diffuse inflammatory infiltrate, constituted by lymphocytes and plasmocytes, Fungi were frequently found dispersed in connective tissue and inside MGC. Susceptible mice showed similar pattern, with disseminated diffuse granulomas presenting numerous fungi and MGC and influx of neutrophils, lymphocytes, and plasmocytes.
The overall aspect of the lesions of a patient treated for 6 months with remission of the symptoms was similar to that observed in resistant mice, showing few, compact lesions.
Based on these results, we can conclude that paracoccidioidomycosis is a condition affecting mainly male adult patients in south of Minas Gerais state. The lesions present predominance of an intense mononuclear inflammatory infiltrate, diffusely distributed in the tissues. The small numbers of compact granulomas can indicate a severe depression of cellular immunity in these patients, analogous to that described in susceptible mice.

P4.06.10
Cutaneous candidiasis in BALB/c mice

T. G. Campois[1]*, A. Z. Zucoloto*[1]*, G. F. S. Quirino*[1]*, L. A. Custodio*[1]*, I. C. Costa*[1]*, E. E. J. Araújo*[1]*, T. I. E. Svidzinski*[2]*, I. Felipe*[1]*;*
[1]Universidade Estadual de Londrina, Londrina, Brazil, [2]Universidade Estadual de Maringá, Maringá, Brazil.

Individuals with diabetes mellitus are predisposed to cutaneous candidiasis. BALB/c mice were chosen as model of chronic cutaneous candidiasis because in further studies, this mycosis will be studied in diabetic BALB/c. *C. albicans* pseudohyphae ($5X10^6$) were injected in the deep dermis of the hindpaw and PBS in the contralateral paw. After 0, 1, 4, 7,14 and 21 days of infection the mice were euthanized and tissues injured by infection and the popliteal lymph nodes collected for histopathological and cytokines analysis. The extent of the inflammatory area was evaluated daily with a paquimeter. The peak of inflammatory area occurred at day 6 of infection (2.64 ± 0.57 mm), persisted until day 9 (2.70 ± 0.54 mm), reducing significantly in size until day 15 as compared to day 9. *C. albicans* caused significant thickening of the epidermis and induced migration of inflammatory cells to the lesion site. IFN-γ, IL-6, TNF-α and IL-10 were found in low levels at the infection sites, whereas the immune response at the popliteal lymph nodes was intense: the levels of IFN-γ (994±54 pg) and TNF-α (437±31pg) were high until day 4 of infection; those of IL-6 were high (520±8pg) until day 4 and those of IL-10 remained low in the very initial phase and increased from day 4 on. These cytokines at these levels could play important roles in this model of cutaneous candidiasis: IFN-γ and TNF-α in *Candida* antigens processing and presentation and therefore fungal clearance, IL-6 in neutrophils migration and IL-10 in lesion repair.

P4.06.11
Immune response investigation in a murine model of sporotrichosis

L. Souza Ferreira, L. Carolina de Abreu Ribeiro, D. Cardoso Geraldo Maia, T. de Cássia Negrini, P. Alegranci, D. Cordeiro de Matos, M. Bassi Quiles, M. Campos Polesi Placeres, ***I. Carlos****;*
UNESP, Araraquara, Brazil.

Major constituents of Sporothrix schenckii cell wall are peptido-polysaccharide complexes containing rhamnose, mannose and galactose. These complexes are organized in two distinct layers in the yeast's cell wall and those forming the inner one are called cell wall peptido-polysaccharide (PPC), which is being used as antigen in this study along with the heat-killed S. schenckii yeast (HKSS). Antigens released by the fungus directly participate in evasion of the immune system, also serving as targets for fungus elimination by binding of antibodies or innate immune cells like macrophages. Our results showed that PPC induces inflammatory cytokines in a more pronounced way when compared to HKSS, which induces higher levels of IL-10. We also suggest that, in the animal model used, IL-10 doesn't act as a suppressor of splenocytes proliferative response, and that IL-4 plays a role at the resolution phase of the infection, but not as a means of immunologic escape by the fungus. Also, we've shown for the first time that the assayed antigens are capable of inducing IL-17 secretion in splenocytes cultures, in a pattern close to that of the Th1 cytokines evaluated. In conclusion, the inflammatory response is slightly better triggered by the PPC, while IL-10 seems specially more responsive to HKSS. However, both antigens have been capable of inducing IL-17A liberation, suggesting, for the first time, Th17 response involvement in sporotrichosis. Financial support: FAPESP and CNPq.

P4.06.12
Identification of NETs (neutrophil extracellular traps) in tegumentary lesions of patients with paracoccidioidomycosis

A. M. D. Coletta[1], *T. F. Bachiega*[2], *J. C. Q. Silva*[1], *B. R. S. Silva*[1], *S. A. Marques*[3], *M. E. A. Marques*[1], *J. Defaveri*[1], *A. M. V. C. Soares*[2], *L. A. Dias-Melicio*[1];
[1]*Departamento de Patologia, Faculdade de Medicina de Botucatu, UNESP – Univ Estadual Paulista, Botucatu, Brazil,* [2]*Departamento de Microbiologia e Imunologia, Instituto de Biociências de Botucatu, UNESP – Univ Estadual Paulista, Botucatu, Brazil,* [3]*Departamento de Dermatologia e Radioterapia, Faculdade de Medicina de Botucatu, UNESP – Univ Estadual Paulista, Botucatu, Brazil.*

Paracoccidiodomycosis is a systemic mycosis caused by Paracoccidioides brasiliensis (Pb), which is endemic in Latin America. In recent years, works in paracoccidioidomycosis have focused the role of neutrophils (PMNs), since the literature has demonstrated the dynamic involvement of these cells in host defense against various microorganisms. Recent studies have shown that neutrophils may use a third strategy to destroy microorganisms called NETosis, a type of neutrophil death, reported to be distinct from apoptosis, phagocytosis-induced cell death, and necrosis. This cell death pathway involves the release of extracellular traps by activated neutrophils, known as neutrophil extracellular traps (NETs). The NETs are composed by fibers containing decondensed chromatin, histones and several other granular proteins such as elastase, which in addition to ensnare and/or kill microorganisms, increase the inflammatory response. It has been proposed that NETs destroy microorganisms that were not phagocytosed by neutrophils, and this could be proposed for the Paracoccidioides brasiliensis, since the fungus yeast can present various sizes and morphologies. In this context, the objective of this study was identify the presence of NETs in vivo, analyzing tegumentary lesions of patients with paracoccidioidomycosis. Tissue section from formalin-fixed biopsies were stained with DAPI, anti-elastase (FITC) and anti-histone (Texas-Red); and analyzed by confocal imunofluorescence microscopy. The images revealed the presence of NETs constituents, nuclear and extracellular localization of DNA stained with DAPI, co-localization of elastase and histone, which was confirmed by the overlay of these 3 stains. Thus, we identified the mechanism of NETosis in paracoccidioidomycosis patient lesions. Financial Support: FAPESP/CNPq/Fundunesp

P4.06.13
High-throughput miRNA sequencing of human monocyte-derived dendritic cells confronted with Aspergillus fumigatus

K. Czakai[1], *I. Leonhardt*[2], *M. Walter*[3], *M. Bonin*[3], *O. Kurzai*[2], *H. Einsele*[1], *J. Loeffler*[1];
[1]*University Hospital Wuerzburg, Medical Clinic and Policlinic II, Wuerzburg, Germany,* [2]*Department of Molecular and Applied Microbiology, Leibniz Institute for Natural Product Research and Infection Biology-Hans-Knoell-Institute, Jena, Germany,* [3]*Eberhard-Karls-Universitity Tuebingen, Medical Genetics, Microarray Facility, Tuebingen, Germany.*

Aspergillus fumigatus is an ubiquitous mold which normally lives in soil and decaying biomass. While in healthy individuals its reproductive spores, called conidia, are recognized and eliminated by the innate immune system, they can germinate in the lung of immunocompromised patients and enter the blood vessels. MicroRNAs (miRNAs) specifically bind to mRNA targets thereby leading to translational repression or target degradation and gene silencing. The role of miRNAs and their influence on innate immune cells during A. fumigatus infections are not well understood.
Isolated monocytes from healthy donors were differentiated to monocyte-derived dendritic cells (moDCs) and co-cultivated either with A. fumigatus conidia, germlings (MOI 1) or LPS (1µg/ml). Following total RNA isolation, miRNA sequencing (Illumina HighSeq® System, FDR < 0.05) and mRNA expression arrays (Affymetrix HGU 219) were performed.
Germlings induced n=16 miRNAs to be regulated after 6 h with a time dependent increase of 20 miRNAs after 12h. In contrast, conidia only induced miRNA regulation after 6h (11), but not after 12h. LPS as positive control had the strongest influence on the miRNA profile, with 22/38 regulated miRNAs after 6 and 12 h of stimulation, respectively. Interestingly, miR-155-5p was regulated by germlings and LPS at both time points, while miR-132-3p/5p, miR-212-5p and miR-222-5p were characteristic for the stimulation with germlings. In parallel, mRNA levels showed significant changes in chemokine/cytokine expression. In summary, we were able to describe new significantly regulated miRNAs by A. fumigatus and their influence on mRNA levels in moDCs.

P4.06.14
Involvment of Notch-TLR signaling in experimental paracoccidioidomycosis

L. M. Dal'Mas Romera*, S. R. de Almeida;*
University of São Paulo, São Paulo, Brazil.

Introduction: Paracoccidioidomycosis is a systemic mycosis of deep nature and granulomatosis that preferentially affects the lung tissue caused by *Paracoccidioides brasiliensis*, a thermal dimorphic fungus. It interacts with macrophages, cells that play an important role in regulation of immune response. Recently it has been demonstrated the importance of Notch receptors in regulating the activity of macrophages. Given that Notch signaling may be involved in modulating macrophage function, we evaluated the ability of the fungus modulate the activation of this pathway. **Methods and Results:** J774 macrophages, pre-stimulated with LPS or not, were interacted with yeast fungus, followed by analysis of real-time-PCR, phagocytosis-index and ELISA. The transcriptional analysis of Notch1 revealed an increased level of transcription in 24 hours, while there is a reduction of its ligand Delta4. However, we found that the fungus alone is not able to induce transcription of NF-kB, but when we stimulated with LPS together inhibition of Notch pathway, an increased level of transcripts was observed, suggesting that this factor is activated in the absence of Notch. In the same context, we observed that phagocytosis of yeasts by macrophages became more efficient. It was possible to verify that the fungus has the ability to promote the production of IL-6 via TLR-Notch, making us assume that this cytokine is important to the establishment of the disease. We also observed that the increased level of IL-6 is associated with decrease of TNF-α. In resume ours results suggest that *P.brasiliensis* uses the Notch signaling pathway as an escape mechanism.

P4.06.15
Thymic alterations during Paracoccidioides brasiliensis infection

R. Di Gangi*, T. Alves da Costa, C. Francelin, R. Thomé, L. Verinaud;*
UNICAMP, Campinas, Brazil.

Thymus is a lymphoid organ responsible for the development and maturation of T lymphocytes. To exercise this function, the thymic microenvironment should be preserved by a fine control of chemokines and growth factors released by stromal components. Such soluble thymus components directly influence the migration of T lymphocyte precursors from perivascular space to the region cortical and subsequent migration to the medullar region. Despite its importance, the thymus has been reported as a target organ in several pathologic conditions, e.g. infections. Studies from our laboratory have shown that experimental infection with Paracoccidioides brasiliensis (Pb), the causative agent of the most prevalent systemic mycosis in South America, is able to invade the thymus and to induce thymic microenvironmental changes. Herein, thymuses from mice infected with the P. brasiliensis virulent isolate (Pb18) in its yeast phase were analyzed for thymic index, changes in thymic architecture, accumulation of adipose tissue, and expression of matrix metalloproteinases (MMPs) as well as their tissue inhibitors (TIMPs). Our results show severe thymic atrophy, which is accompanied by loss of its architecture and replacement of stromal cells by adipose tissue. Besides, an enhanced expression and widespread distribution of MMP-2, MMP-9, TIMP-1 and TIMP-2 were observed in thymus from Pb-infected animals. We assume that these thymic alterations are related to the high death of thymocytes and premature egress of immature thymocytes to the peripheral lymphoid organs. Our results reinforce the idea that thymic compartment disturbances may be involved in the immunossupressive phenomenon frequently associated to Pb infection.

Anti-DEC-205 receptor carrying P10 induces protective response in experimental Paracoccidioidomycosis

S. S. Dos Santos[1], *E. Rampazzo*[1], *K. S. Ferreira*[2,1], *C. P. Taborda*[1], *S. B. Boscardin*[1], *S. R. Almeida*[1];
[1]*University of Sao Paulo, Sao Paulo, Brazil,* [2]*Federal University of São Paulo, Sao Paulo, Brazil.*

Paracoccidioidomycosis is a systemic mycosis caused by *Paracoccidioides brasiliensis*, a thermally dimorphic fungus. It occurs in Latin America and is the most frequent endemic systemic mycosis in many countries of South America, where almost 10 million people are believed to be infected. In Brazil, it is ranked as the tenth cause of death among chronic infectious and parasitic diseases. It is likely that vaccines will need to elicit strong T cell-mediated immunity composed of IFNγ secreting $CD4^+$ helper and $CD8^+$ cytolytic T lymphocytes. To induce such responses, it would be valuable to harness the dendritic cell (DC) system of antigen-presenting cells. To assess the potential of targeting P10, a peptide derived from gp43 secreted by the fungus, directly to DCs, we cloned its sequence in fusion with a monoclonal antibody to the DEC-205 receptor, an endocytic receptor abundant on these cells in lymphoid tissues. We verified that αDEC/P10 antibody response induced large IFNγ-producing cells after single dose administration in relation to P10, even being administered at a lower concentration. However, this response was not maintained after the second dose of the antibody. After challenge of animals immunized with two doses of the antibody, we detected high levels IFNγ and IL-4 in the lung tissue was statistically higher in αDEC/P10 and ISO/P10 compared to administration of P10 and control Poly I:C. The results obtained indicate that targeting of P10 through αDEC/P10, in the presence of Poly I:C, is a promising strategy for vaccination against *P. brasiliensis*.

Concanavalin-A induces IL-17 production during the course of *Candida albicans* infection

I. Felipe[1], *P. G. C. de Carvalho*[1], *L. A. Custodio*[1], *I. Conchon-Costa*[1], *C. G. T. J. Andrade*[1], *G. F. S. Quirino*[1], *E. Burger*[2], *R. S. Almeida*[1];
[1]*Universidade Estadual de Londrina, Londrina, Brazil,* [2]*Universidade Federal de Alfenas, Alfenas, Brazil.*

In a previous study, our group verified that 100% of mice survived to a lethal dose of *Candida albicans* following pretreatment with concanavalin-A (Con-A) for 3 days. This work proposed to investigate whether treatment could mediate an adaptative immune response involving TH17 cells. A significant increase in IL-17 levels at 6 h postinfection was observed and was maintained up to 18 h in the Con-A group, whereas in control mice, a reduction in this cytokine was verified. In addition, TH17 cells develop in the presence of TGF-beta, IL-1 beta, and IL-6 that were increased significantly 2 h postinfection in Con-A-treated mice. Macrophages were involved in the process, engulfing greater numbers of yeast cells, and were activated through TNF-alpha and interferon-c produced at significant levels at 2 h postinfection. A significant increase in IL-12 levels was also observed at 2 h postinfection. Thus, activated macrophages were probably more capable of killing and processing *Candida* antigens, signalizing an adaptative immune response. Macrophages from controls did not prevent yeast-to-hyphae transition and were partially destroyed, as shown in scanning microscopy. These results suggest that treatment with Con-A facilitated the triggering of TH17 and TH1 responses via IL-17 and IFN-gamma production, leading to the resolution of *C. albicans* infection.

P4.06.18

Inhibition of PGE_2 and LTB_4 production by dendritic cells induced by *Paracoccidioides brasiliensis* is associated with the non maturation of these cells

R. K. Fernandes, *T. F. Bachiega, D. R. Rodrigues, M. A. Golim, L. A. Dias-Melicio, H. A. Balderramas, R. Kaneno, Â. M. V. C. Soares;*
Universidade Estadual Paulista - Unesp, Botucatu, Brazil.

The fungus *Paracoccidioides brasiliensis* is the etiological agent of paracoccidioidomycosis, a systemic mycosis endemic in Latin America. Dendritic cells (DCs) play a crucial role in the detection of pathogens, triggering an initial response from the host as well as the instruction of the adaptive immune response. Mediators released by DCs, by an autocrine way, modulate their functions. Among these, we highlight the prostaglandins and leukotrienes. We therefore assessed whether human DCs produce PGE_2 and LTB_4 in response to fungus, the participation of recognition receptors of molecular patterns (PRRS) in this production, as well as the modulating role of these eicosanoids on phenotypic maturation of these cells. Human immature DCs ($CD14^-$/ $CD1a^{high}$/$CD83^{low}$) derived from the differentiation of monocytes cultured with GM-CSF and IL-4 (7 days) released substantial concentrations of PGE_2 and LTB_4 which increased significantly in the case of PGE_2, with incubation with LPS for 1h, 2h, 4h, 8h, 12h, 18h, 24h or 48h. However, the levels of PGE_2 and LTB_4 were significantly inhibited after challenge with two different strains of the fungus. Assays using monoclonal antibodies to block PRRS showed the involvement of mannose receptor in PGE_2 inhibition by the fungus. Additionally, phenotyping assays showed that after challenge with the fungus, DCs did not change their phenotype of immature cells to mature ones. Accordingly, we detected a clear association between inhibition of the production of PGE_2 and LTB_4 fungus and inability to induce maturation of DCs. Assays using exogenous PGE_2 and LTB_4 confirmed this association.

Therapy with scFv transfected-dendritic cells induce a decrease levels of specific IgG2b upon Paracoccidioides brasiliesnsis infection

G. P. J. Jannuzzi[1], *J. R. F. A. Almeida*[1], *S. R. A. Almeida*[1], ***K. S. F. Ferreira***[2];
[1]*USP, São Paulo, Brazil,* [2]*UNIFESP, Diadema, Brazil.*

Paracoccidioidomycosis is a systemic mycosis and the etiologic agent of disease is the *Paracoccidioides brasiliensis (Pb)*. A gp43 is the major antigen of *Pb*. It has been shown that mice immunized with anti-gp43 monoclonal antibodies (Ab1), induce the idiotypic cascade, which produced of anti-Id antibodies (Ab2). Ab2 inhibited the binding of gp43 to Ab1, suggesting that the Ab2 binds to the idiotope, thus fulfilling the internal image criteria. To better characterization of Ab2 we developed antiidiotypic antibody single chain variable fragments (scFv) and we showed that dendritic cells (DCs) transfected with scFv from Ab2 mimicking original antigen gp43 induces protection against experimental paracoccidioidomycosis. Since DCs are not typically found in normal muscle tissue, the objective of this study was analyze the capacity of DCs in migrate to the site of DNA inoculation and analyze if DCs may then either take up the plasmid DNA directly or cross-present expressed antigen to initiate immune responses. Mice were immunized with scFv and we observed an increased of DCs into regional lympho nodes with a decrease level of IL-4. These DCs expressed high levels of CD40, CD8, DEC205 and MHCII suggesting the capacity of presenting antigen and a decreased of regulatory T cells also was observed. Besides, therapy with scFv transfected-DCs induced increased levels of IgG2b upon *Pb* infection. These studies describe that scFV can be utilized to recruit DCs into regional lymph nodes and initiate the immune responses of T lymphocytes, besides to induce an efficiently immune response with a protector antibody production.

In pulmonary paracoccidioidomycosis, IDO exerts a protective effect to susceptible mice but a deleterious effect to resistant mice

***E. Frank de Araujo**, V. L. G. Calich;*
USP - University of São Paulo, São Paulo, Brazil.

In pulmonary paracoccidioidomycosis, the regulatory mechanisms mediated by innate and cellular immunity are still unclear. It is known that indoleamine 2,3-dioxygenase (IDO), an IFN-ɣ-induced enzyme which catalyzes the tryptophan metabolism, can control pathogen growth due to tryptophan starvation and inflammation by its immunosuppressive effects on innate and adaptive immunity. Our previous studies demonstrated that P. brasiliensis infected mice showed increased IDO expression, controlling fungal growth but suppressing T cell responses of resistant (A/J) and susceptible (B10.A) mice to P. brasiliensis infection. The aim of this study was to further characterize the role of IDO in the behavior of pulmonary dendritic cells and the expansion of T cell subpopulations. B10.A and A/J mice were treated with 1-methyl-DL-tryptophan (1MT, an IDO inhibitor) or left untreated, and intratracheally infected with yeasts. Our data demonstrated that in both mouse strains IDO activity reduced the migration of IL-6+ DCs, but increased the numbers of TGF-B+ and IL-12+ DCs in A/J and B10.A mice, respectively. IDO expression also reduced the migration of IL-17+ CD4+ and CD8+ T cells concomitantly with an increased influx of Treg cells to the lungs of B10.A and A/J mice. Furthermore, mortality and histopathological studies revealed that IDO exerted a protective effect on B10.A mice due to its inhibitory activity on the pro-inflammatory response associated with their susceptible pattern, but a deleterious effect on A/J mice due to its enhancing effect on the tolerogenic activity of DCs and the expansion of Treg cells, which delayed the expression of protective T cell immunity.

P4.06.21

Evaluation of infiltration with important acquired immune cells in kidney and spleen of mouse model in groups affected by systemic candidiasis, treated by etanolic extract of Zataria multiflora Boiss. in comparison to control groups

***H. Ghazanfari**[1], N. Hassannejad[2], M. Bayat[3], P. Dehghan[4], S. Hejazi[4], S. Ghanadian[5];*
[1]Department of Immunology, School of Medicine, Isfahan University of Medical Sciences, Isfahan, Iran, Isfahan, Iran, [2]Department of Cellular and Molecular Biology; Faculty of Sciences, Science and Research Branch of Islamic Azad University, Tehran, Iran, Tehran, Iran, [3]Department of Medical and Veterinary Mycology, Faculty of Specialized veterinary sciences, Science and Research Branch, Islamic Azad University, Tehran, Iran, Tehran, Iran, [4]Department of Parasitology and Mycology, School of Medicine, Isfahan University of Medical Sciences, Isfahan, Iran, Isfahan, Iran, [5]Isfahan Pharmaceutical Research Center, Isfahan University of Medical Sciences, Isfahan, Iran, Isfahan, Iran.

Systemic candidiasis is a disease mainly caused by Candida albicans. This disease has increased dramatically in recent years and therefore use of effective fungalcidal drugs such as fluconazole turned with the emergence of resistance to these drugs in human societies. So now, one of the major challenges in relation to pharmaceutical researches, manufacturing of antimicrobial drugs from natural resources such as *Zataria multiflora* Boiss. Because Candida albicans is a stimulator of cellular immunity, evaluation of increase or decrease in different subgroups of T cells in involved tissues, which can image a desirable mechanism in terms of extract impact on the immune system. In this study, *Zataria multiflora* Boiss extract and selective antifungal drugs were injected in patient groups including balb/c mice over IP (intra peritoneal). After 7 days of treatment, spleen and kidney mononuclear cells (SMNCs & KMNCS) of them were cultured in the presence of heat killed Candida albicans (HKC) and anti-CD28 and the cell precipitate was assessed by flow cytometric techniques. Briefly, the percentage of Th1 cells and Th17 in SMNCs & KMNCS of group received extract were significantly higher than other groups ($P < 0.05$).In total, regarding to doses of this extract and other pharmaceutical drugs, including fluconazole, thymol and carvacrol were used in this study and useful effect of the extract in reducing fungal burden and strengthen the immune system, we can hope to application of the extract and its obtained fraction in the systemic candidiasis, especially in patients with acuired immunodeficiency syndrome(AIDS).

P4.06.22

Dectin-2 mediated adaptive immunity to Candida glabrata

***D. C. Ifrim**[1,2], J. Quintin[1,2], L. A. B. Joosten[1,2], I. Verschueren[1,2], N. A. R. Gow[3], H. van Krieken[1], J. W. M. van der Meer[1,2], M. G. Netea[1,2];*
[1]UMC St Radboud, Nijmegen, Netherlands, [2]Nijmegen Institute for Infection, Inflammation and Immunity (N4i), Nijmegen, Netherlands, [3]Institute of Medical Sciences, Aberdeen, United Kingdom.

The C-type lectin receptor dectin-2 *(Clec4n)* is mostly expressed by dendritic cells, macrophages and neutrophils. It recognizes mannan structures and plays an important role in host defense against fungi by preferentially inducing Th17 cell differentiation. Little is known about dectin-2 recognition of *Candida glabrata*, the second most important pathogenic *Candida* species. In order to investigate the role of dectin-2 in fungal infections, we modified genetically mice to lack *Dectin-2* (*Dectin-2*$^{-/-}$ mice) and assessed the susceptibility of these mice to disseminated *C. glabrata* infection at three time points following the infection. *Dectin-2*$^{-/-}$ mice were significantly more susceptible to *C. glabrata*, as shown by a delayed elimination of the fungus from the kidneys on day 7 and 14 of infection. This increased susceptibility to infection was accompanied by 30 to 50% lower production of Th-derived cytokines by spenocytes of *Dectin-2*$^{-/-}$ mice, while the macrophage-derived cytokines were less affected. In an *ex-vivo* phagocytosis and killing assay, Clec4-/- activated peritoneal macrophages had a 15-20% lower capacity to kill *C. glabrata*. Dectin-2 $^{-/-}$ neutrophils also exhibited a significantly decreased phagocytosis and killing of live *C. glabrata*, which correlates with up to 25% less ability of deficient neutrophils to secrete reactive oxygen species (ROS) upon recognition of both *C. glabrata* and *C. albicans*. Understanding the nature of activation of the innate immune cells by Dectin-2 represents an important step towards elucidating the host defense mechanisms against this important fungal pathogen, which may lead to the design of novel immunotherapeutic approaches.

P4.06.23

Differential immune reactivity of Paracoccidioides brasiliensis phylogenetic species S1, PS2 and P. lutzii antigens by paracoccidioidomycosis patients` sera

***E. N. Itano**[1], A. Lenhard-Vidal[1], J. P. Assolini[1], A. Sano[2], C. S. O. Bredt[3], M. A. Ono[1];*
[1]State University of Londrina, Londrina, PR, Brazil, [2]University of the Ryukyus, Okinawa, Japan, [3]State University of Western Paraná, Cascavel, Brazil.

Paracoccidioidomycosis (PCM) is a systemic mycosis and recent researches show that its agent *Paracoccidioides brasiliensis* can be divided into phylogenetic species S1, PS2, PS3 and *P. lutzii,* which have distinct geographical distributions. The aim of this work was to evaluate the serum levels of IgG to soluble antigens of *P. brasiliensis* phylogenetic species S1, PS2 and *P. lutzii* in chronic PCM. Patients' sera (n= 35) from the northern and west regions of Paraná, Brazil were evaluated by ELISA. *P. brasiliensis* B339 (S1), IFM 54649 (PS2) and *P. lutzii* (*Pb01-like*; IFM 54648) were used to obtain cell free antigens (CFA) and 43 kDa (gp43) antigens from each strain. ELISA results, expressed as O.D. at 492 nm, showed higher reactivity of sera with CFA from *P. brasiliensis* S1 than PS2 and *P. lutzii* ($p < 0.05$) and also reactivity was higher with gp43 from *P. brasiliensis* S1 than PS2 ($p<0.05$) and PS2 higher than *P. lutzii* ($p<0.05$). In conclusion, chronic PCM patients' sera may distinctly recognize antigens from *P. brasiliensis* phylogenetic species S1, PS2 and *P. lutzii* and this difference is possibly related to geographical distribution of these agents.

FIBCD1 binds to Aspergillus fumigatus PAMPs and modulates the inflammatory response

C. E. S. Jepsen[1], *L. K. Dubey*[1], *J. B. Moeller*[1], *M. A. Hammond*[1], *O. Nielsen*[2], *A. Schlosser*[1], *G. L. Sorensen*[1], *U. Holmskov*[1];
[1]*University of Southern Denmark, Odense, Denmark,* [2]*Odense University Hospital, Odense, Denmark.*

We have recently identified and characterised fibrinogen C domain-containing protein 1 (FIBCD1) as a homotetrameric type II transmembrane protein expressed by epithelial cells. FIBCD1 is an endocytic receptor that binds crab chitin and other acetylated compounds calcium- and acetate-dependently through the C-terminal fibrinogen-related domain (FReD).
In the present study, we investigate the role of FIBCD1 in the immune reaction against Aspergillus fumigatus (Afu), a pathogenic fungus involved in the development of asthma and allergy in western society.
We show that FIBCD1 binds the Afu cell wall alkaline-insoluble fraction (AIF), which is primarily composed of chitin, beta-glucan, and galactomannan, in a calcium- and acetate-independent manner. We demonstrate that FIBCD1 recognises chitin-rich zones in the fungal cell wall in different cellular stages of Afu and that FIBCD1 is expressed in ciliated airway epithelial cells from patients with aspergillosis.
We show that conidia, AIF, chitin, and beta-glucan induce IL-8 secretion from A549 lung epithelial cells in a time- and dose-dependent manner. Furthermore, our results indicate that FIBCD1-transfected A549 cells display reduced IL-8 secretion compared to sham-transfected A549 cells when stimulated with any of these compounds and that this reduction is significantly increased when the compound is a FIBCD1 ligand.
Collectively, these results indicate that FIBCD1 is present in human airway epithelial cells, binds Afu cell wall PAMPs, and influences the inflammatory response in the lung.

P4.06.25
Protein-based Mycosis Vaccines: Mechanism and Prospects for Future Human Use

M. Kalkum*, D. Diaz-Arevalo, J. Champer, T. B. Hong, K. Vega, J. I. Ito;*
City of Hope, Duarte, CA, United States.

Invasive aspergillosis (IA) has a persistently high mortality rate and is the main one obstacle for the treatment of lymphoma, leukemia and other hematological malignancies by hematopoietic stem cell transplantation (HCT). Between 5.8 to 8.1% of all HCT recipients contract IA or similar fungal infections, and a staggering 57.8% of HCT recipients with IA die. Here we present our research on the development of an aspergillosis/mycosis vaccine to prevent IA and other mycoses in HCT recipients.
We previously developed a protein vaccine that protects mice from IA. Is was based on vaccinations with recombinant Asp f3, and induced both antibody and T cell responses. While antibodies were not protective, Asp f3-specific $CD4^+$ T cells mediate protection in cortisone acetate immunosuppressed mice. Neutrophils, although present in high numbers at the site of a pulmonary *A. fumigatus* infection, were dispensable for vaccine protection. Apart from mice, the rAsp f3 vaccine was also used to safely immunize South African penguins.
To broaden the spectrum of protection to fungal pathogens other than *A. fumigatus*, and to enhance the potency of the vaccine, we have conducted a quantitative analysis of fungal cell wall proteomes. Promising vaccine candidates were proteins with high abundance, high degrees of sequence homology between fungi, and little homology to human or mouse. We produced several of the most promising candidates as recombinant multivalent multi-epitope protein vaccines, and are presenting data on their protective effect. We will discuss the prospects of our strategy to implement a mycosis vaccine for human use.

P4.06.26
Preliminary evaluation of antigens from Paracoccidioides brasiliensis responsible for protective immune response induced in P. brasiliensis-infected mice by treatment with complete Freund's adjuvant

T. N. Landgraf*, F. F. Fernandes, G. Peron, A. A. M. Coelho-Castelo, A. Panunto-Castelo;*
University of São Paulo, Ribeirão Preto, Brazil.

Paracoccidioidomycosis (PCM) is an infectious disease caused by the dimorphic fungus Paracoccidioides brasiliensis. Among the deep mycoses, PCM is the most prevalent in Latin America and represents a major public health problem in countries where there is a higher incidence of the disease. In Brazil, PCM corresponds to the eighth leading cause of death among chronic or recurrent infections and parasitic diseases. Previous results from our group have shown that complete Freund's adjuvant (CFA) has a therapeutic effect in P. brasiliensis-infected mice. In the current study, we propose to isolate P. brasiliensis antigens associated with the protective immune response induced by CFA in infected mice. Exoantigens (ExoAg) and somatic antigens (SoAg) were isolated from yeast cells of virulent Pb18 strain of P. brasiliensis, and electrophoresis of the preparations showed high complexity of proteins. Both antigenic preparations were able to induce delayed-type hypersensitive (DTH) reactions in BALB/c mice previously infected with the fungus, though more prominent and significant DTH reactions were elicited when the mice were treated with CFA. Moreover, these preparations induced a proliferation in CFSE-labeled CD3+ spleen cells from mice infected with P. brasiliensis and treated with CFA significantly higher than those from only infected mice. These results suggest that ExoAg and SoAg contain antigens that are potential target to immunotherapeutic intervention in PCM. Others assays in vitro and in vivo are being conducted to isolate antigens from P. brasiliensis capable of inducing and/or enhancing the development of a protective cellular immune response.

P4.06.27
CD5 modulates the inflammatory response to fungal cell wall components

M. Orta[1], *E. Carreras*[1], *R. Fenutría*[1], *I. Simões*[1], *C. Raman*[2], *F. Lozano*[1,3,4];
[1]*IDIBAPS, Barcelona, Spain,* [2]*Department of Medicine, University of Alabama at Birmingham, Birmingham, AL, United States,* [3]*Servei d'Immunologia, Hospital Clínic, Barcelona, Spain,* [4]*Departament de Biologia Cel.lular, Immunologia i Neurociències, Universitat de Barcelona, Barcelona, Spain.*

The lymphocyte surface receptor CD5 is a member of the Scavenger Receptor Cysteine-Rich superfamily, expressed in all T cells and certain B cell types (B1a, B10). CD5 is physically associated with the TCR and BCR, modulating their intracytoplasmic signals during lymphocyte activation and differentiation. CD5 can also bind and signal the presence of β-glucans, fungal PAMPs present on saprophytic and pathogenic species. Accordingly, the infusion of a recombinant soluble form of CD5 (rshCD5) in a septic shock-like model induced by zymosan, a fungal cell wall derivative from Saccharomyces cerevisiae, significantly improved the survival of CD1 mice. To gain further insight into the putative role of CD5 in host response to fungal structures, the same model was evaluated in wild-type (WT) and CD5-deficient (CD5KO) mice of C57BL/6 background. Ex vivo experiments showed that 15 µg/mL rshCD5 significantly reduced the zymosan-induced activation of purified spleen CD4+ and CD8+ T cells from WT mice as measured by the expression levels of CD69 surface marker. In vivo experiments showed that WT mice exhibited an increased response to zymosan challenge as reflected by a worse clinical condition, a more robust inflammatory response (higher plasma levels of pro- and anti-inflammatory cytokines as well as circulating monocytes in the blood) and higher early mortality compared to CD5KO. Infusion of 25µg rshCD5 either 1h before or after zymosan challenge decreased the peritoneal cytokine levels without improving mice survival. These results highlight the immunomodulating role of CD5 (both soluble and membrane-bound) in the inflammatory response induced by fungal structures.

P4.06.28
Host parasite interaction in Drosophila melanogaster

***F. Paparazzo**, S. Hutter, A. Tellier, W. Stephan;*
Ludwig Maximilian University, Martinsried, Germany.

Drosophila melanogaster is a model organism to study innate immunity in invertebrates. Temperate and tropical D. melanogaster populations are exposed to different environments and have possibly to face different parasites and parasite pressures. This could result in differences in immune investment. In order to test this hypothesis we have to assess the immune ability of D. melanogaster populations and the response they unfold upon infection. Here we infected two tropical and two temperate D. melanogaster out-cross populations with two genotypes of the fungal entomopathogen Beauveria bassiana. Mortality rate is recorded for all populations and early transcriptional response is assessed both by full genome microarray and RNA sequencing. Genes that are similarly induced among populations and genes induced privately in each population are identified. Genetic variability is assessed for candidates from both categories in a panel of D. melanogaster sequenced lines from all continents in order to assess pattern of selection at the promoter region of these genes.

P4.06.29
Inhibition of neutrophil extracellular traps (NETs) by Cryptococcus neoformans: involvement of the capsular polysaccharide Glucuronoxylomannan (GXM)

***J. D. B. Rocha**[1], M. M. T. C. Nascimento[2], M. P. Nunes[1], D. Decote-Ricardo[3], G. A. DosReis[1], E. M. Saraiva[2], C. G. Freire-de-Lima[1];*
[1]Instituto de Biofisica Carlos Chagas Filho, UFRJ, Rio de Janeiro, Brazil, [2]Instituto de Microbiologia Prof. Paulo de Goes, UFRJ, Rio de Janeiro, Brazil, [3]Instituto de Veterinaria, UFRRJ, Seropedica, Brazil.

We characterized the production *in vitro* of human NETs (neutrophil extracellular traps) induced by the opportunistic fungus *Cryptococcus neoformans*, evaluating participation of capsular polysaccharides GXM and GalXM in this phenomenon. The strain CAP67 (mutant non-capsulated) and the capsular polysaccharide GalXM were capable of inducing the production NETs. In contrast, we observed that the wild-type strain and the polysaccharide GXM were not capable of inducing the release of NETs. We described that wild-type *C. neoformans* and GXM inhibited NETs production by PMA. In parallel, we found that the NETs induced by the fungus CAP67 had microbicidal action on the wild-type strain and that the neutrophil elastase, myeloperoxidase, collagenase and histone were key killing components of NETs. We investigated the signaling pathways associated with the NETs induction, focusing on the role of reactive oxygen species (ROS), we concluded that both strains were able to induce the production of ROS. Finally we evaluated whether the GXM and GalXM modulate signaling pathways that lead to the production of ROS by neutrophils; and we observed that alone, both capsular polysaccharides do not induced the production of ROS; however in neutrophils activated with PMA, both capsular polysaccharides were capable of inhibiting ROS production. Therefore we described that the *C. neoformans* and its capsular polysaccharide GXM inhibited NETs production, and this processes could be considered a description of a new virulence mechanism of this pathogen.

P4.06.30
The resistance to infection by Paracoccidioides brasiliensis requires production of IL-6, IL-17 and IL-23

***F. A. Rocha**, N. Ketelut-Carneiro, J. S. Silva;*
University of São Paulo - School of Medicine of Ribeirão Preto, Ribeirão Preto, Brazil.

Paracoccidioides brasiliensis (Pb), a thermally dimorphic fungus, is the causative agent of one of the most frequent systemic mycosis that affects the rural population in Latin America. Th17 cells are an arm of the immune system that enhances host protection against several infections, including mycosis. To better understand the mechanisms which are involved in resistance to P. brasiliensis infection we evaluated the role of IL-6, IL-17 and IL-23 during the PCM experimental. We showed that Pb triggers the secretion of IL-6, IL-17 and IL-23 by splenocytes. Intravenous infection of C57BL/6 (WT) mice with 1x106 yeast forms of Pb18, a highly virulent Pb strain, also induced an increased production of these cytokines compared with uninfected mice. We observed that the absence of IL-6, IL-17R and IL-23 impaired the control of the fungal replication at lung, liver and spleen from knockout mice in relation to WT group. Histopathological analysis showed that IL-6 and IL-17 contribute to compact granulomas formation due to adequate production of reticulin fibers. The deficiency of these cytokines was accompanied of disorganized CD4+ T cell infiltration at lung. The absence of IL-6, IL-17R or IL-23 resulted in lower production of IFN-γ and IL-10 compared with WT lung. Additionally, the frequency of Th17 cells, as well as IL-17 production, was decreased in IL-6-/- or IL-23-/- mice. This was associated with an impaired neutrophils and macrophages recruitment. Taken together, these results demonstrate that IL-6, IL-17 and IL-23 contribute to control of experimental Pb-infection through an efficient granulomatous organization.

P4.06.31
***In situ* expression of regulatory cytokines in oral paracoccidioidomycosis lesions**

***D. B. R. Rodrigues**[1,2], M. S. Araujo[2], P. M. Alves[1], S. A. L. Pereira[1,2], L. M. B. Lima[2], M. F. Silva[2], V. Rodrigues[1];*
[1]Universidade Federal do Triângulo Mineiro, Uberaba, Brazil, [2]Universidade de Uberaba, Uberaba, Brazil.

Paracoccidioidomycosis (PCM) is the most prevalent systemic mycosis in Latin America. The disease is caused by the dimorphic fungus *Paracoccidioides brasiliensis*. In humans, the disease is characterized by a broad spectrum of clinical manifestations ranging from localized mucocutaneous lesions to widespread manifestations. Immune response mediated by CD4 + T cells is critical for the outcome of infection. The role of different effector and regulatory cytokines needs to be established on PCM oral lesions. Biopsies from 16 patients with oral lesions (PCM) and health controls were analyzed by immunohistochemistry.
It was observed a significantly lower number of mast cells in patients with PCM compared with the control group. Conversely, fibrosis was significantly higher in PCM patients. The expression of IL-10, IL-4, IL-17 and FoxP3 were significantly higher in patients with oral PCM compared with the control group. Moreover, when PCM biopsies were categorized by level of organization, the expression of IL-10 and IL-4 were significantly higher in patients with biopsy of no organized granuloma when compared with organized granulomas. These cytokines appear to play an important role in the control of infection and the development and maintenance of lesions in the oral PCM. The better understanding of the mechanisms involved in immunoregulation of PCM oral lesions has applicability on therapeutical approaches and differential diagnosis with other oral pathologies.

P4.06.32
Interferon-gamma production by human neutrophils upon challenge with *Paracoccidioides brasiliensis*

***D. R. Rodrigues**[1], R. K. Fernandes[1], H. A. Balderramas[1], T. F. Bachiega[1], S. A. Calvi[1], L. A. Dias-Melicio[1], M. Penitenti[2], M. R. V. Ikoma[2], A. M. V. C. Soares[1];*
[1]UNESP - Universidade Estadual Paulista Júlio de Mesquita Filho, Botucatu, Brazil, [2]Fundação Amaral Carvalho, Jaú, Brazil.

Paracoccidiodomycosis is a systemic mycosis caused by the fungus *Paracoccidioides brasiliensis* (Pb), endemic in Latin America. Our laboratory has studied the relationship between human neutrophils (PMNs) / Pb focusing the effector mechanisms of these cells against the Pb. Studies have shown that PMNs can modulate the immune response with production and release cytokines. We have evaluated whether PMNs stimulated with Pb can modulate the immune response to a Th1 phenotype through the production of IFN-γ and the role of pathogen recognition receptors (PRRs) TLR2, TLR4 and Dectin-1. Furthermore, we have determined if cell activation by IL-12, IL-15 and IL-18 could result in increased levels of these cytokines.

Peripheral blood PMNs obtained from 20 healthy donors were nonactivated or activated with IL-12, IL-15 or IL-18 in different concentrations and challenged with Pb (18) strain for 24h and 48h and evaluated for IFN-γ production, by ELISA. In other experiments, PMNs were treated with monoclonal antibodies anti-TLR2, TLR4 and Dectin-1, challenged with Pb and evaluated for IFN-γ production. We found that Pb induces human PMNs to produce IFN-γ, probably by binding TLR4 and Dectin-1 receptors expressed by these cells. Moreover, cytokine levels were significantly increased when cells were activated with each of the tested cytokines or a combination of two of them, the association IL-12 plus IL-15 the most effective. The results support our hypothesis that during infection by Pb, human PMNs via the production of IFN-γ modulate the adaptive immune response to a Th1 response pattern. Support: FAPESP 2010/17405-5.

Cellular immune response is the most effective expression of defense in human paracoccidioidomycosis (PCM), an endemic mycosis in Latin America; however, the role of dendritic cells (DCs) in human PCM has not yet been explored. We investigated monocyte-derived DCs from patients with treated (TP) and active PCM (AP) compared to healthy non-PCM donors (CO). DCs from the TP group stimulated with either 43kDa glycoprotein (gp43) or cell-free antigen (CFA) from *Paracoccidioides brasiliensis* showed higher expression of HLA-DR and CD86 and higher levels of IL-12p40 compared to CO, whereas AP showed similar expression to CO. Production of IL-10 was up-regulated by gp43 and TNF-α only on the TP group when compared to DCs treated with TNF-α alone. CFA induced a stronger autologous lymphocyte proliferation and higher levels of IFN-γ and TNF-α on TP and AP groups when compared to CO while gp43 showed little or no effect over the proliferation. CFA may be a suitable antigen to induce cellular response through DCs antigen presentation even on active PCM patients. Higher expression of surface molecules with increased IL-12p40 may indicate a better activation of DCs after treatment of PCM. Our findings suggest that DCs may be crucial in the protective response to P. brasiliensis and that in vitro-generated DCs might be useful in enhancing antifungal immunity, especially during active PCM.

P4.06.34

Frequencies of Heterologous Serum Agglutination (FHSA) Heterologous Representativeness Index (HRI) and Autologous Reactivity as indicators of variability in binder activity anti-Candida albicans - Evaluation in age groups of healthy individuals carriers of the yeast in oral cavity

N. Semprún Hernández[1,2], *A. Bohórquez Visier*[3], *M. Ribas*[2], *R. Colmenares*[2], *S. Azuero*[2];
[1]*UNE Rafael María Baralt, Cabimas, Venezuela,* [2]*Laboratorio de Inmunología, Facultad Experimental de Ciencias, Universidad del Zulia, Maracaibo, Venezuela,* [3]*Laboratorio de Biología de Virus, Centro de Microbiología y Biología Celular, IVIC, Caracas, Venezuela.*

Serological diagnosis of candidiasis has highlighted problems of specificity and sensitivity. Considering the importance of protecting agglutinating antibodies were evaluated: a) FHSA: amount of heterologous sera (HS-for isolate not own) causing agglutination of a variable number of heterologous strains (HS), b) HRI: extent to which each strain agglutinated by a variable number of heterologous serum (HS), c) Autologous Reactivity (for isolate itself), as indicators of variability in binding activity (IgM) anti-Candida albicans. Was isolated and identified yeast (YMAB and Crhom-Agar) from mouth of age groups of healthy subjects (n = 129). The IgM was measured by agglutination plates. Autologous reactivity was> 75% in almost every age group and 57% for 4-9 years, with titles from 1:1-1:64. The most representative FHSA corresponded to 0-3, 10-18, 19-45 and 56-64 years: 100%, 87.5%, 69.2% and 66.7% (> 50%) of HS respective were pelleted by more than 40% of HS (minimum value selected as representative serum). The FHSA were low at 4-9, 46-55 and 65-85: <40% of HS agglutinated more than 50% of HS (minimum value selected as representative for strains), indicating low variability in the response. HRI (HS agglutinating HRIstrainX = # x / # total HS) revealed that few strains are recognized by more than 90% of HS, despite of being the same species. Evaluated parameters can be used as indicators of response variability.

P4.06.35

IL-18 does not modulate dectin-1 expression on human monocytes challenged with Paracoccidioides brasiliensis

M. B. Cestari[1], *T. F. Bachiega*[2], *R. K. Fernades*[2], ***J. C. Q. Silva***[1], *M. A. Golim*[3], *A. M. V. C. Soares*[2], *L. A. Dias-Melicio*[1];

IL-18 is a proinflammatory cytokine and its role in paracoccidioidomycosis, a deep mycosis caused by Paracoccidioides brasiliensis (Pb) is not fully understood. Recently, we demonstrated that this cytokine, by modulating TLR4 and MR expression, play an important role on human monocytes response to P. brasiliensis. The aim of this study was first to evaluate the involvement of dectin-1 on IL-18, TNF-α and IL-10 production by human monocytes in response to P. brasiliensis. Moreover, we asked whether IL-18 can modulate the production of these cytokines by altering the expression of this receptor. Monocytes were stimulated with IL-18 and treated with specific neutralizing antibody anti-dectin-1 before challenge with more virulent (Pb18) and less virulent strain (Pb 265) of the fungus . After, dectin-1 expression was analyzed by flow cytometry and IL-18, IL-10 and TNF-α production by ELISA. Results showed that higher levels of IL-18 and IL-10 were detected after challenge with Pb 18, in comparison to Pb 265. By other hand, Pb 265 strain induced higher levels of TNF-α. However, only TNF-α induced by the strains were decreased after blocking dectin-1 receptor, showing the involvement of this receptor only in the production of this cytokine. Moreover, cells preincubation with IL-18 did not affect cytokines production by monocytes in response to P. brasiliensis, as well as dectin-1 expression. We can hypothesize that at least in relation to dectin-1 receptor expression, lack of modulation by IL-18 could contribute to susceptibility of the response against the fungus. Financial Support: FAPESP 2012/01836-2.

P4.06.36

Dectin-1 plays a prominent role in the immune response against the dermatophyte "Trichophyton rubrum" in murine model

F. S. Y. Yoshikawa*, S. R. de Almeida;*
Faculty of Pharmaceutical Sciences / University of São Paulo, São Paulo, Brazil.

Introduction: *Trichophyton rubrum* is the main agent of dermatophytosis in humans. However, little is known about the immunological mechanisms underlying these mycoses.
Dectin-1 is an immune receptor involved in responses to fungi. It can induce production of cytokines and shape the immune response, like IL-1β, a key cytokine for the induction of T_H17 responses.
The aim of this study was to elucidate the role of Dectin-1 in the immune response against *T.rubrum*.

Materials and Methods: Bone-marrow derived macrophages (BMMs) from C57BL/6 mice (wild-type and dectin-1$^{-/-}$) were primed with LPS and incubated with *T.rubrum* conidia for 4, 6, 8 and 10 hours. The interaction was evaluated by optical microscopy and IL-1β levels were measured by ELISA.
Groups of 3 C57BL/6 mice (wild-type and dectin-1$^{-/-}$) were infected with *T.rubrum* conidia intraperitoneally. Animals were maintained for 7 and 14 days before being euthanized. Liver and spleen were collected for determination of fungal burden and cytokine measurements (IL-1β, IFN-γ, IL-4).
Results: Wild-type BMMs phagocytosed conidia and secreted IL-1β in response to the pathogen, but were destroyed by the fungal growth. Dectin-1$^{-/-}$ counterparts, however, showed reduced phagocytose and cytokine production, but conidia were unable to become hyphae.
Dectin-1$^{-/-}$ mice could not control the fungal burden and showed higher production of IFN-γ and IL-4, but lower levels of IL-1β, than their wild-type correlates.
Conclusions: Results showed that Dectin-1 is important for phagocytose of *T.rubrum* conidia and production of IL-1β. *In vivo* results suggest that dectin-1 is necessary for infection control by induction of IL-1β.

P4.06.37
The role of IL-6 and IL-8 in vulvovaginal candidiasis in adolescent Girls

U. K. Ziyadullaev*;*
Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan.

Vulvovaginal candidiasis (VVC) - one of the diseases of modern civilization. Currently, this infection ranks second among of all infections of the vulva and vagina and is one of the most common reasons for treatment of female medical help. According to modern ideas, the imbalance of cytokine production, and in particular IL-6 and IL-8 plays a key role in the pathogenesis of many diseases. The aim of this study was to establish the degree of descriptiveness pathogenic cytokine production of serum IL-6 and IL-8 in patients with VVC to optimize the diagnostic and therapeutic and preventive measures. We examined 44 adolescent girls age from 12 to 15 suffering from VVC . Verification of the diagnosis VVC was conducted according to the WHO classification (ICD-X column in 37.3 and N 77.1). IL-6 and IL-8 serum levels were determined by ELISA ("Vector-Best", Russia). IL-6 and IL-8 levels can provide additional criteria to evaluate the inflammatory response in patients with various forms candid infection vagina (mostly asymptomatic candid carriers, acute and chronic relapsing forms). Changes in the parameters studied could reflect the state of the immune system and the inflammatory response characteristic of each VVC form.

P4.07.01
Involvement of Treg and alternatively activated macrophages in evasion strategies during hydatidosis

M. Amri*, C. Touil-Boukoffa;*
University USTHB, Faculty of Biological Sciences, Laboratory of Cellular and Molecular Biology, Algiers, Algeria.

Human hydatidosis is caused by the parasite *Echinococcus granulosus* (*E.g.*). It is one of the world's major zoonotic infections. It usually manifests as unilocular cyst(s) mainly located in the liver. We have previously highlighted an evident role of laminated layer (LL, accelular layer of hydatic cyst) in parasite survival by impairment of Th1 protective response.
The purpose of this study was first, to investigate the effect of LL extract (LLs) on IL-10 production by human mononuclear cells (PBMC) *ex vivo*. Second, the effect of LLs on macrophages phenotype and expression of some M1/M2 markers was also investigated. In this way, NOS2 and Arginase activities were assessed in PBMC cultures induced by LLs. Moreover, implication of mannose receptor (MR) and TGF-β on Arginase activity were evaluated using mannose (MR antagonist) and Anti-TGFβ. Activity of NADPH oxidase was also evaluated by chemiluminescence. Finally, TLR2, CD14 and CD23 expression was measured by flow cytometric immunoassay.
Interestingly, we showed that LLs enhanced IL-10 production. Moreover, while NOS2 and NADPH oxidase activities are inhibited, Arginase activity is activated. MR and TGF-β are involved in the Arginase induction by LLs. Furthermore, LLs increases TLR2 and CD14 expression and decreases CD23 expression in monocytes.
Collectively, ours finding suggest that *E. g.* laminated layer induced M2 phenotype. These macrophages induce Treg cells and impair M1/Th1/Th17 protective responses allowing parasite survival. Inhibition of these mechanisms constitutes an important issue to address an anti-hydatic treatment design.

P4.07.02
Galectin-like molecule in parasite inhibits remission of experimental autoimmune encephalomyelitis by enhancing auto-reactive B cells

S. Bing*[1], D. Ha[1], S. Lee[1], J. Cho[1], S. Park[2], H. Yu[2], Y. Jee*[1];*
[1]College of Veterinary Medicine, Jeju National University, Jeju, Republic of Korea, [2]Department of Parasitology, School of Medicine, Pusan National University, Yangsan-si, Gyeongsangnam-do, Republic of Korea.

Although the expression and function of host galectins have been extensively appreciated, there is still scarce information on the repertoire of 'galectin-like molecules' expressed by pathogens and associated to their virulence. In a recent study, researchers reported that rTl-gal isolated from an adult worm of the gastrointestinal nematode parasite Toxascaris leonina attenuated clinical symptoms of inflammatory bowel disease in mice treated with dextran sulfate sodium (DSS). Noting that the role of rTl-gal in the inflammation disease, we tried to elucidate the effect of parasite via its galectin-like molecules (rTl-gal) on experimental autoimmune encephalomyelitis (EAE), a mouse inflammatory and demyelinating autoimmune disease model of human multiple sclerosis (MS). When we administered rTl-gal to EAE mice, no significant difference in clinical disease severity was observed between rTl-gal-treated and control group at peak stage. At remission stage, interestingly, rTl-gal-treated mice not only failed to recover after the peak of disease but also showed increased EAE severity, leading to autoreactive inflammation cell activation and persistent CNS damages such as neuroinflammation, demyelination, gliosis and axonal damages. We further verified the cell population whose infiltration was altered by rTl-gal treatment and observed that rTl-gal-treated EAE mice markedly increased the infiltration of CD45R/B220+ B cells. Consistent with these, cell population of CD45R/B220+ B cell and autoantibody production in periphery were significantly up-regulated. Our results suggest that galectin-like molecule isolated from a gastrointestinal parasite can deliver a harmful effect to EAE via strengthening autoreactive B cell function contrary to its beneficial effect on inflammatory bowel disease.

P4.07.03
Anisakis simplex allergens remain biologically active after canning and simulated gastric fluid treatment of parasitized fish

N. Carballeda-Sangiao*[1], A. Rodríguez-Mahíllo[1], F. Olivares Ponce[2], M. Tejada[2], M. Careche[2], I. Moneo[1], M. Gonzalez-Muñoz[1];*
[1]Hospital Carlos III, Madrid, Spain, [2]Instituto de Ciencia y Tecnología de Alimentos y Nutrición (ICTAN-CSIC), Madrid, Spain.

Background: The ingestion of parasitized fish with *Anisakis simplex* live larvae L3 can result in the development of anisakiasis and sometimes can induce IgE-mediated reactions. Allergic episodes can be elicited by infection or exposure to allergen remaining in food containing dead larvae. It is believed that is due to heat stable and pepsin resistant allergens.
Objective: The aim of this work was to detect the presence of biologically *A. simplex* allergens after canning and simulated gastric fluid treatment of parasitized fish muscle.
Material and methods: Tuna fish fillets (*Thunnus thynnus*) were artificially parasitized with *A. simplex* and subjected to autoclaving during 40 minutes at 121ºC as an equivalent method to industrial

canning. Fish extracts were obtained by grinding followed by sonication and centrifugation. Then, extracts were incubated with simulated gastric fluid (SGF) for 30 and 60 minutes. The extracts were assayed by IgE-immunoblotting and a flow cytometric basophil activation test on *A. simplex*-sensitized patients (n=5).
Results: *A. simplex* allergens in parasitized fish after autoclaving and SGF treatment were able to activate basophils from sensitized patients. The capacity to induce basophil activation seemed to be patient-dependent since it ranged from 74% to 2% after 60 minutes of SGF incubation. Apparently there was not any relationship between patients' anti-*A. simplex* IgE values and percentage of activated basophils. IgE-immunoblotting analyses showed the presence of low-molecular weight allergens (about 20 and 18kDa) after both treatments.
Conclusion: *A. simplex*-sensitized patients can be exposed to biologically active parasite allergens when eating canned fishery products

P4.07.04
Immunomodulatory effect of Toll-like receptor 7/8-agonist (imidazoquinoline Resiquimod) in experimental secondary hydatidosis infection

M. Conchedda[1]*, V. Seu*[1]*, A. Caddori*[2]*, A. Caredda*[1]*, F. Gabriele*[1]*;*
[1]Department of Life and Environmental Sciences, Lab of Parasitology, Cagliari University, Monserrato (Cagliari), Italy, [2]Internal Medicine, SS. Trinità Hospital, Cagliari, Italy.

A variety of avoidance strategies are believed to be involved in cystic echinococcosis (CE) metacestode infection. Clinical evidence has demonstrated Th2 bias in chronic infection, functional to parasite survival, while a Th1 cytokine profile appears to typically dominate in effective chemotherapy treatments, indicating a role in the process of cyst degeneration.
Experimental secondary infection, by intra-peritoneum infection of mice with protoscoleces (PSC) of *Echinococcus granulosus*, constitutes the laboratory model for this study.
BALB/C mice have been experimentally infected with 100 or 3000 PSC and treated p.i with the Toll like receptor 7/8 agonist Resiquimod, an Imidazoquinolinamine with immune response modifying properties via IL-12 and IFN production and IL-4 and IL-5 inhibition.
A substantial reduction in the number of recovered cysts, together with a significant decrease in parasite load is observable in mice treated after infection with 100 PSC with respect to controls. Treatment of 3000 PSC-infected mice reduces the number of recovered cysts by more than 40%, comparable to Albendazole treatment. Parasite load was also found to be lower than controls, but less so in benzimidazole-treated animals, where most cysts are completely collapsed and have thickened walls.
Overall results indicate Th0/Th1 polarization during early developmental stages of secondary experimental hydatidosis, with a subsequent Th2 bias, functional to parasite survival. Imidazoquinolinamine has demonstrated potency in reducing cyst development, highlighting that Th1 response correlates with protective immunity, opening the way to new immunomodulatory strategies potentially useful also for natural infection.

P4.07.05
Immunomodulation by TLR-7-agonist, IL-27 or IL-25 in Hymenolepis diminuta infection in rats

M. Conchedda*, V. Seu, S. Capra, A. Caredda, F. Gabriele;*
Department of Life and Environmental Sciences, Lab of Parasitology, Cagliari University, Monserrato (Cagliari), Italy.

During infection with the intestinal Cestode *Hymenolepis diminuta,* a Th-2 bias is reported both in mice (unnatural host) and rats. Expulsion occurs only in severe infections, as higher levels of IL-13 increase smooth muscle contraction, goblet cell hyperplasia and increased mucin release, leading in turn to increased mucus entrapment of the worms progressively expelled.
To gain greater insight into the complex mechanism of dose-dependent expulsion and the role of Th1/Th2 polarization, Wistar rats have been infected with 3 or 50 Hd cysts before or after treatment with Resiquimod (imidazoquinolamine, agonist of TLR7/8 inducing Th-1-mediated immune response) or with regulatory cytokines IL-25 (regulator of Th2-cell response) or IL-27 (pivotal to driving naive cells into Th1 subset and with immunosuppressive property to Th17). Resiquimod is able to inhibit worm loss during expulsion in severe infection, both in pre- and post-infection treatment, with long lasting inhibition of at least up to 42 days p.i.. Vice versa no differences are observable respect to controls during mild infection irrespective of sacrifice time. Accordingly, experiments carried out using IL-25 showed accelerated destrobilation and loss of worms as early as 14 days p.i. Vice versa IL-27 appears to be able to prevent worm expulsion up to 35 days p.i. with a pattern similar to TLR7/8 agonist. Overall results clearly indicate different Hd expulsion features in Th1 or Th2-biased environments confirming a role for helminths as innovative approach to immunological distraction or regulation in autoimmune or inflammatory diseases.

P4.07.06
An essential role of galectin-1 in driving Th2-polarized responses during helminth infection

S. Dergan Dylon[1]*, J. Ilarregui*[1]*, L. Rutitzky*[2]*, M. Stadecker*[2]*, G. Rabinovich*[1]*;*
[1]Institute of Biology and Experimental Medicine, Buenos Aires, Argentina, [2]Department of Pathology, Tufts University School of Medicine, Boston, MA, United States.

Schistosomiasis, a disease caused by Schistosoma mansoni, affects approximately 238 million people in tropical and sub-tropical areas. Despite considerable efforts in elucidating the mechanisms underlying immune protection and evasion during S. mansoni infection, the endogenous mediators responsible of driving Th2-polarized reactions remain uncertain. Here we identified a crucial role for galectin-1 (Gal-1) an endogenous glycan-binding protein, in driving Th2 responses during S. mansoni infection. Schistosome Egg Antigen (SEA) induced a dose-dependent up-regulation of Gal-1 in bone marrow-derived dendritic cells (DCs), as shown by western blot, real time qPCR and ELISA ($p<0.05$). Analysis of the cytokine profile of wild type (WT) and Gal-1-deficient (Lgals1-/-) DCs exposed to SEA (DCSEA) revealed no significant differences in IL-23, IL-27, IL-10 and IL-12p70 secretion. In contrast, Lgals1-/- DCs showed lower IL-5 and IL-10 ($p<0.05$) and higher production of IFN-γ ($p<0.05$) than WT DCSEA in allogeneic co-cultures using Balb/c splenocytes. An in vivo infection model confirmed our findings showing that, compared to their WT counterpart, splenic DCs isolated from Lgals1-/- infected mice induced allogeneic T cells to produce lower amounts of IL-5 and IL-10 ($p<0.01$) and higher IFN-γ ($p<0.01$). This effect correlated with an increased Th2 response observed in T cells isolated from WT lymph nodes (LN) and spleen ($p<0.05$). Likewise Lgals1-/- infected mice displayed smaller size of granulomas and WT granulomas expressed higher amounts of Gal-1 as shown by qRT-PCR an IHC. These results show a pivotal role for Gal-1 in driving Th2 responses during helminths infection.

P4.07.07
The change of CD4+CD25+ regulatory T cells and related cytokines in mice infected with *Echinococcus multilocular*

J. Ding[1]*, X. Ma*[1]*, H. Zhao*[1]*, Y. Zhu*[1]*, F. Zhang*[1,2]*, H. Wen*[3]*;*
[1]Xinjiang Medical University, Urumqi,Xinjiang, China, [2]First affility hospitol of Xinjiang medical university, Urumqi,Xinjiang, China, [3]First affility hospital of Xinjiang Medical University, Urumqi,Xinjiang, China.

Echinococcus multilocularis infection is considered one of the most deadly diseases due to worm infection. In order to clarify the role of variations in CD4+CD25+ regulatory T cells and related cytokines IL-10 and TGF-β in E. multilocularis persistent infection and to explore the relationship between immune evasion mechanisms and the immunosuppressive effects of CD4+CD25+ regulatory T cells. During the early stages of E. multilocularis persistent infection, the ratios of CD4+CD25+ regulatory T cells in peripheral blood mononuclear cells (PBMC), splenocytes and lymph node lymphocytes were found to be low or significantly decreased compared to the control. As the infection progressed, the number and size of E. multilocularis cysts in

mice gradually increased, and the ratio of CD4+CD25+ regulatory T cells significantly increased. Especially in PBMC the ratio substantially increased in the middle stages of E. multilocularis infection. Furthermore, the related cytokines IL-10 and TGF-β were also augmented by infection.Therefore, CD4+CD25+ regulatory T cells may be a key part of the strategies employed by E. multilocularis for long-term survival in the host.

P4.07.08
***Heligmosomoides polygyrus* L4 stage from inflammatory *milieu* effects on dendritic precursor JAWSII cells**

K. Donskow-Lysoniewska, K. Brodaczewska, ***M. Doligalska****;*
University of Warsaw, Faculty of Biology, Department of Parasitology, Warsaw, Poland.

Infection with intestinal L4 stage *Heligmosomoides polygyrus* reduces inflammation in an experimental model of *colitis*. The protective effect of prior larvae which inhabit the small intestine on *colitis* is associated with macrophages and neutrophils infiltration into the small intestine and high concentration of pro-inflammatory cytokines IL-1β, IL-6, TNF-α and opioids in the small intestine and inhibition of those in the colon (Parasite Immunology, 2012, 34: 536–546). Interestingly, the active inflammatory reaction in the small intestine promotes development of the *H. polygyrus* L4. Enhanced number and length of L4 and different larvae location on the small intestine was detected. The weaker recognition and better adaptation of the nematode larvae in the small intestine was associated with different composition and activity of antigen presenting cells APC; dendritic cells, macrophages and B-cells of Payer's patches.
In the present study, we detected the effect of somatic, excretory-secretory antigen and live L4 stage of *H. polygyrus* from control infection and from mice with DSS-induced colitis on dendritic precursor JAWSII cells. L4 from mice with *colitis* induced higher expression of MHC class II, CD80/CD86 co-stimulatory molecules on JAWSII cells than control L4 *H. polygyrus* and higher production of IL-6, MCP-1, IL-22 with inhibition of IL-17A and no effect on regulatory cytokines IL-10 and TGF-β. Our studies show that the L4 larvae from the inflammatory *milieu* better induce phenotypic and functional maturation of dendritic precursor JAWSII cells than larvae of control infection.

P4.07.09
Chitosan stimulates lymphocyte proliferation during muscle phase of *Trichinella spiralis* infection in mice

K. Brodaczewska, N. Wolaniuk, K. Donskow-Lysoniewska, ***M. Doligalska****;*
University of Warsaw, Faculty of Biology, Department of Parasitology, Warsaw, Poland.

Chitosan is intensively studied as a potential vaccine adjuvant that can combine high efficacy with low toxicity. Yet mixed information is available, how the polysaccharide affects immunity. It was observed that antibody titers were raised when antigen was administered with chitosan but it is not clear what mechanisms are involved in the phenomenon. As parasitic infection down regulates immune response, modification of suppressed reactions may be promising for the anti-parasitic protection.
Aim of the study was to evaluate the effect of chitosan administration on lymphocyte proliferative response in mice infected with *T. spiralis*.
C57Bl6 mice were intra-peritonealy injected with 500 µg of chitosan (> 375 kDa) dissolved in adipic acid, every day 5 days before till 9 days after infection with 400 L1 *T. spiralis*. Mesenteric lymph node cells were cultured without or with TCR stimulation (anti-CD3 and -CD28 antibodies); levels of proliferation and cytokines were measured.
Chitosan treatment restored cell responsiveness; they proliferated intensively and were again sensible to TCR stimulation. Also cytokine secretion was altered. Nonetheless the cells regained reactivity, the level of infection was intensively raised after chitosan treatment; over two times more muscle larvae were recovered from mice that obtained polysaccharide injections.
Although chitosan stimulated lymphocyte response, the effect of treatment was not protective.
Research was supported by Faculty of Biology, University of Warsaw Intramural Grant (BW 501/86-102307).

P4.07.10
The role of TLR3 in the development of a protective immune response against Plasmodium

M. Draheim*, J. Roland, S. Pied;*
Institut Pasteur de Lille, Lille, France.

The understanding of mechanisms involved in the initiation of a protective immune response during *Plasmodium (P.)* infection is essential for developing tools and strategies to control the disease. An early innate immune response involving NK and NKT cells is implicated in the control of the primary *P. yoelii* infection in C57Bl/6 (B6) mice. Pattern Recognition Receptors such as Toll Like Receptors (TLR), which are expressed by innate immune cells, could be involved in the recognition of parasitic molecules during Plasmodium infection. Herein, we studied the role of TLR molecules in the clearance of *P.yoelii* in B6 mice. Our results showed that TLR3 deficient mice developed lower parasitemia compared to B6 mice. In this context, a phenotypique analysis of lymphocyte populations was conducted and showed an increase of the number of B cells correlated to immunoglobulins level in TLR3 KO mice when compared to wild type mice. We also observed a positive correlation between parasitic clearance and the B cell response. Further studies will be focused on the study of the antibody repertoire implicated in the elimination of *Plasmodium*.

P4.07.11
Oral Fluids: utility in parasitic infections diagnosis

Y. Galai*[1], M. Benabid[1], F. Amri[2], K. Aoun[1], A. Bouratbine[1];*
[1]Pasteur Institute of Tunis, Belvedere Tunis, Tunisia, [2]Kairouan Regional Hospital, Kairouan, Tunisia.

Current diagnostic methods of various parasitic diseases require invasive sampling procedures e.g visceral aspiration and/or blood drawing. Thus, the development of diagnostic tests using oral fluid, easier to collect would be more simple and practical especially under field conditions. In this regard, oral fluid samples were screened for the presence of anti-*Leishmania* and anti-*Echinococcus granulosus* in visceral leishmaniasis (VL) and hydatid cysts' patients respectively.
Oral fluid and blood samples of 37 VL cases and 40 healthy controls were analyzed by rK39 ELISA to detect specific *Leishmania* antibodies in oral fluids and sera. Moreover, anti-hydatid fluid antigens (HFA) IgG antibodies were screened by ELISA in oral fluids and sera of hydatid cysts' patients (n=37) as well as in healthy controls (n=30).
Leishmania antibodies detection in saliva had a sensitivity of 100% and a specificity of 97.5%. Antibody levels measured in sera and saliva showed a significant positive correlation (rho=0.655 and p=0.01). Salivary anti-HFA IgG showed a sensitivity of 86.5% and a specificity of 80%. A positive correlation was observed between anti-HFA IgG in saliva and in serum (rho=0.364 and p=0.02).
The detection of specific anti-parasite IgG promises to be interesting in the diagnosis of parasitic diseases.

P4.07.12
Schistosomiasis vaccine discovery using high throughput schistosome tegument proteins microarray recognition

S. T. Gaze Jangola*[1], P. Driguez[2], J. Bethony[1], D. MacManus[2], D. Doolan[2], R. Correa-Oliveira[1], P. Felgner[3], A. Loukas[4];*
[1]Fiocruz, Belo Horizonte, Brazil, [2]QIMR, Brisbane, Australia, [3]UC Irvine, Irvine, CA, United States, [4]JCU, Cairns, Australia.

Schistosomiasis is a neglected tropical disease that affects more than 207 million people worldwide, and 700 million people are at risk in 74 endemic countries. Immunoepidemiological investigations have

shown a very small percentage of exposed populations in Brazil are naturally resistant to schistosomiasis despite never being drug-treated (praziquantel). We propose to evaluate the humoral response of endemic area individuals to schistosome tegument antigens spotted onto a protein microarray to understand the mechanisms involved and the antigens targeted by these individuals. To identify antigens that are uniquely/preferentially recognized by resistant compared with susceptible individuals, we constructed a protein microarray with S. mansoni and S. japonicum proteins. We used sera from individuals from Minas Gerais, Brazil, who were putatively resistant or chronically infected with low, moderate and heavy eggs counts per gram of feces or unexposed controls. We evaluated IgG subclasses and IgE responses comparing their recognition profiles. Resistant and infected groups recognised many of the proteins on the array. In general, we observed proteins with multiple antibody subtypes response and others had a unique subtype response. High throughput protein array is an excellent tool for protein discovery in helminthiasis. In schistosomiasis, it proved to identify the immune response in resistant compared to infected individuals. The search for pre-existing IgE response is crucial and should be excluded in further investigations. This report describes the construction and screening of a schistosome protein array with human sera, and the results presented will be valuable in the selection of antigens for human vaccine for schistosomiasis.

P4.07.13
Schistosomes: Potential of Dynein Light Chains as Vaccine

E. K. Githui[1], *S. P. Tabu*[2], *K. Muinamia1*[3];
[1]*National Museums of Kenya, Molecular Genetics Lab., Nairobi, Kenya,* [2]*Department of Biochemistry, Kenyatta University, Nairobi, Kenya,* [3]*Department of Biochemistry, University of Nairobi, Nairobi, Kenya.*

Schistosomes are blood flukes that reside in human mesenteric veins and cause a chronic debilitating disease, Schistosomiasis. Millions of people in the tropical third world are affected by this diseases. The syncytial tegument of these parasites represents a dynamic interface that regulates nutritional and immunological interactions with the host. Dyneins are motor proteins that are important in the biogenesis and maintenance of Schistosome's tegument. Studies have identified dynein light chains (dlc) fragment (Sm10) as a possible vaccine candidate and immunolocalized it in the tegument. Other motor proteins that have been tested as Schistosomes vaccines include paramyosin and myosin-v and the EF-motif dyneins. In this study we have analyzed the three components of dlc: L8 (Sm10), L7 (roadblock) and Tctex in Schistosomes. We characterized these genes in the different life stages of schistosomes and their processing to cDNA. The transcripts are present in *S. mansoni*, *S. haematobium* and *S. japonicam,* the three species that infect human. These peptides can make conjugate peptide for vaccine evaluation.

P4.07.14
Differential expression of ovine TLR2 and TLR4 in peripheral blood mononuclear cells cultured with hydatid cyst derived antigens

A. Haghparast[1,2], *N. Soleymani*[1], *H. Borji*[1], *A. Naghibi*[1], *F. Taran*[1], *J. Mehrzad*[1,2], *M. Nazem Shirazi*[3], *M. Torabi*[3];
[1]*Ferdowsi University of Mashhad, Mashhad, Iran,* [2]*Institute of Biotechnology, Mashhad, Iran,* [3]*Central laboratories of Khorasn Razavi Veterinary Organization, Mashhad, Iran.*

Recognition of helminth derived pathogen associated molecular patterns (PAMPs) by pattern recognition receptors (PRRs), including toll like receptors (TLRs) is the first step towards initiating anti-helminth immune responses. Understanding the molecular basis of innate immune recognition of different stages of parasite antigens will provide a better understanding of disease pathogenicity as well as the potential immunostimulatory and/or immunoregulatory roles of these antigens.
Using hydatid cyst derived antigens of Echinococcus granulosus, causative agent of cystic echinococcosis, the expression of ovine TLR2 and TLR4 in peripheral blood mononuclear cells (PBMCs) was analysed by real-time quatitative reverse-transcription polymerase chain reaction (qRT-PCR). Somatic and exceretory/secretory antigens of protoscoleces (PSC), germainal layer (GL) and hydatid cyst fluid (HCF) antigens were prepared to stimulate ovine PBMCs. A higher expression of TLR2 and TLR4 was observed in PBMCs cultured with somatic antigens of PSC, whereas only TLR2 was up-regulated by ES antigens of PSC. Similarly, we detected an increased level of TLR2 and TLR4 expression in PBMCs cultured with GL antigens. In contrast, the expression of TLR2 and TLR4 in PBMCs was down-regulated by HCF antigens. The results presented in this study suggest that, PSC (Somatic and excretory/secretory antigen) and GL antigens have immunostimulatory effects whereas HCF antigens exhibit an immunoregulatory effect on peripheral immune cells. In conclusion, this study provide for the first time evidence of induction of TLRs in ovine PBMCs by PSC, GL and HCF antigens of Echinococcus.

P4.07.15
Induction of regulatory T cells by Opisthorchis viverrini

C. Kaewraemruaen[1], *R. W. Sermswan*[1], *S. Wongratanacheewin*[1,2];
[1]*Faculty of Medicine, Khon Kaen University, Khon Kaen, Thailand,* [2]*Melioidosis Research Center, Khon Kaen University, Khon Kaen, Thailand.*

Opisthorchis viverrini is a liver fluke that prevalence in Thailand and neighboring countries. Our previous studies demonstrated that this helminthic infection could induce Th2 and regulatory T cell (T reg)-like cytokines, such as TGF-β, IL-4 and IL-10 in infected hamsters. This study aims to investigate CD4+ T cell responses against O. viverrini infection in hamsters. Hamsters were infected with 50 Mc for 10 months. The mononuclear cells of spleen and mesenteric lymph node (MLN) from infected or control groups were stimulated with 10 µg/ml of crude somatic antigen (CSAg) for 24 hrs and stained for CD4, CD25, IL-4, IL-10, IFN-γ and TGF-β, detected by flow cytometer. The IL-4+ and TGF-β+ CD4+ T cells in MLN were found significantly higher than control whereas IL-4+ and IL-10+ CD4+ T cells were increased in infected spleens. In contrast CD4+IFN-γ+ T cells in both spleen and MLNs were not significantly different between infected and control groups. Furthermore significant numbers of TGF-β+ CD4+ T cells in O.viverrini infected group in MLN were found to be CD25+. The result indicated the induction of IL-4+CD4+ T cells in systemic immune responses whereas TGF-β+CD4+ T cells are predominated in mucosal immune responses. To confirm the induction of regulatory T cells by parasite, Balb/c mice were immunized with CSAg, antigen-specific T cell clones were established and found to be TGF-β producing T reg cells. Taken together, our study demonstrated that O.viverrini could stimulate the T reg lead to down regulation of the host immune system making parasite survival.

P4.07.16
Down regulation of NKG2D and Fc gamma receptor I in peripheral blood mononuclear cells induced by excretory-secretory antigens from the third stage Gnathostoma spinigerum larvae (L3)

Y. Maneerat[1], *S. Benjathammaraksa*[2], *Y. Eshita*[3], *R. Kumsiri*[4], *K. Wetchabut*[1], *S. Nuamtanong*[5], *T. Kalambaheti*[6], *J. Waikagul*[5];

Natural killer (NK) cells and monocytes play roles in protective immunity to helminth infection. The understanding in survival and evasion of Gnathostoma spinigerum (G. spinigerum) L3 from human cellular immunity for months or years is still obscure. This study aimed to demonstrate the excretory secretory antigens from G. spinigerum L3 (G. spinigerum ES) could interfere in human monocyte and NK cell functions via down regulating their receptor expression.

Cultures of normal peripheral blood mononuclear cells (PBMC) were used as immune cells within the circulation. Firstly, PBMCs co-cultured with the G. spinigerum ES for 18 hours were screened for the gene profiling correlated with the immune response by DNA microarray analysis. The profound gene groups associated with innate and cytotoxic immunity, particularly NK cell receptor; lectin like family (NKR) and Fc gamma Receptor-I (FcγRI) significantly down regulated. To verify the transcriptional regulation by the G. spinigerum ES, we determined the expression of NKG2D on NK cells and FcγRI on monocytes in PBMC cultured with the ES by flow cytometry, and quantitative real time PCR. The results revealed that NK cells co-cultured with the ES markedly decreased expression of NKG2D and FcγRI during 72 hours. These findings were consistent with the related mRNA expression during 90 min. Taken together, the down regulation of NK cell receptor and FcγRI expressions were markedly observed in PBMC co-cultured with low dose of the G. spinigerum ES. Our findings gain the understanding in a mechanism of the immune-evasive strategy of the G. spinigerum L3.

P4.07.17
Swiprosin-1/EFhd2 limits autoantibody and IgE levels by restricting co-stimulation dependent B cell activation

*S. Brachs[1], A. Turqueti-Neves[2], C. Lang[1], B. Brachvogel[3], M. Bösl[4], T. Winkler[5], D. Voehringer[2], H. Jäck[1], **D. Mielenz**[1];*
[1]University of Erlangen-Nuremberg, Division of Molecular Immunology, Erlangen, Germany, [2]University of Erlangen-Nuremberg, Division of Infection Biology, Dept. of Microbiology, Erlangen, Germany, [3]University of Cologne, Institute for Biochemistry II, Center for Molecular Medicine, Cologne, Germany, [4]University of Würzburg, Institute of Experimental Biomedicine, Würzburg, Germany, [5]University of Erlangen-Nuremberg, Chair of Genetics, Erlangen, Germany.

Peripheral checkpoints account for appropriate selection of activated B cells by regulating their apoptosis and survival. Failure of this process can result in the occurrence of auto-antibodies. Furthermore, dysregulation of immunoglobulin subtypes, such as IgE, can contribute to hypersensitivity reactions. The Ca2+ binding adaptor protein EFhd2 (also named Swiprosin-1) is able to promote apoptosis in activated B cells. We therefore hypothesized that EFhd2 is involved in selection of activated B cells, and established EFhd2-/- mice. B and T cell development and basal immunoglobulin levels were normal but EFhd2-/- mice developed anti-nuclear antibodies spontaneously. Moreover, EFhd2-/- mice developed enhanced germinal center reactions. Upon immunization with trinitrophenol-lipopolysacharide or nitrophenol-keyhole limpet hemocyanin elicited higher antigen-specific IgM or IgG1 antibody titers EFhd2-/- but we did not observe enhanced affinity maturation towards the hapten nitrophenol. Iinfection with the hookworm Nippostrongylus brasiliensis induced strongly exaggerated IgE responses in EFhd2-/- mice and led to enhanced occurrence of IgG1+ and IgE+ plasma cells in a B cell intrinsic manner. This propensity to hyperactivation resulted in pronounced IL-6 production and induction of two NF-kappa B target genes, nfkbia and irf4, after combined BCR and CD40 stimulation of EFhd2-/- B cells. We conclude that EFhd2 constrains selection of activated B cells activation, with implications for autoimmunity, parasite biology and type I hypersensitivity reactions.

P4.07.18
Regulation of intestinal immune response by selective removal of the anterior, posterior, or entire pituitary gland in Trichinella spiralis infected golden hamsters

*R. Hernández-Cervantes[1], A. Quintanar-Stephano[2], V. López-Salazar[1], L. López-Griego[1], R. Hernández-Bello[1,3], J. C. Carrero[1], K. E. Nava-Castro[4], **J. Morales-Montor**[1];*
[1]Departamento de Inmunología, Instituto de Investigaciones Biomédicas, Universidad Nacional Autónoma de México, México, D.F., Mexico, [2]2Departamento de Fisiología y Farmacología, Centro de Ciencias Básicas, Universidad Autónoma de Aguascalientes, Aguascalientes, Mexico, [3]Departamento de Microbiología, Facultad de Medicina. Universidad Autónoma de Nuevo León, Monterrey, NL., Mexico, [4]Facultad de Química. Departamento de Biología. Universidad Nacional Autónoma de México, México, D.F., Mexico.

The influence of anterior pituitary hormones on the gastrointestinal tract of humans and animals has been previously reported. Hypophysectomy (HYPOX) in the rat causes atrophy of the intestinal mucosa, and reduction of gastric secretion and intestinal absorption, as well as increased susceptibility to bacterial and viral infections. However, to our knowledge, no findings have been published concerning the immune response following HYPOX during worm infection, particularly that caused by the nematode *Trichinella spiralis*. The aim of this work was to analyze the effects of total or partial HYPOX on colonization of *T. spiralis* in the intestinal lumen, together with duodenal and splenic cytokine expression. Our results indicate that 5 days post infection, only neurointermediate pituitary lobectomy (NIL) reduces the number of intestinally recovered *T. spiralis* larvae. We observed that the mean intensity of all tested Th1 cytokines was markedly diminished, even in the duodenum of infected controls. In contrast, a high level of expression of these cytokines was noted in the NIL infected hamsters. Likewise, a significant decrease in the fluorescence intensity of Th2 cytokines (with the exception of IL-4) was apparent in the duodenum of control and sham infected hamsters, compared to animals with NIL surgeries, which showed an increase in the expression of IL-5 and IL-13. NIL hamsters showed an exacerbated inflammatory infiltrate located along the lamina propria in the duodenal mucosa. We conclude that hormones from each pituitary lobe affect the gastrointestinal immune responses to *T. spiralis* through various mechanisms.

P4.07.19
The effects of astaxanthin in improving age associated declines of Th2 immune responses

***M. Morimoto**, S. Abe, N. Azuma, S. Kamei, K. Dewa;*
School of Food, Agricultural and Environmental Sciences, Miyagi University, Sendai City, Miyagi, Japan.

Objective. Astaxanthin is one of the natural antioxidant carotenoid mainly derived from crab,salmon and trout. This study aims to determine whether dietary astaxanthincould modulate mucosal immunity in the gut in aged mice.
Method. Aged (18 months old) Balb/c female mice were orally administered with6mg/kg body weight of astaxanthin or saline for 4 weeks. After 3 weeks, micewere infected with *Nippostrongylus brasiliensis(Nb)*, which is gastroinfectional nematode in rodents. Tissues were taken from the small intestine, and total RNA was extracted and analyzed by real time PCR for IL-4, IL-13, IL-10, IFNγ and NOS2. For lipid peroxidation measurements in the liver, the thiobarbituric acid (TBA) assay was also performed.
Results. The lipoperoxide level in the 18M mice were significantly higher compared with that in the 3 months old mice. However, it significantly decreased after astaxanthin administration. Aged mice failed worm expulsion with declining Th2 immune responses, while Th2 cytokine gene expression was recovered and worm expulsion progressed in astaxanthin-fed aged mice. INFγ didn't show any change. NOS2 was down-regulated and IL-10 increased after infection in astaxanthin fed-mice. FACS analysis revealed that CD4+CD25+Foxp3- T cells increased in aged mice, but these cells disappeared after astaxanthin administration.
Conclusions. These data showed that astaxanthin exhibited the effect of inhibition of oxidative stress and improved Th2 immune responses which declined during aging.

P4.07.20
Dendritic cell capture and transfer of HIV-1 to CD4$^+$ T lymphocytes is inhibited by helminth parasite antigens

E. E. I. M. Mouser[1], *H. H. Smits*[2], *M. Yazdanbakhsh*[2], *E. C. de Jong*[1], *G. Pollakis*[1], *W. A. Paxton*[1];
[1]*Academic Medical Centre of the University of Amsterdam, Amsterdam, Netherlands,* [2]*Leiden University Medical Centre, Leiden, Netherlands.*

Areas endemic for parasitic infections often have a high HIV-1 prevalence. Helminths are known for their immuno-modulatory properties however, their impact on HIV-1 susceptibility is unknown. We have studied the effects of soluble egg antigen (SEA) of *Schistosoma mansoni* and whole *Brugia malayi* adult (BMA) worm antigen extract for their capacity to interfere with HIV-1 infection. These antigens bind C type lectin receptors (CLRs) which could influence direct and indirect HIV-1 infection of CD4$^+$ T cells. Additionally, CLR signaling on DCs can modulate the induction of Th cell populations, potentially affecting their susceptibility for HIV-1 infection and replication. Direct infection, as determined by viral outgrowth in CD4$^+$ T lymphocytes pre-incubated with SEA or BMA, was unchanged for both CCR5 and CXCR4 using HIV-1 isolates. Contrary, utilizing a DC-SIGN-Fc/gp120 binding ELISA we observed that both SEA and BMA potently inhibited HIV-1 Env from binding DC-SIGN. Furthermore, this was confirmed by showing that both SEA and BMA could prevent Raji-DC-SIGN cells and the more physiologically relevant moDCs from capturing HIV-1 and supporting *trans*-infection of CD4$^+$ lymphocytes. Currently, we are testing the HIV-1 susceptibility of Th cells induced by moDCs matured in the presence of either SEA or BMA, since the cytokine/ chemokine profile of CD4$^+$ T lymphocytes can influence HIV-1 infection and replication. We have demonstrated that helminth parasite antigens can block HIV-1 from interacting with DC-SIGN thereby disrupting a pathway important for HIV-1 transmission and subsequent propagation.

P4.07.21
Helminth infection alters mood and short-term memory as well as neurotransmitter and cytokine levels in the mouse hippocampus

K. E. Nava-Castro[1], *J. Morales-Montor*[2], *O. Picazo*[3], *H. Besedovsky*[4], *R. Hernández-Bello*[2], *L. López-Griego*[2], *E. Becerril*[5], *J. Moreno*[6,7], *L. Pavón*[5], *I. Camacho-Arroyo*[1];

Helminthic infections are important causes of morbidity and mortality in many developing countries, where children bear the greatest health burden. The ability of parasites to cause behavioral changes in the host has been observed in a variety of host-parasite systems, including the *Taenia crassiceps*-mouse model. In murine cysticercosis, mice exhibit a disruption in sexual, aggressive and avoidance predator behaviors. The present study was undertaken to characterize short-term memory, depression-like behavior as well as neurotransmitters and cytokine levels in the hippocampus of cysticercotic male and female mice. Chronic cysticercotic infection induced a decrease in short-term memory in male and female mice, being the effect more pronounced in females. Interestingly, infected females showed a significant increase in forced swimming tests with a decrease in immobility. In contrast, male mice showed an increment in total activity and ambulation tests. Serotonin levels decreased by 30% in the hippocampus of infected females whereas noradrenaline levels significantly increased in infected males. The expression of IL-6, IFN-γ in the hippocampus was markedly increased in infected male and female mice. The expression of IL-4 increased in infected female mice, but decreased in infected male mice. Our study suggests that intraperitoneal chronic infection with cysticercus leads to persistent deficits in tasks dependent on mice hippocampal function. Our findings are a first approach to elucidate the role of the neuroimmune network in controlling short-term memory and mood of *T. crassiceps* infected mice.

P4.07.22
CD28 is required for protection against Nippostrongylus brasiliensis secondary infection and recall of memory responses in inducible CD28 deleting mice

H. H. Ndlovu[1], *M. Darby*[1], *M. Froelich*[2], *W. Horsnell*[1], *F. Ludher*[3], *T. Hunig*[2], *F. Brombacher*[1];
[1]*University of Cape Town, Cape Town, South Africa,* [2]*University of Wurzburg, Wurzburg, Germany,* [3]*University Medical Center Gottingen, Gottingen, Germany.*

IL-13 driven Th2 immunity is indispensable for host protection against infection with the gastrointestinal nematode *Nippostronglus brasiliensis*. Disruption of CD28 mediated costimulation impairs development of adequate Th2 immunity, showing an importance for CD28 during the initiation of an immune response against this pathogen. However, any requirement for CD28 during recall immunity to secondary infection with pathogens has remained largely controversial. In this study, we used global CD28$^{-/-}$ mice and a novel mouse model that allows for inducible deletion of the *cd28* gene by oral administration of tamoxifen (CD28$^{-/lox}$Cre$^{+/-}$+TM) to address these questions. Following primary infection with *N. brasiliensis*, CD28$^{-/-}$ mice failed to expel adult worms in the small intestine in contrast to wild-type C57BL/6 mice. Impaired expulsion was associated with reduced production of Th2 cytokines, particularly IL-13, reduced humoral immunity and failure to develop CXCR5$^+$ T_{FH} cells. Interestingly, interference with CD28 expression in CD28$^{-/lox}$Cre$^{+/-}$ mice by oral administration of tamoxifen prior to secondary infection with *N. brasiliensis* resulted in impaired worm expulsion. This correlated with reduced production of Th2 cytokines IL-13 and IL-4, diminished serum titres of antigen specific IgG1 and total IgE and reduced CXCR5$^+$ T_{FH} cell populations. Importantly, abrogation of CD28 during secondary infection inhibited the recruitment of central and effector memory CD4$^+$ T cells and follicular B cells to the draining lymph node. Therefore, it can be concluded that CD28 is essential for the development of protective memory Th2 immunity against *N. brasiliensis* infection and for expansion of CXCR5$^+$ T_{FH} cells and follicular B cells.

P4.07.23
Analysis of Schistosoma mansoni candidate antigens as diagnostic targets for schistosomiasis

P. O. Ogongo[1], *A. R. Wilson*[2], ***T. M. Kariuki***[1];
[1]*Institute of Primate Research, Nairobi, Kenya,* [2]*University of York, York, United Kingdom.*

Demonstration of schistosome eggs in stool/urine is the definitive clinical test for clinical examination of schistosomiasis but this test has low sensitivity. Antibody based assays cannot distinguish between past and active infections thus unsuitable for follow up after drug administration while molecular techniques are expensive and unavailable at the point of care centers. Bioinformatics and Proteomics can be used to characterize schistosome proteins from different life cycle stages that include worm gut, worm tegument, egg secretions or released products of dead eggs that are released into the bloodstream and/or urine forming good diagnostic targets. We identified three schistosome proteins; Cathepsin B (Sm31), Asaparaginyl endopeptidase (Sm32) and Sm200 tegument protein using these approaches. Peptide sequences from these proteins synthesized as multiple antigenic peptides (MAPs) were used to immunize rats. Serum from immunized rats were used to test the suitability of these targets using Enzyme Assays, Blot Assays and Immunocytochemistry with worm sections. Results show that antibodies to MAPs raised in rats have good specificity for the peptides and native schistosome antigens which identifies them as possible diagnostic targets that can be developed further to assess

their sensitivity aiming at developing an assay capable of detecting the lowest number of worms in the host.

P4.07.24
Leukocyte adhesion to mesenteric endothelial cells mediated by $P2Y_1$ receptor activation during schistosomiasis

S. D. S. Oliveira[1], *N. F. Oliveira*[2], *R. Coutinho-Silva*[3], *C. L. M. Silva*[2]; [1]*Universidade Federal do Rio de Janeiro, IBCCF and ICB, Rio de Janeiro, Brazil,* [2]*Universidade Federal do Rio de Janeiro, ICB, Lab. Biochemical and Molecular Pharmacology, Rio de Janeiro, Brazil,* [3]*Universidade Federal do Rio de Janeiro, IBCCF; Instituto Nacional para Pesquisa Translacional em Saúde e Ambiente na Região Amazônica, Conselho Nacional de Desenvolvimento Científico e Tecnológico/MCT, Rio de Janeiro, Brazil.*

Introduction: Previous work showed a downregulation of endothelial purinergic P2X7 receptor during chronic inflammation associated with schistosomiasis (Oliveira et al., 2013, Purinergic Signal. 1:81). We also observed an increased ectonucleotidase enzymatic activity, which produces ADP, an agonist of $P2Y_1$ receptors ($P2Y_1R$) that stimulates leukocyte adhesion to endothelial cells. Present work evaluated $P2Y_1R$ signaling in mesenteric endothelial cells (MECs) during schistosomiasis.
Methods: Cultured MECs and mononuclear leukocytes (control and infected mice) were obtained as previously described (Oliveira et al., 2011, PloS One 6:e23547). Western blotting assays investigated MECs $P2Y_1R$ expression and fluorimetric assays evaluated intracellular Ca^{2+}. We used the agonist 2-MeSATP in the absence or presence of the selective antagonist MRS2179 (0.3 µM).
Results: In the control group, 2-MeSATP (30 and 60 µM) increased MECs intracellular Ca^{2+} and leukocyte adhesion from 9.4 ± 1.3 to 24.5 ± 1.6 and 28.7 ± 1.7 cells/field, respectively (n=26-36 replicates, $P<0.01$). MRS2179 prevented cell adhesion (9.2 ± 1.2 cells/field, n=36). However, in the inflammation model, there was an increased spontaneous adhesion (22 ± 2.0 cells/field, n=33), and the agonist had no significant effect. No alteration of $P2Y_1R$ expression was observed, but, the antagonist MRS2179 reduced basal adhesion (9.6 ± 1.0 cells/field, n=33), *i.e.*, in the absence of 2-MeSATP. One possible explanation is that $P2Y_1R$ were being continuously activated by locally produced ADP.
Conclusion: Schistosomiasis primes MECs *in vivo* which keep the acquired phenotype *in vitro*. These data indicate that schistosomiasis activates MECs $P2Y_1R$ signaling and consequently leukocyte adhesion.

P4.07.25
Purinergic signaling in mesenteric endothelial cells and peritoneal macrophages in chronic inflammation

S. D. S. Oliveira*, N. F. Oliveira, J. R. Meyer-Fernandes, C. L. M. Silva, R. Coutinho-Silva;*
Federal Universty of Rio de Janeiro, Rio de Janeiro, Brazil.

Introduction Schistosomiasis causes a chronic inflammation related with physiological vascular alterations. Our group evaluated the immunomodulation of the purinergic signaling in mesenteric endothelial cells (MECs) and macrophages from *S. mansoni*-infected mice. Methods: The P2X7 receptor (P2X7R) function was evaluated by ATP-inducing membrane permeabilization to ethidium bromide (BE) measured by flow cytometry in MECs and macrophages. P2X7R expression was accessed by Immunocytochemistry and Western blotting. P2X7R-mediated nitric oxide (NO) production and ectonucleotidase activity were evaluated in MECs. Results: Schistosomiasis reduced the P2X7R expression in MECs and macrophages. We observed that 3 mM ATP was less efficient in inducing BE-uptake in MECs from infected (25 ± 2%; n=8) than uninfected mice (43 ± 1%, n=10). The selective P2X7R agonist BzATP induced a smaller NO synthesis in MECs from infected than control mice (5 ± 2% and 22 ± 2%, n=15, respectively). On the other hand, the ectonucleotidase activity was higher in MECs from infected than control mice (17 ± 3 and 7 ± 1 pmol Pi/µg of protein, n=16-14, respectively). The infection reduced the BE-uptake induced by 1 mM ATP in macrophages (95 ± 2% and 54 ± 6%, infected and uninfected mice respectively, n=12). Preliminary results also showed a reduced BzATP-mediated Ca^{2+} mobilization and increase of anti-inflammatory cytokine TGF-β in macrophages from infected-mice. Conclusion: Altogether, our data indicate that schistosomiasis modulates P2X7-receptor signaling in two cells types important to immune response. This could limit vascular inflammation and morbidity. Atopic responses among pre-school children in a schistosomiasis endermic community in Zimbabwe

N. H. Paul[1,2], *N. Rujeni*[3], *F. Chidzwondo*[2], *N. Midzi*[4,5], *F. Mutapi*[3], *T. Mduluza*[2], *T. Mduluza*[2], *T. Mduluza*[2], *T. Mduluza*[2], *T. Mduluza*[2], *T. Mduluza*[2];
[1]*Scientific and Industrial research and development Centre, Harare, Zimbabwe,* [2]*University of Zimbabwe, Harare, Zimbabwe,* [3]*University of Edinburgh, Scotland, United Kingdom,* [4]*National Institute of Health Research, Harare, Zimbabwe,* [5]*Research Council of Zimbabwe, Harare, Zimbabwe.*

The study was conducted in the Mashonaland East Province of Zimbabwe where *Schistosoma haematobium* is endemic. A longitudinal, community-based study survey was conducted at Magaya and Chitate schools. Parasitology collection, questionnaires and treatment of the study population was done. A skin prick allergen reaction test on mother and child only were carried out. Blood samples were obtained and used to determine immunological profiles. Magaya area had high infection prevalence greater than 50% and Chitate area had moderate infection (10> prevalence<50%). All infected participants were treated with praziquantel tablets. The overall prevalence of skin prick reactivity was 19% and the most prevalent allergic response was directed against the house dust mite with 12% of the population reacting against it. Anti-schistosome treatment with praziquantel did not result in an increase in atopic responses 6 months after treatment in children aged 6 months -5 years of age. Most infected individuals did not have any marked allergenic responses to the testing antigens. Treatment resulted in significant increase in protective IgE which has been associated with protection against re-infection. IgE and IgG4 antibodies against Derp-1 increased after treatment but the ratio IgE: IgG4 significantly decreased in the high transmission area suggesting that removal of the parasites by PZQ treatment decreases allergic responses, contrasting with the hygiene hypothesis.

Impaired CXCR4/CXCL12 chemokine receptor/ligand axis limits filarial infection

N. Pionnier[1,2], *E. Brotin*[2], *G. Karadjian*[1], *N. Vallarino-Lhermitte*[1], *A. Nieguitsila*[1], *P. Hémon*[2], *M. Aknin*[2], *F. Bachelerie*[2], *C. Martin*[1];
[1]*Muséum National D'Histoire Naturelle, Paris, France,* [2]*UMR-S996 Cytokines, Chemokines and Immunopathology, Clamart, France.*

Filariases are chronic diseases affecting 160 million people worldwide. Despite considerable effort to reduce disease burden, particularly through mass drug administration programs, filarial infections remain a major public health problem requiring new therapeutic approaches. In our study, we used *Litomosoides sigmodontis* as a well-established murine model of filarial infections. Previous studies have shown that the CXCL12 chemokine and its receptor CXCR4 participate to the mice resistance mechanism to the filarial infection, suggesting CXCR4 and CXCL12 as potential therapeutic targets. To decipher their role on the infection progression, we used a newly developed murine model of a rare combined human immunodeficiency disorder (WHIM: Warts, Hypogammaglobulinemia, recurrent Infections and Myelokathexis) caused by a gain of CXCR4 function and also characterised by a profound lympho-neutropenia. WHIM mice reproduce this leucopenia, associated with defective thymopoiesis and B-cell development and lymph node disorganised architecture. Our results on filarial infection in those mice showed that filarial parasitic success was drastically decreased by 70% in WHIM mice compared to control wild-type mice. In addition, a significant neutrophilia became noticeable from 15 days

post-infection, normalising the circulating neutrophils to the control levels although the lymphopenia remained in the WHIM mice throughout the infection. Moreover, 6 hours post filarial infection, cell recruitment in the skin was more important in those WHIM mice, suggesting a stronger local immune response to *L. sigmodontis*. Further analyses are currently conducted in order to elucidate the mechanisms behind this immune response in respect to the role of the CXCL12/CXCR4 axis in filarial infection.

Opisthorchis viverrini induces Th17 cytokine responses in hamsters

S. Polyiam[1,2], *Y. Huang*[3,4], *R. Anderson*[3,4], *S. Wongratanacheewin*[5,2], *R. W. Sermswan*[1,2];
[1]*Department of Biochemistry, Faculty of Medicine, Khon Kaen University, Khon Kaen, Thailand,* [2]*Melioidosis research center, Khon Kaen University, Khon Kaen, Thailand,* [3]*Department of Microbiology and Immunology, Dalhousie University, Halifax, NS, Canada,* [4]*Canadian Center for Vaccinology, Dalhousie University, Halifax, NS, Canada,* [5]*Department of Microbiology, Faculty of Medicine, Khon Kaen University, Khon Kaen, Thailand.*

Opisthorchiasis, a major helminthic disease in many parts of Southeast Asia, is caused by the liver fluke Opisthorchis viverrini (OV). Disease ranges from asymptomatic to diarrhea, epigastric pain, fever and jaundice. Long term chronic inflammation may lead to cholangiocarcinoma. Since the discovery of Th17 cells, our current knowledge of T helper (Th) cell responses and their roles in OV infection is incomplete. In particular the production of cytokines from Th1, Th2, Th17 and Treg cells requires careful examination. Although the hamster is the best animal model, immunological studies in the hamster have been limited due to the lack of available reagents. In this study, we infected hamsters with different doses (5, 50 and 100 metacercariae) and examined cytokine levels at different times (2, 8 and 24 weeks) after infection. Th17-related cytokines including TGF-β, IL-6, IL-23, IL-17A and IL-21 were assayed in the spleens, livers and mesenteric lymph nodes (MLNs) using RT-qPCR. Hamster sera Th1/Th2/Th17/Treg cytokine levels were quantified using a bead-based Luminex technology. The results showed that Th17 cytokines were detectable together with Th1, Th2 and Treg cytokines. Generally TGF-β was expressed, correlated with dose and increased with time up until at least 6 months in all organs. In contrast IL-17A and IL-21 were only expressed in spleen. Th17 cytokine transcripts were higher in MLNs than spleen and liver where the pathology occurs. This study provides important insights in immunity to opisthorchiasis and suggests possible roles for Th17 cytokines in immunoprotection and/or immunopathology.

P4.07.29
Study of nitric oxide metabolites(NOx) production during human hydatidosis: Relationship with cyst fertility

Z. Razika[1], *T. Chafia*[2];
[1]*USTHB and UMOB, Algeria, Algeria,* [2]*USTHB, Algeria, Algeria.*

Nitric oxide (NO) and its stable metabolites nitrite and nitrate (NO2−+ NO3−) have been identified as major effector molecules during the majority of parasitic infections. Production of NO has been shown to be induced by interferon gamma (IFN-γ) during human hydatidosis suggesting the relevant role of NO in the host defense. This parasitic infection constitutes a major health problem in Algeria. It is characterized by a prolonged coexistence of Echinococcus granulosus and its host without effective rejection of the parasite. In this study, we investigated in vivo production of NO products NOx (NO2−+ NO3−) in sera of Algerian patients carrying different cyst locations. NOx levels were evaluated by the Griess method. Our results indicated that the levels of NOx were significantly higher in the sera of hydatic patients than those of healthy controls supporting the possible involvement of NO in antihydatic action. The levels of NOx in sera of the patients with hepatic hydatidosis were significantly higher than those with pulmonary infection. The lower serum NOx levels were observed in the relapsing cases. In the current study, our results show high levels of NOx in fertile liver and lung fluids compared to infertile fluids. Our results suggest that the presence of NO products in hydatic fluids seems to be related to the location and the fertility of hydatic cysts. In addition, the presence of NO products in the cyst fluid suggests a possible local NO production by the larvae.

P4.07.30
Evaluation of CCA urine test for diagnosis of *Schistosoma mansoni* infection in Brazil

A. M. S. Silveira[1], *C. Caffrey*[2], *M. H. Hsieh*[3], *D. Ray*[4], *B. Suzuki*[5], *L. A. O. Fraga*[1];
[1]*Universidade Vale do Rio Doce, Governador Valadares, Minas Gerais, Brazil,* [2]*University of California, San Francisco, CA, United States,* [3]*Stanford University, Stanford, CA, United States,* [4]*University of California, San Fransisco, CA, United States,* [5]*Univversity of California, San Francisco, CA, United States.*

The circulating cathodic antigen (CCA) immune-chromatographic dipsticks was developed as an alternative diagnostic test, which indicate the presence of alive worms by detecting excreted schistosome antigens in host urine. A fresh urine sample was tested with a commercially available circulating cathodic antigen (CCA) assay (Rapid Medical Diagnostics, Pretoria, South Africa). In the present study we compared the accuracy of CCA testing to Kato-Katz (duplicate thick smears from tree stool samples collected in consecutive days). Feces and urine sampling took place in August and September 2012 in tree rural districts in Governador Valadares, Minas Gerais, Brazil. A total of 106 individuals aged 7-89 years old participated of this study. For the Kato-Katz test, 45 individuals were egg negative and 61individuals were egg positive, showing a range of 4 to 2288 eggs/g of feces. Results from the CCA test were recorded according to the visual intensity of the CCA reaction band: trace, weak (+), medium (++) and strong (+++). Kato-Katz examination and CCA testing were in broad agreement, revealing mean prevalence of 58% and 53%, respectively. Following urine testing with CCA dipsticks, we observed that 13%(14/106) of results were categorized as trace, 16% (17/106) as single positive, 10% (11/106) as double positive and 13% (14/106) as triple positive. The sensitivity (SS) was found to be 82% and specificity (SP) 85%, when trace was considered as positive. Our results suggest that urine-based assays for CCA may be valuable in screening for *S. mansoni* infections. Financial support: BWF/UCSF and UNIVALE

P4.07.31
High IL-4 production related to granuloma development in high-tolerogenic mice infected with *Schistosoma mansoni*

D. A. Tavares[1], *A. C. da Silva*[1], *A. M. L. Xavier*[2];
[1]*Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil,* [2]*Universidade Federal Fluminense, Niteroi, Brazil.*

The *Schistosoma mansoni* infection was studied in two strains of mice genetically selected for extreme phenotypes of susceptibility (TS) and resistance (TR) to oral tolerance. TR strain present good inflammatory responses and a non-tolerogenic profile while TS are non-inflammatory but high-tolerogenic, with high percentages of CD4+CD25+Foxp3+ T regulatory cells, and able to produce high levels of inhibitory citokynes such as IL-10. The aim of this study is to correlate the cytokines production to the pathology caused by infection. TS strain have higher weakness, apathy, prostration and mortality due to hepatosplenomegaly more intense due to the larger size of hepatic granulomas and extensive fibrosis of these granulomas. Both strains produced IFN-γ, but TS produced IL4 and IL-10 in a larger quantity, however IL-10 was not able to regulate the growth of hepatic granulomas exacerbated this lineage. High levels of IL-4 in TS strain are consistent with the exacerbation of granulomas, since IL-4, as well as IL-13, induces collagen synthesis and is related to the development of fibrosis in schistosomal granuloma. Additional studies are needed to confirm our proposals and to understand the mechanisms underlying the difference in immune response of these strains in the schistosoma-host relationship.

P4.07.32
Reduction of B lymphocytes production in mice genetically selected for humoral response and infected with *Schistosoma mansoni*

A. M. L. Xavier[1]*, M. F. S. da Silva*[2]*, E. Hayashi*[3]*, A. C. da Silva*[2]*, D. A. G. Tavares*[2]*;*
[1]Universidade Federal Fluminense, Niteroi, Brazil, [2]Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil, [3]Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil.

The *Schistosoma mansoni* infection was studied in two strains of mice genetically selected for extreme phenotypes of susceptibility (TS) and resistance (TR) to oral tolerance. TR strain present good inflammatory responses and a non-tolerogenic profile while TS mice are non-inflammatory but high-tolerogenic profile. The aim of this work is the study of the production of B lymphocytes in mice selected for humoral response to oral tolerance infected with *S. mansoni*. TS strain has higher weakness, apathy, prostration and mortality due to anemia and hepatosplenomegaly more intense due to the larger size of hepatic granulomas. We observed a reduction of percentage of T CD4+ lymphocytes in the liver of infected mice in both strains and a reduction in all subpopulations of B lymphocytes in bone marrow (precursors, immature, mature and plasma cells) more pronounced on TS strain than TR strain, possibly due to extensive mobilization of immature B cells induced by inflammation and hematopoiesis deviation for synthesis of granulocytes in TS mice. TR strain didn´t show changes in their subpopulations of B lymphocytes. Additional studies are needed to confirm our proposals and to understand the mechanisms underlying the difference in immune response of these strains in the schistosomal-host relationship.

P4.07.33
Ultrastructural alterations in adult *Schistosoma mansoni* harbored in low-inflammatory mice

A. M. L. Xavier[1]*, M. F. S. da Silva*[2]*, E. V. Guimarães*[3]*, A. C. da Silva*[2]*, A. H. A. Moraes Neto*[3]*, D. A. G. Tavares*[2]*;*
[1]Universidade Federal Fluminense, Niteroi, Brazil, [2]Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil, [3]FIOCRUZ, Rio de Janeiro, Brazil.

The *Schistosoma mansoni* infection was studied in two strains of mice genetically selected for extreme phenotypes of susceptibility (TS) and resistance (TR) to oral tolerance. The objective was to analyze by Transmission Electron Microscopy the influence of the host immune regulatory profile on the worm morphology. Parasites recovered from TR mice showed no morphological changes. However, specimens collected from TS mice, exhibited tubercle swelling with blunted and shortened spines in lower density. These tegument alterations were similar to those described with artemether or praziquantel treatment, supporting observations that the host immune system influences the tegument development and function of worms harbored in non anti-helminthic treated TS mice. The ileum oogram from TS mice showed a higher percentage of dead eggs and a lower percentage of immature eggs than TR mice, but had similar quantities of collected eggs. This suggests that in TS mice the alterations in adult worm tegument prevented egg development, as a consequence of decreased glycogen granules and extensive lysis of internal structures, but not egg production reduction. These results corroborate our previous Scanning Electron Microscopy study indicating the influence of the host immune regulatory profile on the development and function of the worm reproductive system and tegument.

P4.07.34
Contribution of IL-33-activated type II innate lymphoid cells to pulmonary eosinophilia in *Strongyloides venezuelensis*-infected mice

K. Yasuda*, T. Muto, M. Matsumoto, Y. Sasaki, K. Matsushita, T. Yoshimoto, K. Nakanishi;*
Hyogo College of Medicine, Nishinomiya, Japan.

When animals are infected with helminthic parasites, resistant hosts show Th2 immune responses to expel worms and develop eosinophilic inflammation in their lungs. But the mechanism for this lung eosinophila is not clear. Here we show the relevant roles of endogenous IL-33 for *Strongyloides venezuelensis* (*S. venezuelensis*) infection-induced lung eosinophilic inflammation by using *Il33*$^{-/-}$ mice. We found alveolar epithelial type II cells (ATII) but not macrophages express IL-33 in their nucleus, and infection with *S. venezuelensis* increases in the number of ATII cells and in the level of *Il33* mRNA and IL-33 protein. Recently, newly identified type II innate lymphoid cells (ILC2) are shown to express ST2 and produce IL-5 and IL-13 when stimulated with IL-33. *S. venezuelensis* infection induces pulmonary accumulation of ILC2 in IL-33 dependent manner, and these cells produce IL-5 and IL-13 ex vivo. Furthermore, *Rag2*$^{-/-}$ mice increase the number of ILC2 and eosinophils in their lungs after infection, while *common*$\gamma^{-/-}$*/Rag2*$^{-/-}$ mice, in which ILC2 are absent, do not show these responses. Finally, IL-33-stimulated ILC2 produce IL-5 and IL-13, which in turn induce lung eosinophilic inflammation, and might aid to expel infected worms in the lungs.

P4.08.01
CCL3, CCL4 and CXCL8 chemokines mRNA expression in human neutrophils in response to *Leishmania infantum*

A. Hematzadeh[1]*, S. Pakzad*[2]*, T. Naji*[3]*,* ***S. Ajdary***[4]*;*
[1]Islamic Azad university-Pharmaceutical sciences branch (IAUPS), Science and new technology faculty,, Tehran, Iran, [2]Food and Drugs control laboratory and research centre, Tehran, Iran, [3]Islamic Azad university-Pharmaceutical sciences branch (IAUPS), Science and new technology faculty, Tehran, Iran, [4]Pasteur institute of Iran, Tehran, Iran.

Zoonotic visceral leishmaniasis caused by *Leishmania infantum (Li.)* is potentially fatal; however, subclinical forms are relatively common. Initial cytokine response at the early stage of infection is important in the outcome of infection. Polymorphonuclears (PMN) are the first cells that recruited to sites of *Leishmania* infection, where they can influence the recruitment of other immune cells by producing chemokines. Little is known about chemokines produced by human PMN in response to *Leishmania*. In this study, we investigated CCL3, CCL4 and CXCL8 mRNA expressions from PMN treated with or without *Li.* promastigotes. The mRNA expression of chemokines was quantified by qRT-PCR. The mean dCT (CT number of chemokine gene - CT number of reference gene (β-actin)) for treatment and the mean dCT for control for each chemokine were compared by t-test. The results showed that PMN express significantly higher CXCL8 after stimulation with *Li.* ($p=0.007$). However, CCL3 and CCL4 expression were suppressed in 65% and 62%, and remained unchanged in 12% and 8% of individuals, respectively. There was a significant correlation ($p<0.0001$) in mRNA expression between CCL3 and CCL4. Our Findings suggest that induced CCL8 and suppressed CCL3 and CCL4 expression in *Li.*-stimulated PMN, induce PMN and suppress early macrophages recruitment. Since early influx of PMN has been demonstrated to be beneficial for *Leishmania* survival and early arriving macrophages does not seem to be a suitable host for free extracellular promastigotes this selective release of chemokines will favor parasite survival and establishment.

P4.08.02

Trypanosoma cruzi oral/intragastric infection in murine model: infection and immune response features of the host

J. B. Albuquerque[1], *D. S. Santos*[1], *L. R. Berbert*[1], *C. E. Carvalho-Pinto*[2], *A. R. Pérez*[3], *O. Botasso*[3], *E. Roggero*[3], *R. Manarin*[3], *W. Savino*[1], *J. de Meis*[1];
[1]*Oswaldo Cruz Foundation, Rio de Janeiro, Brazil,* [2]*Fluminense Federal Universtity, Niterói, Brazil,* [3]*National University of Rosario, Rosário, Argentina.*

Nowadays Trypanosoma cruzi oral transmission through ingestion of contamined food promotes acute Chagas' disease outbreaks in several Brazilian states and other Latin America countries. Few reports address carditis and immune response on this model, so our study has evaluated parasitologic and immunologic features, and also target organs after T. cruzi oral/intragastric infection. In this purpose we have infected BALB/c mice with $5x10^4$ trypomastigotes (Tulahuen strain) through intraperitoneal (IP), intragastric (IG) or oral (IO) route. IP group have presented higher parasitemia and mortality than IG and IO (0%, 45% e 20% respectively remain alive after 31 dpi), and also IO group have presented higher values than IG. Initially evaluating target organs histopathology, hearts have presented microinfiltrates that have enlarged through time and from 9, 12 and 15 dpi, amastigotes nests in IP, IG and IO groups, respectively. Besides, liver has showed mild/moderate lesions in IG group that were smaller and less than IP. Concerning to host immune response, we have observed that serum cytokine profile in IP group was mainly T_H1 and in IG, T_H2. Therefore we have analyzed cellularity and lymphocyte phenotyping in subcutaneous (SCL) and mesenteric (ML) lymph nodes, spleen and Peyer patches (PP). IP group presented hyperplasia in SCL (increased $CD8^+/CD19^+$ population) and spleen (increased $CD4^+/CD8^+/CD19^+$ population) earlier than IG. PP hypoplasia (decreased $CD19^+$ population) was observed in IP and IG groups. Our results suggest that IO/IG infection affects parasitemia, mortality and target organs commitment, triggering alterations in serum cytokines and secondary lymphoid organs compared with IP.

P4.08.03

Congenital infection with *Trypanosoma cruzi* primes cord blood Vδ2 T cells to proliferate in response to isopentenyl pyrophosphate

C. Alonso-Vega*;*
Universidad Mayor de San Simón, Cochabamba, Bolivia, Plurinational State of.

Trypanosoma cruzi is the protozoa agent of Chagas' disease in South America. Our team has previously demonstrated that newborns congenitally-infected with *T. cruzi* develop a parasite-specific CD8 αβ T cell immune response *in utero*. In the present study, we have investigated whether cord blood TCRVδ2 T cells were also involved in such response, by analysing their phenotype and their capacity to proliferate in response to isopentenyl pyrophosphate (IPP) in both uninfected and congenitally-infected newborns. We found that Vδ2 T cells can be expanded following congenital infection with *T. cruzi*. Cord blood Vδ2 T cells from congenitally-infected newborns expressed inhibitory NK cell receptors such as NKG2A and killer inhibitory receptors. Moreover, they vigorously expand in response to IPP combined with IL-2. Altogether these results demonstrate that Vδ2 T cells can be activated *in utero* and that these cells can be primed to respond to phosphoantigens.In conclusion.In conclusion, this work demonstrates that congenital infection with *T. cruzi* induces significant activation of fetal γδ T cells *in utero*, and supports the notion that it's possible to boost the γδ T cell immune response in early life

P4.08.04

Phenotypic and functional analysis of CD4+FoxP3+ regulatory T cells (TREG) in the early phase of murine infection with Trypanosoma cruzi

B. Villas-Bôas, R. S. do Nascimento, M. D'Império-Lima, ***J. M. Alvarez****;*
Biomedical Sciences Institutes, São Paulo, Brazil.

Introduction: We previously observed that in T. cruzi-infected mice (Y strain) depletion of TREGs by anti-CD25 mAb treatment does not affect acute parasitemia, suggesting that TREGs do not regulate the early anti-T. cruzi response. Using FoxP3+GFP+ mice, we now studied the phenotypic changes in spleen TREGs along the early infection with SylvioX10/4 T. cruzi parasites and evaluated their suppressive activity.
Results: Peak spleen cellularity and CD4+ cell number occurred on the 11th day post-infection (d.p.i.). No major changes in TREG number were observed from the 4-18 d.p.i., despite an increase in large TREG cells. Regarding expression (MFI) of different markers by TREGs, we observed a slight increase in FoxP3 at 7-14 d.p.i., small increases in Fas at 11 and 18 d.p.i., strong increases in CD25 that peaked at 14 d.p.i. and late increases in GITR and FasL. No significant changes in OX40 or CD127 were observed. Of note was the appearance of TREG subsets with higher expression of CTLA-4 (at 7 d.p.i.), CD69 (from 7-14 d.p.i.) and ICOS (from 7-18 d.p.i.) that peaked at 7 d.p.i.. According to their suppressive activity upon the anti-CD3-induced proliferation of CD4+FoxP3- splenocytes and upon IFN-γ production by total splenocytes, there were no major differences between TREGs cells from control and 7d-infected mice. Moreover, responding 7d-CD4+FoxP3- splenocytes showed similar susceptibility to suppression by control and 7d-TREGs than control CD4+FoxP3- cells.
Conclusion: We demonstrate that during the early infection by T. cruzi TREGs maintain their suppressive activity and responding CD4+cells do not become resistant to suppression.

P4.08.05

Phagocyte-derived from cells B1 (B1CDP) facilitate Leishmania major infection in vitro via IL-10 and PGE-2 secretion

A. F. Arcanjo[1], *I. F. La Roque de Freitas*[2], *J. D. B. Rocha*[3], *M. P. Nunes*[3], *A. Popi*[4], *M. Mariano*[4], *C. Bandeira-de-Melo*[3], *G. A. DosReis*[3], *D. Decote-Ricardo*[2], *C. G. Freire-de-Lima*[3];
[1]*Programa de Imunologia e Inflamação, UFRJ, Rio de Janeiro, Brazil,* [2]*Instituto de Veterinaria, UFRRJ, Seropedica, Brazil,* [3]*Instituto de Biofisica Carlos Chagas Filho, UFRJ, Rio de Janeiro, Brazil,* [4]*Universidade Federal de São Paulo, São Paulo, Brazil.*

B1 cells are a small fraction of the population of B lymphocytes of the spleen and they represent the major population of B lymphocytes in the pleural and peritoneal cavity. It has been demonstrated that B1 cells secrete IL-10 and thereby they modulate the phagocytic activity of macrophages. Furthermore, they described a new role for B-1 cells as part of mechanisms that suppress the immune system via production of IL-10. Reports over the past years have shown evidence that both lymphoid and myeloid lineage unexpectedly run a close relationship. This information is based on studies showing that, in mice and human, B1 cells can generate offspring phagocytic, exhibiting similar characteristics to those of macrophages. The B1 cells in primary cultures proliferate and become a mononuclear phagocyte. These cells were called phagocyte-derived from cells B1 (B1CDP). This information motivated us to study the actions of B1CDP cells in infectious and inflammatory processes and for this propose we will use the model of experimental infection with *Leishmania major*. Our data demonstrated that B1CDP are more susceptible to infection by *L. major* in vitro and this effect is blocked when added doses of neutralizing anti-IL-10 but not TGF-beta. Also, we observed the presence of a large number of lipid bodies in B1CDP and PGE-2 production. *B1CDP cells are defective in IL-10 production in response to COX-2 inhibitors. These data suggest that B1CDP cells are cellular component that might compromise host immune responses to infection diseases.*

P4.08.06
Analysis of Metalloproteinases and their Inhbitors in Chronic Chagas'Cardiomyopathy

M. A. Baron[1,2,3], *P. C. Teixeira*[1,2,3], *R. H. Santos*[4], *E. C. Mairena*[1], *I. C. Navarro*[1,2,3], *N. A. Stolf*[4], *A. Fiorelli*[5], *J. Kalil*[2,3], *L. R. P. Ferreira*[1,2,3], *E. C. Neto*[1,2,3];
[1]*Laboratory of Immunology, Heart Institute (InCor), School of Medicine, USP, São Paulo, Brazil,* [2]*Division of Clinical Immunology and Allergy, School of Medicine, USP, São Paulo, Brazil,* [3]*Institute for Investigation in Immunology (iii), INCT, São Paulo, Brazil,* [4]*Heart Institute (InCor), USP, São Paulo, Brazil,* [5]*Heart Institute (InCor),USP, São Paulo, Brazil.*

Trypanosoma cruzi infection affects 10 million persons in Latin America. Around 30% of those develop chronic Chagas disease cardiomyopathy (CCC), an inflammatory dilated cardiomyopathy characterized by an intense cardiac remodeling, hypertrophy, fibrosis and a myocarditis rich in T cells and macrophages. The survival of patients with is shorter than that of patients with dilated cardiomyopathies of non-inflammatory etiology. Pathological cardiac remodeling includes the restructuring of the extracellular matrix (ECM) which is mediated largely by matrix metalloproteinases (MMPs) and they specific inhibitors (TIMPs). 25 MMPs have been described in humans where modification of their expression and/or activity correlates to various pathological conditions including cardiovascular diseases. We have assessed the expression of major MMPs and TIMPs by Real Time PCR and immunoblotting in myocardial tissue samples of explants from patients subjected to heart transplantation of end-stage CCC, idiopathic dilated cardiomyopathy (DCM), and from donor hearts not used from transplantation (CONT). We observed upregulation of gene expression of MMP2 and TIMP2, an inhibitor of MMP2, in DCM vs. CCC. We also observed by immunoblotting an increased expression of MMP2 and TIMP2 in CCC and DCM as compared to CONT. These results suggest that of MMP2 might be involved in cardiac remodeling in CCC as well as DCM.

P4.08.07
Role of IL-9 in the intestinal inflammation induced after Toxoplasma gondii infection

L. Benevides*, M. S. Dias, M. Souza, D. M. Fonseca, J. S. Silva; Universidade de São Paulo -USP, Ribeirão Preto, Brazil.*

IL-9 is a pleiotropic cytokine and functions as both a positive and negative regulator of immune responses. IL-9 has long been thought to be a Th2 cytokine, as it promotes allergic inflammation and is associated with various Th2 responses. Recent studies revealed that the IL-9 is produced mainly by T cells generated in the presence of the cytokines TGF-β and IL-4 termed Th9. However, whether IL-9 and Th9 cells are involved in infection immunity by intracellular pathogen has not been investigated. In this work, we evaluated role of IL-9 and Th9 cells in model the inflammation intestinal induced by T. gondii. Susceptible (C57BL/6) and resistant (BALB/c) mice were orally infected with 100 cysts of the ME49 strain of T. gondii and after 7 days post infection, we evaluated the expression of IL-9 by qPCR and the frequency of Th9 (CD3+CD4+IL-9+) cells in spleen and mesenteric lymph nodes by FACS. Our results shown that infection by T. gondii induce the expression of IL-9 in gut on both the lineages of mice. In additon, we found an increase the Th9 cells during disease progression. At day 7 of infection, an intense intestinal inflammation is observed in C57BL/6 but not BALB/c mice. However, the C57BL/6 mice exhibited a lower frequency of Th9 cells compared with BALB/C mice that have an increase these cells in the spleen and mesenteric lymph nodes. Taken together, these findings suggest that IL-9 plays an important role in immune response regulation favoring resistance to T. gondii infection.

P4.08.08
Splenic phagocytes shape the immunity to Plasmodium infection in distinct but complementary ways

H. Borges Da Silva[1], *P. J. Spence*[2], *S. Reece*[3], *J. Thompson*[4], *N. Van Rooijen*[5], *J. Langhorne*[2], *C. Tadokoro*[6], *M. R. D'Império Lima*[1];
[1]*Department of Immunology, Institute for Biomedical Sciences, University of Sao Paulo, Brazil, São Paulo, Brazil,* [2]*Division of Parasitology, Medical Research Council National Institute for Medical Research, London, United Kingdom,* [3]*Centre for Immunity, Infection, and Evolution, University of Edinburgh, Edinburgh, United Kingdom,* [4]*Institute of Immunology and Infection Research, School of Biological Sciences, University of Edinburgh, Edinburgh, United Kingdom,* [5]*Department of Molecular Cell Biology, Faculty of Medicine, Vrije Universiteit, Vrije Universiteit Medical Center, Amsterdam, Netherlands,* [6]*Laboratory of Immunoregulation, Instituto Gulbenkian de Ciência, Oeiras, Portugal.*

During experimental malaria, several changes in structure and cell numbers occur in spleen. The effects of these modifications on phagocytosis by spleen dendritic cells (DCs) and macrophage subsets are so far unknown, and the relative importance of this activity is not well understood. By using different in vivo and ex vivo approaches, we described some aspects of parasite phagocytosis and the implications to immune responses to infection. In naïve mice, DCs and F4/80+ red pulp macrophages (RpMOs) promptly recognized and internalized parasites, and enhanced the ability of making stable contacts with T and B cells inside spleen, respectively. The importance of DCs and RpMOs to activation of respectively T and B cells, as well as for survival after infection, was confirmed by depletion strategies. During the parasitemia peak, migrating inflammatory monocytes (MMs) were also able to phagocytize parasites, thus helping the parasitemia elimination observed in this model. However, these MMs were also crucial for controlling excessive CD4+ T cell activation by production of nitric oxide (NO); this control was necessary for full CD4+ T cell memory responses to parasite challenge. Thus, DCs, RpMOs and MMs contribute in distinct ways for parasite elimination and the induction of a massive, yet controlled, immune response to blood stage malaria.

P4.08.09
Neutrophil migration during placental malaria

S. Boström[1], *A. van der Does*[2], *B. Amulic*[3], *M. Troye-Blomberg*[1];
[1]*Department of Molecular Biosciences, The Wenner-Gren Institute, Stockholm University, Stockholm, Sweden,* [2]*Department of Physiology and Pharmacology, Karolinska Institute, Stockholm, Sweden,* [3]*Department of Cellular Microbiology, Max Planck Institute for Infection Biology, Berlin, Germany.*

Neutrophils play an important role in the innate immune response against invading pathogens. The role of neutrophils, especially during placental Plasmodium falciparum (P. falciparum) infections, has been poorly investigated. The aim of this study was to investigate the role of neutrophils during placental malaria. For this purpose an in vitro model system was used to assess immunological changes induced in a placental cell line (BeWo) and in neutrophils by P. falciparum parasites. BeWo cells were stimulated with either purified infected red blood cells (iRBC) or uninfected red blood cells (uRBC) and the supernatants were collected and analyzed for cytokines, chemokines and angiogenetic proteins by cytometric bead arrays and proteome profile arrays. The results show that BeWo cells are secreting a lot of immunoregulatory proteins and cytokines upon stimulations with P. falciparum parasites. One dominant factor produced was IL-8 which is a known chemoattractant for neutrophils. To test if P. falciparum parasites could induce neutrophil recruitment by BeWo stimulated cell-culture supernatants, a chemotaxis assay was set up. The results show that neutrophil migration towards iRBC supernatants is enhanced compared to migration towards supernatants from uRBC stimulations. By performing neutralization assays we hope to further define the factor(s) of importance for this increased migration. These findings show that trophoblast cells are immunologically active during placental malaria and secrete factors that are capable of influencing and/or contributing to the local maternal environment, in this case by recruiting neutrophils to the infected placenta. In addition, we will also focus on phenotyping the recruited neutrophils.

P4.08.10
Histopathological study in intestinal wall of dogs naturally infected with Leishmania in the intestines

***W. A. Buzetti**, D. T. Silva, M. F. Neves, A. G. S. Lins;*
UNESP, Ilha Solteira, Brazil.

Canine Visceral Leishmaniasis (CVL) is caused by a protozoa parasite of the specie *Leishmania* (*L.*) *infantum,* endemic for humans and dogs in many regions of Brazil. The purpose of the present study was to evaluate the histopathological alterations in intestinal tissues naturally infected with *Leishmania* amastigotes in a group of polisymptomatic CVL dogs. Intestinal tissue samples, including small and large intestines were harvested from 11 dogs euthanized by Zoonotic Disease Control Center. By histo and immunohistochemical techniques, *Leishmania* amastigotes as well as inflammatory cells were quantified in the intestinal wall layers of dogs. *Leishmania* amastigotes were detected in lamina propria of mucosa submucosa and muscular layer from small intestines and in mucosa and submucosa from colon in 05/11 (45.5%) dogs. Amastigote forms were detected inside hypertrophic macrophages abundant in the mucosa at the tip of villi in small intestines, and surrounding crypts and submucosa in the colon. The inflammatory reaction was characterized by a chronic infiltrate of mononuclear cells; macrophages, lymphocytes and plasma cells in those animals intensely infected with the parasite. Mast cells quantified in these animals indicated less concentration of these cells in the mucosa where amastigotes were detected in higher numbers. Neutrophils and esosinophils were detected in higher numbers in dogs with low parasitic burden. In conclusion, positive dogs by intestinal leishmaniasis with high parasitic load had a chronic mononuclear inflammation, while dogs with low intestinal parasitic burden had an acute inflammatory reaction characterized by hemorrhagic enteritis, mast cell and polymorphonuclear hyperplasia.

P4.08.11
Comparative evaluation of rK39 and soluble antigen ELISA, IFAT and parasitological tests for Canine Visceral Leishmaniasis diagnosis

*D. T. Silva, **W. A. S. Buzetti**, M. F. Alves, M. S. Paixão, M. S. Tenorio;*
UNESP, Ilha Solteira, Brazil.

Canine Visceral Leishmaniasis (CVL) is a chronic parasitic infection caused by Leishmania (L.) infantum that infect dogs and humans in rural and urban areas. The aim of the present work were to compare the serological methods by ELISA using two antigens (recombinant-rK39 and soluble extract-SE antigens), indirect fluorescence antibody test (IFAT) and parasitological exams (PA) in order to evaluate a better and safer method for CVL diagnosis. For this study, serum and lymph node aspirate samples of 70 dogs were used for serological and parasitological exams. The statistical comparative analysis was done using Kappa (k) index and the interpretation of the data was according to Nigel Paneth classification, which k > 0.80 was considered excellent; k= 0.60 - 0.80 was good; k= 0.40 - 0.60 was regular and k< 0.40 was bad concordance. According to the results there was good agreement among the diagnostic methods for CVL in 34.3% (24/70) dogs. 100% of positive dogs by PE were also good by ELISA-SE in 68.7%, k=0.4217. Similar results were observed between PA x IFAT with 71.6% of concordance and k= 0.4654. In contrast, the agreement between ELISA-SE x ELISA-rk39 was 58.6%, k=0.0330 (41/70) and IFAT x ELISA-rk39 was 52.8%, k=0.0069 (37/70), bad agreement. ELISA-SE x IFAT were the methods that presented excellent and the highest agreement in 82.8%, k=0.7237 (60/70). The results of positivity indexes of the dogs revealed that parasitological exams in association with ELISA-SE and IFAT was more appropriated for CVL diagnosis.

P4.08.12
Role of L-arginine during acute phase of Chagas disease in pregnant Wistar rats infected with the Y strain of *Trypanosoma cruzi*

***A. A. Carraro Abrahão**[1], C. M. Bronzon da Costa[1], M. R. Barbosa de Freitas[1], V. Brazão[1], C. D. dos Santos[1], C. C. Kuehn[1], M. A. Sala[2], J. C. do Prado Júnior[1];*
[1]Universidade de São Paulo - Faculdade de Ciências Farmacêuticas de Ribeirão Preto, Ribeirão Preto, Brazil, [2]Universidade de São Paulo - Faculdade de Odontologia de Ribeirão Preto, Ribeirão Preto, Brazil.

Chagas disease induces a strong immune response during acute phase of infection, mobilizing different compartments of the immune system. L-arginine is an essential amino acid that plays an important role in homeostasis of the immune system. During pregnancy, the immune and endocrine systems underwent important changes in order to establish a protective role in the feto-maternal relationship, avoiding fetus rejection and at the same time keeping adequate maternal host defense mechanisms to fight infection. The aims of this study were to evaluate parasitemia, corticosterone levels, peritoneal macrophage counts, production of nitric oxide (NO) and histopathology of heart and placenta. Twenty pregnant Wistar rats (180-220g) were grouped in: pregnant control (PC), pregnant control and L-arginine supplied (PCA), pregnant infected (PI), pregnant infected and L-arginine supplied (PIA). Females were infected with $1x10^5$ tripomastigotes of the Y strain (3rd day of pregnancy). Animals were supplied with 21 mg of L-arginine/Kg/day (gavage) during 14 days. PIA showed significant decreased levels of corticosterone and parasitemia. For control groups, L-arginine supplementation did not show any alteration in NO production by peritoneal cells; for PIA, enhanced nitrite concentrations were observed as compared to PI, despite similar levels of macrophages. A reduction in the amastigote burdens in cardiac tissue was observed with L-arginine therapy but similar placental parasitism was found when comparing PIA and PI. Based in these results, the administration of L-arginine can be considered a co-adjuvant alternative therapy during acute phase of Chagas disease, enhancing the immune response. Financial support: Fapesp and Capes.

P4.08.13
Zinc intake improves immune response during pregnancy in wistar rats infected with Y strain of *Trypanosoma cruzi*

***A. A. Carraro Abrahão**[1], C. M. Bronzon da Costa[1], M. R. Barbosa Freitas[1], V. Brazão[1], C. D. Santos[1], M. A. Sala[2], J. C. Prado Júnior[1];*
[1]Universidade de São Paulo - Faculdade de Ciências Farmacêuticas de Ribeirão Preto, Ribeirão Preto, Brazil, [2]Universidade de São Paulo - Faculdade de Odontologia de Ribeirão Preto, Ribeirão Preto, Brazil.

Several changes in the levels of various hormones and serum factors occur during pregnancy. Occurrence of infectious diseases such as Chagas disease during pregnancy has significant effects on maternal health and can lead to adverse pregnancy outcomes. It is known that zinc is an essential element important for the normal function of the immune system. The objective of this work was to examine the potential role of zinc supplementation during the acute phase of Chagas disease in pregnant Wistar rats. Twenty pregnant Wistar rats (180-220g) were grouped in: pregnant control (PC), pregnant control supplied with zinc (PCZ), pregnant infected (PI) and pregnant infected supplied with zinc (PIZ). Females were i.p. infected with $1x10^5$ tripomastigotes of Y strain of *T. cruzi* on the 3rd day of pregnancy. Rats were orally supplied (gavage) with zinc sulphate (20 mg/kg) once a day during the experiment. On day 18 of pregnancy (15º day post infection) some parameters were evaluated such as parasitemia, IFN-γ and TNF-α concentrations, peritoneal macrophages counts and histological analysis of heart, placenta and fetuses stained with haematoxylin and eosin. PIZ group showed a significant reduction of parasitemia levels, enhanced concentrations of IFN-γ and significant reduction of amastigotes nests in the placentas and hearts. Absence of parasites in fetal tissues was observed. Upon this scenario, zinc intake during the early pregnancy period plays a vital protective role, improving immune response and consequently preventing adverse outcomes. Supported by Fapesp and Capes.

P4.08.14
T cell immunoglobulin- and mucin-domain-containing molecule-3 secretion by patients with active cutaneous leishmaniasis

L. R. Castellano[1,2], *D. Correia*[3], *M. V. Silva*[2], *H. Dessein*[4], *A. Dessein*[4], *V. Rodrigues*[2];
[1]*Escola Técnica de Saúde da UFPB, Universidade Federal da Paraíba, João Pessoa, PB, Brazil,* [2]*Laboratory of Immunology, Universidade Federal do Triângulo Mineiro, Uberaba, MG, Brazil,* [3]*Infectious Diseases Division, Universidade Federal do Triângulo Mineiro, Uberaba, MG, Brazil,* [4]*U399 INSERM, Marseille, France, Marseille, France.*

Defective IFN-gamma and increased IL-10 production favors the occurrence of ulcerative lesions and therapeutic failure in human cutaneous leishmaniasis (CL). Recently, it has been demonstrated that T-cell immunoglobulin, mucin domain-3 (Tim-3) is a regulatory membrane protein expressed on mature IFN-gamma secreting Th1 cells. Soluble sTIM-3 isoform was detected in mice only. Here, fifteen patients with active lesions (aCL), 12 patients with healed lesions (hCL) and 13 asymptomatic without clinical record of leishmanial lesion (rCL) were enrolled. Peripheral blood was collected and PBMC separated by centrifugation gradient. Cells were cultured in the absence or presence of 5ug/mL PHA or L. braziliensis antigens (AgLb) alone or with 10ug/mL recombinant human IFN-gamma (rhIFN-gamma). Levels of TIM-3 were measured by ELISA in supernatants using commercial mAbs. Patients with active CL lesions secreted higher amounts of sTim-3 in response to AgLb and AgLb+rhIFN-gamma stimulation than cells from hCL or rCL subjects. However, when the capacity of PBMC to respond to these stimuli was evaluated compared to baseline production of sTIM-3, results varied among groups. In the presence of AgLb alone, higher detection of sTIM-3 was observed in cells from rCL subjects whereas stimulation of cells with AgLb+rhIFN-gamma improved sTim-3 secretion by cells from aCL and hCL patients but not from rCL subjects in comparison to PBMC cultured in medium alone. This is the first detection of a soluble TIM-3 isoform in human samples. New perspectives in understanding the events regulating the immune system that control human parasitic diseases are expected.

P4.08.15
Trypanosomiasis-associated modulation of B cell lymphopoiesis and immune function

J. Cnops[1], *V. Bockstal*[1], *F. Kauffmann*[1], *P. Garside*[2], *M. Radwanska*[3], *C. De Trez*[1], *S. Magez*[1];
[1]*Vrije Universiteit Brussel, Brussels, Belgium,* [2]*University of Glasgow, Glasgow, United Kingdom,* [3]*Cooperation for Science and Technology ESF, Brussels, Belgium.*

African Trypanosomiasis is a parasitic disease affecting both humans and livestock in Sub-Saharan Africa. The disease in cattle approximately causes an annual loss of 4,5 billion dollars and has therefore a major impact on the socio-economic development of the affected rural areas. Polyclonal B cell activation has long been described as a hallmark of African trypanosomiasis. Recently, we have shown that murine T. b. brucei infection induces depletion of B cells in developmental, immature and mature stages and induces loss of vaccine-induced memory B cell responses, even against non-related antigens. In order to understand the extent of this problem, we have so far taken two parallel approaches. First, we studied trypanosomiasis-associated destruction of various B-cell compartments in a Hen Egg Lysozyme specific B cell transgenic mouse model (MD4). In this model depletion occurs with the same kinetics as in infected WT mice, indicating that the detrimental infection-associated effects occur independent of B cell receptor specificity. Second, we have addressed the possibility of B-cell compartment restoration following drug cure of trypanosomiasis. Infected mice were treated with berenil (diminazene aceturate), a widely used chemotherapeutic agent for animal Trypanosomiasis. B-cell recovery was shown to take place over a period of three weeks following treatment. Future work using other anti-trypanosome drug compounds as well as drug-resistant parasite models will provide further insights in the mechanisms that govern both B-cell destruction and recovery.

P4.08.16
Towards an immunosense vaccine to prevent toxoplasmosis

H. Cong, *Q. Yuan;*
Shandong University, Jinan, China.

The ideal vaccine to protect against toxoplasmosis in humans would include antigens that elicit a protective T helper cell type 1 immune response, and generate long-lived IFN-γproducing CD8+ T cells. Herein, we utilized bioinformatic algorithms to identify novel, T. gondii-derived, CD8 + T cell epitopes restricted by the HLA-A02, -A03, and -B07 supertypes, which collectively provide broad coverage 90% of the human population worldwide. A total of 19 surface and secreted proteins from the type II T. gondii strain, ME49, were selected for bioinformatic analysis. Peripheral blood mononuclear cells from seropositive T.gondii donors were tested for response to these peptides by using IFN-γElispot assays. 15 peptides elicited production of IFN-γfrom PBMC of HLA-A02, -A03, and -B07 supertype persons seropositive for T. gondii infection. These peptides displayed high affinity binding to HLA-A02, -A03, and -B07 supertype. Immunization of HLA-A*0201, -A*1101, -B*0702 transgenic mice with these pooled peptides, with a universal CD4+ epitope peptide called PADRE, formulated with adjuvant GLA-SE, induced high CD8+ T cell IFN-γproduction and protected against parasite challenge. Peptides identified in this study provide candidates for inclusion in immunosense epitope-based vaccines.

P4.08.17
Effect of congenital toxoplasmosis on the uNKs cells population and their products in a mouse model

D. Correa, *A. Besné-Mérida, C. Cedillo-Peláez, C. Rico-Torres, F. García-Vázquez, J. Farfán-Morales, J. Vargas-Villavicencio;*
Instituto Nacional de Pediatría, Mexico, Mexico.

Uterine natural killer (uNK) cells reside in the placenta at early gestational stages. They mainly produce VEGF-A, IFN-γ and IL-18 which induce an inflammatory environment which protects the fetus from infection. Nevertheless, *Toxoplasma gondii* infection might exacerbate the Th1 immune response locally, which could lead to abortion. In order to evaluate the effect of *T. gondii* on fertility, uNKs, inflammation and fetal damage, female Balb/c mice were infected with different doses of ME49 strain tachyzoites at 10th days of gestation. Samples from maternal spleen and maternal-fetal interface (MFI) were taken 72 hours later to assess damage and parasite load by histopathology and qPCR. The number of fetuses reabsorbed was significantly higher in the cases inoculated with 10 million tachyzoites than in other groups. From the 5 million-dose on, parasites were found in the placenta and the fetuses, but the former presented around 100 times the burden than fetuses. MFI presented discrete focal coagulative necrosis, more intense at the maternal side, as well as congestive changes especially in the decidua and the chorionic labyrinth. The number of uNK VEGF-A+-cells was similar among groups, consistent with no changes in the number of blood vessels. The number of local IFN-γ+ uNKs increased in relation to parasite dose as it did the magnitude of inflammation and variety of inflammatory cells. In conclusion, *T. gondii* alters the local structure at the MFI, increasing the IFN-γ+-uNKs which augment the Th1 inflammatory environment, and consequently triggers fetal death.

P4.08.18
Metalloproteinases 2 and 9 are differentially expressed in patients with indeterminate and cardiac clinical forms of Chagas disease

R. Correa-Oliveira[1], *J. A. S. Gomes*[2], *L. R. Garzoni*[3], *M. M. Saraiva*[4], *R. M. Saraiva*[5], *R. M. Saraiva*[5], *L. C. Sangenis*[5], *M. C. Chambela*[5], *F. F. Araujo*[1], *A. [1]*FIOCRUZ - Minas, Belo Horizonte, Brazil,* [2]*Instituto de Ciências Biológicas - UFMG, Belo Horizonte, Brazil,* [3]*Instituto de Ciências Biológicas - UFMG, Rio de Janeiro, Brazil,* [4]*Instituto Oswaldo Cruz - FIOCRUZ, Belo Horizonte, Brazil,* [5]*Instituto Evandro Chagas - FIOCRUZ, Rio de Janeiro, Brazil,* [6]*Faculdade de Medicina - UFMG, Belo Horizonte, Brazil.*

Dilated chronic cardiomyopathy (DCC) from Chagas disease is associated with myocardial remodeling and interstitial fibrosis, resulting in extracellular matrix (ECM) changes. In this study, we characterized for the first time, the serum MMPs 2 and 9 levels, as well as their main cell sources in peripheral blood from patients presenting the indeterminate (IND) or cardiac (CARD) clinical forms of Chagas disease. Our results showed that serum levels of MMP-9 are associated with the severity of Chagas disease. The analysis of MMPs production by T lymphocytes showed that CD8+ T cells are the main source of both MMP-2 and MMP-9 molecules. Using a new 3-dimensional model of fibrosis we observed that serum from patients with Chagas disease induced an increase in the extracellular matrix components in cardiac spheroids. Furthermore, MMP-2 and MMP-9 showed different correlation with matrix proteins and inflammatory cytokines in patients with Chagas disease. Our results suggest that MMP-2 and MMP-9 show distinct activities in Chagas disease pathogenesis. While MMP-9 seems to be involved with the inflammation and cardiac remodeling of Chagas disease, MMP-2 does not correlate with inflammatory molecules.

P4.08.19
Kinetics of the IgG antibodies acquisition in Plasmodium vivax infected individuals living in a low malaria transmission area in Brazil

M. G. Cunha[1], *M. M. Póvoa*[2], *E. S. Silva*[1], *A. M. Ventura*[2], *M. D. Ohnishi*[3], *N. Sepulveda*[4], *P. H. Corran*[4], *E. Riley*[4], *C. Drakeley*[4];
[1]*Universidade Federal do Pará, Belém, Brazil,* [2]*Instituto Evandro Chagas, Belém, Brazil,* [3]*Universidade do Estado do Pará, Belém, Brazil,* [4]*London School of Hygiene and Tropical Medicine, London, United Kingdom.*

In malaria, antigens from asexual stage of the Plasmodium life cycle are key driving-forces towards host acquired immunity. Among these antigens, the Merozoite Surface Protein 1 (MSP1) and Apical Membrane Antigen (AMA-1) are the most studied and well characterized. The main goal of the study was to assess the kinetics of IgG antibodies to P. vivax and P. falciparum MSP1 and AMA-1 antigens. Serological samples from 285 malaria-infected individuals were collected at days 0, 7, 14, and 30. Individuals were divided into three groups, according to their data collection profile; group 1 (days 0 and 7), group 2 (days 0 and 14) and group 3 (days 0, 7 and 30). Antibody levels were assessed and determined using ELISA. At day 0, the sero-prevalence across all groups was 86.7% (PvHis6MSP119), 70.5% (PvGSTMSP119), 51.9% (PvAMA1), 11.2% (PfMSP119) and 9.8% (PfAMA1). We observed that IgG antibodies response against PvMSP1 was higher than PvAMA-1. In group 1, the positivity to PvHis6MSP119 was 86.0% and 99.0% at days 0 and 7, respectively. In group 2, it was 80.5% (day 0) to 95.1% (day 14). In group 3, it was 86.5%, 94.2%, and 98.08% at days 0, 7 and 30, respectively. For PvAMA-1, we observed similar qualitative behavior up to 30 days. For P. falciparum antigen, seropositivity to each antigen individually was low. In P. vivax infection, antibody positivity against MSP1 and AMA-1 antigens seems to remain stable, or even increased, up to 30 days after treatment thus not showing a significant decay during this timeframe.

P4.08.20
Molecular basis of CD8+T cell's protective response to Toxoplasma infection

W. Gao[1], *H. Chu*[2], *E. Robey*[2], ***S. Dai***[1];
[1]*National Jewish Health, Denver, CO, United States,* [2]*University of California Berkeley, Berkeley, CA, United States.*

Toxoplasma gondii infects up to a third of the world's population. Recent studies showed *Toxoplasma* Infection may link to schizophrenia, suicide. In immune-compromised patients, reactivation of latent disease can cause life-threatening encephalitis. Infection acquired during pregnancy may also cause severe damage to the fetus. An immunodominant and protective decapeptide HF10 confers protection against toxoplasmosis, which is mediated by GRA6 reactive CD8+ T cells. GRA6 is a polymorphic protein secreted in the parasitophorous vacuole. We have determined the crystal structure of GRA6 TCR bound to HF10 presented by H-2Ld MHC class I(MHCI). Surprisingly, the GRA6 TCR recognizes the MHCI and peptide (pMHC) in an unconventional orientation. GRA6 TCR docks on pMHC almost parallel to the HF10 peptide. The GRA6 TCR CDR2 and CDR3 loops of both α and β chains interact extensively with Ld α2 helix. However, there are almost no contacts between the TCR and Ld α1 helix. The decapeptide does not bulge out the binding groove. Instead, HF10 peptide forms a helical structure in the peptdie binding groove, and interacts with both CDR3s loops. The GRA6 TCR CDRα3 undergoes major conformational change to better the binding to HF10 peptide, compared with unbound GRA6 TCR structure. The current structural analysis provides an alternative docking framework that enables the TCR interaction with infectious pathogens and shed light on how HF10 elicits protective immunity.

P4.08.21
NOD2-dependent Th1 response impairs host survival during N. caninum infection

M. Davoli Ferreira[1], *C. Martins Mota*[2], *D. Morais da Fonseca*[1], *D. Lima Junior*[1], *J. Santana da Silva*[1], *T. Mineo*[2];
[1]*Universidade de São Paulo, Ribeirão Preto, Brazil,* [2]*Universidade Federal de Uberlândia, Uberlândia, Brazil.*

Neospora caninum is an intracellular parasite that infects a wide range of warm-blooded hosts worldwide. NLRs represent an important family of microbial sensor proteins that have been identified as key host molecules in innate immune recognition and the inflammatory response to microbial products. However, the role of NLR in the induction of adaptative immune response against intracellular protozoan infection is unclear. In this study, we evaluated the role of NLRs in host response to *N. caninum* infection. For that purpose, $Nod2^{-/-}$ and WT mice were infected with *N. caninum* tachyzoites to evaluation of acute phase parasitism, inflammatory cell migration and cytokine production. $Nod2^{-/-}$ mice exhibited higher parasite burden to WT mice. Inflammatory cell migration was impaired in both compartments, as $Nod2^{-/-}$ mice presented decreased migration of DCs, B and T lymphocytes to the peritoneal cavity. Mononuclear cell infiltrates were also significantly reduced in the lungs of $Nod2^{-/-}$ mice, as compared to WT. Additionally, we observed that dendritic cells and macrophages from Nod2-/- mice presented lower MHCII expression, fact that was associated to lower IFN-γ production in spleen cell antigenic recall, and in lung and brain homogenates. However, no difference in IL-10 production was observed. Surprisingly, Nod2-/- mice demonstrated increased survival than WT mice. Based on the results herein presented we proposed that Nod2 has an important role in T_H1 programming initial immune responses to *N. caninum.* This additional activation of T_H1 response appears to be important to parasite clearance, but could contribute to pathogenesis and mortality during *N. caninum* infection.

P4.08.22
Glucocorticoid mediated caspase-8 and caspase-9 activation promotes thymocyte apoptosis and thymus atrophy in Trypanosoma cruzi infection

D. A. Farias-de-Oliveira, D. M. S. Villa-Verde, P. H. N. Panzenhagen, D. S. dos Santos, L. R. Berbert, W. Savino, ***J. de Meis****;*
Fundação Oswaldo Cruz - FIOCRUZ, Rio de Janeiro, Brazil.

Trypanosoma cruzi acute infection leads to thymic atrophy, largely as a result of death of immature CD4+CD8+ (DP) T cells. In a second vein, the glucocorticoid hormone imbalance promotes DP T cell apoptosis in infected mice. Herein, we assessed the involvement of glucocorticoid and caspase signaling in thymocyte death during T. cruzi acute infection. BALB/c mice were infected with 100 trypomastigote forms of T. cruzi and analyzed from 7 to 19 dpi. Thymocyte apoptosis was observed in early stages of infection, increasing along with time postinfection. Immature CD4-CD8- (DN) and DP as well as CD4+ and CD8+ thymocytes from infected mice showed increased activation of caspase-8, -9, and -3. In vitro treatment of thymocytes from infected mice with a general caspase inhibitor or the combination of caspase-8- and caspase-9-specific inhibitors increased the number of living thymocytes. Intrathymic injection of the general caspase inhibitor, but not caspase-8 or -9 inhibitors individually, prevented thymic atrophy and thymocyte depletion in infected mice. Moreover, blockade of glucocorticoid receptor activity with RU486 prevented DP thymocyte apoptosis, together with caspase-8 and -9 activation. These findings indicate that DP T cell apoptosis following experimental T. cruzi acute infection is dependent on glucocorticoid stimulation, promoting caspase-8 and -9 activation.

P4.08.23
Melatonin and lycopene role on immune system against Chagas'disease.

J. do Prado Júnior*, M. D. Filipin, V. . Brazão, M. A. Toldo, F. H. Santello;*
College of Pharmaceutical Sciences of Ribeirão Preto (FCFRP), University of São Paulo, Ribeirão Preto, Brazil.

Chagas'disease is an infectious illness caused by the protozoa *Trypanosoma cruzi*, affects over 15 million people being responsible for the high indices of morbidity/ mortality. Melatonin is a pleiotropic hormone secreted by the pinealocytes displays several functions such as to regulate other hormones, keep the body's circadian rhythm, antioxidant effects and immunomodulating actions. Lycopene, a potent antioxidant and immunomodulatory carotenoid is synthesized by some commonly consumed plants such as tomatoes, but not synthesized by animals. This work aims to evaluate the influence of oral melatonin and lycopene treatment in i.p. *T. cruzi* infected male *Wistar* rats, (1 x 105 blood trypomastigotes of the Y strain). Animals were treated with melatonin (5 mg/kg) and lycopene (10mg/kg) once a day over the course of the experiment. Phenotypic and functional macrophage analysis, expression of CD11b/c marker on spleen cells and blood parasitaemia were performed. Animals were grouped in: control, infected, melatonin infected and lycopene infected. Studies were performed on 7 days after infection. Peritoneal cells were adjusted to 2×106 cells/ml, being phenotyped by means of cytofluorometric analysis. Parasites were counted by Brener's method. Melatonin and lycopene treated animals displayed a significantly reduced number of parasites when compared to untreated counterparts. Infected and treated groups showed enhanced significant number of macrophages, as well as on its functional analyze (RT1B+) between infected treated and untreated groups. There was an increase on CD11b/c (APC marker) for treated infected groups. It seems that melatonin and lycopene contribute to reduce parasite replication and exert an immune regulating role.

P4.08.24
Impact of the absence of galectin-3 on the course of experimental *Trypanosoma cruzi* infection

D. S. dos Santos[1]*, J. B. de Albuquerque*[1]*, L. R. Berbert*[1]*, D. A. Farias-de-Oliveira*[1]*, L. V. C. Guillermo*[2]*, W. Savino*[1]*, J. de Meis*[1]*, D. M. S. Villa-Verde*[1]*;*
[1]*Instituto Oswaldo Cruz, Rio de Janeiro, Brazil,* [2]*UNIRIO, Rio de Janeiro, Brazil.*

Galectin-3, a β-galactoside binding lectin, is expressed in cells of the immune system such as macrophages and lymphocytes, modulating activation and cytokine production. Chagas' disease, caused by the protozoan *Trypanosoma cruzi,* is a public health problem, without effective vaccines and therapeutics. Here we evaluated the involvement of galectin-3 in experimental *T. cruzi* infection. Wild-type (WT) and galectin-3 deficient (Gal-3$^{-/-}$) mice were infected with the Tulahuén strain. Cytokine levels were determined by ELISA in culture supernatants of activated T cells obtained from subcutaneous lymph nodes (LSC) and spleen. Quantification of cell number and presence of CD4, CD8, CD19, CD25 and FoxP3 were analyzed by flow cytometry. To evaluate macrophage susceptibility to infection, Gal-3$^{-/-}$ and WT peritoneal macrophages were infected *in vitro* and intracellular amastigote numbers were counted. Our results showed that Gal-3$^{-/-}$ mice are more susceptible to infection than WT, with higher mortality rate and increased blood parasitemia. In addition, infected Gal-3$^{-/-}$ mice had lower cell expansion in LSC and spleen, with a decrease in CD4^{+}, CD8^{+} and CD19^{+} cell numbers in LSC and CD19^{+} cell number in spleen, compared to infected WT mice. Analysis of the supernatants from infected Gal-3$^{-/-}$ mice showed a decrease in IL-4, IL-5 and an increase in IFN-γ secretion. Preliminary data showed that infected Gal-3$^{-/-}$ macrophages are less effective in eliminating intracellular parasites than those from WT animals. Our results suggest that galectin-3 is important in modulating the host response against *T. cruzi*, with implications for susceptibility to infection.

P4.08.25
Casein diets prevent experimental cerebral malaria by enhancing host pro-inflammatory immune responses during early stage

Y. Feng*, X. Sun, X. Wei, J. Liu, Y. Cao;*
China Medical University, Shenyang, China.

Cerebral malaria (CM) is still a severe complication threatening children under five in malaria endemic areas. Malaria infection reduces the nutritional status of children, and malnutrition aggravates malaria mortality. Casein hydrolysate can regulate host immune responses. Here, we investigate the related immune mechanisms in casein diet preventing experimental cerebral malaria (ECM). C57BL/6 mice were fed 0% (NC group), 5%, 20% and 35% casein diet for one month before infection with Pb ANKA, respectively. Casein diets can reduce parasitemia and prolong survival of ECM mice. On d3 p.i., casein diets increased splenic Th1 cells and macrophages ($P<0.05$), and a similar trend was observed in IFN-γ, TNF-α and NO levels ($P<0.05$). However, on d5 p.i., Th1 cells and macrophages and related IFN-γ, TNF-α and NO levels were significantly lower than NC group ($P <0.05$), and CD4+, CD8+ T cells, neutrophils and IFN-γ, TNF-α, ICAM-1, VCAM-1 mRNA levels in the brain, and ICAM-1 and VCAM-1 expression levels in the brain vascular endotheliocyte were significantly down-regulated in casein diet groups (compared with NC group, $P <0.05$). Casein diet does not affect the number of Treg and IL-10 levels. These data present the mechanism of casein diets in preventig ECM by improving host pro-inflammatory immune responses to control parasitemia during the early stage of infection, thereby reducing inappropriate pro-inflammatory immune responses to maintain blood-brain barrier integrity, which offers a new theoretical basis for the prevention of children CM.

P4.08.26
Association of IL-1β in the severity of diffuse cutaneous leishmaniasis

E. Fernández[1], *C. Rangel*[2], *K. Carrillo*[2], *N. Salaiza*[1], *I. Becker*[1];
[1]*UNAM, Mexico, Mexico,* [2]*INMEGEN, Mexico, Mexico.*

Leishmania mexicana can cause two types of the disease localized (LCL) and diffuse (DCL) cutaneous leishmaniasis. Yet, little is known about factors regulating disease severity in affected patients. We present our findings of a case-control study about severity association to SNPs in IL-1β -511, CXCL8 -251, IL-1RA +2018, IL-10 (-819, -592, -1082), IL-6 -174, TNF-α (-308, -238), CD14 260, TLR-4 299 and IRAK-1 532 in a cohort of Mexican mestizo patients with LCL and DCL. Results show a significant difference in the distribution of IL-1β (-511 C/T) genotypes between patients and controls (heterozygous OR), with respect to the reference group CC. This suggests that this SNP in IL-1β represents a variable influencing the risk to develop the disease in these patients. Additionally, the *in vitro* production of IL-1β shows an increase in monocytes. Expression of this cytokine in sera correlates with the severity of the disease being significantly higher in DCL patients heavily infected with *L. mexicana*. Also, the distribution of IL-1β in lesions varied according to the number of parasites harbored in the tissues. Among heavily infected LCL patients and in all DCL patients, the cytokine was scattered diffusely throughout the lesion. In contrast, in LCL patients with lower numbers of parasites in the lesions, IL-1β was confined to the cells. These data suggest that IL-1β plays a key role determining the severity of the disease in DCL patients. The analysis for all others SNPs showed no significant differences.

P4.08.27
Oxidized ATP action on macrophage during infection with Leishmania amazonensis

V. R. Figliuolo da Paz[1], *S. P. Chaves*[1], *G. F. Santoro*[2], *C. M. L. M. Coutinho*[3], *J. R. Meyer-Fernandes*[1], *B. Rossi-Bergmann*[1], *R. Coutinho-Silva*[1];
[1]*UFRJ, Rio de Janeiro, Brazil,* [2]*UFRJ/ FIOCRUZ, Rio de Janeiro, Brazil,* [3]*FIOCRUZ/ UFF, Rio de Janeiro, Brazil.*

Leishmaniasis is a disease caused by parasites of the genus Leishmania. By affecting 12 millions of people around the world have been investigated for the discovery of new drugs. Previously we have described that macrophage treatment with ATP impairs intracellular growth of Leishmania amazonensis through triggering of P2X7 receptor. In the present study, we evaluated the directly effect of periodate-oxidized ATP (oATP), a P2X7 antagonist, in parasite control in leishmania-infected macrophages.
We found that oATP impaired the attachment / entrance of L. amazonensis promastigotes to C57BL/6 mouse macrophages in a P2X7 receptor-independent manner, as macrophages from P2X7-/- mice were similarly affected. Although oATP directly inhibited the growth of axenic promastigotes in culture, promoted rapid ultrastructural alterations, and impaired their internalization by macrophages, it did not affect intracellular parasite multiplication. Upon infection, phagosomal acidification was diminished in oATP-treated macrophages, and this was accompanied by reduced endosomal proteolysis. Likewise, MHC-II expression and ectoATPase activity was decreased by oATP added to macrophages at the time of parasite infection. These inhibitory effects were not due to a cytotoxic effect, as no additional release of lactate dehydrogenase was detected in culture supernatants. Moreover, macrophage capacity to produce NO and ROS was not affected in the presence of oATP during the infection.
We conclude that oATP directly affects extracellular parasite integrity and macrophage functioning.

P4.08.28
Purinergic receptor functionality controls murine infection by L. amazonensis

V. R. Figliuolo da Paz[1], *S. P. Chaves*[1], *L. E. Savio*[1], *É. Salles*[2], *H. Guedes*[1], *M. R. D'Império*[2], *B. Rossi-Bergmann*[1], *R. Coutinho-Silva*[1];
[1]*UFRJ, Rio de Janeiro, Brazil,* [2]*USP, São Paulo, Brazil.*

P2X7 is a purinergic receptor associated to control of parasite infection, such as caused by Toxoplasma gondii and macrophage infection by Leishmania amazonensis. Leishmania is the causative agent of leishmaniasis, a disease that affects millions of people around the world. On this ground, we decided to perform in vivo experiments to study its importance on leishmaniasis control.
P2X7 knockout (KO) and wild type (WT) mice were inoculated in footpad and the lesion was accompanied during the infection. We observed the lesion developed earlier in P2X7 KO than WT mice. Furthermore, P2X7 KO mice had more parasitic load and cellularity in footpad in PID 47, as evaluated through limiting dilution assay and count of viable cells after macerating of the footpad. We found that peritoneal macrophages of P2X7 KO mice produced less oxide nitric and reactive oxygen species upon stimulation by LPS and Zymosan in vitro, when compared with macrophages from WT mice. The analysis of popliteal lymph node has shown a larger cellularity in P2X7 KO than WT mice, despite P2X7 KO mice exhibit less cells in this lymphoid organ. The proliferation of T lymphocytes was larger in P2X7 KO after in vitro incubation with anti-CD3, evaluated by CFSE staining. Finally we verified that P2X7 KO mice have had a decreased ectonucleotidase activity in cells from popliteal lymph node, when compared with WT mice, using a colorimetric assay of Pi generation.
Our findings reveal that the P2X7 receptor is important to control the in vivo infection by L. amazonensis.

P4.08.29
A non-regulated Th1/Th2 inflammatory immune response is linked to clinical problems in congenital toxoplasmosis

Y. Flores-García[1], *R. Figueroa-Damián*[2], *I. Cañedo-Solares*[1], *D. Correa*[1];
[1]*Instituto Nacional de Pediatría, Mexico City, Mexico,* [2]*Instituto Nacional de Perinatologia, Mexico City, Mexico.*

Toxoplasma gondii is a ubiquitous intracellular parasite with worldwide distribution which may be vertically transmitted and cause clinical problems to the fetus. In adults a Th1 polarized immune response is protective if regulated by IL-10 or TGF-β. An early Th2 profile does not inhibit parasite replication and thus is non-protective. Paradoxical observations about immune response in congenital toxoplasmosis in animal models have been reported: a but it may induce sterile abortion because of inflammatory damage at the placenta if not regulated or may favor parasite passage to thefetus. The aim of this work was to analyze the cellular/humoral pattern in *T. gondii* infected pregnant women and their newborns and to relate it with perinatal and neonatal problems. IgE and IgG1 to IgG4 specific antibodies were determined by ELISA. Specific PBMCs proliferation and cytokine production were measured by flow cytometry. Specific type/ subtype antibodies correlated with cellular immune response profile. T-CD4+ cell proliferation was observed in all cases, including newborns, while CD19+ and CD8+ specific responses were found in some of them. A Th1/Th2 inflammatory non-regulated immune response was found in adults. In newborns, a non- regulated Th2-polarized response prevailed, which correlated with systemic clinical problems observed in these neonates. Finally a lower immune response was observed in the cases of newborns in comparison with adults, as described in the literature. These preliminary results support the hypothesis that an inflammatory Th1/Th2 non-regulated response is responsible for clinical problems in congenital toxoplasmosis in humans.

Sero-immunoproteomics of Leishmania infantum: a reappraisal of the role of antibodies in protection to the development of kala-azar and antigen discovery for the design of bio-markers and vaccines

L. G. A. Gardinassi[1], *G. R. Garcia*[1], *S. R. Maruyama*[1], *F. O. Silva*[2], *C. H. N. Costa*[2], *R. P. Almeida*[3], *A. M. R. Jesus*[3], *I. K. F. M. Santos*[1];
[1]*Ribeirao Preto School of Medicine - USP, Ribeirao Preto, Brazil,* [2]*Nathan Portella Tropical Diseases Institute - UFPI, Teresina, Brazil,* [3]*Healthy and Biological Sciences Center - UFS, Aracajú, Brazil.*

The majority of infections with the etiological agent of visceral leishmaniasis in Brazil, Leishmania infantum, do not result in disease. The scientific consensus is that antibodies do not have a role in this outcome and may contribute to susceptibility to visceral leishmaniasis; nevertheless recent studies challenge this view. We hypothesized that individuals presenting asymptomatic infections with L. infantum produce antibodies with functional properties that differ from those produced by individuals who develop visceral leishmaniasis. Sera were collected from 208 kala-azar patients, 197 from individuals with asymptomatic infection and 138 healthy donors living in endemic areas. ELISAs were performed in order to screen IgG antibodies against soluble antigens (SA), membrane antigens (MA) and secreted/excreted antigens (SEA) of L. infantum. We show that kala-azar patients present higher absolute OD of IgG (~10 fold) against L. infantum SA, MA and SEA than asymptomatic individuals. Despite this data, a statistically significant difference between asymptomatic individuals and healthy controls was observed (p<0,001), which indicates that specific IgG properties (such as their subclasses) should be evaluated. Furthermore MA was recognized by 58% of asymptomatic individuals, contrasting with SA, recognized by 48% and suggests that MA may be more suitable for the identification of asymptomatic infection by immunoassays. MA and SEA were separated by 2D polyacrilamide gel, and western blots were performed with sera from kala-azar patients or infected asymptomatically. Indeed, the pattern of recognition of sera from asymptomatic individuals recognizes a set of antigens that differs both by specificity and intensity compared to kala-azar patients.

P4.08.31

Myeloid-derived suppressor cells are key players to balance the exacerbated inflammatory response during acute Trypanosoma cruzi infection

A. Arocena, L. Onofrio, A. Paroli, M. Aoki, ***S. Gea****;*
CIBICI-CONICET, Dpto Bioq. Clínica, Fac. de Cs Químicas, UNC, Córdoba, Argentina.

Myeloid-derived suppressor cells (MDSC), CD11b+Gr1+, are main players of the immune suppressive network. Previously, we reported that during acute infection with the causative agent of Chagas disease, *Trypanosoma cruzi*, BALB/c mice showed a lesser inflammatory response and improved survival than B6 mice which developed severe inflammation and pathology. Recent studies have demonstrated the MDSC presence in this scenario though the suppressor mechanisms have not been fully explored. In this study we demonstrated a higher increase of MDSC in spleen and liver of infected BALB/c compared to B6 mice. The phenotypic analysis of two major MDSC subsets revealed a greater number of granulocytic cells ($CD11b^{+}LY6G^{+}LY6C^{low}$) in spleen from BALB/c respect to B6 mice whereas monocytic population ($CD11b^{+}LY6G^{-}LY6C^{high}$) was the predominant subset in the liver of both mouse strains. Notably, splenic MDSC purified from infected BALB/c mice inhibited the ConA induced splenocyte proliferative response. Mechanistic studies demonstrated that inhibitors of reactive oxygen species (NAC) and nitric oxide synthase (L-NMMA) restored the proliferation. In addition, an up-regulation of NADPH oxidase p47 phox subunit and p-STAT3 occurred in MDSC. A higher number of infected CD8+ T-cells suffered surface-nitration compared to uninfected controls. Infected IL-6 deficient mice showed less recruitment of MDSC and impaired survival. Remarkably, the in vivo depletion of MDSC by 5FU led to an increased production of IL-6, IFNγ and Th17 response with increased parasitemia and mortality. In summary, our data show for the first time the mechanisms of MDSC as crucial regulators of inflammation during *T. cruzi* infection.

Evaluation of immunological responses against cocktail DNA vaccine of *Leishmania major* genes in BALB/c mice

F. Ghaffarifar[1], *A. Dalimi*[2], *Z. Sharifi*[3], *Z. M. Hassan*[2], *O. Jorjani*[4], *F. Tabatabaie*[5];
[1]*Parasitology and Entomology Dept., Faculty of Medical Sciences, Tarbiat Modares University, Tehran, Iran,* [2]*TMU, Tehran, Iran,* [3]*Research Center of Iranian Blood Transfusion Organization,, Tehran, Iran,* [4]*2Department of Biotechnology, Faculty of Advanced Medical Technology, Golestan University of Medical Sciences,, Gorgan, Iran,* [5]*Tehran University of Medical Sciences,, Tehran, Iran.*

Leishmaniasis is caused by *Leishmania* species which in the infected host is obligate intracellular parasite. LACK and TSA are immuno-dominant antigens of *Leishmania major*. In the present study, we constructed a DNA cocktail, containing plasmids encoding LACK and TSA genes of *Leishmania major* and evaluated the immune response and survival rate in comparison with control groups in BALB/c mice. IgG and IFN-γ values were markedly increased in the group immunized with DNA cocktail vaccine, which were significantly higher than control groups (p<0.05) following the immunization and after challenging with *Leishmania major*. IL-4 values significantly decreased in the immunized group compared to controls (p>0.05**)**. The mice immunized with the cocktail DNA vaccine presented a significant reduction in lesion diameter compared to control mice (p<0.05). The survival time of mice immunized with the DNA cocktail vaccine was significantly higher, after challenge with *Leishmania major*, than controls (p<0.05). The mice immunized with DNA cocktail vaccine had significantly lower parasite load compared to control mice (p<0.05). These findings indicate that the cocktail DNA vaccine increases the cellular response and survival rate and induces partial protection against infection with *Leishmania major* in BALB/c mice.

P4.08.33

Role of arachidonic acid metabolites in *Trypanosoma cruzi* infection

N. A. Guerrero, M. Fresno, ***N. Gironès****;*
Centro de Biología Molecular Severo ochoa, CSIC-UAM., Madrid, Spain.

Cardiac inflammation plays an important role in the pathophysiology of Chagas disease, caused by *Trypanosoma cruzi*. Lipid mediators derived from arachidonic acid (AA), like prostaglandins and leukotrienes, are considered regulators of homeostasis and inflammation. These molecules are produced by a biosynthetic pathway controlled by enzymes as cyclooxygenases and lipoxygenases. The role of cyclooxygenase-2 (COX-2) in immunosuppression during the acute phase of *T. cruzi* infection has been described using non-steroidal anti-inflammatory drugs, which are inhibitors of this enzyme. In this study, we first investigated the expression of enzymes involved in AA metabolism during *T. cruzi* infection. Susceptible and non-susceptible mouse models of infection were used to further analyze the role of lipid mediators in *T. cruzi* infection. Our results confirm the expression of several of these enzymes in *T. cruzi*-infected heart, in particular COX-2. $CD68^{+}$ heart-infiltrating macrophages were the major cell type expressing COX-2. $CD11b^{+}$ heart-infiltrating myeloid cells were purified and they were able to produce prostaglandins PGE_2 and $PGF_2\alpha$. Studies using gene-deficient mouse models indicated that regulation of COX-2 and PGE2, through PGE2 receptor 2 signaling, was in part responsible of cardiac inflammation in *T. cruzi* infection. The key role of lipid mediators in Chagas disease inflammation and the availability of drugs that inhibit their synthesis and their receptors could be useful for the treatment of this neglected disease.

P4.08.34
Role of B-1 cells in experimental Leshmania amazonensis infection

W. F. K. M. Gonzaga[1], *M. M. Geraldo*[2], *B. C. Vivanco*[1], *J. D. Lopes*[1], *P. Xander*[2];
[1]*Federal University of São Paulo, São Paulo, Brazil,* [2]*Federal University of São Paulo, Diadema, Brazil.*

Leishmaniasis belong to a group of diseases caused by protozoan parasites from *Leishmania* genus. *L. amazonensis* can lead to various clinical manifestations of leishmaniasis. Experimental evidence suggests that B cells and/or antibodies are potentially involved in the development of infection caused by *L. amazonensis*. B-1 cells are a subtype of B lymphocytes whose role in the physiology of the immune system as well as in the pathogenesis of various diseases is still poorly understood. These cells have ability to engulf pathogens, to migrate to inflammatory focus and to modulate immune response in several experimental models, such as paracoccidioidomycosis and murine melanoma. In addition, B-1 cells produce large amounts of IL-10 cytokine, which plays a key role in immunosuppression in several diseases, such as leishmaniasis. However, the importance of these cells in leishmaniasis has not been clarified. The objective of this study was investigate the role of B-1 cells in experimental infection of *L. amazonensis*. Preliminary results demonstrated that Balb/c mice subcutaneously infected at the right hind-foot with $1x10^7$ promastigotes of *L. amazonensis* for 70 days showed significant reduction in peritoneal B-1 cells population (28,46% ± 5,43), as compared to non-infected group (45,30% ± 5,05; p<0,01). These preliminary data suggest that B-1 cells population can be modulated in response to *L. amazonensis* infection. Further studies have been conducted to better understand the biological significance of these findings. The role of B-1 cells in the development of cutaneous leishmaniasis is also under investigation in our lab.

P4.08.35
Identification of *Toxoplasma gondii* sequences of potential diagnostic value via cDNA library immunoscreening

H. Hajghani;
Kerman Medical University, Kerman, Iran.

Laboratory diagnosis plays a major role in diagnosis of toxoplasma infection and research on improvements of the diagnosis of the infection is still ongoing. This includes identification of antigens that can be used as diagnostic markers. Thus in this study, *T. gondii* cDNA library was immunoscreened with selected set of serum samples in order to identify cDNA sequences of potential diagnostic value.
First, pooled positive serum samples from Group I and polyclonal anti-human IgM-HRP were used as primary and secondary antibodies respectively. Screening of *T. gondii* cDNA library was also performed using pooled positive sera (from Group I) and probed with anti-human IgG-HRP. Finally three clones were found to show the best differentiation between negative and positive serum samples, namely clones,5ii 7aG and 11aG, and tested with the 45 individual sera samples. The use of a combination of clones 7aG and 11aG produced sensitivity of 88% and specificity of 80% for IgG detection of sera from toxoplasmosis patients. The three clones (clones 5II, 7aG and 11aG) were then sent for sequencing, followed by database search using Toxo DB website. The DNA sequencing revealed that clone 5ii coded for dense granule protein while both 7aG and 11aG coded for hypothetical proteins. In conclusion, this study has identified three *T. gondii* cDNA sequences of potential diagnostic value. The results of this study are potentially useful for development of IgM and IgG detection tests for toxoplasmosis.

P4.08.36
Effect of Phlebotomus papatasi saliva extracts on humoral and cellular immune response in individuals living in an endemic area for leishmania major infection

W. Kammoun Rebai[1], *I. Naouar*[2], *A. Toumi*[2], *A. Ben Salah*[2], *H. Louzir*[2], *A. Meddeb-Garnaoui*[1];
[1]*Laboratory of Medical Parasitology,Biotechnology and Biomolecular, Pasteur Institute, Tunis, Tunisia,* [2]*Laboratory of Transmission Control and Immunobiology of Infection, Pasteur Institute, Tunis, Tunisia.*

Cell proliferation, IFNg and IL10 responses were analyzed after stimulation by salivary gland extracts (SGE), alone or in the presence of anti-IL10 antibody, in 378 individuals subdivided according to the leishmanin skin test response and the presence or absence of scars. We demonstrated significant proliferative and IFNg only in naive individuals. However, the use of anti-IL10 antibody was associated with an increase in proliferative and IFNg responses in healed and asymptomatic groups. No IL10 production was observed after SGE stimulation. Evaluation of humoral responses (mean relative OD: mROD) to SGE in 763 individuals showed a positive response in all groups. A multivariate analysis performed on 29 new CL cases observed after one year transmission showed that the main risk factor to develop CL was the IgG anti-SGE. Indeed, individuals with mROD≥4 had a risk factor of 2,65 (p=0.023) to develop infection. Interestingly, no new CL cases were observed among the naïve individuals, with positive SGE proliferative responses unlike those with negative proliferative responses (6 new cases). These results suggest that cellular responses developed against SGE in the absence of parasites may induce a protection against Leishmania infection. We used Luminex technology to measure up to 30 cytokines and chemokines levels in 5 Healed individuals showing positives IFNg anti-SGE and 5 naïve individuals with negative IFNg responses to SGE. We observed significant IL-6 and IL-2R levels in the first group, after SGE stimulation. Analysis of these profiles may allow to better understand the mechanisms of immune response against leishmaniasis in humans.

P4.08.37
Cytokine responses & parasite genotypes associated with pathogenesis of human African trypanosomiasis trypanosomiasis in North-eastern Uganda

C. D. Kato*, P. Alibu, E. Matovu;*
Makerere University, Kampala, Uganda.

Human African trypanosomiasis (HAT) or sleeping sickness is caused by protozoan parasites of the genus trypanosoma. The disease is a major cause of human morbidity and mortality in 36 countries in sub-Saharan Africa. Mouse models have indicated that a balance between pro- and counter-inflammatory cytokines is central to the outcome of the disease. Pro-inflammatory cytokines like TNF-α have been shown to control parasitaemia by direct trypanocidal effect. However, over production of these pro-inflammatory cytokines (TNF-α & IFN-γ) has been liked with exacerbated pathology and also favor parasite growth. In a study of HAT in Uganda, early and late stage infections were characterized by elevated levels of IFN-γ, TNF-α and IL-10. CSF of both T. b. gambiense and T. b. rhodesiense patients has been characterized by increased levels of IL-10 and IL-6. In this study we aim to determine the role of the host inflammatory cytokines (Th1 and Th2) and parasite genotype in the pathogenesis of HAT. HAT diagnosis will be done by microscopic detection of trypanosomes in wet blood films or giemsa stained thick blood films prepared from finger prick blood. After admission, a detailed clinical history and a physical examination is performed on all HAT patients. Both neurological and non-neurological signs of HAT will be recorded. Neurological involvement will be assessed using the GCS. Ten milliliters of blood is obtained before commencement of treatment using EDTA vacutainers. Plasma and CSF concentrations of IL-1β, IFN-γ, TNF-α, IL-6, TGF-β and IL-10 is quantified using solid phase sandwich ELISA.

P4.08.38
Induction of protective immune responses against cutaneous leishmaniasis in BALB/c mice by a vaccine containing a new low pathogenic strain of Leishmania major along with imiquimod

V. Khaze[1], *M. Alimohammadian*[1], *S. Ajdary*[1], *B. Laamrad*[2], *F. Riazi-Rad*[1], *H. Darabi*[1], *F. Bahrami*[1];
[1]*Department of Immunology, Pasteur Institute of Iran, Tehran, Iran,* [2]*Department of Biology, Payame Noor University, Tehran, Iran.*

Despite decades of research in countries around the world, an effective vaccine against leishmania infections has not yet been established. Selection of *Leishmania major* strains with low pathogenicity might be a straight way to protect the susceptible mice against cutaneous leishmaniasis for vaccine studies.
Here we used a new low pathogenic strain of *L. major* (MHOM/IR/03/IPI-DA39), isolated from an endemic area of cutaneous leishmaniasis located in north of Iran (Damghan) for vaccination compared to a high pathogenic reference strain of Iran (MRHO/IR/75/ER) which has been used previously in some clinical trials. Whole killed parasites of both strains were inoculated in the hind footpad along with imiquimod as a Th1 adjuvant. BALB/c mice immunized in three doses at two weeks intervals and challenged with reference strain parasites, two weeks after the last immunization. Parasite burden by limiting dilution assay and IFNγ, IL4 mRNA expression by qRT-PCR were performed four weeks post challenge. Lesion size measurements were followed for twelve weeks.
The group vaccinated with DA39+imiquimod, revealed significant decrease in the parasite burden compared to the reference strain group ($3.41\times10^8\pm2.19\times10^8$ and $3.21\times10^9\pm1.2\times10^9$ live parasites/lymph node, respectively; p=0.05). In DA39+imiquimod group, smaller lesion size in the footpad was observed from week five to week twelve (p<0.001). Mean fold increase of IFNγ mRNA also exhibited a dominant Th1 response in DA39+imiquimod compared to reference strain group (350.80±10.55 and 198.61±45.43, respectively; p=0.01).
The results indicated that using a low pathogenic strain of *L. major* could lead the immune responses toward partial protection against cutaneous leishmaniasis.

P4.08.39
Antiparasitic effects of Foeniculum vulgare extracts against Toxoplasma gondii

F. Khoshzaban[1,2], *F. Ghaffarifar*[3];
[1]*Shahed University, Tehran, Iran,* [2]*Medical sciense Shahed University, Tehran, Iran,* [3]*Tarbiat Mdaress University, Tehran, Iran.*

Toxoplasma gondii is a common parasite of animals and humans and can cause serious opportunistic infections. However, the majority of infections are asymptomatic, possibly because the organism has co-evolved with its many vertebrate hosts and has developed multiple strategies to persist asymptomatically for the lifetime of the host. Fennel (Foeniculum vulgare) is a plant species in the genus Foeniculum, has been used in folk medicine as a medicinal plant, as well as a spice and food in many countries. This research was carried out to evaluate the antiparasitic effect of Fennel (Foeniculum vulgare) extracts (aqueous - ethanol - acetone) against Toxoplasma gondii (T.gondii) in vivo.
The effect of these extracs against the proliferation of T. gondii was evaluated by animal testing.
T. gondii in a dose-dependent manner compared with sulfadiazine. After T. gondii invasion, the viability of T. gondii-infected mice treated with Foeniculum Vulgare extracts (aqueous - ethanol - acetone). 15 groups of BALB/c mice selected to during the period of the experiment. The animals were infected with T. gondii RH strain and received single dose from each extracts (100-200-300-400-500 µg/ml) intraperitonally, with survival and the immune response monitored.
These results demonstrate Foeniculum Vulgare extracts (aqueous - ethanol - acetone) not only induced anti-T. gondii effects causing the reduction of T. gondii tachyzoites in the spleen of infected host but also has antiparasitic properties, with lower tissue parasitism observed in infected animals.

P4.08.40
Serum nitric oxide levels in subjects with high bilirubin value in comparison of normal healthy control subjects

R. Kumar;
Department of Biochemistry, Bundelkhand University, Jhansi, Uttar Pradesh, India.

Introduction: Bilirubin is excreted in bile and urine, and elevated levels may indicate certain diseases. Serum bilirubin are inversely related to risk of certain heart diseases. Since nitric oxide (NO) is produced by three types of Nitric Oxide Synthases (NOSs), rapid changes in stable oxidized metabolites (nitrite and nitrate) in the tissues and blood should be represented by the amount of stable forms in serum and may reflect changes in the body. Objective: The aim of this study was to evaluate the correlation between nitric oxide (nitrite & nitrate) production and bilirubin levels in serum. Methodology: The serum samples were collected from individuals with high levels of bilirubin and normal range controls. Nitrite was measured by a Griess reaction while nitrate was measured using the enzymatic one step assay with nitrate reductase. Results: The total 36 samples (18 normal range (N) and 18 high bilirubin values (H)) were evaluated for the NO levels. The age group varies from 4-70 & 5-65 for normal & high levels of bilirubin, respectively. The levels of bilirubin in the normal range & high values varies from 0.81-0.98 (mean=0.88±0.01) & 1.12-20.18 (mean=5.96±2.07), respectively. When the nitrite (14.48±1.05 µM versus 13.42±0.96 µM, P>0.05) and nitrate (25.94±2.04 µM versus 24.69±1.53 µM, P>0.05) levels were compared between these groups no significant differences were observed. Conclusion: There is no correlation between nitric oxide production and the levels of bilirubin.

P4.08.41
CD4-CD8- T cells, B cells and complement are critical for resolution of Babesia microti infection in the absence of CD4

M. Leveque[1], *Z. Silver*[1], *C. Wilson*[1], *J. Su*[1], *S. Telford*[2], *J. A. Gelfand*[3], *P. J. Krause*[4], *E. Vannier*[1];
[1]*Tufts Medical Center, Boston, MA, United States,* [2]*Tufts Veterinary School of Medicine, Grafton, MA, United States,* [3]*Massachusetts General Hospital, Boston, MA, United States,* [4]*Yale School of Public Health, New Haven, CT, United States.*

Babesiosis caused by the protozoan parasite Babesia microti is an emerging infectious disease in the United States. In immunocompromised patients, particularly in those treated with the B cell depleting drug rituximab, babesiosis is severe and persistent. To understand how the immunocompromised host clears B. microti, we developed a mouse model. Intense, persistent parasitemia was observed in athymic mice and in mice lacking MHC class II. Surprisingly, in cd4-/- mice, parasitemia was intense but resolved. In their spleens, CD4-CD8- (DN) T cells, CD8+ T cells and B cells expanded. Parasitemia resolved in cd4-/- cd8-/- mice, but persisted in cd4-/- igh6-/- mice. In cd4-/- mice, the rise in circulating Babesia specific IgGs was delayed but concomitant with resolution of parasitemia. All subisotypes were produced. Fcγ receptors were dispensable for resolution of parasitemia, but C3 was required. DN T cells producing both IL-21 and IFN-γ expanded, but not as fast as CD4+ T cells producing both cytokines in wild-type mice. In contrast, DN T cells producing IFNγ alone expanded as fast as their CD4+ T cell counterparts. DN T cells failed to produce IL-21 alone whereas CD4+ T cells producing IL-21 alone quickly expanded. Parasitemia resolved in cd4-/- mice treated with a neutralizing antibody against IFN-γ. IL-21, however, appeared critical. Our studies indicate that DN T cells and B cells are key for resolution of B. microti infection in the absence of CD4. Despite the production of IgGs, resolution of infection requires complement activation, but not Fc receptors.

P4.08.42
Alteration of s-Fas and s-FasL ligand expression during canine visceral leishmaniasis

***V. M. Lima**, J. Perosso, S. d. Ferreira, K. L. O. Silva, L. M. Melo;*
UNESP, Araçatuba, Brazil.

Apoptosis has been implicated in canine visceral leishmaniasis (VL). A major regulator of apoptosis is the Fas/Fas ligand (FasL) system involved in down-regulation of immune reactions and in T cell-mediated cytotoxicity. Fas (CD95 or APO-1) is a member of the TNF/NGF receptor superfamily which can be expressed in transmembrane or soluble forms. The role of sFas is not understood fully, but is thought to inhibit Fas-mediated apoptosis through neutralizing its ligand, FasL. sFasL is produced by cleavage of the membrane-bound FasL by unidentified metalloproteases. In this study, we measured the levels of sFas and sFasL in extract from spleen dogs with VL and control. Twenty two dogs presenting clinical symptoms compatible with leishmaniasis and diagnosis confirmed by the detection of anti-Leishmania antibodies were studied and eight healthy dogs, from Araçatuba City, Brazil, were used as control. Samples from spleen tissue (300 mg) for each dog were homogenized with an Ultraturrax T50 IKA (Labortechnik, Staufen, Germany) apparatus for 5 min at 4°C. Homogenized tissue was centrifuged at 10,000 × g for 15 min, and the supernatant stored at -20ºC. sFas and sFasL concentration in spleen homogenized were assayed in duplicate by ELISA (Enzyme Linked Immuno Sorbent Assay Kit, Life Science, Houston, USA). sFas levels were lower in dogs with VL when compared to in healthy controls, while sFasL was increased in dogs with VL when compared to healthy controls. These findings suggest that the molecules sFas and sFasL are involved in immunopathogenesis of canine visceral leishmaniasis.

P4.08.43
Phagocytosis of promastigotes of Leishmania amazonensis by B-1 cells

*M. M. Geraldo[1], F. M. C. Barbosa[1], W. F. K. M. Gonzaga[2], B. C. Vivanco[2], P. Xander[1], P. Xander[1], **J. D. Lopes**[2];*
[1]Universidade Federal de São Paulo campus Diadema, São Paulo, Brazil, [2]Universidade Federal de São Paulo, São Paulo, Brazil.

Leishmaniasis are caused by Leishmania parasites which mainly infect macrophages. B-1 cells are a subpopulation of B cells resident in the peritoneal and pleural cavities of mice. These cells are able to differentiate in vitro into mononuclear phagocyte-like cells with phagocytic properties. Nevertheless, the role of B-1 cells in phagocytosis of Leishmania has not yet been clarified. This study aimed to investigate the phagocytosis of L. amazonensis by mononuclear phagocytes derived from B-1 lymphocytes in vitro and in vivo. Phagocytes derived from B-1 cells were able to internalize in vitro promastigotes of L. amazonensis. Our results showed that phagocytic index was higher in phagocytes derived from B-1 (2885 ± 264.46), compared to peritoneal macrophages (1236.33 ± 355.92) and bone-marrow-derived macrophages (421.5 ± 6 36; p <0.001). L. amazonensis stimulated TNF-α production by B-1 cells. TNF-α amounts were higher in B-1 cells that phagocytosed L. amazonensis, as compared with B-1 control (cells non-stimulated with parasites). The in vivo phagocytic ability of B-1 cells was also evaluated. A flow cytometric method was performed to evaluate the peritoneal B-1 cells-L. amazonensis interaction. Parasites were labeled with stable intra-cytoplasmic fluorocrome, 5,6-carboxyfluorescein diacetate succinimidyl ester (CFSE) and subsequently inoculated in peritoneal cavities of mice. After 8, 16 or 24 h peritoneal cells were collected and labeled with anti-CD19 and anti-CD23. We found that many CD19+ CD23- cells were positive for FITC, which we attributed to phagocytosis of the parasite by B-1 cells. This is the first report that B-1 cells can internalize Leishmania species.

P4.08.44
A Mechanistic Insight Into Arabinosylated Lipoarabinomannan (Ara-LAM) Mediated Modulation Of IFN-γ signaling and Different Transcription Factors During Experimental Visceral Leishmaniasis

***S. Majumdar**, S. Majumder, B. Paul Chowdhury;*
Bose Institute, Kolkata, India.

Visceral Leishmaniasis (VL), commonly known as kala-azar is one of the most widespread infectious diseases affecting the third world countries. The hallmark of VL, caused by *Leishmania donovani*, is a strong suppression of the host-protective anti-leishmanial responses in a susceptible host. Arabinosylated Lippoarabinomannan or Ara-LAM isolated from an avirulent strain *Mycobacterium smegmatis* is a TLR2 ligand and has potent immunomodulatory properties such as up-regulation of pro-inflammatory cytokines, NO production and induction of TLR-2 mediated signaling in macrophages. In the present study, we have demonstrated that Ara-LAM confers protection against leishmanial pathogenesis via the modulation of IFN-γReceptor expression as well as its downstream signaling. By inhibiting the ceramide generation, Ara-LAM maintained the cell membrane integrity of the parasitized macrophages and increased the MHC-II expression. Along with this, Ara-LAM, significantly upregulated the phosphorylation level of JAK1 and JAK2 following IFN-γ-stimulation in infected macrophages, which ultimately induced the nuclear translocation of STAT1. Not only that, Ara-LAM was also found to differentially regulate Interferon Reulatory Factors (IRFs), among which IRF8 is directly involved in IFN-γ signaling . Therefore, our study demonstrates that by modulating IFN-γ responsiveness in *L. donovani* infected macrophages, Ara-LAM helps in the improved antigen presentation as well as better parasite clearance.

P4.08.45
Leishmania-induced biphasic ceramide generation in macrophages is crucial for uptake and survival of the parasite

***S. Majumder**[1], R. Dey[1], S. Bhattacharjee[1], A. Rub[2], G. Gupta[1], S. Bhattacharyya Majumdar[1], B. Saha[2], S. Majumdar[1];*
[1]Bose Institute, Kolkata, India, [2]National Center for Cell Science, Ganeshkhind, India.

The initial macrophage-Leishmania donovani interaction results in the formation of membrane platforms, termed lipid rafts that help in the entry of the parasite. Therefore, it is imperative that the parasite designs a strategy to modulate its uptake and survival within the macrophages. Herein, we report Leishmania-triggered biphasic ceramide generation. In the first phase, L. donovani promastigotes induce activation of acid sphingomyelinase (ASMase), which catalyzes the formation of ceramide from sphingomyelin. Inhibition of ASMase resulted in reduced uptake and infection with the parasite. In the second phase, de novo synthesis generates ceramide that reduces the cellular cholesterol level and displaces the cholesterol from the membrane, leading to enhanced membrane fluidity, disruption of rafts, and impaired antigen-presentation to the T cells. The results reveal a novel role for ceramide in the perspective of L. donovani infection and help formulate an antileishmanial strategy that can possibly be applied to other intracellular infections as well.

P4.08.46
Leishmania infantum excreted/secreted proteins impairs differentiation and modulates cytokine production in human dendritic cells and monocytes

*W. Markikou-Ouni[1], S. Drini[1], M. Chenik[1], A. Meddeb-Garnaoui[1], **W. Kammoun**[2];*
[1]Laboratory of Medical Parasitology, Biotechnology and Biomolecules, Institut Pasteur de Tunis, Tunisia, [2]Institut Pasteur de Tunis, Tunis, Tunisia.

Several data have shown that Leishmania (L.) parasites as well as some bioactive compounds they secrete are able to modulate innate immune responses through effects on dendritic cells (DCs) and macrophages. We previously demonstrated that Leishmania promastigotes interfere with differentiation and cytokine production in

human DCs and monocytes. In this study, we examined the immunomodulatory effects of 4 Leishmania excreted/secreted (ES) proteins that have been identified and characterized in our laboratory: Elongation Factor 1-alpha (EF-1a), AAA-ATPase and proteins with unknown functions P15 and P23. We analyzed the capacity of each ES protein to modulate IL-12p70, IL-10 and TNFa production in human monocytes and DCs and to interfere with DCs differentiation. DCs were able to produce significant levels of IL-12p70 when stimulated by ES proteins, unlike monocytes. In presence of IFNg, ES proteins similarly induced a significant enhance of IL-12p70 production by DCs as well as monocytes. ES proteins were also able to induce significant IL-10 and TNFa production by DCs and monocytes, with higher levels observed with P15 and AAA-ATPase. Interestingly, the presence of ES proteins during DCs differentiation led to a significant decrease in CD1a. P15 and AAA-ATPase proteins were able to inhibit up to 80% of CD1a expression. We showed that ES proteins induce IL-12p70 production by DCs, suggesting that they could be potential candidate vaccines. Furthermore, ES proteins and particularly P15 and AAA-ATPase strongly interfere with DCs differentiation suggesting a possible involvement of these proteins in mechanisms established by the parasite for its survival.

P4.08.47

Leishmania infantum excreted/secreted proteins impairs human dendritic cells differentiation and modulates cytokines production by human dendritic cells and monocytes

***W. Markikou-Ouni**, S. Drini, M. Chenik, A. Meddeb-Garnaoui;*
Laboratory of Medical Parasitology, Biotechnology and Biomolecules, Institut Pasteur de Tunis, Tunisia.

Several data have shown that Leishmania (L.) parasites as well as some bioactive compounds they secrete are able to modulate innate immune responses through effects on dendritic cells (DCs) and macrophages. We previously demonstrated that Leishmania promastigotes interfere with differentiation and cytokine production in human DCs and monocytes. In this study, we examined the immunomodulatory effects of 4 Leishmania excreted/secreted (ES) proteins that have been identified and characterized in our laboratory: Elongation Factor 1-alpha (EF-1a), AAA-ATPase and proteins with unknown functions P15 and P23. We analyzed the capacity of each ES protein to modulate IL-12p70, IL-10 and TNFα production in human monocytes and DCs and to interfere with DCs differentiation. DCs were able to produce significant levels of IL-12p70 when stimulated by ES proteins, unlike monocytes. In presence of IFNγ, ES proteins similarly induced a significant enhance of IL-12p70 production by DCs as well as monocytes. ES proteins were also able to induce significant IL-10 and TNFα production by DCs and monocytes, with higher levels observed with P15 and AAA-ATPase. Interestingly, the presence of ES proteins during DCs differentiation led to a significant decrease in CD1a. P15 and AAA-ATPase proteins were able to inhibit up to 80% of CD1a expression. These results showed that ES proteins induce IL-12p70 production by DCs, suggesting that they could be potential candidate vaccines. Furthermore, ES proteins and particularly P15 and AAA-ATPase strongly interfere with DC differentiation, suggesting a possible involvement of these proteins in mechanisms established by the parasite for its survival.

P4.08.48

Role of neutrophils in parasite persistence and in host immunity during the initial phase of *L. chagasi* experimental infection

***C. Marques**[1], S. Falcão[2], F. Novais[2], D. M. Santos[2], A. Rodrigues[1], F. Passero[3], D. Mateus[1], G. M. Santos-Gomes[1], A. Barral[2], C. I. de Oliveira[2];*
[1]Centro de Malária e outras Doenças Tropicais-Instituto de Higiene e Medicina Tropical, Lisboa, Portugal, [2]Centro de Pesquisa Gonçalo Moniz – Fundação Oswaldo Cruz, Salvador-Bahia, Brazil, [3]Faculdade de Medicina-Universidade de São Paulo, Lisboa, Portugal.

Leishmania chagasi is the aetiological agent of visceral leishmaniasis (VL). In the last years the role of neutrophils or polymorphonuclear cells (PMN) during *Leishmania spp*. infection has been the subject of great interest from the scientific community. This immune cell population is described to play protective functions but also with responsibility in disease progression.
The main purpose of this work was to evaluate the role of PMN during the initial phase of experimental *L. chagasi* infection, by immunophenotyping different leukocyte subsets recruited to the site of parasite inoculation, quantification of chemokine and Toll-like receptors expression on the infection site and quantification of cytokine expression in internal organs after PMN depletion in C57BL/6 mice.
It was observed that the absence of PMN did not interfere with chemokine and TLR-4 expression and leukocyte recruitment to the site of infection, although it seems to be a delay in parasite elimination. Nevertheless, *Leishmania* parasites spread to cervical lymph nodes. In these organs, PMN depletion influences cytokine profile induced by the parasite in the beginning of infection (3 hours), leading to expression of pro and anti-inflammatory cytokines (IL1-β, TNF-α,TGF-β and IL-17). 144 hours post infection, serine protease granzyme B production along with IFN-γ inhibition appear to be a reflection of the initial deficiency of PMN.
With this work we provided evidence that PMN have a major role on cellular immunity during the early phases of *L. chagasi* infection that could be important for the development of alternative strategies for the control of VL.

P4.08.49

Salivary antigen SP32 is the immunodominant target of the antibody response to Phlebotomus papatasi bites in humans

***S. Marzouki**;*
Pasteur Institut of Tunis, Tunis, Tunisia.

Introduction: Zoonotic cutaneous leishmaniasis (ZCL) due to *Leishmania major* is highly prevalent in Tunisia and is transmitted by a hematophagous vector, *Phlebotomus papatasi (P. papatasi)*. While probing for a blood meal, the sand fly injects saliva into the host's skin, which contains a variety of highly immunogenic compounds. We recently showed that the presence of anti-saliva antibodies was associated with an enhanced risk for leishmaniasis and identified the immunodominant salivary protein of *P. papatasi* as a protein of approximately 30kDa. **Material and methods:** We cloned and expressed in mammalian cells two salivary proteins from *P. papatasi*, PpSP30 and PpSP32, with predicted molecular weights close to 30kDa. We tested both recombinant proteins in serological experiments using sera from individuals living in endemic areas for ZCL and naturally exposed to *P. papatasi* bites. While recombinant PpSP30 (rPpSP30) was poorly recognized by sera, rPpSP32 was strongly recognized by all the tested samples. The binding of IgG antibodies to native PpSP32 was inhibited by the addition of rPpSP32. Consistently, experiments in mice showed that PpSP32 induced the highest levels of antibodies compared to other *P. papatasi* salivary molecules while PpSP30 did not induce any detectable antibodies. **Conclusion:** We demonstrate that PpSP32 is the immunodominant target of the antibody response to *P. papatasi* saliva. We also show that the recombinant form of PpSP32 is similar to the native one and represents a good candidate for large scale testing of human exposure to *P. papatasi* bites and perhaps for assessing the risk of contracting the disease.

P4.08.50

Role of P2X7 receptor in the response of phagocytes to Plasmodium chabaudi infection

***M. Menezes**[1], É. Salles[1], A. Cassado[1], E. Amaral[1], H. Silva[1], J. Álvarez[1], R. Coutinho-Silva[2], M. D'Império Lima[1];*
[1]University of São Paulo, São Paulo, Brazil, [2]Federal University of Rio de Janeiro, Rio de Janeiro, Brazil.

Malaria is characterized by intense activation of the immune system that seems to contribute to protection and pathogenesis. ATP recognition by P2X7R in immune cells is important for cell activation and death. In this study, we evaluated the effects of P2X7R-mediated signaling in phagocytes during infection with *Plasmodium chabaudi*. C57BL/6 and P2X7R$^{-/-}$ mice were infected with *P. chabaudi* infected red blood cells (iRBC) and clinical parameters were measured.

Kinetics of phagocytic cells and cell death in the spleen of infected animals was determined by flow cytometry. *In vitro* assay was performed with bone marrow derived macrophages (BMDM) from both mice strains in presence of iRBC and ATP. Between days 9 and 17 post-infection, 80% of $P2X7R^{-/-}$ mice died, while the C57BL/6 group presented no death. Clinical manifestations and their improvement were delayed in knockout mice in comparison to wild-type. $P2X7R^{-/-}$ mice showed a higher number of $CD11b^{+}$ cells at day 7 post-infection compared to the wild-type mice. The percentage of cell death found in spleen in the same day was lower in knockout group. Moreover, BMDM from C57BL/6 mice became significantly more sensitive to ATP when exposed previously to iRBC in a P2X7-dependent way when compared to that without iRBC. Thus, mice lacking the P2X7R seem to be more susceptible to *P. chabaudi* infection, presenting more severe clinical manifestations. Furthermore, the elevated number of phagocytes in spleen from $P2X7R^{-/-}$ mice when compared to C57BL/6 mice could be due to the reduced rate of cell death found in those cells.

P4.08.51
Relationship between parasite load and renal lesion in acute experimental Chagas disease

C. B. Miguel[1], *W. F. Rodrigues*[1], *J. R. D. Lemos*[1], *R. C. Parreira*[1], *R. B. Miguel*[2], *A. P. Rogério*[1], *C. J. F. Oliveira*[1], *J. E. Lazo-Chica*[1];
[1]*Federal University of Triângulo Mineiro, Uberaba, Brazil,*
[2]*Portuguese Beneficent Hospital of Uberaba, Uberaba, Brazil.*

Introduction: The acute phase of Chagas` disease is documented as being multifactorial. Besides the heart another affected organ is the kidney. Unfortunately, the pathophysiology and mechanisms of renal dysfunction associated with acute Chagas disease remains unclear. Thus, we evaluate the Influence of Parasite Load on Renal Function in Mice Acutely Infected with *Trypanosoma Cruzi*.
Methodology/results: Low, medium and high parasite loads were generated by infecting C57BL/6 mice with $3x10^2$, $3x10^3$ or $3x10^4$ "Y" strain trypomastigotes. By analyzing different parameters related to kidney injury, we demonstrated that mice infected with *T. cruzi* trypomastigotes show increased renal injury in a parasite load-dependent manner. The infections with low, medium and high doses of trypomastigotes resulted in reduced urinary excretion and creatinine clearance. We also observed a marked elevation in the ratio of urine volume to kidney and body weight, blood urea nitrogen, chloride ion, nitric oxide, pro- and anti-inflammatory cytokines as well as the number of leukocytes in the blood and/or renal tissues of infected mice. In addition we showed the presence of the parasite in the cortical/medullary and peri-renal region, an increase in the inflammatory infiltrate and in the vascular permeability of the kidney.
Conclusion: These data support the idea that *T. cruzi* impairs kidney function in a parasite load-dependent manner. Moreover, the data allow us to suggest that in addition to the cardiovascular effects, renal injury may be an important indicator of the magnitude of the infection and the severity of the illness.
Key words: kidney, *Trypanosoma cruzi*, parasite load

Leishmania are pathogenic protozoan, obligate intracellular pathogens that develop mainly in macrophages. These cells act as a safe shelter for the pathogens and also as effector cells responsible for their killing. Macrophages are able to secrete a diverse set of regulators known to influence the physiological functions and differentiation of neighboring cells to trigger an adaptive immune response of the protective Th1-type cells, whereas parasites have developed a wide range of mechanisms to circumvent the host's immune responses. Most of our understanding of this host-parasite conflict has been gleaned from studies investigating the macrophage infection at unique time points after infection.
Here we have analyzed the transciptomic profile of monocyte-derived human macrophages at different time points during the first 24h upon in vitro infection, using a high-throughput microarray platform.
The gene expression profile of 17,838 genes showed high expression variability among human donors at different time points post-infection. To circumvent this, only genes that underwent common modulation in the three donors were analyzed. Cross comparison allowed the identification of a common set of expressed genes coding for inflammatory and chemotactic molecules, transcription factors, apoptosis inhibition such as members of the NR4A sub-family, glucose synthesis and heme metabolism such as HMOX-1.
Our findings suggest that transcriptome dynamics of macrophages early during the first 24h post infection enables the identification of the different key pathways deregulated at early time points upon L. major invasion.

P4.08.53
MAP kinases activation in macrophages during infection with Neospora caninum

C. M. Mota[1], *A. M. Oliveira*[1], *M. D. Ferreira*[2], *F. M. Santiago*[1], *P. S. C. Barros*[1], *J. Mineo*[1], *T. W. P. Mineo*[1];
[1]*Universisade Federal de Uberlândia, Uberlândia, Brazil,*
[2]*Universisade de São Paulo, Ribeirão Preto, Brazil.*

Due to the high prevalence and economic importance of neosporosis by N. caninum, the development of safe and effective vaccines against this parasite preventing abortions and vertical transmission in cattle has been a priority in the field and it is crucial to limit infection in natural hosts. The major aim of the present study was to approach the signaling mechanisms in bone marrow-derived macrophages (BMDMs) under N. caninum infection to understand the mechanisms of immune response to the development of an effective method. It was evaluate the immune response from BMDMs infected with N. caninum and stimulated with its soluble antigen (NLA), and the role of MAPKs. The immune response in BMDMs was determined from IL-12 and IL-10 production in BMDMs culture supernatants treated with inhibitor of MAPKs and infected by N. caninum. Phenotyping of BMDMs was determined by expression of costimulatory molecules and MHC. According to these results, the p38 inhibitor (SB203580) was the inhibitor with the most relevant results. Thus, in vivo assay was performed with immunization of NLA, NLA plus SB203580 inhibitor in C57Bl/6 mice. These experiments demonstrated that the SB203580 is more important in the immune response by N. caninum, as a modulation of cytokines production, expression of the costimulatory molecules. These results clearly showed that N. caninum can use mainly the p38 via to regulate the host immune response and to develop an infection. Therefore, this piece of information can be useful to develop a cellular vaccine against neosporosis.

P4.08.54
Seroepidemiology of toxoplasmosis in childbearing women of eastern azarbaijan - iran

M. Naghavi - Behzad[1], *A. Naghavi-Behzad*[1], *R. Piri*[1], *N. Nezami*[2];
[1]*Students' Research Committee, Tabriz University of Medical Sciences, Tabriz, Iran,* [2]*Tabriz University of Medical Sciences, Tabriz, Iran.*

Background: *Toxoplasma gondi* (*T. gondi*) is cause to the most common parasitic infection in the world. Congenital transmission, prenatal mortality and abortion are major problems of T. gondi. Prevalence of toxoplasmosis is high in Iran. Current literature reviewed in this paper reveals results pertaining to various regions of Iran. The present study was designed to evaluate the seroprevalence of toxoplasmosis in childbearing women of Azerbaijan.

Methods: In this cross-sectional e-study, we evaluated 1659 women in childbearing age from different cities of Eastern Azerbaijan (Tabriz, Maragheh, Ahar, Marand, Sarab, Miane) from July 2009 to August 2010. Women aged between 20 to 40 years (childbearing period) and seeking prenatal care were enrolled in the study. Subjects' sera were examined with indirect fluorescent antibody (IFA).
Results: A total of 1659 subjects were examined. Titers ranged 1:100-1:800. 889 (54.13%) subjects were seropositive. The highest frequency of seropositivity was shown in 1:200 dilution (36.08%) and in subjects from Maragheh (84% of 211 subjects). There was a direct linear relationship between seropositivity and age ($p<0.001$). Also, seroprevalance of toxoplasmosis was higher in subjects with primary school/lower educational level ($p<0.001$) and subjects living in rural regions ($p<0.001$).
Conclusions: More than 50% of women in childbearing age were at risk of toxoplasmosis in Eastern Azerbaijan. Increasing seroprevalance of toxoplasmosis with age was a predictable result because of longer time of exposure to the bacterium. The relationship between increasing seroprevalence and lower educational level as well as living in rural region is in line with latest epidemiological findings which also show such relationships due to lower socioeconomic status.

P4.08.55
A successful safety trial of gentamicin-attenuated Leishmania infantum vaccine in an endemic area in Southeast of Iran

M. J. Namazi[1,2]*, H. Daneshvar*[3,4]*, H. Kamyabi*[3]*;*
[1]Sabzevar university of medical sciences, Sabzevar, Iran, [2]University og Glasgow, Glasgow, United Kingdom, [3]Kerman university of medical sciences, Kerman, Iran, [4]University of Glasgow, Glasgow, United Kingdom.

Leishmania infantum is an obligatory intracellular protozoan and causative of visceral leishmaniasis in human and dogs. Vaccine development in the reservoir host, the domestic dog, is a current research priority. The aim of this study was to conduct safety trial of gentamicin-attenuated L. infantum (L. infantum H-line) in dogs in the endemic area of Southeast Iran.
The household dogs were vaccinated subcutaneously with L. infantum H-line. The prospective incidence of natural infection by this vaccine was assessed during a two-year follow up period. The number of animals vaccinated and non-treated control groups was 70 and 50 respectively. The safety of the vaccine on the interruption of the endemic area transmission of the disease was assessed by monitoring the clinical signs and measuring the serum specific anti-Leishmania IgG. No clinical signs of disease including anorexia, apathy, local swelling on injection site, vomiting and diarrhea were developed or observed after the vaccine injection. Therefore, our gentamicin-attenuated L. infantum vaccine induced a significant and strong protective effect against canine leishmaniasis and the consequent transmission to human in the field.

P4.08.56
Excreted/secreted proteins of Leishmania major induce production of IFN-g and granzyme B by CD4+T cells

I. Naouar, T. Boussoffara, M. Ben Ahmed, N. Belhaj Hmida, A. Ben Salah, H. Louzir, ***W. Kammoun****;*
Institut Pasteur de Tunis, Tunis Belvedere, Tunisia.

Previous reports have shown that the excreted/secreted proteins released by Leishmania in the phagolysosomal compartment are strongly immunogenic and protective in mice and dogs. The protective mechanisms involve both Th1 and cytotoxic T cells. The potential immunogenicity of Leishmania major excreted/secreted proteins (LmES) was evaluated in humans using peripheral blood mononuclear cells (PBMCs) from donors whith a previous contact with L. major parasite and from appropriate healthy controls. PBMCs from all immune individuals proliferate and produce high levels of IFN-γ. Interestingly, granzyme B (GrB), used as a marker of activated cytotoxic T cells, was also highly produced by PBMCs of all immune individuals when stimulated with LmES. Total leishmania antigens also induce both IFN-γ and GrB by PBMCs from immune individuals. ell depletion experiments showed, unexpectedly, that both IFN- γ and GrB were mainly produced by CD4+ T cells after stimulation with LmES or SLA antigens. In attempt to identify the sub-population of CD4+T cells involved in IFN-γ and GrB production, CD4+CD25+ and CD4+CD25- T cell subsets were purified from the peripheral blood of a representative set of immune individuals. Our results showed that both populations produced IFN-γ and GrB when stimulated with LmES. Further experiments showed that CD4+CD25+CD127dim/- regulatory T cells were not involved in such production. Collectively, our data indicate that excreted/secreted proteins from L. major are highly immunogenic in humans constituting a potential candidate of vaccine. Our results also emphasize the involvement of potentially cytotoxic CD4+ T cells in immune response and protection against Leishmania.

P4.08.57
Polymorphisms of cytokines genes associated with ocular toxoplasmosis

C. Naranjo[1]*, J. Sepúlveda Arias*[1]*, J. Gómez*[2]*, A. De la Torre*[2]*;*
[1]Universidad Tecnológica de Pereira UTP, Pereira, Colombia,
[2]Universidad del Quíndio, Armenia, Colombia.

Toxoplasmic retinochoroiditis (TR) is a consequence of the congenital or acquired infection at birth with T gondii parasite. The genetic functional polymorphisms in the cytokine genes can interfere with the expression of such molecules and they play an essential role in the genetic regulation of the inflammatory response and the infectious diseases resistance or susceptibility. To consider the associated risk to polymorphisms in cytokines genes with ocular toxoplasmosis. To determine the polymorphisms prevalence in the IL-1α, IL-1β, IFN-ɣ, TNF-α, IL-10, IL-12 and IL-17R cytokines genes and P2RX7 and TLR9 receptors in general population and patients with ocular toxoplasmosis. The minisequencing technique or "ddNTP first extension" will be used Previous extraction of the genomic DNA of obtained of peripheral blood cells, the amplification of the regions that contain the SNPs to be studied will be amplified. The product will be analyzed by capillary electrophoresis by using the ABI prism 3100-Avant analyzer. The multiplex standardization for the polymorphisms evaluation in the cytokines genes and receptors already mentioned was made by defining the experimental conditions that allowed to detect several polymorphisms in a same amplification reaction with 15 samples of TR patients and 15 healthy controls. The preliminary results show that the studied polymorphisms are found in our population. There is a tendency for the $IL\text{-}10^{-1082G/A}$ polymorphism that indicates a possible association of this polymorphism to (TR) resistance and a tendency to the $TNF\text{-}\alpha^{-857C/T}$ polymorphism to be TR susceptibility associated.

P4.08.58
Immunomodulation of Leishmania infection by murine mesenchymal stromal cells in vitro

A. P. Nazario*, A. E. Vargas, A. P. Dagnino, P. S. Almeida, E. Engster, P. R. T. Romao;*
UFCSPA, Porto Alegre, Brazil.

Leishmania are protozoa that cause leishmaniasis disease in animals and humans. Despite the identification of several molecular targets, there is no vaccine for leishmaniasis or new drugs anti-leishmania. Mesenchymal stromal cells (MSCs) have been used in therapy for some disorders mediated by the immune system, but little is known about the effects of MSCs on protozoa. We evaluated the influence of MSCs on the production of NO and leishmanicidal activity of macrophages. We also investigated the interaction between MSCs from adipose tissue of C57BL/6 mice and *L. amazonensis*. NO production by activated MSCs, and by macrophages stimulated with LPS/IFN-gamma in the presence of MSCs' conditioned medium (CM) and/or aminoguanidine, was assessed by Griess. The influence of MSCs on the leishmanicidal capacity of macrophages was determined by quantifying the number of alive promastigotes after their growth *in vitro*. After 3 and 6 hours of infection, we observed the intracellular presence of amastigote forms of *L. amazonensis* in MSCs. Activation of MSCs with LPS significantly increased NO production (3 to 8-fold) suggesting that MSCs may exert microbicidal activity dependent on NO. It was also found that the CM of MSCs

inhibited NO production by macrophages by up to 95%, and increased the survival of pathogens by up to 61.6%. These results suggest that MSCs may serve as reservoirs for *Leishmania*, as well as contribute to the establishment of infection in macrophages by reducing their leishmanicidal activity.

P4.08.59
Effect of *Entamoeba histolytica* calreticulin in the immune response of patients with acute amoebic liver abscess

***M. E. Nieves-Ramirez**, E. Gonzalez, P. Moran, A. Valadez, M. Garcia, L. Rojas, O. Partida-Rodriguez, E. Hernandez, R. Cerritos, C. Ximenez;*
National Autonomous University of Mexico, Mexico City, Mexico.

Entamoeba histolytica is a human intestinal parasite that causes amoebiasis, which in Mexico is considerate as an endemic disease. Some molecules are involved in pathogenicity and virulence of *E. histolytica*. It was previously reported that *E. histolytica* calreticulin (*Eh*CRT) is a highly immunogenic protein in patients with amoebiasis. The aims of this work were to characterize the isotype of antibody response in serum samples of patients during the acute phase of amoebic liver abscess (ALA), to measure the ability of *Eh*CRT to bind human C1q protein and to define the stimulation properties of *Eh*CRT upon peripheral mononuclear blood cells (PMBC). We compared individuals with ALA and healthy subjects, which were characterized by coproparasitoscopic and ELISA assays and took a peripheral blood sample to obtain serum and mononuclear cells. PMBC were isolated and cultured in an *in vitro* system and stimulated with recombinant r*Eh*CRT. The stimulation index was calculated. Results show that the major isotypes of serum antibodies against *Eh*CRT were IgM and IgG class. Levels of IgA in serum were low and levels of IgE isotype of antibodies were extremely low. Besides, r*Eh*CRT-C1q caused the inhibition of classical complement pathway *in vitro*. PMBC of patients with ALA display a comparatively higher stimulation index to control PMBC. These preliminary results suggest that *Eh*CRT can be a useful antigen and have a modulating role to the adaptive immune response in invasive amoebiasis. Work performed with support PAPIIT/UNAM: IN226511 and CONACYT 210CO1-140990.

P4.08.60
Polymorphism of *lcr1* gene in different *Leishmania* species

***H. M. Niknam**[1], F. Firoozeh Abrishami[1], K. Kiana Fatemi[2], H. Azimian[3];*
[1]Pasteur Institute of Iran, Tehran, Iran, [2]Islamic Azad University – Pharmaceutical science branch, Tehran, Iran, [3]Islamic Azad University, Science and research branch, Tehran, Iran.

Introduction: *Leishmania* parasites are the causative agent of a wide range of diseases in human and other mammals. There is no efficient preventive measure for these diseases and their therapy remains difficult with many side effects. Hence, search for a vaccine for this disease is important. *Lcr1* is an immunogenic gene discovered in *Leishmania infantum chagasi* that causes immunologic response in human, so its molecular identification will be very important. The aim of this research is to study the DNA sequence of *lcr1* gene by molecular methods in some species of *Leishmaina* parasites.
Materials and Methods: *Two Leishmania infantum* isolates (strains MHOM.IR.04.IPI-UN10 and MCAN/IR/2010/Meshkinshahr) and one *Leishmania tropica* isolate (strain MHOM.AF.88.KK27) were cultured in NNN media and genomic DNA were extracted. Parasite species were verified as by sequencing of ITS1 gene. *Lcr1* gene was amplified by *lcr1* specific primers in all the strains. The PCR products were electrophoresed and their restriction fragment patterns were defined. All PCR products were sequenced at least twice by forward and reverse primers specific for *lcr1.* The DNA sequences were analyzed by softwares and the correct sequence were determined.
Conclusion: Our results show that *lcr1* gene is completely conserved between the two strains of *Leishmania infantum* and it is nearly conserved in *Leishmania tropica*. Conservation of this immunogenic gene (*lcr1)* adds to its value as an immunogenic molecule with potential in prevention, diagnosis, and treatment of leishmaniasis.

Support: This research received financial supports from Pasteur Institute of Iran (Research Project No. 314).

P4.08.61
Analysis of the cardiac disorder caused by the intracellular parasite *Toxoplasma gondii*

***K. Norose**[1], T. Ishikawa[1], K. X. Li[1], T. Ogura[2], H. Nakaya[2], M. Furuya[3], M. Osawa[4];*
[1]Dept. Inf. Host Defense, Grad. Sch. Med., Chiba Univ., Chiba, Japan, [2]Dept. Pharmacol., Grad. Sch. Med., Chiba Univ., Chiba, Japan, [3]Dept. Mol. Pathol., Grad. Sch. Med., Yokohama City Univ., Yokohama, Japan, [4]Dept. Cell. Mol. Med., Grad. Sch. Med., Chiba Univ., Chiba, Japan.

Toxoplasma gondii is known to cause serious heart disease. The detailed mechanism, however, still remains to be investigated. In this study we described experimental heart diseases caused by *T. gondii* in wild type (WT) and interferon gamma knockout (GKO) mice as a model of immunocompetent and immunocompromised hosts, respectively. C57BL/6 WT mice and GKO mice with C57BL/6 background were infected perorally with Fukaya strain of *T. gondii*. Parasite load, mRNA expression levels of cytokines, chemokines, chemokine receptors, and adhesion molecules, types of infiltrating cells, and pathologic findings were analyzed. Parasite load in WT mouse hearts reached a peak 14 days after infection, and decreased thereafter, whereas that in GKO mouse hearts kept increasing. In WT mouse heart the expression levels of IFN-γ, CCL2, CCL3, CCL4, CCL5, CXCL2, CXCL10, CCR2, CCR5, CCR7, CXCR2, CXCR3, and ICAM-1 increased, reaching peaks 14-28 days after infection. On the other hand, in GKO mice these molecules, except IFN-γ, CXCL10, CXCR3, and ICAM-1, increased slightly. The expression levels of CXCR4 and CXCR5 were absent in both mice during the course of infection. While $CD4^+$, $CD8^+$, monocyte, and neutrophil cell numbers increased significantly in the infected hearts of WT mice, the neutrophils in the infected hearts of GKO mice increased dramatically. In the heart of WT mice increased cell types controlled the infection, although increased neutrophils in GKO mice could not. Thus, IFN-γ plays a pivotal role in the pathogenesis of heart disease caused by *T. gondii*.

P4.08.62
Adoptive transfer of Treg ($CD4^+Foxp3^+$) cells to B6 mice during *Toxoplasma gondii* infection induces down-modulation of exacerbated inflammatory immune response but does not generate protection

***J. E. Olguín**[1], J. Fernández[1], C. Castellanos[1], J. Campuzano[2], N. Salinas[1], R. Saavedra[1];*
[1]Instituto de Investigaciones Biomédicas, UNAM, Ciudad de México, Mexico, [2]Facultad de Medicina, Veterinaria y Zootecnia, Ciudad de México, Mexico.

Toxoplasmosis is an infection disease affecting one third of the world population and is caused by the protozoan parasite *Toxoplasma gondii*. T_H1 immune response is necessary for protection, IFN-γ being the major mediator of resistance. An exacerbated T_H1 immune response however, is detrimental. Regulatory T (Treg) are $CD4^+Foxp3^+$ cells that actively suppress pathological and physiological immune responses, thereby contributing to the maintenance of immune homeostasis. It has been reported that during acute toxoplasmosis in B6 mice, Treg cell number decreases. In order to analyze if Treg cells are involved during *T. gondii* infection, we carried out adoptive transfer of Treg cells to infected mice. We observed a decreased mortality when Treg cells were adoptively transferred but an increased number of cysts in brain was detected. A decreased pathology in the small intestine, a decreased production of IFN-γ in serum, a decreased activation in $CD4^+$ cells, and a decreased production of IFN-γ by $CD4^+$ cells was also observed in the same mice. IL-2 levels in sera however, remain unchanged. All these results suggest that adoptive transfer of Treg cells during *T. gondii* infection down-modulate the exacerbated immune response, but it does not generate protection in B6 mice.

P4.08.63
Natural isotypic response against potential vaccine candidate *Plasmodium falciparum* Glutamate-Rich Protein (GLURP) in individuals living in Brazilian malaria-endemic area

L. R. Pratt-Riccio[1], *J. C. Lima-Junior*[1], *L. J. M. Carvalho*[2], *M. Theisen*[3], *F. Santos*[4], *J. Oliveira-Ferreira*[1], *C. T. Daniel-Ribeiro*[1], *D. M. Banic*[1];
[1]*Fiocruz, Rio de Janeiro, Brazil,* [2]*Fiocruz, RIo de Janeiro, Brazil,* [3]*Statens Seruminstitut, Copenhagen, Denmark,* [4]*LACEN, Rondonia, Brazil.*

The *Plasmodium falciparum* Glutamate-Rich Protein (GLURP) is a malaria vaccine candidate undergoing clinical trials. Studies have shown association between high levels of anti-GLURP antibodies with low parasitemia and protection against clinical malaria. The aim of this study was to evaluate the antibody response profile induced by GLURP in naturally exposed individuals from a Brazilian endemic area. The study was carried out in the farming area of Colina (CL) and the riverside fishing community of Ribeirinha (RB), Rondonia state. The population of CL consists of migrants from non-endemic areas, and the population of RB consists of natives from the Amazon Basin. The antibody response against immunodominant regions of the GLURP (R0 and R2) and synthetic peptides (*R0*: P3, P4, P5, P8, P9, P10, P11, S3; *R2*: S4) was evaluated by ELISA. The results showed a high prevalence of individuals with antibodies against R0 (72% and 92% in CL and RB groups, respectively) and R2 regions (79% and 97% in CL and RB groups, respectively). The R0-induced antibodies were predominantly IgG1 and R2-induced antibodies were predominantly of cytophilic subclasses. S4 and P11 epitopes were identified as immunodominant B-cell epitopes. However, in RB group, P3 and S3 epitopes induced higher levels of cytophilic antibodies. Our results show that GLURP is immunogenic in natural conditions of exposure and the seropositivity to GLURP increases with exposure. Also, GLURP is able to induce cytophilic antibodies that can participate of protective acquisition immunity. In conclusion, our results highlight the importance of GLURP like a malaria vaccine candidate.

P4.08.64
Th2-skewed response depends on Insulin-like growth factor I in Leishmania (Leishmania) major-infection

L. C. Reis, *E. Ramos-Sanchez, H. Goto;*
Instituto de Medicina Tropical de São Paulo, Universidade de São Paulo, IMT-USP, São Paulo, Brazil.

In Leishmania infection extrinsic insulin-like growth factor-I (IGF-I) favors the parasite proliferation and the infection development. To study the role of constitutively expressed macrophage intrinsic IGF-I in Leishmania infection, we evaluated the parasitism under optical microscopy and IGF-I mRNA expression by qRT-PCR and confocal microscopy in Leishmania (Leishmania) major-infected RAW 264.7 macrophage cell line upon IGF-I mRNA silencing with 150µM small interfering RNA (siRNA) and Th2 cytokine IL-4 (2ng/ml) and IL-13 (5ng/mL) stimuli. siRNA treatment of cells resulted in 70% reduction of IGF-I mRNA expression. The parasitism in the control without IGF-I siRNA was 149 (median) parasites per 100 cells. With siRNA treatment it decreased to 93 ($p<0.05$). Cells under IL-4 plus IL-13 stimuli had the parasitism increased to 160. In siRNA-treated cells with IL-4 and IL-13 stimuli instead of an increase we observed a decrease to 102. Using individual cytokine stimulus, IL-4 stimulus increased the parasitism to 171 but in siRNA-treated cells IL-4 stimulus did not induced an increase but a decrease to 87. Similarly IL-13 stimulus increased the parasitism to 157 but in siRNA-treated cells IL-13 stimulus induced a decrease to 76. Expression of IGF-I mRNA expression accompanied the increase or decrease of parasitism. These results suggest that IGF-I is directly related to parasitism and that even with the cytokine stimuli the presence of IGF-I is required to promote susceptibility, strongly suggesting the dependence of the presence of IGF-I for the effect of Th2 cytokines in Leishmania infection.

P4.08.65
Modulation of T helper immune response by photodynamic therapy in experimental leishmaniasis

V. Rodrigues*, P. M. Alves, M. F. Silva, D. M. Souza, S. M. C. F. Carlos, M. V. Silva, T. P. Paulino, D. B. R. Rodrigues;*
Universidade Federal do Triângulo Mineiro, Uberaba, Brazil.

Cutaneous Leishmaniasis is a parasitic disease caused by protozoan flagellates that belong to the *leishmania* genus. *Leishmanias* develop inside the macrophage and Th1 cytokines are essential in protecting against all *Leishmania* infections due to NO production. Conversely, the Th2 cytokines are associated with susceptibility. Photodynamic Therapy (PDT) utilizes an otherwise nontoxic chemical to create oxidative damage in cells when exposed to light. In this study, we analyzed the local and systemic expression of Th1 and Th2 cytokines in BALB/c mice experimentally infected with *L. braziliensis* after PDT-Aminolevulinic acid. Skin foot pad and spleens from infected animal, submitted or not to 1, 2 or 3 PDT sections were homogenized, centrifuges and supernatants were used for cytokines titration by CBA. Parasite burden were evaluated in skin imprints'. We observed that IFN-gamma and IL-4 levels were higher in skin lesions than in spleens whereas levels of TNF-alpha, IL-2 and IL-5 were similar. Also, after a single PDT an increase of IL-4 levels and a decrease of IFN levels were observed only on skin samples. After the second and the third sections, levels of these cytokines were restored. Levels of TNF-alpha, IL-2 and IL-5 were not affected by PDT in any therapeutical approach used in this study. Moreover the parasites number decreased after a first PDT section and maintaining reduced during consecutive sections (about 4 times). This data suggested that a single PDT section affect Th1/Th2 balance, probably due to a direct effect on T lymphocyte or an indirect effect on *Leishmania* lyses.

P4.08.66
Th17 and Tc17 cells on pregnant women seroposite and seronegative for toxoplasmosis

V. J. Rodrigues[1], *J. L. A. Silva*[1], *K. R. Oliveira*[2];
[1]*Universidade Federal do Triângulo Mineiro, Uberaba, Brazil,* [2]*Universidade Federal de Uberlândia, Ituitaba, Brazil.*

The immune response is an important mechanism to control infection by *Toxoplasma gondii*. Is clearly established the major role of Th1 cytokines, however, e role of IL-17 is not clearly established, especially during pregnancy. Cells that produce IL-17 (Th17) are responsible for the recruitment of neutrophils, important early in the control of parasite infection. The objective was to evaluate the synthesis of cytokines (Th1 and Th2) by mononuclear cells after culture with live tachyzoites of *T. gondii* and to characterize the role of Tc17 and Th17 cells in pregnant and non-pregnant seronegative and seropositive women for toxoplasmosis. CBA's method was used to measure cytokine (IL-2, TNF-α, IFN-γ, IL-4, IL-5 and IL-10) and immunophenotyping method for characterizing and CD8+ and CD4+ cells expressing IL-17 (Tc17 and Th17). The addition of live tachyzoites in cultures induced a significant increase on the synthesis of IL-5, IL-10 and TNF-α by seronegative pregnant women. In cell cultures stimulated with live *T gondii*. the expression of IL-17 was significantly higher on CD4+ T cells in relation to the CD8+. Furthermore, the addition of *T. gondii* promotes a significant increase of IL-17 on CD4+ cells only on seropositive non pregnant women. We conclude that both, CD4+ and CD8+ T cells are able to produce IL-17 and that there is a repertoire of Th17 cell specific against *T. gondii*, on seropositive non-pregnant women, suggesting that these cells contribute on eliminating the parasite.

P4.08.67
Inflammatory response of a prostate stromal cell induced by live *Trichomonas vaginalis*

***J. Ryu**, S. Im, N. Gu, M. Ahn;*
Department of Environmental Biology & Medical Parasitology, Hanyang University College of Medicine, Seoul, Republic of Korea.

Trichomonas vaginalis cause urogenital infectious diseases in men as well as women. More than 50% of men is reported to be suffered by prostatitis in their life. *T. vaginalis* has been accounted for about 10% of pathogenic organisms causing prostatitis. The objective of this study is to identify whether *T. vaginalis* is able to induce inflammatory response in prostate stroma. To address this goal human prostate stromal cell line, WPMY-1, and *T. vaginalis,* were used. When WPMY-1 was stimulated with live trichomonads, various inflammatory mediators including IL-8, MCP-1, showed increased production. Increased expression of TLR4 mRNA on WPMY-1 was suggested that this receptor may involved in upstream pathways of signaling on stimulation of *T. vaginalis* to the cell. Signalling molecules such as ROS, MAPK and NF-κB were also increased when WPMY-1 cocultured with *T. vaginalis*. Agents inhibiting of ROS, MAPKs, NF-κB activities significantly reduced IL-8 and MCP-1 production compared to control. These findings suggested that ROS, MAPKs and NF-κB may be involved in IL-8 and MCP-1 production. On the other hand, the culture supernatant of WPMY-1 coincubated with *T. vaginalis* (=WPMY-1 conditioned medium) including IL-8 and MCP-1 induced increased migration of human neutrophil and monocyte (THP-1) compared with those of culture supernatant of WPMY-1 without trichomonads. In conclusion, it is suggested that *T. vaginalis* is able to induce inflammatory responses in prostate stroma via production of IL-8 and MCP-1.

P4.08.68
Do different T cell receptor sequences dictate the phenotype of memory CD8 T cells in the Toxoplasma gondii-infected brain?

***A. Sanecka**, E. Frickel;*
MRC, NIMR, London, United Kingdom.

The protozoan parasite *Toxoplasma gondii* is the most common parasitic infection in man. In immunocompetent hosts the acute phase of infection is generally asymptomatic and proceeds to the chronic phase, which is incurable and defined by tissue cyst formation preferably in the brain. The parasite poses a serious health threat to immunocompromised individuals, especially AIDS patients. IFNγ and CD8 T cells are essential for the control of chronic *Toxoplasma* infection.
We are defining how affinity of TCR-MHC interaction shapes the phenotype of memory CD8 T cells in the chronically *Toxoplasma*-infected brain. I am using CD8 T cells from three lines of transnuclear mice that harbour in its endogenous locus a different T cell receptor expressed on CD8 T cells specific for the same *Toxoplasma* antigenic epitope Rop7. Our preliminary data show that these three CD8 T cell clones have a distinct and fixed hierarchy in effector function e.g. in *ex vivo* cytokine production, proliferation capacity and ability to control acute phase *Toxoplasma* load in the peritoneum. With the unique tool, we will be able to show if trafficking, maintenance and effectiveness of CD8 T cells against *Toxoplasma* is dependent on their varying T cell receptor affinities. This research will advance the knowledge of control of *Toxoplasma* by CD8 T cells specifically and memory CD8 T cell in brain in general.

P4.08.69
Chagas'disease: evaluation of melatonin and lycopene influence on cytokines'profile during acute phase

***F. H. Santello**, M. D. Filipin, V. Brazão, M. A. Toldo, J. do Prado Júnior;*
College of Pharmaceutical Sciences of Ribeirão Preto (FCFRP), University of São Paulo, Ribeirão Preto, Brazil.

Inflammatory mediators and cytokines play important roles in the pathogenesis of a vast number of human illnesses, including Chagas disease. The antigens of *Trypanosoma cruzi* have the ability to induce an inhibitory/regulatory action over Th1 profile, as a strategy to maintain immune homeostasis. Lycopene, a carotenoid that is mainly present in tomato and its products, is an antioxidant, anticarcinogenic and antithrombotic activities, besides exerting an immunomodulatory effect reflected by enhanced levels of IL-2 and IL-4, T helper cell populations in healthy individuals. Melatonin is synthesized and secreted by pineal gland and is able to regulate the imbalance of cytokine network in some diseases. The modulation of cytokines, like CityIFN-γ, StateIL-10, IL-4, placeplaceCityTNF-α, placeIL-12 and IL-6, by melatonin in different models *in vivo* suggests a correlation between melatonin and the immune response. To characterize the immuno-modulatory effects of lycopene and melatonin, this research investigated intracellular cytokines production in $CD4^+$ and $CD8^+$ T lymphocytes. Animals were grouped: control, infected, melatonin infected and lycopene infected. Rats were i.p. infected with 1×10^5 blood trypomastigotes (Y strain) of *T. cruzi* and treated with melatonin (5 mg/kg) or lycopene (10mg/kg) daily, until 7^{th} day after infection and intracellular cytokines (IFN-γ, IL-10, IL-4, TNF-α) production were detected by flow cytometry. Melatonin treatment showed significant differences on IL-10 production and lycopene on TNF-α concentrations of $CD4^+$ lymphocytes, otherwise, $CD8^+$ T lymphocytes produced enhanced concentrations of IFN-γ. We conclude that melatonin and lycopene displayed immuno-enhancing effects in the intracellular cytokines production of distinct immune cell types.

P4.08.70
Increased levels of interleukin-4 (IL-4), interleukin-10 (IL-10) and IFN-γ in Iranian Visceral Leishmaniasis (VL) Children

***N. Seyfizadeh**, Z. Babaloo, M. Bonyadi, N. Seyfizadeh, N. Mirsamadi;*
Immunology Research Center, Tabriz, Iran.

Leishmaniasis is a disease caused by obligate intracellular parasites. Visceral leishmaniasis (VL) as a prevalent type of it is a public health threatening in developing world. Functional immunity to VL depends on cytokine profile. IFN-γ, major cytokine of TH_1, plays a crucial role in immune responses against leishmaniasis in the contrast with IL-4 and IL-10 activity. All active cases in the endemic area were children under 12 years old. Sera from VL patients of north-west area of Iran were analyzed for the concentration of IFN-γ (patients=23, controls=9), IL-4 (patients=26, control=9) and IL-10 (patients=26, control=9) by ELISA method and were studied TH_1/TH_2 paradigm via their associated signature cytokines. We detected circulating levels of IFN-γ in 23 patients (mean=40.57pg/ml) higher than control group (mean=7.18pg/ml) and also the results show increased concentrations of IL-4 in the sera of 26 patients (mean=72.92pg/ml) in comparison with control group (mean=33.28pg/ml).Results achieved from measurement of IL-10 serum levels showed 4 cases with very high IL-10 levels (case1=1512pg/ml, case2=2255pg/ml, case3=1713pg/ml, case4=2031pg/ml) and the mean IL-10 level in 22 patients (34.78pg/ml) was higher than control group (mean=9.37pg/ml, n=9). Accumulating evidence points toward an antagonism between TH_1 and TH_2 and also their associated cytokines in leishmaniasis. In the acute phase of VL, TH_2 responses are dominant and TH_1 cytokines are protective. Our findings suggest that the cytokine pattern in VL patients is not polarized and the profile of these cytokines is not characterized by the TH_2 phenotype as in mice. Although both TH_1 and TH_2 cells appear to have proliferated and be involved in host immune responses.

P4.08.71
Infection with Leishmania major induces a cellular stress response in tissue resident macrophages

A. C. Silva[1]*, A. A. Filardy*[1]*, C. M. Koeller*[1]*, K. G. Pinto*[1]*, M. Menezes Passos Diniz*[1]*, F. L. Ribeiro-Gomes*[2]*, M. F. Lopes*[1]*, C. G. Freire-de-Lima*[1]*, M. P. Nunes*[3]*, G. A. DosReis*[1]*;*
[1]Carlos Chagas Filho Institute of Biophysics, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil, [2]Laboratory of Parasitic Diseases, National Institute of Arthritis and Infectious Diseases, NIH, Bethesda, MD, United States, [3]Instituto Oswaldo Cruz, FIOCRUZ, Rio de Janeiro, Brazil.

We investigated early cellular responses induced in C57BL/6 (B6) macrophages by infection with *Leishmania major*. Infection activated the c-Jun NH2 -terminal kinase (JNK)/c-Jun/FasL cellular stress pathway in resident tissue macrophages, but not in inflammatory macrophages. In addition, infection triggered the secretion of a defined array of cytokines and chemokines, including IL-1ra, IL-6, TNF-α, TIMP-1, KC, MCP-1, MIP-1α, MIP-1β and MIP-2. Infection also increased secretion of metalloproteinases and soluble FasL. In spite of increased Fas and FasL expression, infected macrophages remained viable, as measured by a Lyzozyme release assay. As assessed in FasL deficient *gld* mutant B6 mice, neutrophil recruitment induced by infection did not depend on FasL expression. Moreover, inhibition of JNK, but not ERK, p38 or FasL, reversed *L. major* induction of KC by macrophages and also diminish parasite burden. Altogether, these data argue for a role of JNK in parasite survival and inflammatory responses following infection of resident macrophages.

P4.08.72
Identification of proteins in *Leishmania amazonensis* extract that may enhance the parasite infection

V. M. G. Silva[1]*, C. F. Araújo*[2]*, C. M. Andrade*[1]*, J. P. C. Cunha*[3]*, F. K. Marchini*[4]*, W. L. C. Santos*[2]*, L. C. P. Carvalho*[2]*;*
[1]Universidade Estadual do Sudoeste da Bahia, Jequié, Brazil, [2]Fundação Oswaldo Cruz, Salvador, Brazil, [3]Instituto Butantan, São Paulo, Brazil, [4]Fundação Oswaldo Cruz, Curitiba, Brazil.

Leishmania parasites secrete molecules that modulate the host immune system. The aim of this study was to purify, characterize and identify molecules with immunomodulatory activity in extracts of *Leishmania amazonensis* amastigotes (*La*E). The extract was subjected to electrophoresis in 12% polyacrylamide gel. Fractions with molecules with apparent molecular weights of 68, 45, 36 and 28 kDa were purified, based on previous results. BALB/c mice were injected intradermally with saline, *LaE* or fractions. After one week they were infected in the footpad with *L. braziliensis* promastigotes. The evolution of the lesions was monitored weekly, until six weeks after infection. The fractions of 68 and 28 kDa increased significantly the lesion. Parasite loads in the footpads were estimated by limiting dilution, and injection of the fractions of 28, 36 and 68 kDa produced results significantly different from the injection of saline. No statistically significant differences were observed between IL-4 and IL-10 concentrations in the supernatants from cultures of anti-CD3 - stimulated draining lymph nodes cells of fraction-injected and saline-injected animals. The proteins from these bands were digested in gel and the generated peptides were extracted and analyzed by mass spectrometry. Sixteen, 18, 18 and six proteins were identified in the fractions of 28, 36, 45 and 68 kDa, respectively. One of the identified proteins in the 36 kDa fraction was LACK, which has been shown to induce an infection-enhancing immune response in an elegant experiment using LACK-tolerant mice. No protein with reported immunomodulatory or infection-enhancing activities was identified in the other fractions.

P4.08.73
Theileria parva: Genotypic and antigenic diversity in buffalo and buffalo associated- cattle

T. Sitt[1]*, R. Pelle*[1]*, L. Steinaa*[1]*, W. Weir*[2]*, I. Morrison*[3]*, P. Toye*[1]*;*
[1]International Livestock Research Institute, Nairobi, Kenya, [2]University of Glasgow, College of Medical, Veterinary and Life Sciences, Glasgow, United Kingdom, [3]The Roslin Institute, University of Edinburgh, Edinburgh, United Kingdom.

Theileria parva causes East Coast fever and Corridor disease, diseases of economic importance in Africa. T. parva is an intracellular protozoal parasite transmitted via the tick vector, Rhipicephalus appendiculatus from buffalo to cattle and between cattle. However, most buffalo-derived infections in cattle are not transmissible by ticks. Current evidence suggests that buffalo-derived T. parva are genotypically more diverse than those maintained in cattle. Further analysis of genotypic and antigenic diversity of T. parva populations is required to develop a more complete understanding of immunity, potentially contributing to improvements on the current vaccine. Cattle that recover from clinical infection with T. parva exhibit a strong but strain-specific immunity, believed to be mediated predominantly by CD8 T lymphocytes. Ten T. parva CD8 T lymphocyte target antigens (Tp1 - Tp10) have been identified in immune cattle. The antigenic diversity of parasites was assessed in parasitized buffalo cell lines isolated from 32 naturally infected buffalo in Kenya, and buffalo and cattle in the Laikipia area of Kenya. Tp1 through Tp10 were analysed in the 32 buffalo. Results showed defined polymorphisms within Tp1 andTp2 epitope regions, but little to no variation within the Tp4, Tp5 or Tp8 epitope regions. Mini-, micro-satellite and 454 sequencing are being conducted on the field samples. Additionally, a vaccine trial using the infection and treatment method (ITM) of vaccination is being undertaken to determine its efficacy against buffalo-derived parasites. ITM vaccination involves inoculation of susceptible cattle with a cocktail three T. parva isolates, and simultaneous administration of long-acting oxytetracycline.

P4.08.74
Plasma cytokine as biomarker of cardiac morbidity in Chagas disease

G. R. Sousa[1]*, J. A. S. Gomes*[2]*, R. C. G. Fares*[3]*, M. P. S. Damásio*[4]*, A. T. Chaves*[3]*, N. I. Medeiros*[3]*, K. S. Ferreira*[2]*, M. P. Nunes*[1]*, R. Corrêa-Oliveira*[3]*, M. O. C. Rocha*[1]*;*
[1]Postgraduate Course of Infectious Diseases and Tropical Medicine, School of Medicine, Federal University of Minas Gerais, Belo Horizonte, Brazil, [2]Laboratory of Cell-Cell Interactions, Department of Morphology, Federal University of Minas Gerais, Belo Horizonte, Brazil, [3]René Rachou Research Center, FIOCRUZ, Belo Horizonte, Brazil, [4]Cell Signaling and Immunology Division, University of Dundee, Dundee, United Kingdom.

The present study was designed to determine if the expression of immunological markers in patients with different forms of Chagas disease is associated with determining factors of cardiac morbidity in this disease. Individuals infected with *Trypanosoma cruzi* were grouped as indeterminate (IND) and cardiac (CARD) patients ranging from 23 to 69 years of age (mean of 45.6 ±11.25). The IND group included 82 asymptomatic individuals with no significant alterations in electrocardiography, chest X-ray, and echocardiogram. The CARD group included 94 patients presenting dilated cardiomyopathy, characterized by dilated left ventricle with impaired ventricular systolic function. A total of 24 healthy individuals, ranging from 29 to 55 years of age (mean of 42.6 ±8.8), from a non-endemic area for Chagas disease and showing negative serological tests for the infection were included as a control group (NI). Data analysis demonstrated that IND patients have a higher intensity of IL-10 expression when compared with individuals in the other groups. By contrast, the forms of inflammatory cytokine expression, such as IFN-γ, TNF-α, IL-6, and IL-1β, proved to be the highest in the CARD group. Correlated analysis showed that high IL-10 expression was associated with better cardiac function, as determined by left ventricular ejection fraction and left ventricular diastolic diameter values. Altogether, these findings indicate that a fine balance between regulatory and inflammatory cytokines represents a key element in the establishment of distinct forms of Chagas disease. Furthermore, this study helped to shed light

on the complex cytokine network underlying the immunopathogenesis of chronic chagasic cardiopathy.

P4.08.75
A new highly sensible method for division of patients with different forms of Chagas disease according to cytokine production

G. R. Sousa[1], *J. A. S. Gomes*[2], *R. C. G. Fares*[3], *M. P. S. Damásio*[4], *A. T. Chaves*[3], *K. S. Ferreira*[2], *N. I. Medeiros*[3], *M. P. Nunes*[1], *R. Corrêa-Oliveira*[3], *M. O. C. Rocha*[1];
[1]*Postgraduate Course of Infectious Diseases and Tropical Medicine, School of Medicine, Federal University of Minas Gerais, Belo Horizonte, Brazil,* [2]*Laboratory of Cell-Cell Interactions, Department of Morphology, Federal University of Minas Gerais, Belo Horizonte, Brazil,* [3]*René Rachou Research Center, FIOCRUZ, Belo Horizonte, Brazil,* [4]*Cell Signaling and Immunology Division, University of Dundee, Dundee, United Kingdom.*

The aim of this work was to employ an alternative strategy in an attempt to establish the cut-off edge for a division of patients with different forms of Chagas disease according to cytokine production. A total of 176 patients with positive specific serology for Trypanosoma cruzi were enrolled in this study. In addition, 24 healthy individuals were also included within the control group. Detailed analysis of individual levels of IL-10, IFN-γ, TNF-α and IL-6 expression was obtained for the NI, IND, and CARD groups by Cytometric Bead Array immunoassay kit (BD Biosciences, USA). Data were acquired in a FACScalibur flow cytometer and the analyses were performed using BD CBA software. Sixty-nine percent of CARD patients were defined as high IFN-γ producers, whereas only 4.9% of IND patients presented this profile of IFN-γ expression ($p<0.001$). The CARD group showed 71.3% of high TNF-α producers, as compared to the IND group which was confined to the range established by cut-off points for low and medium TNF-α producers ($p<0.001$). Similar results were identified when analyzing the IL-6 levels in the evaluated groups, although to a lesser extent. A small proportion of IND patients presented high levels of IFN-γ, whereas the most of these patients 76% expressed high levels of IL-10. It is also possible that these patients with high levels of IFN-γ tend to be prone to developing cardiomyopathy in the near future. Furthermore, it is likely that immunoregulatory mechanisms are present in the disease that can strongly influence its clinical evolution.

P4.08.76
High IL-17 expression is correlated with better cardiac function in human Chagas disease

M. O. C. Rocha[1], ***G. R. Sousa***[1], *R. C. G. Fares*[2], *M. P. S. Damásio*[3], *A. T. Chaves*[2], *K. S. Ferreira*[4], *V. A. A. Valente*[4], *M. P. Nunes*[1], *J. A. S. Gomes*[4], *R. Corrêa-Oliveira*[2];
[1]*Postgraduate Course of Infectious Diseases and Tropical Medicine, School of Medicine, Federal University of Minas Gerais, Belo Horizonte, Brazil,* [2]*René Rachou Research Center, FIOCRUZ, Belo Horizonte, Brazil,* [3]*Cell Signaling and Immunology Division, University of Dundee, Dundee, United Kingdom,* [4]*Laboratory of Cell-Cell Interactions, Department of Morphology, Federal University of Minas Gerais, Belo Horizonte, Brazil.*

This study was designed to determine whether IL-17 expression can be correlated with patients' cardiac function. Individuals infected with Trypanosoma cruzi were grouped as indeterminate (IND) and cardiac (CARD) patients ranging from 23 to 69 years of age (mean of 45.6 ±11.25). The IND group included 82 asymptomatic individuals, with no significant alterations in electrocardiography, chest X-ray and echocardiogram. The CARD group included 94 patients presenting dilated cardiomyopathy. A total of 24 healthy individuals, ranging from 29 to 55 years of age, from a non-endemic area for Chagas disease and showing negative serological tests for the infection were included as a control group (NI). A Cytometric Bead Array (CBA) immunoassay kit - Human Th1/Th2/Th17 (BD Biosciences, USA) was used to measure the plasma levels of IL-17 as recommended by the manufacturer and described previously. Data were acquired in a FACScalibur flow cytometer and the analyses were performed using BD CBA software. The results revealed that IND group present a significantly higher plasma levels of IL-17, median of 12.8 ± 8.21, as compared to the CARD group, median of 5.715 ± 2.81 and the NI group, median of 5.44 ± 3.16 ($p<0.0001$). Correlative analysis showed that high IL-17 expression could be associated with better cardiac function, as determined by left ventricular ejection fraction and left ventricular diastolic diameter values ($r=0.878$ and $r=-0.8101$, $p<0.0001$, respectively). Taken together, the results of the present work corroborate with the protective role of IL-17 against cardiac damage in human Chagas disease.

P4.08.77
The effects of recombinant protein based on Trypanosoma cruzi P21-His6 treatment in infected mice with Leishmania amazonensis

C. M. Luise Junior, T. L. Teixeira, F. C. Machado, A. P. N. Quintal, ***M. A. Souza****, C. V. Silva;*
Universidade Federal de Uberlândia, Uberlandia, Brazil.

The cutaneous form of leishmaniasis is caused by the protozoan Leishmania amazonensis. This form of disease cause a lesion in the dermis characterized by a large inflammatory infiltrates composed, among others cell types, by macrophages infected with amastigotes forms inside a parasitophorous vacuole. P21 is a protein expressed in all forms of Trypanosoma cruzi. The recombinant protein based on the T. cruzi P21 (P21-His6) enhances phagocytosis on inflammatory macrophages. In this study we evaluate the effects of the treatment with P21-His6 on the site of lesion in BALB/c mice infected with L. amazonensis, and remove some aspects of the immune response of the hostage. The animals were divided in three groups: (1) Infected with L. amazonensis and not treated; (2) Infected with L. amazonensis and treated with 40µg of P21-His6 each 72 hours; and (3) Not infected and treated with 40µg of P21-His6 each 72 hours. The previous results showed a development of an inflammatory infiltrates in the group (3), composed by different cell types. The group (2) showed an increase of the inflammatory infiltrates and a large number of vacuoles and parasites internalized in comparison of group (1). The assays to measure the cytokines production, and the cell population residing in spleen tissue are being performed, to evaluate some aspects of the immune response against L. amazonensis in the presence of the P21-His6

P4.08.78
Recombinant human thrombopoietin inhibits the development of murine experimental cerebral malaria by decreasing the inflammatory response

X. Sun[1], *Y. Pan*[1], *W. Xu*[1], *J. Liu*[1], *H. Shang*[1], *L. Cui*[2], *Y. Cao*[1];
[1]*China Medical University, Shen Yang, China,* [2]*University of Pennsylvania, Philadelphia, PA, United States.*

Cerebral malaria (CM), a deadly complication of malaria, remains to be a very thorny problem for its relatively high mortality and long-term neurological sequelae for patients. Thrombopoietin (TPO), the primary hematopoietic growth factor responsible for platelet production, has been shown to mediate various extra- hematopoietic functions. In this study, for the first time we demonstrate that recombinant human TPO (rhTPO) prolongs the survival of mice in experimental cerebral malaria (ECM). rhTPO administered on day one post-infection maintained blood-brain barrier integrity and significantly prevented the activation of brain vascular endotheliocyte via the down-regulation of ICAM-1 and VCAM-1 expression. More importantly, we found that rhTPO inhibited the development of murine ECM through decreasing the inflammatory response both in the brain and spleen. In the brain, leukocyte accumulation, levels of $CD4^+$ and $CD8^+$ T cells, as well as inflammatory cytokines (TNF-α and IFN-γ) and chemokines (CXCL9 and CXCL10) mRNA levels were down-regulated by rhTPO. In the spleen, rhTPO treatment reduced the Th1-type immune response, concomitant with decreased mDC proportion as well as DC maturation and activation, but conversely the proportion of Tregs increased. However, these effects were not accompanied by elevation of parasitemia, platelet and erythrocyte counts. These data provide the first evidence of protection against

murine ECM by rhTPO and hint to the mechanisms involved, offering a new theoretical basis for the treatment of CM patients.

P4.08.79
Patients with visceral leishmaniasis present an increased expression of TLR2 and TLR4 in lymphocytes and lipid and protein changes

*M. Gatto[1], M. M. Abreu[1], M. A. Golin[1], J. C. Simão[2], **K. I. Tasca**[1], L. Gollino[1], C. M. C. B. Fortaleza[1], P. C. M. Pereira[1], S. A. Calvi[1];*
[1]UNESP, Botucatu, Brazil, [2]Manoel de Abreu Hospital, Bauru, Brazil.

In order to have the development of adaptive immune response in visceral leishmaniasis is necessary that cellular receptors such as TLR2 and TLR4 recognize and play the parasite effector mechanisms. Moreover, the nutritional profile also has impact on immune response. Our objective was to evaluate the expression of TLR2 and TLR4 in CD14 and CD3 cells and correlate with nutritional status in patients with visceral leishmaniasis, pre and post-treatment. Were evaluated 8 patients pre-treatment, 3 post-treatment and 8 healthy subjects. Analysis of the expression of TLR2 and TLR4 receptors on CD3 and CD14 cells was performed by flow cytometry and the nutritional profile was performed by bioelectrical impedance and biochemical tests. In CD3 cells, expression of TLR2 was higher in patients pre-treatment than those post-treatment ($p < 0.05$) and controls ($p < 0.05$); TLR4 expression was higher in pre-treatment compared to controls ($p < 0.05$). In CD14 cells, TLR2 expression was lower in pre-treatment compared to controls ($p < 0.05$) and TLR4 expression did not differ between groups. Levels of HDL and albumin were lower in pre-treatment compared to post-treatment ($p < 0.05$) and controls ($p < 0.05$), phase angle was lower in pre-treatment than those post-treatment ($p < 0.05$) and triglycerides were higher in pre-treatment compared to controls ($p < 0.05$). Our results suggest that patients with LV activates expressed primarily TLR2 and TLR4 in lymphocytes, suggesting a possible involvement of these receptors in the development of the immune response. Patients also showed nutritional changes that could be interfering with the immune response against the parasite.

P4.08.80
Xanthine oxidase and inducible NOSynthase stress failed to efficiently suppress Leishmania major in BALB/c bone marrow dendritic cells

***N. Tounsi**[1], S. Meghari[2], M. Moser[2], B. Djerdjouri[1];*
[1]University of sciences and technology Houari Boumedienne, Alger, Algeria, [2]Université Libre de Bruxelles, Gosselies, Belgium.

Dendritic cells play a critical role in the initiation of immune response against Leishmania parasites. Moreover, phagocytes-dependent reactive oxygen species (ROS) and nitric oxide (NO) are potent leishmanicidal agents.
This study was performed with BALB/c mice bone marrow dendritic cells (BMDC) differentiated by 20 ng/ml GM-CSF for 8 days. BMDC were infected (1/10: cell/parasite) for 6 h and 24 h with a local strain of Leishmania major LIPA35 promastigotes (MHOM/DZ/06/LIPA35, Institut Pasteur Alger). The parasite load (percentage and index of DCs infection: Parasites number/DCs) was assayed on cytospin slides stained with May Grunwald Giemsa. Nitric oxide levels were determined in cultures supernatants, using Griess reaction. The cells were collected and used for the determination of xanthine oxidase (XO) by the uric acid assay.
Our results showed that Leishmania major enhanced XO activity by 76% ($P < 0.05$) and 235% ($P < 0.001$), respectively at hours 6 and 24, compared to control. Leishmania infection increased the nitrites levels by 52% ($P < 0.01$) only at 24h post infection compared to control DCs. In parallel, Leishmania major infected DCs by 50.33 ±3.05 at 6h vs. 47.66± 4.16 at 24h with an index of infection 2.39 ±0.33 vs. 2.47± 0.16, respectively.
In conclusion, these results suggested that oxidative stress via increasing xanthine oxidase activity and iNOS up regulation impaired Leishmania major killing by BMDC.

P4.08.81
Leishmania-reactive CD3+CD4-CD8- (Double negative) T cells display functional characteristics of memory T cells and protect against secondary challenge

*Z. Mou, I. Okwor, D. Liu, **J. E. Uzonna**;*
University of Manitoba, Winnipeg, MB, Canada.

Although it is generally believed that $CD4^+$ T cells play important role in anti-*Leishmania* immunity, some studies suggest that $CD4^+$ T cells may be dispensable and MHC II-restricted $CD4^-CD8^-$ T cells may be more important in regulating anti-*Leishmania* immunity. Indeed, several studies have reported the expansion of $CD3^+CD4^-CD8^-$ (double negative, DN) cells in the blood of *Leishmania*-infected patients and dogs, and in spleens of *Leishmania*-infected mice. Although these cells have been proposed to contribute anti-*Leishmania* immunity, concrete evidence demonstrating this function has not yet been documented. Here, we report that DN cells are strongly activated, proliferate and produce IFN-gamma in the draining lymph nodes and spleens of mice following primary *L. major* challenge. Furthermore, we demonstrate that DN cells from mice that healed their primary *L. major* infection display functional characteristics of protective anti-*Leishmania* memory-like cells: they rapidly and extensively proliferate and produce IFN-gamma in response to *L. major* challenge *in vitro* and *in vivo*. These cells express predominantly alpha-beta T cell receptor (TCR) and are restricted by MHC class II molecules. Moreover, DN cells from healed mice, (but not from naïve mice), control parasite growth in infected macrophages *in vitro*. Using *in vivo* depletion and adoptive transfer studies, we show that DN cells from mice previously infected with *L. major* contribute to optimal secondary anti-*Leishmania* immunity in mice. Collectively, these results provide concrete evidence that $CD3^+CD4^-CD8^-$ cells play a role in both primary and secondary (memory) anti-*Leishmania* immunity.

P4.08.82
Molecular characterization T. gondii atypical strains isolated from pregnant women and their neonates in Southern Brazil

***R. S. Vaz**[1], V. T. Soccol[2];*
[1]Faculdades Pequeno Príncipe, Curitiba - Paraná, Brazil,
[2]Universidade Federal do paraná, Curitiba - Paraná, Brazil.

Toxoplasma gondii is a protozoan parasite that shows ability to modulate the immune system in diferent ways. Toxoplasmic infection are of clinical importance in immunocompromised patients and pregnant women. There are few described clonal genotypes (I, II and III) seem to be responsible for the majority of toxoplasmic infections. Surface antigen 2 gene (SAG2) has been vastly used to determine genotyping T. gondii isolates. In northern hemisphere countries, human disease causing isolates are mainly type II or III, whereas T. gondii isolates from Brazil are mainly type-I, specially related to congenital toxoplasmosis. Information about the prevalent T. gondii genotypes in Brazil (southern regions) and other South-American countries mostly refers to animals. In this study we report genetic characterization of atypical T. gondii isolates obtained from clinical samples of pregnant women and their neonates. All the samples analyzed corresponded to SAG2 type I isolates, differing clinically from other T. gondii strains isolated in northern hemisphere countries. Our results indicate that further studies to define the prevalence of T. gondii are of outmost importance to better comprehend clinical causes of congenital toxoplasmosis in Brazil and neighboring countries.

P4.08.83
Unusual T. gondii strains associated to congenital toxoplasmosis

***R. S. Vaz**[1], V. T. Soccol[2];*
[1]Faculdades Pequeno Príncipe, Curitiba - Paraná, Brazil,
[2]Universidade Federal do Paraná, Curitiba - Paraná, Brazil.

Congenital toxoplasmosis may lead to several risk factors to pregnant women; as well as to the foetus. Parasitological direct methods and Toxoplasma gondii isolation in vivo and in vitro, constitute an option

to diagnostic determination of this disease. All biological samples were obtained from pregnant women (n= 24) selected through their clinical and immunological status. The analytic methods chosen were: direct observation of amniotic fluid samples, intraperitoneal inoculation of mice, cell culture inoculation and histopathological analysis of placenta, genotype definition through RFLP-PCR. Tachyzoites were observed both in free and intracellular forms during direct parasitological method, in all amniotic fluid and placenta samples. Parasites were also observed in peritoneal exsudate from inoculated mice since the 10th intraperitoneal passage, with a mantainance period of 55 passages. Cerebral cysts were seen in one animal that showed neurological distresss. All T. gondii strains were characterized as genotype-I (atypical strains). During in vitro isolation an average concentration of tachyzoites (222 tachyzoites/mL) in a mean time of 16,7 days was obtained, and during mantainance growth period the average was 1X106 parasites/mL (5 - 6 months). The growth (multiplication) period occurred between 5 -12 months, with a initial average concentration of 6,15 1X107 parasites/mL. Significative histopathological alterations were seen in placental samples. The results obtained in this study revealed that isolated T. gondii strains were atypical both clinically as well as in cell culture and in vivo models.

P4.08.84
Serological prevalence of Toxoplasma gondii antibodies in pregnant women from Southern Brazil

R. S. Vaz, ***R. S. Vaz****;*
Faculdades Pequeno Príncipe, Curitiba - Paraná, Brazil.

The assessment of gestational toxoplasmosis is complex and requires interdisciplinary teams working toward better clinical follow-up, laboratory diagnosis, and treatment. It is essential to observe the clinical and laboratory parameters of pregnant women from the prenatal period to the postnatal period. To determine which diagnostic method(s) is safer; this must constitute the basis of an algorithm for clinical and laboratory-based decision making in monitoring pregnant women. The aims of the present work were to determine the seroprevalence of anti- T. gondii antibodies among pregnant women served by the Health Units of the public service system in the city of Curitiba, Brazil and evaluate the serological profile of that population. 20,389 women showing positive pregnancy tests were included in a serological evaluation of toxoplasmosis prevalence using automated immunoenzymatic assays. Serum samples were tested for the presence of IgG and/or IgM antibodies. Overall, 53.03% of the women were positive for IgG and 3.26% were positive for IgM; the analysis used a chi-square adherence test and significance level of 0.05 (χ2=14,720.35; p=0.00). To discriminate between recent and past infection, IgG avidity tests (n=166) were carried out, of which 28.3% (n=47)presented low avidity. The seroconversion index observed in this study was 0.44%. Seroprevalence results obtained were similar to other regions of Brazil. These data demonstrate the importance of continuous regional and national seroepidemiological inquiries to define public health strategies that can revert and reduce serological prevalence, as described in other countries where toxoplasmosis monitoring is mandatory.

P4.08.85
Congenital Toxoplasmosis: Current Brazilian public health policy

R. S. Vaz*;*
Faculdades Pequeno Príncipe, Curitiba - Paraná, Brazil.

Toxoplasmosis is caused by the protozoan parasite, Toxoplasma gondii. In pregnant women, the prenatal diagnosis should be made as early as possible, so that therapy may be applied to reduce parasitemia and avoid transplacental infection. Despite the high prevalence of infected individuals around the world (20-90%). In Brazil, seroprevalence may vary between 40% and > 80%, reflecting a significant disparity between the public health policies and resources applied in the different regions of the country and the human development index (HDI) of each of them. The lack of consistent and periodical data on seroprevalence per region makes it difficult to understand the significance of this infection and to plan specific public health policies and strategies. Regarding basic and clinical research, toxoplasmosis is not a priority if compared to the allocation of government funds and incentives to other tropical illnesses, such as: Chagas disease, Leishmaniasis, Dengue fever. There are also few study groups in Brazil that focus in this basic area, for genomics and proteomics studies of T. gondii strains-for the design of new methods of diagnosis, antiparasitic drugs and a vaccine model for humans and animals. This study highlights taxonomic and epidemiologic aspects, diagnosis methods, treatment and technical-scientific aspects of Toxoplasma gondii and toxoplasmosis in the Brazilian context.

P4.08.86
Effect of *Leishmania mexicana* amastigotes in the regulation of L-arginine metabolism in classically and alternatively activated macrophages

A. A. Wilkins-Rodríguez*, A. R. Escalona-Montaño, M. Aguirre-García, L. Gutiérrez-Kobeh;*
Universidad Nacional Autónoma de México, México, D.F., Mexico.

Macrophages are decisive effector cells that either kill or host intracellular amastigotes of *Leishmania* depending on the balance of two inducible enzymes, nitric oxide synthase 2 (iNOS) and arginase 1 (Arg-1). These two enzymes share a common substrate, L-arginine, and are competitively regulated by Th1 or Th2 cytokines during macrophage activation. In classically activated macrophages (CAMφ), Th1 cytokines induce the expression and function of iNOS, which oxidizes L-arginine into the leishmaniacidal metabolite nitric oxide (NO). In alternatively activated macrophages (AAMφ), Th2 cytokines induce the expression and function of Arg-1, which hydrolyzes L-arginine into L-ornithine, an amino acid that is a basic source for polyamine synthesis, being these vital for *Leishmania* intracellular development. In the present work, we analyzed the effect of *Leishmania mexicana* amastigotes in the regulation of L-arginine metabolism in murine CAMφ and AAMφ. Bone marrow macrophages were differentiated with M-CSF, infected with *L. mexicana* amastigotes, and classically or alternatively activated with TNF-α+IFN-γ or IL-4, respectively. The enzymatic activities and changes in protein synthesis of iNOS and Arg-1, as well as parasite burdens were determined in both types of macrophages. In CAMφ there were a high iNOS activity and protein synthesis, which increased as a result of the infection with *L. mexicana* amastigotes. On the other hand, in AAMφ a high Arg-1 activity and protein synthesis were detected, which increased with the infection with *L. mexicana* amastigotes. Regarding to parasite burdens, classical activation of macrophages resulted in significant control of *L. mexicana* amastigotes growth, while alternative activation exacerbated it.

P4.08.87
B-1 cells increase susceptibility to murine viscetal leishmaniasis

V. Xavier*[1], B. C. Vivanco[1], W. F. K. M. Gonzaga[1], C. L. Barbieri[1], J. D. Lopes[1], P. Xander[2];*
[1]Federal University of São Paulo, São Paulo, Brazil, [2]Federal University of São Paulo, Diadema, Brazil.

B-1 cells are a subtype of B lymphocytes whose biological role in immunity is not completely elucidated. In this study we investigated the role of B-1 cells in the pathogenesis of visceral leishmaniasis. Experiments were performed with BALB/c, BALB/Xid or BALB/Xid mice that receive adoptively peritoneal B-1 lymphocytes. These groups were infected or uninfected with *Leishmania (Leishmania) chagasi*. Our results showed that BALB/Xid mice, a mouse strain deprived of B-1 cells, infected for 45 days with *L. (L.) chagasi* had a significant reduction in parasite load in the spleen ($0.63 \times 10^7 \pm 0.4$ parasites/mg tissue) when compared to control animals BALB/c ($1.87 \times 10^7 \pm 0.6$ parasites/mg of tissue) or BALB/Xid that received adoptive transfer of B-1 cells ($1.44 \times 10^7 \pm 0.5$ parasites/mg tissue). Flow cytometry analysis demonstrated changes in peritoneal B-1 cell population. Infected BALB/c mice showed a significant increase in the percentage of peritoneal B-1 cells (70.0% ± 1.50) compared to control (63.3% ± 1.88). On the other hand, BALB/Xid that received adoptive transfer of B-1 cells and were infected with *L. (L.) chagasi* showed a significant decrease in the percentage of peritoneal B-1 cells (6.14 ±

3.01%) when compared to uninfected group (25.48 ± 7.60%). The cytokines production was evaluated in supernatants from spleen homogenates of uninfected and infected mice. BALB/Xid that received adoptive transfer of B-1 cells and were infected with parasite had significant higher levels of IL-10 and IFN-γ when compared with unifected mice.

P4.09.01
Comparison of population structure of Plasmodium vivax currently circulating in Sri Lanka and of that a decade ago based on diversity of four selected antigen encoding loci

A. D. D. S. Amarasekara[1]*, T. Wickramaarchchi*[1]*, L. Gunarathna*[2]*, A. Escalante*[3]*, P. V. Udagama*[1]*;*
[1]Department of Zoology, Faculty of Science, University of Colombo, Colombo 03, Sri Lanka, [2]Department of Plant Sciences, Faculty of Science, University of Colombo, Colombo 03, Sri Lanka, [3]3Center for Evolutionary Medicine & Informatics, The Biodesing Institute, Arizona State University,Tempe, Arizona, AZ, United States.

As Sri Lanka achieved malaria pre-elimination status in 2008, understanding population genetic structure of current and previous local Plasmodium vivax isolates is important to (i) examine the degree of genetic isolation of these populations, and (ii) ascertain whether subsequent outbreaks would be due to residual transmission or due to introduction of new parasite strains to the parasite population.
Sequences of four polymorphic antigen encoding loci of P. vivax isolates collected a decade ago were retrieved from the Genebank (pvmsp3α: N=17; pvdbp, pvmsp1 and pvcsp:N=30). PCR amplification and sequencing of these four loci were carried out using 16 isolates collected recently (2011-2012). DNasp 5.1 software was used to examine the expected heterozygocity (He) and the genetic differentiation (Fst), to draw comparison of current and previous population genetic structures.
Low mean He in the current P. vivax population (He=0.76) compared with previous population (He=0.92) was observed for all four genes. Genetic differentiation amongst the two test populations was highest in pvmsp3α (Fst=0.20719), moderate in pvdbp (Fst=0.06785) and was absent in pvmsp1 and pvcsp (Fst= - 0.02876, Fst= - 0.01103). Though a low degree of overlap of amino acid haplotypes of these four proteins was observed between current and previous populations, most current haplotypes were novel. Thus these results suggest the possibility that new P. vivax variants have been introduced to the island; however, residual transmission of alleles that were not previously detected cannot be ruled out.
Financial support by the Asia Pacific Malaria Elimination Network (APMEN) is acknowledged.

P4.09.02
Targeting a *Plasmodium vivax* merozoite surface protein 1 fragment to the DEC205$^+$ dendritic cell population elicits strong antibody and T cell responses.

K. N. S. Amorim*, M. M. Yamamoto, S. B. Boscardin;*
Universidade de São Paulo, São Paulo, Brazil.

Dendritic cells (DCs) are critical in the interaction between the innate and adaptive immune systems, as they are able to process and present antigens to T and B cells. In the last decade, studies from several groups have shown that it is possible to target antigens directly to different DC populations using monoclonal antibodies (mAbs) to receptors present on the DC surface fused with the antigen of interest. An anti-DEC205 mAb has been used successfully to target antigens to the DEC205$^+$CD8$^+$ DC population. The administration of low doses of the fusion mAb together with DC maturation stimuli is able to activate antigen-specific T cells and induce production of high antibody titers. Here we genetically fused the DEC205 mAb with the 42kDa fragment derived from the *Plasmodium vivax* merozoite surface protein 1 (MSP1), a candidate vaccine for malaria. During *Plasmodium* invasion into the red blood cell, the 42kDa fragment is further cleaved into 33 and 19 kDa fragments. The 19kDa fragment is normally target for antibody response while the T cell epitopes are restricted to the 33kDa portion of the molecule. The administration of two doses of the DEC-MSP1$_{42}$ fusion mAb in the presence of the TLR3 agonist poly I:C to either C57BL/6 or C57B10.A mice induced high anti-MSP1$_{19}$ antibody titers in the immunized mice. We also detected strong T cell immunity against a peptide present in the MSP1$_{33}$ sequence. Overall, our results indicate that targeting a *Plasmodium vivax* antigen to the DEC205$^+$CD8$^+$ DC population improves B and T cell responses.

P4.09.03
T Regulatory cell function in Lethal Plasmodium berghei ANKA and Non-Lethal Plasmodium yoelii infection: Role of Th17

A. Bhattacharyya*;*
University of Calcutta, Kolkata, India.

The outcome of malaria infection is determined, in part, by the balance of pro-inflammatory and regulatory immune responses. Host immune responses in disease including malaria are finely regulated by the opposing effects of Th17 and T regulatory (Treg) cells. Here we have examined the role of Treg cells and Th17 cells during malaria infection and find that low levels of Treg cells influence the outcome of infections with the lethal strain of Plasmodium berghei ANKA (PbA). In contrast, we observed that possibly high level of Treg cells influencing the outcome of non lethal Plasmodium yoelii (P. yoelii) infections. We observed decreased expressions of TGF-β, CD4IL-2 and IL-10 during PbA infection, whereas expression remains high during P. yoelii infection. On the other hand TNF-α, IL-6, IFN-γ and IL-23 expression is high during PbA infection and lower during P. yoelii infection. In combination with functional studies, we posit that Treg may convert to Th17 during PbA infection whereas; Th17 initially high during P. yoelii infection possibly converts to Treg cells. Thus, results from this study suggest that the critical balance between Treg and Th17 might have a key role on host pathogenesis during malaria infection.

P4.09.04
Systems immunology approach to identify the molecular profile of T cells during *Plasmodium* mono and mixed infections

J. G. Burel*, S. H. Apte, J. M. McCarthy, D. L. Doolan;*
Queensland Institute of Medical Research, Brisbane, Australia.

Despite intense research for many decades, the mechanisms of protective immunity against malaria are poorly understood and there is no immune correlate of protection. Recent technological developments provide an opportunity to characterize, at the molecular level, how the *Plasmodium sp.* parasite modulates the host immune response to infection or exert cross-species regulatory effects. Accordingly, we are applying cutting-edge systems immunology approaches to a unique resource of experimental infections in humans to define T-cell molecular profiles associated with *P. falciparum* or *P. vivax* blood stage mono or mixed infection. We are assessing the host-parasite interaction at transcriptional, translational and post-translational levels by investigating messenger and micro RNA expression, cytokine secretion and phenotype of key T cell subpopulations, as well as phosphorylation status of transcription factors involved in immune regulation using PCR arrays, multiparameter and phospho-specific flow cytometry. We hypothesize that the combination of these datasets will identify molecular signatures associated with species-specific immune protection and signatures of cross-species regulation occurring during mixed infections. To date we have identified a specific set of microRNAs expressed in the peripheral blood early post-infection with *P. falciparum,* a species-specific signature for phenotype and phosphorylation status of STATs in T cells during acute infection, and a high degree of polyfunctionality and increased frequency of *P. falciparum* circulating antigen-specific T cells during convalescence. Ultimately, it is anticipated that our studies will shed light on the mechanisms of protective immunity, define robust correlates of T-cell mediated protection against malaria and facilitate the development of a universal malaria vaccine.

P4.09.05
Immunogenicity and efficacy of Plasmodium falciparum MSP3-based immunogens in Saimiri sciureus monkeys

*C. Bianco-Jr[1], P. H. Castro[2], C. Faro[2], F. A. Alves[1], P. Druilhe[3], C. T. Daniel-Ribeiro[1], **L. J. M. Carvalho**[1];*
[1]Laboratory of Malaria Research, Department of Immunology, Instituto Oswaldo Cruz/Fiocruz, Rio de Janeiro, Brazil, [2]National Primate Center - SVS, Belem, Brazil, [3]Vac4All, Paris, France.

Three recombinant protein constructions derived from the merozoite surface protein-3 (MSP3) from Plasmodium falciparum were evaluated for immunogenicity and efficacy against a blood stage challenge in Saimiri sciureus, a WHO-recommended non-human primate model for malaria. Each recombinant protein was formulated in Montanide ISA720 adjuvant and 15µg of the protein injected subcutaneously. Animals received three shots at 4-week intervals. Blood was sampled three weeks after each immunization and antigen-specific antibody titres were measured by ELISA and immunoblot. The non-splenectomized monkeys were challenged intravenously with $2x10^8$ P. falciparum (FUP strain) parasitized red blood cells five weeks after the third immunization. One of the recombinant proteins tested induced a consistent antibody response, with high titers being achieved especially after the third shot. Although all the challenged animals became parasitized, the immunized monkeys showed lower parasitemias compared to monkeys receiving the adjuvant only. All animals cured the infection spontaneously by the third week post-inoculation. The infection induced a potent boost in the anti-MSP3 antibody response in the immunized animals. The results of the experiments with the other two immunogens are currently being analyzed.

P4.09.06
The response of P2X7 deficient and competent immune cells to Plasmodium chabaudi AS infection in chimeric mice

***A. A. Cassado**;*
Institute of Biomedical Sciences, São Paulo, Brazil.

The immune response against the malaria has to be relatedwithboth, protection against infection and pathologic damage to the host. P2X7 receptor is responsible for ATP recognition by immune cells, which promotes inflammassome activation and induces proinflammatory cytokine production and cell death.Our group showed that P2X7 deficient mice were more susceptible than C57BL/6 mice to Plasmodium chabaudi AS infection. Then, ATP released by infected erytrocytes could be an important mechanism to activate the innate immune response. To evaluate the effects of P2X7 in the immune cells specifically and intrinsicly in response to uniform levels of parasitemia we used chimeric mice, ruling out any influence of P2X7 expressed on non-immune cells, what could change the millieu and modify the immune responses. For chimera construction, bone marrow from P2X7-/- donor mice was harvested and injected i.v. into non-lethally irradiated C57BL/6 mice. Blood and splenic monocytes and T-cells are reconstituted as expected (40-45%), while donor cells replaced most B-cells (80%). The basal activation of phagocytes and T-cells is lower on donor compared with recipient cells. P. chabaudi AS infection induced a higher activation on phagocytes from recipient then donor mice at day 8 post-infection. In contrast, CD8-T-cells from donor mice showed the higher activation profile, suggesting a delay on their activation process. Infection also induced an enhancement in 7AAD+ donor cell frequencies, but not in the recipient counterparts. These data suggest that the expression of P2X7 on immune cells is important for their activation during P.chabaudi infection.

P4.09.07
$CD4^+$ T cell promote B cell polyclonal activation in an ICOS-dependent manner during*Plasmodium chabaudi* infection

***S. I. Castillo-Méndez**[1], S. M. Muxel[2], E. P. Amaral[1], C. A. Zago[1], É. Salles[1], L. R. Sardinha[3], N. O. Câmara[1], E. Faquim-Mauro[4], J. M. Álvarez[1], M. R. D´Império Lima[1];*
[1]Institute of Biomedical Science, São Paulo, Brazil, [2]Institute of Bioscience, São Paulo, Brazil, [3]Albert Einstein Hospital, São Paulo, Brazil, [4]Butantan Institute, São Paulo, Brazil.

B cell and antibody response are crucial for protective immunity to blood-stage malaria infections. The early B cell response to *Plasmodium chabaudi* results in intense production of parasite-specific low-affinity IgM and IgG and autoantibodies. According to our results, in the acute phase of the disease, T-B cell cooperation through the MHC class II molecules is essential for B cell activation, proliferation and for antibody production. The $CD4^+$ T cell population involved in the polyclonal B cell activation shows a huge increase of ICOS and OX40 molecules. $CD4^+$ T cells from acute infection also express high levels of CXCR4 but low levels of CXCR5, suggesting that T-B cell interaction occurs in the extra-follicular areas of the spleen. However, with time, the levels of CXCR5 and PD1 on the $CD4^+$ T cells increase, showing characteristics of T_{FH} cells. Moreover, PD1 expression is higher on germinal center T_{FH} than T_{FH} $GL7^-$. Our *in vitro* assays show that T cells from the acute infection are potent helpers for naïve B cells in the presence of iRBC. The IgM and IgG production contribute not only to the uptake of the iRBC exposed to phagocytes, but also to the uptake of BCG mycobacterium. In addition, our results show that during the acute infection $CD4^+ICOS^{HIGH}$ T cells are responsible for polyclonal B cell activation *in vitro* in the presence of iRBC. Our results suggest that the cooperation between conventional $CD4^+$ T cells and B cells has a central role in the polyclonal antibody response to *P. chabaudi.*

P4.09.08
Nitric oxide but not cytokine production by macrophages stimulated with malaria hemozoin is dependent on Nod2 activation

***Y. Corbett**[1], N. Basilico[2], S. Parapini[1], S. D'Alessandro[1], D. Scaccabarozzi[1], B. Rocca[3], K. Fitzgerald[3], D. Golenbock[3], D. Taramelli[1];*
[1]Dipartimento di Scienze Farmacologiche e Biomolecolari, Università degli Studi di Milano, Milan, Italy, [2]Dipartimento di Scienze Biomediche, Chirurgiche ed Odontoiatriche, Università degli Studi di Milano, Milan, Italy, [3]University of Massachusetts Medical School, Division of Infectious Diseases, Worcester, MA, United States.

Hemozoin (Hz) is the detoxification product of heme, released into the circulation during malaria infection. Once phagocytized by host cells, it induces several immune responses, and it is known to synergize with IFN-ɣ to produce Nitric Oxide (NO). The precise signaling leading to NO production has not been elucidated, yet. Nod1/Nod2 are intracellular receptors that have been related to the innate immune response to protozoa parasites including malaria. In the present study, we provide first evidence of the activation of Nod2 using immortalized BM derived macrophages from wild type (BM-Wt) or Nod-2 knock-out Balb/c mice. We observed that BM-Wt stimulation with whole *P. falciparum* infected red blood cells (W-IRBC) or lysates (LY-IRBC) induced higher amount of NO in IFN-ɣ pre-treated compared to non-treated cells. The response was dependent on Nod2. Similarly, IFN-ɣ pre-treatment increased NO production induced by Hz and this was also dependent on the Nod2-Rip2-Card9 signaling pathway and on the activity of iNOS, since in the presence of Apigenin, iNOS inhibitor, NO was impaired. Moreover, immunofluorescence staining showed Nod2 involvement in IFN-γ-primed macrophages stimulated with Hz. mRNA of several cytokines measured by quantitative real-time PCR in non-IFN-γ primed BM treated with Hz was found to be upregulated, but independent from Nod2. The data presented here suggest that parasite products, specifically native Hz, activate Nod2 via Rip2 and Card9 for the production of NO, upon priming with IFN-γ, but not for cytokine production. The relevance for malaria immunity and pathogenesis is discussed.

P4.09.09

High levels of heme correlate with severe malaria pathology and morbidity in patients from endemic areas in India

E. Dalko[1,2], *A. Panda*[3], *F. Herbert*[1], *R. Tripath*[3], *B. Ravindran*[4], *S. Sharma*[5], *B. Das*[3], *S. Pied*[1];
[1]*Institut Pasteur de Lille, Lille, France,* [2]*Université du Québec à Montréal, Montréal, QC, Canada,* [3]*Shri Ramachandra Bhanj Medical College, Cuttack, India,* [4]*Institute of Life Sciences, Bhubaneshwar, India,* [5]*Department of Biological Sciences, Tata Institute of Fundamental Research, Mumbai, India.*

The hemolysis occurring during malaria is characterized by the release of large amounts of heme, a pro-oxidant and immunomodulatory molecule. Previous studies have shown the implication of heme in the induction of experimental cerebral malaria, but its impact in the genesis of severe forms of human malaria remains unclear. Herein, we measured the levels of heme by a colorimetric reaction in the serum of uninfected and *Plasmodium falciparum*-infected patients from Orissa (India), an endemic area for malaria. *P. falciparum*-infected patients showed a panel of clinical phenotypes of the disease, ranging from uncomplicated to multi-organ dysfunctions associated to cerebral malaria. In order to estimate the trend of the immune response, the levels of 26 chemokines/cytokines were measured by flow cytometry. Our data show that heme concentrations are positively associated with the severity of the disease. However, heme levels were higher in the serum of severe non-cerebral forms of malaria when compared to cerebral outcomes. In addition, heme levels positively correlated to the concentration of pro- and anti-inflammatory cytokines, suggesting its implication in the induction of a complex immune response. When only considering severe forms of malaria, heme levels positively correlated to IL-10 concentrations. Thus, heme might favor a deleterious inflammatory environment within the host in the context of *P. falciparum* infections, but might also induce an anti-inflammatory response that would protect against cerebral forms of malaria. In this context, we suspect that host variability in heme scavenging/degrading protein activity or their concentrations may influence the susceptibility to severe malaria.

P4.09.11

Cellular cytokine and chemokine responses associated with susceptibility to severe malaria in children in Papua New Guinea

D. Stanisic[1], *J. Cutts*[1], ***E. Eriksson***[1], *F. Fowkes*[2], *J. Taraika*[3], *M. Laman*[3], *L. Manning*[4], *T. Davis*[4], *I. Mueller*[1], *L. Schofield*[1];
[1]*Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia,* [2]*Burnet Institute, Melbourne, Australia,* [3]*Papua New Guinea Institute of Medical Research, Madang, Papua New Guinea,* [4]*The University of Western Australia, Fremantle, Australia.*

Severe life-threatening malaria is associated with high serum levels of pro-inflammatory cytokines upon presentation. However, to date cellular responses have not been evaluated in relation to disease risk. Therefore we analyzed cellular cytokine and chemokine responses in children with severe malaria (SM; n=201), uncomplicated malaria (UM; n=172) and healthy community controls (HC; n=162) following short-term stimulation with live P. falciparum infected red blood cells in vitro. The samples from infected children were collected during convalescence to ensure normalization of peripheral cellular composition. Cytokine and chemokine outputs and cellular phenotypes were measured by ELISA, fluorescent bead assays and flow cytometry.
Compared to HC and UM, children with severe malaria had significantly higher IL-10, IP-10, MIP-1β and MCP-2 responses ($p \leq 0.05$). The median TNF and MIP-1α were also significantly higher in the severe malaria group compared to the UM group (p=0.0006 and p=0.0005 respectively). In addition, IL-10, IL-6, MIP-1α MIP-1β and MCP-2 was associated with increased odds of severe malaria (OR 1.01-5.74, $p< 0.05$). Furthermore, it was demonstrated that TNF, MIP-1β and MIP-1α were predominantly produced by monocytes and γδ T cells and IL-10 by CD4+ T cells.
The data indicate that production of high amounts of specific cytokines and chemokines in response to P. falciparum by monocytes and γδ T cells is a risk factor for severe malaria.

P4.09.12

Sexual hormones are involved in oxidative stress in mice infected with *P. berghei* ANKA

M. Legorreta-Herrera*, N. A. Mosqueda-Romo;*
Universidad Nacional Autónoma de México, México, Mexico.

Malaria incidence between both sexes is similar. However, men develop higher parasitaemias and more severe pathologies than women. On the other hand, both reactive oxygen and nitrogen species play an important role on malaria parasite elimination. Estradiol is a natural antioxidant and testosterone is associated with immunosuppression. In addition, expression of some immune response genes is modulated by hormones. We studied whether differences in pathology and parasitaemias could be associated with sexual hormones and analysed the effect of gonadectomy on the activity of antioxidant enzymes and on oxidative stress in CBA/Ca mice infected with *P. berghei* ANKA. Groups of male and female mice were gonadectomised and after 28 days were infected with *P. berghei* ANKA. Additional groups of mice were opened and closed to analyse the effect of surgery. Two additionally groups of mice were left intact as controls. Nine days post infection mice were sacrificed. Specific activity of: catalase, superoxide dismutase (SOD) and glutathione peroxidase (GPx) was analysed. In addition, MDA levels were evaluated in blood and in spleen.
Gonadectomy in female mice significantly decreased the specific activity of catalase, SOD and GPx. In addition, levels of MDA were significantly higher in the group of gonadectomised female mice, while in male mice we did not detected significant changes.
Our results suggest that sexual hormones in females are involved in the development of oxidative stress in CBA/Ca mice infected with *P. berghei* ANKA.

Blood group O protects against complicated *Plasmodium falciparum* malaria by the mechanism of inducing high levels of anti-malarial IgG antibodies

A. Nasr[1,2], *M. Eltoum*[3], *A. Yassin*[4], *G. ElGhazali*[5];
[1]*Department of Microbiology, Faculty of Science and Technology, Al-Neelain University, Khartoum, Sudan,* [2]*Department of Basic Medical Science, College of Medicine, King Saud bin Abdulaziz University for Health Sciences (KSAU-HS), Riyadh, Saudi Arabia,* [3]*Department of Haematology, Faculty of Medical Laboratory Science, University of Medical Science and Technology, Khartoum, Sudan,* [4]*John Radcliffe Hospital, Oxford, OX3 9DU, Oxford, United Kingdom,* [5]*Department of Biochemistry, Faculty of Medicine, Malaria Research Centre (MalRC), University of Khartoum, Khartoum, Sudan.*

In a prospective clinical study in North Kordofan (Western Sudan), the possible association between blood groups and anti-malarial antibody responses with clinical outcome of *Plasmodium falciparum* malaria among Sudanese patients was investigated. A total of 184 individuals were consecutively enrolled from an outpatient clinic. Sixty six (35.9%) patients were classified as complicated malaria (CM), 53 (28.8%) with uncomplicated malaria (UM) and 65 (35.3%) were malaria free controls (MFC). Phenotypes of ABO blood groups were typed using commercial anti-sera. The antibody responses to MSP2 malaria antigens were assessed by an enzyme-linked immunosorbent assay (ELISA). The frequency of O blood group was significantly lower in those with CM when compared with MFC and UM patients (*P* value < 0.001 and 0.002 respectively). The levels of IgG1, IgG2 and IgG3 antibodies were statistically significantly higher in UM and MFC compared with CM patients. Statistical analysis indicated that higher levels of total IgG, IgG1, IgG2, and IgG3 specific to the MSP2 (both antigen forms, 3D7 and FC27) were associated with a reduced risk of complicated CM in O blood type carriers than in non-O blood type carriers, *P* value <0.001. Taken together, the current study indicates that blood group O is associated with a reduction in the risk of developing complicated malaria in western Sudan. Our results also revealed that the natural acquisition of immunity against clinical malaria appeared to be more associated with IgG1 and IgG3 antibodies, signifying their roles in parasite-neutralizing immune mechanisms.

P4.09.14
Targeting the Plasmodium chabaudi MSP1(19) protein to the DEC205 dendritic cell population induces faster parasite clearence

***R. H. Panatieri**, H. B. da Silva, M. M. Yamamoto, M. D'Imperio Lima, S. B. Boscardin;*
USP, Sao Paulo, Brazil.

Malaria is an infectious disease distributed worldwide. It's responsible for thousands of deaths every year, affecting mainly children. The acquired immune response during infection is partial and transitory. A membrane antigen of the merozoite is widely used as a vaccine target because of its immunogenic properties. This protein is expressed during schizogony as a precursor of 200kDa that undergoes successive cleavages, finally remaining anchored in the membrane as a portion of 19kDa named MSP-$1_{(19)}$, which has an important role in the reinvasion of the erythrocytes. Several studies have focused on the development of a vaccine against the parasite that leads to the maintenance of a protective memory response to different immunization schedules. A promising vaccine strategy is to target antigens directly to dendritic cells (DC) *in vivo*. This is accomplished by the administration of a monoclonal antibody that recognizes the endocytic receptor DEC205 present at the surface of DCs fused with an antigen of interest. Here we produced a hybrid αDEC205 coupled to the MSP-$1_{(19)}$ from *Plasmodium chabaudi* (AS) and used it to prime C57BL/6 mice that were subsequently boosted with the recombinant MSP-$1_{(19)}$ protein in the presence of Poly (I:C). Anti *P. chabaudi* MSP-$1_{(19)}$ antibodies were only detected in mice that received a boost with the recombinant MSP-$1_{(19)}$ protein. Protection against acute infection correlated with higher antibody titers. Adoptive transfer of blood from immunized and challenged mice showed a faster parasite clearance when MSP-$1_{(19)}$ was targeted to dendritic cells using the αDEC-MSP-$1_{(19)}$ antibody.

P4.09.15
Placental lesions as result of TLR4 activation by Plasmodium berghei are associated with low birth weight

***A. S. Reis**[1], R. Barboza[1], S. B. Boscardin[1], S. Epiphanio[2], C. R. F. Marinho[1];*
[1]University of São Paulo, São Paulo, Brazil, [2]Federal University of São Paulo, São Paulo, Brazil.

Introduction: It has been described that TLR4 recognize components of Plasmodium sp. and influence the host immune response. As this activation during pregnancy can result in a range of complications affecting mother and fetus, the aim of this work was to evaluate the effects of TLR4 absence on the development of placental malaria (PM). Methods & Results: To verify the effects of TLR4 activation on the placental tissue, we infected pregnant mice with P. berghei NK65 on the 13th gestational day. Histopathological analysis of the placentas showed a decrease of vascular spaces in infected wild type (WT) mice when compared with placentas from non-infected control mice. In contrast, we did not observe differences between infected and non-infected placentas from TLR4 knockout (TLR4KO). As the reduction of vascular space can be a consequence of inflammatory processes, our next step was to analyze local immune response induced by the parasite. Our results showed that pro-inflammatory cytokines IL-6 and TNF-alpha expression were abrogated in infected TLR4KO mice and no differences were observed with IFN-gamma production. As a consequence of inflammatory process, fetuses from infected WT mother present a significant body weight reduction. Conclusion: Together, our results point out the importance of a severe local inflammatory response in the development of PM pathogenesis via TLR4 signaling and, additionally, indicate the TLR4 as potential target for future therapies.

P4.09.16
The P2X7 receptor contributes to protection and to ameliorate the clinical manifestations of blood-stage Plasmodium chabaudi malaria

***É. M. Salles**, M. Menezes, A. Cassado, E. Amaral, S. Castillo-Mendez, H. Silva, J. Alvarez, R. Coutinho-Silva, M. D'Império-Lima;*
Universidade de São Paulo, São Paulo, Brazil.

Malaria is a potentially serious infectious disease caused by protozoa parasites of the genus *Plasmodium.* The blood stage of infection is responsible for all symptoms associated with malaria. Recently, it has been shown that innate immune receptors are able to detect signals released by damaged cells, such as ATP. The P2X7 receptor (P2X7R) detects extracellular ATP and therefore could contribute to activate the immune response to *Plasmodium*. In this study, we observed that ATP levels in the serum of C57BL/6 mice that were infected with *Plasmodium chabaudi* AS were significantly higher after the period of rupture of infected red blood cells (iRBCs). Moreover, $CD4^+$ T cells and $CD11c^+$ cells from the spleen of infected mice presented with increased P2X7R-mediated responses to ATP or supernatants from lysed iRBCs, which were measured by the permeability to ethidium bromide. Furthermore, $P2X7R^{-/-}$ (C57BL/6 background) female mice had difficulty in controlling parasitemia and failed to reestablish body temperature and weight after the peak of parasitemia. Accordingly**,** $P2X7R^{-/-}$ male mice died from day 8 to 15 postinfection. Our results suggest that ATP is released from ruptured iRBC and its recognition by the P2X7R contributes to parasite control and to ameliorate the clinical manifestations of blood-stage *P. chabaudi* malaria.

P4.09.17
Polygenic control of human antibody responses to synthetic malaria vaccine

***O. A. Sant'Anna**[1], M. V. Valero[2], A. G. Trezena[3], J. Kalil[4], M. E. Patarroyo[2];*
[1]Laboratório de Imunoquímica, Instituto Butantan, São Paulo, Brazil, [2]Fundación Instituto de Inmunología de Colombia (FIDIC), Bogotá, Colombia, [3]Laboratório de Imunogenética, Instituto Butantan, São Paulo, Brazil, [4]Instituto do Coração, Faculdade de Medicina, Universidade de São Paulo, São Paulo, Brazil.

In nature, all the evolutionary mechanisms are related with diversity, ensuring species survival. In this way two main genetic peculiarities play an essential role: polymorphism and polygenes. The genetic regulation of innate and acquired immunities constitutes the complex network of resistance/susceptibility mechanisms. The analysis of the quantitative antibody production against a chemically synthesized malaria vaccine was performed in three human populations naturally exposed to malaria: Tumaco, a hypo-endemic area and La Tola, a region of higher endemicity, both in Colombia; Las Majadas an endemic province in Venezuela. The IgG antibody titers were determined thirty days after three vaccine dose. The mean antibody titers were 1.3 to 4.5 times higher in women than in men and the frequencies of low responders (titers < 2 log 10) were 10% in Tumaco, 23% in Las Majadas and 49% in La Tola. There is a significant inverse correlation between the IgG titers against the vaccine and the anti-*P. falciparum* pre-immune sera in both La Tola and Las Majadas. Multiple regression analysis of intra-familial antibody responsiveness showed significant correlation between mother vs. daughter, mother vs. son, father vs. son and daughter vs. son. Intra-familial variances were lower than total phenotypic variances in 50% of Las Majadas, in 54% of La Tola and in 80% in Tumaco indicating the importance of genetic constitutions and the relevance of environmental factors to this quantitative character. Moreover, the continuous frequency distributions of antibodies provide evidence for the polygenic control of the immuneresponsiveness to malaria vaccine. Support: CNPq, FAPESP

Inflammatory factors and leucocytes are involved in the pathogenesis of malaria associated acute lung injury/acute respiratory distress syndrome in murine model

M. K. Sercundes[1], *L. d. Ortolan*[2], *D. Debone*[1], *E. H. Aitken*[1], *M. Russo*[1], *J. M. Alvarez*[1], *C. R. F. Marinho*[1], *S. Epiphanio*[2,3];
[1]*University of São Paulo, Sao Paulo, Brazil,* [2]*Federal University of São Paulo, Sao Paulo, Brazil,* [3]*University of São Paulo, São Paulo, Brazil.*

INTRODUCTION: Malaria is a huge burden on global health and caused 2.4 million deaths in 2012. Severe malaria can manifest in the lungs, an illness known as acute lung injury/acute respiratory distress syndrome (ALI/ARDS). Using an experimental model previously established by our group we evaluated the immune cell profile and inflammatory response in malaria associated ALI/ARDS. METHODS AND RESULTS: DBA/2 mice were infected with *Plasmodium berghei* ANKA. Lungs and bronchoalveolar lavage (BAL) were collected 7 days post infection (7dpi). Using the respiratory patterns (enhanced pause and respiratory frequency) and parasitemia from a survival group, we established ROC curves and were able to classify experimental animals euthanized 7dpi as suffering ALI/ARDS or HP (hyperparasitemia). There was an increase in neutrophils, seen by increased *Ncf2* mRNA expression (qRTPCR) and increased numbers of Gr-1^{high} $CD11b^{+}$ cells (flow cytometry), in the lungs of ALI/ARDS mice compared to HP mice. In the lung we observed increased numbers of alveolar macrophages ($F4/80^{+}/CD11_{C}^{+}$) and fewer interstitial macrophages ($F480^{+}$) (flow cytometry) and in the BAL we observed an increase in macrophages and neutrophils (cytospin) in the ALI/ARDS mice. We also found that mRNA expression of *iCAM-1*, *HO-1, IL-10* (anti-inflammatory) and *IFNγ* (pro-inflammatory) genes was elevated (qRTPCR) in the lungs of the ALI/ARDS mice. CONCLUSION: Our data suggests that neutrophils and alveolar macrophages play a role in ALI/ARDS development. We hypothesize that the neutrophil recruitment is partly dependent on increased ICAM-1 expression and that the high *IL-10* mRNA expression is an attempt to re-establish homeostasis.

Extracellular ATP accelerates malaria anemia

K. Suzue[1], *M. Nishimori*[1], *M. Hirai*[1], *T. Imai*[1], *T. Taniguchi*[1], *H. Okada*[1], *C. Shimokawa*[1], *S. Koyasu*[2], *H. Hisaeda*[1];
[1]*Department of Parasitology, Gunma University Graduate School of Medicine, Maebashi, Gunma, Japan,* [2]*Department of Microbiology and Immunology, Keio University School of Medicine, Shinjuku, Tokyo, Japan.*

Although anemia is one of the most common malaria symptoms, its molecular mechanisms still remains unclear. Extracellular ATP and its metabolites are used for intercellular communication and stimulation of immune response. The main supplier of extracellular ATP is RBCs under physiological condition. Here we show that extracellular ATP accelerates malaria anemia. First, to examine the role of extracellular ATP on malaria anemia, we injected ATP to mice infected with non-lethal strain *Plasmodium berghei* XAT. Surprisingly, the severity of malaria anemia was accelerated by injection of ATP. On the other hand, administration of carbenoxolone, the blocker of putative ATP secretion channel pannexin, ameliorated malaria anemia. These data indicated that extracellular ATP is involved with malaria anemia. Next, to determine the receptor for extracellular ATP involved with malaria anemia, various P2 receptor agonists or antagonists were administered to *P. berghei* XAT-infected mice. Injection of brilliant blue G, the selective inhibitor of P2X7 receptor, induced milder anemia, suggesting that P2X7R is involved in malaria anemia. To farther examine the role of P2X7R on malaria anemia, P2X7R deficient mice were infected with *P. berghei* XAT and severity of anemia was examined. P2X7R deficient mice exhibited milder anemia than WT mice upon non-lethal *P. berghei* XAT. Moreover, milder anemia symptom on P2X7R mice was observed by infection of not only *P. berghei* XAT but all other *Plasmodium* parasite we examined, including *P. berghei* ANKA, NK65, *P. yoelii* 17 XL, 17XNL, *P. chabaudi* AS. Collectively, extracellular ATP and its receptor P2X7R were involved with malaria anemia.

P4.09.20
The role of P2X7 receptor in hepatic necrosis caused by Plasmodium chabaudi AS infection

F. Vieira*, A. Freitas do Rosario, M. D'Imperio Lima;*
USP, Sao Paulo, Brazil.

The intense activation of the immune system during the erythrocytic stage of *Plasmodium* is responsible for several syndromes associated with the disease. Purinergic receptors of the P2X family detect extracellular ATP (eATP) and their interaction induces inflammasome activation in macrophages and consequent production of proinflammatory cytokines and cell death. In malaria, ATP is released upon erythrocyte rupture and T cell activation. In the murine model of malaria caused by *Plasmodium chabaudi* AS, infected erythrocytes preferentially adhere to the liver endothelium. Therefore, it is believed that the rupture of parasitized erythrocytes and consequent release of ATP mainly occur in that organ. A study performed by our research group showed that liver necrosis occurs in C57BL/6 mice infected with *P. chabaudi* AS.
To study the role of P2X7R in hepatic necrosis, we infected C57BL/6 and $P2X7R^{-/-}$ mice with *Plasmodium chabaudi chabaudi* AS 10^{6} (i.p.) and 7 days later the livers were collected for histopathological analysis. We observed that infected $P2X7R^{-/-}$ mice, contrary to C57BL/6 mice, do not present/develop liver necrosis. In another approach, we infected DBA/2 mice, which were treated with P2X7-antagonist Brilliant Blue-G (BBG) (45.5 mg/Kg) every 48 hours for 5 days. Seven days after infection the livers were collected for histopathological analysis, peripheral blood and serum were collected for hemoglobin, AST, ALT and LDH measurements. Our results indicate that BBG administration prevents hepatic necrosis.
These data demonstrate that the absence of P2X7 receptor or the administration of BBG ameliorates the severity of hepatic necrosis.

P4.09.21
S-nitrosoglutathione prevents experimental cerebral malaria

G. M. Zanini[1], *Y. C. Martins*[2], *P. Cabrales*[2], *J. A. Frangos*[2], *L. J. M. Carvalho*[3,2];
[1]*Parasitology Service-IPEC, Fiocruz, Rio de Janeiro, Brazil,* [2]*La Jolla Bioengineering Institute, San Diego, CA, United States,* [3]*Laboratory of Malaria Research, Instituto Oswaldo Cruz/Fiocruz, Rio de Janeiro, Brazil.*

Administration of the exogenous nitric oxide (NO) donor dipropylenetriamine-NONOate (DPTA-NO) to mice during Plasmodium berghei ANKA (PbA) infection largely prevents development of experimental cerebral malaria (ECM). In the present study we evaluated whether an alternative, physiologically relevant NO donor, S-nitrosoglutathione (GSNO), was able to prevent ECM at lower doses with minimal side effects. Prophylactic treatment with high (3.5 mg), intermediate (0.35 mg) or low (0.035 mg) doses of GSNO decreased incidence of ECM in PbA-infected mice, decreasing also edema, leukocyte accumulation and hemorrhage incidence in the brain. The high dose inhibited parasite growth and also induced transient hypotension. Low and intermediate doses had no or only mild effects on parasitemia, blood pressure, and heart rate compared to saline-treated mice. PbA infection decreased brain total and reduced (GSH) glutathione levels. Brain levels of oxidized (GSSG) glutathione and the GSH/GSSG ratio were positively correlated with temperature and motor behavior. Low and intermediate doses of GSNO failed to restore the depleted brain total glutathione and GSH levels, suggesting that ECM prevention by GSNO was probably related to other effects such as inhibition of inflammation and vascular protection. These results indicate that ECM is associated with depletion of the brain glutathione pool and that GSNO is able to prevent ECM development in a wide range of doses, decreasing brain inflammation and inducing milder cardiovascular side effects.

P4.09.22
Pys48 and Pys25 DNA Vaccine supplement medicated the inhibitory development of *Plasmodium yoelii* gametocytes into gametes

***L. Zheng**, Y. Cao;*
China Medical University, Shenyang, China.

In addition to vector control and malaria chemotherapy, immunological intervention will be needed to stop the resurgence of malaria. Transmission-blocking vaccine (TBV) is one of the new strategies for controlling malaria. It will be a major method to prevent from malaria if TBV is applicated together with other stages malaria vaccines and anti-malaria drugs. P25 is the major surface protein expressed on the zygote and ookinete of Plasmodium, which is well known as the important candidate for the TBV. In recent years, the specific protein P48 expressed on the surface of gametocytes as a transmission-blocking immune target has caused widespread interesting. Here, we have pursued a vaccination strategy, based on DNA immunization in mice with genes encoding two antigens present on the sexual stages of *Plasmodium yoelii* 17XL (P.y 17XL), Pys48 and Pys25, to induce important antibodies. The DNA vaccines of Pys25 and Pys48 were able to induce high levels of antibodies in mice. The effective transmission blocking activity was confirmed by mosquito feeds and ookinete culture *in vitro*, but the transmission-blocking activity of Pys25 and Pys48 composite immune group was lower than that for either Pys25 or Pys48 simple immune group, moreover the effect has significant antibody titer dependent. Therefore, our research will provide necessary and basic data for identify the role of P25 and P48 in transmission-blocking immune and developing effective compound malaria vaccines.

Tuberculosis and acquired immunodeficiency syndrome

***E. Beiranvand**[1], S. Abediankenari[2], M. Rezaei[3], B. Beiranvand[4], A. Khalili[3];*
[1]Pasteur Institute of Iran,Tehran, Member of Research Committee, Mazandaran University of Medical Sciences, Tehran, Iran, [2]Immunogenetics Research Center, Faculty of Medicine, Mazandaran University of Medical Sciences, Sari, Iran, [3]Faculty of Medicine, Mazandaran University of Medical Sciences, Sari, Iran, [4]Jundishapur University of Medical Sciences, Ahvaz, Iran.

Introduction: HIV-Tuberculosis is life threatening diseases in the world that approximately 1.1 million people have infected. The incidence of drug resistance is common in this group of patients. The immune system is very important to tuberculosis control. Thus, the purpose of this study was to evaluate the prevalence of HIV in TB patients.
Methods: In a descriptive study, 183 TB patients (99 men and 84 women) who were referred to health centers of Mazandaran province were selected after obtaining informed consent. Peripheral blood was drawn from subjects and their serum separated. HIV Ab and western blotting test were analyzed in all samples.
Results: Mean age of tuberculosis patients was 46.8 ± 19.8 years. HIV prevalence in this population showed a prevalence of 2%.The frequency of infections TB / HIV in the men was 3.03% and 1.2% in the women (OR = 2. 5, 95% CI = 0.26±25.4, P=0.3). Also, one of the 4 patients infected TB / HIV patients have a prison record.
Conclusion: According to the low prevalence of HIV among TB patients in this research, it is concluded that control of this patients can be cause to prevent of the disease progression.

Characterization of commensal bacteria based on their effects on human dendritic cell-induced T-lymphocyte polarization

***K. Bene**[1], M. Toth[1], N. Boiko[2], E. Rajnavolgyi[1];*
[1]Department of Immunology, University of Debrecen, Debrecen, Hungary, [2]Department of Microbiology, Immunology, Virology and Aetiology of Infectious Diseases, Medical Faculty, Uzhorod National University, Uzhorod, Ukraine.

Enormous diversity of commensal bacteria determines individual functions acting on the development and activities of the human immune system. These involve specialized macrophage and dendritic cell subsets, expression of unique pattern recognition receptor combinations coupled to evolutionally conserved signaling pathways, transcriptional regulation, post-translational modifications, induction of co-stimulatory molecules, secretion of cytokines, chemokines and type I interferons. This complexity can directly be translated to T-lymphocyte polarization to support tolerance induction or inflammation. We have developed a sensitive in vitro culture system for investigating the response of moDC subsets to commensal bacteria by monitoring the expression of type I/II CD1 proteins, phagocytic activity, secretion of chemokines, pro-inflammatory and T-cell polarizing cytokines. Under physiological conditions the gut microenvironment is conditioned by retinoic acid (ATRA) produced by intestinal epithelial cells and CD103+ DCs. To consider the impact of this special microenvironment on moDC-induced T-lymphocyte responses we compared the effects of selected microbes in absence and presence of ATRA. Selected microbes exerted their modulatory effects in a dose- and strain-dependent manner and ATRA had a significant impact on moDC-induced T-cell responses:
• ATRA inhibited CD1a expression in moDCs without affecting CD83 expression;
• Gene expression involved in retinoid synthesis was enhanced but microbes counter acted this effect;
• Secretion of IL-1β concommitant with NOD2, NLRC4 and NLRP12 gene expression was dramatically enhanced by ATRA but microbes inhibited this effect;
• Opposing activity of NOD2 to NLRC4 and NLRP12 pointed to an autocrine IL-1β-mediated regulation;
• ATRA increased Th17 and decreased Th1 responses significantly.

P4.12.03
Staphylococcus aureus affect T-regulatory cell phenotype and FoxP3-expression

***S. Björkander**[1], Y. Haileselassie[1], L. Hell[1], S. Roos[2], U. Holmlund[1], E. Sverremark-Ekström[1];*
[1]Department of Molecular Biosciences, The Wenner-Gren Institute, Stockholm, Sweden, [2]Department of Microbiology, Swedish University of Agricultural Sciences, Uppsala, Sweden.

Purpose: T-regulatory cells (T-regs) control peripheral and tissue-based immune responses. *Staphylococcus (S.) aureus* and *Lactobacillus (L.) reuteri* are both common bacteria of the neonatal commensal gut microbiota and can potentially interact with, and affect, immune cells. Our previous studies have shown that *S. aureus*, but not *L. reuteri*, strongly promotes inflammatory responses while *L. reuteri* can dampen *S. aureus* induced immune responses. Our aim was therefore to investigate how these bacteria affect the T-reg population.
Materials and methods: HT-29 intestinal epithelial cells (IEC) were stimulated for 24h with media containing 5% of each bacterial supernatant or both in combination. PBMCs were stimulated with the bacteria-conditioned IEC supernatants for 24h, washed and stained for T-regs using the CD4, CD25, CD127 and FoxP3 markers. T-regs were gated based on $CD127^{low}$CD25+ expression and acquired by flow cytometry.
Results: Stimulation with *S. aureus* reduced the percentage of $CD127^{low}$CD25+FoxP3+ T-cells, while increasing the total CD4+ T-cell surface expression of the activation marker CD25. *L. reuteri* alone had no effect on these parameters and it did not prevent the *S. aureus* induced reduction of FoxP3+ cells. However, the cell surface expression of CD25 was reduced by simultaneous stimulation of PBMCs with *S. aureus* and *L. reuteri* compared to *S. aureus* alone.

Conclusions: *S. aureus* may perform its pro-inflammatory activity through down-regulation of FoxP3+ T-regs and by promoting T-cell activation, while *L. reuteri* partially dampen this effect.

P4.12.04
Enterococcusdurans EP1 modulates inflammation in a DSS-induced colitis model in mice

P. Carasi[1]*, S. M. Racedo*[2]*, C. Jacquot*[2]*, M. Serradell*[1]*, M. C. Urdaci*[2]*;*
[1]Faculty of Exact Sciences, La Plata National University, La Plata, Argentina, [2]Bordeaux Science Agro, Bordeaux, France.

Enterococcus durans EP1, a gram-positive coccoid bacteria, has shown various probiotic properties. The objective of this work was to evaluate the immunomodulatory capacity of EP1 in a colitis model induced by dextran sulfate sodium (DSS) in mice. Six weeks old Swiss mice were separated in two groups of 16 animals. During 14 days, one group received daily 108 cfu/mice of EP1 and the other received PBS. On day 14, each of the mentioned groups was separated in two (eight mice each) and administration of DSS 3% w/v started for one of them and lasted seven days. Significant differences in the disease activity index were observed between DSS group and DSS treated with EP1 mice (DSS-EP1), DSS mice´s colons were shorter ($p<0.05$) than the colons from control and DSS-EP1 mice. Histological studies were consistent with these findings. Cytokines production by colon explants ex vivo showed that DSS mice secreted higher levels of IL6, IL17A, IFNγ, TNFα and GM-CSF compared with control and DSS-EP1 mice but no differences were observed for IL10. Gene expression studies demonstrated that in colon the expression of IL17A, INFγ, IL1β and CXCL1 was lower in DSS-EP1 group compared with DSS mice. In mLN, expression of IL23, IL17A, RORγT and GM-CSF was significantly decreased in DSS-EP1 group. Moreover, EP1 treatment partially recomposed the changes in the microbiota induced by DSS. These results indicate that administration of E. durans EP1 attenuates damages generated by DSS by decreasing expression and secretion of proinflammatory mediators, as well as modulating microbiota.

P4.12.05
Butyric acid in the gingival tissue induces mitochondrial oxidative stress while acutely increasing caspase-9 activity

M. E. Cueno[1]*, K. Imai*[1]*, N. Matsukawa*[2]*, T. Tsukahara*[2]*, K. Ochiai*[1]*;*
[1]Nihon University School of Dentistry, Tokyo, Japan, [2]Kyoto Institute of Nutrition and Pathology Inc., Kyoto, Japan.

Butyric acid (BA) is a major extracellular metabolite produced by anaerobic periodontopathic bacteria and is commonly deposited in the gingival tissue. BA retention in the gingival tissue was previously shown to induce mitochondrial oxidative stress, however, its effects on cellular apoptosis was not fully elucidated. In this study, we determined how BA-induced increase in hydrogen peroxide (H_2O_2) amounts affect the cellular apoptosis pathway. Throughout the study, we made use of rat jugular blood taken at 0, 15, and 180 min after BA injection in the gingival tissue. We fractionated both blood mitochondria and blood cytosol, and, similarly, verified the purity of each isolate. Subsequently, we measured blood mitochondrial H_2O_2, heme, superoxide (SOD), and catalase (CAT), whereas, we determined blood cytosolic caspase-9 activity. In blood mitochondrial samples, we found that H_2O_2, heme, SOD, and CAT levels gradually increased with respect to time after BA-injection which would insinuate that mitochondrial oxidative stress was induced. In blood cytosolic samples, we detected high caspase-9 activity 15 min after BA injection which eventually normalized after 180 min which would insinuate that BA acutely increases caspase-9 activity and is somehow regulated in time. We correlated the decrease in caspase-9 activity to the sustained increase in mitochondrial H_2O_2 amounts. Moreover, we suspect that BA-induced increase in mitochondrial H_2O_2 amounts inhibited the caspase-dependent apoptosis by regulating caspase-9 activity. Thus, we hypothesize that BA in the gingival tissues does not induce cellular apoptosis attributable to an increase in mitochondrial H_2O_2 amounts.

P4.12.06
Homology modeling and structural analyses of the six Porphyromonas gingivalis FimA variants

M. E. Cueno[1]*, K. Nagano*[2]*, K. Imai*[2]*, F. Yoshimura*[2]*, K. Ochiai*[1]*;*
[1]Nihon University School of Dentistry, Tokyo, Japan, [2]Aichi Gakuin School of Dentistry, Nagoya, Japan.

Porphyromonas gingivalis is a Gram-negative bacteria primarily responsible for gingivitis. P. gingivalis fimbrillin (FimA) mediates bacterial interaction with host tissues by mediating bacterial adhesion and colonization at targeted sites. FimA is classified into six variants based on nucleotide sequences and each variant differs in bacterial pathogenicity. However, to date, previous attempts to crystallize the FimA protein has failed and the absence of FimA protein structural data has hampered our understanding of this protein. With the advent of various protein prediction and structural analyses software, it is now possible to predict and characterize the FimA structure. Here, we generated FimA homology models and characterized all six FimA variants (Type 1-5 and 1b). We cloned and sequenced five P. gingivalis strains from each FimA variant. Multiple sequence alignment was performed to determine the homologous sequence and, subsequently, used to generate the mature FimA homology models. We determined the quality of all FimA models produced and found that each generated model has an X-ray crystallography quality making all FimA models suitable for structural characterization. Topology analyses showed that FimA Types 1, 1b, 3, 4, and 5 is comprised of 18 beta-sheets, whereas, FimA Type 2 have 16 beta-sheets. Furthermore, we found that all FimA models can be subdivided into three parts which we designated as upper, middle, and lower regions. Interestingly, all FimA models have a structurally conserved middle region which we suspect is important to maintain the overall FimA structure, thus, making the FimA middle region an ideal antibacterial or vaccine target.

P4.12.07
Phytol-derivative PHIS-01 as a vaccine adjuvant and a molecular probe for anti-bacterial immune microenvironment against methicillin-resistant Staphylococcus aureus

R. Roy Chowdhury[1,1]*,* ***S. K. Ghosh***[2]*;*
[1]Indiana State University, Terre Haute, IN, United States, [2]Indiana State University, terre Haute, IN, United States.

Staphylococcus aureus (SA), a commensal Gram-positive bacterium present in about 30% adult population, can be potentially pathogenic emerging as methicillin-resistant MRSA strains and affecting nearly a million individuals every year. Despite significant efforts, there is as yet no clinically approved anti-staph vaccine. To discern underlying problems in developing such vaccine, we asked whether the synthetic diterpenoid PHIS-01 (phytanol) could act as an effective adjuvant in immunization with heat-inactivated MRSA. Our earlier studies in a mouse model have shown PHIS-01 to be effective in engendering protective immunity against methicillin-sensitive *S. aureus.* The present study was designed to evaluate the effectiveness of PHIS-01 against MRSA. PHIS-01-adjuvanted MRSA vaccine significantly reduced bacterial loads upon live challenge in the adjuvanted group relative to unadjuvanted group. Although antibody levels did not differ in the control and adjuvanted groups, significant differences were noted in the expression of antimicrobial peptides, like Bpi and Lcn2, cytokines like IL-1β and Ifnb1 and chemokines like CCl3, CCl4 and Cxcl3. Additionally, the adjuvanted groups showed enhanced expression of inflammasome and TLR associated genes. Assessment of CD4+ T-cell subset induction in terms of specific transcription factors revealed that MRSA could selectively upregulate Foxp3 (T-regulatory cells). Interestingly, PHIS-01 could effectively subvert this effect and also serve as the molecular probe to delineate changes in immune homeostasis that is pivotal in host-parasite interactions.

P4.12.08
The intestinal microbiota triggers epithelial Toll-like receptor expression and impairs neuropilin-1 processing and hedgehog signaling in the small intestinal mucosa

N. Hörmann[1,2], *J. Hahlbrock*[1], *I. Brandao*[1], *F. Bäckhed*[3], *U. Walter*[1], *C. Reinhardt*[1];
[1]*Center for Thrombosis and Hemostasis (CTH), University Medical Center Mainz, Mainz, Germany,* [2]*Graduate School for Immunotherapy, University Medical Center Mainz, Mainz, Germany,* [3]*Department of Molecular and Clinical Medicine & The Wallenberg Laboratory for Cardiovascular Research at Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden.*

A single layer of epithelial cells forms the barrier between gut microbiota and small intestinal lamina propria. Ligation of microbial-associated molecular patterns (MAMPs) to Toll-like receptors (TLRs) expressed on epithelial cells promotes proliferation and regulates intestinal homeostasis. Here, we use germfree mouse technology to explore how MAMPs derived from gut microbes impact epithelial neuropilin-1 (Nrp-1) expression. Recent reports demonstrate that Nrp-1 regulates hedgehog (HH) signaling.
Comparing mice that are colonized from birth with a microbiota (CONV-R) with germfree controls (GF) we found that small intestinal mRNA of TLR2 and its co-receptor TLR1 are increased upon colonization. This effect could be reversed by antibiotic microbiota depletion. Stimulation of the epithelial cell line MODE-K with TLR2 agonists resulted in an increase in TLR2 and TLR1 transcripts and was associated with increased cellular TNFα levels and increased proliferation. Treatment of MODE-K cells with TNFα resulted in decreased Nrp-1 levels. In line with decreased TNFα mRNA levels detected in the small intestine of GF mice we found decreased Nrp-1 levels in colonized mice. Accordingly, stimulation of MODE-K cells with TLR2 agonists decreased Nrp-1 protein levels. Co-immunoprecipitation analyses suggest that Nrp-1 interacts with TLR2. Localization of Nrp-1 to the cell membrane was reduced upon TLR2 stimulation. Similar to decreased Nrp-1 levels colonization of GF mice led to a drop in HH ligand expression.
Collectively, we found that the epithelial TLR2/Nrp1 signaling loop is regulated by MAMPs of the microbiota. This is associated with altered HH signaling which may account for changes in small intestinal morphology.

P4.12.09
Is IutA from Escherichia coli a type 1 Thymus-independent antigen?

T. N. Landgraf*, F. F. Fernandes, A. A. M. Coelho-Castelo, A. Panunto-Castelo;*
University of São Paulo, Ribeirão Preto, Brazil.

Certain strains of Escherichia coli contain a pColV plasmid that encodes IutA, an outer membrane receptor for the iron-aerobactin complex. Preliminary results from our group suggest that IutA is a mitogen for B cells. Here we performed direct stimulation assays of CFSE-labeled B cells with recombinant IutA (rIutA) and indirect assays with B cells cocultured separately with spleen macrophages stimulated with rIutA using transwell membranes or cultured with conditioned medium from IutA-stimulated macrophages. We showed that rIutA was not able to induce directly the proliferation of B cells, but it induced macrophages to release a molecule that acted on B cells. When we used cells from mice MyD88-/-, we determined that MyD88 is crucial for signaling induced by rIutA in B cells, but not in macrophages. A similar analysis with cells from mice TLR4-/- or TLR2-/- revealed that these receptors were not required for rIutA signaling. Since IutA induced macrophages to produce IL-1 and signaling of IL-1 receptor is dependent on MyD88, we thought that IutA stimulated macrophages to produce IL-1 that, in turn, was responsible for B cell proliferation. This hypothesis was confirmed when we observed that B cells pretreated with IL-1 receptor antagonist had a significantly decrease in proliferation in response to conditioned medium from cultures of IutA-stimulated macrophages. Altogether, our results suggest that IutA induces polyclonal B-cell proliferation independently of T cells in a mechanism mediated by macrophages. These results open perspectives for studying IutA as a molecule that stimulates the mucosa-associated lymphoid tissue.

P4.12.10
In vivo **analysis of Staphylococcal Superantigen-Like (SSL) protein production during infection**

R. J. Langley*, J. Choi, F. Radcliff, J. D. Fraser;*
School of Medical Sciences and the Maurice Wilkins Centre for Molecular Biodiscovery. The University of Auckland, Grafton, Auckland, New Zealand.

Staphylococcus aureus is a major human pathogen, a leading cause of hospital-acquired infection and alarmingly a rapidly increasing cause of antibiotic-resistant community-acquired infection. It persistently colonizes 20 - 30% of the population with up to half of us colonized at any point in time. This organism can infect practically any part of the body with disease pathologies covering the full range of severity from soft tissue infections, to joint infections, through to life-threatening conditions including septicaemia, endocarditis, and toxic shock. Its remarkable ability to colonize and infect is due to the abundance of virulence factors it produces. Many host-derived influences affect the expression patterns of virulence genes in *S. aureus* including stresses placed upon the bacteria by attack from the immune system. A family of fourteen secreted molecules named the Staphylococcal Superantigen-like (SSL) proteins are becoming recognised as being amongst the virulence factors responsible for immune evasion by *S. aureus*. Neutrophils and their anti-microbial products appear to trigger regulatory systems that control *ssl* transcription. Research performed in our laboratory using a subcutaneous abscess mouse model has established that SSL proteins are massively up-regulated during the early stages of infection. This up-regulation has been determined at the transcript level using qRT-PCR with subsequent detect of SSL proteins within the abscess by Western analysis revealing that SSLs are important defence molecules produced by *S. aureus* in the face of immune attack during an infection situation.

P4.12.11
The protective role of the intestinal microbiota in the host defense against Streptococcus pneumoniae-induced pneumonia

T. Schuijt[1], ***J. M. Lankelma***[1], *T. van der Poll*[1], *W. M. de Vos*[2], *W. J. Wiersinga*[1];
[1]*Academic Medical Centre, Amsterdam, Netherlands,* [2]*Wageningen University, Wageningen, Netherlands.*

For many years it has been hypothesized that in the critically ill the intestine has an important detrimental role in promoting systemic inflammation and infection. More recently however, the intestinal microbiota has emerged as a key defense system by local support of mucosal defense systems and systemic priming of antibacterial effector mechanisms. In this study, we aimed to investigate the role of the intestinal microbiota in the host defense against severe pneumonia. Therefore, we inoculated mice intranasally with Streptococcus pneumonia and depleted the intestinal microbiota prior to infectious challenge using antibiotic treatment with vancomycin, ampicillin, neomycin and metronidazole. In the intestinal microbiota-depleted mice, we found significantly increased pulmonary outgrowth of S. pneumonia when compared to controls. This corresponded with increased production of interleukin (IL)-6, IL-1β, and chemokines (e.g. CXCL-1) and decreased IL-10. Interestingly however, tumor necrosis factor (TNF)-α levels were downregulated in intestinal microbiota-depleted mice. In addition, microbiota-depleted mice showed reduced survival after S. pneumonia infection. Remarkably, microbiota-depleted mice that received a fecal transplant from untreated control mice showed a largely restored host defense response to S. pneumonia, e.g. less bacterial outgrowth and restored cytokine release. Alveolar macrophages isolated from uninfected, microbiota-depleted mice were found to be less capable in phagocytosing S. pneumonia and were less able to secrete IL-6 and TNF-α in response to LPS or LTA stimulation. Moreover, neutrophils from microbiota-depleted mice were less capable of phagocytosing S. pneumonia. We conclude that the intestinal microbiota plays a protective role in the host defense against S. pneumonia induced pneumonia.

P4.12.12
Probiotics promote protective immunity against enteric bacteria infection by gut immune maturation

***S. Lee**, J. Yang, S. Lee, M. Kweon;*
Internatinal Vaccine institute, Seoul, Republic of Korea.

Commensal bacteria play an indispensable role in gut homeostasis, not only by regulating a composition of dietary components, but also by prohibiting infection with enteric bacteria. In order to clarify the role of probiotics in gut protective immunity, we fed C57BL/6 mice for five days with probiotics including *Lactobacillus* (*L.*) *Rhamnosus* and *L. Acidophilus.* The mice were then orally infected with human-specific pathogen such as enterohemorrhagic *Escherichia coli* O157:H7 (EHEC) strain. For the positive control, mice were treated orally with antibiotics including ampicillin, vancomycin, neomycin, and metronidazole. Significantly lower numbers of bacteria in the gut-associated lymphoid tissues were detected in probiotics-fed mice compared to those of nil and antibiotics-fed mice at three hours post infection. While oral O157 challenge resulted in severe pathology in the gut such as epithelium shedding and paneth cells distortion in the nil and antibiotic-fed mice group, pre-feeding with probiotics maintained a healthy gut. In addition, predominant levels of mucin secretion were found in the probiotics-fed mice when compared with nil and antibiotic-fed mice. Most interestingly, mRNA levels of HB-EGF, CDX2, TFF3 and Vangl1, which are known for stem cell proliferation and goblet cell activation, were significantly higher in the gut epithelium of probiotics-treated mice than in those of nil and antibiotic-fed mice. Taken together, these data suggest that probiotics play a pivotal role in promoting gut stem cell maturation and subsequently in protecting host against enteric bacteria infection.

P4.12.13
Modulation of Enteropathogen-mediated immunity by Sodium Butyrate

***E. Milioris**, V. Iebba, N. K. Klein, M. Bajaj-Elliott;*
University College London, London, United Kingdom.

Background: Sodium butyrate (SB), a short chain fatty acid produced by anaerobic gut bacteria is a major energy source for intestinal epithelial cells (IECs). SB exerts anti-inflammatory effects and inhibits the development of colon cancer through mechanisms that are not completely understood. We hypothesised that SB may modulate and promote host defence in response to enteropathogens implicated in Diarrheal and Inflammatory Bowel Diseases.
Methods: THP-1 monocytes were pre-treated for 12 hours with SB (0.5, 1 and 5mM), the pan-histone deacetylase inhibitor trichostatin-A (TSA) (10, 50 and 100nM) and 5-aza-dC, an inhibitor of DNA-methyltransferase (0.5, 1 and 5μM). Cells were then infected with Adherent invasive *E.coli* (AIEC) (MOI = 10), *Campylobacter jejuni* (CJ) (MOI = 100) and *Salmonella typhi* (S. typhi) (MOI = 5) for 6 hours and supernatants were analyzed for the presence of TNF-α, IL-8 and IL-10 cytokines by ELISA.
Results: Pre-treatment with all three inhibitors led to marked suppression in TNF-α production (> 50%). SB, but not TSA or 5-aza-dC, enhanced IL-10 cytokine levels (>20%) following infection. SB alone enhanced IL-8 production dramatically (>100%) even at low concentration, whereas TSA and 5-aza-dC did not have a significant effect.
Conclusion: Our findings show that SB can enhance the innate immune response to bacterial infection, increasing the production of chemokine and anti-inflammatory cytokines. These effects are independent of the inhibition of histone-modifying enzymes or DNA methylation events.

P4.12.14
Relation between IL-17 gene polymorphisms and *H. pylori* associated gastric diseases

***A. Moravej**[1], M. Rasouli[2], A. Kouhpayeh[3], M. Kalani[2];*
[1]Department of Immunology, Fasa University of Medical Sciences, Fasa, Iran, [2]Professor Alborzi Clinical Microbiology Research Center, Shiraz University of Medical Sciences, Shiraz, Iran, [3]Department of Pharmacology, Fasa University of Medical Sciences, Fasa, Iran.

Introduction: Helicobacter pylori (H. pylori) is the main cause of chronic active gastritis, which can lead to peptic ulcer, gastric adenocarcinoma, and gastric mucosaassociated lymphoma. According to the important role of Interleukin-17 (IL-17) in pathogenesis of inflammatory diseases and the known effect of IL-17 gene polymorphisms on the production of this cytokine, we investigated the association between SNPs of IL-17A gene and the risk of H. pylori related chronic active gastritis and peptic ulcer diseases.
Materials and Methods: The study groups included 100 patients suffering from chronic active gastritis and 50 patients with peptic ulcer in addition to 226 healthy individuals as the control group. Alleles and genotypes at nine polymorphic sites of IL-17 were compared among the study groups by PCR-RFLP.
Result: The results showed that the distribution of A allele at position rs3819024 was significantly more frequent in the gastritis patients than the controls (P=0.0003) and was significantly more frequent in the ulcerative gastritis patients than the controls (P=0.0001). Moreover, homozygous rs3819024GG was significantly more frequent in the controls than the gastritis patients (P=0.0008) and also, it was significantly more frequent in the controls than the ulcerative gastritis patients (P=0.0005). Furthermore, AA (rs4711998A and rs3819024A) haplotype was significantly more frequent in ulcerative gastritis patients than the controls (P=0.0002) and GG haplotype was significantly more frequent in controls than ulcerative gastritis patients (P=0.001).
Conclusion: It could be suggested that IL-17 genetic variants at position rs3819024 can affect resistance or susceptibility to H. pylori-associated gastroduodenal diseases among Iranian population.

P4.12.15
Phenotype and function of lymphocytes in normal and inflamed appendix

***G. Mosayebi**, S. Alizadeh, A. Ghazavi, M. Okhovat;*
School of Medicine, Arak University of Medical Sciences, Arak, Iran.

Introduction: The appendix is considered as part of the gut-associated lymphoid tissue. Appendicitis is one of the most common abdominal inflammatory diseases. The function of appendix is not clearly defined. In this study to understand better the immunological function of the appendix, we investigated the function and phenotypic pattern of lymphocyte subsets in appendix of patients with normal and inflamed appendix tissue.
Materials and Methods: Appendix tissue and appendiceal mononuclear cells obtained from 81 patients (mean age; 23±10.5), who were clinically suspected of having appendicitis. Based on histopathological examination, twenty-five patients had normal appendix while 40 and 16 were diagnosed with acute and gangrenous appendicitis, respectively. The phenotypic characteristics of lymphocyte subsets in appendix analyzed by three color-flow cytometry. The proliferative responses of tissue mononuclear cells assayed by MTT method.
Results: There were significantly different in percentage of CD19/HLA-DR , HLA-DR and CD19 cells between acute, gangrenous appendicitis patients and patients with normal appendix (p=0. 01). There is significant different in the proliferative responses of the appendiceal mononuclear cells to PHA and LPS between acute, gangrenous appendicitis patients and patients with normal appendix(p=0.012).
Conclusion: The phenotypic and function of lymphocytes are different between normal and inflamed appendix tissue. These results show that appendix tissue with special lymphocyte profile maybe effective in preventing or reducing intestinal infections.

P4.12.16
High fat diet impairs respiratory tolerance in a mouse model of allergic asthma

***A. Pizzolla**, D. Y. Oh, J. Rolland, R. O'Hehir, C. Hardy;*
Monash University, Melbourne, Australia.

Obesity is now recognised as a state of chronic low-grade systemic inflammation. Epidemiological studies show that obesity is a risk factor for allergic asthma, and the prevalence of both conditions is increasing worldwide. We hypothesized that obesity limits induction of inhalational respiratory tolerance to airborne antigens, therefore predisposing to allergic asthma. We induced acute allergic airway inflammation (AAI) by sensitising C57BL/6 mice with ovalbumin (OVA) in alum, followed by intranasal OVA challenge. Respiratory tolerance was initiated by administering OVA intranasally prior to induction of AAI. Diet-induced obesity was modelled by feeding C57BL/6 mice for 8 weeks with high fat diet (HFD) prior to tolerance induction. Our data show that respiratory tolerance in mice on normal diet (ND) caused the expected decrease in AAI, characterised by decreased airway eosinophilia and Th2 cytokine production in bronchoalveolar lavage fluid. However, respiratory tolerance was impaired in mice fed with HFD. Similarly, Th2 cytokine production by lung-draining lymph node cells and serum OVA-specific IgE were reduced by respiratory tolerance in ND but not in HFD fed mice. At the cellular level, we observed a higher percentage of plasmacytoid dendritic cells (pDCs) in lungs and spleen of OVA tolerized ND mice compared to OVA tolerized HFD mice, consistent with previous reports of pDCs being tolerogenic in asthma. These data show for the first time that HFD feeding impairs the capacity of mice to become tolerant to airborne antigens, providing a potential explanation for the observed link between diet-induced obesity and allergic asthma.

P4.12.17
Link between Western diet and intestinal inflammation: role of TLRs/NLRs

***C. Sardi**[1], P. Luchini[2], A. Emanuelli[1], L. Manara[1], E. Martini[1], M. Kallikourdis[1], A. Balsari[3], C. Rumio[1];*
[1]Humanitas Clinical and Research Center, Rozzano, Italy,
[2]Dipartimento di Scienze Veterinarie per la Salute, la Produzione Animale e la Sicurezza Alimentare, Milano, Italy, [3]Istituto Nazionale per lo Studio e la Cura dei Tumor, Rozzano, Italy.

Diet and nutritional status are among the most important modifiable determinants of human health and are influenced in part by gut microbial community. The importance of the gut microbiota in intestinal development and homeostasis raises the question of how the host senses the microbial organisms. The Toll-like and Nod-like receptors (TLRs/NLRs) are involved in the host response to bacteria. Breakdown of interaction between commensal bacteria and TLRs/NLRs induces alteration in immune response and may increase susceptibility to inflammation-induced intestinal cancer. Newmark reported that the Western diet (WD), designed to mimic the intestinal cancer risk factors in humans, induces neoplastic lesions, when fed to wild-type mice for 1 year. These findings have important public health implications and reinforce the need to further define the complex relationship between dietary factors and microbiota associated with risk of developing intestinal cancer. Given the importance of the fact that WD influences the diversity of the microbiota and TLRs/NLRs play a major role in the recognition of bacterial products and induction of inflammation, our aim is to elucidate the role of TLRs/NLRs in intestinal inflammation and related mechanisms that can increase risk for intestinal carcinogenesis associated to consumption of WD. Although several studies reported that a WD for 1 year induces intestinal tumors in normal C57Bl/6 mice there are no studies regarding TLRs/NLRs KO mice. For this reason we considered KO and WT mice fed with both WD and AIN-76A for 3, 6, 12 month and we reported data regarding mice sacrificed at each time point.

P4.12.18
Immunoregulatory mechanisms associated with Bifidobacterium infantis 35624 exopolysaccharides

***E. Schiavi**[1], M. Gleinser[2], P. Konieczna[1], R. Ferstl[1], D. Patsch[1], M. Ziegler[1], R. Frei[1], L. O'Mahony[1];*
[1]SIAF, Davos, Switzerland, [2]Department of Microbiology & Alimentary Pharmabiotic Centre University College Cork, Cork, Ireland.

Gastrointestinal disorders are associated with a different gut microbiota composition of patients compared to that of healthy individuals. The use of probiotics to restore the microbial balance in the gut has been proposed as an immunomodulatory approach for prevention and treatment of these diseases. Many mechanisms could explain the probiotics' benefits: the competition with pathogens, the enhancement of the intestinal epithelial barrier function and the generation of regulatory responses. Nevertheless, further studies are needed to clarify these mechanisms as well as the molecular pathways involved in the signal transduction between probiotic MAMP (microorganism-associated molecular pattern) and host PRR (pattern recognition receptor) exposed by innate immune cells. In the interaction with the host, bacterial metabolic products and/or structural components can be responsible for probiotic beneficial effects. Polysaccharides have already showed their capacity to induce IL-10 and IL-12 production in in vitro and animal studies. However, studies in humans or isolated human cells are lacking.
The study on Bifidobacterium infantis exopolysaccharides (EPS) using WT and EPS knockout strains reveals the importance of this structural molecules on its capacity to induce a tolerogenic phenotype in MDDC (monocyte-derived dendritic cells) and to down-regulate their expression of activation markers. In THP-1 and HEK cells, EPS also influence the capacity to reduce the activation of NFkB/AP-1 pathway.
In addition to the administration of live microbes, the identification of microbial factor(s) responsible for immunomodulatory properties of probiotics might represent a chance to use these isolated compound(s) alone.

P4.12.19
Epigenetic control of host genes in intestinal epithelial cells by commensal bacteria

***K. Takahashi**, Y. Sugi, T. Kobayakawa, A. Hosono, S. Kaminogawa;*
College of Bioresource Sciences, Nihon University, Kanagawa, Japan.

The significance of intestinal microbiota to the maintenance of health has recently attracted considerable attention. Although commensal bacteria are not immunological "self" to the host, the intestinal immune system does not exclude them completely, resulting in a symbiotic relationship. There is now increasing evidence that these bacteria are involved in establishing the mutualism by controlling the host cells. In this study, the effect of commensal bacteria on the gene expression of intestinal epithelial cells (IECs) was investigated to clarify the mechanisms underlying the intestinal symbiosis.
IECs were prepared from the large intestine of conventional (CV) and germ-free (GF) mice. Genomic DNA fragments obtained from IECs were pulled down using methyl-CpG binding domain protein 2-coupled beads and analyzed by next generation sequencing to compare the DNA methylation pattern between these mice. The 5'-regions of 453 genes showed more than 1.5-fold change in the annotation frequency between CV and GF mice. *Gm7120* was one of the candidate genes differently methylated in the CpG motifs between CV and GF mice. The *Gm7120* gene was methylated at a higher level and expressed at a lower level in IECs of CV mice than in those of GF mice. Knockdown of *Gm7120* by RNAi resulted in decreased expression of RALDH1, an enzyme mediating the conversion of retinal, derived from vitamin A, to retinoic acid that plays a key role in the immunological homeostasis of the intestine. Collectively, these results indicate that commensal bacteria control specific host genes through epigenetic mechanisms and thereby maintain the intestinal symbiosis.

P4.12.20
Fibre, short-chain fatty acids and microbiota combat the development of asthma

***A. N. Thorburn**;*
Monash University, Clayton, Australia.

Recent studies suggest that the gut microbiota and microbial by-products play an important role in the development of asthma. Fibre and short-chain fatty acids (SCFAs) are highlighted as particularly important, however the role of these elements in the development of asthma and our understanding of the gut-lung axis is poorly defined.
Using a series of studies, we investigated the effect of fibre and SCFAs on the development of allergic airways disease (AAD) using house-dust mite-induced mouse models. Characteristics of AAD that were assessed included airways hyper-reactivity, inflammatory cells and cytokines, and serum IgE.
The development of AAD was reduced in adult mice fed a high fibre diet and exacerbated in mice receiving a low fibre diet. Interestingly, we also demonstrated that low fibre diet in early life, especially in the perinatal phase is a key driver of susceptibility. Our high fibre diet increased levels of SCFAs, particularly acetate, which when administered in the drinking water also reduced the development of AAD. Furthermore, high acetate-producing bifidobacterium suppressed the development of asthma in antibiotic treated mice and monocolonized germ-free mice. Altogether these data show beneficial effects of dietary fibre and acetate in AAD possibly through the of G-protein coupled receptors 41 and 43, histone deacetylases and regulatory T cells.
This collection of studies highlights a novel gut-lung axis involved in the regulation of asthma.

P4.12.22
Remodeling of stromal architecture in the gut mucosa as a mirror of immunological changes under various conditions (germ-free animals, colitis and cancer)

***L. Vannucci**[1], J. Krizan[1], O. Chernyavskiy[2], R. Stepankova[1], F. Caja[1], D. Stakheev[1], L. Rajsiglova[1], J. Dvorak[1], P. Rossmann[1];*
[1]Institute of Microbiology, Prague 4, Czech Republic, [2]Institute of Physiology, Prague 4, Czech Republic.

Comparison between germ-free (GF) versus conventionally (CV) reared animals allows to enlighten the inflammatory environment regulation and cancer microenvironment development. The GF animals present larger bowel, thinner intestinal wall with poorly developed lymphatic infiltrates and follicles. Rapid acquisition of regular bowel anatomy and increased complexity of collagen structures coupled lymphatic follicle enlargement after conventionalization of GF animals. Similar remodeling of lymphatic structures was evidenced after induction of chronic colitis by dextran sodium sulphate (DSS), carcinogenesis by azoxymetane (AOM) or associating both inductions (DSS followed by AOM administration). Inflammatory background accelerated the AOM-induced tumor development in the sigmoid. In CV animals, circulating CD3+CD4+CD25high Treg cells progressively increased during the various inductions, faster after AOM. Contemporarily, collagen architecture of mucosal scaffold showed progressive thickening and distortion. In the left colon/sigmoid mucosa, VEGFa and TGFbeta expression increased but not the inhibitory VEGFb. Reduction of CD3+ cells and higher percentage of NK and NKT cells suggested prevalence of innate immunity in early anticancer responses. In GF animals the percentage of NK and NKT cell are constitutively higher than in CV, and during carcinogenesis, GF cytotoxic activity had lower reduction that in CV animals. Resistant-to-cancer animals showed higher CD8+ levels. Under either AOM-only carcinogenesis or DSS+AOM induction, GFs developed fewer and smaller tumors than CV animals. Concluding, inflammatory stimuli deregulation produces immunological changes that reflect also on tissue scaffold architecture. P4.12.23
The Microbial Landscape Of Breast Cancer: Examination At The Site Of Disease

*C. Xuan[1], J. Shamonki[2], A. Chung[3], P. A. Sieling[1], **D. J. Lee**[1];*
[1]John Wayne Cancer Institute, Santa Monica, CA, United States, [2]Saint Johns Health Center, Santa Monica, CA, United States, [3]Cedars-Sinai, Los Angeles, CA, United States.

Microbes have been reported to influence various disease states including obesity, diabetes and cancer in humans. Breast cancer is the second leading cause of cancer deaths in women, with over 400,000 deaths annually worldwide. Though some risk factors such as diet, age and genetic predisposition have been identified, the majority of breast cancers have unknown etiology. Given the importance of host-microbiota interactions in human health and disease, we investigated the relationship between the breast microbiota and breast cancer. Here, we characterized and compared the bacterial species found in the breasts of healthy women and women with breast cancer. Quantitatively, we found that healthy tissue harbors more bacteria than tumor tissue ($p<0.001$). Qualitatively, we found that there were shifts in the microbiota associated with the diseased state, with certain bacterial genera being more abundant in healthy versus tumor tissue. Specifically, the bacterium Sphingomonas yanoikuyae is enriched in matched normal adjacent tissue compared with tumor tissue from the same patient ($p<0.01$). These data support the hypothesis that the presence of S. yanoikuyae may support a healthy breast environment. Our findings highlight a new area of research into the breast microbiome and its association with breast cancer development and progression.

P4.12.24
Synthesis and pharmacological evaluation of 8-substituted phenyl xanthines for asthma therapy

***R. Yadav**[1], D. Yadav[1], A. Kuhad[2], R. Bansal[2];*
[1]Banasthali University, Banasthali, India, [2]Panjab University, Chandigarh, India.

Xanthines belongs to an important class of drugs used in the treatment of asthma and have been considered to be the most effective prophylactic agents for the control of symptoms of chronic asthma. Currently, adenosine receptor antagonists (AdOR) are reported to be novel therapeutic antiasthmatic agents. Development of receptor target inhibition is a novel approach in current drug design scenario. In the last few year's xanthines have received considerable attention as molecular targets for the development of antiasthmatic agents. Several positions of xanthine skeleton with different substituent have been explored to obtain a variety of potent derivatives.Present investigation has been made to design potent selective xanthine derivatives, synthesize and screen them in vitro (adenosine antagonism) and in vivo (BAL analysis) for antiasthmatic activity. To observe the effects of morpholino substituted group, a new series of 8-(substituted-phenyl) xanthines has been synthesized and compounds were evaluated for their affinity for A1 and A2A adenosine receptors (AR) using radioligand-binding assays. The synthesized xanthine derivatives exhibited varying degrees of affinity and selectivity towards A1 and A2A receptor subtypes. As a part of research study, we further examined the dynamic changes in cellular profile of bronchoalveolar lavage (BAL) fluid after lipopolysaccharide (LPS) challenge in the male wistar rats of synthesized xanthine derivatives.In general, the newly synthesized compounds displayed significant antiasthmatic activity. The outcome of the current work is the generation of an important pool of new xanthine derivatives.

P4.12.25
Comparative fecal microbiome of Holstein and Nelore bovines: differential bacterial composition can be related to susceptibility to ectoparasites

***A. F. Zangirolamo**, T. M. Banin, I. K. F. M. Santos, S. R. Maruyama; Ribeirão Preto School of Medicine, University of São Paulo, Ribeirão Preto, Brazil.*

The microbial composition of gastrointestinal tract plays important role in immunological status in animals. Bovine breeds present different levels of immunity to tick infestations; zebu are resistant and taurine are susceptible. Since microbial metabolites can be associated with the innate immunity of hosts, we evaluated the fecal microbiome from a zebu and taurine breed, for analyzing if the diversity found could be related to traits such as ectoparasites susceptibility. We extracted genomic DNA of fecal samples collected from rectum of 6 Nelores (zebu) and 6 Holsteins (taurine), under same feed and animal management system. The 16S rRNA genes were amplified using primers for V5-V6 region and pyrosequencing of samples was performed using Roche FLX high-thoughput sequencing. The taxonomic assignment was achieved at phylum, family and genus level. As expected, the most abundant phyla were Firmicutes and Bacteroidetes for both breeds. Some genera presented differential prevalence according to the breed (compared with test-t). We highlight the *Bacteroides* genus, significantly more frequent in Holstein (50.4% *vs* 31.1% in Nelore, p=0.02). *Bacteroides* bacteria generate metabolites from aromatic aminoacids. Noteworthy, the skatole metabolite (derived from tryptophan) is attractive to insects, therefore, we believe that the major prevalence of *Bacteroides* in feces of Holsteins might be related to attraction of ectoparasites, such as myiasis-causing flies and ticks. Thus, the odor generated in feces would be one among several factors that contribute for susceptibility to tick infestations in Holstein breed.

P4.13 Immune regulation at barrier sites

P4.13.01
Host defense peptide CRAMP acts as a potent mast cell chemoattractant and mediator release stimulus

***E. Bąbolewska**, P. Witczak, A. Słodka, A. Pietrzak, E. Brzezińska-Błaszczyk;*
Department of Experimental Immunology, Medical University of Łódź, Łódź, Poland.

Cathelicidins, a family of cationic peptides, are well known for their role in innate host defense, particularly against bacteria. Apart from direct killing of microbes through the membrane disruption, cathelicidins can also indirectly regulate immune response by affecting activity of cells involved in antibacterial defense mechanisms. Considering important role of mast cells (MCs) in protection against bacterial infection, the aim of this study was to determine whether CRAMP, rat-derived cathelicidin, can induce MC degranulation and histamine release (spectrofluorometric method), cysteinyl leukotrienes (cysLTs) generation, TNF and CXCL8 synthesis (ELISA methods), as well as MC migratory response (Boyden microchamber assay). Experiments were conducted *in vitro* on fully mature rat peritoneal MCs. We have stated that MC stimulation with CRAMP resulted in a dose-dependent generation and release of significant amounts of cysLTs, but failed to induce MC degranulation and histamine release. Moreover, MC activation *via* CRAMP led to TNF, but not CXCL8 synthesis. We also documented that CRAMP acts as a strong MC chemoattractant. MC response to CRAMP stimulation was observed when cathelicidin was used at concentrations of≥ 20 μg/mL, i.e. significantly higher than physiological level. To gain some insight into CRAMP-mediated signal transduction pathways in MC, we examined the effect of the several inhibitors specific to PLC/PLA_2, PI3K, ERK and p38 MAPK signaling molecules. Our results suggest that cathelicidins may enhance antibacterial inflammatory response *via* attracting MCs to pathogen entry site and *via* induction of MC-derived mediator release. This work was supported by the Medical University of Łódź (Grant No. 502-03/6-164-01/502-64-004).

P4.13.02
Chemerin is an antimicrobial agent in human epithelium

***M. Banas**[1], K. Zabieglo[1], M. Kapinska-Mrowiecka[2], J. Drukala[3], K. Murzyn[4], B. A. Zabel[5], E. C. Butcher[6], J. M. Schroeder[7], A. Schmidtchen[8], J. Cichy[1];*
[1]Department of Immunology, Faculty of Biochemistry, Biophysics and Biotechnology, Jagiellonian University, Cracow, Poland, [2]Department of Dermatology, Zeromski Hospital, Cracow, Poland, [3]Department of Cell Biology, Faculty of Biochemistry, Biophysics and Biotechnology, Jagiellonian University, Cracow, Poland, [4]Department of Computational Biophysics and Bioinformatics, Faculty of Biochemistry, Biophysics and Biotechnology, Jagiellonian University, Cracow, Poland, [5]Palo Alto Institute for Research and Education, VA Palo Alto Health Care System, Palo Alto, CA, United States, [6]Stanford University School of Medicine, Stanford, CA, United States, [7]Department of Dermatology, University Hospital Schleswig-Holstein, Kiel, Germany, [8]Division of Dermatology and Venerology, Department of Clinical Sciences, Lund University, Lund, Sweden.

Chemerin, a protein ligand for the G-protein coupled receptor CMKLR1 (chemokine-like receptor 1), selectively attracts specific subsets of immunoregulatory antigen presenting cells, including dendritic cells and macrophages. C-terminal chemerin sequence, F149 S157 plays key role in mediating chemotactic activity through CMKLR1 receptor. Chemerin is predicted to belong to the structural cathelicidin/cystatin family of proteins comprised of antibacterial polypeptide cathelicidins and inhibitors of cysteine proteinases (cystatins). Chemerin is widely expressed in healthy epithelium, a natural body barrier, although the biological significance of chemerin in this tissue remains unknown. We hypothesized that chemerin may be involved in host defense by functioning as an antimicrobial agent in epithelial cells. Here we show that chemerin is abundant in human keratinocytes and bronchial epithelial cells in situ. Chemerin-replete exudates from primary epidermis cultures inhibit bacteria growth and chemerin represent a quantitatively significant fraction of anti-bacterial activity in the products of cultured keratinocytes. The internal region Val66-Pro85 of chemerin mediates the majority of the antibacterial activity that is comparable in potency to other antimicrobial proteins. Collectively, our work uncovers a novel protective function for endogenous chemerin in human epithelium that is independent of its role as a leukocyte chemoattractant.

P4.13.03
Bcl3 expression is increased in Irritable Bowel Syndrome (IBS) patients independently of IL-10

***C. J. Beltrán**[1], A. M. Madrid[1], C. Defilippi[1], K. Nally[2], S. Melgar[2], J. F. Cryan[3,4], T. G. Dinan[3,5], E. M. Quigley[6,7,8];*
[1]Gastroenterology Division, Hospital Clínico Universidad de Chile, Medicine Faculty, Universidad de Chile, Santiago, Chile, [2]Host Response and Inflammation Group, Alimentary Pharmabiotic Centre, University College Cork, National University of Ireland, Cork, Ireland, [3]Laboratory of Neurogastroenterology, Biosciences Institute, Alimentary Pharmabiotic Centre, University College Cork, National University of Ireland, Cork, Ireland, [4]Department of Anatomy and Neuroscience, University College Cork, National University of Ireland, Cork, Ireland, [5]Department of Psychiatry, Cork University Hospital, University College Cork, National University of Ireland, Cork, Ireland, [6]Department of Medicine, Cork University Hospital, University College Cork, National University of Ireland, Cork, Ireland, [7]Alimentary Pharmabiotic Centre, University College Cork, National University of Ireland, Ireland, Cork, Ireland, [8]Gastroenterology and Hepatology Division, The Methodist Hospital, Houston, TX, United States.

Irritable bowel syndrome (IBS) is characterised by a state of low-grade inflammation. B-cell leukemia/lymphoma 3 (Bcl3) is a co-transcriptional gene regulator activated by the NF-kB pathway. An immunosuppressive role, exerted by IL-10, has been ascribed to Bcl3 in the intestinal mucosa. The status of Bcl3 has not been characterised in IBS. We hypothesised that altered expression of Bcl3 is relevant to inflammation reported in IBS. AIM: To compare expression levels of Bcl3 and their correlation with expression of IL-10 in intestinal mucosa of IBS patients and healthy-controls (HC). METHODS: Colonic biopsies of IBS patients and HC from Cork University Hospital and Hospital Clínico Universidad de Chile were analysed for Bcl3 and IL-10 expression by qPCR and tissue distribution of Bcl3 was defined by immunofluorescence. The effect of

supernatants from colonic biopsies, 24h cultured in the presence or absence of CD3/CD28 antibodies, on Bcl3 expression in the intestinal epithelial (IE) cell line (DLD-1) was evaluated using qPCR and immuno-blotting. RESULTS: We observed a significant increase in Bcl3 expression, but not IL-10, in IBS patients compared to HC (p=0.0115). Immunofluorescence demonstrated a predominantly nuclear distribution of Bcl3 in the IE of both groups. Bcl3 expression was more significantly induced in DLD-1 cells by the supernatants of stimulated biopsies from IBS compared with HC. CONCLUSION. Our results suggest that Bcl3 expression is increased in the IE of IBS patients, as a regulatory mechanism independent of IL-10 expression. Supported by FONDECYT-11121527, MECESUP-0608 and Science Foundation Ireland through a grant to the Alimentary Pharmabiotic Centre.

Soluble factor produced by Staphylococcus aureus modulates the cell cycle of eukaryotic cells

N. Berkova[1], *E. Ladier*[1], *L. Alexseeva*[1], *M. Deplanche*[1], *S. Almeida*[2], *V. Azevedo*[2], *S. Even*[1], *F. Taieb*[3], *Y. Arlot-Bonnemains*[4], *Y. Le Loir*[1];
[1]*INRA, Rennes, France,* [2]*ICB-UFMG, Belo Horizonte MG, Brazil,* [3]*INRA, Toulouse, France,* [4]*CNRS, Rennes, France.*

Staphylococcus aureus can cause life-threatening infections such as bacteremia, pneumonia, osteomyelitis, endocarditis and sepsis.
Epithelial cells are able to sense microbes, creating an early line of defense. We investigated S. aureus-host epithelial cells interaction using multidisciplinary approaches. Bacteria slowed down cell proliferation and induced a cytopathic effect. We observed an enlargement of host cells at MOI (Multiplicity of Infection) 20:1, which started being visible from 72h post-infection. Increasing MOI to 100:1 resulted in the induction of apoptosis. Using flow cytometry analysis, we demonstrated that S. aureus induces a G2/M phase delay in synchronized HeLa cells, which was associated with accumulation of the cyclin-dependent kinase Cdk1/cdc2, a key inducer of mitosis entry, and with the accumulation of unphosphorylated histone H3, which was correlated with a dramatic reduction of the mitotic cell number. This delay required the presence of live S. aureus since the addition of the heat-killed bacteria did not alter the cell cycle. Culture supernatants of S. aureus strains induced a similar G2/M phase transition delay, suggesting a soluble factor is involved in the transient cell cycle arrest. Analysis of S. aureus proliferation in asynchronous, G1- and G2-phase-enriched HeLa cells showed that the G2 phase was preferential for bacterial infective efficiency, suggesting that the G2 phase delay may be used by S. aureus for propagation within the host. Our findings reveal the potential of S. aureus in the subversion of key cellular processes such as cell cycle progression, and shed light on the biological significance of host cell cycle alteration.

Aedes aegypti is an important mosquito species and transmits diseases such as yellow fever, Chikungunya fever and dengue fever. In order to successfully nourish themselves, these hematophagous mosquitoes find the immunological system of their hosts as a major challenge. During the millions of years of co-evolution with their hosts, these insects developed a salivary cocktail with an arsenal of molecules presenting several immunomodulatory properties. In the present work, we characterized a lymphocyte inhibitor present in Ae. aegypti salivary gland extract (SGE). Our results reveal that Aedes aegypti saliva possesses a potent inhibitor of T cell proliferation able to induced apoptosis in naïve, but not memory T cells. Fractionation of salivary gland extract (SGE) by FPLC showed one dominant active fraction with apparent molecular mass of >400 kDa. The analysis of the fractions by mass spectrometry revealed a single candidate in which the amount detected correlated with the observed activity. Serum from mice previously immunized with the active fraction and Complete Freund Adjuvant was able to neutralize the SGE-induced modulatory activity. We also observed that cells from MRL/lpr mice (FAS mutant mice) and Bim KO mice were discreetly less affected by SGE in comparison to wild type mice, suggesting that both signaling pathway of apoptosis might be involved or acting as compensatory pathways. Activation of caspase-8 was also analyzed by Western Blot and seems to be involved in the SGE-induced apoptosis. Further studies will be required to better understand the mechanisms of action underlying such effects.

P4.13.06

Expression and regulation of TSLP in human oral mucosa and cultured oral keratinocytes

L. Bjerkan[1], *O. Schreurs*[1], *L. Farkas*[2], *F. Jahnsen*[3], *E. Baekkevold*[3], *I. Blix*[4], *K. Schenck*[1];

Epithelial cells at mucosal surfaces are exposed to a variety of antigens, including pathogenic and commensal bacteria, food antigens and allergens. The ability of the immune system of the oral cavity to protect against infection while avoiding destructive inflammatory responses is
essential for maintaining oral health. Thymic stromal lymphopoietin (TSLP) is an epithelial-derived cytokine known to activate dendritic cells and regulate immune responses in several tissues. The aim of this study was to investigate the expression and regulation of the two TSLP transcript variants in oral mucosa. Oral mucosal biopsies were taken and processed for immunohistochemistry (IHC). Other biopsies were used to establish cultures of oral mucosal keratinocytes which were stimulated with various inflammatory mediators and thereafter harvested for examination by real time PCR. IHC analysis showed that TSLP was constitutively expressed in the gingival epithelium. In cultured oral keratinocytes exposed to poly(I:C), TNFα/IL-1β or IFNγ, the expression of long form TSLP (lfTSLP) transcript but not that of short form (sfTSLP) transcript was significantly increased. These results show that lfTSLP is the regulated form associated with inflammation in oral keratinocytes. Due to its extensive expression in gingival biopsies, however, TSLP might also have other, non-immunological roles in oral epithelia, e.g. participate in modulation of barrier functions or epithelial differentiation.

P4.13.07

Induction of Interleukin-10 expression by the commensal microbiota in intestinal regulatory T-cells

J. Bollrath[1], *M. Barnes*[1], *A. Johnson*[1], *M. Asquith*[1], *H. Waldmann*[1], *R. Flavell*[2], *S. Hori*[3], *K. Maloy*[1], *F. Powrie*[1];
[1]*University of Oxford, Oxford, United Kingdom,* [2]*Yale University, Oxford, CT, United States,* [3]*RIKEN-RCAI, Yokohama, Japan.*

Interleukin-10 (IL-10), a pleiotropic cytokine, is a crucial anti-inflammatory mediator playing a non-redundant role in the intestine. The importance of this cytokine has been illustrated by knock-out mice which develop a lethal colitis in response to colonic bacteria. Recent studies have shown that IL-10 is predominantly expressed by Foxp3+ T-cells in the colonic lamina propria. In this study we aimed to further characterize this subset of IL-10 secreting Foxp3+ T-cells and to dissect the mechanisms governing their activation in the intestine, employing a novel dual reporter mouse for Foxp3 and IL-10. We found that the induction of IL-10 expression ultimately depends on the commensal flora and colonization with the pathobiont Helicobacter hepaticus (H.h.) significantly enhanced the frequency of Foxp3+ IL-10+ T-cells in the intestine. Induction of IL-10 did not require candidate cytokines such as IL-21 or IL-27, as well as MyD88, the

universal adaptor protein for the induction of TLR signaling. Using TCR Vb-chain spectrotyping we show that IL-10+Foxp3+ T-cells contain a broad TCR Vb-chain repertoire suggesting broad specificity which did not show a particular enrichment in a single TCR Vb-chain following H.h. infection. Our data show that resident intestinal bacteria not only promote the expansion of effector T-cell subsets but are as well crucial in the induction of immune-regulatory pathways.

P4.13.08

***Helicobacter pylori* HP0175 promotes the production of IL-23, IL-6, IL-1β and TGF-β.**

C. Della Bella[1], *A. Amedei*[1], *F. Munari*[2], *E. Niccolai*[1], *M. Benagiano*[1], *G. Zanotti*[2], *M. de Bernard*[2], *M. Kundu*[3], *M. M. D'Elios*[1];
[1]*University of Florence, Florence, Italy,* [2]*VIMM Padua, Padua, Italy,* [3]*Bose Institute, Kolkata, India.*

Helicobacter pylori infection induces a chronic gastric inflammatory infiltrate. *Helicobacter pylori* is a spiral-shaped Gram-negative bacterium that chronically infects the stomach of more than 50% of the human population and represents the major cause of gastric cancer, gastric lymphoma, gastric autoimmunity and peptic ulcer diseases. The World Health Organization classifies *Helicobacter pylori* as a type I carcinogen for distal gastric cancer. Eradicating the bacterium, in high risk populations, reduces incidence of gastric cancer. *Helicobacter pylori* induces an inflammatory response in the gastric mucosa characterized by polymorphonuclear and mononuclear cell infiltration. The host immune response to *Helicobacter pylori* influences the clinical outcome of the infection. This study was undertaken to evaluate the type of the innate immune responses elicited by the secreted peptidyl prolyl cis,trans-isomerase of *Helicobacter pylori* (HP0175). The cytokine production induced by HP0175 in neutrophils, monocytes and dendritic cells was evaluated. HP0175 was able to induce the expression of IL-23 in neutrophils, monocytes and dendritic cells, and IL-6, IL-1beta and TGF-beta in monocytes and dendritic cells. These findings indicate that HP0175 is able to promote the activation of innate cells and the production of a cytokine milieu that may favour the development of Th17 response.

P4.13.09

Mechanistic insights into *Helicobacter pylori* pathogenesis and host response

B. Ho*;*
Department of Microbiolgy, Yong Loo Lin School of Medicine, National University of Singapore, Singapore.

Helicobacter pylori is a Gram negative bacterial gastric pathogen that infects ~50% of the world's population with some progressing to gastric cancer. The indelible link between Helicobacter pylori and severe gastric diseases coupled with the emergence of multiple-antibiotic resistant H. pylori and the high prevalence of gastric cancer necessitate urgent attention. Furthermore, the mechanistic action of pathogenesis has not been firmly established. Among the known pathogenic factors of H. pylori reported, cytotoxin associated gene A (CagA), an oncoprotein, has been cited to induce inflammatory response in host cells and cause disruption of gastric epithelial cell-cell tight junctions. We report here a surface localized heat shock protein that effects the cytoskeleton rearrangement of cells independently, and exacerbates disruption of cell-cell tight junctions through its interaction with CagA. This protein is found in all strains of H. pylori analysed, and that it aids the bacteria in colonizing BALB/c mice. The dynamics of interaction between heat shock protein and CagA intrabacterially, as well as between the bacterial pathogen and the host in the course of H. pylori pathogenesis will be discussed.

[1]*Institute of Microbiology AS CR, Prague, Czech Republic,* [2]*Institute of Immunology and Microbiology, First Faculty of Medicine, Charles University in Prague, Prague, Czech Republic.*

BACKGROUND: Gut forms the largest and most important barrier against the external environment. This barrier is in constant interaction with both gut resident microbiota and mucosal immune system, and its dysfunction could cause the inflammatory or autoimmune disease. Our aim was to analyze how local and systemic inflammation influences the intestinal barrier function and how this deleterious effect can be counteracted by oral treatment with lysate of probiotic bacterium.
METHODS: First, before the induction of colitis we pretreated BALB/c mice with lysate of probiotic *Lactobacillus casei* DN-114001 (Lc) by oral gavage. Next, we induced either systemic or intestinal inflammation in these mice by intraperitoneal injection of lipopolysecchariide or by oral administration of dextran sulfate sodium, respectively. We measured the function of the gut barrier by FITC-labeled dextran method and its molecular properties by changes in expression and localization of tight junction proteins (occludin, ZO-1 and claudin-2) by RT-PCR and immunofluorescence, respectively.
RESULTS: We found that in both systemic and local inflammation the gut permeability for macromolecules is significantly increased. In both models, this functional change is accompanied by increase in expression of proinflammatory cytokines (e.g. IL-6) in colon mucosa. Oral treatment with Lc can prevent the changes in the localization of tight junction proteins, and decrease in their expression, caused by the systemic or intestinal inflammation.
CONCLUSIONS: We conclude that components from probiotic bacteria decrease the sensitivity to both systemic and local inflammation by strengthening the gut barrier function.

Homeostatic proliferation of naïve CD4$^+$ T cells in mesenteric lymph nodes generates gut-tropic Th17 cells

T. Kawabe[1], *S. Sun*[1], *A. Asao*[1], *T. Takahashi*[2], *T. So*[1], *N. Ishii*[1];
[1]*Tohoku University Graduate School of Medicine, Sendai, Japan,* [2]*Central Institute for Experimental Animals, Kawasaki, Japan.*

Homeostatic proliferation of naïve T cells in the spleen supplies memory T cells. This "systemic" proliferative response divides into fast or slow cell division rates. Since the fast proliferation is critical for generation of effector memory T cells, which are abundant in the intestinal tissue, "gut-specific" homeostatic proliferation may be important for generation of intestinal effector memory T cells. However, such organ-specific homeostatic proliferation has not been addressed. In this study, we examined the gut-specific homeostatic proliferation by transferring CFSE-labeled naïve CD4$^+$ T cells into lymphopenic mice and evaluating donor cell division and differentiation in the intestine and mesenteric lymph nodes (MLNs). We found that the fast-proliferating cell population in the intestine and MLNs had a gut-tropic $\alpha_4\beta_7^+$ CCR9$^+$ CCR6$^+$ Th17 phenotype, and that their production was dependent on OX40 costimulation and foreign antigens including commensal bacteria. FTY720 treatment induced accumulation of $\alpha_4\beta_7^+$ IL-17A$^+$ fast-dividing cells in MLNs and eliminated donor cells in the intestine, and mesenteric lymphadenectomy significantly reduced the Th17 cell population in the host intestine, indicating that MLNs rather than intestinal tissues are essential for generating intestinal Th17 cells. Furthermore, the fast-dividing cells survived for at least 60 days in MLNs when they were transferred to Rag2-/- second host mice, suggesting that the fast-dividing population might include gut-tropic memory precursor cells. These results reveal that MLNs play a central role in inducing gut-tropic Th17 cells and in maintaining effector memory CD4$^+$ T cell homeostasis in the small intestine.

P4.13.12
Immunological Common Junctions: Novel Targets for Therapeutic Interventions

***S. C. Murthy Yanamandra**;*
www.writebiomed.com, Hyderabad, India.

Human - pathogen interaction involves a sequence of events that are pre-programmed. Diverse routes taken by pathogenic microorganisms predispose humans to a spectrum of fatal infections. Regardless of immunological barriers, the hunt for human body contact and successful establishment of infection has become an inherent property of many microorganisms. The port of entry which permits microorganisms to pass through important molecular junctions could make a nearer pathway or associated gated channel or receptor undergo functional changes. Although significant strides have been taken in exploring the pathogen entry sites and developing the pathways, the area needs some additional input in search of common immunological junctions. It is anticipated that microorganisms specific to a given target tissue or infection destination pass through these junctions. If the case is, it is unknown how many common junctions currently exist.To this end, algorithms or databases that are specially designed for modeling the pathways could throw light on such junctions.Say, a database of microorganisms that is specific to one infection category leading to skin disorders could help in understanding about the common junctions involved.This could be accomplished in a cross -platform fashion by collaboration between several countries which would submit pathway data specific to a pathogen. A sum total of all data when pooled and analyzed from different countries may furnish insights on the suspected involvement of same junction. Ultimately, novel drugs designed would be efficacious in targeting the junctions. Hence, strategies to block common immunological junctions need exploration.

P4.13.13
The flagellin sensor NLRC4 mediates protection against a mucosal pathogen

***S. Nordlander**, K. J. Maloy;*
Sir William Dunn School of Pathology, University of Oxford, Oxford, United Kingdom.

Pattern recognition receptors (PRRs) enable mammals to discriminate self from non-self through the recognition of microbial signatures, such as bacterial flagellin. Flagellin is detected by the PRR NLRC4, which drives the activation and release of potent pro-inflammatory mediators. We aimed to characterize the role of NLRC4 in acute intestinal inflammation.
We used a model based on the murine pathogen *Citrobacter rodentium*. *Citrobacter rodentium* is a mouse homologue of enteropathogenic *E. coli* and induces acute intestinal pathology and diarrhea in the host.
We found that NLRC4$^{-/-}$ mice developed more severe weight loss, increased bacterial colonization levels and exacerbated intestinal inflammation compared to WT counterparts. Additional experiments using bone marrow chimeras revealed that the protective effects of NLRC4 were mediated by non-hematopoietic cells.
In conclusion, NLRC4 signalling in non-hematopoietic cells provided protection during acute bacterially-induced intestinal inflammation, possibly by limiting bacterial colonization. Further studies are needed to elucidate the mechanism responsible for protection.

P4.13.14
Brucella abortus 2308 induce downregulation of the activation markers in murine B cells

***M. Ramírez-Saldaña**[1], V. Paredes- Cervantes[1,2], M. Aguilar-Santelises[1], J. M. Hernández- Dominguez[2], M. C. Moreno-Lafont[1], R. López-Santiago[1];*
[1]National School of Biological Sciences, México D.F., Mexico, [2]Mexican Institute for Social Security, México D.F., Mexico.

Introduction. It has been demonstrated that Brucella abortus is capable to multiply into professional antigen presenting cells such as macrophages and dendritic cells. However, there are a few reports about Brucella infection into B cells. In this work, we evaluated the ability of B. abortus 2308 for infect the mouse B cell line, A20. Materials and methods. A20 lymphocytes cultured in RPMI medium supplied with L-glutamine and 10% of fetal calf serum were infected with several MOIs of Brucella abortus 2308 transformed by electroporation with the pJC43 (pBBR1MCS-2-gfp-mut3) plasmid to evaluate the entry of green fluorescent Brucella. The percentage of cells containing bacteria was evaluated by flow cytometry at three time points. To evaluate whether Brucella activated the B cells, kinetics of infection was performed and activation markers were analyzed by flow cytometry. Results. Association of Brucella abortus 2308-gfp-mut3 with A20 cells to reach a maximum of 20% of A20 infected cells. Infected cells increase expression of CD80 and MHC II and down-regulation of CD69 and CD86; CD40 was not modified. Conclusions. Brucella abortus 2308 interacts with A20 and induces change in the activation markers and costimulatory molecules.

Transcription factor Spi-B-dependent and -independent pathways for the development of Peyer's patch M cells

***S. Sato**[1,2], S. Kaneto[1], H. Kiyono[1,2];*
[1]The Institute of medical Science, The University of Tokyo, Tokyo, Japan, [2]CREST, JST, Tokyo, Japan.

The mucosal immune response is triggered by antigen uptake from the lumen across the mucous and epithelial cell layers to organized mucosa-associated lymphoid tissues such as Peyer's patches (PPs) in small intestine. This antigen uptake is mediated mainly by microfold cells (M cells) with transcytosis action. Although many of the biological features of M cells, including their function, have been known for many years, the molecular mechanisms of M-cell development, antigen recognition, and transcytosis have remained unclear. Here, we report that *Umod* is a novel M cell–specific gene, the translation products of which might contribute to the uptake function of M cells. We also found that a transcription factor, Spi-B, which is expressed mainly in hematopoietic lineages, was also expressed in M cells but not in other non-hematopoetic lineages. Spi-B-deficient mice showed reduced expression of most, but not all, other M cell–specific genes and M-cell surface markers. A bone marrow transfer experiment indicated that M cell–intrinsic Spi-B activity was important for M-cell development. Whereas uptake of *Salmonella* Typhimurium via M cells into PPs was obviously reduced in Spi-B-deficient mice, the frequency of intra-tissue cohabiting bacteria found in the PPs was comparable between wild-type and Spi-B-deficient mice. These data indicate that there is a small M-cell population with developmental regulation that is Spi-B independent; however, Spi-B is probably a candidate master regulator of M-cell functional maturation and development by another pathway.

P4.13.16
Influenza virus infection induces long-term and compartmentalised derangement of airway and lung dendritic cell subsets

***P. A. Stumbles**[1,2], C. von Garnier[3], M. Smith[2], V. Fear[2], E. Bozanich[2], C. Berry[1], D. Strickland[2], P. Holt[2];*
[1]Murdoch University, Perth, Australia, [2]Telethon Institute for Child Health Research, Perth, Australia, [3]Bern University Hospital, Bern, Switzerland.

Inhaled agents pose a major challenge to immunological homeostasis in the respiratory tract (RT), requiring constant screening for their risk to the host. This requires a balanced network of dendritic cells (DC) and other cells that regulate tolerance or immunity. Respiratory viruses such as Influenza pose a serious threat of long-term disruption of this balance given their potent inflammatory and cytotoxic activities. In this study, we used a mouse model of A/PR8/34 H1N1 Influenza Type A Virus (IAV) infection to examine its long-term effects on DC in airway mucosal (AM) and parenchymal lung (PL) tissue. In adult mice, we found marked differences in the kinetics of DC subsets in the AM and PL compartments, with a generally more acute responses in AMDC that resolved by day 7 after infection, but with persistent depletion of CD11blo PLDC for up to 3

weeks following infection. Similarly, upregulation of CD40 and CD80 was observed on AMDC at day 7, but this was delayed until day 14 in PLDC. A marked depletion in tissue-resident PL macrophages was observed at day 14 post-infection, with these cells showing a persistent activation state. In mice infected at 3 weeks of age, PLDC and macrophages showed persistent changes for up to 5 weeks following IAV infection. These data demonstrate that IAV has differential effects on DC populations in compartments of the RT, leading to long-term derangement in the numbers and activation states of these cells, that may permanently disrupt immunological homeostasis in this environment.

P4.13.17
Translation of Tollip is inhibited in the small but not large intestinal epithelial cells

***Y. Sugi**, K. Takahashi, T. Kobayakawa, A. Hosono, S. Kaminogawa; Food and Physiological Function Laboratory, College of Bioresource Sciences, Nihon University, Fujisawa-shi Kanagawa, Japan.*

Immune responses against gut microbiota should be minimized to avoid unnecessary inflammation at mucosal surface. In this study, we analyzed the expression patterns of Toll-interacting protein (Tollip), an inhibitor of TLR signaling, in intestinal epithelial cells (IECs). Comparable mRNA expression was observed in small and large IECs (S-IECs and L-IECs). However, at the protein level, Tollip was only expressed in L-IECs but not in S-IECs. Similar results were obtained in germ-free mice, indicating that L-IECs-specific Tollip protein expression is not dependent on bacterial colonization. To identify the mechanisms underlying the post-transcriptional repression of the *Tollip* gene expression, 3UTR -mediated translational regulation was evaluated by luciferase assay. By deletion analysis, the region +1876/+2398 was shown to be responsible for the translational repression of *Tollip*. The inhibition of miR-31, whose target sequence was included in this region, resulted in 2-fold increase of the luciferase activity. Furthermore, miR-31 expression was significantly higher in S-IECs than in L-IECs. These data suggested that miR-31 represses the translation of Tollip mRNA in S-IECs. However, since the recovery of the luciferase activity by miR-31 inhibition was relatively modest, another mechanism was possibly involved in the regulation. Consistently, northern blotting analysis showed that the molecular mass of Tollip mRNA was unexpectedly higher in S-IECs than in L-IECs. Therefore, it was suggested that the translation of the *Tollip* gene expression could be inhibited in S-IECs by post-transcriptional modification of its mRNA. Collectively, it is concluded that the translation of Tollip is inhibited in S-IECs by miR-31 and additional mechanisms.

P4.13.18
Monoclonal intestinal IgAs are poly-reactive against commensal bacteria but recognize a single protein expressed by multiple bacteria

***F. Usui**, S. Okai, M. Hasegawa, R. Shinkura; Nagahama Institute of Bio-science and Technology, Nagahama, Japan.*

Immunoglobulin A (IgA) is crucial for defense at mucosal surfaces and for intestinal homeostasis. Commensal bacteria are much diversified and their composition is easily changed by food. Therefore, to maintain gut homeostasis with limited IgA repertoire, the idea is reasonable that each monoclonal IgA recognizes multiple bacterial strains. Yet, how the monoclonal IgA recognizes multiple different bacteria is not known. We generated IgA-producing hybridomas derived from the intestinal IgA-secreting cells of wild-type mice. We selected three hybridomas producing hyper-mutated IgA. Their CDR amino acid sequences in V_H and V_L regions were not related, suggesting they were independently selected clones. Each of three monoclonal IgAs bound to more than 10 different intestinal bacteria with high-affinity. To elucidate their specific antigens, three different bacteria (*Escherichia coli*, *Pseudomonas fulva* and *Staphylococcus aureus*) were lysed and used for SDS-PAGE and Western blotting. Unexpectedly, all three monoclonal IgAs recognized a single protein at the size of about 46 kDa expressed by three different bacteria. On the contrary, three monoclonal IgAs did not recognize any proteins expressed in *Lactobacillus casei.* It suggests the intestinal microenvironment has a sophisticated mechanism to select the IgA-producing cells, whose antibody can regulate a bunch of commensal bacteria through a common antigen, while allowing the beneficial bacterial growth.

P4.13.19
Density of FOXP3+ T cells and CD11c+ dendritic cells in small bowel mucosa in children with atopic dermatitis, celiac disease and functional gastrointestinal disorders

***T. Vorobjova**[1], K. Ress[1], K. Lepik[2], K. Luts[2], O. Uibo[3,4], R. Uibo[1]; [1]University of Tartu, Department of Immunology, Institute of Biomedicine, Tartu, Estonia, [2]Tallinn Children's Hospital, Tallinn, Estonia, [3]University of Tartu, Department of Paediatrics, Tartu, Estonia, [4]Children's Clinic of Tartu University Hospital, Tartu, Estonia.*

Aim: to evaluate Treg and dendritic cells (DCs) in intestinal mucosa of children with atopic dermatitis (AD) and celiac disease (CD) in comparison to children with functional gastrointestinal disorders (FGD).
Material and Method: 75 patients (37 male, mean age 8.4±4.8 years), who underwent small bowel biopsy were studied. AD was diagnosed in 8, AD with coexisting CD (AD+CD) in 5, CD in 9, FGD in 53 patients. Four of 8 AD and 6 of 53 FGD (p=0.006) are sensitized to grain allergens (ImmunCAP IgE fx20 assay (Phadia Oy). Staining for FOXP3, CD4 and CD11c was performed on paraffin-embedded sections of bioptates using the avidin-biotin method (Vectastain ABC Kit).
Results: The densities of all three cell populations were the lowest in AD group. The density of FOXP3 + cells was significantly higher in CD and AD+CD patients comparing with FGD and AD (p=0.004; p=0.03). CD11c+ DCs density was significantly higher in AD+CD patients comparing with AD alone and with FGD (p=0.03). However, in AD group significantly higher density of CD11c + DCs was in persons positive to sIgE fx5 as well as for sIgE fx20 (p=0.04). The number of CD4+ cells was higher in all other three groups comparing with AD being highly different between AD and AD+CD group (p=0.0007).
Conclusion: Densities of all studied cell types were lowest in AD, whereas FOXP3+ cells were the highest in CD patients. The finding of high variability of cell population densities among patients with FGD represents most probably the different etiology of FGD.

P4.13.20
Foxp3+ regulatory T cells promote a protective Th17 cell response against intestinal infection with *Citrobacter rodentium*

***Z. Wang**[1], S. Cording[2], S. C. Pohl[1], C. Friedrich[1], G. Eberl[2], T. Sparwasser[1], M. Lochner[1]; [1]Institute of Infection Immunology, TWINCORE, Center for Experimental and Clinical Infection Research, a joint venture between the HelmholtZ Center for Infection Research (HZI) Braunschweig and the Hannover Medical School(MHH), Hannover, Germany, [2]Lymphoid Tissue Development Unit, Institut Pasteur, Paris, France.*

Intestinal infection with the mouse pathogen *Citrobacter rodentium* induces a strong local Th17 response. While this inflammatory immune response helps to clear the pathogen, it also induces inflammation-associated pathology in the gut and thus has to be tightly controlled. In this project, we therefore studied the impact of $Foxp3^+$ regulatory T cells (Treg) on the infectious and inflammatory processes elicited by *C. rodentium*. Surprisingly, we found that depletion of Treg by diphtheria toxin in the Depletion of REGulatory (DEREG) mouse model resulted in impaired bacterial clearance in the colon, enhanced body weight loss and systemic dissemination of bacteria. Consistent with the increased susceptibility, we found that the local colonic Th17 cell response was impaired in Treg-depleted mice, suggesting that the presence of Treg is crucial for the establishment of a functional Th17 response in the gut. As a consequence of the impaired Th17 response, we also observed less inflammation-associated pathology in the colons of Treg depleted mice. Interestingly, anti-Interleukin (IL)-2 treatment of infected Treg-depleted mice fully restored the colonic Th17 response, indicating

that Tregs support the induction of a protective Th17 response during intestinal infection by consumption of local IL-2.

P4.13.21
Toward prediction of immune signatures of health

N. P. West[1], *P. L. Horn*[2], *D. B. Pyne*[2], *L. Lee*[3], *S. Asad*[3], *S. J. Lahtinen*[4], *M. Lehtinen*[4], *P. A. Fricker*[5], *B. Fazekas de St Groth*[3], *A. W. Cripps*[1];
[1]*Griffith University, Gold Coast, Australia,* [2]*Australian Institute of Sport, Canberra, Australia,* [3]*Centenary Institute of Cell Biology and Cancer Medicine, Sydney, Australia,* [4]*DuPont Nutrition and Health, Finland, Finland,* [5]*Aspire Zone Foundation, Qatar, Qatar.*

Immune parameters are used as surrogate markers of health in studies of functional foods. Phenotypic heterogeneity within the immune system requires assessment of multiple aspects of the immune system to determine changes in immune status. We aimed to characterise variation in immune biomarkers in healthy individuals over 5 months and in relation to diet, physical activity, age, geographic location and faecal microbiota.
We analysed data from 125 healthy adult individuals (60 females, 65 males; mean age 37.6 ± 11.6 y) collected in a 150 day clinical trial. Participants completed a daily illness log. Faecal samples and fasting blood samples were collected at day 0 and day 150 for assessment of bacterial groups and inflammatory markers, the concentration of plasma cytokines, peripheral $CD4^+$ T-cell subsets, peripheral NK cell function and peripheral blood mononuclear cell (PBMC) phagocytosis.
Initial analysis indicates that there was no substantial change in faecal bacterial groups between day 0 and day 150. There was a significant increase in IL-4, IL-12p70 and macrophage inflammatory proteins while a significant decrease in IL-10 and RANTES was observed between the time points. There was a significant difference between day 0 and day 150 in $CD4^+CD25^+CD127^{lo}$ regulatory T-cells, with individuals undertaking higher levels of physical activity exhibiting a greater increase in frequency compared to those undertaking low levels of physical activity. Large variability (~30%) in the functional capacity of NK cells was observed. Our multifactorial dataset is currently being analysed to identify 'signatures' of immunology associated with illness patterns.

P5.01 Cytokine regulation in disease

P5.01.01
Study of IL-23 expression level in liver transplanted patients

A. Afshari[1], *R. Yaghoobi*[2], *M. Karimi*[2], *M. Darbouy*[1];
[1]*Department of molecular genetics, science and Research, Islamic Azad University, Shiraz, Iran,* [2]*Transplant Research Center, Shiraz University of Medical Sciences, Shiraz, Iran.*

IL-23 has role in development of immune diseases. IL-23 induces Th17 cells and strong proinflammatory activity. Association of IL-23 with rejection of liver allograft was rarely investigated. Therefore, in this study the expression level of IL-23 cytokine was evaluated in liver transplant patients.
30 adult patients who received orthotopic liver were enrolled in this study. The EDTA-treated blood samples were collected in 1st, 3rd and 7th days post transplantation. In house_comparative Real-time PCR was designed for analysis of the expression level of IL-23 compared with β-actin control gene. The expression level of IL-23 was evaluated by Livak method (2-ΔΔcT).
The expression level of IL-23 was highly increased in 3rd and also 7th days relative to 1st day post liver transplantation.
Based on results, increase of IL-23 as a proinflammatory cytokine may relate to in post liver transplant inflammation. Also previously it was known that IL-17 is increased after transplantation and as IL-23 is inducer of IL-17 which this results support it.

P5.01.02
Effects of dexamethasone on IL-6 and IL-8 expression induced by TGF-β1 in colon cancer cells

O. Al Shahrani, *M. Alanazi, A. Semlali;*
King Saud University, Riyadh, Saudi Arabia.

Glucocorticoid (GC), one of the most commonly used anti-inflammatory drugs, inhibits the deposition of extracellular matrix independent of its anti-inflammatory effect. The purpose of this study was to investigate the effects of dexamethasone on expression/production of IL-6 and IL-8 induced by TGF-β1 in colon cancer cell lines (Lovo). Dexamethasone significantly inhibited IL-6 and IL-8 mRNA levels induced by TGF-β1 in Lovo cells. The beneficial effect of Dexamethasone on the TGF-β1-induced IL-6 and IL-8 was mediated through the amelioration of ERK, p38 mitogen-activated protein kinase (MAPK) and JNK phosphorylation; however, this effect was not related to the TGF-β1-induced activation of Smad2/3 signaling. By inhibiting the pro-inflammatory cytokine expression, dexamethasone may contribute to therapy of colon cancer but the dexamethasone has a negative effect in colon cancer treatment because these glucocorticoids can to induce the colon cancer cell proliferation.

P5.01.03
Antitumor effect of a hydroalcoholic extract of Uncaria tomentosa in a murine C57BL/6- B16 melanoma model

Y. P. Alvarez Valdivia[1], *I. Lozada-Requena*[1,2], *C. Núñez*[1,2], *S. Dávila*[1], *T. Ysmodes*[1], *A. Vaisberg*[1], *C. Acuña*[3], *J. L. Aguilar*[1];
[1]*Universidad Peruana Cayetano Heredia, Lima, Peru,* [2]*EMINDES S.A.C, Lima, Peru,* [3]*Universidad de Santiago de Chile, Santiago de Chile, Chile.*

Uncaria tomentosa extracts have shown immunomodulatory, antiproliferative and antitumor activity. However, little is known about its effects in immunocompetent cells or Th1/Th2/Th17 cytokines production.Objective: To evaluate antitumor effect of an hydroalcoholic extract of *Uncaria tomentosa* (Cat's Claw) containing 5.03% pentacyclic oxindole alkaloids (UG-POA) in a murine model for melanoma C57BL/6-B16 by measuring lymphocytes, Th1/Th2/Th17 cytokines and tumor weight and volume. Methodology: Treatment with UG-POA extracts (50,500,100 mg/kg) or its dilution vehicle was given orally 7 days before and 21 days after tumor induction with 1x105 B16. Animals were sacrificed on day 22. Weight and tumor volume were assessed. Peripheral blood mononuclear cells (PBMC) were obtained, and analyzed by flow cytometry. Culture supernatants were collected to measure the production of Th1/th2/th17 using Cytometric Bead Array (CBA). +Results: We found a dose-dependent increase of CD3 + CD4 + LT, being statically significant at 50 and 1000 mg/kg compared with positive control group. However, CD4 + CD44 + LT showed a significant dose-dependent decrease compared with positive control group. CD3 + CD8 + LT population showed no differences in relation with positive control, except for a decrease in 50 mg/kg treated group. When evaluating Th1/Th2/Th17, we only found an increase in IL-6 in a dose dependent fashion, being significant at 1000 mg/kg. Tumor weight and volumes showed no significant differences.
Conclusions: It´s likely that UG-POA exhibits an anti-tumor effect modulating the increase and activation of LT CD4+ and IL6, an important cytokine in the host's immune and metabolic responses to cancer.

P5.01.04
Modulation of Oxido-Nitrosative Stress Induced Neuro-Inflammatory Cascade & Monoaminergic Pathway By Resveratrol In Reserpine Induced Pain Depression Dyad In Rats

V. Arora, *K. Chopra;*
University Institute of Pharmaceutical Sciences, Panjab University, Chandigarh, India.

Background: The emerging concept for pain-depression pathogenesis includes dysfunction of biogenic amine-mediated CNS pain control and the possible involvement of oxido-nitrosative stress-induced

neurogenic inflammation. Thus the aim of the present study was to investigate the effect of resveratrol on the basis of its monoamine replenisher and antioxidant potential in reserpine-induced pain-depression in rats.
Methods and Results: Administration of reserpine (1 mg/kg; sc) for three consecutive days in male wistar rats led to a significant decrease in nociceptive threshold as evident from reduced paw withdrawal threshold in Randall Sellitto and von-Frey hair test and a marked increase in immobility time. This behavioural deficit was integrated with decrease in the biogenic amine (dopamine, norepinephrine and serotonin) levels along with increased substance-P concentration, nerve growth factor, oxido-nitrosative stress, inflammatory cytokines (TNF-α & IL-1β), NF-kβ and caspase-3 levels in different brain regions of the reserpinised rats.
Conclusion: These results reveal that common mechanisms appear plausible as co-activating factors which results in neurophysiological overlap between pain and depression. Furthermore, the study demonstrates the effectiveness of resveratrol in ameliorating the behavioral deficits associated with pain and depression by restoring behavioral, biochemical, neurochemical and molecular alterations against reserpine-induced pain depression dyad

P5.01.05
Maternal cytokine production patterns in women with pre-eclampsia

F. Azizieh[1]*, R. Raghupathy*[2]*, M. Makhseed*[2]*;*
[1]*Gulf University for Science and Technology, Kuwait, Kuwait,* [2]*Faculty of Medicine, University of Kuwait, Kuwait.*

A number of studies on unexplained recurrent spontaneous abortion, premature rupture of membranes and preterm delivery in humans have shown a close association of these conditions with increased production of some type 1 cytokines by peripheral blood cells. The objective of this study was to ascertain whether a Th1-biased cytokine production profile exists in women with pre-eclampsia as compared with normal pregnant women at the time of parturition.
PROBLEM: To determine the levels of cytokines produced upon mitogenic or antigenic stimulation of maternal peripheral blood mononuclear cells (PBMC) from women with pre-eclampsia.
METHOD OF STUDY: PBMC from 54 women with a history of successful pregnancy and 32 women undergoing pre-eclamptic delivery were stimulated with a mitogen or with autologous placental cells or with trophoblast antigens, and the levels of cytokines released into the culture supernatants then assessed by enzyme-linked immunosorbent assay. RESULTS: Significantly higher levels of the Th1 cytokines, interferon-gamma, and tumor necrosis factor-alpha were produced by the pre-eclamptic group than by the normal pregnancy group, which on the contrary showed significantly greater production of the Th2 cytokines, interleukin (IL)-4, IL-5, IL-6 and IL-10. A comparison of the ratios of Th2 to Th1 cytokines indicates a higher Th1 cytokine bias in pre-eclampsia as compared with normal pregnancy.
CONCLUSIONS: These data are suggestive of a maternal Th1 cytokine bias in pre-eclampsia.

P5.01.06
Suppressive Role of IL-27 against Pro-inflammatory Role of IL-17A in Patients with Multiple Sclerosis

Z. Babaloo[1]*, R. Kh. Yeganeh*[1]*, M. farhoodi*[2]*, B. Baradaran*[1]*, M. Boniadi*[1]*;*
[1]*Tabriz University of Medical Sciences, Immunology Dept., Tabriz, Iran,* [2]*Tabriz University of Medical Sciences, Neuroscience Research Center, Tabriz, Iran.*

Background: Effector $CD4^+$ T cell subsets have important role in Multiple Sclerosis (MS). Interleukin-27 (IL-27) suppresses Th (Th1, Th2 and Th17) cells and dampens autoimmunity and tissue inflammation via promoting the generation of Tr1 cells. IL-27 significantly inhibits both nonpolarized and IL-23 driven IL-17 production by myelin-reactive T cells. A strong suppressive effect of IL-27 has been demonstrated in active experimental autoimmune encephalomyelitis (EAE). IL-27 can potently suppress the IL-17A effects and effective phase of EAE in vivo and may have potential therapeutic role in autoimmune diseases such as MS.
Objective: The aim of this study was identifying the role of IL-27 and whether this cytokine suppresses the inflammatory cytokine IL-17 in MS patients.
Methods: Venous blood was collected from forty MS patients and forty-three healthy subjects as control group. Serum levels of IL-27 and IL-17A were measured by ELISA method.
Results: This study showed significant difference between serum levels of IL-17A in MS patients (120.68 ± 209.85 pg/ml) and control group (67.26 ± 117.76 pg/ml), ($p < 0.05$). Serum IL-27 levels of MS patients (159.7 ± 581.4 pg/ml) were significantly lower than control subjects (180.35 ± 507.84 pg/ml), ($p < 0.05$).
Conclusion: Our findings suggest the potential inhibitory role of IL-27 on IL-17 mediated inflammatory process of MS disease.

P5.01.07
Immune mechanisms in periodontitis - effect of IL-4 gene polymorphisms on cytokine production

J. Bartova[1]*, P. Borilova Linhartova*[2]*, S. Podzimek*[1]*, K. Svobodova*[1]*, T. Janatova*[1]*, A. Fassmann*[3]*, J. Duskova*[1]*, L. Izakovicova-Holla*[3]*;*
[1]*Institute of Clinical and Experimental Dental Medicine,GUH and First Faculty of Medicine, Charles University, Prague, Czech Republic,* [2]*Department of Pathophysiology, Faculty of Medicine, Masaryk University, Brno, Czech Republic,* [3]*Clinic of Stomatology, Faculty of Medicine MU and St Anne´s University Hospital, Brno, Czech Republic.*

Introduction: Periodontitis is a chronic inflammatory disease of the teeth-supporting tissues in which genetic predisposition, dental plaque bacteria and immune mechanisms play important roles. The aim of this study was to assess the influence of IL-4 gene polymorphisms on cytokine production
Methods: Cytokine production (IL-1α, IL-1β, IL-4, IL-5, IL-6, IL-8 , IL-10, TNF-α, INF-γ) was studied after *in vitro* stimulation of isolated peripheral blood mononuclear cells (PBMC) by mitogens and dental plaque bacteria (*Aggregatibacter actinomycetemcomitans, Escherichia coli, Tannerrella forsythensis, Porphyromonas gingivalis* and Heat Shock Protein 60). Cytokine production was detected by *multiplex cytokine analysis* system Luminex. The results were correlated with IL-4 genotypes in patients with chronic periodontitis (CP) and healthy controls.
Results: We found that mononuclear cells isolated from peripheral blood of CP patients with investigated IL-4 polymorphisms (-589C/T, -33C/T, VNTR in intron 3) significantly changed production of IFN-γ, IL-10, IL-1β and IL-1α, TNF-α, IL-10, MCP-1, IL-6 after stimulation by all selected bacteria and HSP ($p<0.05$).
Conclusion: In patients with CP, IL-4 polymorphisms may influence the function of mononuclear cells to produce not only IL-4 but also other cytokines. The results of this study support Seymour's hypothesis (1999) about the role of TH2 produced cytokines such as IL-4 in genetic predisposition to chronic periodontitis.
The study was supported by PRVOUK-P28/LF1/6 (Ministry of Education, Youth and Sports, Czech Republic) and by grant IGA NT11405-6.

P5.01.08
Concentration Levels of IL -10 and TNF-α Cytokines in Patients with HPV DNA Positive and Negative Cervical Lesions

H. Y. M. Bayazed*;*
Technical Institute-Zakho/Kurdistan, Zakho, Iraq.

The study was performed to assess the immune response in women with HPV DNA positive and negative cervical lesions. Estimation of IL-10 and TNF-α cytokines was performed through utilizing Enzyme linked immunosorrbent assay (ELISA) technique in cervical secretions and serum of the studied patients. Moreover, PCR screening kits were utilized to detect HPV DNA on cervical smears obtained from the studied cases with different cervical lesions. The detected levels of IL-10 (mean ± SE) concentration in cervical secretions of patients with HPV DNA positive and negative states and control group were 88.73 ± 16.90 pg/ml, 24.00 ± 2.84 pg/ml and 8.27 ± 0.59 pg/ml respectively with significant statistical differences

(p<0.05). . Moreover, the observed levels of TNF-α in cervical secretion of the cases with HPV DNA positive and negative states and control group were 12.18 ± 3.49 pg/ml, 9.90 ± 0.73 pg/ml, and 7.90 ± 0.87 pg/ml respectively, but with non statistical significance differences. **:** A raised production pattern of both IL-10 and TNF-α level in secretions of HPV D NA positive women with different cervical lesions were detected. However, the observed higher levels of IL-10 than TNF-α indicate down-modulation of tumor-specific immune response to HPV infected lesions via significant raised concentrations of the first cytokine than the second one. Therefore, this phenomenon seems to provide a tumor progressive microenvironment by the immunosuppressant properties of IL-10 with minimal antitumor activity of TNF-α. This was ascertained by the detected higher levels of IL-10 in lesions with advanced and progressive cytological stages.

The inflammatory cytokine TNFalpha cooperates with hyper-activated Ras in promoting metastasis and turns WT-Ras into an oncogenic entity

*T. Leibovich-Rivkin[1], Y. Liubomirski[1], T. Meshel[1], A. Abahidze[1], A. Abahidze[1], D. Brisker[1], H. Solomon[2], V. Rotter[2], M. Weil[1], **A. Ben-Baruch**[1];*
[1]Tel Aviv University, Tel Aviv, Israel, [2]Weizmann Institute of Science, Rehovot, Israel.

To improve our ability to interfere with processes of cancer growth and progression we need to better understand the relative contribution of oncogenic events vs. cells/factors of the tumor microenvironment to these processes. Our published study of non-transformed cells has shown that inflammatory cytokines had a more prominent impact, compared to oncogenic Ras^{G12V} and deregulated p53, in inducing a "cancer-related chemokine cluster", of which the angiogenic chemokine CXCL8 was a prominent member. In the present study, we extended this research direction to breast tumor cells originally expressing WT-Ras and WT-p53. In contrast to non-transformed cells, in which Ras^{G12V} had to act together with deregulated p53 to induce the chemokines, in the tumor cells, Ras^{G12V} induced CXCL8 without need for accompanying p53 down-regulation. In the tumor cells, TNF and IL-1 synergized with Ras^{G12V}, together leading to amplified elevation in CXCL8 release and mRNA expression. WT-Ras was not active in promoting CXCL8; however, TNF activation has turned WT-Ras into an active, GTP-bound prenylated form, and the joint activities of TNF+WT-Ras have led via MEK activation to increased CXCL8 release by the tumor cells. The additive effects of TNF+WT-Ras were mediated by increased activation of NF-B and AP-1. Jointly, TNF + Ras activities have given rise to increased angiogenesis and pronounced elevation in dissemination of tumor cells to lymph nodes. Thus, in breast cancer patients, where tumors are enriched with TNF, the cytokine may rescue the oncogenic potential of WT-Ras (which is the prevalent form), together giving rise to more aggressive disease.

P5.01.10
Cytokines, depression, and anxiety in patients with colorectal cancer

*D. O. Miranda[1], L. R. Azevedo[2], T. A. S. Lima[3], O. Feres[4], J. J. R. Rocha[4], **G. S. Bisson**[5];*
[1]Programa de Pós-graduação em Enfermagem em Saúde Pública, EERP/USP, Ribeirão Preto, Brazil, [2]Programa de Pós-graduação em Imunologia Básica e Aplicada, FMRP/USP, Ribeirão Preto, Brazil, [3]EERP/USP, Ribeirão Preto, Brazil, [4]Depto. Cirurgia e Anatomia, FMRP/USP, Ribeirão Preto, Brazil, [5]Depto. Enfermagem Materno-Infantil e Saúde Pública, EERP/USP, Ribeirão Preto, Brazil.

Colorectal cancer (CRC) is a leading cause of cancer mortality in the world. Depression and anxiety are the most prevalent psychological disorders in patients with CRC. This study aims to investigate whether there is a correlation between anxiety, depression and serum cytokines in CRC patients. The study group consisted of 19 patients hospitalized for surgical resection of CRC and 20 healthy volunteers comprised the control group. Depression and anxiety were analyzed using the Hospital Anxiety and Depression Scale and serum levels of IL-1, IL-6, IL-12, TNF-α, TGF-β and IL-10 were measured by ELISA. We found that approximately 50% of CRC patients manifested clinically significant levels of anxiety and depression or a combination of severe anxiety and depression. Furthermore, these patients had increased serum levels of IL-1, IL-6 and TNF-α, but lower concentrations of IL-12. Analysis of correlation between HADS scores and serum levels of cytokines in CRC patients revealed a positive association of anxiety and/or depression with IL-1, IL-6 and TNF-α and a negative correlation with IL-12. These initial results indicate a correlation between serum levels of pro-inflammatory cytokines, anxiety and depression in CRC patients and suggest that cytokines are involved in the pathophysiology of these comorbidities.

Autoimmune/lymphoproliferative syndrome (ALPS), and its animal model MRL/Lpr mice, are characterized by autoimmunity, lymphoadenopathy and expansion of TCRαβ+ CD4/CD8 double-negative (DN) T cells and are due to mutations hitting the Fas/FasL system. Dianzani Autoimmune Lymphoproliferative Disease (DALD) is a similar picture, but lacks expansion of DN T cells. In this work, we investigated the role played by IL-17 in ALPS and DALD. We demonstrated that IL-17 (A and F) serum levels were higher, and Th-17 memory cells were expanded, in ALPS and DALD patients than in healthy controls (p<0.05). We then evaluated the effect of recombinant IL-17 (rIL-17) in Fas-induced cell death (FICD). Results showed that rIL-17 (A and F) significantly inhibited FICD of T-cells; this effect was specific since it was reversed by anti-IL-17 neutralizing Ab. Interestingly, IL-17 in the patients' sera was enough to prevent cell death of Fas-sensitive T-cells and surprisingly blocking of IL-17 in patients' sera restored their Fas-sensitivity. These data induced us to set a preclinical study to test the therapeutic effect of an IL-17 blocking Ab. MRL/Lpr treated mice showed reduced lymph nodes and spleen weight, with a decrease in DN T cells, lower dsDNA Abs, and prolonged life span (p<0.01). Collectively, these data suggest that in some ALPS/DALD patients, high levels of IL-17 contribute to the apoptotic defects typical of patients, and is a proof of concept that IL-17 may be a new therapeutic target.

Haplotype analysis of interleukin-8 gene polymorphisms in chronic and aggressive periodontitis

***P. Borilova Linhartova**[1], J. Vokurka[2], H. Poskerova[2], A. Fassmann[2], L. Izakovicova Holla[1,2];*
[1]Department of Pathophysiology, Faculty of Medicine, Masaryk University, Brno, Czech Republic, [2]Clinic of Stomatology, Institutions Shared with St. Anne's Faculty Hospital, Faculty of Medicine, Masaryk University, Brno, Czech Republic.

Objective: Periodontitis is an inflammatory disease characterized by connective tissue loss and alveolar bone destruction. Interleukine-8 (IL-8) variants are important in the regulation of the inflammatory response. The aim of this study was to analyze four polymorphisms in the IL8 gene and their haplotypes in relation to chronic (CP) and aggressive periodontitis (AgP).
Design: A total of 492 unrelated subjects were included in this case-control study. Genomic DNA of 278 patients with CP, 58 patients with AgP, and 156 healthy/non-periodontitis controls were genotyped, using the 5′ nuclease TaqMan® assay for allelic discrimination, for IL8 (rs4073, rs2227307, rs2227306, rs2227532) gene polymorphisms. Subgingival bacterial colonization was investigated by the DNA-microarray based on a periodontal pathogen detection kit in a subgroup of subjects (N=114).
Results: Allele and genotype frequencies of all investigated IL8 polymorphisms were not significantly different between the subjects

with CP and/or AgP and controls (p > 0.05). Nevertheless, the complex analysis revealed differences in IL8 haplotype frequencies. Specifically, the haplotypes A(-251)/T(+396)/T(+781) and T(-251)/G(+396)/C(+781) were significantly less frequent in patients with CP (2.1% versus 5.5%, resp. 4.9%, p < 0.05) and haplotype T(-251)/G(+396)/C(+781) was significantly less frequent in patients with AgP (0.9% versus 4.9%, p < 0.05) than in controls.
Conclusions: Although none of the investigated SNPs in the IL8 gene was individually associated with periodontitis, some haplotypes can be protective against CP and AgP in the Czech population.
Acknowledgements: This study was supported by the project IGA NT11405-6.

Up till now, altered balance of Th1 and Th2 immune cells has been postulated to play an important role in the pathogenesis of autoimmune thyroid diseases (AITD). However, recent studies on thyroid diseases suggest a new role for Th17 (T helper 17) cells. The aim of the study was to estimate the proporcions of circulating CD4+CD161+CD196+ and CD4+IL-17+ Th17 cells and serum concentrations of IL-17 & IL-23 in patients with Graves' disease (GD, n=22, mean age 14.3 ± 4 years), Hashimoto's thyroiditis (HT, n=37, mean age 15±2 yrs) and in healthy controls (C, n=25, mean age 15.2 ± 2 yrs). In untreated HT children we observed an increased percentage of CD4+CD161+CD196+ (p <0.04) and CD4+IL-17+ (p <0.01) Th17 lymphocytes in comparison to the healthy controls. In GD children we did not reveal such abnormalities in the population of these cells. In untreated patients with AITD we observed an increased levels of IL-23 in comparison to controls (GD, p=0.004;HT, p=0.046). Methimazole treatment in GD led to decrease these cytokine levels in a period of 6-12 months. However, during 6-24 months of L-thyroxine therapy in HT there wasn't any reduction of IL-23 concentration compared with HC. IL-17 was elevated in HT cases in comparison to the controls (p=0.021), which normalized during therapy.We conclude that the increased percentage of Th17 cells and elevated level of IL-17 and IL-23 cytokines in children with HT can suggest their role in initiation and development of immune and inflammatory processes in this endocrinopathy.

P5.01.14
Cryoglobulins are involved in pathomechanisms of altered immune response associated with schizophrenia and ischemic stroke

A. Boyajyan*, A. Chavushyan, M. Hovsepyan, M. Hovhannisyan;*
Institute of Molecular Biology NAS RA, Yerevan, Armenia.

The aim of this study was to investigate the effects of abnormal immune complexes, cryoglobulins (Cgs), recently found by us in the blood of patients with schizophrenia (SCZ) and ischemic stroke (IS) on the production of pro-inflammatory cytokines (IL-1β, IL-6, TNF-α), anti-inflammatory cytokine (IL-10), and chemotactic cytokines (IL-8, MCP-1) by peripheral blood mononuclear cells (PBMCs). In this study Cgs isolated from the blood of patients with SCZ and IS and PBMCs isolated from the blood of healthy subjects were used. The enzyme-linked immunosorbent assay (ELISA) and 3-(4,5)-dimethylthiazol-2-yl)-2,5 diphenyl tetrazolium bromide (MTT) assay were used upon study. The results obtained indicated significant increase in IL-1β, IL-6, TNF-α, IL-8, and MCP-1 production by cultured PBMCs when incubating for 24 hours with Cgs in the range of concentrations of 0.2-1.0 mg/ml. The gender difference did not affect Cgs-induced production of these cytokines by PBMCs. No influence of Cgs on production of IL-10 by PBMCs was observed. Based upon the results obtained we concluded that Cgs presented in the blood of SCZ and IS patients are implicated in the immune response alterations associated with these diseased conditions through induction of the expression of pro-inflammatory and chemotactic cytokines. The potential mechanisms of Cgs-induced alterations in pro-inflammatory and cytotoxic cytokines production by PBMCs is proposed, considering implication of the Fc and CR1 receptors as well as the complement cascade in these processes.

P5.01.15
IL-17 plays a critical pathogenic role in lung cancer

S. Chang*, S. Mirabolfathinejad, A. Cumpian, C. Ochoa, L. Gong, S. Moghaddam, C. Dong;*
MD Anderson Cancer Center, Houston, TX, United States.

Lung cancer development is associated with extensive pulmonary inflammation. Lack of understanding on the tumor-promoting mechanisms of inflammation in lung cancer hampers efficient and targeted tumor therapy. IL-17-producing CD4+ helper T cells (Th17 cells) play a critical role in promoting tissue inflammation. While Th17 cells are found in human lung cancer, their role in lung cancer is not known. We have applied a mouse model of lung cancer, in which an oncogenic form of K-ras (K-ras^{G12D}), frequently found in human lung cancer, is restrictedly expressed in lung epithelial cells (CCSP^{cre}). In this model, Th17 and Treg but not Th1 cells are enriched at the tumor tissues. When CCSP^{cre}/K-ras^{G12D} mice were intranasally challenged with lysates of non-typeable *Haemophilus influenza* (NTHi), which accelerated the tumor growth, they showed greatly enhanced Th17 cell infiltration in the lung tissues, suggesting a tumor-promoting role by Th17 cells. Indeed, lack of IL-17, but not IL-17F, results in significant reduction in lung tumor numbers in CCSP^{cre}/K-ras^{G12D} mice and also those treated with NTHi. Absence of IL-17 not only resulted in reduction of tumor cell proliferation and angiogenesis, but also reduced recruitment of myeloid cells and decreased the expression of pro-inflammatory mediators. Taken together, our data demonstrate a critical tumorigenic role of Th17 cell-mediated inflammation in lung adenocarcinoma and may suggest a novel way of prevention and treatment of this disease

P5.01.16
Effects of imiquimod treatment on TNF expression in two-step skin carcinogenesis model in mice

A. A. Chashchina[1,2], *S. V. Bozrova*[1,2], *R. V. Zvartsev*[2], *T. Kammertoens*[3], *V. A. Levitsky*[4,5], *S. A. Nedospasov*[1,2], *M. S. Drutskaya*[1,2];

Aldara, 5% imiquimod cream, is widely used in the clinic for treatment of virus-associated genital warts and several forms of skin cancer. There is evidence indicating a boost in the immune response against virus-infected or transformed cells following imiquimod application. Imiquimod has been initially characterized as an agonist of TLR7/8, however, most recent data suggest that it has a wider mode of action. In particular, it may be involved in regulating cAMP levels resulting in immunosuppression. We found that imiquimod dampens TNF production in both bone-marrow derived and peritoneal macrophages in response to LPS. Moreover, production of TNF is inhibited by imiquimod in vivo - in LPS/D-Gal hepatotoxicity model, as well as in LPS-induced septic shock. As TNF-mediated inflammation has been shown to support tumor formation in skin carcinogenesis, we wanted to assess effects of imiquimod treatment on inflammation during early stages of carcinogenesis. For this purpose, we performed two-step

skin carcinogenesis experiments applying DMBA/TPA to the back skin of Balb/C mice followed by imiquimod treatment. Two weeks after DMBA application followed by six TPA applications, skin samples were harvested and expression profile of several proinflammatory cytokines was analyzed. We found that animals subjected to DMBA/TPA and then treated by imiquimod had significantly decreased levels of TNF and other pro-inflammatory cytokines compared with the controls. Taken together, our data indicate that imiquimod inhibits TNF production in several experimental models, including the two-step skin carcinogenesis, thereby providing a new insight into its mode of action in patients undergoing Aldara treatment.

P5.01.17
Interferon gamma supresses collagen-induced arthritis through regulation of IL-17 : possible role of indoleamine 2,3 deoxygenase

***M. Cho**, J. Jhun, M. Lim, J. Lee, J. Lee, S. Park;*
The Rheumatism Research Center, Catholic Research Institute of Medical Science, The Catholic University, Seoul, Republic of Korea.

C57BL/6 mice are known to be resistant to the development of collagen-induced arthritis (CIA). However, they show a severe arthritic phenotype when the Ifng gene is deleted despite that IFN-γ is generally regarded as a pro-inflammatory cytokine. This study was conducted to 1) clarify that arthritogenic condition of IFN-γ knockout (KO) mice is dependent on the disinhibition of Th17 and 2) demonstrate that IFN-γ-induced indoleamine2,3dioxgenase (IDO) is engaged in the regulation of Th17. The results showed that the IFN-γ KO mice displayed increased levels of IL-17 producing T cells and the exacerbation of arthritis. When Il17 was deleted from the IFN-γ KO mice, only mild arthritis developed without progression of arthritis score. With respect to lymphocyte subtype population, the proportion of CD44highCD62Llow memory-like T cell was elevated in the spleen, draining the lymph node and mesenteric lymph node of IFN-γ KO CIA mice. When Th17 polarized CD4+ T cells of IFN-γ KO mice were co-cultured with their own antigen presenting cells (APCs), a greater increase in IL-17 production was observed than in co-culture of the cells from wild type mice. Of note, pretreatment of 1-methyl-DL-tryptophan, a specific inhibitor of IDO, abolished the inhibitory effects of IFN-γ. Given that IFN-γ is a potent inducer of IDO in APCs, these results suggest that IDO is involved in the regulation of IL-17 by IFN-γ.

P5.01.18
GLK controls Th17-mediated autoimmunity and NF-κB signaling by activating PKC-θ in T cells

***H. Chuang**[1], J. Lan[2], D. Chen[2], T. Tan[1,3];*
[1]Immunology Research Center, National Health Research Institutes, Zhunan Miaoli County, Taiwan, [2]Division of Allergy, Immunology, and Rheumatology, Taichung Veterans General Hospital, Taichung, Taiwan, [3]Department of Pathology and Immunology, Baylor College of Medicine, Houston, TX, United States.

PKC-θ is required for NF-κB activation induced by T-cell receptor (TCR) signaling; however, the direct activator of PKC-θ was unknown. We found that GLK (MAP4K3) directly activates PKC-θ during TCR signaling. TCR signaling activates GLK by inducing its direct interaction with the upstream adaptor protein SLP-76. GLK-deficient mice show impaired immune responses and are resistant to Th17-mediated experimental autoimmune encephalomyelitis. Consistently, systemic lupus erythematosus (SLE) patients show dramatically enhanced GLK expression and PKC-θ-IKK activation in T cells, and the percentage of GLK-overexpressing T cells is correlated with disease severity. Our recent data indicate that GLK overexpression is also involved in adult-onset Still's disease (AOSD), rheumatoid arthritis (RA), and other autoimmune diseases. Data derived from GLK transgenic mice further indicate that GLK plays a critical role in Th17-mediated autoimmunity. IL-17 production in T cells is regulated by GLK signaling; the mechanism of GLK-induced IL-17 production will be discussed. Taken together, GLK is a direct activator of PKC-θ and activation of the GLK-PKC-θ-IKK could be used as novel diagnostic biomarkers and therapeutic targets for Th17-mediated autoimmune diseases. (Supported by NHRI-98A1-IMPP01-014)

P5.01.19
Immune response to a mixture of bacterial lysates in a rat model

***D. Cid Guerrero**[1,2], J. Martinez Castillo[1], I. Vargas Rodriguez[1], S. Sanchez Rodriguez[1], R. Ramirez Santoyo[1], E. Lopez Robles[1];*
[1]Universidad Autonoma de Zacatecas, Zacatecas, Mexico, [2]Hospital General ISSSTE Zacatecas, Zacatecas, Mexico.

Bacterial lysates mixtures are widely used with the intention to generate a protective immune response in patients with repeated respiratory infections. We examined three study groups: group 1 received the injection of a bacterial lysate mixture. Group 2 received lipopolysaccharide (LPS), and group 3 Evans solution. All groups were injected with increasing doses at day 0 and 8. We obtained serum at time 0, 24 h, day 8 and day 15 to measure IL-1β, IL-4, IL-10 and IFN-γ by ELISA assay. In group 1, injected with bacterial lysates, there is an initial response at 24 h followed by a decrease in cytokines compared to basal levels and a final increase at day 15, being more evident for IL-4 (9.3 / 0 / 0 / 56.3pg/ml) and IL-1β (67.7 / 63.1 / 74.1 / 77.5pg/ml). The group 2 response to LPS administration shows an important initial increase at 24 h for IL-10 (39.4 / 117.9 / 53.4 / 23.6 pg/ml), IL-4 (13.4 / 49 / 52.9 / 45.9 pg/ml), IL-1β (72 / 92.6 / 82.1 / 71.8 pg/ml) and IFN-γ (13.2 / 21 / 29 / 17.5 pg/ml) and then a gradual decline practically to basal levels after 15 days. The group 3 responded to IL-10 (32.4 / 56.4 / 17 / 27.7 pg/ml). Our results show a change in cytokine levels to the immune stimulus with lysate bacterial in this rat model, identifying a progressive and gradual response especially for IL-4 and IL-1β.

P5.01.20
Regulation of lymphoma B cell proliferation by IL-31 and its receptor

*E. Ferretti[1], G. Pagnan[1], C. Guarnotta[2], G. Fraternali-Orcioni[3], S. Zupo[4], C. Tripodo[2], V. Pistoia[1], **A. Corcione**[1];*
[1]Laboratory of Oncology, Istituto Giannina Gaslini, Genova, Italy, [2]Tumor Immunology Unit, Department of Health Science, Human Pathology Section, University of Palermo, Palermo, Italy, [3]Unit of Pathology, IRCCS Azienda Ospedaliera Universitaria San Martino – IST – Istituto Nazionale per la Ricerca sul Cancro, Genova, Italy, [4]Laboratory of Diagnostics of Lymphoproliferative Disorders, IRCCS Azienda Ospedaliera Universitaria San Martino – IST – Istituto Nazionale per la Ricerca sul Cancro, Genova, Italy.

Interleukin-31 (IL-31) is a member of the IL-6 cytokine superfamily originally identified as product of activated Th2 cells. IL-31 signals through an heterodimeric receptor composed of a gp130-like (GPL) receptor chain, IL-31 receptor A (IL-31RA), and the Oncostatin M Receptor (OSMR). No information is available on the effects of IL-31 on normal or malignant B cells.
IL-31R complex was expressed in FL B cells both at mRNA and protein level and mediated IL-31 driven cell proliferation by activating the STAT/MAPK signaling pathways. In contrast, the postulated normal counterpart of FL B cells, *i.e.* GC B cells, expressed the IL-31R complex but no signal transduction was detected following exposure to IL-31. IL-31 and IL-31RA expression was investigated in FL tissue samples from patients with different histological grading and found to be significantly increased in grade III compared to grade I samples. Altogether, these findings point to
a role of IL-31/IL31R complex in FL progression. Western blot experiments showed expression of IL-31 both in the cytosol and the surface membrane fractions of FL cells and normal GC B cells, but no IL-31 secretion in culture supernatants was detected by ELISA and Western blot.
These results may suggest that in FL B cells surface IL-31 binds to its receptor and triggers signal transduction in adjacent tumor cells through paracrine loops. An alternative possibility under investigation is that IL-31 is released in fluid phase within microvesicles such as exosomes.

P5.01.21
Evaluation of potential serum biomarkers for periodontal disease in type 1 diabetes mellitus children

C. Duque[1], *M. F. Dib*[2], *F. S. Mariano*[2], *G. A. C. G. Camargo*[3], *N. H. Colombo*[1], *R. O. Mattos-Graner*[2];
[1]*State University of São Paulo - UNESP, Araçatuba, Brazil,* [2]*University of Campinas, Piracicaba, Brazil,* [3]*Federal Fluminense University, Nova Friburgo - RJ, Brazil.*

The most prevalent periodontal disease among children is gingivitis, and it usually becomes more severe in adolescence. If gingivitis is not treated, it may progress to periodontitis. Diabetic patients are considered a high-risk group with greater susceptibility to severe forms of periodontal destruction. A few reports on the relationship between diabetes and periodontal disease have included children and adolescents. New data support the concept that in diabetes-associated periodontitis, the altered host inflammatory response plays a critical role. Among the pro-inflammatory biomarkers, IL1-β, TNF-α and PGE2 are considered modifiers of periodontal disease expression in adult diabetic patients. The aim of this study was to compare periodontal status and the level of serum biomarkers in children with type 1 diabetes versus healthy children. Fifty children (25 diabetic and 25 non-diabetic children) were selected and the clinical parameters, plaque index, gingival index and pocket depth, were recorded. Pro-inflammatory mediators levels (TNF, IL1-β,IL-6 and PGE2) from blood samples were measured using enzyme-linked immunosorbent assays. The results were statistically analyzed using ANOVA one way test ($p<0.05$). Regarding periodontal status, there was no statistical difference between diabetic and non-diabetic children. Among the serum biomarkers evaluated, IL1-β concentration was associated with the severity of gingivitis, but not the presence of diabetes. In conclusion, IL1-β could be an important early biomarker to periodontal disease, regardless the presence of diabetes mellitus. Supported by FAPERJ:grants no.E-26/110.508/2010; E-26/102.275/2011

P5.01.22
Influence of TLR2 in the cytokine profile after S. schenckii infection

C. Duque[1], *T. d. Negrini*[2], *L. S. Ferreira*[2], *P. Alegranci*[2], *M. C. P. Placeres*[2], *R. A. Arthur*[3], *L. C. Spolidorio*[2], *I. Z. Carlos*[2];
[1]*State University of São Paulo - UNESP, Araçatuba, Brazil,* [2]*State University of São Paulo - UNESP, Araraquara, Brazil,* [3]*Federal University of Rio Grande do Sul, Porto Alegre, Brazil.*

Sporotrichosis is a mycosis resulting from Sporothrix schenckii infection that causes skin and subcutaneous lesions. Toll like receptors play an important role in immunity, since they bind to pathogen surface antigens and initiate the immune response. However, little is known about the role of TLR and recognition of S. schenckii by immunological system. The aim of this study was to evaluate the influence of TLR2 in the cytokine profile after mice infection with S. schenckii. Female mice of C57BL/6 Wild type (WT) and C57BL/6 TLR2 Knockout (TLR2-/-) lineages were infected with S. schenckii and over a period of 10 weeks of sporotrichotic infection was measured the production of IL-1β, IL-12 and TNF-α by peritoneal macrophages and IL-4, IL-10 by spleen cells using enzyme-linked immunosorbent assays. The results were statistically analyzed using ANOVA one way test ($p<0.05$). The production of IL-1β, IL-12 and TNF-α was abolished in knockout mice. Regarding the cytokines IL-10 and IL-4, absence of the aforementioned receptor reduced the released levels to below those observed in animals with normal TLR2 expression. In conclusion, the production of these inflammatory mediators was highly dependent of the presence of TLR2 and could interfere with the course of the infection induced by S. schenckii.Supported by FAPESP: grants no. 2009/11999-3 e 2009/07529-1

Lack of correlation between IL-21 and type I IFN signature suggests different roads to pathogenesis in Rheumatoid Arthritis

R. Ettinger[1], *J. L. Karnell*[1], *C. A. Morehouse*[1], *E. Grant*[1], *D. Taylor*[1], *M. Wilson*[2], *R. Goldbach-Mansky*[2], *Y. Yao*[1], *R. Herbst*[1], *L. Carter*[1];
[1]*MedImmune LLC, Gaithersburg, MD, United States,* [2]*National Institutes of Health-NIAMS, Bethesda, MD, United States.*

IL-21 and IFNa are increased in several autoimmune syndromes including Rheumatoid Arthritis (RA). These cytokines have pleiotropic actions on cell types of lymphoid and non-lymphoid origin and both have been reported to induce plasma cell differentiation. In a cohort of RA patients (n=42), we tested if a correlation exists between IL-21 and type I IFN (IFN) and how these cytokines segregate with particular autoantibodies and immunologic mediators. In ~50% of the RA patients examined, IL-21 serum levels were elevated (up to ~500 pg/ml) vs. the majority of normal individuals under 20 pg/ml (n=30/31). Increased IL-21 was not part of general cytokine activation, as only 8/97 analytes measured associated significantly with increased IL-21 levels. Strikingly, a tight correlation existed between IL-21 levels and the presence of IgM Rheumatoid Factor (RF) $p=0.0003$ and to cyclic citrullinated peptide autoantibodies (CCP) $p=0.0155$, but not to anti-ss or -dsDNA Ab titers in which only 6/42 and 5/42, respectively of RA had titers. In this RA cohort, ~20% of the patients had a 4-gene IFN signature of whole blood. Importantly, there was no correlation between increased IL-21 levels and IFN signature score. IFN signature score was independent of RF or anti-CCP titers, but correlated to ssDNA autoantibody titers $p=0.0367$ and trended towards an association with anti-dsDNA autoantibody titers. These data suggest that while both IL-21 and IFN are believed to be involved in the pathogenesis of rheumatic disease, these pathways do not appear to intersect in RA patients, and may represent distinct targets for disease intervention.

P5.01.24
T cell activation markers and inflammatory cytokine profile in patients with diabetic nephropathy undergoing hemodialysis

A. Almeida[1], *N. Costa*[1], *O. M. Lourenço*[2], ***A. L. Fonseca***[2];
[1]*CICS-UBI, Health Sciences Research Centre-University of Beira Interior, Covilhã, Portugal,* [2]*CICS-UBI, Health Sciences Research Centre-University of Beira Interior-Faculty of Health Sciences, Covilhã, Portugal.*

Diabetic nephropathy (DN) is a common complication disease in diabetic patients, and most of them need to be integrated into renal replacement therapy such as hemodialysis (HD). Our objective was to access the expression the activation markers on T cells, as well as the synthesis of inflammatory cytokines, before and after HD. The study was approved by the local ethics committee and involved 17 patients with DN under HD treatment which signed an informed consent. Blood samples before and after one HD session were collected, in order to analyze the expression of CD25, CD69 and CD71 in T cells. We also analyzed the synthesis of IL-12p70, IL-8, IL-10, IL-1β, TNF-α and IL-6 in serum samples by Cytometric Bead Array. After the HD session, there was an increase in CD4/CD8 ratio due to significant alterations in both subsets. The relative percentage of CD25+ T cells and CD8+CD25+ increased significantly after the HD session, while the relative percentage of CD69 T cells decreased. There was a significant decrease of the CD25 Mean Fluorescence Intensity values for CD4+ T, as well as in the case of CD71 in T cell sub-populations, after the HD session. Regarding cytokine synthesis in serum samples, we found a significant increase in IL-10 and IL-6 and a decrease in IL-8 after HD session. This study showed that a HD session in DN patients affects the T cell activation status, and differentially modulates the production of inflammatory cytokines.We thank CENTRO-07-ST24-FEDER-002015 funding.

Expression of cytokine and Chemokine receptors on benign and malignant ovarian tissues

A. Ghaderi[1]*, S. Rezaeifard*[1]*, M. Razmkhah*[2]*, M. Robati*[3]*, M. Momtahan*[3]*;*
[1]*Shiraz Institute for Cancer Research, Department of Immunology, Shiraz, Iran,* [2]*Shiraz Institute for Cancer Research, shiraz, Iran,* [3]*Department of Gynecology, Shiraz University of Medical Sciences, shiraz, Iran.*

Background: Cytokines, Chemokines and their receptors regulate the proliferation and survival of tumor cells, angiogenesis and metastasis to other organs. This network of ligand and receptors has been used in molecular targeting of cancer. Methods: We compared the mRNA expression of CXCR3, IP-10, CXCR4, SDF-1, IL-4 and IL-10 in tissues of benign and malignant ovarian tumors by qRT-PCR method. Results: Our result showed that CXCR4 expressed more in malignant tissues than in ovarian benign cysts (P.value > 0.05). However SDF-1, IP-10, IL-4, CXCR3, and IL-10 had lower mRNA expression in malignant ovarian tissues compare to benign cyst tissues. Except for IL-4 (p= 0.01) and SDF-1 (P.value = 0.02) the data for other factors were not statistically significant. Conclusion: Our data support the notion that increased expression of CXCR4 on malignant ovarian tissues may play an important role in the promotion of ovarian cancer. In addition, lower expression of IL-4 in malignant ovarian tissues requires supporting evidence to determine if this cytokine has an antitumor role in ovarian cancer.

P5.01.26
Role of transcription factor and chromatin remodeler interplay in the regulation of TNFα induced MHC-I gene expression

S. Ghosh*, E. Sen;*
National Brain Research Centre, Gurgaon, India.

Emerging evidences indicate that inflammation contributes to the initiation and/or propagation of a wide range of cancers. Key features of cancer-related inflammation involve aberrant (i) activation of signaling mediators/transcription factors, (ii) expression of inflammatory cytokines. The oxygen sensing transcription factor hypoxia inducible factor (HIF-1α) which is an important contributor of tumor growth, also serves a pivotal link between inflammation and tumorigenesis. As MHC class I is involved in glioma immune evasion and since HIF-1a is a pivotal link between inflammation and glioma progression, the role of TNFα induced inflammation in MHC-I gene regulation was investigated. TNFa induced increase in MHC-I expression and transcriptional activation was concurrent with increased HIF-1α and β-catenin activity. HIF-1α-β-catenin axis mediated increase in CREB phosphorylation was accompanied by its increased enrichment at CRE/site-α on the MHC-I promoter in TNFa treated cells. Importantly, chromatin remodeler hBrm was replaced for Brg-1 as the binding partner for CREB at CRE site, in a β-catenin dependent manner, thus driving MHC-1 gene expression. As MHC-I clustering on cell surface enhance their recognition by T cells, the effect of TNFα on MHC-I clustering was investigated. Increased MHC-I clusters in TNFα treated cells was also regulated by HIF-1α-β-catenin axis. As elevated MHC-I levels have a direct bearing on immune escape mechanism in glioma and as HIF-1a is considered a potential anti-glioma target, future endeavoursto inhibit MHC-I by targeting the HIF-1α-β-catenin axis, may provide a novel therapeutic approach for modulating immune-surveillance in these tumors.

BET bromodomain inhibition by JQ1 suppresses interleukin-6 secretion in myeloma cells

R. R. Ghurye*, H. J. S. Stewart, T. J. Chevassut;*
Brighton and Sussex Medical School, Brighton, United Kingdom.

Background: Multiple myeloma (MM) is a malignant and progressive tumour of plasma cells. Overproduction of interleukin-6 (IL-6), a pleiotropic cytokine, is believed to play an important role in the pathogenesis of MM. Consequently, research has focused on targeting IL-6 as a therapeutic strategy for MM. Bromodomains are a diverse family of protein interaction modules that have a vital role in transcriptional regulation. Recent studies using well-established models of inflammation have shown that inhibitors of the bromodomain and extraterminal (BET) family of proteins suppress the expression of several pro-inflammatory cytokines including IL-6. The aim of this study is to investigate the effect of JQ1, a small molecule bromodomain inhibitor, on human MM cells and IL-6 secretion.
Methods: Primary MM cells were isolated from venous blood of a patient with refractory MM. To explore the effect on IL-6 secretion, primary MM cells were pre-treated with various concentrations of JQ1 then stimulated with lipopolysaccharide (LPS) and an IL-6 ELISA was performed. The effect on cell viability was measured using the WST-1 assay.
Results: Pre-treatment of LPS stimulated primary MM cells with JQ1 led to a dose-dependent suppression of IL-6 secretion. In addition, JQ1 exposure caused a time-dependent decrease in primary MM cell viability.
Conclusion: Treatment with JQ1 is not only cytotoxic to primary MM cells but also suppresses secretion of IL-6. These findings suggest that bromodomain inhibitors such as JQ1 represent a promising new class of immunomodulatory compounds that are highly active against MM.

P5.01.28
Dynamics of IL-1ά, IL-4 and IFN-γ in children with atopic asthma in therapy Leukinferon

N. M. Gulieva*;*
Azerbaijan Medical University, Immunology department, Baku, Azerbaijan.

Intoduction: The immunological mechanisms of atopic inflammation in the pathogenesis of asthma have the attention of researchers. In the inflammation proses variety of soluble mediators and cytokines play a key role. We conducted a study of the levels IL-1ά, IL-4 and IFN-γ in the serum during Leukinferon immunotherapy in children with atopic asthma (BA).
Objective and methods: We observed 42 children with atopic asthma, 28 of them with moderate asthma and 13 children with severe disease. We found that in severe asthma is a significant increase in serum IL-1ά and IL-4 - 4-6 times higher than in the control group (p < 0,001). Serum levels of IFN-γ decreased by 5 times compared with healthy children. In patients with moderate asthma serum levels of IL-1ά and IL-4 is higher than in the control group (p < 0,001). Serum IFN-γ is 3 times lower than in healthy children. For the normalization of imbalance of cytokines in children with asthma, we described immune modulator Leukinferon, containing human leukocyte interferon in dose 10 000TB-6 injections.
Results: After treatment, it was determined significant reduction in asthma exacerbations, longer remission period, a reduction in dose and range of basic therapy. It was determined the significant increase of serum IFN-γ and the decrease of IL-4 and IL-1ά than in the comparison group. Thus, it was demonstrated a significant increase in IFN-γ and a positive clinical dynamics as a positive effect of Leukinferon.

P5.01.29
Cellular responses to *Staphylococcus aureus* alpha-toxin in chronic rhinosinnusitis with nasal polyps

T. Haruna*, M. Okano, S. Kariya, T. Koyama, K. Nishizaki;*
Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan.

Background: In contrast to *Staphylococcus aureus*-derived superantigenic exotoxins, the role of non-superantigenic exotoxins in the pathogenesis of eosinophilic airway diseases remains obscure.
Objective: We sought to characterize *S. aureus* alpha-toxin-induced Th1-, Th2-, Th17-, and Treg-associated cellular responses in chronic rhinosinusitis with nasal polyps (CRSwNP).
Methods: Dispersed nasal polyp cells (DNPCs) and dispersed uncinate tissue cells (DUTCs) were prepared from patients with CRS with and without nasal polyps, respectively. Cells were incubated with various concentrations of alpha-toxin or staphylococcal enterotoxin B (SEB) and then the levels of IL-5, IL-13, IFN-γ, IL-17A, and IL-10 in

the cell supernatants were determined. The effect of blocking the COX pathway and neutralizing HLA-DR and ICAM-1 was examined.
Results: DNPCs produced substantial amounts of IL-5, IL-13, IFN-γ, IL-17A, and IL-10 in response to alpha-toxin. Cytokine production was higher in DNPCs than in DUTCs. The potency of alpha-toxin in stimulating IL-5, IL-13, and IL-10 production was comparable to that of SEB. Neutralization of HLA-DR and ICAM-1 suppressed cytokine production. Inhibition of the COX pathway increased and decreased alpha-toxin-induced production of IL-5/IL-13 and IL-17A/IL-10, respectively.
Conclusions: In addition to *S. aureus*-derived superantigens, non-superantigenic alpha-toxin can provoke inflammation in chronic rhinosinusitis with nasal polyps.

P5.01.30
Imbalance of homeostatic cytokines in APECED

N. Heikkilä[1], *S. M. Laakso*[1], *H. Jarva*[1,2], *T. P. Arstila*[1];
[1]*University of Helsinki, Helsinki, Finland,* [2]*HUSLAB, Helsinki, Finland.*

Autoimmune polyendocrinopathy-candidiasis-ectodermal dystrophy (APECED) is an isolated human autoimmune disease, caused by loss-of-function mutations in the Autoimmune Regulator (AIRE) gene. AIRE is a transcriptional factor that enhances presentation of tissue-specific antigens to developing thymocytes. In the absence of AIRE, the negative selection fails and autoreactive cells escape to the periphery. Patients suffer from chronic candidiasis and autoimmunity targeting multiple endocrine organs. Dysregulation in interleukin-7 (IL-7) pathway has recently appeared as a factor contributing to the loss of self-tolerance in APECED. Our study elucidates the role of three IL-7-related cytokines: IL-15, IL-2 and thymic stromal lymphopoietin (TSLP) in APECED. IL-7, IL-15 and IL-2 use the common γ chain in signaling, whereas TSLP signals through the same α chain as IL-7.
Plasma IL-2 and IL-15 concentrations were moderately elevated in patients, while no TSLP was detected in patient or control plasma samples. Patient CD4+ T cells expressed more IL-15 receptor α chain (IL-15Rα) than control cells. Overnight incubation with IL-15 decreased IL-15Rα expression in controls but not in patients. TSLP receptor was equally expressed in both groups and remained unaffected by incubation with TSLP. Elevated IL-15 concentration was inversely proportional to the expression of CD5, a negative T cell regulator, in patient T cells. Furthermore, IL-2 concentration correlated inversely to the proportion of patient cells bearing markers of activation.
These results suggest a role for IL-2 and IL-15, but not for TSLP, in APECED pathogenesis. An interesting question is whether they only operate in the periphery or already during the thymic development.

P5.01.31
Substantially elevated plasma IL-1β levels and hyporeactivity to IL-1β in APECED

I. Hetemäki[1], *V. Veckman*[2], *H. Jarva*[1,3], *S. Matikainen*[2], *T. P. Arstila*[1];
[1]*Haartman Institute, University of Helsinki, Helsinki, Finland,* [2]*Unit of Systems toxicology, Finnish Institute of Occupational Health, Helsinki, Finland,* [3]*HUSLAB, Hospital District of Helsinki and Uusimaa, Helsinki, Finland.*

APECED is a rare monogenic autoimmune disease, a model for autoimmunity. We set out to study the role of IL-1β, one of the most profound proinflammatory cytokines, in the inflammatory process of APECED. Surprisingly 3 of our patients exhibited substantially elevated plasma IL-1β levels. One patient had over 3000 pg/ml of IL-1b in his plasma, which is more than six times the level normally depicted in sepsis. Older samples from the same patient revealed that he had had equal amounts of IL-1β for the past 10 years.
To find out how the patient survives in such a proinflammatory environment we measured the IL-1 receptor antagonist levels from plasma. No significant differences were observed between the patient and controls. However when the patient's PBMCs were stimulated with recombinant IL-1β and the subsequent expression of IL-6 after 6 hours stimulation was measured by qPCR his PBMCs were markedly hyporesponsive to inflammatory stimulus.
In addition to giving more information about the role of IL-1β in autoimmunity this data opens the first possibility of intervening the autoinflammatory process in APECED with biological IL-1β antagonising treatments. The exact mechanism of the hyporesponsiveness remains to be established.

P5.01.32
Effects of Siegesbeckia orientalis ethanol extract on systemic and local inflammatory reactions

Y. Hong[1], *J. Houng*[2];
[1]*Department of Nutrition, I-Shou University, Kaohsiung, Taiwan,* [2]*Institute of Biotechnology and Chemical Engineering, I-Shou University, Kaohsiung, Taiwan.*

This study aimed to investigate if herbal components that exert anti-inflammatory effects may be used for inflammatory disorders by examining *Siegesbeckia orientalis* ethanol extract(SOEE). The *in vitro* experiments showed that SOEE significantly reduced nitric oxide, interleukin(IL)-6 and PGE_2 production in LPS-stimulated RAW264.7 cells. To further evaluate the anti-inflammatory effects of SOEE *in vivo*, BALB/c or ICR mice were tube-fed with 32 mg SOEE/kg BW/day in 100 μL peanut oil, while the control and PDTC (pyrrolidine dithiocarbamate, an anti-inflammatory agent) groups were tube-fed with 100 μL peanut oil/day only. After one week of tube-feeding, the PDTC group was injected with 50 mg/kg BW PDTC and one hour later, all BALB/c mice were intraperitoneal-injected with LPS for systemic inflammation; all ICR mice were subcutaneous-injected with β-carrageenan(the plantar of right hind paw) for local inflammation. The results showed that the SOEE group had significantly lower serum IL-6 level at 9 hr after LPS challenge, and significantly higher survival rates than the control group. In the local inflammation model, the SOEE group had the reduction in the degree of paw swelling at 4 hr after carrageenan challenge (1.47 ± 0.14 mm^3 vs. 1.74 ± 0.29 mm^3, $P = 0.03$).This study suggests that SOEE can suppress the production of proinflammatory cytokines and alleviate acute inflammatory hazards.

P5.01.33
Metformin modulates inflammatory response through AMPK-NF-κB signaling and restores atherogenic effects

B. Hyun[1], *S. Shin*[1], *A. Lee*[1], *S. Lee*[1], *Y. Song*[1], *K. Cho*[2], *K. Kim*[1];
[1]*Sahmyook University, Seoul, Republic of Korea,* [2]*Seoul Women's University, Seoul, Republic of Korea.*

Metformin is one of the most widely prescribed drugs for the treatment of type II diabetes. Metformin has been reported to mediate inflammatory responses and attenuate development of atherosclerosis besides its antihyperglycemic effect. But the pharmacological and biochemical mechanisms of metformin in immune responses and atherogenesis have not been clearly elucidated. Here we demonstrate that metformin down-regulates pro-inflammatory cytokines and foam cell formation in macrophages. Metformin reduced the production of NO through the suppressed gene and protein expression of iNOS in LPS-stimulated RAW 264.7 cells and peritoneal macrophages. Metformin antagonized the production of proinflammatory cytokines such as TNF-α, IL-1β, and IL-6, leading to suppressed the phosphorylation of IκBα and the translocation of NF-κB p65 subunit into nuclear. Furthermore, scavenger receptors (SR-A, Lox-1) mRNA levels were down-regulated by metformin. These results show that metformin attenuates inflammatory mediators via AMPK-NF-κB signaling, suggesting that metformin would be a potential immunemodulatory agent for treating vascular inflammatory diseases.

P5.01.34
Immunomodulatory effects of N-(2-hydroxy phenyl) acetamide on pro-inflammatory cytokines and ROS in adjuvant-induced arthritic rats

H. Jawed[1], *S. Jamall*[2], *S. U. Simjee*[1];
[1]*H.E.J. Research Institute of Chemistry, International Center for Chemical and Biological Sciences, Karachi, Pakistan,* [2]*2 Department of Biochemistry, University of Karachi, Karachi, Karachi, Pakistan.*

Rheumatoid Arthritis (RA) is characterized by inflammation, tissue injury, pain hypersensitivity and proliferation of synovial cells causing bone and cartilage destruction and ultimate disability of the joints. In the present study, N-(2-hydroxy phenyl) acetamide (NA-2) was evaluated for its disease-modifying effects in the rat model of adjuvant-induced arthritis (AIA) which closely resembles the human rheumatoid arthritis. Gait analysis was used to examine the role of NA-2 in the development of chronic pain associated with arthritis. The pro-inflammatory markers including cytokines IL-1β and TNF-α and reactive oxygen species were also measured along with the cellular immediate-early genes (*c-fos*) which reflects the pattern of neuronal activity and directly regulate the expression of these pro-inflammatory cytokines. Our results showed that NA-2 treatment inhibits not only the macroscopic inflammatory changes but also significantly reverses gait deficits in AIA ($p < 0.002$). Furthermore, expression of *c-fos* gene and c-Fos protein was also markedly decreased with the parallel significant reduction in pro-inflammatory cytokines IL-1β ($p < 0.004$) and TNF-α ($p < 0.009$) and oxidative stress markers i.e., nitric oxide and peroxide ($p < 0.00$ and $p < 0.05$ respectively). The findings of this work study suggest that administration of NA-2 is effective in preventing the chronic inflammation and pain related neuronal hyperactivity/ excitability. It may imply that beside the inhibition of local inflammation, inhibition of central inflammation/sensitization may be involved in the anti-inflammatory and anti-arthritic activity of the salicylic acid derivative N-(2-hydroxy phenyl) acetamide.

P5.01.35
Redox balance of mouse medullary CD4 single positive thymocytes

R. Jin;
Peking University, Beijing, China.

After positive selection, the newly differentiated single positive (SP) thymocytes undergo negative selection to eliminate autoreactive T cells, functional maturation to acquire immunocompetence and egress capability. To investigate whether the intracellular reduction/oxidation (redox) balance plays an important role on SP maturation, the levels intracellular reactive oxygen species (ROS) and the expression of proteins that regulate ROS were compared among the four subsets of mouse $TCR\alpha\beta^{+}CD4^{+}CD8^{-}$ thymocytes (SP1 to SP4) that represent sequential stages of SP differentiation program. A gradual increase of ROS and a gradual decrease of thioredoxin were revealed along the SP maturation process. An early increase of ROS in the immature SP1 thymocytes resulted in enhanced apoptosis whereas an increase in the most mature SP4 cells resulted in enhanced cytokine production upon stimulation. The coculture with thymic epithelial cells increased the ROS level in SP thymocytes. *Aire*$^{-/-}$ mice have a developmental blockage at the SP3-to-SP4 transition and defects in negative selection and showed significantly less ROS in SP3 thymocytes. These results suggest that ROS may be involved in promoting the functional maturation of $CD4^{+}$ SPs and thymic medullary microenvironment contributes to the pro-oxidant shift of SP thymocytes.

P5.01.36
Low level of TNF-alpa in cystic fluid is accompanied with low number of macrophages in cystic wall of odontogenic tumor

V. Jurisic[1], *T. Terzic*[2], *M. Jurisic*[3];
[1]*University of Kragujevac, Faculty of Medicine, Kragujevac, Serbia,* [2]*University of Belgrade, Faculty of Medicine, Patology department, Belgrade, Serbia,* [3]*University of Belgrade, Clinic of Oral Surgery, Belgrade, Serbia.*

Aims: The aggressive behaviour and high recurrence rate of odontogenic keratocyst suggests their neoplastic potential and prompted the World Health Organization Working Group to classify it as a benign tumour with odontogenic epithelium. Since, TNF-α is a pleiotropic cytokine, that is considered as a primary modifier of inflammatory and immune reaction in response to various inflammatory diseases and tumor as well, it is very interesting to analyzed their concentration in our type of tumor.
Methods: We analyzed concentration of TNF-α in cystic fluid of 25 odontogenic keratocysts, obtained from patients undergoing surgery, under local anaesthesia, and after aspiration of cystic fluid from non-ruptured cysts. TNF was determined by ELISA assay. Presence of inflammatory cells in peri-cystic tissues and macrophages was analyzed immunohistochemistry using monoclonal antibodies. Degree of vascularisation and presence of macrophages was estimated by enumeration using light microscopy.
Results: TNF-α is detectable in cysts fluid, but in low values in all investigated cyst (range from 20-50 pg/ml). All cysts have also low number of macrophages in cystic wall. All cysts have a similar concentration of TNF irrespective of the cystic wall,the number of inflamed cells including macrophages, the epithelium proliferation and presence of vascularisation having been analyzed histologically. Also, no significant correlation was found in ration to cyst size and protein concentration (Mann-Whitney U-test, $p > 0.05$).
Conclusions: These results indicated that no inflammation has significant influence on growth as well appearance of these cysts, like to other, inflammatory cystic type in oral region.

P5.01.37
Effect of immunoglobulin E on plasmacytoid dendritic cells in systemic lupus erythematosus pathogenesis through interferon-alpha downregulation

L. Khoryati[1,2], *I. Douchet*[1], *C. Contin-Bordes*[1,2], *P. Blanco*[1,2], *C. Richez*[1,2,3];
[1]*CIRID - UMR CNRS 5164, Bordeaux, France,* [2]*Université Bordeaux 2, Bordeaux, France,* [3]*Département de Rhumatologie, CHU Bordeaux, Hôpital Pellegrin, Bordeaux, France.*

Plasmacytoid dendritic cells (pDCs) are dendritic cells characterized by their unique ability to produce large amounts of type I interferon (IFNalpha/beta) upon Toll-like receptor (TLR) 7/9 triggering. Blood type I interferon signature is the hallmark of several autoimmune diseases including systemic lupus erythematosus (SLE) and pDCs have been shown to play a central role. pDCs express surface regulatory receptors including the high affinity Fc receptor for immunoglobulin E (IgE), FcepsRI, involved in the negative regulation of IFNalpha secretion. We hypothesized that IgE engagement of FcepsRI on pDCs may have an effect on their functions in SLE patients.
First, we observed significantly higher IgE levels in SLE patients (independently of allergy, or parasitic infection) with quiescent disease than with active disease and healthy donors ($p<0.05$). In vitro, blood purified pDCs cultured with monoclonal IgE upregulate the surface expression of FcepsRI in an IgE dose-dependent manner ($p<0.005$). IgE-treated pDCs significantly downregulate IFNalpha secretion upon TLR7, 9 and immune complexes triggering ($p<0.05$). Finally, the coculture of IgE pretreated pDCs with allogeneic CD4+ T-lymphocytes promotes their differentiation into IL-10 -secreting-Tcells. All together, these data suggest a role for IgE in modulating the inflammatory response by pDCs and promoting a tolerance induction. Recently, use of parasitic worms as a therapy in autoimmune disease has been proposed. Our results highlight a complementary mechanism that could be involved in the protective effect of worm infection in SLE.

P5.01.38
Correlation of some Inflammation related cytokines and biochemical markers amongst individuals with high, medium and normal serum FBS levels

***A. Khosravi**, F. Nasiri, K. Sayemiri;*
Ilam university of Medical Sciences, Immunology Dep, Ilam, Iran.

Introduction- Inflammation symptoms are detectable before the onset of diabetes even when only the balance of FBS is changed. The current study aimed to evaluate inflammatory cytokines with different levels of FBS to predict the diabetes status.
Materials and Methods- At this case-control study a total of 41 individuals with FBS higher than normal together with 41 with normal FBS were included. After taking a blood sample from each participant IL-6, IL-1 β and IL-6 and FBS, LDL,HDL, TG, Cholesterol, Albumin and WBC, RBC, Hb, MCV, MCHC and RDW were. Data were analyzed with Logistic Regression Analysis and Pearson correlation tests.
Results- According to the FBS level participants were placed in 3 groups; normal FBS(normal group), FBS of 100-125(middle group) and FBS more than 126 group (high FBS group). The mean HDL was 43.34, 41.33 and 40.32 while the mean, IL-1 β was 85.28, 329.33 and 333.04 in normal, middle and high FBS groups respectively. The mean IL-6 was 315.47, 317.06 and 321.45 and the mean CRP was 4.38, 2.2 and 2.4 respectively. Albumin ranged from 5.09, 5.07 and 4.7 among different groups respectively.
Conclusion- There was a good association between the inflammatory, biochemical and FBS in case and control groups. Regression analysis found that increasing the IL-6 and IL-1 β levels is proportional to increasing in FBS level so that the prediction of FBS can be made by these markers. Evaluation of inflammatory cytokines even in health people can elucidate the status of FBS imbalance and diabetes in future.

P5.01.39
Critical roles of oncostatin M receptor signaling on the polarization of macrophage phenotypes, adipose tissue inflammation, and the development of insulin resistance

***T. Komori**[1], M. Tanaka[2], E. Senba[1], A. Miyajima[2], Y. Morikawa[1];*
[1]Wakayama Medical University, Wakayama, Japan, [2]Institute of Molecular and Cellular Bioscience, University of Tokyo, Tokyo, Japan.

Obesity-induced adipose tissue inflammation is one of the important causes for the development of insulin resistance. Although oncostatin M (OSM), a member of the IL-6 family of cytokines, has various biological functions including the regulation of inflammatory responses, the relationship between OSM and adipose tissue inflammation remains unclear. OSM receptor β subunit (OSMRβ) was expressed in the adipose tissue macrophages (ATMs) of both lean and obese mice, suggesting some important roles of OSM in the regulation of adipose tissue inflammation. OSMRβ-deficient (OSMRβ-/-) mice showed moderate insulin resistance without obesity under normal diet conditions. The percentage of M1-type in total ATMs and the expression of pro-inflammatory markers, such as TNF-α, in the adipose tissue were increased compared to wild-type (WT) mice. Under high-fat diet (HFD) conditions, OSMRβ-/- mice exhibited the increased percentage of M1-type ATMs, the increased expression of pro-inflammatory markers in the adipose tissue, the increase in the body weight, and severer insulin resistance compared to WT mice. To investigate the direct effects of OSM on macrophages, a macrophage cell line, RAW264.7 cells, and mouse peritoneal exudate macrophages (PEMs) were treated with OSM. The expression of M2 markers, including arginase-1 and CD206, were increased by OSM in both RAW264.7 cells and PEMs from WT mice, but failed to increase in PEMs from OSMRβ-/- mice. Thus, OSMR signaling plays some important roles in the suppression of adipose tissue inflammation and the amelioration of insulin resistance, at least in part, through the polarization of phenotypes of macrophages to M2-type.

P5.01.40
Serum soluble IFNAR2 levels in autoimmune diseases suggest that chronic IFN signaling leads to elevated levels of sIFNAR2

*T. Fatakdawala, M. Skawinski, T. Stauffer, J. Ferriera, **T. B. Lavoie**;*
PBL InterferonSource, Piscataway, NJ, United States.

The Type I Interferon (IFN) receptor consists of a heterodimer of chain 1 (IFNAR1) which is required for signaling and chain 2 (IFNAR2) which binds tightly to IFN. Soluble forms of IFNAR2 can be produced either by proteolytic cleavage or production of an alternatively spliced (?) transcript. Soluble IFNAR2 can be found in serum and urine however its role and regulation are poorly understood. Studies have suggested that sIFNAR2 is elevated in MS patients, advanced cancer patients and hepatitis C infected patients. Using a newly developed ELISA for sIFNAR2 we have examined commercially sourced serum/plasma samples from autoimmune patients and normal healthy donors. In comparison to 35 normal donors, MS patients on IFN therapy (n=29) had significantly (p=0.0005) increased levels of sIFNAR2. Those on other therapies (n=24) were not different from the normal population but were significantly different than the MS patients on IFN therapy (p=<0.0001). sIFNAR2 levels showed no correlation with treatments such as vitamin-D, copaxone or natalizumab. Systemic Lupus patients (n=67) had elevated sIFNAR2 (p=0.009) while rheumatoid arthritis (n=16) were not significantly different from normal. Sjogren's patients (n=11) and scleroderma patients (n=10) - is there something missing here? Although evidence of Type I IFN activation has been observed in RA, Sjogren's and Scleroderma patients, the frequency and intensity is thought to be less than that observed for MS patients on IFN-therapy and in Systemic Lupus. These data suggest a model where long term IFN signaling above a certain threshold leads to elevated sIFNAR2.

P5.01.41
IL-4: a key cytokine in acutely rejected neo-antigen specific skin grafts

***V. M. Leb-Reichl**[1], S. Kitzmueller[1], D. Peckl-Schmid[1,2], M. Ettinger[1], H. Hintner[1], J. W. Bauer[1];*
[1]Division of Experimental Dermatology and EB House Austria, Department of Dermatology, Paracelsus Medical University, Salzburg, Austria, [2]Department of Blood Group Serology and Transfusion Medicine, Paracelsus Medical University, Salzburg, Austria.

Null-mutations in genes coding for structural proteins of the skin are quite common in patients suffering from genodermatoses. Correcting defective genes by *ex vivo* skin gene therapy is becoming a promising therapeutic modality for the treatment of epidermolysis bullosa, however, bearing the risk of provoking unwanted immune responses against the introduced neo-antigen expressed by the skin graft. The aim of this study is the characterization of the immune response towards the neo-antigen, human type XVII collagen (hBPAG2), in order to selectively block rejection of gene-corrected cells. In our model system we graft full-thickness skin from a transgenic mouse strain expressing hBPAG2 in the murine epidermal basement membrane onto syngeneic wild-type C57BL/6 recipients. To analyze the immunological reaction in rejected grafts a mouse Th-RT[2] Profiler PCR array was performed. In cytokine blocking studies transplanted mice were injected rat anti-mouse IL-4 i.p. to neutralize IL-4 activity. The cytokine profile array of acutely rejected grafts expressing hBPAG2 was characterized by increased levels of IFNgamma, IL-4, IL-6 and TGF-beta1 compared to controls. Interestingly, expression of the Th2 cytokine IL-4 was restricted to mice grafted with hBPAG2-tg skin. In a transplantation study we demonstrated that the rate of graft acceptance could be improved by blocking IL-4 activity. Since histological assays show infiltration of mast cells we plan to further characterize the role of mast cells in transplantation.

P5.01.42
Aryl hydrocarbon receptor negatively regulates type I interferon production in murine lupus

***S. Lee**, R. Barry, I. Chinen, D. Millrine, T. Kishimoto;*
iFReC, Osaka University, Osaka, Japan.

Systemic lupus erythematosus is a highly heterogeneous multi-organ disorder and is characterized by the production of diverse autoantibodies. Recent studies suggest an important role for type I interferon in the pathogenesis of this disease. Production of type I interferon is under the control of the transcription factor IRF7, while type I interferon signaling requires the STAT1 transcription factor. Here, we show that production of type I interferon in cultured pDCs from aryl hydrocarbon receptor knockout mice is significantly higher compared to wild-type mice stimulated with TLR 7/9 agonists. Furthermore, treatment of pDCs from wild-type mice treated with the aryl hydrocarbon receptor agonist L-kynurenine significantly inhibits TLR 7/9-mediated type I interferon production. We demonstrate that through TLR 7/9 signaling, expression of aryl hydrocarbon receptor is induced, which in-turn forms an inhibitory interaction with IRF7 and STAT1, thus attenuating both type I interferon production and signaling. In addition, we found that production of type I interferon and expression of interferon stimulation genes in aryl hydrocarbon receptor knockout mice is much higher than in wild-type mice when we induce lupus-like disease by pristane treatment. Our results show that aryl hydrocarbon receptor is a critical negative regulator of TLR-mediated type I interferon production and inhibits type I interferon signaling in murine lupus. We are currently evaluating protective effects of aryl hydrocarbon receptor agonists in the development of murine lupus.

P5.01.43
Proinflammatory cytokines in patients with chronic traumatic encephalopathy

***Y. Lekomtseva**[1], G. Gubina-Vakulik[2];*
[1]State Institute of Neurology, Psychiatry and Narcology, Kharkiv, Ukraine, [2]Kharkiv National Medical University, Kharkiv, Ukraine.

Cytokines could be important in mechanisms of chronic traumatic encephalopathy (CTE) development as they can activate microglia-network to release a number of neurotoxic mediators, chemokines, prostaglandins involved in alteration of endothelial dysfunction, astrocytes respond of dysfunctional brain blood barrier, and neuronal dysfunction. The aim was to examine the proinflammatory cytokine profile in patients with CTE.
Methods. Patients with CTE (n=26; 19-46 years) after closed brain trauma (mean disease duration: 8.62±5.73 years) and controls (n=24; 21-44 years) were investigated. Serum interleukins (IL) IL-6, IL-1b, IL-8 were measured by standard immunoenzyme assays using Vector Best reagents.
Results. As compared to controls, CTE showed an elevated percentage of IL-6 level suggesting that increased IL-6 (mean±SD: 26.65±6.29 pg/ml; range 14.5-38.6 vs. 4.4±1.5; range: 1.5-6.9) might be generated from activation of cytokine microglia-astrocyte network ($P<0.01$; $t=2.69$). IL-6 is an immunoregulatory cytokine acting as proinflammatory and anti-inflammatory secreted by T-cells, macrophages to stimulate immune response, by neurons, activated microglia and hypertrophic astrocytes. General IL-1b range in all patients: 19.3-45.5 pg/mL where 11 CTE (42.31 %) had higher IL-1b level with mean 32.16 vs 24.84 pg/mL ($P<0.01$; $t=2.74$), these patients had partial epilepsy (3), neurological deficit (5), severe headaches (9), cognitive decline (11) and IL-1b levels were positively correlated with high seizure frequency ($P<0.05$). CTE showed no differences in IL-8: mean 6.87; range: 4.1-22.7 pg/ml vs 4.64; range: 3.0-5.2.
Conclusions. Neuroinflammatory processes are important in clinical understanding of CTE outcome; CTE revealed a highly proinflammatory serum IL-6 level condition that could play role in disease progression.

P5.01.44
Effect of lithium carbonate treatment in mRNA levels of pro- and anti-inflammatory cytokines and expression of Wnt/beta-catenin pathway genes in PBMC of bipolar patients

***M. C. A. Luque**, T. M. Ali, C. Moreira, B. Lafer, J. Kalil, E. Cunha-Neto;*
University of São Paulo Medical School, São Paulo, Brazil.

Bipolar disorder (BD) manifests as episodes of depression and mania. Many aspects of its pathophysiology are not thoroughly understood. Pro-inflammatory cytokines and the Wnt/β-catenin signaling pathway may play important roles. Lithium salts, used in the treatment of BD, modulate this signaling pathway. We analyzed the expression of pro- and anti-inflammatory cytokines in BD patients and healthy control subjects and whether lithium administration modulates cytokine expression in peripheral blood mononuclear cells (PBMC) in BD subjects, as well as the expression of the Wnt/β-catenin pathway genes.
We used PBMC from BD patients (n=7) prior to and after an eight-week lithium carbonate treatment, and healthy controls (n=12). Real-Time RT-PCR data were calculated using the 2-ΔCt method and the Kruskal-Wallis test with Dunn's post-test for statistical analysis. Inflammatory (TNF-α, IFN-γ and IL-8) and anti-inflammatory (IL-10 and IL-4) cytokines were analyzed. IL-10 levels were significantly lower in BD patients when compared to healthy controls, regardless of treatment. TNF-α was significantly lower in untreated BD patients, while IFN-γ was significantly lower in treated BD patients when compared to healthy controls. We failed to find differences due to treatment in BD patients. We analyzed the modulation of Wnt pathway genes comparing BD patients and control subjects. Our results show significant differences in GSK-3β, TCF4 and cyclin D1 expression between pre-treated bipolar patients and controls. We also observed significant differences between BD patients under treatment and controls (GSK-3β, TCF4 and HIG2) indicating that not only the manifestation of the disorder but also its treatment can affect Wnt signaling.

Elevated concentrations of interleukin-12 and 18 in chronic kidney disease patients synergistically induce T cell production of interferon-gamma and proliferation *in vitro*

***M. J. Mannion**[1,2], W. H. Lim[2];*
[1]University of Western Australia, Perth, Australia, [2]Sir Charles Gairdner Hospital, Perth, Australia.

Background: Elevated pro-inflammatory cytokines interleukin (IL)-12 and IL-18 have been observed in CKD patients, which may contribute in the pathogenesis of CVD through T cell activation. We aim to examine whether CKD concentrations of IL-12 and 18 are capable of inducing T cell activation *in vitro*.
Methods: Serum levels of IL-12 and 18 were quantified in a cross-sectional study of 69 healthy controls and 139 stage 3-5 pre-dialysis CKD patients by ELISA. CD3-positive T cells were cultured in the presence of IL-12 (0.1ng/mL) and/or 18 (0.5ng/mL) in complete medium (10% v/v fetal calf serum) and the levels of interferon-gamma (IFN-γ) in supernatant (ELISA) and T cell proliferation (bromodeoxyuridine [BrdU]-incorporation) determined.
Results: CKD patients had higher serum concentrations of IL-12 and 18 compared to healthy controls (IL-12: 81 vs 30 x pg/mL and IL-18: 455 vs 357, *Mann-Whitney U test, p<0.001)*. T cells cultured for 48-72hrs with IL-12/18 produced a 75-fold and 138-fold increase in IFN-γ (*t-test,* $p<0.01$), compared to unstimulated cells (below detection threshold). IL-12/18
stimulation is suppressed 3-fold by IL-12 and IL-18 blockers (both 10µg/mL) *in vitro* (*t-test,* $p=0.01$). There was a 1.3-fold increase in T cell
proliferation compared to unstimulated cells at 48-72hrs (*t-test,* $p<0.02$).
IL-12 or IL-18 alone did not induce T cell activation.
Conclusions: Serum concentrations of IL-12 and 18 are 1.5-3-fold greater in stage 3-5 pre-dialysis CKD patients compared with healthy controls. Concentrations of IL-12/18 detected in CKD patients are capable of inducing a strong T cell response *in vitro*.

P5.01.46
T cell production of interferon-gamma and proliferation is suppressed in vitro when stimulated with interleukin-12 and 18 or anti-CD3/CD28 under uremic conditions *in vitro*

M. J. Mannion[1]*, W. H. Lim*[2]*;*
[1]University of Western Australia, Perth, Australia, [2]Sir Charles Gairdner Hospital, Perth, Australia.

Background: It has been shown that CKD patients have elevated concentrations of IL-12 and 18 compared to healthy individuals. Previous in vitro studies shave demonstrated that uraemic medium-cultured dendritic cells (DC) induced T cell activation and proliferation, which may contribute the higher risk of cardiovascular disease in this population. However, the effect of uraemic serum on T cell function in the absence of DC interaction remains unclear.
Methods: Immunomagnetic-bead isolated CD3-positive T cells from healthy blood donors were cultured in uraemic medium (10% v/v uraemic serum from pooled stage 3-5 CKD patients) compared to normal medium (10% v/v pooled healthy individuals) stimulated with IL-12 and 18 (2.5 and 12.5ng/mL), and anti-CD3/28 (1µg/mL each). T cell production of interferon-gamma (IFN-γ) from culture supernatant and proliferation were determined by ELISA and bromodeoxyuridine [BrdU]-incorporation respectively.
Results: T cells cultured in uraemic medium stimulated with IL-12/18 or anti-CD3/28 produced a 1.8-fold and 1.5-fold decrease in IFN-γ respectively (*t-test, p<0.005)*, corresponding to 1.2 -fold and 1.3-fold decrease in proliferation (*t-test, p<0.02)* compared to T cells cultured in complete medium. T cells stimulated with IL-12/18 for 24 - 72hrs *in vitro* maintained lower proliferation and IFN-γ production for each given time-point when cultured in uraemic medium compared to those cultured in normal medium (*t-test,* p<0.03).
Conclusions:
Stimulated T cells cultured in the presence of uraemic medium in the absence of DC exhibited a reduction of IFN-γ production and proliferation *in vitro*.

P5.01.48
Anti-inflammatory effects of high-dose IgG on TNF-α-, but not IL-1β-activated human coronary artery endothelial cells

A. Matsuda*, H. Morita, H. Unno, K. Motomura, H. Saito, K. Matsumoto, J. Abe;*
National Research Institute for Child Health and Development, Tokyo, Japan.

[Background and Purpose] Kawasaki disease (KD) is an acute systemic vasculitis of unknown etiology in infants and young children, and it is frequently associated with coronary artery aneurysms. High-dose infusion of IgG (IVIG) effectively reduces systemic inflammation and the incidence of coronary artery lesions in 80-90% of KD. However, for reasons that remain unclear, some patients do not respond to IVIG. In order to obtain clues to the cause of IVIG resistance, we compared the in vitro effects of high-dose IgG on cultured human coronary artery endothelial cells (HCAECs) exposed to various inflammatory stimuli.
[Methods] HCAECs were stimulated with TNF-α, IL-1β or Poly (I:C) in the presence and absence of 20 mg/ml human polyclonal IgG for 48 hours. G-CSF and IL-6 mRNAs and proteins were measured by qPCR and ELISA, respectively.
[Results] High-dose IgG completely inhibited TNF-α-induced expression of G-CSF and IL-6, which are known to be crucially associated with the pathogenesis of acute KD. In contrast, high-dose IgG only partially inhibited Poly (I:C)-induced expression of these cytokines and did not inhibit IL-1β induced expression at all.
[Conclusion] The pathogenesis of IVIG-resistant KD may be associated with viral-induced or IL-1β-induced inflammatory reactions, and blockade of those pathways may be a new therapeutic target for IVIG-resistant KD.

P5.01.49
Association of modulatory cytokine gene polymorphisms in resistance and susceptibility to polyparasitism infection in Zimbabwe

T. Mduluza[1]*, N. Midzi*[2]*, P. Chitongo*[1]*, E. Gori*[1]*, T. Ruwona*[1]*, G. Mlambo*[3]*, S. L. Mutambu*[2]*, N. Kumar*[4,3]*;*
[1]University of Zimbabwe, Harare, Zimbabwe, [2]National Institute of Health Research, Harare, Zimbabwe, [3]Jonhs Hopkins School of Public Health, Baltimore, MD, United States, [4]Tulane School of Public Health & Tropical Medicine, Tulane University, New Orleans, LA, United States.

Single nucleotide polymorphisms within the cytokine genes, TNF-α (-308 G/A), IFN-γ (+874 A/T), TGF-β (T/C codon 10 and G/C codon 25) and IL-10 (-1082 G/A and -819 T/C) associated with moderation or severity of parasitic infections were examined in samples from school children aged between 5 - 16 years. About 72.8% were infected with either malaria and/or different helminths. Genotyping was carried out using the ARMS-PCR method. The frequency of TNF-α (GG) associated with low cytokine production was 76.1%, while 22.2% and 1.6% were predictors of medium and high production of TNF-α, respectively. For IFN-γ (+874 A/T), 70.5% were (AA) associated with high cytokine secretion, 4.4% (TT) and 25.1% (AT) associated with low cytokine production. Limited analysis on the samples also revealed that at the TGF-β locus (T/C codon 10) 88.5% were TT, which predicts high production of the cytokine, whereas 9.2% were CC. Similar analysis at another locus of TGF-β (G/C codon 25) showed that only 2.3% showed GC predicting high TGF-β production. Equal distribution of IL-10 (-819 G/A) and the rare occurrence of allele associated with low IL-10 (-1082 AA) production would suggest moderate to high IL-10 responses in the population. Finally, the high prevalence of TGF-β genotype (TT) predicting high cytokine production and the existence of IL-10 (high producer) might suggest the dominance of an anti-inflammatory environment when faced with acute P.falciparum infection in the population. These observations may also suggest a complex interaction between various cytokine gene polymorphisms and high burden parasitic infections in the area.

Interleukin-17A involvement in host defense against Echinococcus granulosus infection

D. Mezioug*, C. Touil-Boukoffa;*
Laboratory of Cellular and Molecular Biology- Faculty of Biological Sciences- University of Sciences, PB 32, El-Alia, Algeria.

Human hydatidosis is severe chronic parasitic disease, caused by the larval stage of Echinococcus granulosus. It constitutes a serious public health problem in various parts of the world, particularly in Algeria. The clinical evolution of these cysts is silent for several months, and the symptoms are not specific. Diagnosis is difficult and surgery constitutes the only therapy. We have previously shown the role of cytokines Th1 and Th2 in human hydatidosis. Our analysis of circulating cytokines production in sera from hydatid patients showed the immuno protective role of Th1 cytokines, especially IFN-γ and IL-12, and pathological role of Th2 cytokines during Echinococcus granulosus infection.The present study was focused on determining the role of IL-17A in the immune response against Echinococcus granulosus infection. We investigated IL-6, IFN-γ and IL-17A production in sera from Algerian hydatic patients with liver and lung hydatid cyst. IL-6, IFN-γ and IL-17A were also determined in PBMC culture supernatants from patients stimulated by a major parasitic antigen. The elevated activity of IL-6, IFN-γ and IL-17A were observed in most sera from patients. Our in vitro results indicate a positive correlation between IL-6, IFN-γ and IL-17A production in PBMC culture supernatants. However, IL-6, IFN-γ and IL-17A activity was low in sera and supernatants of PBMC cultures from relapsing patients and did not display any immune response against parasitic antigen. Collectively, our results show that IL-17A was involved in the host defense mechanisms against Echinococcus granulosus. Our data suggest that IL-17A play immunoprotective role in this parasitic helminth infection.

EBI3 functions as an intracellular molecule to regulate the development of colitis in naive CD4+CD25- T cells

***I. Mizoguchi**[1], K. Mitobe[1], R. Tsunoda[1], K. Higuchi[1,2], J. Mizuguchi[2], T. Yoshimoto[1];*
[1]Department of Immunoregulation, Institute of Medical Science, Tokyo Medical University, Tokyo, Japan, [2]Department of Immunology, Tokyo Medical University, Tokyo, Japan.

Epstein-Barr virus-induced gene 3 (EBI3) encodes a protein, which associates with IL-27p28 and IL-12p35 to form heterodimeric cytokines, IL-27 and IL-35, respectively. IL-27 is expressed in myeloid cells and IL-35 is expressed in CD4+CD25+ Treg cells. Since we recently found that EBI3 expression is induced in naive CD4+CD25-CD62L+ T cells by the stimulation with anti-CD3/anti-CD28, we herein investigated the role of EBI3 in naive CD4+ T cells. EBI3-decificent naive CD4+CD25-CD62L+ T cells failed to induce the colitis after adoptive transfer into RAG-deficient mice. Intracellular cytokine staining revealed that the production of IFN-γ but not IL-17 was significantly reduced in intestinal lamina propria of EBI3-deficient mice. Similarly reduced production of IFN-γ but not IL-17 was also observed when lymphocytes in the intestinal lamina propria were restimulated in vitro. Moreover, the production of IFN-γ but not IL-17 in EBI3-deficient CD4+ T cells differentiated in vitro under Th17 polarizing conditions were significantly reduced compared with that in wild-type CD4+ T cells. To examine whether EBI3 functions as a soluble factor like a cytokine or an intracellular factor, equal number of naive CD4+ T cells obtained from EBI3-deficient and EBI3-intact GFP-transgenic mice were mixed and differentiated under Th17 polarizing conditions. Intriguingly, the IFN-γ production was significantly reduced in only EBI3-deficient GFP-CD4+ T cells but not in EBI3-intact GFP+CD4+ T cells. Taken together, the present results suggest that EBI3 functions as an intracellular molecule to regulate the development of colitis by regulating IFN-γ production in naive CD4+CD25- T cells.

Prostaglandin D_2 represents contradicting roles in dermatitis

*H. Sarashina[1], Y. Tsubosaka[1], K. Aritake[2], T. Nakagawa[1], M. Hori[1], H. Ozaki[1], Y. Urade[2], **T. Murata**[1];*
[1]The University of Tokyo, Tokyo, Japan, [2]Osaka Bioscience Institute, Osaka, Japan.

Prostaglandin D_2 (PGD_2) is one of cyclooxgenase-metabolites and implicated in the pathogenesis of various inflammatory diseases. However there have been controversial reports showing its pro-inflammatory or anti-inflammatory role in various inflammatory disease models. The role of PGD_2 in inflammation is still elusive. In the present study, we investigated the role of PGD_2 in croton oil-induced dermatitis using transgenic mice (TG) overexpressing hematopoietic PGD synthase (H-PGDS). Administration of 2.5% croton oil caused tissue swelling and vascular leak in mice ears. Comparison with WT, TG ears produced more PGD_2 and showed decreased inflammatory responses at early phase (2 h), but showed more severe manifestations at late phase (6 h). The data obtained from the bone marrow transplantation between WT and TG suggested that the tissue resident cell-derived PGD_2 attenuated the early-phase inflammation, while the PGD_2 produced from hematopoietic cells exacerbated the late-phase inflammation. There are two distinct PGD_2 receptors, DP and CRTH2. In TG, treatment with a DP antagonist reinstated the inhibited inflammation at early phase, while treatment with a CRTH2 antagonist inhibited the aggravated inflammation at late phase. *In vitro* experiment showed that treatment with PGD_2 or a DP agonist, but not a CRTH2 agonist enhanced vascular endothelial barrier formation. Collectively, in H-PGDS-overexpressing mice ears, tissue resident cell-derived PGD_2 suppresses dermatitis via DP at early phase, while hematopoietic cell-derived PGD_2 stimulates CRTH2 and promotes inflammation at late phase. This is the first report showing that PGD_2 represents opposite roles in inflammation depending on disease phase *in vivo*.

P5.01.54
ST2/IL-33 signaling worsens immune-mediated hepatitis from drug haptens

*S. Goodman, J. Cho, L. Kim, M. Haham, **D. Njoku**;*
Johns Hopkins University, Baltimore, MD, United States.

Susceptible persons develop immune-mediated drug-induced liver disease (Im-DILI) following exposure to certain drugs. Antibodies in Im-DILI are detectable in other forms of hepatitis suggesting that animal models of Im-DILI may uncover innovative therapeutic options for Im-DILI and other forms of hepatitis. IL-33 is an IL-1 family member that drives Th2 cytokines, cells and injury in asthma (Verri *et al*., 2010), but protects in atherosclerosis and Con A hepatitis. In experimental anesthetic Im-DILI, IL-1β, IL-2, IL-6 and IL-13, were demonstrated, in addition to neutrophils, mast cells, eosinophils, NK and NKT cells (Njoku *et al*., 2005). Furthermore, hepatitis was successfully transferred to naive mice using CD4+T cells. We hypothesized that signaling via ST2/IL-33 worsens experimental Im-DILI. To test our hypothesis we immunized female BALB/c mice with our catalytic site epitope of CYP2E1 (JHDN-5) that was covalently altered by a trifluroacetyl hapten (TFA) on days 0 and 7 ± IL-33 blocking antibody. Three weeks later liver supernatants were tested for IL-6, TARC, IL-33 and ST2 by ELISA. Hematoxylin and eosin-stained slides were scored for inflammation. Sera were tested for TFA, S100 and CYP2E1 antibodies. We found significantly elevated IL-6, TARC and IL-33 in TFA-JHDN-5 - immunized mice; additionally, anti-IL-33 diminished inflammation scores from 2.8 ± 1.1 to 1.6 ± 0.6 but increased TFA, S100 and CYP2E1 antibodies ($p<0.05$, Mann-Whitney*U*). We confirm that IL-33 worsens Im-DILI and suggest protective roles for antibodies. This preliminary study suggests that anti-IL-33 and other antibodies may offer therapeutic options to diminish Im-DILI and possibly other forms of hepatitis.

P5.01.55
Lack of TNF-Rp55 delays thrombus resolution in a stasis-induced DVT model through reduced MMPs and uPA expression

M. Nosaka[1]*, Y. Ishida*[1]*, A. Kimura*[1]*, Y. Kuninaka*[1]*, N. Mukaida*[2]*, T. Kondo*[1]*;*
[1]Department of Forensic Medicine, Wakayama Medical University, Wakayama, Japan, [2]Division of Molecular Bioregulation, Cancer Research Institute, Kanazawa University, Kanazawa, Japan.

Deep vein thrombosis (DVT) is multifactorial and often results from a combination of risk factors such as genetic conditions, obesity, drugs, pregnancy, aging, trauma, and malignancy. We examined the pathophysiological roles of TNF-α-TNF-Rp55 axis in the thrombus resolution using *Tnfrp55* KO mice. Upon the ligation of the inferior vena cava (IVC) of wild type (WT) mice, venous thrombi formed and grew progressively until 5 days, and the thrombus weight decreased less than 50% at 14 days. Concomitantly, intrathrombotic gene expression of *Tnfa* and *Tnfrp55* was enhanced as post-ligation intervals were extended. When *Tnfrp55* KO mice were treated in the same manner, thrombus mass was larger than WT mice. Moreover, the thrombosed IVC blood flow was less recovered in *Tnfrp55* KO than in WT mice. And intrathrombotic *Plau*, *Mmp9* and *Mmp2* mRNA expression were significantly reduced in *Tnfrp55* KO mice than WT ones. Supportingly, the administration of anti-TNF-α monoclonal antibody delayed the thrombus resolution in WT mice. On double-color immunofluorescence analysis, we found out the MMP-2, MMP-9 and uPA were produced mainly by intrathrombotic infiltrating macrophages. Furthermore, TNF-α treatment enhanced gene expression of *Plau*, *Mmp9* and *Mmp2* in WT-derived macrophages but not *Tnfrp55* KO-derived ones. And the gene expression of *Mmp9* and *Mmp2* was reduced respectively by ERK and NFkB inhibitor in WT-derived macrophages treated by TNF-α. Collectively, the lack of *Tnfrp55* can have a detrimental role in the thrombus resolution by suppressing uPA, MMP-2 and MMP-9 expression. Thus, TNF-α-TNF-Rp55 axis can be a good molecular target for the DVT treatment.

P5.01.56
Impaired production of IL-10 in response to *Staphylococcus aureus* alpha-toxin is closely associated with pathophysiology and postoperative outcome in chronic rhinosinusitis with nasal polyps

M. Okano*;*
Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan.

Background: *Staphylococcus aureus* can modulate chronic airway inflammation by producing various toxins. However, in contrast to *S. aureus*-derived superantigenic toxins such as enterotoxins, the role of non-superantigenic toxins in the pathogenesis of chronic rhinosinusitis with nasal polyps, one of the major inflammatory upper airway diseases in humans, remains obscure.
Objective: We sought to characterize Th1-, Th2-, Th17-, and Treg-associated cytokine productions following the exposure to *S. aureus* alpha-toxin, the major non-superantigenic toxin, in chronic rhinosinusitis with nasal polyps using a human *ex vivo* model.
Methods: Dispersed nasal polyp cells were prepared from patients with chronic rhinosinusitis with and without nasal polyps. Cells were incubated with alpha-toxin, and the levels of IL-5, IL-13, IFN-γ, IL-17A, and IL-10 in the cell supernatants were determined. The pathophysiological significance of alpha-toxin-induced cytokine production by nasal polyp cells was also determined.
Results: Nasal polyp cells produced substantial amounts of IL-5, IL-13, IFN-γ, IL-17A, and IL-10 in response to alpha-toxin. Alpha-toxin-induced IFN-γ, IL-17A, and IL-10 production by nasal polyp cells negatively correlated with the degree of eosinophil infiltration into nasal polyps. Furthermore, alpha-toxin-induced IL-10 production by nasal polyp cells correlated negatively with postoperative CT score and positively with radiological improvement assessed 6 months after sinus surgery.
Conclusions: Th1-, Th2-, Th17-, and Treg-associated cellular responses were provoked following the exposure to non-superantigenic alpha-toxin in chronic rhiosinusitis with nasal polyps. These responses, especially failure to synthesize IL-10, regulate the pathophysiology of this disease including local eosinophila and postoperative outcome.

IL6 trans-signaling promotes functional recovery of hypofunctional phagocytes through STAT3 activation during peritonitis

T. Onogawa[1]*, T. Saito-Taki*[2]*, H. Yamamoto*[1]*, T. Wada*[1]*;*
[1]Kyorin University Faculty of Health Sciences, Hachioji, Tokyo, Japan, [2]Kitasato University School of Allied Health Sciences, Sagamihara, Kanagawa, Japan.

Objective: The role of high interleukin 6 (IL6) levels has not been clearly explained in severe sepsis. We show that the augmentation of the IL6 signal by recombinant IL6 receptors (rIL6R) delivery allows the functional recovery of phagocytes in a peritonitis mouse model.
Materials and Methods: Mice were challenged intraperitoneally (i.p.) of live *Staphylococcus aureus* for effect of IL6R delivery on the 24h-survival, bacterial clearance and cellular responses. In additional experiments to assess of effect of IL6R delivery on phagocytosis, the model was i.p. inoculated with heat-killed *S. aureus* with or without rIL6R and the peritoneal lavage fluid and cells were collected at 1 h after the i.p. inoculation of *S. aureus*.
Results: The IL6R delivery tended to improve 24-h survival and increase bacteria clearance from the septic mice. The rIL6R treatment to heat-killed bacteria challenged mice augmented the uptake of bacteria and phagosome acidification, inducing the phosphorylation of STAT3 in peritoneal cells within 1 hour after the IL6R delivery. Furthermore, the rIL6R delivery prevented the extracellular release of neutrophil elastase activity and myeloperoxidase (harmful factors).
Conclusions: These results indicate that augmentation of IL6 signaling appears to be critical for the effective management of hypofunctional neutrophils during severe inflammation, such as sepsis.

Cytokines as molecular biomarkers for cancer cachexia

C. Penafuerte*, J. Sirois, M. L. Tremblay, B. Gagnon;*
McGill University, Montreal, QC, Canada.

Introduction: Cachexia is a multifactorial syndrome defined by irreversible loss of skeletal muscle mass with or without loss of fat mass. Cachexia is characterized by a negative protein and energy balance that causes disorders in homeostasis such as progressive wasting, weakness, anorexia and anemia. Solid malignancies trigger an intrinsic undesired chronic inflammatory state that leads to an abnormal increase of inflammatory factors that induce cachexia. In the present clinical study, we have analyzed and correlated the cytokine profile and muscle function data of 71 patients with advanced cancer.
Methods: Cancer patients include cases of head and neck cancer, non-small cell lung cancer, pancreatic cancer, hepatobilliary cancer, colorectal cancer and upper gastro-intestinal cancer. Human blood samples were drawn into EDTA-coated collection tubes and 16 cytokines in plasma were measured using Human Cytokine bio-plex technology. The cytokine profile and muscle function data were correlated using Partial Least Squares (PLS) regression.
Results: Cancer patients with impaired muscle function are characterized by elevated levels of IL-1β, IL-6, IL-4, IFNγ, CRP (C-reactive protein) and LDH (lactate dehydrogenase). IL-6 and IL-1β induce protein catabolism and inhibit protein anabolism through the activation of NF-kB signaling pathway. IL-6 also induces an acute phase response (APR) characterized by elevated levels of CRP. On the other hand, IL-1β and tumor-induced hypoxia may induce HIF-1 (hypoxia inducible factor 1) and increase the transcription of LDH causing the accumulation of lactate. **Conclusion:** Abnormal levels of IL-1β, IL-6, IFNγ, CRP and LDH could be used as biomarkers for cancer cachexia.

P5.01.59
Cytokine profile changes following exposure to Hemiscorpius lepturus scorpion venom under experimental conditions

M. Pipelzadeh[1], *A. Khodadadi*[1,2], *Y. Heike*[3], *M. Assarehzadegan*[1], *M. Assarehzadegan*[1], *B. Vazirianzadeh*[1];
[1]*Ahvaz Jundishapur University of Medical Sciences, Ahvaz, Iran,* [2]*cancer research center of Ahvaz Jundishapur University of Medical Sciences, Ahvaz, Iran,* [3]*National Cancer Hospital, Tokyo, Japan.*

Introduction: A previous clinical study showed that it produces a marked increase in TNFα level in patients envenomed by this scorpion. The aim of the present study was to further assess the changes in change other cytokine levels following in vitro exposure to this venom.
Method: Heparinized blood and peripheral blood mononuclear cells (PBMC) samples were exposed to 1 µg/ml of H. lepturus venom for 24 hr. Control samples of both preparations were treated similarly in the absence of the venom. The cytokine levels in the supernatant media and serum from whole blood samples were measured by MSD multi-array 96-well 10 small spot plates. The collected data were analyzed by WINMDI software.
Results: IFNγ and IL2 show significant 2.5 and 10 fold increased respectively. While IL10, showed a significant increase (by 4.5 fold) and IL-5 and IL-3 by 2 fold. TNF-α IL-12p70 increased by 4 fold. Overall trends of changes following exposure to H Lepturus venom in both whole blood and PBMCs had similar trends.
Conclusion: Besides its cytotoxic properties which were shown by the increase in TNF-α and IL-12p70; this venom has direct immune suppressive and possible indirect immune stimulating actions which may be utilized in development of novel agents that may be identified and used for treatment of different immune mediated illnesses.

The knock-out of TWEAK receptor/Fn14 ameliorates lupus nephritis in MRL/lpr mice

Y. Xia[1], *L. Herlitz*[2], *L. Burkly*[3], *R. Pawar*[1], *S. Gindea*[1], *P. Wu*[3], *J. Michaelson*[3], ***C. Putterman***[1];
[1]*Albert Einstein College of Medicine, Bronx, NY, United States,* [2]*Columbia-Presbyterian Medical Center, New York, NY, United States,* [3]*Biogen Idec, Cambridge, MA, United States.*

Renal mesangial cells, podocytes, and tubular cells express Fn14, the receptor for the TNF-family member cytokine TWEAK. TWEAK engagement of Fn14, the sole known biologic receptor for TWEAK, induces kidney resident cells to produce multiple inflammatory mediators including MCP-1 and RANTES. In the chronic graft-versus-host and nephrotoxic nephritis models of antibody-mediated renal disease, genetic deficiency of Fn14, or treatment with an anti-TWEAK monoclonal antibody, decreases kidney inflammation and proteinuria without affecting systemic autoantibody titers. These studies suggest that inhibition of TWEAK/Fn14 interactions might be efficacious in spontaneous models of lupus nephritis (LN). We assessed the role of the TWEAK/Fn14 pathway in the well-established MRL/lpr lupus prone mouse strain. We found that at 26 weeks of age, MRL/lpr Fn14 wild-type (WT) mice had significantly higher levels of proteinuria as compared to MRL/lpr Fn14 knockout (KO) mice. Furthermore, MRL/lpr Fn14 KO mice had significantly improved renal histopathology, with less glomerular immune deposition, endocapillary hypercellularity, mesangial proliferation, tubulointerstitial lesions, and perivascular inflammation. By immunohistochemistry, there were significantly fewer Ki-67+ proliferating cells in both glomerular and tubular compartments, as well as decreased KIM-1 staining, in MRL/lpr Fn14 KO mice. However, there were no differences between the strains in autoantibody titers at several time points, suggesting that TWEAK likely acts by modulating events locally in the kidney. Our results convincingly demonstrate that inhibition of TWEAK signaling significantly attenuates renal disease in murine lupus, suggesting that the TWEAK/Fn14 axis may be a novel therapeutic target for LN.

P5.01.61
Inhibiting TWEAK (TNF-like weak inducer of apoptosis) signaling ameliorates neuropsychiatric disease in MRL/lpr mice

C. Putterman;
Albert Einstein College of Medicine, Bronx, NY, United States.

Systemic lupus erythematosus (SLE) is a systemic autoimmune disease characterized by involvement of multiple organs, including the central nervous system. While neuropsychiatric involvement in systemic lupus erythematosus (NPSLE) is relatively common and appears early, the underlying mechanisms are not fully understood. TWEAK is a cytokine member of the TNF superfamily; the TWEAK receptor, Fn14, is expressed in the brain in endothelial cells, astrocytes, microglia and neurons. TWEAK/Fn14 interactions can lead to cytokine production, neurodegeneration, and increases in blood brain barrier (BBB) permeability. Furthermore, patients with neuropsychiatric SLE demonstrate high levels of TWEAK in the cerebrospinal fluid. To elucidate a possible role for TWEAK signaling in the pathogenesis of NPSLE, comprehensive neurobehavioral tests were employed to assess neuropsychiatric manifestations in MRL/lpr Fn14 wild type (WT) and MRL/lpr Fn14 knockout (KO) mice. We found that Fn14 deficiency significantly ameliorates NPSLE, as seen by dramatically less depressive-like behavior and improved cognitive function (memory) in MRL/lpr Fn14 KO mice. Moreover, RANTES, C3 and IgG were reduced in the brains of MRL/lpr Fn14KO mice. Additionally, MPRL/lpr Fn14KO mice had decreased albumin concentrations in the cerebrospinal fluid, indicating preserved BBB integrity. However, there were no differences between MRL/lpr Fn14 WT and KO mice in the serum levels of autoantibodies associated with NPSLE. Finally, Fn14 KO mice display reduced apoptosis of brain cells. Thus, TWEAK/Fn14 interactions play a central role in the pathogenesis of lupus associated neuropsychiatric disease, suggesting a novel target for therapeutic intervention for this major disease manifestation.

All trans retinoic acid enhanced the markers of T regulatory cells while reducing nitric oxide synthase 2 expression and proinflammatoy cytokines production in peripheral blood mononuclear cells from Algerian patients with inflammatory bowel disease

H. Rafa[1], *H. Saoula*[2], *M. Belkhelfa*[1], *A. Boukercha*[1], *I. Soufli*[1], *Y. De launoit*[3], *O. Moralès*[3], *M. Nakmouche*[2], *N. Delhem*[3], *C. Touil-boukoffa*[1];
[1]*Team: Cytokines and NOSynthases, Laboratory of Cellular and Molecular Biology (LBCM), Faculty of Bio, Algiers, Algeria,* [2]*Department of Gastroenterology, Maillot Hospital, Algiers, Algeria,* [3]*Institut de Biologie de Lille, UMR 8161, CNRS, Institut Pasteur de Lille, Universite´ Lille-Nord de France, Lille, France.*

Inflammatory bowel diseases (IBDs) are chronic inflammatory diseases of the gastrointestinal tract, which are clinically present as one of two disorders, Crohn's disease (CD) or ulcerative colitis (UC). The immune dysregulation in the intestine plays a critical role in the pathogenesis of inflammatory bowel disease, involving a wide range of molecules including cytokines and Nitric Oxide (NO). The maintenance of host integrity relies on the constant resetting of tissue homeo¬stasis by regulatory networks. One cardinal feature of this regulation is associated with the ability of lymphocytes with constitutive or induced regulatory properties to accu¬mulate at the disrupted site and limit tissue damage. This study was designed to investigate the effects of All trans Retinoic Acid (AtRA) on NO, Urea and cytokines (IL-10, TGF-β, IL-2, TNFα, IFNγ) production in periphal blood mononuclear cells (PBMC) cultures from Algerian patients with IBD. We also investigate the effect of AtRA on Nitric oxide synthase 2 (NOS2) and Treg markers expression using transcriptomic analysis. Our results suggest that AtRA is potent inhibitors of NO and proinflammatory cytokines. In contrast, AtRA increased Urea and TGF-β production, but not IL10 production. AtRA up regulated mRNA transcripts expression of Treg markers in PBMC of all IBD groups. Our study also shows that AtRA down regulated mRNA transcripts expression of NOS2 in PBMC. Collectively, our study indicates that AtRA plays pivotal role in regulatory networks of immune system in IBD patients.

P5.01.63
Serum level of immunoglobulins in patients with respiratory allergic diseases

B. Rahnama[1]*, B. Hazhirkarzar*[2]*, H. Ghaffari*[1]*, M. Zamanlu*[3]*;*
[1]*tabriz university of medical science-immunology department, tabriz, Iran,* [2]*Student Research Committee, Immunology department, Tabriz university of medical sciences, Tabriz, Iran,* [3]*Neuroscience Research Center, Tabriz University of Medical Sciences, Tabriz, Iran.*

Allergic diseases are immunologically common diseases in which the immunoglobulins, as important components of the immunity system play an effective role in their pathogenesis. Allergic diseases have a great range from allergic dermatitis, allergic rhinitis to allergic asthma and so on. The aim of this research was to investigate the relation of serum level of IgE, IgA, IgM, IgG in patients with allergic rhinitis and asthma separately and both together.
In this research the serum levels of immunoglobulins including IgG, IgM, IgA, IgE was measured in 130 patients suffering from respiratory allergic disease, which who were referred to Isfahane Issabne Maryam Hospital Allergy And Asthma Clinic and in 120 healthy individuals. Both patients and control groups were matched considering age and sex.
A significant reverse relation was observed between the serum IgA and IgE in patients with both asthma and allergic rhinitis ($r=-0.396, p<0.05$). A direct and significant relation between IgE and IgM serum level in patients with both asthma and allergic rhinitis ($r=0.448, p<0.05$). In this study, a significant reverse relation was observed between serum IgA and IgM in patients with asthma and both asthma and allergic rhinitis ($r=-0.252$, $p<0.05$) and ($r=-0.423$, $p<0.05$) but not in patients with allergic rhinitis($p>0.1$). As conclusion, our results show that IgA deficiency is in relation with an increase in IgE and respiratory allergic diseases.

P5.01.64
The electromagnetic fields affect T-helper balance in rats

B. Rahnama[1]*, M. Zamanlu*[2]*, B. Hajir Karzar*[3]*, M. Bonyadi*[1]*, A. Khaki*[4]*;*
[1]*Department of Immunology, Tabriz University of Medical Sciences, Tabriz, Iran,* [2]*Neuroscience Research Center, Student Research Committee, Tabriz University of Medical Sciences, Tabriz, Iran,* [3]*Student Research Committee, Tabriz University of Medical Sciences, Tabriz, Iran,* [4]*Department of Embrology and Anatomy, Tabriz University of Medical Sciences, Tabriz, Iran.*

The biologic influences of ElectroMagnetic Fields (EMFs) are being investigated for decades and the World Health Organization (WHO) established the International EMF Project, to determine the scientific evidence of possible health effects of EMFs. These fields have been classified as probable human carcinogen. Among all investigations, immunologic experiments, especially assessing cytokines, are rare. The present study undertakes to search for the T-helper (Th) balance otucome of exposure to these fields. Thirty Wistar rats were divided to three groups, one group included the control rats, another, rats for one month exposure, and the last group rats for 2 month exposure. An EMF in the frequency of 50 Hertz, 0.5 mili-Tesla was used, and the serum levels of cytokines of IL-4 (indicating Th2 activity) and INFγ (indicating Th1 activity) were measured. The results showed that after one month, the serum levels of IL-4 increased highly significantly (P value: 0.009), and the levels of INFγ decreased significantly (P value: 0.032). After 2 months these levels returned to the levels statistically similar to the control group (P value: 0.627 & 0.402 respectively for IL-4 & INFγ). As a conclusion of our results, in short periods, as much as one month, EMFs weigh the T-helper balance to the Th2 side in rats, however, in longer periods, as much as 2 months, the biologic homeostasis of rats causes *tolerance* to this influence of the EMFs.
This research was supported by the Research Deputy of Tabriz University Medical Sciences.

TWEAK Affects Keratinocyte G2/M Growth Arrest and Induces Apoptosis through the Translocation of the AIF Protein to the nucleus

S. Sabour Alaoui*;*
Université Chouaib Doukkali, El Jadida, Morocco.

The soluble TNF-like weak inducer of apoptosis (TWEAK, TNFSF12) binds to the fibroblast growth factor-inducible 14 receptor (FN14, TNFRSF12A) on the cell membrane and induces multiple biological responses, such as proliferation, migration, differentiation, angiogenesis and apoptosis. Previous reports show that TWEAK, which does not contain a death domain in its cytoplasmic tail, induces the apoptosis of tumor cell lines through the induction of TNFα secretion. TWEAK induces apoptosis in human keratinocytes. Our experiments clearly demonstrate that TWEAK does not induce the secretion of TNFα or TRAIL proteins. The use of specific inhibitors and the absence of procaspase-3 cleavage suggest that the apoptosis of keratinocytes follows a caspase- and cathepsin B-independent pathway. Further investigation showed that TWEAK induces a decrease in the mitochondrial membrane potential of keratinocytes. Confocal microscopy showed that TWEAK induces the cleavage and the translocation of apoptosis inducing factor (AIF) from the mitochondria to the nucleus, thus initiating caspase-independent apoptosis. Moreover, TWEAK induces FOXO3 and GADD45 expression, cdc2 phosphorylation and cdc2 and cyclinB1 degradation, resulting in the arrest of cell growth at the G2/M phase. Finally, we report that TWEAK and FN14 are normally expressed in the basal layer of the physiological epidermis and are greatly enhanced in benign (psoriasis) and malignant (squamous cell carcinoma) skin pathologies that are characterized by an inflammatory component. TWEAK might play an essential role in skin homeostasis and pathology.

P5.01.66
PI3K/PTEN axis in APCs is regulating Th17-dependent autoimmune pathology

E. Sahin[1]*, V. Saferding*[2]*, J. Brunner*[1]*, J. Kral*[1]*, N. Neuwinger*[1]*, I. Kollmann*[1]*, K. Thell*[1]*, S. Blüml*[2]*, G. Schabbauer*[1]*;*
[1]*Center for Physiology and Pharmacology, Medical University of Vienna, Vienna, Austria,* [2]*Division of Rheumatology, Internal Medicine III, Medical University of Vienna, Vienna, Austria.*

Background: $CD4^+$ T cells, especially those polarized towards the Th1/Th17 subsets, play a critical role in the pathogenesis of autoimmune diseases. Therefore, it is important to understand pathways controlling Th17-mediated autoimmunity. Antigen-presenting-cells (APCs) control adaptive immune responses by activation of antigen-specific T cells. However, signal transduction pathways in APCs that govern the development of Th17 cells are incompletely understood. The Phosphatidylinositol-3-kinase (PI3K) pathway is one of the most important signal transduction pathways, regulating fundamental processes. Here we report that control of PI3K signalling by PTEN specifically in APCs is essential for the development of Th17 mediated autoimmune diseases such as experimental-autoimmune-encephalomyelitis (EAE).
Methods/Results: We studied EAE, a model for the early inflammatory stage of human multiple sclerosis that is strictly mediated by pathogenic T cells polarized towards the Th17 linage. We induced EAE in animals with a celltype-specific (LysM, CD11c-cre) deletion of PTEN ($pten^{-/-}$) to test the selective role of PTEN-deficient APCs on the induction of autoimmunity without affecting other cell types, especially T cells. $Pten^{-/-}$ mice had almost no clinical signs of EAE, in contrast wt mice developed typical symptoms of paralysis and had a significant weight loss. Splenocytes and lymphocytes isolated at day 8, 12, 16 and 21 after EAE induction and restimulated *in-vitro* with myelin-oligodendrocyte-glycoprotein (MOG) had reduced amounts of Th17 polarising factors as a result of reduced generation of IL-17 and IL-22 producing T-cells determined by ELISPOT and ELISA.
Conclusion: Our findings show that the PI3K/PTEN axis in APCs is regulating Th17-dependent autoimmune pathology.

P5.01.67
Cytokine patterns during high-risk human papillomavirus and HIV co-infection in cervical cancer patients and controls in Kwazulu-Natal (South Africa).

***D. Sebastian**, A. G. Assounga;*
University of KwaZulu-Natal, Durban, South Africa.

Cytokines including IL2, IL6 and TNFα production is reported correlates with response to therapy in cervical cancer and in HIV disease.
Aim: To analyse cytokines levels in cervical cancer patients and controls according to HIV status.
Materials and Methods: Serum samples from 134 cancer patients and 84 controls from KwaZulu-Natal were analysed for the cytokines, IL2, IL6 and TNFα using commercially available ELISA.
Results: IL2 levels were higher in the control group (9.55±1.92) than in the cancer group (4.98±1.45) (p=0.0001). IL-6 concentration was higher in cervical patients than in controls, while the opposite was found for TNFα (Table 1). HIV infection had no additional effect on the production of IL-2, IL-6 and TNFα in cervical cancer patients. The same was true for controls, with the exception of IL-6 levels found higher in HIV positive than in HIV negative controls.
Table 1 Levels of cytokine IL2, IL6 and TNFα in Cervical Cancer Patients and in Controls
cytokine cervical cancer controls
n x±SEM n x±SEM
p value
IL2 134 4.98 ± 1.45 83 9.55 ± 1.92 0.0001٭
IL6 134 52.47 ± 22.81 83 7.48 ± 1.99 0.0038٭
TNFα 134 1.69 ± 1.01 83 8.28 ± 3.05 0.0368٭
٭ statistically significant (Mann Whitney test)
Discussion: This study confirms the shift from Th1 to Th2 immune response in cervical cancer as reported elsewhere. The lack of HIV influence on the above cytokines levels in cervical cancer patients suggests that cervical cancer might have maximally stimulated them such that HIV has no further impact.

P5.01.68
Mechanisms of immunosuppression and interleukin 2 in complex treatment of severe acute pancreatitis

***M. Shavarova**, S. Chooklin;*
Medical University, Lviv, Ukraine.

Introduction. In pathogenesis of acute pancreatitis the important role are play pro- and anti-inflammatory cytokines. Their disbalance leads to depletion of immunocompetent cells and defines the expressed secondary immunodeficiency, which after 7-14 days becomes a leading pathogenic link of severe acute pancreatitis (SAP). Therefore adequate immunotherapy may play obvious role in complex treatment of this severe pathology.
Materials and Methods. Plasma levels of IL-2, IL-4, IL-8, TNF-α, populations of lymphocytes were measured in 36 patients with SAP. Twenty patients received in complex therapy recombinant interleukin-2 in a dose of 3 million MO. Sixteen patients examined as control.
Results. The mean value of serum all cytokines levels in patients with SAP was significantly higher than in healthy volunteers. The lymphocyte count was decreased below the normal range, and was significantly negatively correlated with severe score. CD4- and CD8-positive lymphocyte counts on admission and the lymphocyte count on day 14 after admission may be useful for predicting infection. Changes of cytokines status after interleukin 2 therapy are noted too. Authentic levels depression of all cytokines in peripheral blood is established. The level of IL-2 tended to normalisation in comparison with a disease debut, but remains lower, than in healthy donors. After therapy normalization of T lymphocytes level is noticed.
Conclusion. A significant depletion of circulating lymphocytes was found in severe acute pancreatitis with infectious complications. Use of interleukin 2 in complex treatment of severe pancreatitis is expediently for correction immunoparalysis and prevention of purulent-septic complications.

P5.01.69
Tuberculosis infection diagnosis by Quantiferon TB Gold In-Tube Test assessment in Namibian patients

***J. A. Sheehama**[1,1], J. J. Nelongo[1], E. E. Nepolo[1], S. N. Iipinge[2];*
[1]UNAM School of Medicine, Windhoek, Namibia, [2]UNAM School of Nursing and Public Health, Windhoek, Namibia.

Introduction: Conventional diagnostic methods take long for results to come out, and active TB patients can spread infection while waiting laboratory confirmed results. The QFN TB Gold In-Tube method shortens the time need for TB diagnosis, especial in country with low TB prevalence. It was important to assess the usefulness of bio-markers in QFN supernatant plasma diagnostic approach for TB in Namibia context. The research has component to monitor the levels of IFN-γ in QFN supernatants of TB patients as a measure of response to treatment in the Namibian settings. Methodology: The study population include 84 TB suspects, 18 years and older, HIV negative and positive suspects, living in Windhoek and meeting AE-TBC requirements, at the moment of visiting Katutura State Hospital. The main target number is 100 TB suspects, the samples collected goes through the routine testing (AFB Auramine microscopy and Culture), and Quantiferon test to detect the level of IFN-γ, suspected to be released in infected individuals. The effect of treatment on the level of IFN-γ in plasma was also monitor in patient's at 2 months and 6 months after treatment.
Results: A total of 84 suspects was recruited,tested using culture and Quantiferon test. All recruited 21.4% were TB positive in microscopy, 14.3% TB positive in culture and 53.6% were positive in Quantiferon TB Gold In-Tube.
Conclusion: The use of Quantiferon TB Gold In-Tube for TB diagnosis in Namibia, has shown unreliably false positive results in comparison to TB culture.

P5.01.70
Antiplatelets drugs reduces the immunoinflammatory response in a rat model of periodontal disease

***L. Spolidorio**[1], J. Steffens[1], M. Nicolas Muscará[2], C. Rossa Jr[1], D. Graves[3], L. Santana Coimbra[1];*
[1]Faculdade de Odontologia de Araraquara, UNESP-Univ Estadual Paulista, Araraquara, Brazil, [2]Institute of Biomedical Sciences, Universidade de São Paulo, São Paulo, Brazil, [3]Penn Dental Medicine School University of Pennsylvania, Philadelphia, PA, United States.

Background: Platelets are cellular corpuscles that once activated express biological mediators that modulate the inflammatory process including pro-inflammatory cytokines, chemokines and growth factors. We hypothesized that drug-induced platelet inactivation may interfere in the inflammatory process in experimental periodontal disease in rats by suppressing the release of biological mediators from platelets to the site of injury.
Methods: Effects of treatment of rats with Asp (30 mg/kg) and Clo (75 mg/kg) given intragastrically for 3 days on ligature-induced periodontal disease were assessed. After experimental period the animals were sacrificed and right and left hemi-mandibles were used to the hystologic and histometric evaluation as well as mieloperoxidase (MPO) activity. Expression of CCL5 and CXCL4 levels were measured by enzyme-linked immunosorbent assay.
Results: Significant anti-inflammatory effects and consequently fall of alveolar bone loss were observed at doses of the drugs-induced platelet inactivation. The degree of anti-inflammatory effects at the site of inflammation correlated significantly with reduction of MPO activity. At these doses, Clo significantly increased the expression of CXCL4 and decreased CCL5 ($P<0.001$) whereas Asp only decreased in the expression of CXCL4 ($p<0.05$). Treatment with antiplatelet drugs did not influence the expression of CCL5 at the site of inflammation.
Conclusion: Systemic administration of Clo could therefore play a crucial role in platelet-expressed biological mediators and in turn could regulate the process of immunoinflammation associated with periodontitis.

P5.01.71

Vitamin D and Interferon-beta act synergistically at physiological levels to modulate cytokine expression *in vitro* in peripheral blood mononuclear cells

N. J. Stewart[1]*, S. Simpson Jr.*[2]*, B. Taylor*[2]*;*
[1]*University of Tasmania, Hobart, Australia,* [2]*Menzies Research Institute Tasmania, Hobart, Australia.*

Background: Current treatments for the autoimmune disease Relapse Remitting Multiple Sclerosis (RRMS) are limited, with Interferon-beta (IFNβ) being one of the most effective. Part of its efficacy is due to its effect on the cytokine profile, suppressing inflammatory cytokines and increasing anti-inflammatory Interleukin-10 (IL-10). Vitamin D is also known to have immunomodulatory effects, therefore we asked whether a combination of IFNβ and calcitriol (the physiologically active form of vitamin D) has synergistic effects on cytokine secretion by peripheral blood mononuclear cells (PBMC) from healthy people.
Methods: We separated the PBMC from the blood of 22 healthy people, and treated them as follows: stimulated (20ug/ml Concanavilin A); stimulated + 100pg/ml calcitriol; stimulated + 100 IU or 400 IU IFNβ; stimulated + 100pg/ml calcitriol + 100 IU or 400 IU IFNβ. The cytokines IL-2, -4, -6, -10, TNFα, IFNβ and IL-17 were measured flow cytometrically (BD Scientific).
Results: The majority of subjects were female (59%), and the median serum 25(OH)D was 69.5 nmol/L. Calcitriol alone suppressed IL-2, -4, -6 and 17. IFNβ alone suppressed IL-2, -6 and TNFα, but increased IL-10 four fold. Calctriol and IFNβ acted synergistically to further suppress IL-2, -6, TNFα and IFNγ. No consistent effect of age or serum 25(OH)D on cytokine expression was observed.
Significance: Co-administration of vitamin D with IFNβ could aid in RRMS by suppressing inflammatory cytokine responses and promoting IL-10. This may also have implications for other inflammatory conditions

P5.01.72

Carbon monoxide (CO) as a novel approach for treatment of islet-directed autoimmunity

S. Stosic-Grujicic[1]*, I. Nikolic*[1]*, M. Vujicic*[1]*, T. Saksida*[1]*, F. Nicoletti*[2]*, I. Stojanovic*[1]*;*
[1]*Department of Immunology, Institute for Biological Research "Sinisa Stankovic", University of Belgrade, Belgrade, Serbia,* [2]*Department of Biomedical Sciences, School of Medicine, University of Catania, Catania, Italy.*

Recent studies identified carbon monoxide (CO) as a potential therapeutic molecule due to its anti-inflammatory and anti-apoptotic abilities. Since a pharmacologically designed CO-releasing molecule CORM-A1 liberates controlled quantities of CO in the cellular systems, in this study we investigated possible therapeutic value of CORM-A1 in the model of autoimmune diabetes. We have already shown that CORM-A1 administration during diabetes induction in C57BL/6 mice by multiple low doses of streptozotocin (MLDS) improves clinical and histological signs of the disease. To determine the effect of CORM-A1 within the local environment of the endocrine pancreas, infiltrated mononuclear cells were isolated from pancreata at days 8-10 of disease induction and phenotype of cell infiltrates was determined by flow cytometry and real-time PCR. The percentage of $CD4^+$, $CD8^+$, $B220^+$ and pro-inflammatory $F4/80^+CD40^+$ macrophages was reduced, while anti-inflammatory $F4/80^+CD206^+$ macrophage cell number was unchanged in pancreatic infiltrates of CORM-A1-treated mice compared to diabetic mice. Also, the proportion of Th1 ($CD4^+$IFN-γ^+) infiltrated cells was reduced and of Th2 ($CD4^+$IL-4^+) cells was increased in CORM-A1-treated mice compared to control MLDS-treated mice. However, Th17 cells remained unchanged in both groups. In line with this, mRNA expression of Th signature cytokines, IFN-γ and IL-4, was inversely regulated resulting in lower IFN-γ/IL-4 ratio in CORM-A1-treated mice. Our study suggests that CORM-A1 suppresses autoimmune response by preventing the infiltration of cells and shifting the balance towards protective Th2 cells, thus interfering with cytokine-mediated pro-apoptotic stimuli within endocrine pancreas. CORM-A1 may thus represent a novel candidate drug for treatment of autoimmune diabetes.

P5.01.73

IL-2 induces robust inflammatory responses in the lung that synergize with influenza virus to exacerbate immunopathology

T. M. Strutt*, K. K. McKinstry, S. L. Swain;*
University of Massachusetts Medical School, Worcester, MA, United States.

Interleukin-2 (IL-2) is an important T cell growth factor central for the homeostasis and function of regulatory CD4 T cells (Tregs) that maintain tolerance and dampen inflammation. Systemic administration of IL-2 expands Tregs and improves autoimmune disease and transplant acceptance. On the other hand, IL-2 expands CD8 T and NK cells and cancer therapies aimed at improving the function of these subsets through administration of IL-2 are often complicated by severe side effects including systemic inflammatory cytokine (IFN-γ, TNF, and IL-5) production, eosinophelia, and death. To better understand the pro versus anti-inflammatory roles of IL-2 in vivo, we administered soluble cytokine, or IL-2 complexed with antibodies that target its delivery to specific cell types to unmanipulated mice and analyzed protein expression of over 40 inflammatory cytokines and chemokines. IL-2 up-regulates a remarkably broad array of these molecules, unexpectedly, even when targeted to Tregs. The IL-2 driven inflammation is as dramatic in lungs as it is systemically, and multiple T cell subsets, NK cells, and neutrophils, but not eosinophils, are involved in the inflammatory response. We next assessed whether IL-2 driven pulmonary inflammation is beneficial or detrimental during respiratory influenza A virus (IAV) infection as it is unclear whether concurrent infections exacerbate complications that arise during IL-2 therapy. IL-2 and virus synergized to markedly enhance inflammation that correlates with lower IAV titers, but morbidity was also strikingly increased. Our findings highlight the need to better understand the regulation of inflammation during pathogen infection and have implications for improving IL-2 based therapies.

P5.01.74

Lnk/Sh2b3, an intracellular adaptor associated with celiac disease and autoimmune diabetes, regulates accumulation of inflammatory T cells and prevents intestinal villous atrophy

T. Mori[1]*, H. Katayama*[1]*, Y. Iwasaki*[1]*, Y. Seki*[1]*, M. Iseki*[1]*, M. Ikutani*[2]*, N. Yoshida*[3]*, K. Takatsu*[2]*,* ***S. Takaki***[1]*;*
[1]*Dept. Immune Regulation, National Center for Global Health and Medicine, Ichikawa, Chiba, Japan,* [2]*Dept. Immunobiol. Pharmacological Genetics, University of Toyama, Toyama, Japan,* [3]*Lab. Developmental Genetics, Inst. Med. Sci., University of Tokyo, Tokyo, Japan.*

The intracellular adaptor Lnk/Sh2b3 regulates cytokine signals that control lymphohematopoiesis, and Lnk-/- mice show overproduction of B cells, megakaryocytes and hematopoietic stem cells. In humans, mutations in the LNK/SH2B3 gene are found in myeloproliferative disease patients, and LNK/SH2B3 polymorphisms have been demonstrated to be associated with celiac disease and autoimmune diabetes. However, no data linking Lnk/Sh2b3 function with a risk for autoimmune-mediated inflammation have been reported so far. In this study, we revealed a previously unrecognized function of Lnk/Sh2b3 in preventing the accumulation of inflammatory CD8+ T cells and intestinal villous atrophy. Generation of an Lnk-Venus reporter mouse revealed low but apparent expression of Lnk/Sh2b3 in mature T cells. CD44hiIFN-γ+CD8+ effector/memory T cells were increased in Lnk-/- mice, and many mice exhibited villous atrophy in the small intestine. Lnk-/- CD8+ T cells survived longer and proliferated even in non-lymphopenic host animals in response to IL-15. Transfer of Lnk-/- CD44hiCD8+ T cells together with wild-type CD4+ T cells into RAG2-deficient mice recapitulated villous atrophy in ileum. In addition, DCs in spleen and peripheral lymph nodes were increased in the absence of Lnk/Sh2b3, and were hypersensitive to IL-15 and GM-CSF. Lnk-/- DCs supported differentiation of IFN-γ producing T cells from naïve CD4+ T or CD8+ T cells compared to normal DCs. Our results provide for the first time a missing link between Lnk/Sh2b3 and autoimmune-like tissue destruction or inflammatory immune responses.

P5.01.75
Molecular Regulation of IL-10 during Antibody-dependent Enhancement of Dengue Virus Infection is Important for Viral Replication

***T. Tsai**, C. Lin;*
Institute of Basic Medical Sciences of National Cheng Kung University, Tainan, Taiwan.

Dengue virus (DENV) infection is a emergency global public health issues, and so far there is no effect of vaccines and therapeutic drugs. Interleukin (IL)-10 levels are increased in DENV-infected patients with severe disorders. A hypothetical intrinsic pathway has been proposed for the IL-10 response during antibody-dependent enhancement (ADE) of DENV infection; however, the mechanisms of IL-10 regulation remain unclear. We found that DENV infection alone was sufficient to induce increased expression of IL-10 and its downstream regulator suppressor of cytokine signaling 3 in human monocytic THP-1 cells. IL-10 production was controlled by activation of cyclic adenosine monophosphate response element-binding (CREB), primarily through protein kinase A (PKA)- and phosphoinositide (PI) 3-kinase/PKB-regulated pathways, with PKA activation acting upstream of PI3K/PKB. DENV infection also caused glycogen synthase kinase (GSK)-3β inactivation in a PKA/PI3K/PKB-regulated manner, and inhibition of GSK-3β significantly increased DENV-induced IL-10 production following CREB activation. Silencing of C-type lectin domain family 5 member A (CLEC5A) expression and pharmacological inhibition of spleen tyrosine kinase (Syk) activity decreased DENV-induced IL-10 production. ADE of DENV infection greatly increased IL-10 expression by enhancing Syk-regulated PI3K/PKB/GSK-3β/CREB signaling. We also found that viral load, but not serotype, affected the IL-10 response. Finally, modulation of IL-10 expression could affect DENV replication. These results demonstrate that IL-10 production is regulated by ADE through both an extrinsic DENV/CLEC5A/Syk- and an intrinsic DENV/Fcγ receptor/Syk-regulated PI3K/PKB/GSK-3β/CREB pathway, both of which impact viral replication.

P5.01.76
Role of TNF-α, their receptors and gene‘s polymorphism in patients with coronary atherosclerosis

***E. Turmova**, A. Silaev, E. Shkorik, E. Markelova, R. Cromovoy;*
Pacific State Medical University, Vladivostol, Russian Federation.

Under supervision were 138 patients aged 45-75 years with the diagnosis: coronary atherosclerosis, ischemic heart disease. As control has been used 100 healthy donors. The content of TNF-α, receptors: TNF-αRI and TNF-αRII has been carried out in blood serum by the immune-enzyme analysis (R&D Diagnostics Inc. reactants, USA). Gene‘s polymorphic loci of TNF-α rs1800629 (308G/A) have been carried out by chain polymerization. The statistical analysis of results have been used by Stat Plus (2009) applied program. Results: increasing of TNF-αRI and TNF-αRII has been registered in patients. However the patients aged 45 - 59 years had lower level TNF-αRI than more senior patients. At high angina pectoris functional class decreasing of TNF-α level has been registered. Within three months after the myocardial infarction incident the highest level of TNF-αRII has been detected. At atrial extrasystole the TNF-αRII level was higher than without violation rhythm. At unstable angina pectoris the level of TNF-αRII was higher than at stable one current. At high level of blood general cholesterol and triglycerides the TNF-αRI level was lower, than at normal their indices. At coronary atherosclerosis G/G variant of gene TNF-α rs 1800629 was prevalent (79,8%). The high level of TNF-α was also associated with presence at a genome of G/G allele gene TNF-α.

P5.01.77
Abnormal peripheral cytokine profile detectable before clinical onset of Huntington’s disease

***I. Valekova**[1,2], H. Kupcova Skalnikova[1], J. Klima[1], S. Juhas[1], J. Motlik[1];*
[1]Institute of Animal Physiology and Genetics, AS CR, Libechov, Czech Republic, [2]Department of Cell Biology, Faculty of Science, Charles University in Prague, Prague, Czech Republic.

Huntington’s disease (HD) is a hereditary progressive neurodegenerative disorder with no cure available. Although it is not thought of as an inflammatory disease, it has been shown that there is a parallel immune activation in CNS and the periphery. The cytokines that are increased earliest in the disease course, before the onset of neurological symptoms, are involved in the innate immune response. This phenomenon designates components of innate immunity as potential biomarkers of HD progress.
To monitor the early HD progression, we have established a biomedical model of HD - a miniature pig transgenic for N-terminal part of mutated human huntingtin. The immunological characteristics have been studied on age-matched control and transgenic minipigs with the same genetic background. The levels of chosen cytokines in the blood serum were examined by targeted proteomic profiling using porcine antibody microarrays and immunoassay. Aims: (i) characterization of immune activation in control and transgenic animals, (ii) monitoring the cytokine levels during ageing and disease course, (iii) detection of monocyte activation as a possible source of peripheral cytokines.
Our data indicate the significant changes between control and transgenic minipigs mainly in levels of IL-8, both in blood serum and in monocytes extracts. The cytokine profiling together with monitoring of monocyte activation will longitudinally continue in three month intervals to follow up the disease progression.
Early changes founded in HD transgenic pigs may help to clarify development mechanisms of pathological changes in the disease, and so they can provide new opportunities for therapeutic effect of adverse developments.

Aberrant CD200/CD200R1 expression and function in systemic lupus erythematosus contributes to abnormal T-cell responsiveness and dendritic cell activity

***Y. Yin**[1], Y. Li[1], L. Zhao[1], S. Qian[1], L. Tong[1], D. Ba[2], W. He[2], X. Cao[2], X. Zhang[1], P. Lipsky[3];*
[1]Department of Rheumatology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China, [2]Department of Immunology, School of Basic Medicine, Peking Union Medical College and Institute of Basic Medical Sciences, Chinese Academy of Medical Sciences, Beijing, China, [3]Formerly National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD, United States.

Introduction: CD200 is a transmembrane glycoprotein that can regulate the activation threshold of inflammatory immune responses and maintain immune homeostasis. We therefore evaluated the functional status of CD200/CD200 receptor 1 (CD200R1) interactions in subjects with systemic lupus erythematosus (SLE).
Methods: Serum CD200 level was detected by ELISA. The expression of CD200/CD200R1 by CD4+ T cells and dendritic cells (DCs) was examined by flow cytometry, and then compared between SLE patients and healthy controls. Peripheral blood mononuclear cells were stained with CFSE and annexin V/propidium iodide for evaluation of the effect of CD200 on cell proliferation and apoptosis. In addition, the effect of CD200 on DC function was determined by transwell migration assay as well as by measurement of binding and phagocytosis of apoptotic cells.
Results: In SLE patients, the number of CD200+ cells and the level of soluble CD200 were significantly higher than in healthy controls, whereas the expression of CD200R1 by CD4+T cells and DCs was decreased. Furthermore, the increased CD200 expression by early apoptotic cells contributed to their diminished binding and phagocytosis by DCs in SLE. Importantly, the engagement of CD200 receptor on CD4+ T cells with CD200-Fc fusion protein in vitro reduced the differentiation of Th 17 cells and reversed the defective induction of CD4+CD25highFoxP3+ T cells by transforming growth

factor beta in SLE patients. Conversely, blockade of CD200-CD200R1 interaction with anti-CD200R1 antibody promoted CD4+ T cell proliferation.
Conclusion: CD200/CD200R1 expression and function are abnormal in SLE and may contribute to the immunologic abnormalities in SLE.

P5.01.79
BAFF induces IL-6 production in human monocytes through signaling pathways that involve NF-kB and PI3 kinase

K. Yoshimoto[1]*, M. Tanaka*[1]*, M. Kojima*[1]*, H. Ogata*[1]*, K. Suzuki*[1]*, H. Kameda*[1]*, T. Abe*[2]*, T. Takeuchi*[1]*;*
[1]Keio University School of Medicine, Tokyo, Japan, [2]Saitama Medical University, Kawagoe, Japan.

Background and Purpose: BAFF plays an important role in the development of autoimmune diseases such as Sjögren's syndrome (SS). In our previous study, we found that soluble BAFF (sBAFF) induced abnormal increase in the production of IL-6 by SS monocytes as compared to normal monocytes. Therefore, elucidation of the regulatory mechanism of the abnormality is important to understand the mechanism of pathogenesis of SS. For this purpose, we investigated signaling pathway for sBAFF in THP-1, a human monocytic leukemia cell line that recapitulates the characteristics of monocytes of autoimmune diseases.
Materials and Methods: THP-1 stimulated with recombinant human IFN-gamma (rIFN-gamma) were cultured in the presence of sBAFF as well as inhibitors against NF-kB or PI3 kinase. The expression levels of IL-6 and a BAFF receptor (BR3) were measured by ELISA and/or quantitative RT-PCR.
Results and Discussion: rIFN-gamma remarkably enhanced the expression of BR3 in THP-1. In addition, stimulation of rIFN-gamma-primed-THP-1 with sBAFF induced robust increase in the production of IL-6. These data strongly suggest that sBAFF is involved in the production of IL-6 by monocytes. When these cells were further treated with NF-kB inhibitors (BAY11-7082, BAY11-7085) or a PI3 kinase inhibitor (LY294002), the production of IL-6 was significantly decreased in a dose dependent manner. These data suggest that sBAFF plays a role in the induction of IL-6, which is one of major players in inflammatory responses, through NF-kB and/or PI3 kinase pathways.

P5.01.80
Increased levels of IL-6, TNF-a, MIF, IL-8, and MCP-1 in schizophrenia

R. Zakharyan*, S. Atshemyan, A. Boyajyan;*
Institute of Molecular Biology NAS RA, Yerevan, Armenia.

Schizophrenia is a serious psychiatric disease with chronic symptoms and significant impairment in psychosocial functioning. Although numerous antipsychotic drugs have been developed, the main symptoms of this disease are still untreated. Inflammatory and immune response regulating proteins are thought to play an important role in the generation and progression of schizophrenia. However, recent findings on the role of proinflammatory and chemotactic cytokines in schizophrenia remain controversial and required further clarification. In this study we evaluated the levels of the IL-6, TNF-a, MIF, IL-8, and MCP-1 in patients with paranoid schizophrenia and age-, sex-matched healthy volunteers (controls) using enzyme-linked immunsorbent assay. According to the results obtained, all studied cytokines were overexpressed in the blood of schizophrenia patients when compared to controls ($p<0.0001$). No significant difference in the levels of cytokkines between neuroleptic-treated and non-treated patients was detected ($p>0.05$). These findings suggested that schizophrenia is characterized by upregulation of chemo-cytokine network that can be further used for the development of cytokine-targeted therapeutic approaches.

P5.01.81
Assay of IL-22/IL-25 in serum, whole blood and peripheral blood mononuclear cells cultures of patients with severe asthma

A. Zamani[1]*, E. Nadi*[2]*, M. Arjipour*[2]*, S. Sharifi*[3]*;*
[1]Department of Immunology, School of Medicine, Hamadan University of Medical Sciences,, Hamadan, Iran, [2]Department of Internal medicine, School of Medicine, Hamadan University of Medical Sciences, Hamadan, Iran, [3]Research Institute, Hamadan University of Medical Sciences, Hamadan, Iran.

Although some studies on the airways show IL-22/IL-25 playing a critical role in the pathogenesis of asthma, limited evidence about the systemic production of these cytokines is available. Therefore, the aim of this study was to assay IL-22/IL-25 levels in serum, in mitogen-activated whole blood (WB) and in mitogen-activated peripheral blood mononuclear cells (PBMCs) cultures of patients with severe asthma. In this cross-sectional study, to determine the severity of the asthma, a questionnaire was administered. The questionnaire asked information including clinical signs, clinical symptoms, and past medical history so all active or ex-smoker patients were excluded. Then, a trained observer assessed airway reversibility, peak flowmetry and spirometry in the patients. Twenty one patients with severe asthma and simultaneously, twenty age and sex-matched healthy controls were selected. Ten ml sterile blood was taken from each person. The sera were isolated and anticoagulant bloods used to WB and PBMCs cultures and hematological tests. Phytohemagglutinin (PHA) and Lipopolysaccharide (LPS) used to activate WB and PBMCs. Data of two groups were compared with Student's t-test and nonparametrical statistic test. Except total white blood cells count that was increased in the asthmatic group, other hematological indices and IL-22/IL-25 levels in the two groups were not significantly ($p<0.05$) different. The levels of IL-22/IL-25 in patients with severe asthma are not higher than in healthy people and their roles in asthma could be related to local immunological process.

P5.01.82
Status of cytokine line and morphological changes in endocrine glands of rats with tentative thyrotoxicosis

V. Zdor (Lazanovich)*, E. Markelova, Y. Tikhonov;*
Vladivostok state medical University, Vladivostok, Russian Federation.

Model of experimental exogenous thyrotoxicosis was implemented on six-month-old Wistar rats with application of levothyroxine and was sustained with estimation of thyroid hormones rate. Cytokine level in biomaterial of rats was specified by IFA method with specific diagnostic sets of "R&D Diagnostics Inc.", USA. Histological assay samples were stained with hematoxylin/eosin and silver nitrate. Observed rats were found out significant elevation in serum rates of pro-and-anti-inflammatory cytokines: IL-1β (Me 15,42 pg/ml as compared with check group Me 1,90 pg/ml, $p<0,05$), IFNγ was Me 19,58 pg/ml against 5,96 pg/ml ($p<0,01$) and IL10 - 16,59 pg/ml against 5,62 pg/ml($p<0,01$) in control. IFN-γ / IL-10 correlation both in system and organs were determined close to1with minor dominance of Th2 marker cytokines in situ of healthy rats and tenfold ratio change towards Th1 marker cytokines at organ level in thyrotoxicosis. Morphological changes in thyroid were evinced in mastocytar focal infiltration of follicles stroma indicating activation of T-cell population of lymphocytes. Augmentation of cells with proliferative phase of cell cycle with amitotic activity was detected in glomerular and fasciculate zone of adrenal glands and in adenohypophysis. Hereby findings prove interdependence of hormone, morphological and immune changes in endocrine system under thyrotoxicosis and enlarge our view about the conception of Grave's Disease development.

Lithium treatment reduced microglia activation and inflammation after irradiation to the immature brain

***C. Zhu**, K. Zhou, C. Xie, K. Blomgren;*
University of Gothenburg, Göteborg, Sweden.

To evaluate the effects of lithium on microglia activation and inflammation after irradiation to the immature brain, male rat pups were injected 2 mmol/kg lithium chloride i.p. on postnatal day 7 (P7), additional lithium injections, 1 mmol/kg, were administered at 24 h intervals. Pups were subjected to whole brain 6Gy irradiation on P11. The pups were sacrificed at 6h and 24h after IR. Microglia scattered in the brain can be detected by counting their numbers, their size, engulfment of cell debris or by the production of cytokines and chemokines. Microglia were stained using the marker Iba-1, revealing the presence of these cells throughout the brain under normal conditions, and apparently higher numbers and bigger sizes after IR, particularly in areas where cell death occurred. Quantification of Iba-1+ cells in the GCL of DG showed a significant increase after IR, but with a lower increase in the lithium-treated brains. The concentration of MCP-1, IL-1α, IL-1β, GRO/KC in the hippocampus were increased significantly at 6h after IR compared with non-irradiation control. Lithium treatment significantly inhibited the increase. There was no significantly difference with these cytokines/chemokines at 24h after IR between lithium and vehicle treated group. These data indicate that lithium can specifically reduce inflammation through GSK3-ß inhibition or modified microglia activation.

IL-17 and IFNγ decrease in the gut of rats with experimental fibrosis. "Possible association with bacterial translocation"

***M. R. Bueno Topete**[1], E. Sánchez[2], S. Zepeda Morales[3], E. Rodríguez[3], S. del Toro Arreola[4], L. García Benavides[5], M. Fafutis Morris[6], A. Domínguez[3], F. Muñoz Valle[7];*
[1]Instituto de Enfermedades Crónico Degenerativas, CUCS, University of Guadalajara,, Guadalajara, Mexico, [2]Instituto de Enfermedades Crónico Degenerativas, CUCS, U de G., Guadalajara, Mexico, [3]Instituto de Enfermedades Crónico Degenerativas, CUCS, U de G., Guadalajara, Mexico, [4]Laboratorio de Inmunología, CUCS, U de G., Guadalajara, Mexico, [5]Unidad de Investigación Cardiovascular, CUCS, U de G., Guadalajara, Mexico, [6]CIINDE CUCS, U de G., Guadalajara, Mexico, [7]Grupo de Genómica Funcional, CUCS, U de G., Guadalajara, Mexico.

Background. Bacterial translocation (BT) in cirrhotic patients, is a trigger of peritonitis and septicemia, with a mortality rate of 30-50%. Alterations in the "intestine" immune response is a new field of study. BT has been reported in experimental models of liver fibrosis CCl4 and Thioacetamide (TAA). However, Th1 cytokines (IFN γ) and Th17 (IL-17) have been little explored in the gut of rats with experimental liver fibrosis. Aim. To analyze the expression of IL-17 and IFNγ in the gut of rats with fibrosis by TAA. Methods. Liver fibrosis was induced by thioacetamide administration (200 mg/kgi.p.). Fibrotic animals were euthanized after 3.5 and 8 weeks. Small and large gut tissue homogenates were used to detect IL-17 and IFNγ by Western-blotting. Gut sections were stained with hematoxylin/eosin to evaluate histological alterations. Results. Intestine IL-17 showed two molecular forms in the blots; 25KDa (glycosylated form) and 18KDa (non-glycosylated form). Both forms decreased 50% and 80% respectively compared with control group. These changes were evident in both early fibrosis and established cirrhosis. IFNγ decreased 65% compared to control group in the cirrhotic stage. Histological analyses showed hyperplasia of Peyer's patches, epithelial inflammatory infiltrate and mucus hypersecretion.
Conclusion. Gut bacterial overgrowth is associated with bacterial translocation process, which is closely linked to the dramatic decrease of IL-17 and IFNγ in the gut of rats with experimental fibrosis. These cytokines orchestrates antiparasitic important events at intestinal mucosal level and also activation of macrophages and neutrophil recruitment.

P5.02.02
Experimenrtal cholestasis is associated with increased IL-17 and IFN-γ expression

*S. M. Zepeda Morales[1], S. del Toro Arreola[2], M. Fafutis Morris[3], E. Bastidas Ramírez[1], V. Delgado Rizo[2], **M. R. Bueno Topete**[1];*
[1]Instituto de Enfermedades Crónico Degenerativas, CUCS, U de G,, Guadalajara, Mexico, [2]Laboratorio de Inmunología, CUCS, U de G,, Guadalajara, Mexico, [3]CIINDE, CUCS, U de G,, Guadalajara, Mexico.

Background. IL-17 play a central role in the pathogenesis of liver fibrosis through production of type-I collagen in hepatic stellate cells. However, IL-17 and RORγ have been little explored in experimental fibrosis by cholestasis. Also, the classical Th1 cytokine IFN-γ is poorly known in this model.
Aim. To analyze the expression of IL-17 and IFN-γ∀ and the transcriptional factors RORγ and T-bet in liver of rats with experimental fibrosis by bile duct ligation (BDL).
Methods. Liver fibrosis was induced by BDL. Fibrotic animals were sacrificed after 8 and 30 days. qRT-PCR for RORγ and T-bet was achieved with total RNA. Liver homogenates were used to detect IL-17 and IFN-γ by Western-blotting. Liver sections were stained with hematoxylin/eosin and Masson trichrome to verify chronic injury and collagen deposition
Results. At protein level, IL-17 and IFN-γ showed important changes during progression of liver injury by BDL. A significant increase was observed accordingly to the fibrosis intensity when compared with control group. Interestingly, RORγ and T-bet gene expresion was significantly increased only at 8 days after BDL. Histological analyses showed characteristic alterations of the cholestatic process, such as inflammation, bile duct proliferation and collagen deposition.
Conclusions. Our results suggest that IL-17 and IFN-γ are involved in the cholestasis-induced liver fibrosis pathogenesis. Additionally, Th1 and Th17 cells appear to be important at the beggining of the liver fibrosis, at least under our experimental model. Finally, other sources of IL-17 e IFNγ, such as NKT and NK cells remain to be explored in liver fibrosis.

P5.02.03
ITF2357 inhibits corneal fibrosis and inflammation via JAK/STAT3 signaling pathway

***S. S. Chaurasia**[1,2,3], A. Tan[1], R. Lim[1], Y. Liu[1], J. S. Mehta[1];*
[1]Singapore Eye Research Institute, Singapore, Singapore, [2]Signature Research Program in Neuroscience and Behavioral Disorders, Duke-NUS Graduate Medical School, Singapore, Singapore, [3]Department of Ophthalmology, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore.

Purpose: In this study, we investigated the mechanism of action of a histone deacetylase inhibitor, ITF2357 on fibrosis and inflammation in a corneal wound healing model.
Methods: In vivo experiments were conducted with 20 rabbits that underwent -9.0D photorefractive keratectomy (PRK) surgery in one eye and were divided into 3 groups based on post-op treatment with a single dose of saline (3 days), ITF2357 (0.02% for 3 days) or MMC (0.02% for 60 sec post-surgery). Post-op clinical examination was made for 4 weeks using slit lamp microscopy and in vivo confocal microscopy (IVCM). In vitro experiments were performed with cultured primary human corneal fibroblasts (pHCFs) to study the ITF2357-induced activation of IL-10 and JAK/STAT signaling pathway using specific signaling inhibitors by immunocytochemistry, western blot and ELISA.
Results: ITF2357 is non-toxic and effective in nM concentrations to significantly reduce corneal haze and extracellular matrix formation on IVCM and immunohistochemitry. IL-10 expression was up-regulated in the ITF2357 treated PRK corneas compared to the MMC treated. Cultured pHCFs with ITF2357 produced elevated levels of IL-10 in a time-dependent manner. This in turn, resulted in the activation of pSTAT3 and downstream signaling with overexpression of SOCS3 expression. Inhibition of recruitment of STAT3 to the receptor complex with a specific inhibitor blocked the phosphorylation of STAT3, preventing its nuclear entry and hence decreased IL-10 production.
Conclusions:ITF2357 upregultes IL-10 levels via activation of JAK/STAT signaling pathway to inhibit fibrotic and inflammatory activity in corneal disease model

P5.02.04
Osteopenia and inflammation in postmenopausal women

*L. Ginaldi, **F. Ciccarelli**, M. De Martinis;*
L'Aquila University, L'Aquila, Italy.

Osteoporosis is a condition characterized by low bone mass and increased bone fragility, putting patients at risk of fractures. Osteoporosis is currently attributed to various endocrine, metabolic and mechanical factors. However, emerging clinical and molecular evidences suggest that inflammation also exerts significant influence on bone turnover, inducing osteoporosis. A shift towards an activated immune profile has been hypothesized as important risk factor, even in the absence of a manifest autoimmune, rheumatic or inflammatory disease. Subclinical chronic inflammation may be a determinant pathogenetic factor. The purpose of this study was to examine the relationship between bone mineral density (BMD), evaluated by calcanear ultrasonography and/or dual x-ray absorptiometry, expressed as T-score, and serological markers of inflammation, such as C reactive protein (CRP), erythrocyte sedimentation rate (ESR), autoantibodies (rheumatoid factor-RF, antinuclear antibodies-ANA, anti-thyroid peroxydase-TPO, and vitamin D levels, in 551 postmenopausal women (mean age 64) without overt diseases. The study sample included 101women with T-score into the normal range and 240 with osteopenia/osteoporosis), None of them were taking osteoporosis inducing drugs. CRP and ESR mean levels were significantly higher in osteopenic/osteoporotic compared to control women (9 and 32 vs 5 and 19 respectively). Serum autoantibodies were present in 27% of women with T-score<-1,5 and 23% of controls. Vitamin D levels in postmenopausal women were lower than controls (21 and 26 respectively). These data support the view that inflammation significantly contributes to the aetiopathogenesis of osteoporosis.

P5.02.05
Type 2 Innate Lymphoid Cells (ILC2) are present in mouse models of lung and skin fibrosis and their numbers correlate with disease severity

***P. Dasgupta**, T. Burwell, R. Johnson, J. Bakken, R. Herbst, J. Connor, R. Lemaire;*
MedImmune, Gaithersburg, MD, United States.

Fibrosis is a physiological tissue repair process that becomes unchecked in pathological conditions such as scleroderma and idiopathic pulmonary fibrosis (IPF), leading to overproduction of extracellular matrix (ECM). The T_H2 cytokine, IL-13, is a key fibrogenic effector mediating its effects by inducing and activating TGFβ. IL-13 can also directly stimulate fibroblasts, epithelial cells and smooth muscle cells, promoting fibrosis. Recently, several groups have demonstrated that type 2 innate lymphoid cells (ILC2) secrete IL-13 and regulate allergic airway inflammation as well as lung homeostasis. Since IL-13 plays an important role in fibrosis, we hypothesized that ILC2 cells contribute to this disease as well. Here we show that ILC2 cells were present in the lung during the fibrotic phase but not the inflammatory phase of the murine bleomycin model of lung fibrosis. Moreover, there was a 3 fold increase in ILC2 numbers in lungs of bleomycin treated mice as compared to PBS treated mice. ILC2 numbers strongly correlated with the levels of hydroxyproline in the lung. When cultured *in vitro*, ILC2s expressed the IL-33R (T1/ST2) and IL-13. Interestingly, ILC2 conditioned media induced expression of fibronectin and the myofibroblast marker, smooth muscle actin (SMA), in cultured murine fibroblasts suggesting that ILC2s can directly influence fibroblast function. Finally, ILC2 cells were also detected in the skin and their numbers significantly increased during the fibrotic phase in a murine graft-versus-host disease model of skin fibrosis. These data pave the way for further characterization of ILC2 and elucidation of their function in fibrosis.

P5.02.06
Prevalence of skin sensitivity to aeroallergens in Iranian patients with nasal polyposis

***M. Fereidouni**[1], M. Bakhsahee[2], S. Nourani hasan kiadeh[1];*
[1]Asthma, Allergy & Immunology Research Center, Birjand University of Medical Sciences, Birjand, Iran, [2]ENT Research Center, Mashhad University of Medical Sciences, Mashhad, Iran.

Background: Sinonasal polyposis (SNP) is a chronic inflammation with unknown origin. There are some evidences about the role of allergy in pathogenesis of nasal polyposis although there is some controversy surrounding this hypothesis. The aim of this study was to assess the prevalence of allergy to common regional aeroallergens among a group of Iranian patients with SNPs with or without asthma.
Methods: Diagnosis of nasal polyposis was done based on physical examination as well as CT scan. Skin prick tests were performed with a battery of twenty common regional aeroallergens including moulds, mites, cockroach, fungus, grasses and trees in ninety three patients with SNPs. All patients were evaluated for the presence of asthma and aspirin sensitivity based on history and physical examination.
Results: Ninety percent of patients showed asthma-related symptoms. None of the patients had aspirin sensitivity. Prevalence of skin sensitivity to one or more allergen was 32% in SNP without asthma SNP patients with asthma showed higher rate of skin sensitivity (32% vs. 40%, P<0.05). Grasses, mites and fungus were the most common allergens (32%, 16 % and 13%, respectively) in both SNP without asthma and SNP with asthma.
Conclusion: The results of this study suggest that allergy to common aeroallergen is fairly high among patients with SNPs, especially in patients with SNPs and asthma and allergy to aeroallergens may contribute to nasal polyposis pathogenesis.

P5.02.07
Crucial role of basal p53 in attenuation of inflammation and fibrosis in hereditary glomerular nephritis, Alport syndrome

***R. Fukuda**[1,2], K. Koyama[1], T. Koga[1], Y. Kai[1], K. Omachi[1], K. Motomura[1], M. A. Suico[1], T. Shuto[1], H. Kai[1];*
[1]Dept of Molecular medicine, graduate school of pharmaceutical science, Kumamoto University, Kumamoto, Japan, [2]Research Fellow of Japan Society for the Promotion of Science, Tokyo, Japan.

Alport Syndrome (AS) is one of the hereditary progressive kidney diseases. AS is caused by mutations in Col4a3, 4 or 5 genes that compose the glomerular basement membrane (GBM). Aberrant GBM structure results in podocyte detachment from GBM and proteinuria leakage. Persistent proteinuria leakage induces chronic inflammation and fibrosis of kidney. Continuous exposure to inflammation and fibrosis-inducing cytokines leads to development of kidney failure. We found that the protein expression of tumor suppressor gene p53 in the kidney is reduced as AS progresses. p53 is known to induce various effects such as cell cycle arrest, cell apoptosis, DNA repair and anti-inflammation by regulating functional genes expression. To determine the role of p53 in AS, we made p53 knock out (-/-) and heterozygote (+/-) AS mouse model and compared them with p53 wild type (+/+) AS mouse model. p53-/- and +/- AS mice show rapid progression of proteinuria and significantly lower rate of survival compared to p53+/+ AS mice. p53+/- AS mice also showed higher glomerular injury score than p53+/+ AS mice. Consistent with these results, inflammatory cytokine genes (IL-6, KC, IL-1β and TNF-α) expression and fibrotic region were significantly increased in p53+/- AS mice kidney than in p53+/+ AS mice. Furthermore, mRNA expression of BMP-7, which is important for renal anti- fibrosis, was lower in p53-deficient kidney and primary podocytes. These results suggest that basal p53 expression is essential for suppression of glomerular nephritis progression.

P5.02.08
Intramuscular administration of MMP-8 adenoviral vector reduces inflammation up-grade induced by vector delivery and allows prevention of liver fibrosis

J. García-Bañuelos[1], *E. Oceguera-Contreras*[1], *D. Gordillo-Bastidas*[1], *A. Sandoval-Rodríguez*[1], *B. Bastidas-Ramírez*[2], *J. González-Cuevas*[1], *J. Macias-Barragan*[1], *B. Gómez-Meda*[1], *J. Armendariz-Borunda*[1,3];
[1]*Institute of Molecular Biology in Medicine and Gene Therapy, CUCS, University of Guadalajara, Guadalajara, Mexico,* [2]*Institute of Degenerative Chronic Diseases, CUCS, University of Guadalajara, Guadalajara, Mexico,* [3]*OPD Hospital Civil, Guadalajara, Mexico.*

BACKGROUND. Multiple protocols regarding liver fibrosis gene therapy using adenoviral vectors systemically delivered, have been reported. Unfortunately, a decrease in the efficiency of liver transduction and increase in proinflammatory cytokines have been exhibited when utilizing these delivering strategies. AIM. To establish a model to deliver therapeutic genes, focused in the prevention of liver fibrosis without promoting an inflammatory process by intramuscular administration using an adenoviral vector containing MMP8 gene (AdMMP8). MATERIAL AND METHODS. Experimental liver fibrosis was induced in male Wistar rats by TTA administration for 7 weeks. Four groups were included: control (no fibrosis), TAA induced-cirrhosis (TAA), TAA+AdGFP (irrelevant gene) and TAA+AdMMP8 (therapeutic gene). At the fifth week of TAA intoxication, administration of vectors in soleum muscle was accomplished. Subgroups of rats (n=5) at first, second and third week after vector administration were sacrificed. Percentage of fibrosis, liver function, MMP8 gene expression, proinflammatory (IL1β, TNFα), profibrogenic (COLIA1, TGFβ) and antifibrogenic (MMP1, MMP9) genes were determined. RESULTS. Liver and serum expression of MMP8 protein was sustained, fibrosis decreased up to 48%, proinflammatory genes expression was not modified, profibrogenic gene expression decreased, antifibrogenic genes expression increased, reduction of liver function was not statistically significant. According to Knodell score, intramuscular administration of AdMMP8, shows a diminishment of inflammatory cells infiltration in comparison with animals treated with AdGFP. CONCLUSION. AdMMP8 delivered in muscle did not generate liver inflammation in fibrotic animals, MMP8 gene was expressed in muscle with satisfactory functions in the liver.

P5.02.09
Mac-3 positive and enlarged foamy macrophage as an effector in radiation-induced pulmonary fibrosis

H. Park, ***S. Jo****, U. Jung;*
Korea Atomic Energy Research Institute, Jeongeup-si, Republic of Korea.

Thoracic radiation therapy is used to treat lung, breast, and lymphoid cancers. However, radiation-induced pneumonitis and pulmonary fibrosis are common dose-limiting complications in the radiotherapy. In this study, we investigated the characteristics of effective immune cells that related to pneumonitis and fibrosis after irradiation. After anesthesia, the whole thorax of C57BL/6 mice was irradiated at 14 Gy. As expected, the deposition of collagen was increased in the lung of irradiated mice. At 4 months after irradiation, the numbers of macrophages and lymphocytes as well as neutrophils were increased dramatically in the lung. Interestingly, the macrophages recruited post-irradiation had enlarged foamy morphology. In addition, the expressions of chemokines (CCL-2, CCL-3, CXCL-10 and CXCL1) for attraction of macrophages, T cells, and neutrophils, were higher in the lung of irradiated mice. The high expressions of these chemokines except CXCL1were sustained up to 6 months following irradiation. Next, we found that the ratio of Mac-3 positive macrophages was increased in the lung after irradiation. Interestingly, the expressions of Arg-1 and MMR, as the hallmark of alternatively activated macrophages, were increased in the lung of irradiated mice and the levels of IL-4 and IL-13 were higher in BALF of irradiated mice. Taken together, we reached the conclusion that thoracic irradiation might lead to pulmonary fibrosis at least partially through increasing the influx of Mac-3 positive and enlarged foamy macrophages, i.e. alternatively activated macrophages.

P5.02.10
Mild electrical stimulation with heat shock ameliorates nephritis and proteinuria in mouse model of X-linked alport syndrome

Y. Kai*, T. Koga, R. Fukuda, S. Morino-Koga, M. A. Suico, K. Koyama, T. Sato, T. Shuto, H. Kai;*
Molecular medicine, graduate school of pharmaceutical science, Kumamoto University, Kumamoto, Japan.

Alport Syndrome (AS) is a hereditary nephritis caused by defects in the genes encoding type IV collagen (COL4A3, COL4A4, COL4A5) in the glomerular basement membrane. Previously, we showed that the combination treatment of mild electrical stimulation (MES) and heat shock (HS) suppressed pro-inflammatory cytokine expression in mouse model of hepatic ischemia/reperfusion (I/R) injury. Here we evaluated the effect of MES+HS on progressive nephritis and renal injury in mouse model of X-linked AS. Six- to seven-week-old male X-linked AS mice were treated with MES+HS for 10 min twice a week. As a result, MES+HS improved histopathologic abnormalities such as glomerular atrophy and widespread infiltration of inflammatory cells. The suppression of pro-inflammatory cytokines (IL-6, TNF-α, IL-1β, KC), pro-fibrotic gene (TGF-β1), and kidney injury marker (Lcn-2) were observed in kidney of MES+HS-treated mice. Moreover, MES+HS ameliorated progressive proteinuria and serum creatinine in AS mice. Next, to determine the mechanism of how MES+HS improves various patho-phenotypes in AS mice, we analyzed the effect of MES+HS in vitro and ex vivo. The anti-inflammatory effect of MES+HS was mediated by glomerular activation of JNK1/2 and p38-dependent pathways ex vivo. Interestingly, the anti-proteinuric effect of MES+HS treatment was mediated by podocytic activation of PI3K-Akt and HSP72-dependent pathways in vitro and in vivo. Collectively, our studies show that combination MES+HS ameliorates progressive nephritis and proteinuria through the activation of multiple signaling pathways including PI3K-Akt, Hsp72, JNK1/2, and p38 pathways, suggesting a novel therapeutic strategy for the treatment of inflammatory disease like AS.

P5.02.11
Interleukin-17 isoforms are differentially expressed in the skin of Systemic Sclerosis and Morphea patients compared to healthy skin

P. Lonati[1,2], *N. Brembilla*[2], *L. Fontao*[3], *E. Laffitte*[3], *G. Kaya*[3], *P. Meroni*[1,4], *C. Chizzolini*[2];
[1]*Istituto Auxologico Italiano, Milan, Italy,* [2]*Immunology and Allergy, University Hospital and School of Medicine, Geneva, Switzerland,* [3]*Dermatology, University Hospital and School of Medicine, Geneva, Switzerland,* [4]*Department of Clinical and Community Sciences, University of Milan, Milan, Italy.*

Interleukin (IL)-17A, a proinflammatory cytokine, is increased in biological fluids and skin of systemic sclerosis (SSc) individuals. Our aim was to investigate whether IL-17 family members other than IL-17A were expressed in the skin of SSc and Morphea patients compared to healthy donors (HD).
Skin biopsies were obtained from the involved skin of 14 SSc and 5 Morphea and from 8 HD undergoing plastic surgery. We set up immunohistochemistry and immunofluorescence techniques to identify the presence of IL-17A+, IL-17C+, IL-17F+ and IL-17E/IL-25+ cells, and we developed an application of the Metamorph/MetaXpress software to quantify the number of positive cells in the tissue.
Positive cells for each of the IL-17 isoforms were present in the dermis of all the individuals tested, though with variable frequencies. IL-17A+ cells were distinctly more numerous in SSc than Morphea or HD. IL-17C+ cells were less abundant in SSc and Morphea than in HD. Similarly, IL-17F+ cells were less abundant in SSc than in HD. Finally, IL-17E/IL-25+ cells tended to be more numerous in SSc and Morphea than in HD. Single cells could be positive for one or more of the isoforms, with no preferential association, nor correlation.
Concordant low IL-17C and high IL-17E/IL-25 frequency of positive cells specifically characterizes both SSc and Morphea when compared to HD. This particular combination of IL-17 family members may participate to enhanced extracellular matrix accumulation, thus playing a role in the development of fibrosis. Functional studies are needed to provide support to this hypothesis.

P5.02.12
IL-33 precursor drives inflammation without engaging T1/ST2 or Th2

I. G. Luzina[1,2], *V. Lockatell*[1,2], *N. W. Todd*[1,2], *S. P. Atamas*[1,2];
[1]*University of Maryland, Baltimore, MD, United States,* [2]*Baltimore VA Medical Center, Baltimore, MD, United States.*

Interstitial lung disease, a combination of chronic pulmonary inflammation and excessive scarring, is debilitating and deadly, particularly in patients with systemic sclerosis (SSc) or idiopathic pulmonary fibrosis (IPF). Immunohistochemical analyses of lung sections from five patients with SSc and nine patients with IPF revealed a marked increase in the numbers of IL-33-expressing cells compared with four healthy controls. Much of the elevated IL-33 was intracellular, and there were minimal signs of Th2 activation, suggesting that precursor IL-33 (PRIL33), rather than mature IL-33 cytokine (MIL33), was increased. Western blot assays of lung tissue homogenates confirmed minimal maturation of PRIL33 into MIL33. Analysis of the subcellular distribution of overexpressed IL-33 forms in normal primary fibroblast cell cultures revealed that PRIL33 is localized almost exclusively (>95%) in the cell nucleus and is not secreted from the cells, whereas MIL33 is predominantly cytoplasmic and secreted. Recombinant adenoviral gene delivery of PRIL33 and MIL33 to mouse lungs resulted in strikingly different phenotypes: PRIL33 induced pulmonary lymphocytosis and neutrophilia, whereas MIL33 induced eosinophilia, goblet cell hyperplasia, and increases in IL-4, IL-5, IL-13, and IL-17. Germline deficiency of the MIL33 receptor T1/ST2 abrogated the effects of MIL33 gene delivery but not the effects of PRIL33 delivery. Gene delivery of MIL33 in cell culture and in vivo caused elevation of the expression of CCL2, IL-6, MMP3, MMP10, MMP13, and HSP70 mRNAs and proteins, which are all known to contribute to inflammation and scarring. Thus, the IL-33 precursor can drive inflammation by remaining intranuclear and regulating gene expression.

5-methyl-1-phenyl-2-(1H)-pyridone reveals immunomodulatory anti-fibrotic effects associated to antioxidant system activation in primary culture of human Hepatic Stellate Cells

J. Macias-Barragan[1], *A. Caligiuri*[2], *E. Novo*[3], *M. Parola*[3], *J. Vera-Cruz*[4], *J. García-Bañuelos*[4], *S. Lucano-Landeros*[4], *M. Pinzani*[2], *J. Armendáriz-Borunda*[4];
[1]*University of Guadalajara, Ameca, Mexico,* [2]*University of Florence, Florence, Italy,* [3]*University of Turin, Turin, Italy,* [4]*University of Guadalajara, Guadalajara, Mexico.*

Background. Hepatic stellate cells (HSC) profibrogenic cytokines are key targets of anti-fibrotic therapies. 5-methyl-1-phenyl-2-(1H)-pyridone or pirfenidone (PFD) is a small molecule indicated for treatment of chronic inflammation and fibrogenesis. Oxidative stress is directly involved in the onset of hepatic fibrosis by HSC activation. Aim. In order to identify whether anti-inflammatory and anti-fibrogenic effects of PFD are related to activation of the endogenus antioxidant system, HSC were incubated with PDGF or 2-methyl-1,4-naphthoquinone (MEN) a ROS-inducer. Methods and Results. PFD was able to inhibit PDGF or MEN-induced pro-fibrogenic actions, including cell proliferation, cell motility and *de novo* synthesis of Collagen type I, TGFβ, TIMP-1, IL-1 and TNFα. These effects were associated with an increase of nuclear Nrf2 assessed by western blotting and confocal microscopy. Because PFD activates JNK, which stimulates Nrf2 transcriptional factor, through siRNA-mediated silencing we examined downstream antioxidant targets as antioxidant enzimes. JNK blockade by siRNA and SP600125 down-regulates Nrf2 activation. Also PFD induced a dose- and time-dependent activation of several antioxidant genes, (Glutamyl cysteine synthetase catalytic subunit, Glutamyl cysteine synthetase regulatory subunit and Heme oxygenase 1) and increase glutathione content, whose activity may contribute to the down-regulation of ROS-induced pro-fibrogenic and pro-inflammatory effects. Conclusion. These results provide molecular insights in anti-fibrogenic immunmodulatory action of PFD by counteracting ROS-induced pro-fibrogenic signalling, and by regulation of the biosynthesis of antioxidant proteins. This study indicates that activation of the antioxidant system plays an essential role in the modulation of inflamatory and fibrogenic cytokines in HSC.

P5.02.14
Phenotypical characterization of the peripheral blood T cells in celiac disease patients

M. Masjedi[1], *H. Hossein Nataj Arab*[2], *M. Emami*[1], *F. AlSahebfosoul*[1], *M. Mokhtari*[1];
[1]*Isfahan University of Medical Sciences, Isfahan, Iran,* [2]*Mazandaran University of Medical Sciences, Sari, Iran.*

Background and objective: Celiac disease (CD) is a small intestine enteropathy caused by permanent wheat gluten intolerance. One of the earliest signs of mucosal immune activation in CD is an increase in the intestinal intraepithelial lymphocytes (iIELs) count in the small intestinal epithelium. Though most of those iIELs express αβTCR, CD is characterized by an increase in $\gamma\delta TCR^+$ iIELs. The present study aimed to establish whether these immunological changes seen in the intestinal epithelium of CD patients could also be detected in the peripheral blood lymphocyte populations with special emphasis on the $\gamma\delta TCR^+$ T cells. Methods: Peripheral blood T cells were analyzed by two color flow cytometry in 12 untreated patients with CD and 16 healthy controls. Results: There were significant differences between the mean percentages of $\gamma\delta TCR^+$ T cells in the patients and the controls (7.5 ± 3.7% in the patients versus 4.9 ± 2.5% in the controls, $P < 0.05$). However, the mean percentages of the $\alpha\beta TCR^+$ T cells were significantly lowered in the untreated patients (90 ± 3.5% in the patients versus 93.3 ± 2.8% in the controls, $P < 0.05$). There were no significant difference between the mean percentages of T cells expressing the CD4 and CD8 molecules in the patients and the controls. Conclusions: The change in the peripheral blood T cells expressing the γδTCR and αβTCR markers in the celiac patients is, therefore, a consequence of an ongoing immunological process.

P5.02.15
GSK-3: a key mediator of the balance between matrix-metalloproteinases (MMPs) and their tissue inhibitors (TIMPs) in bleomycin (BLM) - induced pulmonary fibrosis.

B. Montini[1,2], *F. Cinetto*[1,2], *M. Gnoato*[2], *N. Compagno*[1], *C. Gattazzo*[1,2], *F. Piazza*[1,2], *F. Lunardi*[3], *F. Calabrese*[3], *G. Semenzato*[1,2], *C. Agostini*[1,2];
[1]*Dipartimento di Medicina, Padova, Italy,* [2]*Venetian Institute of Molecular Medicine, Padova, Italy,* [3]*Dipartimento di Patologia, Padova, Italy.*

Background: Airway remodelling occurs during lung fibrosis and an imbalance between MMPs and TIMPs could be involved in the aberrant tissue repair leading to lung function impairment. We previously demonstrated the anti-inflammatory and anti-fibrotic effects of the pharmacologic inhibition of the kinase GSK-3 in a mouse model of BLM-induced pulmonary fibrosis.
Aims of the study: We want to assess the trend of the expression of MMP-2, MMP-9, TIMP-1 and TIMP-2, in the inflammatory and fibrotic phases of our BLM mouse model. Next, we want to study whether *in vivo* inhibition of GSK-3 with SB216763 could modulate MMP activity and their balance with TIMPs.
Materials and Methods: MMP activity was assessed by zymographic analysis in supernatant of BALFs and in lung homogenates. MMP and TIMP expression levels were evaluated by Real Time PCR and Western Blotting in BALF cells and in lung homogenates. Their tissue localization was evaluated by immunostaining analysis.
Results and Conclusions: We found strong activity of MMP-9 and -2 in BALFs during the inflammatory response. In particular, interstitial alveolar macrophages (IAMs) showed very high expression levels of MMP-9 and -2 and of their TIMPs while, in lung parenchyma, only epithelial injured cells were found positive for these markers. During fibrotic phase, we found very high positivity for MMP-2 in lung parenchyma. Importantly, SB216763 down-modulated MMP-9 and -2 expression in inflammatory and epithelial cells during inflammation and fibrosis, suggesting that GSK3 inhibition could play an important role in restoring the extracellular matrix turnover altered in response to lung injury.

P5.02.16
Genes affecting MMP expression are down-regulated in patients with COPD and bronchial asthma

Z. Navratilova[1], *T. Krsjakova*[1], *E. Novosadova*[1], *J. Zatloukal*[2], *V. Kolek*[2], *M. Petrek*[1];
[1]*Laboratory of Immunogenomics and Immunoproteomics, Institute of Molecular and Translational Medicine, Olomouc, Czech Republic,* [2]*Dept. of Respiratory Medicine and Tuberculosis, Faculty of Medicine and Dentistry, Palacky University, Olomouc, Czech Republic.*

Proteolytic enzymes such as matrix metalloproteinases (MMPs) and others are up-regulated in chronic obstructive pulmonary disease (COPD) and bronchial asthma (BA). Their exceeding expression and proteolytic activity could result from insufficient inhibition and deregulated mRNA stability. We, therefore, investigated two inhibitors of MMPs (RECK and PTEN) and also RNA-binding proteins affecting mRNA stability (AUF1, HuR and PCBP2) in the both diseases. Real time-PCR method with PSMB2 as housekeeping gene was used to quantify the relative expression of RECK, PTEN, AUF1, HuR and PCBP2 in bronchoalveolar cells from 22 control subjects, 30 COPD patients and 19 patients with BA. The numbers of RECK (p=0.004, p=0.03)and AUF1 (p=0.01, p=0.02) mRNA transcripts were lower in both groups of COPD and BA patients than those in healthy control subjects. In comparison to controls, mRNA expression of HuR was decreased in COPD patients (p=0.03). There was a positive correlation between RECK expression and AUF1 (p<0.001), PCBP2 (p<0.001) and HuR (p=0.02), respectively. Overall, expression of the investigated genes did not differ between COPD patients and those with BA (p>0.05), smoking status was reflected in our analyses. In conclusion, the down-regulation of RECK observed in this study may contribute to protease/anti-protease imbalance in COPD and BA. As this has been the first investigation of RNA-binding proteins in these inflammatory diseases, further studies are needed to clarify the involvement of these molecules in COPD and/or BA pathomechanisms. Grant support IGA PU LF 2013_009 and CZ.1.05./2.1.00/01.0030

P5.02.17
Altered response of tympanosclerotic fibroblasts to interacting mast cells: implication for tissue remodeling

T. K. Pawelczyk*, M. Sakowicz-Burkiewicz, J. Kuczkowski;*
Medical University of Gdansk, Gdansk, Poland.

Background: Inflammation is increasingly recognized as an important factor in development of tympanosclerosis, which finally results in hearing loss. The exact pathomechanisms of tympanosclerosis (TS) is not yet resolved, but the typical pathologic route of TS proceeds through destruction of the connective tissue, fibroblast invasion, and calcification. Thus, the objective of our study was to investigate the response of fibroblasts to mast cells interaction.
Methods: Experiments were performed on primary fibroblasts and human mast cells (HMC-1) co-cultured at 1:1 ratio. Fibroblasts were isolated from tympanic membranes (TM) of patients with tympanosclerosis and from morphologically normal TM of persons died of sudden cause (control). HMC-1 cells were induced with NGF (20 ng/ml) to express the FcepsilonR1alfa and stimulated by crosslinking with antibody to FcepsilonR1alfa.
Results: Addition of stimulated HMC-1 cells to fibroblast culture resulted in an increase of TNF-alfa, IL-6, bFGF, and MMP-9 levels in cell culture media, but this changes were ~2-fold higher in culture of fibroblast from TS patients. No changes in TGF-beta were evident. We observed that the level of collagen types 1-4 expression in control fibroblasts were not affected by HMC-1 cells, whereas in fibroblast from TS patients 2-fold and 4-fold higher level of COL2A1 and COL4A1 transcripts were observed, respectively. The changes in transcript levels correlated with the proteins content.
Conclusion: The sensitivity of fibroblast isolated from TM of patients with tympanosclerosis to stimulation by interacting mast cells is significantly increased. Moreover, altered interaction of fibroblasts and mast cells might greatly contribute to pathomechanisms of tympanosclerosis.

P5.02.18
The crosstalk of kinin receptors on Experimental Focal and Segmental Glomerulosclerosis

R. L. Pereira[1], *R. Felizardo*[2], *M. Cenedeze*[2], *M. Hiyane*[1], *R. C. Silva*[2], *C. F. Aguiar*[1], *J. B. Pesquero*[2], *R. C. Araújo*[2], *A. P. Silva*[2], *N. O. S. Câmara*[1];
[1]*Universidade de São Paulo, São Paulo, Brazil,* [2]*Universidade Federal de São Paulo, São Paulo, Brazil.*

Focal and Segmental Glomerulosclerosis (FSGS) is one of the most important causes of chronic renal disease. Experimental FSGS models consist in reproduce in rodents the main signals of the human disease, like podocyte foot process effacement associated with albuminuria. New targets of the disease have been studied in recent literature, like kinin receptor 1 (B1RBK). On the other hand the role of the second kinin receptor, B2RBK has showed no data. The role of both receptors has been studied in also other renal diseases. The lack of effective treatments for FSGS in clinic encourages the search for new targets of treatment; we propose to evaluate the role of B2RBK, a receptor deeply involved with inflammatory disorders associated with kidney diseases.
We induce FSGS in mice by a single injection of Adriamycin (ADM) and treat them with specific kinin receptors antagonists in order to evaluate FSGS progression.
We observed that treatment with HOE-140 (B2RBK antagonist) protected mice from FSGS, diminishing albuminuria, renal fibrotic and pro-inflammatory proteins and mRNA expression and prevented podocyte damage. On the other hand B2KO mice induced FSGS showed a worse prognosis associated with higher proteinuria and podocyte damage. In order to solve this possible contradictory result we treated B2KO mice with DALBK (B1RBK antagonist), that surprisingly revert most ADM signs of the disease. We observed that differently from WT, the B2KO mice presented up regulation of B1RBK, showing a possible crosstalk of kinin receptors in FSGS.

P5.02.19
M2 muscarinic acetylcholine receptor modulates rat airway smooth muscle cell Proliferation

F. A. Placeres-Uray*;*
Instituto de Medicina Experimental. Universidad central de Vevezuela, Caracas, Venezuela.

Airways chronic inflammatory conditions in asthma and COPD are characterized by tissue remodeling, being smooth muscle hyperplasia, the most important feature. Non-neuronal and neuronal acetylcholine acting on muscarinic receptors (MAChRs) has been postulated as determinant of tissue remodeling in asthma and COPD by promoting proliferation and phenotypic changes of airway smooth muscle-cells (ASMC). The objective was to evaluate proliferative responses to muscarinic agonist as carbamylcholine (Cch) and to identify the MAchR subtype involved. ASMC were isolated from tracheal fragments of Sprague-Dawley rats by enzymatic digestion. Proliferation assays were performed by MTS-PMS method. Viability was confirmed by trypan blue exclusion method. Mitogens, as epidermal growth factor (EGF), tumor necrosis factor-alpha (TNF-α) and fetal bovine serum (FBS) increased ASMC proliferation (p<0.05, n=5). Cch alone increased ASMC proliferation at 24 and 48 hrs. However, combination of Cch with other mitogens exhibited a dual effect, a synergistic proliferative effect in the presence of EGF (5ng/mL) and 5% FBS, and an inhibitory effect induced by 10% FBS, EGF (10ng/mL) and TNF-α (10ng/mL). To determine the MAChR subtype involved in these biological responses, a titration curve of selective muscarinic antagonists were performed. The Cch stimulatory and inhibitory effects on ASCM proliferation was blocked by AF-DX-116 (M2AChR selective antagonist), in greater proportion than 4-DAMP (M3AChR selective antagonist), suggesting that the modulation of muscarinic agonist-induced proliferation is mediated by M2AChR. Thus, M2AChR can activate multiple signal transduction systems and mediate both effects on ASMC proliferation depending on the plethora and variable airway microenvironments existing in asthma and COPD.

P5.02.20
Periostin modulates the course of IL-13 dependent chronic inflammation and liver fibrosis

***T. R. Ramalingam**, A. Talley, M. M. Mentink-Kane, T. A. Wynn;*
National Institutes of Allergy and Infectious Diseases, Bethesda, MD, United States.

Chronic progressive liver fibrosis (cirrhosis) and post cirrhotic complications are a leading cause of morbidity and mortality worldwide. Periostin is a matricellular protein that has been studied in the context of several chronic inflammatory, fibrotic and neoplastic diseases. Periostin has shown potential as a surrogate for disease severity and study stratification and even been suggested as a therapeutic target in some of these conditions. We used a murine model of Th2-mediated inflammation induced by the helminth, Schistosoma mansoni, to explore the regulation and function of periostin during liver fibrosis. In wild type mice, serum periostin levels increased between 9 to 24 wks post infection — but this increase was abrogated in mice lacking the functional IL-13 receptor (IL-13Ra1), suggesting a requirement for IL-13 signaling. Correspondingly, in mice engineered to mount an uncontrolled IL-13 response, significantly increased periostin expression was detected in the liver, correlating well with the degree of fibrosis and procollagen VI expression. Microscopically, periostin was abundantly found within the fibrotic granuloma, radiating to surrounding parenchyma. In mice deficient in periostin, we found that the granuloma formation around S. mansoni eggs was unimpaired, but liver fibrosis was significantly increased compared to littermate controls. In vitro, macrophage response to IL-13 was diminished in the presence of recombinant periostin. Our data show that periostin is induced by IL-13 in the liver, where it can serve as a robust biomarker for fibrosis and is also capable of modulating IL-13 activity in a feedback regulatory loop.

P5.02.21
In vivo multi-photon molecular imaging technique visualizes immune and inflammatory cell cross-talks in metabolic diseases

***N. Satoshi**, M. Nagasaki;*
University of Tokyo, Tokyo, Japan.

To elucidate the underlying mechanisms of adult common diseases based on chronic inflammation, it is vital to examine the immune and inflammatory cell kinetics in living animals. Therefore, we developed in vivo imaging technique based on single- and multi-photon microscopy, and we assessed dynamic cellular interplay in diseased conditions.
We found that large numbers of CD8+ effector T cells infiltrated into obese adipose, and these cells were essential for the initiation and development of adipose inflammation and fibrotic reponses. In addition, we identified a novel B cell subset that is abundant in adipose tissue. Immunological or genetic B cell depletion, and B cell-specific Il10 deletion enhanced CD8+ T cell activation and adipose inflammation, and exacerbated insulin resistance in obesity. Adipose environmental factors supported B cell survival and IL-10 production. Adipose B cells also exhibited unique surface phenotypes, distinct from those of known regulatory B cell subsets. Our findings indicate that adipose B cells are a naturally occurring regulatory B cell subset that is essential for negative regulation of diet-induced adipose inflammation and maintenance of homeostasis within adipose tissue, and that B cell dysfunction pivotally contributes to the progression of inflammatory and fibrotic processes.
Our results also clearly demonstrated the power of our imaging technique to analyze complex cellular interplays in inflammatory diseases, especially parenchymal and stromal cell cross talks, and to evaluate new therapeutic interventions against them.

P5.02.22
Metformin modulates lipolysis and inflammation through the modulation of T cell priming in obese-induced Type II diabetic mice

***S. Shin**, B. Hyun, A. Lee, S. Lee, H. Kong, S. Han, Y. Song, K. Kim;*
Sahmyook University, Seoul, Republic of Korea.

Inflammation is regarded as a key process underlying metabolic diseases in obese individuals where adipose tissue shows features characteristic of active local inflammation. Metformin is used for treating of T2D and have been suggested that metformin has anti-inflammatory properties. This study investigated the therapeutic effect of metformin on diabetic symptoms in DIO mice. Here we show metformin attenuates metabolic disorder in DIO mice and suppresses MHC-restricted antigen presentation in DCs. Metformin decreased aipogenesis related genes, FAS, SCD-1, GPAT, SREBP1a, and lipases, LPL, ATGL, HSL, but also suppressed innate cytokines expression through APPL1-AMPK-sirt1 signaling. Metformin decreased both class I- and class II-restricted presentation of exogenous OVA in DCs. Metformin also decreased expression of the co-stimulatory molecules, ICAM-1 and B7-1/-2, and MHC class I and II molecules but not phagocytic activity. Metformin decreased MHC class II-restricted exogenous antigen presentation in peritoneal macrophages *in vivo*. These results show that metformin attenuates adipogenesis and suppresses immune responses through APPL1-AMPK-sirt1-NF-κB signaling and followed by decreases MHC-restricted presentation of exogenous antigen. Theses finding suggests that modulation of the antigen presentation pathway by metformin could provide a novel means for regulating T cell responses in terms of controlling of inflammation in metabolic diseases.

P5.02.23
The role of surfactant protein D in cigarette smoke-induced pulmonary pathology

H. Wulf-Johansson[1], C. Støttrup[1], S. Hansen[1], A. Schlosser[1], C. H. Nielsen[2], N. Palaniyar[3], J. Vestbo[4], C. S. Stevenson[1], U. Holmskov[1], ***G. L. Sorensen**[1];*
[1]University of Southern Denmark, Odense, Denmark, [2]Copenhagen University Hospital, Odense, Denmark, [3]Sick Kids Research Institute, Toronto, ON, Canada, [4]Odense University Hospital, Odense, Denmark.

Background: Surfactant protein D (SP-D) is an innate immune factor involved in clearance of microbes and apoptotic host cells. SP-D deficient mice (*Sftpd-/-*) develop pulmonary emphysema-like pathology accompanied by increased numbers of apoptotic alveolar macrophages and phospholipid accumulation. Cigarette smoke (CS) is the main risk factor for development of emphysema.
Hypothesis: We hypothesize that genetic ablation of SP-D leads to increased lung inflammation and decreased lung function in response to CS exposure in mice.
Methods: C57BL/6N *Sftpd+/+* and *Sftpd-/-* littermate male mice where exposed to CS for 2x50 min/5 days/12 weeks and control mice received room air. Inflammatory cell counts were performed in bronchoalveolar lavage (BAL) and lung mechanics were performed with a computer-controlled respirator (FlexiVent, Scireq Inc). Chemokines and cytokines were measured by a multiplex immunoassay, and phospholipids were measured by mass spectrometry.
Results: Total cell count in BAL fluid showed significant induction in CS exposed Sftpd-/- mice relative to Sftpd+/+ mice. Alveolar macrophages were increased approximately 3-fold. BAL levels of macrophage inflammatory protein (MIP-1) were significantly induced, but there were no detectable *Sftpd* dependent changes in BAL cytokines, matrix metalloproteinases 2 and 9, phosphatidycholine, or dipalmitoylphosphatidylcholine. Respiratory resistance, but not compliance, was increased in mice exposed to CS-exposure and was independent of *Sftpd*.
Conclusion: SP-D is predominantly involved in pulmonary macrophage infiltration or removal after CS exposure. The increased level of alveolar macrophages did not affect the inflammatory profile in BAL indicating that the cells might be malfunctioning. CS induced increase of airway resistance appeared independent of SP-D.

P5.02.24

High-mobility group box 1, actively secreted by cardiac fibroblasts, might be a novel culprit of myocardial contractility dysfunction and cardiac collagen deposition

Z. Su[1], *J. Yin*[1], *R. Ma*[1], *T. Wang*[1], *F. Kong*[2], *H. Shen*[3], *H. Xu*[1];
[1]*Department of Immunology & Laboratory Immunology, Jiangsu University, Zhenjiang, China,* [2]*The Affiliated People's Hospital of Jiangsu University, Zhenjiang, China,* [3]*2The Affiliated People's Hospital of Jiangsu University, Zhenjiang, China.*

High mobility group box 1 (HMGB1), a non-histone nuclear protein, is actively secreted by immune cells, cardiomyocytes, hepatocytes, pituicytes or passively released by necrotic cells. HMGB1 has been implicated in inflammatory diseases. The present work was to assess whether viable cardiac fibroblasts could secrete HMGB1 and whether HMGB1 could affect myocardial function. Primary cardiac fibroblasts were isolated from BALB/c mice and challenged by LPS; the HMGB1 levels of mRNA and protein significantly increased after 24h; active secretion of HMGB1 has been demonstrated through activation of PKCβ and Erk1/2 pathway; and after LPS challenge, the collagen type I, III (Col1/3) and osteopontin (OPN) expression were obviously increased. *In vivo*, no inflammatory cells infiltration was noted and ultrasound diagnosis showed that actively secreted HMGB1 contributed to myocardial contractility dysfunction and cardiac fibrosis. Therefore, cardiac fibroblasts, a non-immune cell type, could actively secrete HMGB1, which was associated with myocardial function.

P5.02.25

Knee injury with concomitant osteochondral fracture is associated with increased synovial fluid concentrations of SPARC, IL-8 and TNF-α

P. Swärd*, A. Struglics, M. Englund, H. Roos, R. Frobell;*
Department of Orthopaedics, Institution of Clinical Sciences, Lund University, Lund, Sweden.

Purpose: Approximately 50% of patients with an anterior cruciate ligament tear also sustain an osteochondral (OC) fracture in association with the injury. The aim of the present study was to investigate if concentrations of cartilage and bone markers and pro-inflammatory cytokines in synovial fluid (SF) collected from acutely injured knees were different between acutely injured knees with/without an OC fracture.
Methods: Synovial fluid with hemarthrosis was aspirated from acutely injured knees of 111 individuals (mean age 27 years, range 13-64 years, 22% women) in median 1 (range 0-23) day after the injury. Concentrations of sulphated glycosaminoglycan, cartilage ARGS, COMP osteocalcin, secreted protein acidic and rich in cysteine (SPARC), osteopontin and pro-inflammatory cytokines (IL-1β, IL-6, IL-8 and TNF-α) were analyzed. Ninety-eight of the 111 patients underwent MRI (1.5 Tesla) of the injured knee in median 8 (range 1-38) days after the injury.
Results: Thirty-eight of the acutely knee injured patients had an OC fracture with discontinuity of the cortical bone and 29 had an OC fracture without discontinuity of the cortical bone in the knee joint. Thirty-one patients did not sustain an OC fracture. Knees with an OC fracture with discontinuity of the cortical bone had significantly higher SF concentrations of SPARC ($p = 0.034$), IL-8 ($p = 0.030$) and TNF-α ($p=0.005$) compared to knees without an OC fracture after adjusting for days between injury and SF aspiration, age, sex and type of knee injury.
Conclusions: An associated OC fracture may cause a higher degree of joint inflammation after knee injury.

P5.02.26

Implication of antigen-driven mechanisms in the pathogenesis of interstitial pneumonia associated with polymyositis

A. Takeda[1,2], *Y. Fukushima*[3], *T. Matsutani*[4], *Y. Haji*[2], *R. Rokutanda*[2], *Y. Suyama*[2], *M. Kishimoto*[2], *K. Yamaguchi*[2], *M. Okada*[2];
[1]*Division of Clinical Immunology & Rheumatology, International University of Health and Welfare Hospital, Nasushiobara, Japan,* [2]*Division of Allergy & Rheumatology, St. Luke's International Hospital, Tokyo, Japan,* [3]*Department of Pulmonary Medicine and Clinical Immunology, Dokkyo University School of Medicine, Mibu, Japan,* [4]*Laboratory of Immune Regulation, Wakayama Medical University, Wakayama, Japan.*

Objective: Polymyositis (PM) is a major CTD characterized by chronic inflammatory lesions of muscle and other organs, including critical pulmonary involvement. Interstitial lung diseases, mainly interstitial pneumonia (IP), have been recognized in 30% - 70% of PM patients and have a poor prognosis. While the presence of myositis-specific autoantibodies suggests an autoimmune etiology of PM, the pathogenesis of PM-associated IP remains unclear. The aim of this study was to elucidate the role of T cells in this pulmonary complication.
Methods: We took advantage of a rare opportunity to carefully study two cases of earliest-stage IP associated with PM by utilizing lung biopsy tissue. We characterized the phenotype of lung-infiltrating lymphocytes from lung biopsy specimens obatained by video-assisted thoracoscopy, and analyzed T-cell receptor (TCR) variable region repertoires of T-cells infiltrating the lung tissues using a validated adaptor ligation polymerase chain reaction (PCR)-based microplate hybridization assay, comparing these to peripheral blood lymphocytes (PBL).
Results: Both cases demonstrated substantial CD3+ T cell lung infiltrates. The usage of repertoires of TCR in the lung differed from those in PBL, with certain TCR V gene families detected more frequently in lung tissue, suggesting a pivotal role for T cells in the pathogenesis of IP associated with PM. This is the first robust demonstration of selective TCR repertoire usage and its differential expression in lung tissue versus PBL.
Conclusion: These findings strongly suggest a pathogenic contribution of organ-specific oligoclonal T cell accumulation through antigen-driven mechanisms, implying potential development of immunospecific treatments such as molecular-targeted therapies.

P5.02.27

Intrinsic epithelial activation in Primary Sjogren's syndrome: Evidence of significantly reduced constitutive expression of PPAR-gamma in cultured non-neoplastic salivary gland epithelial cell lines

A. G. Vakrakou*, A. Kapogiannatou, V. Gourzi, E. K. Kapsogeorgou, M. N. Manoussakis;*
Dpt Pathophysiology, University Athens, Athens, Greece.

PPAR-gamma is an essential transcription factor that participates in the regulation of lipogenesis, whereas it also exerts significant anti-inflammatory actions. Primary Sjogren's syndrome (SS) is characterized by chronic inflammatory lesions of epithelial tissues and experimental evidence has indicated the occurrence of chronic intrinsic activation of salivary gland epithelial cells (SGEC). Thus, SGEC are probably both the target and the inducer of inflammatory responses. Here, we sought to investigate the constitutive expression of PPAR-g in cultured non neoplastic SGEC lines from SS patients and non-SS controls, as well as to define potential cellular activators that affect PPAR-g expression. The
constitutive PPAR-g mRNA (Real-time PCR) and protein expression (Western Blot) in the SGEC from patients with SS (n=19), was significantly reduced compared to controls (n=11) ($p=0.0001$). The activation of cultured SGEC by stimulation with PolyI:C, LPS, IFN-g and IL-1β resulted in significant down-regulation of PPAR-g mRNA expression (in all cases; by 80 -85% at 12 hours, $p<0.05$), whereas IL-4 caused a two-fold increase in basal PPAR-g expression levels. Our results indicate that PPAR-g expression in human SGEC is significantly reduced following activation via TLRs and the pro-inflammatory cytokines INF-g and IL-1β. Furthermore, the present study demonstrates for the first time the significantly reduced expression of PPAR-g in the SGEC of SS patients. This finding likely

owes to the chronic intrinsic activation, which characterizes the epithelia of SS patients.

P5.02.28
IL28B polymorphisms may be associated with Chlamydia pneumoniae infection in patients with cardiac disease

***A. C. Vallinoto**, B. Brasil Santana, N. Almeida, R. Bezerra Hermes, R. Ishak, M. O. G. Ishak;*
Federal University of Para, Belem, Brazil.

The present study aimed to investigate whether three polymorphisms in the IL28B gene (rs12979860, rs8099917, rs8103142) are associated with the Chlamydia pneumoniae infection, as well as, with the outcome of cardiac disease. The blood samples were collected from 159 patients with chronic cardiac disturbs submitted to revascularization surgery and 300 healthy subjects (control group). All samples were previously tested for the presence of antibodies to C. pneumoniae using an enzyme immune assay. In order to identify the frequencies of the polymorphisms, DNA samples were extracted from PBMCs and analyzed by real time polymerase chain reaction (qPCR). There was a higher prevalence of mutant genotypes (rs12979860TT, rs8099917GG, rs8103142CC) among the control group than within patients with cardiac disease (p=0.0008, p=0.0073 and p= 0.0049, respectively). On the other hand, as both groups were classified according to the presence of antibodies to C. pneumoniae, a significantly higher prevalence of rs12979860CC, rs8099917TT and rs8103142TT genotypes were recorded among cardiac patients as compared to the infected control group (p=0.0011, p=0.0050 and p=0.0063). The polymorphism rs8099917 showed the presence of genotype GG only among seronegative controls (15,6%) as compared to the patient who were antibody positive to C. pneumoniae (p=0.0048). Distribution of genotype frequencies were not significant when both groups were negative to the presence of antibodies. The present results suggest that the IL28B polymorphisms investigated herein may be associated with the susceptibility to C. pneumoniae, as well as, with the possible outcome of cardiac disease, but further studies should confirm this preliminary finding.

P5.02.29
Accumulation of tolerogenic cells at the site of granulomatous foreign-body reaction

***D. Vucevic**[1,2], S. Vasilijic[1,2], J. Djokic[1], B. Bozic[3], I. Majstorovic[1], S. Tomic[2], M. Vasiljevska[1], B. Draskovic-Pavlovic[1,2], M. Colic[2];*
[1]Institute for Medical Research, Military Medical Academy, Belgrade, Serbia, [2]Medical Faculty of the Military Medical Academy, University of Defense, Belgrade, Serbia, [3]Institute for Physiology and Biochemistry, Faculty of Biology, University of Belgrade, Belgrade, Serbia.

The granulomatous foreign-body reaction (GFBR) is a special type of chronic inflammation characterised by infiltration of inflammatory cells (ICs). Using a model of subcutaneous implantation of polyvinyl sponges in rats, we studied the phenotypic and functional characteristics of these cells, with particular reference to the properties of antigen presenting cells and lymphocytes. ICs were isolated from sponge exudates at days 1-21 after implantation. Dendritic cells (DCs) and lymphocytes were purified using a combination of separation gradients, adherence to plastics, and immunomagnetic sorting. We showed that dominant population of ICs at day 1 and 3 were granulocytes, followed by their decrease thereafter. The number of mononuclear cells (MNCs), macrophages and DCs, progressively increased after day 3, reaching maximal values at day 7. Maximal number of lymphocytes was detected at day 10. In addition, total ICs isolated from day 7 till day 10 exerted significant suppressive activity in co-culture with autologous ConA-stimulated thymocytes and alogeneic lymph node T cells. This finding correlated with the increased level of IL-10 in culture supernatants and the increased proportion MHC class II+ IDO+ DCs and CD3+ CD25+ Foxp3+ lymphocytes at day 7 and day 10, respectively. We did not find any significant difference in the number of these cell populations between regional lymph nodes MNCs and peripheral blood MNCs of experimental animals compared to controls. In conclusion, accumulation of cells with tolerogenic characteristics in GFBR might be relevant for the suppression of inflammation and the prevention of unwanted immune response.

P5.02.30
EBP-1 specific T cell responses correlate with liver damage in chronic hepatitis B

***L. Wang**[1], l. Jiang[2], X. Chen[3], X. Chen[3], Y. Wu[1];*
[1]1. Institute of Immunology PLA & Department of Immunology, Third Military Medical University, Chongqing, China, [2]2. Institute of Infectious Diseases, Southwest Hospital, Third Military Medical University, Chongqing, China, [3]Institute of Immunology PLA & Department of Immunology, Third Military Medical University, Chongqing, China.

The immune mechanisms especially the autoreactivity that cause liver damage in chronic hepatitis B virus (HBV) infection are not completely understood. The presence of HBV-specific $CD8^+$ T cells does not correlate with liver damage, and liver pathology is deemed to be largely caused by the non-HBV-specific immune cells including bystander $CD8^+$ and $CD4^+$ T cells. Chronic HBV infections have been linked to autoimmune phenomena. Although autoantibodies are commonly detected in chronic HBV infection, autoreactive T-cell responses have not been characterized yet. By using serologic proteome analysis, ErbB-3-binding protein-1(EBP-1) was identified as a novel autoantigen in Chinese patients with chronic hepatitis B (CHB). The prevalence and levels of serum anti-EBP-1 autoantibodies, which were detected by ELISA, were closely associated with the clinical severity of liver disease in patients with chronic HBV infection. Notably, the EBP-1 autoreactive T cells producing high levels of interferon-γ and interleukin (IL)-17, but not IL-10 and IL-4, were obviously detectable in CHB patients but not healthy controls. In addition, enhanced EBP-1 specific T-cell responses significantly correlated with features of more severe liver diseases. The expression level of EBP-1 in HBV-infected hepatocytes correlated with the histological inflammation grade of liver tissue. Thus, we assume that the majority of bystander T cells in the inflamed liver tissue may be autoreactive T cells targeting the local upregulated autoantigens e.g. EBP-1, which contribute liver damage in chronic HBV infection.

P5.02.31
Human kidney proximal tubule epithelial cells (PTEC) modulate autologous immune responses by contact dependent mechanisms

***R. Wilkinson**, S. Sampangi, A. Kassianos, X. Wang, H. Healy;*
Queensland Health/RBWH, Brisbane, Australia.

We have demonstrated that human kidney proximal tubule epithelial cells (PTEC) down modulate autologous human T and B cell proliferative responses and modulate the development and activation of autologous dendritic cells (Wilkinson et al NDT 2011, 2012). We have extended this research by analyzing PTEC effects on B cell antibody (Ab) production and culturing T cells and DC in the presence of autologous PTEC using contact dependent and independent culture systems in an effort to define the mechanisms of this modulation. B cells, T cells and DC were cultured with or without PTEC in the presence of various stimuli. The numbers of B cells producing Ab was analysed using isotype specific ELISPOT, whilst readouts for T cells and DC included proliferation, Ag expression and cytokine secretion. PTEC significantly reduced the number of B cells that produced Ab in response to Toll-like receptor stimulation. PTEC also down modulated T cell responses and this modulation was ablated when the cells were separated by a transwell membrane. Similarly, PTEC down modulation of DC differentiation was ablated when the DC and PTEC were separated by a transwell membrane resulting in mature MoDC development and low levels of IL-10 expression. These results demonstrate for the first time that human autologous PTEC can regulate B cell Ab production and that their modulatory effects on T cells and DC are, at least in part, contact dependent. We will elucidate these mechanisms further in an effort to identify novel clinical targets for therapy in renal disease.

P5.02.32
Systemic inflammation in patients with end-stage renal disease (ESRD) receiving different types of renal replacement therapy

*L. V. Solomatina[1], **I. Zhuravleva**[1], E. Panshina[2], E. Gusev[1];*
[1]Institute of Immunology and Physiology, Ural Branch of RAS, Ekaterinburg, Russian Federation, [2]Sverdlovsk Regional Hospital №1, Ekaterinburg, Russian Federation.

Objective. To assess the degree of chronic SI (CSI) in patients with ESRD receiving different types of renal replacement therapy.
The study included the following groups: patients with ESRD receiving program hemodialysis (12 hours per week, blood samples taken prior to dialysis session (n=42), renal transplant patients with normal allograft function (n=23), patients with chronic allograft dysfunction (CAD, n=24). The control group included 50 healthy people.
Chronic glomerulonephritis was the condition that resulted in the development of ESRD in all the patients. Blood plasma was tested for the following SI indicators: CRP, IL-6, IL-8, IL-10, TNFα, D-dimers, cortisol, myoglobin, troponin I. On the basis of these markers using an original method we calculated the integral index of intensity of chronic SI (from 0 to 8 points).
Results. CSI was diagnosed only in hemodialysis patients (90.9%) and in the CAD group (43.5%). The incidence of systemic inflammation reaction and tissue alteration was the highest (90.9% and 90.9%) in hemodialysis patients. Patients in the CAD group most often presented systemic inflammation reaction (91.3%) and distress of neuroendocrine system (56.5%). While elevated levels of proinflammatory cytokines and CRP (41.7%), distress of neuroendocrine system (29.2%), and microthrombosis (4.2%) were recorded in the normal allograft function group, on the whole, there were no cases of CSI.
Conclusion. CSI is a severe ESRD complication in hemodialysis patients. Following the renal transplantation CSI is found only in patients with CAD, proving that CSI is an additional link in the CAD pathogenesis.

P5.03.01
Contribution of Lewis blood group types and their genes to genetic susceptibility and autoimmune response in Grave's disease

***K. H. Ali**;*
University of Al-Mustansirya, Baghdad, Iraq.

Lewis blood groups antigens are structurally and genetically defined molecules. Their association with autoimmune diseases is increasingly reported. One hundred women patients having Grave's disease and a similar number of healthy controls were studied. The Lewis antigens typing was carried out on erythrocytes, while Lewis genes frequently were derived using Hardy-Weinberg Equilibrium Test.The results showed that Le(a) carrying phenotypes were significantly associated with Grave's disease. Among these phenotypes, Lea+b+ was detected in 47% patients compared to 9% in controls (Odds ratio 8.97,95% Cl 3.85-21.44, p=0.00000002).On the other hand, the genotype frequencies of Lewis (Le) genes showed a non-significant association with the disease. Importantly, secretor homozygous genotype (SeSe) was detected in 19% of patients versus 36% in control (OR 0.42, 95% Cl 0.21-0.83, Chi-square=7.248, P 0.007).Non-secretor homozygous genotype (sese) was seen among 32% versus 16% in control (OR 2.47, 95%Cl 1.19-5.17,Chi-square=7.018,P 0.008).Heterozygous (Sese) showed a non-significant differences. The presence of anti-O-Lewis antigens was studied, the results showed that Lewis (a) patients demonstrated a hem-agglutinating anti-O-Le (a) with a mean titer of 232+/-67.5 versus a mean titer of 17.25+/-70 of control, (p=0.007),furthermore those patients gave a mean anti-O-Le a +b+ titer of 84+/-17.10 versus 15.5+/-3.90 mean titer in control (P=0.002). Our findings provide evidence suggestive of an association of Lewis antigens and their genes in susceptibility to Grave's disease.

P5.03.02
Functional study of TNF-α gene promoter polymorphisms in Algerian patients with ankylosing spondylitis

***H. Amroun**[1], N. Kechout[1], R. Allat[2], S. Salah[1], A. Alliouche-Kerboua[1], F. Mecabih[1], H. Djoudi[2], R. Tamouza[3], M. C. Abbadi[1];*
[1]Service d'Immunologie, Institut Pasteur d'Algérie, ALGER, Algeria, [2]Service de rhumatologie, Hôpital de Douéra, DOUERA, Algeria, [3]Laboratoire d'immunologie et d'histocompatibilité, APHP, IUH, INSERM, PARIS, France.

Objective: the aim of our study was to correlate the variability of TNF-α production to single nucleotid polymorphisms (SNPs) located at four positions: -238, -308, -857 and -1031 in the TNF gene.
Patients and Methods: Twenty patients with ankylosing spondylitis (AS) and twenty healthy subjects were included in this study. TNF polymorphisms (G/A-308, G/A-238) were genotyped by Life Codes Cytokine SSO Typing kit and TaqMan technology for TNFα C/T-857, T/C-1031 polymorphisms. TNF-α production after LPS stimulation was evaluated using a whole blood culture model and TNF-α levels were measured by multiplex immunoassay FIDIS cytokine.
Results: In healthy subjects, TNF-α production after LPS stimulation of whole blood cell culture was higher among -857 CC carriers than among -857 CT heterozygotes (169.126 pg /ml vs. 31.25 pg /ml with p = 0.04). This finding is consistent with that obtained in association studies, where this genotype was found protective (50% in patients and 87% in controls with $p=7.2\ 10^{-7}$). For polymorphisms -308G/A, -238 G/A and -1031T/C TNF-α, no statistically significant result was found. In AS patients, no association was observed for any of the four polymorphisms studied (-238 G/A, -308 G/A,-857C/T and -1031 T/C) and the rate of production of the cytokine. No significant difference was observed between controls and patients for different genotypes of the four polymorphisms. In conclusion, the SNP at position -857 in the TNF gene may influence TNF-α production in healthy individuals.

P5.03.03
Association of LGALS3 gene polymorphism and Rheumatoid arthritis in Zahedan, southeast Iran

***M. Atabaki**[1], M. Hashemi[1], H. Daneshvar[2], Z. Zakeri[1];*
[1]zahedan university of medical sciences, zahedan, Iran, [2]Kerman university of medical sciences-Department of Immunology, Kerman, Iran.

Introduction: Rheumatoid arthritis (RA) is a systemic, multi-factorial autoimmune disease characterized by chronic inflammation and destruction of joints. Enhanced infiltration of lymphocytes and macrophages can be observed in inflamed synovium. Up-regulation of pro-inflammatory cytokines is evident in the synovial fluids. In this study we aimed to evaluate the possible association of LGALS3 rs4652 gene polymorphism and rheumatoid arthritis (RA) in a sample of Iranian population.
Method: This case-control study was performed on 120 patients (104 female, 16 male) with rheumatoid arthritis with an average age of 44.6 ± 12.9 years fulfilling the American College of Rheumatology (ACR) criteria for RA. The control group consisted of 120 healthy individual (76 female, 44 male) with a mean age of 43.2 ± 10.3 years and unrelated to RA patients. Genomic DNA was extracted from whole blood and LGALS3 polymorphism were determined using tetra amplification refractory mutation system-polymerase chain reaction (T-ARMS-PCR).
Results: The results showed that LGALS3 AC genotype was a risk factor for susceptibility to RA (OR=11.622 95%CI=4.47-28.65, p=0.001).
Conclusion: In conclusion, we found an association between LGALS3 rs4652 polymorphism and the risk of RA in a sample of Iranian population. our data showed that LGALS3 (+292 A>C) polymorphism is a genetic factor for susceptibility to RA. In agreement with our findings, one study found a positive association between LGALS3 rs4652 (+292 A>C) polymorphism and susceptibility to RA.

Molecular Analysis of Interleukin-17A Gene Polymorphisms in Patients with Multiple Sclerosis

Z. Babaloo[1], *R. Kh. Yeganeh*[2], *E. Sakhinia*[3], *M. Farhoodi*[4], *B. Baradaran*[1];
[1]*Tabriz University of Medical Sciences, Immunology Dept., Tabriz, Iran,* [2]*Tabriz University of Medical Sciences, Tabriz, Iran,* [3]*Tabriz University of Medical Sciences, Genetic Dept., Tabriz, Iran,* [4]*Tabriz University of Medical Sciences, Neuroscience Research Center, Tabriz, Iran.*

Introduction: Multiple sclerosis (MS) is a complex autoimmune disease that damages central nervous system. Both environmental and genetic factors are involved in pathogenesis of this disorder. Th17 cells and their related cytokines, most importantly IL-17, have crucial role in immunopathology of MS.
Methods: In this study, gene sequences of exons 2 and 3 of IL-17A gene were analyzed in forty individuals who suffered from MS disease and forty-four normal subjects as controls. Genomic DNA was obtained from all MS patients and controls. Two exons of the IL-17A gene and their flanking intronic sequences were amplified from the extracted genomic DNA samples. After genotyping by direct sequencing method, distribution of polymorphisms detected in the IL-17A gene.
Results: In exon 3, 25% of MS patients had 3566G>A, 7.5% had 3419A>T, and 7.5% had E125V SNPs. In normal controls, 40% had 3566G>A, and 2.5% had 3480A>G SNPs. There was a significant difference in frequency of the these SNPs in both MS patients and healthy controls in exon 3 of IL-17 gene (p = 0.041 <0.05). In Exon 2 : only 15% of MS patients had SNPs : 7.5% had 1509A>T, 2.5% had R29Q, 2.5% had 1429A>T, and 2.5% had 1587A>G SNPs. 85% of MS cases had not any SNPs in Exon 2. Normal group had not had any SNPs in exon 2. The difference in frequency of SNPs in exon 2 of MS patients and control group was not significant

Role of the GULP gene in renalglomerular macrophage phagocytosis in the autoimmune disorder Systemic Lupus Erythromatosus (SLE) model mice MRL/LPR mesangial cells

H. N. Banerjee[1,2], *A. Alikhan*[3,4], *C. Krauss*[5], *C. Reilly*[6];
[1]*Banerjee, Kolkata, India,* [2]*Calcutta National Medical College, Kolkata, India,* [3]*Banerjee, Kolkata, India,* [4]*ElizabethCity State University-University of North Carolina, Elizabeth City, NC, United States,* [5]*ElizabethCity State University, ElizabethCity, NC, United States,* [6]*Virginia Tech University, Blacksburg, VA, United States.*

SLE is a major autoimmune disorder affecting a vast majority of people,very little is known about the etiology of the disease or any effective therapeutic advances have taken place.90% of the SLE patients die as a complication of renal failure.Several earlier reports have suggested that there is a defect in macrophage phagocytosis in SLE patients.In this study we investigated the role of the GULP gene in phagocytosis capability of the glomerular macrophage mesangial cells isolated from the SLE model MRL/LPR mice. The protein encoded by this gene is an adapter protein necessary for the engulfment of apoptotic cells by phagocytes.Our initial phagocytosis assays showed decreased phagocytosis by the SLE derived renal macrophage mesangial cells when compared to normal RAW 264.7 cells (a mouse leukaemic monocyte macrophage cell line).We analyzed the GULP gene expression in MRL/LPR mesangial cells in comparison to the normal macrophages, RAW cells by Real Time PCR and Western Blot.Our results showed both in the transcriptional level and the translational level there is a decreased expression of the GULP gene.We further transfected the MRL/LPR mesangial cells with GFP fused pCMV-GULP construct .We tested the GULP transgenic cells for increased GULP expression by Real Time PCR and GFP expression by fluroscence microscopy.The GULP transgenic MRL/LPR glomerular mesangial cells showed increased phagocytosis capabilities when compared with nontransfected cells.Thus, our results show a decreased phagocytosis in the diseased SLE model mouse glomerular mesangial cells and a role for the GULP gene in this process.

P5.03.06
HLA DRB1-genotype in families with T1DM patients

M. N. Boldyreva[1], *L. Zilberman*[2], *T. Yankevic*[1], *L. Alexeev*[1], *I. Dedov*[2];
[1]*Institute of Immunology FMBA of Russia, Moscow, Russian Federation,* [2]*Endocrinology Research Center, Moscow, Russian Federation.*

We have previously shown in population studies that the high risk of T1DM was associated with HLA-DRB1 genotypes, including two any variants of the following: DRB1*01,*03,*04,*08,*09,*10 - «T1DM associated DRB1-genotype» (T1DAG). Now we examined 357 members of the families with type T1DM: 160 parents without T1DM, 117 children with T1DM and 80 children without signs of T1DM at the time of the study. 300 blood donors were the control group. HLA-DRB1 SSP typing at low resolution was done. The highest proportion of T1DAG was found in children with T1DM (72%), without gender differences. The proportion of T1DAG was 39% in children with no symptoms of T1DM at the time of the study. Differences in proportions T1DAG between T1DM children and their brothers and sisters, not sick at the time of the study were highly significant (p <0,0000). 40% mothers and 49% fathers have T1DAG, so they have the same proportion of T1DAG as their children without T1DM, but they have significantly lower proportion of T1DAG than that of their children with type 1 diabetes (p <0,01). The proportion of T1DAG in the control blood donors (13%) was significantly lower than in families with T1DM: in parents (p <0,000) and in children without T1DM (p <0,000) and in children with T1DM (p <0,000). More significant proportion of T1DAG in parents and children without T1DM compared to control, suggesting that for the implementation of HLA-induced genetic predisposition to disease, there must be additional, yet unidentified factors that require further investigation.

P5.03.07
Epigenetic regulation of HLA class II genes and their role in autoimmune diseases

M. Černá, *P. Čepek, M. Zajacová, A. Kotrbova-Kozak;*
Third Faculty of Medicine, Charles University in Prague, Prague 10, Czech Republic.

Background: Type 1 diabetes (T1D) is a multifactorial autoimmune disease. The highest T1D risk is associated with HLA (human leukocyte antigen) class II genes. HLA class II expression is controlled by regulatory module that is situated 150 - 300 base pairs upstream of the transcription initiation site in all HLA class II genes. There were identified several promoter alleles (named QAP) in the *HLA DQA1* gene promoter region. Most of the polymorphisms appear to be conserved within haplotype.
Aims: Our aim was to define methylation profile of *HLA DQA1* promoters and determine the mRNA expression of individual alleles of *HLA DQA1* gene in T1D patients.
Methods: 30 diabetic patients (age range 21 to 76 years), were included in this pilot study.
The genotyping of *HLA DRB1, HLA DQA1* and *HLA DQB1* was performed using PCR with sequence specific primers. Genomic DNA was treated with sodium bisulfite, promoter region of *HLA DQA1* gene was amplified and cloned into the *E. coli*, strain DH5α. Positive transformants were selected on agar plates containing ampicillin X-Gal, and IPTG. Positive transformation was confirmed by colony PCR. Sequencing of individual clones was performed.
Results: We found statistically significant differences in total QAP methylation and in methylation at nucleotide position -311. The most significant result in total QAP methylation was found between 2.1 and 1.3 alleles (P = 0.0280). While 2.1 QAP allele was completely methylated at position -311, 1.4 allele was not methylated at all (P = 0.0064).

P5.03.08
Pristane-induced arthritis loci interact with *Slc11a1* gene to determine susceptibility in mice selected for high inflammation

M. De Franco[1]*, M. Correa*[1]*, A. Borrego*[1]*, J. R. Jensen*[1]*, W. H. C. Cabrera*[1]*, N. Starobinas*[1]*, O. G. Ribeiro*[1]*, A. Galvan*[2]*, T. A. Dragani*[2]*, O. M. Ibañez*[1]*;*
[1]Instituto Butantan, Sao Paulo, Brazil, [2]Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy.

AIRmax (maximal inflammation) and AIRmin (minimal inflammation) mice show distinct susceptibility to pristane-induced arthritis (PIA). *Slc11a1*, which regulates macrophage and neutrophil activity, is involved in this disease. AIRmax^{SS} mice homozygous for the non-functional *Slc11a1 S* (gly169asp) allele are more susceptible than the other lines. The aim of this work was to identify genes in acute inflammatory reaction loci that interact with *Slc11a1* alleles to modulate PIA. Mice received two ip injections of 0.5 mL pristane with 60 days of interval. Global gene expression analysis was performed on Affymetrix mouse 1.0 ST bioarrays (27k genes) using RNA (n=4) from arthritic or control paws. In parallel, genome wide linkage studies were performed to search for arthritis QTL in an F2 (AIRmax x AIRmin, n=290) population. Significant (LODscore > 4) arthritis QTL on chromosomes 5 and 8, and suggestive QTL on chromosomes 7, 17 and 19 were detected. Global gene expression analysis demonstrated significantly (P<0.001) over-represented genes related to inflammatory response and chemotaxis in AIRmax^{RR} and AIRmax^{SS} mice, as well as in the AIRmax heterozygous group. Higher up-regulation of chemokine genes *Cxcl1*, *Cxcl9*, *Cxcl5*, *Cxcl13* on chromosome 5 was observed in AIRmax^{SS} than in the other lines. In chromosome 8, *macrophage scavenger receptor 1* and *heme oxigenase (decycling) 1* genes were also more expressed in AIRmax^{SS} mice. RT-qPCR experiments validated microarray analyses. Results revealed that the gene expression profile of two arthritis QTL (on chromosomes 5 and 8) correlates with *Slc11a1* alleles, resulting in enhanced AIRmax^{SS} mice susceptibility to PIA.

P5.03.09
Clinical relevance of typing HLA-DR7-DQ2 haplotype in celiac disease

J. Delgado de la Poza[1]*, M. Amengual Guedán*[1]*, A. Veraguas Imbernon*[1]*, E. Rodríguez Sánchez*[1]*, M. De los Santos de Pelegrín*[2]*, M. Guallarte Alias*[2]*;*
[1]Immunology Section Laboratory. UDIAT-CD. Corporació Sanitària i Universitària Parc Taulí, Sabadell, Spain, [2]Pediatric Service. Corporació Sanitària i Universitària Parc Taulí, Sabadell, Spain.

Celiac disease is a systemic immune-mediated disease that affects genetically predisposed individuals when they are in contact with a gluten diet. It has a strong association with HLA-DQ2 and HLA-DQ8 haplotypes. These haplotypes have the ability to present gliadin peptides to reactive T cells in gut. More than 95% of patients present HLA-DQ2 heterodimer in *cis* (HLA-DR3-DQA1*05:01-DQB1*02:01) or in *trans* (HLA-DR7-DQA1*02:01-DQB1*02:02; DR11-DQA*05:05-DQB1*03:01). The rest presents HLA-DQ8 heterodimer (DR4-DQA1*03:01-DQB1*03:02).
The aim of this study was to compare clinical, histological and analytical characteristics of celiac patients carrying HLA-DR7-DQ2 *versus* HLA-DR3-DQ2 haplotypes. Since 2010 we have typed the HLA-DR7-DQ2 together with HLA-DR3-DQ2 for testing HLA-DQ2.
A total of 85 celiac disease patients were studied, 96.5% were HLA-DQ2 and 4.7% were HLA-DQ8. 16.5% of patients carried only HLA-DR7-DQ2 haplotype, 63.5% carried only HLA-DR3-DQ2 and 16.5% carried HLA-DR3-DQ2 together with HLA-DR7-DQ2. We did not find significant differences between HLA-DR7-DQ2 and HLA-DR3-DQ2 patients with respect to histological damage and anti-tissue transglutaminase and anti-endomysium autoantibody levels. We also compared clinical characteristics and we did not observe significant differences between these haplotypes except for irritability. This characteristic is more frequently associated with HLA-DR7-DQ2 than HLA-DR3-DQ2 patients (14.3% vs. 0.0%, p=0.041).
In contrast to what has been published by some groups, celiac patients with HLA-DR7-DQ2 haplotype have the same clinical behaviour than HLA-DR3-DQ2 patients. Moreover there is a stronger association with irritability in HLA-DR7-DQ2 patients.
For a correct typing HLA-DQ2, HLA-DR7-DQ2 haplotype has to be performed due to its frequency and clinical presentation, at least in our geographical population.

P5.03.10
Association of BANK-1 and Cytokine gene polymorphisms with Type 1 diabetes: A family-based and case-control study

F. Zouidi[1]*, **M. Dkhil***[1]*, H. Fourati*[1]*, O. Abida*[1]*, J. Costa*[2]*, M. Ben Ayed*[1]*, T. Kammoun*[3]*, M. Hachicha*[4]*, C. Penha-Gonçalves*[2]*, H. Masmoudi*[1]*;*
[1]Immunology Department , Habib Bourguiba University Hospital, Sfax, Tunisia, [2]Instituto Gulbenkian de Ciência, Oeiras, Portugal, [3]Pediatric Departement Hedi Cheker University Hospital, Sfax, Tunisia, [4]Pediatric Department, Hedi Chaker Hospital, Sfax, Tunisia, Sfax, Tunisia.

Type 1 diabetes (T1D) is an autoimmune disease (AID) with both genetic and environmental components. We aimed to investigate the genetic association of polymorphisms in genes previously linked with other AIDs, namely the BANK1, IL15, IL21 and IL2 genes. Twelve polymorphisms in the BANK1, IL15, IL21 and IL2 genes were genotyped in cases (76 T1D patients), unrelated controls (n = 162), and multicase families (59 nuclear families; 86 T1D cases and 169 first degree relatives) from Southern Tunisia.
In the BANK1 gene, G allele and the GG genotype of rs3733197 and TT genotype of rs17266594 were significantly increased in the T1D patients group compared to healthy controls. Furthermore, one IL15 SNP (rs13117878) exhibited a marginal association with the T1D, whereas the family study revealed a significant association of the rs2221903 in IL-21 gene with the disease.
Interestingly, the IL-15/ IL-2: G-C-A-T and A-T-T-T haplotypes exhibited a significant effect on T1D susceptibility. In addition, a significant gene-gene interaction between the BANK1/IL-15/IL-21 (TGGT) significantly increases in T1D patients as compared to controls.
These results suggest that common variants of the BANK1 gene are involved in the genetic component conferring general susceptibility to T1D, whereas IL-15 and IL-21 appears to play a minor role in the pathogenesis of the diseases. This work provides motivation for studies aiming to replicate these findings in larger populations.

Causes of Multiple Sclerosis: a functional genomics approach

M. A. Jordan[1]*, J. Field*[2]*, G. Foo*[3]*, L. Johnson*[2]*, L. Laverick*[3]*, M. Gresle*[3]*, T. Spelman*[4]*, H. Butzkeuven*[3]*, A. Baxter*[1]*;*
[1]Comparative Genomics Centre, Townsville, Australia, [2]The Florey Neuroscience Institutes, Melbourne, Australia, [3]The Department of Medicine, University of Melbourne, Melbourne, Australia, [4]Burnet Institute, Melbourne, Australia.

Multiple Sclerosis (MS) is the most common disabling neurological disease affecting young adults in Western Society. To date, 55 strongly associated single nucleotide polymorphisms have been discovered. We now need to identify causal genes. While T-cells as targets for therapeutic intervention have rarely proven useful, there is strong clinical and in-vitro data identifying NK cell deficiencies in patients, and key roles for monocytes in myelin and axon destruction and autoantigen presentation. RNA extracted from magnetic bead sorted monocytes and NK cells, of healthy controls (HC) and untreated patients with relapsing remitting MS (RRMS), was labelled and hybridised to Affymetrix Human Gene 1.0 ST arrays. Expression values were standardized across chips using RMA and quantile normalization as implemented in GenePattern. Genes were ranked by expression difference significance by Mann Whitney U test and ANOVA. To date, we have analysed monocytes of 30 patients and 39 HC, and NK cells from 25 patients and 32 HC. Expression differences of those genes adjacent to MS associated risk SNPs lying between 110kb upstream and 40kb downstream of a candidate gene were considered. We have identified three genes worthy of further analysis on this basis: RGS1, HHEX and THEMIS. To test the relevance of these candidates to central nervous system (CNS) autoimmunity, we aim to mimic phenotypes associated with these expression quantitative trait loci (eQTL) in in-vitro cultures of purified NK cells and monocytes, and in-vivo in a mouse model of MS - experimental autoimmune encephalomyelitis (EAE).

P5.03.12
Significance of single framework mutations for DNA-binding and hydrolyzing activity of antibodies from mice with autoimmune disorders

A. V. Kozyr[1]*, A. V. Kolesnikov*[2]*, G. A. Savchenko*[1]*, A. E. Khlyntseva*[1]*, A. G. Bogun*[1]*, I. G. Shemyakin*[1]*, A. G. Gabibov*[3]*;*
[1]SRCAMB, Obolensk, Russian Federation, [2]Institute of Immunological Engineering, Lubuchany, Moscow Region, Russian Federation, [3]IBCH RAS, Moscow, Russian Federation.

Anti-DNA autoantibodies are known as important factors of tissue injury in autoimmune diseases and may reveal DNA-hydrolyzing activity.
DNA-binding and catalytic activity of BV04-01 antibody from (NZBxNZW) F1 mice and its recombinant scFv (SCA04-01) derivative produced in *E. coli* suggested that significant conformation changes in antibody-DNA complex are necessary for activation and cleavage of the phosphodiester bond, and subsequent product release.
Autoantibody MRL-4 from mrl/lpr mice contained VH domain that differed from VH of BV04-01 by only few residues. Recombinant MRL-4 scFv, produced in *E. coli,* displayed no DNA-hydrolyzing activity, while replacement of BV04-01 VL by MRL-4 VL in SCA04-01 yielded antibody with DNA-hydrolyzing activity indistinguishable from SCA04-01.
Site-directed mutagenesis of MRL-4 and BV04-01 has shown that reversion of the P23 in the MRL4 scFv to A23, encoded by germline gene, resulted in significant loss of DNA-binding capacity of this antibody. Both DNA-binding and DNA-hydrolyzing activity of A23P SCA04-01 were decreased due to A23P mutation in SCA04-01 VH. SPR data on DNA-binding capacity of mutant and wild-type variants of MRL-4 scFv and SCA04-01 indicated that the biggest decrease in DNA binding efficiency was found in SCA04-01 VH A23P mutant.
Dramatic changes in DNA-binding and DNA-hydrolyzing activity due to single proline mutation permit hypothesizing that some DNA-binding Abs, possessing intrinsic low affinity to DNA, can first evolve via classic antigen-driven process using a (self)antigen of proteinaceous or other (LPS, viral capsid) origin, and then acquire high affinity to DNA by some mutation causing major conformational rearrangement in the mature antibody molecule.

P5.03.13
CTLA4 +49G allele in combination with HLA-DR3 associates with type 1 diabetes as well as its onset in North Indians

N. Kumar[1]*, G. Kaur*[1]*, U. Kanga*[1]*, N. Tandon*[2]*, S. C. Zucman*[3]*, N. K. Mehra*[1]*;*
[1]Dept of Transplant Immunology & Immunogenetics, All India Institute of Medical Sciences, New Delhi, India, [2]Dept of Endocrinology & Metabolism, All India Institute of Medical Sciences, New Delhi, India, [3]Institut National de la Santé et de la Recherche Médicale (INSERM), Paris, France.

Type 1 diabetes is a complex autoimmune disease with a strong genetic influence. We have investigated the role of the CTLA4 (Cytotoxic T-lymphocyte associated antigen -4) exon 1 A49G polymorphism and its role as a risk factor for T1D in the North Indian population. We studied 232 type 1 diabetic patients and 200 healthy controls by PCR amplification followed by restriction enzyme digestion with FnU4HI. Allele G at +49 position in codon1 of CTLA 4 gene was significantly increased in type 1 diabetic patients as compared to that in healthy controls (37.3% in patients vs 29% in controls, p= 0.012, OR=1.46, 95%CI= 1.09-1.94). Further, the frequency of homozygous GG genotype was significantly increased among patients than controls (15.5% vs 5.0%, p=0.001, OR=3.49 (95% CI=1.7-7.13)). The patients with younger age at onset of disease (<14 years) had a significantly high frequency of G positive genotypes (A/G or G/G) than those with an older age at onset of disease ≥(14 years) (66% vs 47.1%, p=0.007, OR=2.18 (95%CI=1.27-3.76). Further analysis involving the HLA data revealed that the CTLA4 +49G allele is not in linkage disequilibrium with the reported susceptible HLA-DR3 allele, however the susceptibility conferred by +49G allele as well as its effect on the disease onset was observed to be dependent on the presence of HLA-DR3 allele. These results suggest that CTLA4 +49G allele in the presence of HLA-DR3 allele not only confers susceptibility to T1D and but is a strong marker for acceleration of disease development

P5.03.14
TRIM39R, but not TRIM39B regulates type I interferon

R. Kurata[1]*, A. Tajima*[2]*, T. Yonezawa*[1]*, H. Inoko*[3]*;*
[1]Research institute for biomedical sociences, Tokyo University of Science, Chiba, Japan, [2]The University of Tokushima, Tokushima, Japan, [3]Tokai University, Isehara, Japan.

Behçet's disease (BD) is a chronic systemic inflammatory disease characterized by recurrent oral and genital ulcers, skin legions, uveitis and arthritis and its pathogenesis is not fully elucidated. However, the onset of BD is biased among regions and human races, thus, both genetic factor such as HLA-B*51 and environmental factor such as infection of some kind of bacteria or virus are thought to be important for the pathogenesis. Previously, we identified two SNPs are associated with BD. One is l is located on tripartite motif 39 (TRIM39) coding exon and another is also located on ribonuclease P/mitochondrial RNA processing 21 kDa subunit (Rpp21).
Recent studies suggest that a few member of family play an important role for regulation of innate immune pathway including type I interferon and defenses of viral infection. Moreover, TRIM39 fused Rpp21 (TRIM39R) probably generated by intergenic splicing, which is expressed in human normal tissues although conventional TRIM39 (TRIM39B) is also expressed. We hypothesized that TRIM39 may be involved in immune responses such as anti-virus response and type I interferon pathway and the pathogenesis of BD. We found TRIM39B, TRIM39R and RPP21 protein is expressed in human T and B cells. However, molecular function of TRIM39 including both TRIM39B and TRIM39R remains to be unidentified.
In this study, in order to identify the molecular function, we thus established gain of function models using CMV promoter-mediated overexpression and performed microarray analysis. Our results indicate that TRIM39R, but not TRIM39B, regulates type I interferon pathway.

P5.03.15
A "candidate-interactome" analysis of genome-wide association data in multiple sclerosis

R. Mechelli[1]*, R. Umeton*[1]*, C. Policano*[1]*, V. Annibali*[1]*, G. Coarelli*[1]*, V. A. G. Ricigliano*[1]*, A. Fornasiero*[1]*, -. IMSGC WTCCC2*[2]*, G. Ristori*[1]*, M. Salvetti*[1]*;*
[1]Centre for Experimental Neurological Therapies, S. Andrea Hospital-site, Department of Neuroscience, Mental Health and Sensory Organs (NESMOS), Faculty of Medicine and Psychology, Sapienza University, Rome, Italy, [2]The International Multiple Sclerosis Consortium & the Wellcome Trust Case Control Consortium 2, Oxford, United Kingdom.

The study of gene-environment interactions in multifactorial diseases is crucial for interpreting the relevance of non-heritable factors and prevents from overlooking genetic associations with small but measurable effects. We propose a "candidate interactome" (i.e. a group of genes whose products are known to physically interact with environmental factors that may be relevant for disease pathogenesis) analysis of genome-wide association data in multiple sclerosis. We looked for statistical enrichment of associations among interactomes that may be representative of gene-environment interactions of potential, uncertain or unlikely relevance for multiple sclerosis pathogenesis: Epstein-Barr virus, human immunodeficiency virus, hepatitis B virus, hepatitis C virus, cytomegalovirus, HHV8-Kaposi sarcoma, H1N1-influenza, JC virus, human innate immunity interactome for type I interferon, autoimmune regulator, vitamin D receptor and a panel of proteins targeted by 70 innate immune-modulating viral open reading frames from 30 viral species. Interactomes were either obtained from the literature or were manually curated. The P values of all single nucleotide polymorphism mapping to a given interactome were obtained from the last genome-wide association study of the International Multiple Sclerosis Genetics Consortium & the Wellcome Trust Case Control Consortium,2. The interaction between genotype and Epstein Barr virus emerges as relevant for multiple sclerosis etiology. However, in line with recent data on the coexistence of common and unique strategies used by viruses to perturb the human molecular system, also other viruses have a similar potential, though probably less relevant in epidemiological terms.

P5.03.16
Immunological relations between autoimmune diseases in Thyroid Screening with Vitiligo

V. Mehrotra[1]*, G. Awasthi*[2]*, A. Hamidy*[2]*;*
[1]*Himalayan Institute of Medical Sciences, Dehradun, India,* [2]*Dolphin Institute of Para Medical Sciences, Dehradun, India.*

Objectives: Vitiligo is a well-recognized pigmentary disorder known as an autoimmune disease. Autoimmune plays an important role in the pathogenesis of Vitiligo. Autoimmune thyroid disease is also a common autoimmune disease, and it is related to Vitiligo. The objectives of our study were to find the relationship of between autoimmunity, autoimmune thyroid disease and Vitiligo.
Methods: Our study was planned to evaluate Immunological the thyroid function test (Free T3, Free T4 and TSH) and to detect the presence of anti-TPO in patients with Vitiligo in our population.
Results: According to our study the rate of anti-TPO positivity was found to be 22.44% which shows statistically significant in Vitiligo patients compared with control. The difference in the prevalence of anti-TPO was significant in male cases compared with female. There was also a significant difference between the means of FT3, FT4 and TSH between patients and control group. Serum levels of FT4 and TSH was lower and higher respectively in Vitiligo patients as compared with controls.
Conclusions: Cellular immunity plays an important part in the pathogenesis of Vitiligo. Vitiligo cases are shown to be more at risk of evolution toward subclinical thyroid disease particularly; hypothyroidism and Thyroid dysfunction may result in the progress of Vitiligo.

P5.03.17
Alteration of promiscuous gene expression in the thymus is associated to susceptibility to autoimmune type 1 diabetes mellitus in mice

E. H. Oliveira*, C. Collares, C. Macedo, E. Sakamoto-Hojo, E. Donadi, G. Passos;*
Universidade de São Paulo, Ribeirão Preto, Brazil.

Thymic central T cell self tolerance is a process dependent of promiscuous gene expression (PGE), which is characterized by ectopic expression of peripheral tissue antigens (PTAs) in medullary thymic epithelial cells (mTECs) a phenomenon partially controlled by Aire. Autoimmune type 1 diabetes (T1D) results from the breakdown of T cell self tolerance to pancreatic β cells autoantigens. Based on these evidences we hypothesized that alterations of PGE in mTECs might contribute to T1D susceptibility. To test this, we compared such expression of mTECs from two mouse strains: NOD (autoimmune, which develops T1D) and BALB/c (non-autoimmune). The expression profiles of PTA genes were evaluated in mTECs cells from 5-6 week female animals by the microarray method. Hierarchical clustering of microarray expression profiles showed that expression of Aire was not changed between strains. Nevertheless, the major known diabetes autoantigens such as Ins1, Ins2, Gad1, Gad2, and Ica1 were comparatively down regulated in NOD mice whereas IA-2 was up regulated. Interestingly, the qRT-PCR analyses for Aire showed that in NOD mice and during T1D development, the expression of this gene is higher in the pre diabetic period while T1D autoantigen genes are decreased. Taking on account the recent evidence that Aire also controls the expression of microRNAs, the opposite correlation between the expression of this gene and T1D autoantigens might be due to post-transcriptional effect of Aire-dependent microRNAs. These results contribute to a better understanding on transcriptional and post-transcriptional control of PGE and central tolerance.

P5.03.18
Analysis of B-cell activating factor (BAFF) gene polymorphisms (-2841 T/C, -2704 T/C, -2701 T/A, -871 C/T) and soluble BAFF levels in primary Sjögren´s syndrome

B. A. Treviño-Talavera[1]*, C. A. Palafox-Sánchez*[1,2]*, J. F. Muñoz-Valle*[1]*, M. Vázquez-Villamar*[1]*, R. E. Navarro-Hernández*[1]*, G. Orozco-Barocio*[2]*, M. Vázquez-Del Mercado*[3]*,* ***E. Oregon-Romero***[1]*;*
[1]*Grupo de Inmunogenética Funcional, CUCS, Universidad de Guadalajara, Guadalajara, Mexico,* [2]*Servicio de Reumatología Hospital General de Occidente (SSJ), Zapopan, Mexico,* [3]*IIRSME, CUCS, Universidad de Guadalajara, Guadalajara, Mexico.*

B cell activating factor (BAFF) has been found over expressed in primary Sjögren´s syndrome (pSS) patients. BAFF may be responsible of an exacerbated survival, recruitment and differentiation of autoreactive B cells in salivary gland of pSS patients. Haplotypes inferred from polymorphisms -2841T>C, -2704T>C, -2701T>A, and -871C>T in BAFF gene, may be associated with over expression of this cytokine. We included 104 pSS patients and 115 healthy subjects. SSDAI/SSDDI activity and damage indexes were applied. Genotypes were identified by PCR-RFLP technique. Linkage disequilibrium and haplotype inference were performed using SNPAnalyzer v2.0 and Arlequin v.3.5.1.3. Soluble BAFF levels (sBAFF) were quantified by ELISA test. Statistical analysis was performed using PASWv.18.The C allele carriers of -2704T>C polymorphism, showed increased damage disease (p=0.038). The A allele carriers of the -2701 T>A polymorphism showed high levels of rheumatoid factor (p=0.024). Polymorphisms were in linkage disequilibrium; twelve haplotype was inferred. TTTC haplotype was associated with susceptibility to pSS (p=0.023), but only 2.3% of patients were carriers. Elevated sBAFF levels were found in pSS (p=0.042). Association between sBAFF levels and SSDDI index was found (p=0.001). In patients, no significant differences for sBAFF levels, according to alleles, genotypes or haplotypes were found. Our findings suggest an association of -2704T>C and -2701T>A polymorphisms with an increased severity of pSS. Despite high sBAFF levels in pSS patients and the association of TTTC haplotype with susceptibility to pSS, given its low frequency is not feasible to use it as a genetic marker for susceptibility to the pSS in our population.

P5.03.19
Interleukin-10 gene polymorphisms (-1082 A/G, -819 C/T, -592 C/A) in primary Sjögren's syndrome

M. Vázquez-Villamar[1]*,* ***E. Oregon-Romero***[1]*, D. C. Salazar-Camarena*[1]*, B. A. Treviño-Talavera*[1]*, G. Orozco-Barocio*[2]*, J. F. Muñoz-Valle*[1]*, Y. Valle*[1]*, C. A. Palafox-Sánchez*[1,2]*;*
[1]*Grupo de Inmunogenética Funcional, CUCS, Universidad de Guadalajara, Guadalajara, Mexico,* [2]*Servicio de Reumatología Hospital General de Occidente (SSJ), Zapopan, Mexico.*

Introduction: Primary Sjögren´s syndrome (pSS) is an autoimmune disease of unknown etiology affecting primarily salivary and lacrimal exocrine glands. It is characterized by a progressive lymphocytic infiltration where B cells produce a great variety of antibodies, including those against ribonucleoproteins Ro and La. IL-10 plays an important role in pSS by promoting the differentiation of B cells and inducing antibody production. Three polymorphic sites located at positions -1082 (A/G), -819 (C/T) and -592 (C/A) in the IL-10 promoter show a linkage disequilibrium and form haplotypes that may influence the IL-10 production and consequently an increased activity of the disease. Objective: To determine the frequency of haplotypes in the IL-10 promoter gene in patients with pSS. Methodology: The study included 113 Mexican mestizo patients with pSS, classified according to the American-European Consensus criteria, from the Department of Rheumatology (Hospital General de Occidente, SSJ). As control group, 154 clinically healthy subjects were included. The polymorphisms were genotyped by PCR/RFLP technique. Statistical analysis was carried out with the Stata 9.0 and EmHapFre software. Results: Polymorphisms were in Hardy-Weinberg equilibrium (-1082 A/G p=0.8377, -819 C/T p= 0.1174, -592 C/A p=0.7953) and showed high linkage disequilibrium (100%, pc=1.42 x 10-34).The most frequent haplotypes were: ACC (41-61%), ATT (21.38%), GTA (14.86%), and GCC (11.18%). GTC haplotype was associated with a 4.35-fold less probability to develop pSS [OR; 95%CI: 0.23 (0.064-

0.792) p= 0.01]. Conclusion: Our results suggest that carriers of the GTC haplotype have a protective status for the development of pSS.

P5.03.20
Association between cytokine genes' polymorphism and susceptibility to and severity of mixed connective tissue disease (MCTD)

***A. Paradowska-Gorycka**, A. Felis-Giemza, M. Jurkowska, M. Olesinska;*
Institute of Rheumatology, Warsaw, Poland.

Introduction. Mixed connective tissue disease (MCTD) is a relatively rare systemic autoimmune disease (about 10 cases/100 000). The altered pattern of cytokines or/and immune cells may contribute to the pathogenesis of MCTD and their balance determinates disease activity. In our study we analyzed the potential association of the cytokine gene variants encoding IL-10, IL-12 and IL-17F with disease susceptibility and clinical phenotype in MCTD patients.
Methods. A study group consisted of 68 patients with MCTD and of 106 healthy individuals. The SNPs in the IL- 10, IL-12B and IL-17F genes were investigated by PCR-RFLP approach. Results were correlated to clinical and laboratory parameters.
Results. The frequency of the IL-10-592CA, -592AA, -1082GA and -1082AA genotypes were higher in MCTD patients compared with the control group (p=0,0001, p=0,0419, p=0,0004 and p=0,0336, respectively). The homozygous wild genotype for IL-17F (+7488AA genotype) was observed in 80% of patients with MCTD and in 92% of controls (p=0,0334). In addition the -1082G/A IL-10 gene polymorphism was associated with puffy hands, esophageal involvement, ESR/CRP elevation and with anti-U1-A and -C antibodies positivity in our group. The IL-17 +7488A/G variant showed correlation with esophageal involvement anti-SmB and anti-DNA antibodies presence, while the IL-17F +7383A/G variant was associated with Sjögren syndrome. The IL -12 SNP +1188A/C correlated with sclerodactyly in MCTD patients.
Conclusion. Our results for the first time showed the relationship between IL-10, IL-12B and IL-17F gene polymorphisms and susceptibility to and severity of MCTD pinpointing gene variants that may be considered as risk factors in that entity.

P5.03.21
Dysfunction of ABIN1 as genetic basis for lupus nephritis

*D. Caster[1], E. Korte[1], K. McLeish[1], P. Gaffney[2], I. Adrianto[2], S. Nanda[3], P. Cohen[3], **D. Powell**[1];*
[1]University of Louisville School of Medicine, Louisville, KY, United States, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK, United States, [3]Phosphorylation Unit Dundee, Dundee, United Kingdom.

It is estimated at least five million people worldwide have a form of systemic lupus erythematosis (SLE).Lupus nephritis (LN) occurs in about 50% of patients with SLE, and it is a major cause of morbidity and mortality. Recent studies implicate NF-κB and MAPK activity in the pathogenesis of LN. We previously reported that a knock-in mouse with native A20 binding inhibitor of NF-κB 1 (ABIN1) replaced by ABIN1[D485N] demonstrated enhanced activation of NF-κB and MAPKs in immune cells in response to TLR agonists and developed lupus-like autoimmune disease. In the current study we show that ABIN1[D485N] mice develop progressive glomerulonephritis similar to the most common and severe form of human LN. To investigate a clinical relevance for ABIN1 dysfunction, we genotyped 5 single nucleotide polymorphisms in the ABIN1 gene TNIP1 previously associated with systemic sclerosis, psoriasis, and SLE in European-ancestry, African American, Asian, Gullah and Hispanic populations. Comparing SLE cases with nephritis versus SLE cases without nephritis showed strong associations with LN at rs7708392 in European Americans and rs4958881 in African Americans. Our data suggest that polymorphisms in the TNIP1 gene participate in the pathogenesis of LN, via aberrant ABIN1 regulation of NF-κB and MAPK activity. Further, this mouse model closely replicates the human disease and, therefore, potentially serves as an effective tool to study diagnostic and therapeutic strategies for SLE and LN.

P5.03.22
Neurotransmitter GABA-A MAY regulate immune system functions as detected by gene networks of peripheral blood TCD4$^+$, TCD8$^+$ and CD14$^+$ cells of recently diagnosed Type 1 Diabetes Mellitus

*D. M. Rassi, A. F. Evangelista, G. Martelli-Pallomino, J. O. Crispim, I. J. Wastowski, M. Foss-Freitas, M. C. Foss, E. T. Sakamoto-Hojo, G. A. Passos, **E. A. Donadi**;*
University of Sao Paulo, Ribeirao Preto, Brazil.

Gamma-aminobutyric acid (GABA) is a major inhibitory neurotransmitter primarily produced by neurons and pancreatic beta cells. GABA functional receptors (GABRA) are expressed in brain, pancreas and peripheral blood lymphomononuclear cells (PBMC). After evaluating the differential gene expression in PBMC of recently diagnosed type 1 diabetes mellitus patients (T1D), three GABRA networks were observed, modulating the expression of genes of the immune system. The study was conducted on T CD4$^+$, T CD8$^+$ and CD14$^+$ cells obtained from 20 pre-pubertal patients and 20 age and sex-matched healthy controls, using cDNA microarrays. Significant and differentially expressed genes, revealed using the SAM program, were studied for gene networks. Three different GABRA subunit class genes (alpha1, alpha6 and beta1) up-regulated the expression of the genes related to cell cycle (CNNB1 cyclin M1, STOM stomatin), apoptosis control (FAS, TNF receptor superfamily, BAT3, HLA-B associated transcript 3), cellular receptor (IL1RAP, interleukin 1 receptor accessory protein, BCAP29, B cell receptor, IK cytokine, down-regulator of HLA II), complement control (CD93, C1q receptor), glucose metabolism (PFKFB2, 6-phosphofructo-2-kinase), insulin receptor (INSR), ubiquitins (UBC, ubiquitin C, UBE2Z ubiquitin-conjugating enzyme E2Z, UBR4 ubiquitin protein ligase E3 component recognin 4, and UBAP, ubiquitin associated protein 1), growth factor (COL6A2, collagen, FGF13, fibroblast growth factor 13, FGF9, Fibroblast growth factor 9). Although the role of GABA and GABRA in the pathogenesis of diabetes has not been established, some studies have shown that GABRA down regulates many immune system functions. This study further supports the role of these neurotransmitters on the pathogenesis of T1D.

P5.03.23
The PRL -1149 G/T polymorphism is associated with rheumatoid arthritis and anti-CCP antibodies in Mexican population

***Z. Reyes-Castillo**[1], A. L. Pereira-Suárez[2], C. A. Palafox-Sánchez[3], E. Oregón-Romero[3], J. F. Muñoz-Valle[3];*
[1]Doctorado en Ciencias Biomédicas, Universidad de Guadalajara, Guadalajara, Jalisco, Mexico, [2]Laboratorio de Inmunología, Universidad de Guadalajara, Guadalajara, Jalisco, Mexico, [3]Grupo de Inmunogenética Funcional, Universidad de Guadalajara, Guadalajara, Jalisco, Mexico.

Background. Prolactin (PRL) is a hormone-cytokine that has been involved in autoimmunity due to its immunoregulatory and lymphoproliferative effects. It is produced by various extrapituitary sites including immune cells, under control of an alternative promoter that contains a single nucleotide polymorphism -1149 G/T and could influence PRL mRNA expression.
Objective. To associate the *PRL* -1149 G/T polymorphism with mRNA expression and clinical activity in rheumatoid arthritis (RA) patients from Mexico.
Methods. We enrolled 258 RA patients and 333 control subjects (CS). The clinical indexes (DAS-28, Spanish HAQ-DI) and laboratory assessments (ESR, CRP, RF, anti-CCP, PRL) were performed. The genotypes were identified using the PCR-RFLP method and the *PRL* mRNA expression was determined by qPCR.
Results. According to the dominant model of inheritance, we found an association between the T allele (GT+TT) and decreased RA susceptibility (OR 0.64, 95% CI 0.45-0.92; *p*=0.011). Furthermore, the carriers of the T allele had lower titers of anti-CCP antibodies in comparison to the carriers of the G allele [66 U/mL (10-171) *vs* 125 U/mL (24-222); *p*= 0.03]. The PRL mRNA expression was as follows: GG>GT>TT in both groups (RA: 1>0.72>0.19; HS: 1>0.54>0.28). 5.7% of the RA patients had hyperprolactinaemia, however, the PRL serum levels were similar in both groups (RA: 8.6±8.5 ng/mL; HS: 7.4±5.2 ng/mL).

Conclusions. The *PRL* -1149 T allele is a genetic marker for decreased RA susceptibility and is associated with lowers titers of anti-CCP antibodies in Mexican population. We suggest influence of the genotype upon PRL mRNA expression.

P5.03.24
Combinatorial control of Th17 and Th1 cell function by genetic variation at genes associated with the IL-23 signaling pathway in spondyloarthritis

M. Rybczynska[1], *M. Coffre*[1], *M. Roumier*[1], *E. Sechet*[1], *H. Law*[1], *L. Gossec*[2], *M. Dougados*[3], *E. Bianchi*[1], *L. Rogge*[1];
[1]*Institut Pasteur, Paris, France,* [2]*Hospital Cochin, Department of Rheumatology B, Paris, France,* [3]*Hopital Cochin, Department of Rheumatology B, Paris, France.*

Genome-wide association studies have revealed numerous genetic associations between specific single nucleotide polymorphisms (SNPs) and immune-mediated inflammatory diseases, pointing to new directions in the study of disease mechanisms. The current challenge is to correlate the genetic variants with the effector mechanisms implicated in pathogenesis, to allow translation of the genetic data into novel diagnostics and treatment strategies. We have investigated the link between genetic variation at loci associated with spondyloarthritis (SpA) and the effector function of $CD4^+$ T lymphocyte subsets involved in chronic inflammatory disease.
We found that the effector functions of Th17 and Th1 cells in SpA patients are under combinatorial control by multiple SNPs at genes associated with the IL-23/Th17 pathway. SpA patients carrying risk-associated alleles of genes in this pathway expressed the highest levels of genes involved in the differentiation and function of Th17 and Th1 cells, whereas the presence of protective alleles was associated with low-level expression of these genes. In contrast, variation at loci genetically linked to SpA, but not associated with the IL-23 pathway, did not affect the expression of Th17 and Th1 genes, suggesting that these SNPs may contribute to SpA pathogenesis through distinct cellular mechanisms. Our results show that genetic variation at genes associated with the IL-23 signaling pathway affects the effector functions of Th17 and Th1 cells in SpA patients and provide a framework to delineate the mechanisms by which genetic variants contribute to pathology.

UCLA, Los Angeles, CA, United States.

Most autoimmune diseases are more common in women than men. Studies in animal models suggest a role of sex chromosome genotype in modulating autoimmune susceptibility. Here, we begin to translate these murine findings onto humans. Our hypothesis is that X chromosome dosage, rather than the female sex itself, imparts susceptibility to autoimmune diseases. Results show that levels of IgG anti-chromatin, anti-nucleosome and anti-histone (H2A, H2B and H3) autoantibodies were significantly higher in men with sex chromosome aneuploidy (47,XXY) compared to 46,XY men. XXY men, however, did not have non-specific B cell hyper-reactivity, as the levels of anti-thyroid peroxidase antibody that is associated with autoimmune thyroiditis were similar between the two groups. A preliminary analysis of clinical questionnaire revealed an increase in autoimmune conditions when compared with known population prevalence of these diseases. Immune phenotyping of blood cells conducted thus far showed a higher frequency of natural killer T-cells in 47,XXY men than in 46,XY men. These data suggest a role of X chromosome dosage in inducing autoimmunity in humans. Since animals and humans with autoimmune diseases have reduced numbers and/or functions of natural killer T-cells, our observation of reduced natural killer T-cells in 47,XXY men may be related to increased autoimmunity in these men.

P5.03.26
Study of programmed cell death 1 (PDCD1) genepolymorphims in Iranian patients with Ankylosing Spondylitis

N. Soleimanifar*;*
Department of Molecular Medicine, School of Advanced Medical Technologies, Tehran University of Medical Sciences, Tehran, Iran.

Ankylosing spondylitis (AS) is a chronic inflammatory disease, characterized by axial arthritis in which the genetic-environmental factors seem to be involved in the pathogenesis of the disease. This study was performed to investigate the role of polymorphisms of the programmed cell death 1 (PDCD1) gene on susceptibility to AS. In this study, 161 Iranian patients with AS and 208 normal controls were enrolled; two single-nucleotide polymorphisms (SNPs) of the PDCD1 gene PD-1.3 (G, A) in nucleotide position +7146 of intron 4 and PD-1.9 (C, T) in nucleotide +7625 of exon 5 were studied. Analysis of PD-1.3 revealed that 82% of patients and 79% of controls had GG genotype, while GA and AA genotypes were detected in 17% and 0.6% of patients, respectively, and 20% and 1.4% of controls, respectively. Moreover, the genotype CC (PD-1.9) was present in 92% of patients and 97% of controls. Although these differences were not statistically significant between patients and controls, comparisons of genotypes frequencies in the AS patients, based on human leukocyte antigen (HLA)-B27, revealed that all patients who had CT genotype (PD-1.9) were HLA-B27 positive, whereas 30% of patients with CC genotype were HLA-B27 negative.There was no evidence of association for PDCD1 SNPs with AS in our study, but CT genotype (PD-1.9) seems to be associated with HLA-B27 positivity in the patients with AS.

Endocrine orgam-specific autoimmunity in myasthenia gravis with thymoma related to defective function of the autoimmune regulator (*AIRE*)

A. S. B. Wolff[1], *K. Kisand*[2], *J. Owe*[3], *N. Gilhus*[1,3], *M. M. Erichsen*[3], *B. E. V. Oftedal*[1], *N. Willcox*[4], *E. S. Husebye*[1,3];
[1]*University of Bergen, Bergen, Norway,* [2]*University of Tartu, Tartu, Estonia,* [3]*Helse-Bergen, Bergen, Norway,* [4]*University of Bergen, Oxford, United Kingdom.*

There are unexplained parallels between patients with the monogenic auto-immune polyendocrine syndrome type I (APS-I), caused by *AIRE* gene mutations, and with thymoma. The parallels include autoantibodies neutralizing type I interferons and IL-17/ IL-22. To test our hypothesis that these parallels extend beyond cytokine antibodies, we screened 239 MG patients with or without thymoma for the seven endocrine autoantibodies we routinely test in our APS-I patients. Conversely, we also tested 38 APS-I patients for autoantibodies against acetylcholine receptor and titin. Forty-four per cent of MG/thymoma patients had antibodies against at least one of the APS-I-type autoantigens, and 8.3% of the MG/thymoma-patients had clinical manifestations typical of APS-I, but they did not always co-occur in the same individuals: both were rare in other MG subgroups. By contrast, no APS-I patient had antibodies against the muscle antigens tested, nor did any of them show the muscle weakness characteristic of MG. The obvious connection between these autoimmune syndromes is thymopoiesis in the absence of AIRE. We demonstrate that thymoma expression of AIRE correlates with thymoma expression of some APS-I antigens although not with others. Antibody presence against APS-I targets did not correlate to either AIRE expression nor to the corresponding autoantigen for the panel we analysed. Notably, large individual differences were seen.
These results indicate a one-way clinical and serological overlap between thymoma and APS-I patients. We propose that the AIRE-deficiencies in the thymic epithelial cells in each syndrome create a hostile microenvironment against selected available AIRE-independent tissue-specific antigens, including abundant cytokines.

P5.03.28
Behçet's Syndrome in Iranian Azari People

F. Zare Shahneh[1,2]*, B. Baradaran*[2]*, S. Moradi*[2]*, F. Hamzavi*[2]*, B. Bayazi*[2]*;*
[1]*Student Research Committee, Faculty of Medicine, Tabriz University of Medical Sciences., Tabriz, Iran,* [2]*Immunology Research Center, Tabriz, Iran.*

Behçet's syndrome (BS) is a chronic recurrent multisystemic inflammatory disorder characterized by oral and genital ulcers, ocular inflammation. Behçet's syndrome has a complex genetic etiology. However, epidemiological studies recommend that genetic factors have a significant influence to its pathogenesis, alike to other autoinflammatory disorders. Epidemiological statistics, clinical records and Human Leukocyte Antigen (HLA) typing were studied in Iranian Azari patients with Behçet's syndrome. This investigation is considered HLA associations with BS, and HLA with certain clinical characteristics, age and sex in the (Tabriz) Iran, which has an ethnically homogeneous population. HLA-A and HLA-B typing was performed in 290 BS patients, conforming to International Study Group criteria and in 300 blood donors, as controls. Patient records were retrospectively reviewed and patients reassessed clinically. HLA-B5, HLA-B35, HLA-51, HLA-B52, and HLA-CW4 presented significantly high frequencies in all patients. No other HLA type was associated. There was a significant HLA link with male sex in BS patients and Mean age (34 ± 1.1) was determined. We present the frequency and correlation between Iranian Azari patients with Behçet's syndrome and particular HLA antigens. All patients had mouth ulceration, 64% genital ulceration, 72% skin lesions, and 52% ocular involvement. This study supports HLA-B5, HLA-B35, HLA-51, HLA-B52, and HLA-CW4 immunogenetic predisposition in an ethnically homogeneous (Iranian Azari) population.

P5.05 Environmental factors in autoimmunity and allergy

P5.05.01
Nutrition has relation with lifetime asthma diagnosis in middle-aged

M. Akhbardeh*, A. Sadeghi;*
Boston Medical Group, Hawthorn, MI, United States.

Background: There is abundant research relevant to genetic and environmental influences on asthma and hayfever, but little is known about dietary risk factors in Australian adults. This study's purpose was to identify dietary factors associated with lifetime asthma (AS) and asthma or hayfever (AS/HF) diagnosis in Australian middle-aged and older adults.
Methods: From The 45 and Up Study baseline self-report data, this study included 156,035 adult men and women. Participants were sampled from the general population of New South Wales, Australia in 2006-2009. About 12% of participants reported ever receiving an AS diagnosis (men 10%; women 14%) grains/alcohol) or five factors for women (meats; fruits/vegetables.
Results: For men, the meats/cheese factor was positively associated with AS (AOR = adjusted odds ratio for highest versus lowest quintile = 1.18, 95%CI = 1.08, 1.28; P_{trend} = 0.001) and AS/HF (AOR for highest versus lowest quintile = 1.22, 95%CI = 1.14, 1.29; P_{trend} < 0.001). Poultry/seafood was also associated with AS/HF in men (AOR for highest versus lowest quintile = 1.11, 95%CI = 1.04, 1.17; P_{trend} = 0.002). For women, significant risk factors for AS/HF included meats (AOR for highest versus lowest quintile = 1.25, 95%CI = 1.19, 1.31; P_{trend} = 0.001P_{trend} = 0.011). In contrast, the cheese/
Conclusions: Generally, diets marked by greater intakes of meats, poultry, and seafood were associated with diagnosed AS and AS/HF. Taken together, these findings suggest that adherence to a more meat-based diet may pose risk for AS and AS/HF in Australian adults.

P5.05.02
High psychological stress in children may alter the immune response

E. Carlsson[1]*, A. Frostell*[2]*, J. Ludvigsson*[2]*, M. Faresjö*[1]*;*
[1]*Department of Natural Science and Biomedicine, School of Health Sciences, Jönköping University, Jönköping, Sweden,* [2]*Division of Pediatrics, Department of Clinical and Experimental Medicine, Faculty of Health Sciences, Linköping University, Linköping, Sweden.*

Psychological stress is a public-health issue in children and has been associated with a number of immunological diseases. The aim of this study was to examine the relationship between psychological stress and immune response in healthy children, with special focus on the insulin-producing beta-cells.
Psychological stress was based on a composite measure of stress in the family across the domains: 1) serious life events; 2) parenting stress; 3) lack of social support and 4) parental worries. Peripheral blood mononuclear cells (PBMC), collected from five-year-old high-stressed children (n=26) and from five-year-old children without high stress within the family (n=52), from the All Babies In Southeast Sweden (ABIS)-cohort, were stimulated with antigens (tetanus toxoid and beta-lactoglobulin) and diabetes-related autoantigens (GAD_{65}, insulin, HSP60 and IA-2). Immune markers; cytokines and chemokines, clinical parameters; C-peptide, pro-insulin and glucose; cortisol, in serum and hair, as an indicator of stress, were analysed.
Results: Children from families with high psychological stress showed a low spontaneous immune activity (IL-5, -10, -13, -17, MIP-1α, MCP-1 and IP-10 ($p<0.01$)) but an increased immune response to tetanus toxoid and beta-lactoglobulin and the autoantigens GAD65,HSP60 and IA-2 (IL-5, -6, -10, -13, -17, IFN-γ, TNF-α, MIP-1α, MCP-1 and IP-10 ($p<0.05$)). Children within the high-stress group showed higher levels of cortisol, pro-insulin and C-peptide compared to the control group ($p<0.05$).
Conclusion: Psychological stress may contribute to an imbalance in the immune response but also to a pathological effect on the insulin-producing beta-cells.

P5.05.03
Infection with the respiratory pathogen *Bordetella pertussis* modulates the course of experimental autoimmune encephalomyelitis

S. Edwards*, S. C. Higgins, N. McGuinness, K. H. G. Mills;*
Immune Regulation Group, School of Biochemistry and Immunology, Trinity Biomedical Sciences Institute, Trinity College Dublin, Dublin, Ireland.

Epidemiological studies have described an association between infection with certain bacteria or viruses and development of autoimmune diseases, such as multiple sclerosis (MS). Conversely, infection with helminth parasites has been associated with a reduced incidence and severity of autoimmunity. Whooping cough is a re-emerging vaccine-preventable infectious disease caused by the bacteria *Bordetella pertussis*. Clearance of the bacteria is associated with the induction of Th1 and Th17 cells. However, the infection is persistent and is also associated with the induction of and recruitment of Treg cells to the lungs during the acute stage of disease. In this study we have used a murine model of MS, experimental autoimmune encephalomyelitis (EAE), to examine the effect of infection on development of autoimmunity. Our data reveal that concurrent infection with *B. pertussis* significantly reduced the clinical scores and weight loss in mice with EAE. This reflected a significant reduction in the frequency of infiltrating IL-17$^+$, IFN-γ$^+$ and IFN-γ$^+$IL-17$^+$ CD4 and γδ T cells into the central nervous system (CNS) of *B. pertussis* infected compared with uninfected mice with EAE. An examination of antigen-specific T cell responses in lymph nodes and spleen revealed that systemic IL-17A and IFN-γ production was significantly enhanced in infected mice with EAE. Our findings demonstrate that a bacterial infection can attenuate the course of EAE in mice and that this may reflect the suppressive effect of bacteria-induced Treg cells, which appear to be capable of preventing Th1 and Th17 cells from entering the CNS.

P5.05.04
Bisphenol A suppresses interferon-gamma production and related biochemical pathways in human PBMC

*E. Raggl[1,2], S. Geisler[1,2], H. Schennach[3], J. M. Gostner[1,2], **D. Fuchs**[1,2];*
[1]Biocenter, Innsbruck, Austria, [2]Medical University, Innsbruck, Austria, [3]Central Institute of Blood Transfusion and Immunology, Innsbruck, Austria.

Bisphenol A (BPA) is one of the most widely distributed chemicals. Humans are exposed to it mainly via polycarbonate plastics that are used for food packaging and plastic bottles and contain BPA as a softener. There is accumulating evidence of a carcinogenic and allergy-promoting effect of BPA. *In vitro* we investigated the impact of BPA on freshly isolated human peripheral blood mononuclear cells (PBMC) from healthy donors. PBMC were incubated with increasing doses of BPA, and after 30 min either left unstimulated or stimulated with the mitogen phytohemagglutinin (PHA) and cell viability was controlled.
After 48 h, formation of interferon-γ (IFN-γ), macrophage product neopterin as well as tryptophan breakdown by indoleamine 2,3-dioxygenase (IDO), expressed as the kynurenine to tryptophan ratio (Kyn/Trp), were monitored. All these immunobiochemical pathways are characteristic for cell-mediated (= Th1-type) immune response. Upon PHA stimulation, neopterin production and tryptophan breakdown increased significantly compared to unstimulated cells. BPA exerted a dose-dependent suppressive effect in unstimulated and in PHA-stimulated PBMC at 12.5 - 200 µM concentrations. Due to the cross-regulation of Th1- and Th2-type immunity, the suppressive effects of BPA on Th1-type immunity could relate to the allergy-promoting properties of the compound. Moreover, the inhibition of IFN-γ production and its related antiproliferative effects could be of relevance for the tumor-promoting effect of this chemical. On the other side, the antioxidant compound could also have beneficial effects, possibly delaying or even preventing Th1-type immunopathologies.

P5.05.05
Epicutaneous exposure to nanoparticles is potential initiator of IgE-mediated hypersensitivity induced by IgG reduction

***T. Hirai**[1], Y. Yoshioka[1], H. Takahashi[1], K. Ichihashi[1], N. Nishijima[1], T. Yoshida[1], S. Tsunoda[2,3], K. Higashisaka[1], Y. Tsutsumi[1,2,3];*
[1]Laboratory of Toxicology and Safety Science, Graduate School of Pharmaceutical Sciences, Osaka University, Osaka, Japan, [2]Laboratory of Biopharmaceutical Research, National Institute of Biomedical Innovation, Osaka, Japan, [3]MEI center, Osaka University, Osaka, Japan.

It is widely known that exposure to ambient particulate matter (PM), such as diesel exhaust or crystalline silica, exacerbate allergic disorders. Because lung-related disorders were often observed after PM exposure and PM might not penetrate the skin barrier, we have believed the importance of inhaled PM for PM-related allergic disorders. On the other hand, recent studies suggest the involvement of sensitization of skin with airborne antigens in the pathogenesis to asthma. We further revealed that nano-sized particle (≦100 nm) can penetrate the skin barrier. Considering the recent reports that PM contains a large nano-sized particles fraction together, it is possible that PM-related allergic disorders might be induced not only by inhaled exposure, but also epicutaneous exposure to PM. Here we investigated the effect of epicutaneous exposure to silica nanoparticles (nSP) on epicutaneous sensitization in NC/Nga mice. Repeated epicutaneous applications of mixture of mite extract antigen (Dp) with nSP did not change Dp-specific IgE levels compared with Dp-alone. In contrast, the Dp-specific IgG levels were significantly reduced by epicutaneous exposure to nSP30. It is known that allergen-specific IgG work as blocking antibody to inhibit IgE-mediated allergic responses and we showed nSP-mediated reduction of IgG induced IgE-mediated hypersensitivity in Dp-mediated anaphylaxis model. We also showed that the changes of antigen dynamics by the interaction between nSP and antigen might be critical determinant to induce IgE-mediated hypersensitivity. Our results suggested that epicutaneous exposure to PM including nano-sized particles potentially contributed to induction of PM-related allergic disorders.

P5.05.06
Serum levels of pro-inflammatory cytokines in rats exposed to car exhaust and cigarette smokin

***M. Hosseinzadeh**[1], A. Khosravi[2], K. Sayemiri[2], M. Motavali[2];*
[1]tehran university of medical sciences, tehran, Iran, [2]Ilam University of Medical sciences, Ilam, Iran.

Background: The immune system mechanisms are changed due to the smoking and airborne pollutant but it is not completely understood to what extent such changing are happening. The current study was conducted to evaluate the smoking exposure and resulted cytokine variations in rat. Materials and methods: Pathogen-free male Wistar rats 4 to 5 weeks old were obtained from the Pasteur Institute of Iran. The rats were placed in three groups each of 8 rats; cigarette smokers, car smokers and the control groups. Rats were placed in some designed racks during smoking so that the smoke can reach them similar to what happens in heavy traffic and what a cigarette smoker does daily. After one month of exposure the blood samples were extracted from the rats and cytokine profiles were measured by ELISA using related diagnostic kit. Data were analyzed using Post Hoc analyzing method and LSD test to compare the mean of cytokine levels within the groups. Results: Car smoke suppressed the production of IL-2, IFN-γ and TNF-α by more than 50 %.amongst all the rat in cases groups while the control group had no changing in their cytokine profile. In contrast, cigarette smoke inhibited production of TNF-α and increased production of the IL-2 and IFN-γ.
Conclusion: This study indicated that cigarette and exhaust smoke contains potent inhibitors and/or suppressor of cytokine production even in a short term exposure time.

P5.05.07
Autoimmune pulmonary alveolar proteinosis and exposure to industrial spray paint

***T. Imran**, Z. Al-Khateeb, P. Jiang;*
Rutgers University, Newark, NJ, United States.

Pulmonary aleveolar proteinosis is a rare disease characterized by accumulation of surfactant lipids and proteins in the alveolar spaces resulting in impaired gas exchange (1). We report the case of a 52 year-old man employed as a spray painter in an automobile shop for 20 years who presented with increasing dyspnea and weight loss for 3 months. CT chest showed diffuse bilateral consolidations with ground glass opacities, interlobular and intralobular septal thickening suggestive of a crazy paving pattern. Subsequent bronchoscopy and right lung lavage showed eosinophilic proteinaceous material, consistent with alveolar proteinosis. Blood tests revealed elevated GM-CSF autoantibodies. PAP is generally classified as autoimmune, acquired, or congenital (2). The autoimmune type, which makes up the majority of reported cases is caused by autoantibodies against GM-CSF (granulocyte-macrophage colony stimulating factor). Environmental exposure to airborne dusts such as aluminum and silicone dioxide has been associated with acquired PAP (3). The clinical presentation may vary greatly from asymptomatic disease to life threatening pulmonary complications (4). Industrial spray painters are known to be exposed to isocyanates and chromium compounds, both of which are linked to asthma. Furthermore, PAP is associated with occupational exposures including silica dust, titanium, aluminum, cement, and tin. Our patient had elevated GM-CSF antibodies, which suggests autoimmune PAP. However, his long-term exposure to industrial spray paint may have served as an environmental trigger to his underlying autoimmune condition. PAP should thus be considered in a patient presenting with respiratory symptoms with occupational exposure to industrial spray paint.

P5.05.08
The investigation of prevalence of allergic rhinitis and single nucleotide polymorphisms of STAT6, IL-4R in Xinjiang of China

***X. f. Jiang**, G. Li, Y. Qing, D. J. hong, M. N. re, Z. Xiu, L. F. tai;*
Xinjiang Medical University, Urumqi, China.

Objective To investigate the prevalence of allergic rhinitis (AR)and the effect factors in North and South Xinjiang.And study the relationship of polymorphism of STAT6(rs167769,3024974,304015,703817), IL-

4R (rs6498011) and IL-4(rs2243283) between allergic rhinitis.Methods Cross-sectional epidemiological study was carried out,and the questionnaires,nasal examination and nasal mucous membrane pathological examination were used to diagnose the prevalence of allergic rhinitis.The relevant factors were analyzed by using the multivariate Logistic regression analysis.Results Among the investigated 4254 cases,644 cases of allergic rhinitis were diagnosed,the total prevalence rate was 15.1%,and the prevalence rate in Uigur population was12.8%.which was less than that in Han (26.1%,P<0.01).The differences of distribution frequencies of genotypes and allelic genes(STAT6 rs703817, IL-4R rs6498011) between AR group and control group were statistically significant (P< 0.05).Conclusion The prevalence rate of allergic rhinitis in Han is much more popular and there is a significant ethnic distribution difference in Xinjiang of China.The STAT6 rs703817 A/G and IL-4R rs6498011A/G may be associated with allergic rhinitis in Uygur.

Immunological analysis of allergic reactions to the carbohydrate α-Gal

D. Kollmann[1], *C. Ebner*[2], *W. Emminger*[3], *A. Mangold*[4], *H. J. Ankersmit*[4], *B. Bohle*[1];
[1]*Department of Pathophysiology and Allergy Research, Medical University of Vienna, Vienna, Austria,* [2]*Allergy Clinic Reumannplatz, Vienna, Austria,* [3]*Allergy Clinic Rennweg, Vienna, Austria,* [4]*Department of Surgery, Medical University of Vienna, Vienna, Austria.*

Purpose. Galα1-3Galβ1-4GlcNAc-R (α-Gal) is a carbohydrate expressed by non-primate mammalians and has recently been described as an important allergenic structure in meat allergy. Since the role of carbohydrates in allergy is still controversial, we sought to investigate the relevance of α-Gal in meat allergy.
Methods. We included 20 patients who had experienced generalized urticaria after consuming meat and showed IgE-reactivity (>0,35 kUA/l) to beef or pork in ImmunoCAP. Additionally, 20 non-meat-allergic patients with birch pollen-allergy and 20 non-allergic individuals were included. α-Gal-specific IgE and IgG1-4 was analysed by ELISA. Protein extracts produced from beef were used in immunoblots to test IgE-reactivity to individual meat proteins.
Results. 19/20 meat-allergic patients showed α-Gal-specific IgE. In immunoblots, 13/19 α-Gal sensitized patients showed IgE-reactivity with a protein at approximately 160 kDa, equivalent to bovine gamma globulin (BGG). IgE-reactivity to BGG was completely abolished after pre-incubation of sera with α-Gal. All individuals displayed α-Gal-specific IgG. Meat-allergic patients showed significantly higher levels of α-Gal-specific IgG, IgG1 and IgG3 than birch pollen-allergic and non-allergic individuals. α-Gal-specific antibodies were mainly IgG1 whereas IgG4 dominated the response to the major birch pollen-allergen Bet v 1 in birch pollen-allergic patients. Addition of sera with high levels of α-Gal-specific IgG to sera of meat-allergic, birch pollen-allergic and non-allergic individuals did not inhibit IgE-binding to α-Gal.
Conclusion. Our data indicate that IgE-reactivity to α-Gal on BGG is important in meat allergy and that it is directed exclusively against the sugar-epitope. The high levels of α-Gal-specific IgG antibodies have no IgE-inhibiting activity.

P5.05.10
Both reactive oxygen species and reactive nitrogen species participate in the redox-regulation of toluene diisocyanate-induced lung inflammation

P. Lo[1], *C. Shieh*[1,2];
[1]*Institution of Clinical Medicine, College of Medicine, National Cheng Kung University, Tainan, Taiwan,* [2]*Department of Pediatrics, National Cheng Kung University Hospital, Tainan, Taiwan.*

Toluene diisocyanate (TDI) is one of the oxidizing chemicals which induce occupational asthma. Workplace exposure to TDI leads to airway inflammation with distinct leukocyte infiltration. Our previous research showed that leukocyte NADPH oxidase is essential for inducing pulmonary inflammation with TDI. To clarify the role of the redox regulation in TDI-induced pulmonary inflammation, we investigated the redox regulation in wild type (WT) mice, NADPH oxidase subunit p47phox single knockout mice (*Ncf1*$^{-/-}$), iNOS single knockout mice (*iNOS*$^{-/-}$), and Ncf1 and iNOS double knockout mice (*Ncf1*$^{-/-}$*iNOS*$^{-/-}$). We found that TDI induce stronger airway hyperresponsiveness (AHR) in WT than in *Ncf1*$^{-/-}$ and *iNOS*$^{-/-}$ mice. Immunochemical staining revealed a marked increase of inflammatory cells in the bronchovascular bundle of WT mice and *Ncf1*$^{-/-}$*iNOS*$^{-/-}$ mice after TDI stimulation. Different from the strong tissue inflammation found in WT mice and *Ncf1*$^{-/-}$*iNOS*$^{-/-}$ mice, the lung tissue from *Ncf1*$^{-/-}$ mice and *iNOS*$^{-/-}$ mice showed milder cell infiltration. In addition, the major cell type of infiltrated cell in *Ncf1*$^{-/-}$ *iNOS*$^{-/-}$ mice was B cell. The levels of IFN-γ and IL-17A in WT mice and *Ncf1*$^{-/-}$*iNOS*$^{-/-}$ mice were significantly higher than that in *Ncf1*$^{-/-}$ mice and *iNOS*$^{-/-}$ mice. Although there was no significant difference in the level of IL-10 in WT, *Ncf1*$^{-/-}$ and *iNOS*$^{-/-}$ mice, the level of IL-10 in *Ncf1*$^{-/-}$*iNOS*$^{-/-}$ mice was significantly higher than that in other groups. We hence conclude that both ROS and RNS participate in the redox-regulation of TDI-induced lung inflammation and the balance between NADPH oxidase and iNOS determines TDI-induced lung inflammation.

P5.05.11
Screening for celiac disease in patients with Hashimoto's thyroiditis

S. Hamdane[1], ***A. Mankai***[2,3], *W. Sakly*[3,4], *M. Chadli-Chaieb*[5], *I. Ghedira*[1,3];
[1]*Laboratory of Immunology, Farhat Hached Hospital, Sousse, Tunisia,* [2]*High School of sciences and techniques of health, Tunis el Manar University, Tunis, Tunisia,* [3]*Research unit (03UR/07-02), Faculty of Pharmacy, Monastir University, Monastir, Tunisia,* [4]*Faculty of Sciences, University of Gabes, Gabès, Tunisia,* [5]*Department of Endocrinology, Farhat Hached Hospital, Sousse, Tunisia.*

Aim. To perform a serological screening for celiac disease (CD) in patients with Hashimoto's thyroiditis (HT).
Patients and methods: Sera from 156 patients with HT were collected and stored at -20° C between January 2010 and June 2012. The control group consisted of 2500 blood donors. All sera were tested for anti-endomysium antibodies (EmA) using indirect immunofluorescence on cryostat sections of human umbilical cord.
Results: The mean age of our patients was 42 years 10 months and the sex ratio F/M was 6,1. EmA were identified in two patients out of 156 (1,28%) and they were present in seven subjects in the control group (0,28%). The frequency of EmA was higher in male patients with HT (4,54%, 1/22) than in females (0,74%, 1/134) but the difference was not statistically significant. In men, the frequency of EmA found in patients with HT was higher than that found in control group but reaching a borderline significance (4,54% vs. 0,23%, p = 0.06).
Conclusion: In this study, the frequency of CD in patients with HT was 1.28%. However, the small size of our sample may represent a limit to our study. Prospective studies involving a larger number of patients are needed.

P5.05.12
The influence of Professional Contact to Fungal Allergens on developing Respiratory Allergy Disorders in workers of bakeries in Georgia

N. Mitskevich[1], *K. Machavariani*[2], *A. Telia*[2], *G. Khechinashvili*[3];
[1]*Iv. Javakhishvili Tbilisi State University, Departement of Immunology and Micrbiology, Tbilisi, Georgia,* [2]*Tbilisi State Medical University, Departement of Allergy and Clinical Immunology, Tbilisi, Georgia,* [3]*Georgian Foundation of Tuberculosis and Lung Deseases, Tbilisi, Georgia;, Tbilisi, Georgia.*

Introduction: The inducing role of sensitization to fungal Allergens of RA (Respiratory Allergosis) originated from exposure to wheat flour environmental dust - has not been studied in Georgia.The aim of the research is to study the specifics of the spread, epidemiological issues of RA induced by professional contact with Fungal Allergens. According to the Global Strategy for Asthma Management and Prevention (NHLBI/WHO), one of the main reasons of developing RA in adults is occupational sensitizing agents.

Materials and Methods: We studied 390 people working in bakeries. They were divided into 2 groups: (1)workers with symptoms of RA [AR(Allergic Rhinitis), BA(Bronchial Asthma) and SEAA(Syndrome of Extrinsic Allergic Alveolitis)] ; (2)workers with no symptoms. There were selected 2 control groupswithout contact with the professional environment : (1)with RA symptoms; (2)healthy individuals.
There was used the unified three-stage respiratory questionnaire (National Heart, Lung and Blood Institute,USA). For the skin tests were used the fungal allergens AF(*Aspergillus fumigatus),* MR(*Mucor racemosus*), AT(*Alternaria tenius),* PN*(Penicillium notatum),* RN*(Rhizopus nigricans)* .
Results: In workers with AR and BA symptomes the sensitization was similary: the highest to AF, high to all three fungal allergens MR, PN and RN (66,7%), The workers with BA were mainly sensitized to the AF(80%) and the sensitization to the MR and PN were revealed to be the least of all. In subjects with SEAA, the highest sensitization was to AF(77,8%).
Conclusion: The professional contact to grain dust frequently induces RA and the reciprocal influence of fungal sensitization significantly increases the risk of RA development.

P5.05.13
Lack of association between serotonin transporter gene polymorphisms and asthma

***M. Moghtaderi**, S. Farjadian, S. Aleyasin, S. Kashef;*
Allergy Research Center-Shiraz University of Medical Sciences, Shiraz, Iran.

Background: Asthma is a worldwide disease which genetic factors play a major role in its pathogenesis. Serotonin (5-hydroxytryptamine, 5-HT) likely has effect on pathophysiology of asthma because higher levels of free serotonin in plasma of asthmatic patients. Serotonin clearance is mediated by a specific protein called the serotonin reuptake transporter (SERT or 5-HTT). Polymorphisms in the promoter region and intron 2 of this gene have effects on transcriptional activity, resulting in altered serotonin reuptake efficiency. The aim of this study was to investigate the relationship of SERT genetic polymorphisms and asthma.
Methods: The 5-HTT LPR, rs25531 and STin2 VNTRs polymorphisms of serotonin transporter gene were assessed by PCR and PCR-RFLP in 100 patients with asthma and 100 healthy controls.
Results: Serotonin reuptake transporter polymorphisms were found to be similar in asthmatic patients and healthy controls and there was no significant difference in allele, genotype, and haplotype frequencies between patients and controls.
Conclusion: Our findings suggest that genetic polymorphisms in the gene encoding for the serotonin transporter is not associated with asthma. While the interaction between environmental factors and predisposing genetic factors are important in the pathophysiology of asthma, further genetic and epigenetic investigations may provide novel insights of the mechanisms contributing in asthma.

P5.05.14
Effect of the indoor air pollutant 2-ethyl-hexanol on immune cells

***K. Morita**, Y. Song, T. Nakanishi, Y. Yoshida;*
University of Occupational and Environmental Health, Fukuoka, Japan.

The polyvinyl chloride floor coverings in damp office buildings emit the 2-ethyl-hexanol (2-EH). 2-EH is related to asthma symptoms by epidemiological investigation, and it is suggested that 2-EH is a causative agent of the sick building syndrome (SBS). However, biological effects of 2-EH have not been fully elucidated. The present study investigated the effects of 2-EH on immune cells from C57BL/6 mice using splenocytes, bone marrow-derived dendritic cells (BMDC) and bone marrow-derived macrophage (BMDM). After the 2-EH was administered intranasally to mice, the mice were sacrificed, and then splenocytes and bone marrow cells were isolated. We examined the splenocytes proliferative response to mitogen-stimulation (e.g., IL-2 and LPS) and the expression of surface makers (e.g., T cells, B cells, macrophages, dendritic cells, and costimulatory molecules) on splenocytes by flow cytometry. Furthermore, BMDC and BMDM were differentiated by culture with granulocyte macrophage-colony stimulating factor (GM-CSF), and then its function was analyzed by the measurement of cytokine secretion, the expression of costimulatory molecules and MHC class II molecules.
As a result, the mitogen-induced proliferation of splenocytes and cytokine productions of the BMDC and BMDM were enhanced in 2-EH administrated mice. This may suggest that 2-EH causes the disorder to the primary and secondary lymphoid tissues, and also may be considered as one of the evidence that 2-EH is associated to the immune disorders.

P5.05.15
Therapeutic potential of Allium cepa L. and the flavonoid quercetin in an experimental model of respiratory allergy

***T. Oliveira Teixeira**[1], K. M Dourado[1], A. Cerqueira-Lima[1], E. da Silva Velozo[2], L. C Pontes de Carvalho[3], N. Maria Alcântara Neves[1], C. Alexandrina Viana de Figueiredo[1];*
[1]of Health Sciences, Federal University of Bahia, Brazil., Salvador, Brazil, [2]Faculty of Pharmacy, Federal Universiy of Bahia, Brazil., Salvador, Brazil, [3]Gonçalo Moniz Research Institute - FIOCRUZ, Brazil., Salvador, Brazil.

Asthma is characterized by chronic pulmonary inflammation. It is stimulated by environmental allergens. Corticosteroids are the most commonly used drugs, because they act in controlling symptoms, however producing multiple side effects. Some plants, such as species Allium cepa L., are popularly used for the treatment of asthma. The objective of this study was to assess the therapeutic potential of the methanol extract of Allium cepa L. (AcE) and its flavonoid quercetin (Qt) in vivo. These experiments, AJ mice were sensitized (100µg per animal - sc) and challenged (10mg per animal - in) with extract of mite Blomia tropicalis (BtE). The sensitized animals were treated or not with AcE (100 or 1000mg/Kg) or Qt (30mg/Kg) to analyze the following parameters: BAL, EPO in the lung; total serum IgE levels, levels of IL-4, IL-5, IL-13 in BAL, and histopathological changes in the lung. In vivo, there was a reduction in the total number of BAL cells in sensitized animals that were treated with AcE and Qt when compared to untreated allergic animals. EPO, in lung, also suffered deletion in the treatment with AcE (100 or 1000mg/Kg).Treatment with AcE (1000mg/Kg) or Qt (30mg/Kg) was able to reduce IL-4 and IL-5 in BAL. However, there was no significant reduction in serum IgE levels and levels of IL-13. The results of this research suggest that Allium cepa L. and Qt have significant potential as drugs antiasthma with immunomodulatory properties and may be future candidates for drugs to make up the therapeutic arsenal of this pathology.

P5.05.16
Characteristics of effector and regulatory T cell subsets in the lungs of smoking and non-smoking healthy individuals

***M. Ostadkarampour**[1], M. Müller[2], S. Kullberg[1], A. Eklund[1], J. Grunewald[1], J. Wahlström[1];*
[1]Respiratory Medicine Unit, Department of Medicine Solna and CMM, Karolinska Institutet and Karolinska University Hospital, Stockholm, Sweden, [2]Rheumatology Research Unit, Department of Medicine Solna and CMM, Karolinska Institutet, Stockholm, Sweden.

Smoking influences the immune system in many ways and it has also been linked to risk of disease in a number of important inflammatory and autoimmune disorders, such as rheumatoid arthritis and multiple sclerosis. Recently, the lung has been implicated in the induction of these diseases. T cells are of central importance for the pathogenesis of autoimmune diseases, but the precise effects of smoking on pulmonary effector and regulatory T cells have not been well characterized. The aim of this ongoing study was to investigate frequencies and characteristics of lung and blood CD4+ and CD8+ T cell subsets such as T helper 1 (Th1) cells, Th17 cells and regulatory T cells (T reg). Samples were obtained by bronchoalveolar lavage (BAL) and from the peripheral blood of healthy smokers (1-5 pack years smoking history) and non-smokers. Cells were stimulated in vitro by anti-CD3/anti-CD28 and intracellular cytokines and select lineage-specific transcription factors were analyzed by flow cytometry. Our data indicate that smokers have higher frequencies of T cells expressing IFN-gamma as well as IL-10 in their lungs, and also that

they have elevated numbers of the lung IFN-gamma/IL-10 and IFN-gamma/IL-17 double-producing cells. Our results indicate that smoking is associated with distinct changes in the cytokine profiles of pulmonary T cells. The altered frequencies of “hybrid” phenotypes such as Th1/Th17 cells may indicate an effect of smoking on the plasticity of T cells subsets in the lung, which could be of importance for the induction or maintenance of smoking-associated inflammatory or autoimmune diseases.

P5.05.17
Immune markers in oral discomfort patients before and after elimination of oral galvanism

***S. Podzimek**, M. Tomka, J. Bartova, J. Prochazkova;*
Institute of Clinical and Experimental Dental Medicine, First Faculty of Medicine and GUH, Charles University, Prague, Czech Republic.

An enhanced release of metals in the mouth due to galvanic cell formation is considered to be one of the causes of oral discomfort. The aim of this study was to investigate the influence of galvanic cell on salivary immune defense factors. The levels of IgA1, IgA2, secretory IgA, lysozyme and antiIgA/HSP60 were evaluated in representative samples from 159 patients with galvanism, from 177 patients without galvanism and in two control groups. All the participants underwent personal history taking, clinical examination, galvanic currents measurement and saliva collection. Electro active dental materials were removed in 30 patients. There was a significant increase in IgA2 level, a significant decrease in antiIgA/HSP60 levels and an increase in IgA1, secretory IgA and lysozyme levels found after the removal of electro active restorations. Morphological symptoms disappeared in 70 % of the treated patients. The study confirmed that pathologic galvanic phenomena influences the immune defense reactions in the oral cavity and thus deteriorates the symptoms of oral discomfort. A measurement of the galvanism and a subsequent removal of electro active restorations should become a common therapeutic procedure in the patients with oral discomfort.
The study was supported by PRVOUK-P28/LF1/6 (Ministry of Education, Youth and Sports, Czech Republic) and by NT 13087-3 (Ministry of Health, Czech Republic).

P5.05.18
Prolonged exposure to type-I IFN inhibits IL-10 signaling in memory and regulatory T cells: a new mechanism contributing to the development of autoimmune diseases

***G. Raimondi**[1], Y. T. Nicholson[2], L. C. Chen[2];*
[1]Johns Hopkins School of Medicine, Baltimore, MD, United States, [2]Starzl Transplantation Institute - University of Pittsburgh School of Medicine, Pittsburgh, PA, United States.

Interleukin 10 (IL-10) is a fundamental immunoregulatory cytokine. Mice with memory T cells (Tmem)- or regulatory T cells (Treg)-specific depletion of the IL-10 receptor (IL-10R) develop fatal autoimmune diseases. However, no correlation is known between pathological conditions and altered IL-10 signaling in T cells.
We investigated the influence of prolonged exposure to the supernatant of mouse maturing dendritic cells, exposed to LPS, on the integrity of the IL-10 signaling pathway in Tmem and Treg. Following 36-48h incubation, a block in phosphorylation of STAT3 in response to IL-10, but not in response to IL-6, was evident. This IL-10-specific unresponsiveness was not associated with reduction in surface IL-10R expression, or with reduced STAT3 cytoplasmic availability. Additionally, this inhibition was not induced by IL-6 or IL-1. Instead, incubation with IFN-β impaired IL-10 signaling in both Tmem and Treg. This effect was not blocked by AKT inhibition, suggesting a role for Jak/STAT or other IFN-β-initiated signaling pathways. In NOD mice, a model of human type-1 diabetes (T1D), the spontaneous development of diabetes is linked to high levels of type-I interferons in pancreatic lymph nodes (PNC-LN). We analyzed the IL-10 response in T cells from spleen, PNC-LN, other LNs, and pancreata of NOD mice and discovered that around 4 weeks of age, Tmem and Treg in PNC-LN and pancreata display suppressed responses to IL-10, while the same subsets in all other tissues remain unaltered.
Overall, these data reveal a new molecular mechanism that controls the early development of autoimmunity and the pathogenesis of T1D.

P5.05.19
Novel immunoregulatory function of the carcinogen Acrolein: inhibition of allergic sensitization and promotion of tumor growth in BALB/c mice

***F. Roth-Walter**[1], A. Willensdorfer[1], C. Stremnitzer[2], C. Schultz[2], S. Diesner[2,3], K. Szalai[1], J. Fazekas[2], A. Moskovskich[1], H. Birnleitner[1], E. Jensen-Jarolim[1,2];*
[1]University of Veterinary Medicine Vienna, Messerli Research Institute, Comparative Medicine, Vienna, Austria, [2]Medical University of Vienna, Department of Pathophysiology and Allergy Research, Vienna, Austria, [3]Medical University of Vienna, Department of Pediatrics and Adolescent Medicine, Vienna, Austria.

Background: Since allergic sensitization has been linked to smoking, we investigated the contribution of acrolein, a compound generated in large during smoking, during nasal sensitization and - based on the surprising intermediate results - on tumor growth.
Methods: BALB/c mice were nasally sensitized 5 times in biweekly intervals with KLH alone or in conjunction with acrolein. Airway hyperreactivity as well as KLH-specific anaphylactic reaction was monitored. Levels of specific antibodies as well as cytokine profile of KLH-stimulated splenocytes were analyzed. Further, D2F2-tumor was grafted to the flanks and tumor growth monitored in mice previously exposed to acrolein or buffer.
Results: Nasal application of KLH as model antigen induced specific IgG1-, IgG2a-, IgA- and IgE-levels. The same mice secreted elevated levels of IL5, IL13, IL10 and IFN-γ φρομ τηειρ σπλενοχυτεσ. They showed increased airway-hyperreactivity and had a significant drop in body temperature upon allergen challenge. Pointing towards tolerance, and against our expectations, presence of acrolein in the KLH-antigen significantly reduced specific antibody-titers, resulted in lower splenocyte cytokine production and prevented anaphylaxis. The impaired immune response also led to a significantly higher tumor growth in mice exposed to acrolein than in the control group.
Conclusion: Acrolein in smoke - best known for its carcinogenic effect - decreases the risk of sensitization towards a specific antigen by inhibiting immune activation. Our data further suggest that Acrolein via the same mechanism acts tumor promoting in smokers.

P5.05.20
Effect of petrochemical pollutants on *Avicennia marina* pollens allergenicity

***M. Salehi**[1], Z. Pourpak[2];*
[1]Kharazmi University, Tehran, Iran, [2]Immunology, Asthma and Allergy Research Institute, Tehran University of Medical Sciences, Tehran, Iran.

Allergic diseases due to the pollens are increasing. The reason of this phenomenon is not clear but probably air pollution intensifies allergic reactions. *Avicennia marina* in Bushehr province of Iran grows in two regions: Assaluyeh and Bordekhoon. Contrary to Bordekhoon, Assaluyeh is industrial city with petrochemical factories. We tried to compare pollen allergenicity of this plant in Bordekhoon and Assaluyeh in order to investigate the effects of petrochemical pollution on pollen allergenicity. Pollens were collected from the two regions and extracted in PBS. BALB/c mice were divided into four groups. The first group was treated with Bordekhoon pollen extract plus Alum and the second group was treated with Assaluyeh pollen extract plus Alum. The third and fourth groups served as controls and received PBS and Alum respectively. Intradermal skin test showed no differences in wheal diameter between the second group and first group. IgE level and rate of eosinophils increased in second group compared to the first group but this increase was significant only for IgE level. SDS-PAGE revealed that pollen proteins patterns were different in two regions. The immunoblotting analysis showed two bands in each region that reacted with IgE antibodies induced in treated mice. Results of this research showed that pollen exposure to petrochemical pollutants in Assaluyeh region intensified some allergic characteristics of *Avicennia marina* pollens.

P5.05.21
Treatment of patients with severe Pneumonia and Pneumonia associated with Diabetes

***T. Slavyanskaya**, R. Sepiashvili;*
People's Friendship University of Russia, Moscow, Russian Federation.

The purpose of this work was the development of combined lymphotropic immunotherapy (CLIT) for patients with severe pneumonia (P) and diabetes (D). 121 patients aged from 15 to 65 years were enrolled: 45 patients with P, 27 patients with P+D, and 11 patients with D (control group). Patients were subdivided into groups. Group I (22 patients with P) and group II (12 patients with P+D), received only TT (antibacterial, pathogenetic, physiotherapy and symptomatic treatment indications). Group III (23 patients with P) and group IV (15 patients with P+D) received CLIT and TT for 10 days. Patients in groups III and IV showed normalization of phagocytosis, reliable reduction of cytotoxic immune complexes, restoration of imbalances in antibody and CD4/CD8 cell levels. Patients receiving CLIT, compared with patients receiving TT only, showed also an improvement in general conditions, reduction of symptoms, and over 30% decreased hospitalization time . Patients in groups I and II, receiving only TT, did not experience T-cell recovery of to the control group level. Thus, the inclusion of CLIT in an integrated therapy program in patients with severe P and P+D significantly increases the effectiveness of treatment and the quality of life.

P5.05.22
From gut immune regulation to self-tolerance: preventing autoimmune diabetes in the gut mucosa

***C. Sorini**[1], V. Usuelli[1], D. Cavalieri[2], K. Honda[3], E. Bosi[4], M. Falcone[1];*
[1]Experimental Diabetes Unit – DRI, San Raffaele Scientific Institute, Milan, Italy, [2]Fondazione Edmund Mach di San Michele all'Adige, Trento, Italy, [3]Department of Immunology, Graduate School of Medicine, University of Tokyo, Tokyo, Japan, [4]Clinical Diabetes Unit, Department of Internal Medicine, San Raffaele Scientific Institute, Milan, Italy.

Type 1 Diabetes (T1D) results from the autoimmune destruction of pancreatic beta cells. Environmental factors acting at the intestinal level such as diet and microbiota modulate the pathogenesis of T1D in humans and pre-clinical models (NOD mice). We hypothesize that those factors affect T1D by altering the gut immune system. Many immune regulatory mechanisms that originate in the gut "educate" the immune system to maintain immune tolerance towards self-antigens outside the gut. These mechanisms include extrathymic development and/or expansion of regulatory T cells, driven by tolerogenic dendritic cells (DCs). We recently reported a defect of FoxP3+ Treg cells in the intestinal mucosa of T1D patients compared with healthy subjects, which correlated with the impaired capacity of gut DCs to elicit their conversion in vitro (Badami E et al Diabetes 2011). We are testing the hypothesis that alteration of diet and microbiota alterations affect T1D in NOD mice by shaping gut immunity. We found that NOD mice carry a significantly reduced numbers of tolerogenic DCs and have an increased Th17/Treg cell ratio in the gut mucosa compared to non-autoimmune mice. A gluten-free diet rescued the number and tolerogenic function of intestinal DCs and restored a normal Th17/Treg cell ratio in the gut and pancreatic lymph nodes. This was associated with protection from clinical diabetes and reduced percentages of diabetogenic effector T cells. We are testing the hypothesis that altered gut immunitty in NOD mice and improved tolerogenic mechanisms promoted by gluten-free diet correlate with modulation of microbiota species and genes.

P5.05.23
Thymic Atrophy Induced by Malaria Infection Aggravates Experimental Autoimmune Encephalomyelitis (EAE)

***R. Thomé**, L. K. Issayama, T. Alves da Costa, R. D. Gangi, C. Francelin, A. d. Farias, L. M. B. Santos, L. Verinaud;*
State University of Campinas – UNICAMP, Campinas, Brazil.

Background: Malaria is the most prevalent infectious disease in the world causing one million deaths per year. We showed that malaria infection in mice causes thymic atrophy (Ta) by apoptosis and release of immature lymphocytes to the peripheral immune system. The presence in the periphery of cells that failed to experience negative selection may alter the severity and susceptibility to autoimmune diseases, such as Autoimmune Encephalomyelitis (EAE). In this context, we aimed to evaluate whether thymic atrophy previously induced by malaria infection modulates EAE.
Methods/Principal findings: Ta was induced in C57BL/6 mice by infection with Plasmodium berghei NK65. Treatment with chloroquine (CQ, 5mg/kg for five consecutive days) was initiated at the peak of Ta (7dpi) to eradicate parasites. Three days after the last dose of CQ, mice were immunized with MOG35-55 peptide and Pertussis toxin to induce EAE. Our results show that mice previously infected with P.berghei developed aggravated EAE with higher clinical scores, and infiltration of inflammatory cells in the Central Nervous System when compared to the control groups (CQ+EAE and only EAE). Also, the frequency of regulatory T cells was reduced in the periphery of previously P.berghei infected-EAE mice while INF-γ- and IL-17-producing cells were higher in this group than on the other two control groups.
Conclusion: Collectively, our results strongly demonstrate that thymic atrophy induced by malaria infection aggravates experimental autoimmune disease.
Support: This work was supported by Fundação de Amparo a Pesquisa do Estado de São Paulo (#2011/13191-3, #2011/17965-3).

P5.05.24
Natural tolerance towards peanuts in African allergic patients

***E. Wollmann**[1], E. Sibanda[2], C. Hamsten[3,4], A. Önell[5], D. Gallerano[1], C. Lupinek[1], R. Valenta[1], M. van Hage[3];*
[1]Division of Immunopathology, Department of Pathophysiology and Allergy Research, Center for Pathophysiology, Infectiology and Immunology, Medical University of Vienna, Vienna, Austria, [2]University of Zimbabwe Medical School, Harare, Harare, Zimbabwe, [3]Department of Medicine, Clinical Immunology and Allergy Unit, Karolinska Institutet and University Hospital, Stockholm, Sweden, [4]Center for Inflammatory Diseases, Karolinska Institutet, Stockholm, Sweden, [5]Thermofisher Scientific ImmunoDiagnostics, R&D, Uppsala, Sweden.

Background: Peanut allergy is known to cause severe and life-threatening allergic reactions.
Objective: To investigate allergic patients from Africa who show IgE reactivity to peanuts but regularly eat them without experiencing allergic reactions.
Methods: Sera from 54 African allergic patients with IgE sensitization to peanut were analyzed regarding total IgE levels and IgE antibody levels to peanut allergen extracts using quantitative ImmunoCAP measurements. A detailed analysis of the IgE and IgG reactivity profiles towards more than 145 purified natural and recombinant allergen molecules including 6 peanut allergens (Ara h 1, 2, 3, 6, 8, 9) was done using an allergen microarray.
Results: Each of the patients showed IgE reactivity to peanut extract. Notably, 44% of the patients showed IgE reactivity towards at least one of the peanut allergens (Ara h 1, 2, 3, 6 and 9) which reportedly cause severe anaphylactic reactions. These patients also had elevated allergen-specific IgG. One patient displayed IgE reactivity to the less allergenic Ara h 8. Forty-eight percent of the patients showed IgE reactivity only carbohydrate epitopes (MUXF3, nCup a 1, nCry j 1, nCyn d 1, nPhl p 4), but not to the peanut proteins.
Conclusion: In approximately half of the patients the lack of peanut symptoms can be explained by exclusive IgE reactivity to non-allergenic peanut epitopes. In the other patients natural clinical tolerance to peanuts may be caused by the development of allergen-specific IgG due to continuous peanut uptake.

P5.05.25
Resveratrol modulates collagen-induced arthritis by inhibiting Th17 and B-cell function

D. Xu[1]*, x. Gao*[1]*, M. Komai-Koma*[1]*, B. P. Leung*[2]*, I. B. McInnes*[1]*;*
[1]*Glasgow biomedical research centre, University of Glasgow, United Kingdom,* [2]*Tan Tock Seng Hospital, Novena, Singapore.*

Rheumatoid arthritis (RA) is an inflammatory disease in which T and B cells play pathogenic roles. Resveratrol, a safe, plant-derived compound, possesses anti-inflammation and immune-regulatory properties. We therefore evaluate the therapeutic effect of resveratrol on collagen-induced arthritis (CIA) and its putative immune modulation in mice.
CIA was induced in DBA1 mice by immunisation with collagen II. Different doses of resveratrol were administered before or after the development of CIA. Either prophylactic or therapeutic administration of resveratrol attenuated clinical parameters and bone erosion in CIA mice. The arthritis-protective effects were associated with markedly reduced serum levels of pro-inflammatory cytokines and collagen-specific, but not total, IgG, and with reduced numbers of Th17 cells and the production of IL-17 in DLN.
Thus, resveratrol may offer a novel, effective and safe pathway whereby novel agents could be developed to treat RA.

P5.06 Regulatory T cells in autoimmunity and allergy

P5.06.01
CD4+ T cells limit their own-pathogenicity by activating regulatory T cells by different mechanisms in different inflammatory conditions

A. Baeyens[1]*, D. Saadoun*[1]*, F. Billiard*[1]*, Y. Grinberg-Bleyer*[1]*, S. Gregoire*[1]*, E. Piaggio*[1]*, K. Loser*[2]*, B. L. Salomon*[1]*;*
[1]*UMR7211, U959 immunology, immunopathology, immunotherapy, Paris, France,* [2]*Cell Biology and Immunobiology of the Skin", University Hospital Münster, Münster, Germany.*

The CD4+CD25+Foxp3+ regulatory T cells (Tregs) play a major role in peripheral tolerance. The suppressive effect of Tregs on CD4+ effector T cells (Teffs) has been extensively studied; however, the reverse in vivo impact of Teff activation on Tregs is poorly known. Under condition of autoimmune diabetes, we show that the activation of pancreatic islet antigen-specific Teffs strongly boosts the expansion and suppressive activity of Tregs with similar antigen-specificity in the pancreas and its draining lymph nodes. This Treg boost was partially dependent on TNFα and OX40 but not on IL-2. Interestingly, plasmacytoid dendritic are also involved in this Teff-dependent Treg boost. In another condition, we observed another Teff-dependent Treg boost that has a different mechanism. In a context of strong inflammation in draining lymph nodes of mice injected with complete Freund adjuvant and cognate peptides for Teffs and Tregs, the presence of activated Teffs increased Treg activation that depend on IL-2 but not on TNFα. Altogether, this data show that Teff activation increase activation of Tregs with different mechanisms that depend on the inflammatory condition. A better understanding of this feedback regulatory loop between Teffs and Tregs may be crucial to limit the development of autoimmune diseases and other immune responses.

P5.06.02
Role of Follicular Regulatory T cells in Multiple Sclerosis

T. Dhaeze[1]*, B. Broux*[1]*, B. Van Wijmeersch*[2]*, P. Stinissen*[1]*, N. Hellings*[1]*;*
[1]*University of Hasselt - BIOMED, Diepenbeek, Belgium,* [2]*REVAL Rehabilitation Research Center, Dpt. Healthcare, PHL University College, Diepenbeek, Belgium.*

Both autoreactive T cells and autoantibodies are identified as key players in the immunopathogenesis of multiple sclerosis (MS). These overt autoimmune responses may results from disturbances in regulatory T cells ($CD4^+CD25^+FoxP3^+$ T cells) important for the maintenance of peripheral tolerance. Recently a new subset of regulatory T cells was discovered in mice. These follicular regulatory T cells (T_{FR}, $CD4^+CXCR5^{hi}PD\text{-}1^{hi}FoxP3^+$) participate in germinal responses by controlling the maturation of B cells and the production of (auto)antibodies.
We recently identified a similar Treg subset in human blood. The goal of this study is to investigate the functionality of T_{FR} in MS patients. Therefore, the frequency, phenotype and function of T_{FR} in the blood of MS patients and healthy controls are compared. In addition, the effect of current treatment regimens on this cell population is taken into account.
A significant difference (p=0.0401) could be found in the percentage of T_{FR} between MS patients without treatment (0.1252 ± 0.01052 % of T_{reg}, n=74) compared to healthy controls (0.1631 ± 0.01509% of T_{reg}, n=38). Furthermore, we have shown that this human subset is able to suppress $CD4^+CD25^-$ responder T cells *in vitro.* We are currently investigating T_{FR} functionality in MS patients.
Unravelling the functionality of T_{FR} and its association with B-cell alternations will help elucidate the involvement of this subset in autoimmune disease.

P5.06.03
Monocytes drive the induction of CD8+FOXP3+ regulatory T cells via the production of membrane TNF-alpha

S. D. P. Ellis*, M. R. Ehrenstein, C. A. Notley;*
University College London, London, United Kingdom.

Limiting the severity and the eventual resolution of an inflammatory response is vital for the protection of host tissues from the damaging effects of chronic inflammation. The induction of $CD8^+$ regulatory T cells (Treg) expressing FOXP3 has been described within the context of chronic inflammation in cancer, infection and autoimmunity. For instance, we have shown that a small population of $CD8^+FOXP3^+$ Treg exists in the periphery of patients with inflammatory arthritis, which is not found in healthy individuals. The aim of our study was to dissect the mechanism of FOXP3 induction in CD8+ T cells after T cell receptor signalling, using CD3-specific antibodies. Our results found that anti-CD3 antibodies variably induce, not expand, a potent $CD8^+FOXP3^+$ Treg population. These Treg suppress $CD4^+$ T cell proliferation, IL-17 and IFN-γ production in vitro and express TGF-β and CTLA-4. Investigation into the derivation of these cells determined that monocytes are crucial for the induction of FOXP3 expression following CD3 activation. In particular, monocytes provide co-stimulation through CD86 and membrane TNF-α. In vitro, these signals could be substituted with agonist antibodies to CD28 and TNFR2. Artificial expression of membrane TNF-α on monocytes was found to drive FOXP3 expression in a proportion of $CD8^+$ T cells initially unresponsive to anti-CD3 stimulation. Our data identify the signalling pathways required for FOXP3 induction by $CD8^+$ T cells and that these pathways are amenable to manipulation to augment regulatory capacity during autoimmunity or limit their effects in cancer and infection.

P5.06.04
Diverse T-cell profiles in children with type 1 diabetes and/or celiac disease

M. Faresjö[1]*, K. Åkesson*[2]*, A. Kivling*[3]*, A. Rydén*[3]*;*
[1]*Department of Natural Science and Biomedicine, School of Health Sciences, Jönköping University, Jönköping, Sweden,* [2]*Clinic of Pediatrics, Ryhov County Hospital, Jönköping, Sweden,* [3]*Department of Clinical and Experimental Medicine, Faculty of Health Sciences, Linköping University, Linköping, Sweden.*

Type 1 diabetes (T1D) and celiac disease (CD) are both characterized by an autoimmune outcome. As T1D and CD share the same risk genes, patients have risk of developing the other disease subsequently. This study aimed to investigate the expression of T-helper (Th)-, T-cytotoxic (Tc)- and T-regulatory (Treg) cells in children with T1D and/or CD in comparison to healthy children.
Subgroups of T-cells (CD4+ or CD8+); naïve (CD27+CD28+CD45RA+CCR7+), central memory (CD27+CD28+CD45RA-CCR7+), effector memory (early

differentiated;CD27+CD28+CD45RA-CCR7- and late differentiated;CD27-CD28-CD45RA-CCR7-), terminally differentiated effector cells (TEMRA;CD27-CD28-CD45RA+CCR7-) and Treg (CD4+CD25+FOXP3+CD127-) cells, and their expression of CD39, CD45RA, CD101 and CD129, were studied by flow cytometry in children with T1D and/or CD or without any of these diseases (references).
Children with exclusively T1D had higher MFI of FOXP3 ($p<0.05$) but lower percentage of CD39+ and CD45RA+ within the Treg population (CD4+CD25+FOXP3+CD127-) ($p<0.05$). Children with exclusively CD had a higher MFI of CD101 ($p<0.01$) as well as a higher percentage of CD129+ ($p<0.05$), in the CD4+CD25hi lymphocyte population, compared to references. Children diagnosed with both T1D and CD showed higher percentage of terminally differentiated (TEMRA) CD4+ cells ($p<0.05$), but lower percentages of effector, both early and late, memory CD8+ cells ($p<0.05$), compared to references.
In conclusion, children with combined T1D and CD have higher percentage of differentiated Th-cells, compared to Tc-cells. T1D children show signs of low CD39+ Treg cells that may indicate loss of suppressive function. On the contrary, CD children show signs of CD101+ Treg cells that may indicate suppressor activity.

P5.06.05
$^{+}$ Foxp3 $^{+}$ Treg and its ICOS $^{+}$ Subsets in Patients with Myocardial Infarction

***S. Ghorbani**;*
Isfahan Medical Science, Isfahan University, Isfahan, Iran.

Atherosclerosis is a multifactorial disorder with chronic inflammatory conditions in which immune cells play a significant role in its pathogenic process. Regulatory T cells (Treg), as a part of immune system, are involved in controlling autoimmune and inflammatory diseases. Quantitative and/or functional alteration of Tregs has been shown to play an atheroprotective role and may also promote plaque stabilization. To assess if inducible costimulatory molecule (ICOS) expression on one subtype of Treg cells with high suppressive potential correlates with the pathogenesis of atherosclerosis. Methods: Patients with myocardial infarction (MI) and/or stable angina (SA), diagnosed as atherosclerosis by angiography, and a group of individuals with normal coronary angiography (NCA) were recruited for the present study. Peripheral blood mononuclear cells (PBMCs) were prepared and the expression of ICOS, Foxp3 and CD4 molecules was tested by flowcytometry. The percentage of CD+Foxp3+Treg cells was reduced in MI group compared to NCA and SA groups ($p<0.005$). Evaluation of the two Treg subsets according to ICOS expression showed a decreased ICOS+/ICOS- Treg ratio in MI and SA groups compared to NCA individuals ($p=0.002$ and $p=0.048$, respectively). The present data indicate that Tregs and its ICOS+ subsets are decreased in patients with MI or SA, suggesting a potential role for Treg in atherosclerosis progression or onset of acute coronary syndrome.

P5.06.06
Association between T cell immunoglobulin domain and mucin domain-1 gene polymorphisms with Allergic Rhinitis patients

***H. Hassannia**[1], F. Hosseini[1], S. Abedian[2];*
[1]Tehran University of Medical Sciences, Tehran, Iran, [2]Mazandaran University of Medical Sciences, Mazandaran, Iran.

Allergic rhinitis is one of the most common chronic inflammatory disease of nasal airways induced by IgE-mediated type I hypersensitivity that is caused by the interaction of multiple genetic and environmental factors. The aim of present study is to analyze the association between T cell immunoglobulin domain and mucin domain (TIM-1) gene polymorphisms with susceptibility to allergic rhinitis.
In a case-control study, 155 allergic rhinitis patients and 163 allergy-free controls were analyzed. Two TIM-1 promoter single nucleotide polymorphisms (SNPs), −416G/C and -1454G/A were investigated by using polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP). X^2 test and Logistic regression analyses were used for calculating the risk associated with individual alleles and genotypes between case and control groups by using SPSS 18 software.
We found that there was statistically significant difference in TIM-1 −416 C allele and -1454 A allele (OR = 1.64, P = 0.006; OR = 1.55, P = 0.041, respectively) with susceptibility of allergic rhinitis. In addition, the total serum IgE and peripheral blood eosinophil number in the subgroup with homozygous genotype of -416 CC variation site were significantly higher than the subgroup without this SNP (p= 0.001, p= 0.02 respectively).

P5.06.07
Glycogen synthase kinase-3 regulates IL-10 production in Th1 cells

***E. V. Hill**, T. H. S. Ng, D. C. Wraith;*
University of Bristol, Bristol, United Kingdom.

The ubiquitous serine/ threonine kinase glycogen synthase kinase-3 (GSK3) is a point of convergence of several signaling pathways. In the immune system GSK3 has been shown to have an important role in the balance of production of pro- and anti-inflammatory cytokines. GSK3 inhibition has been shown to have an anti-inflammatory effect in several disease models and in monocytes, macrophages and human memory T cells has been shown to increase production of the anti-inflammatory cytokine IL-10. We have used inhibitors of GSK3 to examine its role in the production of IL-10 by $CD4^{+}$ T cells from myelin basic protein (MBP)-specific TCR transgenic (Tg4) mice. Treatment with GSK3 inhibitors of naive cells from Tg4 mice does not affect their production of IL-10. However, in differentiated Th1 cells, culture in the presence of the GSK3 inhibitors CHIR99021, SB216763 or SB627772 leads to a dramatic increase in the production of IL-10. These GSK3 inhibitor treated cells caused less severe disease than control treated cells in adoptive transfer experiments where experimental autoimmune encephalomyelitis (EAE) was induced. Inhibition of GSK3 in Th1 cells can therefore enhance the differentiation of IL10-Tregs and redirect the fate of pathogenic Th1 cells to a regulatory cell type. These findings are particularly important in the context of Th1-mediated autoimmune disease where it may be possible to reprogram disease-causing cells by GSK3 inhibition to become regulatory, disease-suppressing cells.

P5.06.08
Enhanced regulatory T cell function and attenuated DSS-induced colitis in the mice deficient with GPx1 and catalase

***H. Kim**, H. Kim, J. Seoh;*
Department of microbiology, Ewha Womans Univiersity Medical Center, Seoul, Republic of Korea.

Reactive oxygen species (ROS) are highly reactive and are likely to induce cellular damage and tissue destruction. Enhanced autoimmunity was observed in the mice in which ROS production was reduced, such as Ncf1 or Nox2 deficiency, as well as in human disease, such as chronic granulomatous disease. On the contrary, inflammatory response was attenuated in the mice in which ROS level was elevated, such as glutathione peroxidase 1 (GPx-1) deficiency. The recent observations bring about an innovative concept on the protective role of ROS in inflammation and tissue damage. Meanwhile, the underlying cellular mechanism is not yet sufficient. Regulatory T cell (Treg) function was studied only in the mice in which ROS level was reduced. To address this issue, in the present study, we investigated the function of $CD4^{+}CD25^{+}$ Tregs in the GPx-1 and catalase knockout mice in which ROS level was elevated. We also investigated on the colitis symptoms induced by 3% dextran sodium sulfate (DSS). The results showed enhanced Treg function and attenuated DSS-colitis symptoms in the $GPx1^{-/-}$ x $Cat^{-/-}$ mice. N-acetyl cysteine (NAC) or catalase decreased Treg function in vitro and in vivo, while DSS-colitis symptoms were aggravated in the $GPx1^{-/-}$ x $Cat^{-/-}$ mice as well as in the WT mice. Taken together, the results suggest that ROS level is pivotal to the functional activity of Tregs that play a key role in the regulation of immune responsiveness in vivo.

P5.06.09
The extrinsic factors blocking regulatory T cell function in the pathogenesis of SLE

***H. Kim**, H. Kim, J. Seoh;*
Department of microbiology, Ewha Womans Univiersity Graduate School of Medicine, Seoul, Republic of Korea.

Systemic lupus erythematosus (SLE) is an intractable autoimmune disease. The pathogenesis of SLE still remains to be unknown. Recently, many investigators have studied on the role of regulatory T cells (Tregs) in the pathogenesis of SLE. Meanwhile, both the results of quantitative and functional studies are controversial. One of the possible reasons is the unreliable conventional in vitro functional assays for Tregs. However, we have established an accurate quantitative assay for the suppressive function of Tregs. Employing our quantitative assay, we analyzed that the suppressive function of Tregs from MRL/lpr mice were not decreased, rather enhanced, suggesting that intrinsic functional defect was not critical and other extrinsic factors might be more important in the pathogenesis of SLE.
Moreover, we established the mouse model of induced SLE by using pristane in C57BL/6 WT and $GPx1^{-/-}$ x $Cat^{-/-}$ mice which have stronger suppressive activity of Tregs. Then, we confirmed lipogranuloma formation in their peritoneum and the suppressive function of Tregs from induced SLE animal model was consistent with that of MRL/lpr mice. In addition, interstitial fibrosis was observed in their kidney and follicles were induced in lung. On the other hand, decreased IL-2 and increased IL-4 and IL-6 are consistently observed in the serum from C57BL/6 WT and $GPx1^{-/-}$ x $Cat^{-/-}$ mouse. IL-2 enhances, whereas IL-6 inhibits, the development and function of Tregs. Accordingly, we hypothesized that the decreased IL-2 and/or increased IL-6 may contribute to the pathogenesis of SLE, extrinsically inhibiting development or function of Tregs and induce differentiation to Th2.

P5.06.10
Targeting PAI-1 signaling results in the enhancement of iTreg and reduction of mortality in a mouse model of septic shock

***H. H. Mu**, M. Nourian, H. Jiang;*
University of Utah School of Medicine, Salt Lake City, UT, United States.

Mycoplasma arthritidis causes arthritis and septic shock in natural infections of rodents. Here we show that the level of type 1 plasminogen activator inhibitor (PAI-1), the primary inhibitor of tissue-type plasminogen activator (tPA) and urokinase-type plasminogen activator (uPA), is markedly increased in septic shock-susceptible mouse strains injected with live *M. arthritidis*. We also show that *M. arthritidis*-infected mice exhibit severe septic shock with elevated levels of inflammatory cytokines TNFα, IL-1β but lower level of TGFβ production. Repeated injections of animals with anti-PAI-1 blocking antibody effectively prevent mice from lethal toxicity and suppress production of inflammatory cytokines. Importantly, anti-PAI-1 treatment results in increased level of TGFβ and IL-10 expression in livers as well as in lymphoid organs. Parallel results demonstrate that, the expression of Foxp3, a marker of regulatory CD4+ T cells, is significantly increased in anti-PAI-1-injected mice with *M. arthritidis* infection. Furthermore, the treatment of disease animals with anti-PAI-1 antibody induces tolerogenic DCs that promotes the suppressive function of inducible Treg (iTreg) contributing to the alleviation of mortality and morbidity in septic shock animals. Thus, these results reveal a novel function of PAI-1 in developing septic shock in *M. arthritidis*-infected mice and suggest a potential therapeutic target for the treatment of inflammatory diseases.

P5.06.11
General control nonrepressed 2 (GCN2) kinase participation in the remission phase of experimental autoimmune encephalomyelitis (EAE) in mice

***H. Orsini**[1,2], L. Pires[1], J. Maricato[1], B. A. Castilho[1], M. Mariano[1], A. S. Basso[1];*
[1]Universidade Federal de São Paulo, UNIFESP, São Paulo, Brazil,
[2]Universidade Paulista (UNIP), São Paulo, Brazil.

Experimental autoimmune encephalomyelitis (EAE) is an animal model widely employed to study immune mechanisms involved in multiple sclerosis. Although evidences suggest that the remission phase in EAE is associated with a decrease in infiltrating Th1 and Th17 lymphocytes and an increase in regulatory T cells within the CNS, the mechanisms governing this process are poorly understood. Recent researches demonstrated that chemically induced amino-acid starvation response (AAR) might suppress CNS immune activity. However, the exact mechanisms by which it occurs and if AAR could be physiologically involved in the modulation of CNS inflammation are still open questions. This study verified the participation of the general control nonrepressed-2 kinase (GCN2), a key regulator of AAR, in EAE course. By immunizing wild type (WT) and GCN2 knock-out mice (GCN2-KO) with MOG35-55, it was noted that GCN2-KO showed higher clinical scores and levels of CNS inflammatory infiltration, specially during the remission phase of the disease. These animals also showed lower levels of regulatory T cells (Treg) compared to the WT group. Higher levels of IDO (indoleamine 2,3-dyoxigenase) and plasmacytoid dendritic cells (pDCs), which seems to present immunosuppressive effects, were found at the peak of the disease in the CNS of WT animals. Moreover, pDCs from WT animals were able to induce higher levels of Treg differentiation in naïve T cells from WT animals. The results obtained suggest that the presence of GCN2 kinase, due to the activation of AAR, contributes to the EAE remission by suppressing CNS inflammation and probably promoting Treg differentiation/expansion.

P5.06.12
Effect of fetal therapy on T-regulatory cells during development of experimental allergic encephalomyelitis

***I. A. Porozhan**, N. N. Babenko, M. V. Ostankov, A. N. Goltsev;*
Institute for Problems of Cryobiology and Crymedicine of the National Academy of Sciences of Ukraine, Kharkov, Ukraine.

Recovery of functional activity of T-regulatory cells (Tregs) must be in the base of therapy of autoimmune diseases, including multiple sclerosis (MS). Today fetal neural cells (FNCs) have proved themselves well for MS treatment. However the data on FNCs effect on the state of T-regulatory link of immunity are virtually absent.
The research aim was to investigate the effect of cryopreserved FNCs on formation of natural and induced Tregs in development dynamics of experimental allergic encephalomyelitis (EAE).
The studies were performed in white outbred rats with induced EAE. FNCs of the rats of 11 gestation day were cryopreserved and intraperitoneally introduced to the animals to the 14th day of EAE development. Native FNCs and adult animals' neural cells served as the control. CD4+CD25+Foxp3+ and dendritic cells (DCs) were examined every 7 days within a month with the method of flow cytometry in thymus and peripheral blood.
It has been found that on the peak of pathology development the content of nTregs significantly increased (in 3.5±0.13 times) and the one of iTregs decreased almost in 30 times versus the control. This is related to the thymus disordered export function at EAE. The content of DCs in thymus of the animals with EAE was one-way changed with the number of nTregs. This fact testifies to a direct participation of thymic DCs in the formation of nTregs. Introduction of cryopreserved FNCs contributed to the recovery of thymus export function. Possible mechanisms of FNCs effect on T-regulatory link of immunity are under consideration.

P5.06.13
Regulatory T cell depletion reveals a large polyclonal population of self-reactive T cells in the normal peripheral T cell repertoire

D. M. Richards[1], *E. Ruggiero*[2], *A. Joschko*[1], *J. P. Sefrin*[1], *M. Schmidt*[2], *C. von Kalle*[2], *M. Feuerer*[1];
[1]*German Cancer Research Center (DKFZ), Heidelberg, Germany,* [2]*German Cancer Research Center (DKFZ) & National Center for Tumor Diseases, Heidelberg, Germany.*

The ability to actively suppress immune responses makes Treg cells important elements of peripheral tolerance. In fact, acute depletion of Treg cells in otherwise normal adult mice results in systemic and catastrophic autoimmunity.
We have found that 48 hr after acute depletion of Treg cells, there is a significant increase in the number of both CD4+ and CD8+ T cells expressing markers of recent activation. In addition, a significant accumulation of differentiated/effector cells occurs in the secondary lymphoid organs beginning 4 d post-depletion. Simultaneous adoptive transfer of polyclonal and monoclonal TCR-transgenic T cells confirmed that this T cell activation/differentiation is due to specific TCR stimulation and not just a response to generic factors, such as space or cytokines.
To more precisely examine the TCR, we sorted recently activated (48 hr) and effector CD4+ T cells (7 d) following Treg depletion and determined TCR rearrangements by deep sequencing. We found that recently activated as well as 7 d effector T cells were highly diverse.
Analysis of T cell proliferation suggests that 4.5% of the initially transferred polyclonal T cells responded following Treg depletion. Additionally, examination of T cells from Nur77 reporter mice following depletion further suggested that specific TCR stimulation occurs in approximately 5% of the T cell population.
Taken together these data suggest that normal adult mice harbor a highly diverse and high frequency of self-reactive T cells. Together, these findings raise many questions about negative selection of self-reactive T cells in the thymus.

P5.06.14
IL-10 and NOx are associated with CD4(+)FoxP3(+) regulatory T-cell subsets in the Systemic Lupus Erythematosus patients

A. A. Silva*, A. L. B. Santos, N. F. Rosário, A. C. A. Pires, C. Gagliardi;*
UFF, Niteroi, Brazil.

The Systemic Lupus Erythematosus (SLE) is an inflammatory chronic disease characterized by cytokine and natural regulatory T cells (Treg) imbalance. Many data point to defective aspects, both quantitative and qualitative, are involved in SLE pathogenesis and flares of activity. Based on this, it is tempting to correlate the frequency of T cell population and inflammatory molecules with disease activity. This study aims to quantify and compare the inflammatory profile and the frequency of CD4+FoxP3+ Treg subsets (CD4+CD25highFoxP3+, CD4+CD25lowFoxP3+ and CD4+CD25-FoxP3+). In this work we considered the activity of disease.Thirty-six female SLE diagnosed patients, including 23 with active (SLEDAI>6) and 13 with inactive disease (SLEDAI<6) were enrolled in this study, together with 15 healthy volunteers. Circulating IL-2, IL-10, IL-17, TNF and IFN-g were unchanged in SLE patients. Only IL-1, IL-6 cytokines and Nitric Oxide (NOx) showed statistic differences when compared with control individuals or activity disease. When compared with control group the T CD4+ CD25Low FoxP3 + T cells subset showed elevated in PBMC from SLE patients. Independent of Treg subsets, the active SLE patients presented statistic differences compared to inactive or control group. The CD4+CD25HighFoxP3+ and CD4+CD25LowFoxP3+ showed negative correlation with SLEDAI score and CD4+CD25negFoxP3+ showed positive correlation. Only circulating IL-10 is correlated with T CD4+CD25LowFoxP3+ regulatory-T cells subset. Together, the results suggest that IL-10 and NOx in association with the CD25high and CD25low Treg subsets may be considered SLE activity markers. However, further longitudinal investigations need to be executed to confirm this hypothesis.

P5.06.15
Activin-A-induced human regulatory T cells: novel controllers of allergic asthma

S. Tousa[1], *M. Semitekolou*[1], *I. Morianos*[1], *A. Banos*[1], *M. Kapasa*[1], *K. Samitas*[2], *M. Gaga*[2], *G. Paraskevopoulos*[3], *C. Hawrylowicz*[4], *G. Xanthou*[1];
[1]*Biomedical Research Foundation of the Academy of Athens, Athens, Greece,* [2]*Sotiria Chest Hospital, Asthma Center, Athens, Greece,* [3]*General Military Hospital of Athens, Athens, Greece,* [4]*Kings College London, Guys Hospital, London, United Kingdom.*

Regulatory T cells (Tregs) are essential for the maintenance of airway tolerance. Our previous studies have uncovered activin-A as an inducer of mouse Tregs that restrain Th2 responses and protect from experimental asthma. Still, whether activin-A can drive the generation of human Tregs remains elusive. Our data reveal that activin-A inhibits naïve $CD4^+$ T cell proliferation, IL-5 and IL-13 release during stimulation with allergen *in vitro*. Activin-A-treated $CD4^+$ T cells remain hyporesponsive upon secondary allergen stimulation. Importantly, activin-A-treated $CD4^+$ T cells suppress allergen-driven responses by human naïve T responders, pointing to the generation of a Treg population (act-A-iTregs). Act-A-iTregs are $CD4^+ICOS^+$, do not express Th2 cytokines but produce significantly increased IL-10. Notably, a major induction in the mRNA levels of the transcription factor Aryl hydrocarbon Receptor (AhR) and its gene target, CYP1A1, is observed. In fact, addition of an AhR antagonist reverses activin-A-mediated induction of $ICOS^+IL\text{-}10^+$ Tregs, indicating a novel link between activin-A and AhR in the generation of human IL-10-secreting Tregs. Using a humanized mouse model of asthma, we show that act-A-iTregs remain hyporesponsive upon transfer *in vivo* and do not induce allergic airway inflammation. Furthermore, adoptive co-transfer of act-A-iTregs with Th effectors ameliorates cardinal asthma features *in vivo* and allergen-specific Th2 responses. Of clinical relevance, act-A-iTregs restrain robust Th2 responses in asthmatics *ex vivo*. Collectively, our findings introduce activin-A as a novel inducer of functional human Tregs and may pave the way for the use of act-A-iTregs in adoptive-transfer cell therapy regimes aiming at re-establishing airway tolerance.

Immune regulation in lupus nephritis: role of CD4+CD25high FOXP3+ T regulatory cells and related cytokines (IL-6, IL-10, TGFβ)

K. Tselios*, A. Georgiadou, P. Klonizakis, A. Sarantopoulos, I. Gkougkourelas, M. Pantoura, P. Boura;*
Clinical Immunology Unit, 2nd Department of Internal Medicine, Hippokration General Hospital, Aristotle University of Thessaloniki, Thessaloniki, Greece.

Background: Platelet-derived microparticles (PDMPs) represent small vesicles that promote coagulation by exposure of negatively charged phospholipids. Aim of this study was the assessment of PDMPs in systemic lupus erythematosus (SLE) patients and their association with disease activity, presence of antiphospholipid antibodies (aPL) and previous thrombosis.
Patients and Methods: Forty consecutive SLE patients (38 females, 2 males, mean age 50±16.4 years, mean disease duration 110.7±26.4 months) were included. PDMPs were isolated from citrate-treated plasma and characterized by flow cytometry using Annexin-V and CD41 antibodies to platelet surface markers.
Results: SLE patients had significantly increased concentrations of PDMPs (1800±293MP/UI, normal range <1000MP/UI), irrespectively to disease activity, as PDMPs did not differ between active and inactive disease (1879±186 vs. 1805±343MP/UI, p=NS). Interestingly, PDMPs were detected in higher levels (although non significantly) in patients with a previous history of arterial or venous thrombosis (1855±219 vs. 1781±396MP/UI). In accordance, they were marginally elevated in patients with antiphospholipid syndrome (APS) (1892±233 vs. 1776±360MP/UI). Moreover, PDMPs were found in higher levels in patients with positive anti-dsDNA antibodies (1907±317 vs. 1762±303MP/UI) and low levels of C3/C4d complement fragments (1982±334 vs. 1721±256MP/UI, $p<0.05$).
Conclusions: PDMPs were found in higher levels in lupus patients with a previous history of thrombosis or concomitant APS. Elevated PDMPs in patients with positive anti-dsDNA antibodies and low complement levels suggest that these microparticles may further

induce thrombosis via the induction of immune complexes formation. These results warrant further characterization of PDMPs in SLE to elucidate their role in disease pathogenesis.

Intravenous immunoglobulin selectively enhances $CD4^+CD25^+FOXP3^+$ Treg function in patients

***R. van Gent**, A. S. W. Tjon, T. Tha-In, H. J. Metselaar, L. J. W. van der Laan, Z. M. A. Groothuismink, P. A. W. te Boekhorst, M. van Hagen, J. Kwekkeboom;*
Erasmus MC, Rotterdam, Netherlands.

High-dose intravenous immunoglobulins (IVIg) is used as anti-inflammatory therapy for auto-immune diseases and protect against acute transplant rejection. In mice, we observed that prevention of skin allograft rejection by IVIg is mediated by $CD4^+CD25^+FOXP3^+$ regulatory T cells (Tregs). To determine whether IVIg stimulates Tregs in humans *in vivo*, we studied Treg activation and suppressive function in patients treated with either low- (≤0.6g/kg, n=12) or high-dose (>0.6g/kg, n=15) IVIg monotherapy (indications: hypogammaglobulinaemia or autoimmune diseases). Blood was collected before, immediately after, and 7 days after IVIg infusion. Treg numbers and activation status were measured by flowcytometry, while suppressive capacity of $CD4^+CD25^+CD127^-$ Tregs purified from blood was determined in an *ex vivo* assay using IFN-γ secretion by autologous PHA-stimulated $CD4^+CD25^-CD127^+$ T-helper cells as read out. High-dose, but not low-dose, IVIg treatment enhanced the activation status of circulating Tregs, as shown by increased HLA-DR (+31% at day 7, $p<0.01$) and FOXP3 (+30% at day 7; $p<0.01$) expression, while numbers of circulating Tregs remained unchanged. The suppressive capacity of purified Tregs was increased by 42% at day 7 after IVIg treatment ($p=0.001$). Interestingly, the activation status of Tconv was not affected by IVIg. In conclusion, we show that IVIg treatment can selectively activate and enhance the suppressive capacity of Tregs in humans *in vivo*. We propose that Treg stimulation may be one of the mechanisms by which IVIg controls autoimmune and systemic inflammatory disorders.

P5.06.18
Deficient differentiation of Treg cells in a murine model of Sjögren's syndrome

***A. Yamada**, R. Arakaki, M. Kurosawa, T. Kondo, K. Yamada, Y. Kudo, Y. Hayashi, N. Ishimaru;*
Institute of Health Biosciences, The University of Tokushima Graduate School, Tokushima, Japan.

Foxp3+ regulatory T (Treg) cells play key roles in the maintenance of immunologic self-tolerance. Disruption in the development or function of Treg cells is a primary cause of autoimmune. Sjögren's syndrome (SS) is an autoimmune disorder characterized by lymphocytic infiltrates and destruction of the salivary and lacrimal glands. However, how autoimmune lesions develop in SS remains unclear. In this study, we examined the roles of Treg cells in pathological immune response of SS.
We first examined whether Treg cells suppress proliferation of effecter T cells using a SS-model, NFS/sld mutant mouse thymectomized at 3 days after birth. Treg cells from SS-model mice expressed similar level of CTLA4, a functional marker Treg cell, to that of control Treg cells and were capable of suppressing in vitro proliferation of effecter T cells comparable to control Treg cells. In addition, the number of Treg cells in SS-model mice was significantly reduced compared with that in control mice. In vitro differentiation of Treg cells from naïve CD4+ T cells of SS-model mice using TGF-β was considerably inhibited compared with that of control mice.
These data suggest that deficient differentiation of the Treg cells in SS-model mice may influence the pathogenesis of SS-model mice. Moreover, to understand phenotypic differences or functions of Treg cells between control and SS-model mice, we are trying to perform DNA microarray analysis.

Biochemical studies on glyoxal mediated glycated histones; Implications for presence of serum antibodies against the glycated histones in patients with type 1 diabetes mellitus

***N. A. Ansari**[1,2], D. Dash[3];*
[1]Hind Instt. of Medical Sciences, Lucknow, India, [2]Department of Biochemistry, Institute of Medical Sciences, Banaras Hindu University, Varanasi, India, [3]Department of Biochemistry, Institute of Medical Sciences Banaras Hindu University,, Varanasi, India.

Reactive carbonyl species (RCS) reacts non-enzymatically with amino groups of lysine and arginine to form advanced glycation end products (AGEs). In the present study role of glyoxal mediated glycoxidation of histone in type 1 diabetes was undertaken. Histone was modified with glyoxal and it was characterized by polyacrylamide gel electrophoresis, UV and fluorescence spectrophotometry. RCS-induced modification was confirmed by quenching study involving penicillamine and aminoguanidine as carbonyl scavengers. Presence of antibodies against glycoxidated histone in sera of type 1 diabetes patients was evaluated by solid phase enzyme immunoassay. Spectral analysis and electrophoresis of the protein clearly demonstrate structural perturbation in the histone by glyoxal. Glyoxal produce AGE specific absorbance and fluorescence in the protein together with cross-linking of histone leading to aggregation. The findings indicate that as a result of structural perturbation in histone by glyoxal, the modified histone was involved in production of serum antibodies in the diabetes patients.
This research work was supported by a grant [No. F.4-2/2006(BSR)/13-192/2008(BSR)] from UGC DS Kothari Post-Doctoral Fellowship Scheme, India.

P5.07.02
Effect of IL-7 on T cell differentiation during autoimmunity

***C. A. Arbelaez**;*
Benaroya Research Institute, Seattle, WA, United States.

Experimental autoimmune encephalomyelitis (EAE) is an autoimmune disease of the central nervous system mediated by autoreactive CD4+ T cells. IL-17-producing CD4 T (Th17) cells represent a major pathogenic T cell subset in multiple sclerosis and EAE. These cells, which are generated by the combination of IL-6 and TGF-β, require IL-23 receptor-mediated signaling for their maintenance and effector functions. IL-23R- and IL-23p19-deficient mice are resistant to the development of EAE, demonstrating the importance of Th17 and IL-23 in CNS autoimmunity. IL-7 has been proposed to serve as a growth factor for Th17 cells, and IL-23R-deficient T cells were shown to have diminished IL-7Rα expression, preventing sustained IL-7 signaling. Using a transgenic mouse system that constitutively expresses the IL-7R alpha chain (IL-7RαTg), we determined whether sustained expression of IL-7Rα could rescue Th17 expansion and EAE development in IL-23R-deficient (IL-23R KO) mice. Similarly to IL-23R KO mice, IL-7RαTg/IL-23R KO mice were resistant to the development of EAE, indicating that IL-7 itself cannot promote Th17 expansion in the absence of IL-23. Furthermore, IL-7RTg/IL-23R KO cells did not display a proliferative or survival advantage over the IL-23R KO cells upon immunization for EAE. Instead, we observed an inhibitory effect of IL-7 on the differentiation of Th17 cells and the promotion of IFN-γ and GM-CSF secretion by activated T cells. These results address the contribution of IL-7 and IL-23 for Th17 development and maintenance in CNS autoimmunity.

Systemic autoimmunity caused by a chronic innate response to intracellular nucleic acids

R. Behrendt[1], *B. Hiller*[1], *T. Schumann*[1], *K. Peschke*[1], *M. Achleitner*[1], *N. Schubert*[1], *R. Naumann*[2], *A. Dahl*[3], *W. Mueller*[4], *A. Roers*[1];
[1]*Institute For Immunology Medical Faculty TU Dresden, Dresden, Germany,* [2]*Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, Germany,* [3]*DFG-Center for Regenerative Therapies Dresden, Dresden, Germany,* [4]*Bill Ford Chair of Cellular Immunology, University of Manchester, Faculty of Life Sciences, Manchester, United Kingdom.*

Chronic type I interferon (IFN) production is a hallmark of the systemic autoimmune disease Lupus erythematosus (LE) and the rare hereditary condition Aicardi-Goutières Syndrome (AGS), a monogenic variant of LE. Although both conditions were associated with spontaneous production of the antiviral type I IFN, a disease-triggering virus could not be detected. Mutations in the genes encoding one of the four intracellular enzymes Trex1, RNase H2, SAMHD1 or ADAR1 have been shown cause AGS. All proteins are involved in nucleic acid metabolism. We generated RNase H2- or SAMHD1-deficient mice. RNase H2 deficiency triggered a spontaneous DNA damage response that lead to early embryonic lethality, caused by defective removal of misincorporated ribonucleotides from genomic DNA. It is presently unclear whether in mice RNase H2 deficiency can also lead to a spontaneous IFN response. In SAMHD1-/- mice, however, we found spontaneous IFN production. Thus, these mice recapitulate an important feature of LE and AGS pathogenesis. The nature of the IFN-inducing nucleic acids in cells defective for one of the AGS-associated enzymes is unclear. All four enzymes were demonstrated to affect retroviral replication. Trex1 deficiency was associated with enhanced retrotransposition of endogenous retroelements. These findings suggest that defects of AGS-associated enzymes could lead to uncontrolled activity of endogenous retroelements. Sensing of their replication intermediates by cellular nucleic acid sensors could activate the IFN response and trigger autoimmunity.

P5.07.04
Lack of T-bet does not inhibit dendritic cell ability to initiate an immune response in a dendritic cell driven model of experimental eutoimmune encephalomyelitis

H. E. Cambrook*, R. J. Mellanby, R. C. McPherson, D. G. Turner, M. D. Leech, R. A. O'Connor, S. M. Anderton;*
University of Edinburgh, Edinburgh, United Kingdom.

Experimental autoimmune encephalomyelitis (EAE) is a commonly used model of the demyelinating central nervous system (CNS) disease multiple sclerosis (MS). EAE is primarily a CD4 T-cell driven disease, requiring interactions between the innate and adaptive immune cells to initiate disease. Previous studies showed that although CD4 T helper cells with a Th1 phenotype (IFN-ɣ producing) are enriched in EAE, knocking-out or neutralising IFN-ɣ exacerbates disease. Subsequently, the master Th1 transcription factor T-box 21 in T cells (T-bet), has been shown to be required in EAE. T-bet is also present in other leukocytes including dendritic cells (DC), therefore may have a role at multiple stages of disease. In studies using T-bet KO mice and our DC driven EAE model, we have been able to study the interactions between DCs and CD4 T-cells. This has allowed us to independently study the role of T-bet in initiating an immune response in DC, and the resulting inflammatory response to antigen in CD4 T cells. Our data suggest that when provided with activating TLR signals and antigen, T-bet KO DC are able to up-regulate co-stimulatory molecules and induce proliferation in TCR transgenic CD4 cells *in-vitro*. *In-vivo,* these DC are able to provide appropriate stimulation to CD4 T cells, allowing for the induction of EAE. This model provides evidence that T-bet is not required in the innate elements of the EAE immune response, and that the role of T-bet may be restricted to the adaptive elements of the immune response in EAE.

P5.07.05
Genistein derivatives down-modulates pro-inflammatory cytokines in activated J774A.1 cells and reverses clinical signs of experimental autoimmune encephalomyelitis

S. B. R. Castro[1], *C. O. R. Junior*[1], *C. Souza Alves*[1], *A. T. Dias*[1], *M. A. Juliano*[2], *M. C. M. N. Castanon*[1], *M. V. Almeida*[1], *H. C. Teixeira*[1], *A. Ferreira*[1];
[1]*Universidade Federal de Juiz de Fora, Juiz de Fora, Brazil,*
[2]*Universidade Federal de Sao Paulo, Sao Paulo, Brazil.*

Genistein down modulate pro-inflammatory cytokine by inhibiting the NF-κB signaling pathway. Although genistein has some potential in clinical application, it has some disadvantages related to its chemical structure, such as rapid in vivo metabolism and a low concentration in serum after oral administration. In this report, the immunomodulatory effect of genistein derivatives on the production of pro-inflammatory cytokines by activated macrophages and their applications in EAE model were investigated. J774A.1 macrophages were incubated in the presence of genistein or genistein derivatives. Supernatants were collected for cytokine, NO and MTT assay. C57BL/6 mice were immunized with MOG35-55 and treated or not with genistein or genistein derivative. Mice were sacrificed on the 21st dpi and brains were removed for histological, cytokine production and cell markers analysis. In J774A.1 macrophages the genistein has inhibited both IL-12 and TNF-α, the lipophilic derivatives showed high capacity to inhibit IL-12 without altering TNF-α, indicating a more specific mechanism in the modulation of IL-12 and the glycosylated derivative AAP37A showed elevated inhibition of NO (100.0±0.5), IL-1β (100.0±12.9) and IL-6 (94.1±5.9). Treatment with O-tetradecanoyl-genistein derivative improved prognosis of EAE by reduction of inflammatory infiltrate, decrease of pro-inflammatory cytokines and reduction of cells producing IL-17 (0.6±0.03 vs. 3.5±0.6), and increasing of cells producing IL-10 (0.6±0.1 vs. 0.1±0.07) and expressing FOXP3 (1.4±0.2 vs. 0.3±0.1) and CTLA-4 (4.8±0.4 vs. 1.0±0.04) in the central nervous system. Thus, these derivatives showed potential to be used in the treatment of inflammatory diseases and deserve further investigations.

Genistein modulates TLR3, TLR4 and TLR9 in antigen presenting cells and delayed clinical signs of experimental autoimmune encephalomyelitis

A. T. Dias[1], ***S. B. R. Castro***[1], *C. Souza Alves*[1], *L. C. Silva*[1], *M. G. Evangelista*[1], *M. A. Juliano*[2], *A. Ferreira*[1];

Genistein is an isoflavonoid derived from soy that can affect many different cellular mechanisms such as the inhibition of NF-κB activation factor, known to play a critical role in inflammation, immune modulation and cell proliferation. In this preliminary report, the immunomodulatory effect of genistein in innate immune response in EAE model, by analyzing the expression of Toll-like receptors were investigated. C57BL/6 mice were treated or not with genistein 7 days before the induction. The EAE were induced by immunization with MOG35-55 emulsified in complete Freund's adjuvant supplemented with 400µg of attenuated *Mycobacterium tuberculosis* H37RA. Pertussis toxin, 300ng/animal, was injected intraperitoneally on the day of immunization and 48h later. Animals were monitored daily until 21st dpi and neurological impairment was quantified. Mice were sacrificed on the 7th dpi and spinal cords were removed for analyses of TLR3, TLR4 and TLR9 by F4/80+ or CD11c+ cells. Genistein treatment delayed clinical signs in the 12th dpi in comparison to group not treated (0.3±0.1 vs. 2.2±0.6). The group treated with genistein showed an elevation of mean fluorescence intensity (MFI) of cells F4/80+ expressing TLR3 (2,232.0±35.1 vs. 1,105.0±86.8), TLR4 (1,219.0±21.9 vs. 1,095.0±39.4) and TLR9 (1,803.0±35.5 vs. 942.7±29.4) in relation to EAE not treated. CD11c+ cells showed increased MFI of TLR3 (1,486.0±53.5 vs. 631.1±76.3) and TLR9 (1,508.0±62.7 vs. 918.7±65.2) in relation to EAE not treated and reduced MFI of TLR4 (596.7±27.1 vs. 743.4±50.9). The results suggest that alterations in the TLR expression could have important roles for the evolution of EAE.

Prolactin levels correlate with abnormal B cell maturation in MRL and MRL/lpr mouse models of systemic lupus erythematosus-like disease

***A. K. Chavez-Rueda**, F. Blanco-Favela, M. V. Legorreta-Haquet, R. Flores-Fernandez, L. Chávez-Sánchez;*
IMSS, Mexico, Mexico.

Prolactin (PRL) has an important role in modulating the immune response. PRL is secreted by the pituitary gland and many other organs and cells, among them lymphocytes. In B cells PRL enhances antibody production, including those with self-specificity; as such PRL has been associated with B cell triggered autoimmune diseases, such as *systemic lupus* erythematosus (SLE). In this study, our aims were to determine the expression of PRL-receptor during bone marrow B cell development and whether the presence of high PRL serum concentration influences receptor expression, absolute numbers of developing populations and disease outcome in lupus-prone murine models. Using real time-PCR and flow cytometry, we observed that the PRL-receptor is expressed in bone marrow early B cells (pro-B, pre-B, immature); in lupus prone mice the highest level of expression was found in pro-Bs and immature cells, an expression pattern that differed with the one of wild type early B cells. In hyperprolactinemia, pro-B cells from lupus prone strains further down-regulated the expression of the PRL-receptor correlating with a decrease in the absolute numbers of both pro-Bs and immature B cells. In this latter population the anti-apoptotic BIRC5 gene was increased in hyperprolactinemia, also coinciding with a higher activity of the disease. These results support an important role of PRL in the early stages of the B cell maturation process, thus helping to clarify its relevance in the development of SLE.

Vitamin D does not boost MOG therapeutic effect in experimental autoimmune encephalomyelitis

***F. Chiuso-Minicucci**, S. F. G. Zorzella-Pezavento, L. L. W. ISHIKAWA, T. G. D. França, P. M. Colavite, L. C. Rosa, A. Sartori;*
Univ Estadual Paulista (UNESP), Botucatu, Brazil.

Multiple sclerosis (MS) is a chronic disease of the central nervous system (CNS) associated with a destructive immune response directed against CNS antigens. Most MS treatments cause general immunosuppression that determines severe side effects. Therefore, induction of antigen-specific tolerance is highly desirable as a disease treatment. The active form of vitamin D3 (vitD3) has immunomodulatory properties as induction of tolerogenic dendritic cells and regulatory T cells. We studied the therapeutic potential of myelin oligodendrocyte glycoprotein (MOG) alone or associated with vitD3 supplementation in experimental autoimmune encephalomyelitis (EAE) that is a MS model. Female C57BL/6 mice were submitted to EAE induction by immunization with MOG emulsified in CFA plus BCG and also injected with two intraperitoneal doses of *Bordetella pertussis* toxin. One day after immunization, mice were treated with MOG or MOG associated with vitD3. Animal were injected every other day for 15 days (on days 1, 3, 5, 7, 9, 11, 13 and 15) with vitD3 (0, 1µg). On days 3 and 11, MOG was coinjected with vit D3 or alone. Both therapeutic schedules were similarly protective. They determined significant reduction in EAE incidence and also in clinical scores. MOG, but not MOG/vitD3 treatment, avoided the characteristic weight loss during the acute phase of the disease. The MOG treated group also produced high levels of IL-10 in response to *in vitro* MOG stimulation. These findings indicate that MOG by intraperitoneal route was highly tolerogenic. They also show that addition of vitD3 did not boost this effect.

P5.07.09
Galectin-9 contributes to enhanced experimental autoimmune encephalomyelitis

***J. Cho**, S. Bing, S. An, A. Kim, Y. Jee;*
Jeju National University, Jeju, Republic of Korea.

Experimental autoimmune encephalomyelitis (EAE) is a typical autoimmune disease which is an inflammatory and demyelinating disease in murine central nervous system (CNS). It is used as an animal model of human multiple sclerosis (MS) because its symptoms are similar to MS. Meanwhile, galectins are a family of glycan-binding proteins and divided into subtypes based on their structure. Some members of galectin family such as galectin-1, galectin-3, and galectin-9 (Gal-9) have been reported to play an important role in the development of innate and adaptive immune responses. Especially, Gal-9 is reported to induce cell death of terminally differentiated Th17 cells via interaction with Tim-3 while it suppresses Th17 development in an IL-2 dependent but Tim-3 independent manner in EAE. In contrast, the role of Gal-9 in the autoimmune disease remains uncertain and its function has not been fully elucidated in EAE. In this study, we examined the association between Gal-9 expression and EAE progression. We observed an incremental rise in Gal-9 level in C57BL/6 mice as EAE progressed, with a sharp rise by peak of disease. This suggests possible biological connection between Gal-9 and EAE warranting further exploration of its function in EAE. It also suggests that the identification of relationship between Gal-9 and EAE progression is critical for better understanding Gal-9 biology. This work was supported by the National Research Foundation of Korea (NRF) grant funded by the Korea government (MEST) (2012011645).

Neutrolphils infiltration, increased IL-1 production and SAPHO syndrome-like phenotype in PSTPIP2 deficiency mice

***I. Chyuan**[1,2], H. Liao[3], C. Wu[4], M. Yen[5], H. Tsai[6,7], P. Hsu[2,3];*
[1]Department of Internal Medicine, National Taiwan University Hospital Hsin-Chu Branch, Hsinchu City, Taiwan, [2]Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan, [3]Graduate Institute of Immunology, College of Medicine, National Taiwan University, Taipei, Taiwan, [4]Division of Rheumatology, Department of Internal Medicine, Far Eastern Memorial Hospital, Taipei, Taiwan, [5]Department of Obstetrics and Gynecology, National Taiwan University Hospital, Taipei, Taiwan, [6]Department of Internal Medicine, Taipei Medical University Shuang Ho Hospital, Taipei, Taiwan, [7]Graduate Institute of Clinical Medicine, College of Medicine, Taipei Medical University, Taipei, Taiwan.

Proline-serine-threonine-phosphatase-interacting protein 2 (PSTPIP2) belongs to the Pombe Cdc15 homology (PCH) family of proteins involved in actin-based cytoskeletal functions, including membrane ruffing, filopodia formation, motility and adhesion, mainly expressed in macrophages. Previous studies have been reported that mice with missense mutation in *Pstpip2* gene developed an autoinflammatory disorder presenting multiple sterile inflammatory bone lesions. In this report, we generated PSTPIP2 knockout (*Pstpip2*$^{-/-}$) murine model. All affected mice developed paw swelling, synovitis, hyperostosis, osteitis, resembling SAPHO syndrome (synovitis, acne, pustulosis, hyperostosis, osteitis), an inflammatory disorder of the bone, skin, and joints. Histological examinations of *Pstpip2*$^{-/-}$ mice revealed multifocal osteomyelitis in the inflamed paws with increased macrophage and marked neutrophil infiltrations in the bone, joint, and skin. Micro-computed tomography revealed profound osteolytic lesions with marked osteoporosis in the paws and limbs. Spenomegaly and enlarged lymph nodes with increased neutrophils also developed. Neutrophil attracting chemokines (CXCL1, CXCL2, CXCL5, MIP-1α and IL-8) and inflammatory cytokines (TNFα, IL-6, and IL-1β) were elevated from macrophages of the inflamed tissues. These studies suggest that PSTPIP2 may play a role in innate immunity and the development of autoinflammatory bone disorders.

Induction of SLE-like syndrome in Balb/c mice by immunization with active chromatin

F. Faraji, *F. Lavi Arab, M. Mahmoudi, M. Rastin, M. Ghoryani, H. Reihani, D. Haghmorad, R. Nosratabadi, N. Tabasi, S. Zamani Taghizadeh Rabe;*
Immunology Research Center, BuAli Research Institute, Faculty of Medicine, Mashhad University of Medical Sciences, Mashhad, Iran.

Introduction: Systemic lupus erythematosus is an autoimmune disease, which is characterized by production of autoantibodies against self- antigens specially DNA. Disease is multifactorial and the main cause of it is still unknown. Thus animal models of SLE can be usefull for studying the cellular and molecular mechanisms which are involved in the disease pathogenesis.
This study aim to stablish a murine model for SLE-like syndrome by immunization with active chromatin for assessment of vitamin D effects on Th17 cells and related cytokines in SLE.
Methods and Materials: Normal female Balb/c mice (6-8 weeks) were immunized subcutaneously with 50 µg active , and non- active chromatin, derivated from spleen lymphocyte cells. Proteinuria was measured by coomassie brilliant blue asssay and anti-ds DNA antibodies determined in peripheral blood samples by using enzyme-linked immunosorbent assay kit. Kidney sections viwed by a pathologist for detection of immune complexes deposition. Blood and urine samples of the mice were collected every two weeks after final immunization for 8 weeks
Results: The mice immunized with active chromatin had higher levels of proteinuria with pick value in the last week in comparison to the mice immunized with non-active chromatin. This project in under study, and the results demonstrating the effects of Vitamin D on lupus like mice will be presented in the the congress.
Conclusion:Active chromatin can induce SLE-like syndrom in normal mice. This modle can help us for studying the pathogenesis of SLE.

X-ray irradiation suppresses SLE-like morbidity in NZBWF1 mice

K. N. Fujita[1], *B. Wang*[2], *T. Kuwabara*[1], *K. Tanaka*[2], *I. Kamata*[1], *Y. Akasaka*[1], *T. Ishii*[1];
[1]*Toho University, Tokyo, Japan,* [2]*National Institute of Radiological Sciences, Chiba, Japan.*

CD180 molecule is a homologue of TLR-4 and expresses on mature B cells. The molecule shows a protective effect against radiation- or dexamethasone-induced apoptosis *in vitro*. CD180 is a key regulator of cell proliferation and death. We previously showed CD180-negative spleen B cells exhibited sensitivity for radiation-induced apoptosis compared with CD180-positive cells *in vivo*. In SLE patients, the number of CD180-negative B cells increased in peripheral blood, and appeared to be associated with the activity of SLE. In addition, such negative cells collected from SLE patients produced autoantibodies *in vitro*. We previously reported CD180-negative B cells might lead to development of SLE morbidity in SLE-model mouse, NZBWF1. In the present study, we attempted to examine the effects of X-ray irradiation on CD180-negative B cells in NZBWF1 female mice. After irradiation, the mean life span of the irradiated mouse group was significantly extended compared with that of the sham-irradiated one. In addition, the latency to the development of grade three-proteinuria in irradiated mouse is significantly longer than in sham-irradiated one. The amount of complement C3 in peripheral blood of the irradiated mouse was sustained at normal level, while that of sham-irradiated mouse was markedly decreased at 3 weeks after sham-irradiation. These findings suggest that radiation could effectively eliminate CD180-negative B cells, leading to reduction of autoantibody production, and thus relieve SLE symptoms. The findings also suggest a possibility that the radiotherapy into autoimmune diseases associated with the expression of CD180-negative cells might be a novel practical application.

P5.07.13
Autoantibody repertoire and inflammatory myeloid cell expansion drive the transition from autoreactivity to autoimmunity in a novel mouse model of systemic lupus erythematosus

S. V. Hai, *V. C. Lam, B. Cook, A. Weiss, M. L. Hermiston;*
University of California, San Francisco, San Francisco, CA, United States.

The mechanisms regulating the transition from autoreactivity (loss of tolerance and autoantibody production) to autoimmunity (immune-mediated end organ damage) are incompletely understood. CD45E613R mice express a point mutation in juxtamembrane wedge that results in dysregulated phosphatase activity. Despite similar hyperactivation of ITAM-mediated signaling pathways in multiple cell lineages, the phenotypic consequences of this mutation vary with genetic background. CD45E613R BALB/c mice develop high titer anti-dsDNA antibodies but no end organ disease while C57Bl/6 (B6)-129 F1 mice develop anti-dsDNA antibodies and severe glomerulonephritis. The genetic separation of autoreactivity from autoimmunity makes this an ideal model system for identifying risk factors and novel targets in lupus nephritis. Interestingly, both B6-129 F1 and BALB/c CD45E613R mice have extensive IgG/immune complex and C3 deposition in their kidneys. However, comparison of the autoantibody repertoire in B6-129 F1 and BALB/c CD45E613R mice indicate that CD45E613R B6-129 F1 mice have a broader repertoire of autoantibodies, particularly of the more pathogenic IgG2a subtype. Using flow cytometric and immunohistochemical approaches to compare infiltrating and resident hematopoietic cells in the kidneys reveals an expansion of monocytes and skewing towards an M1 macrophage phenotype in the B6-129 F1 background. Consistent with this, IL-1α, IL-6, TNF-α and MCP-1 are elevated in B6-129 F1 but not BALB/c CD45E613R mice. Taken together, these data support a model in which an expanded antibody repertoire combined with altered kidney immune cell subsets and increased inflammatory cytokines mediate the transition from autoreactivity to autoimmunity.

P5.07.14
Specificity of antinuclear antibodies in Swiss Webster mice following exposure to gold salts and mercury

S. Havarinasab;
IKE, Linköping, Sweden.

Exposure with gold in genetically susceptible inbred mouse strain, A.SW (H-2s), indicated that gold caused autoimmunity characterized by lymphoproliferation, development of anti-nuclear antibodies targeting the nucleolar protein fibrillarin, hypergammaglobulinemia and development of immune-complex deposits. In this study we investigated the effect of gold on the immune system of the outbred Swiss Webster (SW), and the congenic A.SW strain derived from A/WySn and Swiss Webster.
Mice were given either weekly intramuscular injections of gold in the form of natrium aurothiomaleate (AuTM) for 15 weeks and ontrols received equimolar amounts of PBS.
Using indirect immunofluorescence detection of serum antibodies in response to AuTM, all SW mice developed anti-nuclear antibodies while A.SW mice produced significant amounts of anti-nucleolar antibodies. Further investigation of the autoantibodies specificity by line immunoassay (LIA) and Western blotting indicated that gold-induced autoantibodies in SW mice targeting mainly nucleosomes, histone H1 and H2A whereas; autoantibodies developed in A.SW were targeted fibrillarin. The effects of gold on lymphocyte subpopulations were determined by flow cytometry indicating lymphoproliferation of T- and B-cells, proliferation of T-helper cells and particularly proliferation of CD8 cytotoxic T-cells in SW mice.
Based on these observations we conclude that i) in these mice the interaction between gold and the immune system may differ by generation of autoantibodies targeting different nuclear- and nucleolar proteins, and ii) presence of particular and known susceptible genes play a key role in development of murine autoimmune response.

P5.07.15
Effect of mercury (Hg) and silver (Ag) in mice model of autoimmunity- Re-challenging of mice by additional heavy metal exposure leads to acceleration of the autoimmune response

***S. Havarinasab**;*
IKE, Linköping, Sweden.

The effect of mercury (Hg) and silver (Ag) in genetically susceptible A.SW mice is characterized by anti-nucleolar antibodies (ANoA), lymphoproliferation and systemic immune-complex (IC) deposits. We used A.SW mice to see whether the autoimmune response is stronger and faster following a secondary exposure, implying a memory in the immune system.
The mice receiving mercury, silver or drinking water during 3 weeks (phase-1). The following thirteen weeks the mice groups were given only tap water (phase-2) followed by exposure with mercury in all groups for further 5 weeks (phase-3). Controls were given drinking water until phase-3. Analyses were consisted of ANA, IgG concentration, immune-complex depositions in kidney and spleen, and accumulation of mercury in the whole body retention (WBR) and organs using a gamma counter.
Regardless of the phase-1 exposure, mice that were exposed with either mercury or silver induced a higher and faster increase of fraction of ANoA IgG subclasses as well as the deposition of splenic and lymphatic nodes of Hg compared with control mice at phase-3. The level of IgG1 and IgG2a accelerated faster in phase-3 when mice were exposed to two different metals. Renal immune-complex deposits were more marked when mice treated twice with heavy metals.
We conclude that for certain parameters i.e. ANA and tissue- and WBR mercury deposits, an B-cell restricted immunological memory plays important role while increased amount of IgG1 and IgG2a is particularly controlled by sensitization of mice twice with at heavy metals.

P5.07.16
Human parvovirus B19 NS1 protein aggravates hepatic fibrosis in NZB/W F1 mice

***T. Hsu**[1], B. Tzang[2,3], C. Tsai[1], C. Chiu[1];*
[1]Institute of Microbiology and Immunology, Chung Shan Medical University, Taichung, Taiwan, [2]Institute of Biochemistry and Biotechnology, Chung Shan Medical University, Taichung, Taiwan, [3]Department of Biochemistry, School of Medicine, Chung Shan Medical University, Taichung, Taiwan.

Human parvovirus B19 (B19) has been associated with a variety of diseases. However, the effects of B19 viral proteins on liver in SLE are still obscure. Therefore, we aimed to investigate the effects of B19 on liver in NZB/W F1 mice by injecting subcutaneously with PBS, recombinant B19 nonstructural protein (NS1), VP1 unique region (VP1u) or VP2, respectively. Our results revealed that B19 NS1 protein significantly enhanced the transforming growth factor β (TGF-β)/Smad fibrotic signaling by increasing the expressions of TGF-β, Smad2/3, phosphorylated Smad2/3, Smad4 and Sp1. The consequent fibrosis-related proteins, PAI-1 and α-smooth muscle actin (SMA), were also significantly induced in livers of NZB/W F1 mice receiving B19 NS1 protein. In addition, markedly increased collagen deposition was also observed in livers of NZB/W F1 mice receiving B19 NS1 protein. Meanwhile, no significant difference was observed in livers of NZB/W F1 mice receiving B19 VP1u or VP2 as compared to the controls. These findings indicate that B19 NS1 plays a crucial role in exacerbating liver fibrosis in NZB/W F1 mice through enhancing the TGF-β/Smad fibrotic signaling.

P5.07.17
RORγt transgenic mice developed spontaneous sialadenitis like Sjögren's syndrome

***M. Iizuka**[1], H. Tsuboi[1], H. Asashima[1], Y. Kondo[1], S. Takahashi[2,3], I. Matsumoto[1], T. Sumida[1];*
[1]Department of Internal Medicine, Faculty of Medicine, University of Tsukuba, Tsukuba, Japan, [2]Department of Anatomy and Embryology, Faculty of Medicine, University of Tsukuba, Tsukuba, Japan, [3]Laboratory Animal Resource Center, University of Tsukuba, Tsukuba, Japan.

[Backgrounds] The aim of this study was to clarify the pathological role of RORγ in sialadenitis using RORγt transgenic (Tg) mice under the promoter of hCD2 which spontaneously developed sialadenitis like SS.
[Methods] 1) Histological analysis of salivary glands (SG) was determined and saliva flow was measured. 2) Infiltrating cells of SG were analyzed by fluorescent immunostaining and flow cytometry. 3) Analysis of CD4+ T cells in spleen, cervical lymph node (cLN) and SG were performed by quantitative PCR. 4) Splenic CD4+ or CD4- cells were transferred to Rag2-/- mice (CD4+or CD4-→Rag2-/-) and histological analysis was examined.
[Results] 1) RORγt Tg mice developed the severe sialadenitis like SS. Saliva flow of RORγt Tg mice was significantly decreased than that of C57BL/6 mice. 2) Majority of infiltrating cells was CD4+ T cells at early phase of sialadenitis, and B cells were gradually increased at late phase. 3) CD4+ T cells from spleen, cLN and SG retained effecter memory phenotype. Expression of T-bet, GATA3 and Bcl6 in CD4+ T cells were significantly higher than in SG than in spleen and cLN. Subset of Th17 (IL-17, IL-23r), Th1 (IFN-γ, T-bet), Th2 (IL-4, GATA3) and Tfh (IL-21, Bcl-6) related molecules were increased in salivary glands. 4) In CD4+↔Rag2 -/-, sialadenitis was observed, but not in CD4-→Rag2-/-.
[Conclusion] These results suggested that the overexpression of RORγt on CD4+ T cells play a crucial role in the development of spontaneous sialadenitis like SS.

P5.07.18
Early local IL-12p40/p(40)2 production and intensity of peritoneal inflammation correlate with susceptibility to pristane induced arthritis.

*C. Rossato, L. L. Albuquerque, O. G. Ribeiro, N. Starobinas, M. Spadafora-Ferreira, W. H. K. Cabrera, A. Borrego, O. M. Ibañez, M. De Franco, **J. R. Jensen**;*
Instituto Butantan, São Paulo, Brazil.

Genetically selected HIII (high antibody producer) mice are resistant, while LIII (low antibody producer) are susceptible to pristane-induced arthritis (PIA). The peritoneum (PerC), site of PIA induction, is rich in myeloid and lymphoid cells and might be the site where the genetic divergence in susceptibility of HIII/LIII mice would translate into functional differences, affecting the early inflammatory cell response and cytokine balance. Mice were injected with 0.5mL pristane i.p. and after 48h, 4, 7, 15 or 30 days, the PerC was washed with RPMI1640+10%FBS. The supernatant was used for cytokine ELISA and cells were counted in hemocytometric chambers and phenotyped by FACS. Inflammatory cell infiltration was highest in LIII mice at 7 days, with increased numbers of most cell populations. Leukocyte infiltration in HIII mice, consisting mostly of neutrophils, increased slowly until d30, while monocytes/macrophages and lymphocytes were reduced. Dendritic cells and T cells increased only in pristane treated LIII mice. Both lines produced similar amounts of CCL-2, IL-1beta, IL-6, IL-4, and low levels of IL-12p70 after pristane injection, while IFN-gama was not detected. However, IL-12p40/p$(40)_2$ was produced only in LIII mice, increasing from d4 to d30. Our results suggest that the divergent susceptibility of HIII/LIII mice might be linked to their distinct peritoneal response to pristane, and that IL-12p40/p$(40)_2$, which is mainly produced by dendritic cells, might be involved by promoting dendritic cell recruitment and migration to lymph nodes, thereby increasing the potential of autoreactive T cell activation in susceptible LIII mice.

P5.07.19
Immune regulation of monophasic experimental autoimmune uveitis influencing relapsing disease

***U. Kaufmann**, M. Diedrichs-Möhring, G. Wildner;*
Ludwig-Maximilians-University, Munich, Germany.

Rat experimental autoimmune uveitis (EAU) can be induced with S-Ag peptide PDSAg, (monophasic EAU) or IRBP peptide R14 (relapsing EAU). We have previously shown different dynamics of intraocular T cell populations during the two types of EAU, but the exact mechanisms behind the disease courses remain elusive. Here we used different combinations of the two antigens for immunization (either administered separately at contralateral sides or as a mixture of both) to investigate the mutual influence on the disease course and the immune response. Clinical uveitis was determined daily and cytokine pattern (IFN-γ, IL-17, IL-10) and Foxp3-expression of intraocular cells was determined at onset, peak and resolution of disease. Data of the combined immunizations were compared with that from the conventional PDSAg and R14 immunizations. While in R14-induced EAU 75% of the eyes developed relapses, none of the PDSAg- or PDSAg/R14-mixture immunized rats had recurrences. However, contralateral administration of both antigens allowed relapses in 12.5% of eyes. The cytokine pattern of intraocular cells looked similar in those animals immunized with both antigens, but differed from the pattern of the rats which were immunized with PDSAg or R14 only. Rats immunized with both antigens showed an R14-like cytokine pattern at onset of EAU and a PDSAg-like cytokine expression at resolution. Disease course and cytokine pattern of intraocular cells confirmed a dominant role of the monophasic, PDSAg-specific immune response. These data indicate a strong peripheral (mixed immunization: no relapse) and a slightly less stringent intraocular regulation (contralateral immunization) of the autoimmune response.

P5.07.20
Restriction of TCR diversity in NOD mice inhibits the development of Type I Diabetes but not Sjögren's syndrome

***J. M. Kern**, R. Drutel, R. Pacholczyk;*
Georgia Regents University, Augusta, GA, United States.

The NOD mice serve as a well-established model of independently developing autoimmune diseases, Type 1 Diabetes (T1D) and Sjogren's syndrome (SjS). One of the striking differences in their development is that T1D depends on exclusive presence of I-Ag7 molecules, whereas SjS develops regardless of the MHC haplotype, suggesting different sensitivity to diversity of self MHC/peptide complexes. So far it has been shown that restriction of TCR precursor frequency in TCRβ transgenic NOD mice doesn't prevent development of T1D. It suggests that, regardless of the initial TCR diversity it's the inherent defect in the thymic selection that allows for escape of pathogenic T cells.
Surprisingly, when we generated transgenic mice using TCRVβ14 chain originally selected on I-Ab molecule we didn't observe development of T1D but SjS developed normally. This lack of T1D development is associated with absence of CD4 cells specific to islets antigens in the periphery, as we didn't detect CD4 cells specific for INSp9-23 or GAD65p524 peptides and co-transfer of wild type CD8 cell didn't help in initiation of the disease. This suggests that reduction of TCR precursor frequency in NOD mice allows for efficient thymic selection that prevents escape of T1D-pathogenic T cells. To further reduce TCR diversity, we generated NOD.mini mice, where the same TCRβ chain is co-expressed with TCRα chains from TCRα.mini locus. This greater restriction of TCR repertoire still allows for SjS development indicating that onset of the disease for SjS is less dependent on a particular antigen for CD4 cells than onset of T1D.

P5.07.21
Spatial learning and memory impairment in an acute experimental autoimmune encephalomyelitis

***D. Kosanovic**, A. Stojkovic, N. Vukov, K. Jovanova-Nesic;*
Biomedical Center of the Institute Torlak, Belgrade, Serbia.

Experimental autoimmune encephalomyelitis (EAE) could be associated with cognitive disturbances, so the aim of the study was investigation of spatial learning in mice with EAE. EAE was induced in eight-week-old C57BL/6 female mice by subcutaneous immunization (MOG35-55 in complete Freund's adjuvant) and pertussis vaccine intraperitoneally. Animals were scored daily for clinical signs of EAE. Morris water maze test (MWM), consisting of a circular tank filled with water and a submerged platform in a fixed spot was performed before and after EAE induction. The path, time, and motor funcion during MWM test were observed. Hematoxylin-eosine staining of brain tissue was used for histological examination. After two trials mice mostly swam in the quadrant with the platform and after 8 training days all the mice swam directly to the platform. 50 % of mice with EAE showed partial loss of tail tonicity approximately 13 days post immunization. In all mice with EAE hind limb weakness after swimming was observed 18 days post immunization. Significant difference ($p<0.05$) in the time for finding the platform was found between mice with mild clinical signs of EAE in comparison with other mice (EAE without symptoms and non-treated). Interindividual behavioural difference within mice with EAE signs were observed, in 40 % there were no changes while in 60 % signs of disorientation and anxiety-like behaviour was noted. Histopathological examination showed lesions in the brain parenchyma, especially in the hippocampal region of EAE mice. Hippocampal tissue destruction in EAE mice indicates the cognitive learning and memory impairment detected.

P5.07.22
Altered Lyn activity leads to exaggerated Th2-immunity or multiple chronic obstructive pulmonary disease-like changes in mouse

***M. Iau**[1,2], E. Tsantikos[2], E. Duan[2], M. J. Maxwell[2], G. P. Anderson[1], M. L. Hibbs[2];*
[1]The University of Melbourne, Dept of Pharmacology, Melbourne, Australia, [2]Monash University, Dept of Immunology, Melbourne, Australia.

Lyn tyrosine kinase is intricately important in both signaling initiation and down modulation as there are multiple implications with altered Lyn's activity. Lyn knock out (Lyn(-/-)) mice develop lupus-like autoimmune disease and has allergic traits. The Th1/Th2 paradigm explain autoimmunity and allergy/atopic disease manifestations as caused by extremes of two opposing immune responses which creates an apparent contradiction of coexisting autoimmune disease and atopy in the Lyn(-/-) mouse model. To investigate this balance between Th1 versus Th2-immune responses, the regulator of Th2 immunity, STAT6 was deleted. Atopy and spontaneous peritoneal eosinophilia, characteristic of Lyn(-/-) mice, were lost in young Lyn(-/-)STAT6(-/-) mice; however, autoimmune disease was markedly exacerbated. Furthermore, aged Lyn(-/-)STAT6(-/-) mice showed dramatically increased levels of serum IgE but minimal IgG1, suggesting that class-switching to IgE can occur in the absence of an IgG1 intermediate. The results show that Lyn-deficient mice can overcome the effects of disabling Th2 immunity, highlighting the importance of Lyn in down modulating Th2 immune responses. On the other hand, deregulated signaling initiation by Lyn was implicated in myeloid leukemia and several types of epithelial cancer. The Lyn knock in (Lyn(up/up)) mutant mouse was created to investigate putative proto-oncogenic roles of Lyn. Lyn(up/up) mice develops chronic lung inflammation, emphysema at young age and some eventually had lung tumors. The Lyn(up/up) mouse will provide an excellent model to investigate the co-determinant that leads to both airspace tissue destruction and lung cancer which deceivably seems like two opposite outcomes of lung disease that co-develops in COPD patient.

Introduction: Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by auto-reactiveT cells and serological presence of anti-double-stranded DNA and lethal glomerulonephritis. The etiology of the SLE is not clear yet, but is considered combination of multiple genetic and environmental factors involved in the pathogenesis of disease. Vitamin D is one of the main environmental factors that have immunomedulatory effects on immune system. The majority of SLE patients are reported to have insufficient or deficient serum levels of vitamin D. In this study we aim to assay Vitamin D effects on SLE in lupus-like syndrome induced mice models.
Materials and Methods : Normal female Balb/c mice (6-8 weeks) were fed 50 ng/day active form of vitamin D from two weeks before immunization with 50 µg active DNA and some of mice fed vitamin D at the same time of immunization for 8 weeks. Urine and blood samples were collected every two weeks after final immunization and examined for protein and anti-ds DNA respectively.
Results: Proteinuria decreased in mice which received vitamin D compared with control mice and didn't show any clinical aspects of SLE disease. This project in under study, and the results demonstrating the effects of Vitamin D on lupus like mice will be presented at the congress.
Conclusions: Studies on vitamin D effects on autoimmune diseases can provide new therapeutic strategies in the treatment of SLE.

P5.07.24

B lymphocyte-induced maturation protein 1 (BLIMP-1) attenuates autoimmune diabetes and encephalomyelitis by suppressing Th1 and Th17 cells

***M. Lin**[1], L. Yeh[2], H. Chiou[3], S. Fu[4], K. Lin[5], S. Chen[6], D. Chang[7], H. Sytwu[1];*
[1]Department and Graduate Institute of Microbiology and Immunology, National Defense Medical Center, Taipei, Taiwan, [2]Graduate Institute of Medical Sciences, National Defense Medical Center, Taipei, Taiwan, [3]Graduate Institute of Life Sciences, National Defense Medical Center, Taipei, Taiwan, [4]Taiwan International Graduate Program, Graduate Institute of Life Sciences, National Defense Medical Center and Academia Sinica, Taipei, Taiwan, [5]Genomics Research Center, Academia Sinica, Taipei, Taiwan, [6]Department of Pediatrics, Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan, [7]Department of Internal Medicine, Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan.

Recently, Blimp-1 expands its control over T cells and is associated with susceptibility to colitis in mice with T cell-specific Blimp-1 deficiency. However, its role in regulating other autoimmune diseases is unclear. We demonstrate that transgenic expression of Blimp-1 in T cells significantly decreases the incidence of diabetes and MOG_{35-55}-induced encephalomyelitis in NOD mice. In contrast, mice lacking Blimp-1 in T cells developed markedly increased Th1 and Th17 cells and exacerbated encephalomyelitis. Our results reveal that Blimp-1 orchestrates a T cell-specific modulation on autoimmunity by affecting the cell proliferation, Th1 and Th17 cell differentiation, and Treg cell function. We also demonstrate that Blimp-1 suppresses IL-23R and GM-CSF which are essential for Th17 pathogenicity and that Blimp-1-mediated Th17 downregulation is through a RORα-RORγt-dependent pathway. Strikingly, overexpansion of Th1 and Th17 cells in CKO mice is significantly restored by introducing a Blimp-1 transgene, reinforcing the emerging role of Blimp-1 in autoimmunity and providing a basis for developing therapeutic strategies.

P5.07.25

Dominancy of encephalitogenic peptide itself directs sustainable remission of a model of multiple sclerosis, through later expansion of 'armoured' effector regulatory T cells: possibility of vaccination for autoimmune disease

***Y. Lin**[1,2], S. Miyake[1], T. Yamamura[1];*
[1]Department of Immunology, National Institute of Neuroscience, NCNP, Tokyo, Japan, [2]Department of Neurology, National Center Hospital, NCNP, Tokyo, Japan.

Autoimmune diseases occur as dysregulation of host defense caused by imbalance of pathogenic and protective cells. The mechanism of their chronicity is still unveiled and even most effective therapy cannot completely inhibit their activity.
Focusing on experimental autoimmune encephalomyelitis (EAE), a model of multiple sclerosis (MS), which represents relapsing-remitting initially and progressing course later, we found out that two correlated non-genetic factors can shut down the chronicity, from the phenomena that immunizing peptide itself determines the difference between monophasic-EAE and relapsing-EAE.
One is kinetics and component of $CD4^+CD25^+$ regulatory T cells (Treg), which are characterized by their expansion after emerging of encephalitogenic T cells and by their subset expressing both CD69 and CD103 (=DP-Treg). DP-Treg is the most efficacious subset showing highest Treg-dominant signatures and exerting stability even under inflammatory milieu due to continuously lowest expression of IL-6R, nevertheless with activated effector phenotype. DP-Treg also possesses hybrid Tregs like $Foxp3^+RORgt^+$ and $Foxp3^+Tbet^+$ cells, concordant to Th17 and Th1. Therefore we term DP-Treg for "armoured" Treg.
The other is hierarchy of encephalitogenic peptide itself, which means that the more dominant peptide can develop acute EAE, the less relapse and re-induction of EAE occurs. The dominancy of peptide is characterized by specificity to itself, that is, it can suppress response to another peptides broadly and lead to permanent remission, unlike peptide-specific tolerance.
Taken together, efficient induction of "armoured" Treg is correlated with dominancy of self-peptide itself, suggesting 'immunological homunculus'. This can be applied for treatment such as tissue-specific vaccination for autoimmune diseases.

P5.07.26

Aged IRF-4-deficient lupus-prone MRL/*lpr* mice show peripheral B-cell deficiency with elevated serum IFN-γ levels and increased expression of IFN-γ-receptor-1 on B cells

***T. Machida**[1], N. Sakamoto[1], K. Honma[2], T. Matsuyama[2], K. Yui[2], H. Sekine[1];*
[1]Department of Immunology, Fukushima Medical University, Fukushima, Japan, [2]Department of Molecular Microbiology and Immunology, Graduate School of Biomedical Sciences, Nagasaki University, Nagasaki, Japan.

The transcription factor Interferon Regulatory Factor-4 (IRF-4) is required for early B-cell development, and is also influential at these later stages of B-cell development and function in antibody somatic hypermutation, class-switch recombination and secretion. IRF-4 is also required for T-cell development in differentiation into Th2/Th9/Th17 cells. At the 14th ICI, we reported that *Irf4*$^{-/-}$ lupus-prone MRL/*lpr* mice developed granulomatous lesions in multiple organs with significantly increased numbers of IFN-γ-producing Th1 cells compared to wild-type littermates. In the present study, we further investigated the role of IRF-4 in B-cell development in MRL/*lpr* mice.
At 6 weeks of age, there was no statistically significant difference of splenic $CD19^+IgM^+$ B-cell numbers between *Irf4*$^{-/-}$ and wild-type C57BL/6 or MRL/*lpr* mice. Unexpectedly, *Irf4*$^{-/-}$ MRL/*lpr* mice showed significant loss of splenic $CD19^+IgM^+$ B cells (<1/20 of wild-type littermates) after 12 weeks of age. Similar splenic B-cell loss was observed in age-matched *Irf4*$^{-/-}$ MRL-*Fas*$^{+/+}$ mice but not in *Irf4*$^{-/-}$ C57BL/6 mice. Multiplex cytokine analysis revealed significant increase in serum IFN-γ levels in *Irf4*$^{-/-}$ MRL/*lpr* mice compared to wild-type littermates and *Irf4*$^{-/-}$ C57BL/6 mice. FACS analysis showed abundant expression of IFN-γ-receptor-1 (IFNgR1) on splenic B cells of MRL/*lpr* and MRL-*Fas*$^{+/+}$ mice, while minimal IFNgR1-expression was observed on those of C57BL/6 mice. *Irf4*$^{-/-}$ *IFNgR1*$^{-/-}$ MRL/*lpr*

mice showed full restoration of splenic $CD19^{+}IgM^{+}$ B cells even after 12 weeks of age.
Our results suggest that lack of IRF-4 has a significant impact on serum IFN-γ levels and peripheral B-cell survival/maintenance likely via IFNgR1 in lupus-prone MRL background.

P5.07.27
Temporal lineage tracing of Aire-expressing cells reveals a requirement of Aire for their maturation program

***M. Matsumoto**, Y. Nishikawa, Y. Mouri, H. Nishijima;*
Institute for Enzyme Research, Tokushima, Japan.

Understanding the cellular dynamics of Aire-expressing lineage(s) among medullary thymic epithelial cells (AEL-mTECs) is essential to gain insight into the roles of Aire for establishing self-tolerance. We sought to monitor the maturation program of AEL-mTECs by a temporal lineage tracing in which bacterial artificial chromosome transgenic mice expressing tamoxifen-inducible Cre recombinase under the control of the Aire regulatory element were crossed with reporter strains. We estimated the half-life of AEL-mTECs subsequent to Aire expression approximately 7~8 days, which was much longer than previously reported due to the existence of post-Aire stage. We found that loss of Aire did not alter the overall lifespan of AEL-mTECs, inconsistent with the previous notion that Aire expression in mTECs might result in their apoptosis for efficient cross presentation of self-Ags expressed by AEL-mTECs. In contrast, Aire was required for the full maturation program of AEL-mTECs as exemplified by the lack of physiological down-regulation of CD80 during the post-Aire stage in Aire-deficient mice, which accounts for the increased CD80high mTECs abnormally seen in Aire-deficient mice. The results further enforce the roles of Aire in the differentiation program of AEL-mTECs.

P5.07.28
Natural killer cells promote induction of experimental autoimmune encephalomyelitis but are protective at the acute stage of disease

***N. Mc Guinness**[1], L. S. Dungan[2], S. Edwards[2], S. C. Higgins[2], M. A. Lynch[3], K. H. G. Mills[4];*
[1]Trinity College Institute of Neuroscience, School of Biochemistry and Immunology, Trinity College Dublin, Dublin, Ireland, [2]Immune Regulation Research Group, School of Biochemistry and Immunology, Trinity College Dublin, Dublin, Ireland, [3]Trinity College Institute of Neuroscience, Trinity College Dublin, Dublin, Ireland, [4]Immune Regulation Research Group, School of Biochemistry and Immunology, Trinity College Biosciences Institute, Dublin, Dublin, Ireland.

Experimental autoimmune encephalomyelitis (EAE) is a widely used animal model of multiple sclerosis and its induction is associated with the infiltration of encephalitogenic T cells into the CNS. Autoantigen-specific IL-17-producing Th17 cells and IFN-γ-producing Th1 cells are central to the pathogenesis of EAE. However, cells of the innate immune system, including γδ T cells and natural killer (NK) cells are also involved. Here we examined the role of NK cells in the induction and effector stages of EAE. Depletion of NK cells with anti-asialo GM1 at the induction of EAE led to a delayed onset of clinical signs with reduced disease severity. This correlated with a reduction in the numbers of Th1, Th17 and NKT cells infiltrating the CNS as well as a marked reduction in microglia in the CNS. In contrast, depletion of NK cells at onset of symptoms increased disease severity, while depletion at induction and throughout the course of EAE delayed the onset of clinical signs but enhanced disease severity once symptoms developed. We observed a similar pattern of delayed onset but more severe disease following induction of EAE in IFN-γ-/- mice (without NK cell depletion). These findings suggest that IFN-γ production by NK cells is involved in the induction of pathogenic immune responses that mediated EAE but is protective at the acute stage of disease, most likely by suppressing pathogenic Th17 cells.

P5.07.29
Expression of CXCR3 on specific T cells is essential for homing to the prostate gland in an experimental model of autoimmune prostatitis

*M. L. Breser, **R. D. Motrich**, V. E. Rivero;*
Centro de Investigaciones en Bioquimica Clinica e Inmunologia (CIBICI)-CONICET, Facultad de Ciencias, Córdoba, Argentina.

Experimental Autoimmune Prostatitis (EAP) is considered a valid a model for the human disease Chronic Prostatitis/Chronic Pelvic Pain Syndrome. In the present report, we analyzed phenotypic characteristics of T cells that gain access to the prostate and induce leukocyte recruitment in mice with different susceptibility to EAP. After EAP induction, NOD mice developed a specific cellular response characterized by a mixed Th1/Th17 pattern with specific T cells mainly expressing CXCR3 that infiltrated and damaged the prostate. In contrast, NOD-IFNg-/- mice, exhibited only Th17 cells mainly expressing CCR6 that were not capable of infiltrating the prostate gland. Adoptive transfer experiments of T cells from NOD or NOD-IFNg-/- mice to NOD-SCID recipients showed that only T cells from NOD mice were detected in the prostate gland. However, after “in vitro” or “in vivo” treatment with rIFNg T cells from NOD-IFNg-/- mice became capable of homing to the prostate and induced leukocyte recruitment. Chemokine levels in prostate tissue from NOD mice showed increased expression of CXCR3 ligands. Additional experiments using adoptive transfer of sorted CXCR3+CD3+ or CXCR3-CD3+ T cells or administrating a CXCR3 antagonist treatment confirmed these previous findings. Results demonstrated that the functional chemokine receptor was required for homing to prostate. Altogether, our results demonstrate that the expression of CXCR3 on effectors T cells is essential for their homing to the prostate gland in EAP model. CXCR3 and their ligands, emerge as a potential therapeutic target to control in an inflammation processes in the prostate gland.

P5.07.30
Analysis of the immune response and the prostate-reactive T cell repertoire in a mouse model of experimental autoimmune prostatitis in NOD mice

***R. D. Motrich**, M. L. Breser, V. E. Rivero;*
Centro de Investigaciones en Bioquimica Clinica e Inmunologia (CIBICI)-CONICET, Facultad de Ciencias, Cordoba, Argentina.

Autoimmunity has been proposed as an etiology of the prevalent disease Chronic Pelvic Pain Syndrome. Experimental Autoimmune Prostatitis (EAP) model has proved useful for the study of CPPS because it has mirrored most findings in patients. Herein, we studied the immune response and the prostate-reactive T cell repertoire in EAP in NOD mice.
Six- to 8-week-old NOD/LtJ mice were immunized with a prostate protein extract (PAg group), purified Prostatein (PSBP group), or vehicle (Control group) at days 0 and 15. Animals were euthanized on days 10 and 24 and the specific immune response was evaluated. CDR3-lenght spectratyping analysis of the prostate-reactive T cell repertoire from spleen, prostate-infiltrating cells and from a PSBP-specific short term cell line was performed.
T-cell-mediated response showed a specific response characterized by enhanced proliferation and high levels of IFN-gamma, IL-2 and IL-17 secretion that could be detected in spleen and draining LN cells of mice from groups PAg and PSBP. Conversely, low-to-null levels of IL-4 were detected. Prostate infiltration and tissue damage accompanied that response. Also, high levels of IFN-gamma secretion were observed in a PSBP-specific cell line from autoimmune animals that transferred disease to naïve recipients. Clonotypes bearing TCR Vβ5.1, Vβ7, Vβ10 and Vβ15 were detected in spleen and prostate infiltrating cells from diseased animals and also in the PSBP-specific cell line.
A strong Th1 response and the public clonotypes Vβ5.1, Vβ7, Vβ10 and Vβ15 are induced after immunization in EAP. These clonotypes secrete high levels of IFN-gamma and infiltrate the target organ causing disease.

P5.07.31
Establishment of collagen-induced arthritis in cynomolgus monkeys, a model for rheumatoid Arthritis

***J. Ni**, J. Liu, J. Deng, G. Cui, L. Le, S. Wang, K. Zhang;*
Prisys Biotechnologies Co., Ltd, Shanghai, China.

Pharmaceutical compounds of new technologies are mostly human-specific, such as biological proteins and sequence-based oligonucleotides or aptamers, etc. Since these compounds frequently cross-react with the corresponding drug targets in non-human primates (NHP), it is apparently a more efficient approach to evaluate them in monkeys for their potential efficacy and pharmaceutical profile in a proper disease models. Collagen-induced arthritis (CIA) in both Rhesus and Cynomolgus monkeys has been reported, however, it is insufficient for characteristically modeling rheumatoid arthritis (RA) due to the hampering of lower incidence and inconsistent disease. To establish a reliable RA model for drug evaluation, we characterized the disease progression following immunization of female Cynomolgus with bovine type II collagen. In our studies, the overall incidence of individual arthritis reached 80% and the average incidence of proximal interphalangeal (PIP) joint arthritis reached near 70%, significantly higher than those reported previously. The PIP joints swelled approximately by 25% from the basal level in average in correspondence to the increase of arthritic scores starting from the third week after first immunization. The pathological changes in joint bone and cartilage were well supportive for the RA disease examined by radiopathology and bone histopathology. The biomarker analysis of C-reactive protein (CRP) and ALP levels in peripheral blood showed a close correlation to the arthritic incidence and severity along with the disease progress. The CIA monkeys also presented anemic symptoms, a solid evidence for the similarity to RA with anemia of chronic disease (ACD) in the patients.

P5.07.32
Activation of T cells around the blood brain-barrier illuminated by a fluorescent NFAT marker

***M. Pesic**[1], I. Bartholomäus[1], N. I. Kyratsous[1], V. Heissmeyer[2], H. Wekerle[1,3], N. Kawakami[1,4];*
[1]Max Planck Institute of Neurobiology, Martinsried, Germany, [2]Helmholtz Zentrum München, Institute of Molecular Immunology, Munich, Germany, [3]Hertie Senior Professor, Munich, Germany, [4]Institute of Clinical Neuroimmunology, Ludwig-Maximilians Universität, Munich, Germany.

We previously showed that auto-reactive T cells infiltrating the central nervous system (CNS) undergo highly dynamic interactions with different structures of the blood brain-barrier (BBB), which may result in intracellular signaling and subsequent T cell activation. We now introduced a truncated nuclear factor of activated T cells (NFAT) fused to GFP (ΔNFAT -GFP), as a fluorescent real-time activation indicator, and used it to elucidate sequential activation events in auto-reactive T cells interacting with different elements of the BBB. Intravital two-photon imaging ΔNFAT -GFP expressing encephalitogenic T cells, documented that perivascular antigen presenting cells (APCs), and not endothelial cells induce cytosol-nuclear translocation of the marker. Activation correlated with reduction of T cell motility, but did not necessarily imply their long-lasting arrest, as activated T cells continued to visit other APCs. In addition, we found that individual APCs in the CNS differ in their ability to present endogenous auto antigen, with some being much more potent than the others. Our data suggest that perivascular APCs in the CNS, presenting endogenous auto antigens, provide stimuli to infiltrating T cells that enable them to migrate further into the CNS parenchyma.

P5.07.33
A mouse model for paraneoplastic neurological syndrome: when efficient anti-tumoral immunity leads to autoimmunity in the CNS

***B. Pignolet**[1], C. Gebauer[1], G. Martin-Blondel[1], C. Dalard[1], S. Desbois-Beaumel[1], D. Brassat[2], R. S. Liblau[1];*
[1]CPTP-INSERM UMR1043 CNRS UMR5282 Université Toulouse, Toulouse, France, [2]CPTP-INSERM UMR1043 CNRS UMR5282 Université Toulouse, pôle neurosciences, Université Paul Sabatier Toulouse, Toulouse, France.

The Hu syndrome, a paraneoplastic neurological disorder, develops in patients with cancer in whom an effective anti-tumoral immune response against antigens shared by tumor cells and normal neurons leads to neurodegenerative disease.
Growing but indirect evidence suggests a role for T cells in the Hu syndrome. However, their contribution still remains to be determined as well as the identification of CD4 and/or CD8 subsets involved. Development of immunotherapeutic approaches to limit neurological insult is also greatly needed.
To address these issues we developed a mouse model for Hu syndrome. To mimic the paraneoplastic situation, we use a tumor cell line expressing the hemagglutinin (HA) of influenza virus to activate a cross-reactive anti-tumoral response in CamK-HA mice expressing HA in most CNS neurons. To promote a T cell response against the HA antigen shared by neurons and tumor cells, naïve HA-specific CD8 T cells alone or in combination with naïve HA-specific CD4 T cells originating from TCR-transgenic animals were transferred into CamK-HA mice bearing HA-expressing tumor.
We showed that HA-expressing tumor cells induce in vivo activation, proliferation and differentiation of naïve HA-specific T cells into effector cells. Both HA-specific CD8 and CD4 T cells were needed to control tumor growth and induce CNS inflammation. Control groups in which either the tumor cells or the recipient mice did not express HA failed to promote neurological disease.
This mouse model increases our knowledge on how successful anti-tumor immunity triggers a cancer-associated autoimmune disease, and helps develop new therapeutic strategies against this disabling condition.

P5.07.34
Induction of systemic lupus erythematosus-like syndrome in BALB/c mice leads to disturbance in peripheral T cell subpopulations

***P. Rahimzadeh**[1], M. Ghayedi[1], S. Morteza Gholi[2], H. Namdari[1], A. Mirshafiey[1], E. Salehi[1];*
[1]Tehran University of Medical Science, Tehran, Iran, [2]Tabriz University of Medical Science, Tabriz, Iran.

Mechanisms underlying the pathogenesis of Systemic Lupus Erythematosus (SLE) have not yet been elucidated. The T cell role in development of disease was intensively studied. Animal models of SLE are valuable tools in the study of pathogenic mechanisms involved in SLE.
We immunized normal BALB/c mice subcutaneously with 50µgr DNA extracted from cells cultured in different conditions: splenocytes+ polyamines, splenocytes+ Con A, splenocytes+ polyamines+ Con A and splenocytes only (control). Anti- ds DNA antibodies were assessed by ELISA, proteinuria was assessed by Bradford method and other SLE associated auto antibodies were determined by immunofluoroscence ANA. Intracellular cytokines and transcription factors of T helper subsets were examined by flow cytometry and Real-Time PCR respectively.
The results showed that serum level of Anti-dsDNA antibody in mice immunized with DNA extracted from ConA+ Polyamine was higher compared to other groups. ANA titer was increased in ConA and then in ConA+ polyamine stimulated groups and level of proteinuria in polyamine and ConA+ polyamine stimulated groups was higher than in control group ($p<0.01$), The ratio of T-bet/GATA3 and T-bet/Foxp3 in mice immunized with DNA from ConA stimulated were insignificantly increased compared with control group. The ratio of IFN-γ/IL-4, IFNγ/Foxp3 and IL-17/Foxp3 of the CD4+ splenocytes in polyamine stimulated group was increased significantly compared with control group. ($p<0.05$, $p<0.01$ and $p<0.05$, respectively).
Our results show that the mice immunized with DNA extracted from splenocytes+ polyamines+ Con A manifested more obvious signs of the disease and increased ratio of Th1/Th2.

P5.07.35
TLR8-deficiency accelerates autoimmunity in a spontaneous lupus mouse model

*N. Tran, **M. Santiago-Raber**;*
Medical School of Geneva, Geneva, Switzerland.

Systemic Lupus Erythematosus (SLE) is a systemic autoimmune disorder characterized by increased B, T and dendritic cells (DCs) activation, by the formation of autoantibodies and subsequent development of immune complex glomerulonephritis (GN). The role of endosomal TLR7 and TLR9 in the development of anti-nuclear autoantibodies, because of their respective recognition of RNA and DNA, respectively, has been extensively studied. TLR7 plays a critical role in SLE development. Little is known on the TLR8 activation *in vivo* in mice, and its interaction with TLR7, we therefore conducted a study on its implication in autoimmune responses in mice. For that purpose, we introduced the TLR8 null mutation into C57BL/6-Nba2.*Yaa* (Nba2.*Yaa*) mouse model and followed the development of SLE, *i.e.* Ig production, GN, mortality, splenomegaly, B, T cells and DCs activations, monocytosis and *in vitro* or *in vivo* cell-response to TLR7-ligation. Nba2.TLR8$^{-/-}$.*Yaa* developed an accelerated mortality (47% vs. 8% at 8 months of age, p=0.001), increased splenomegaly and displayed higher IgM and IgG levels in the sera, compared to Nba2.*Yaa*. TLR8-deficiency resulted in an increased monocytosis which was further enhanced after *in vivo* TLR7 stimulation. TLR7 and MHCII expression were upregulated on Nba2.TLR8$^{-/-}$.*Yaa* APCs. DC capacity to present allogenic antigens to T cells was also improved in TLR8-deficient mice after TLR7 stimulation. In conclusion, TLR8-deficiency in lupus-prone mice induces acceleration of the pathology. We demonstrated an enhanced TLR7-dependent activation of DCs, due to functionally upregulated expression of TLR7, thus providing an explanation for the accelerated autoimmune responses in TLR8 deficient lupus-prone mice.

P5.07.36
Conditional mouse model to study the tissue- and time specific effects of NADPH oxidase 2 -derived reactive oxygen species during arthritis

***O. Sareila**[1,2], P. Rantakari[1,3], C. Hagert[1], S. Jalkanen[1], M. Poutanen[1,3], R. Holmdahl[1,2];*
[1]University of Turku, Turku, Finland, [2]Karolinska Institutet, Stockholm, Sweden, [3]Turku Center for Disease Modeling, Turku, Finland.

Neutrophil cytosolic factor 1 (NCF1) is the key regulatory component of the phagocytic NADPH oxidase 2 (NOX2) complex, and mutations in this gene lead to lowered production of reactive oxygen species (ROS). *NCF1* has been linked to rheumatoid arthritis and mutations in this gene increase arthritis severity in rodents. Interestingly, ROS production protected rodents from autoimmunity implying a regulatory role for ROS in inflammation.
We aimed at generating targeted *Ncf1* knock-in mice with inducible *Ncf1* expression and EGFP reporter to identify the cell type and the time window protecting the mice from arthritis. The mice were successfully generated on a pure C57BL/6N genetic background. As expected, *Ncf1* expression was induced *in vivo* by Cre or FLP recombinase, and the gene activation was followed by EGFP reporter. Furthermore, the targeting silenced the *Ncf1* gene as intended. After activating the targeted knock-in gene by recombination, using universally expressed Cre or FLP recombinase, the expression pattern of NCF1 was similar to that of the wild type mice, mostly showing expression in granulocytes and other cells known to make oxidative burst. After crossed with B10.Q mice, *Ncf1* knock-ins were susceptible to collagen induced arthritis. Granulocyte oxidative burst could be restored by tamoxifen in mice carrying an allele of the inducible ROSA-CreER recombinase. In conclusion, ROS production can be controlled in the *Ncf1* knock-in mice by the Cre or FLP recombinase expression specificity. The model can, thus, be utilized to study the spatiotemporal effects of NOX2 complex derived ROS during experimental arthritis or other conditions.

P5.07.37
Lack of IRF-1 accelerates development of tubulointerstitial nephritis and pulmonary granulomas with predominant Th2 polarity in lupus-prone MRL/*lpr* mice

*T. Machida[1], N. Sakamoto[1], E. Suzuki[2], X. Zhang[2], C. Reilly[3], G. Gilkeson[2], **H. Sekine**[1];*
[1]Department of Immunology, Fukushima Medical University, Fukushima, Japan, [2]Division of Rheumatology and Immunology, Department of Medicine, Medical University of South Carolina, Charleston, SC, United States, [3]Department of Biomedical Sciences and Pathobiology, Virginia Polytechnic Institute and State University, Blacksburg, VA, United States.

The transcription factors Interferon Regulatory Factor-4 (IRF-4) and IRF-1 are involved in the differentiation of naïve CD4$^+$ T cells into Th2/Th9/Th17 and Th1 cells, respectively. At the 14th ICI, we reported that *Irf4*$^{-/-}$ lupus-prone MRL/*lpr* mice lacked serum autoantibodies and Th17 cells but developed proliferative glomerulonephritis (GN) and granulomas containing Langhans-type multinucleated giant cells (MGCs) in multiple organs with significant increase in serum IFN-γ and IFN-γ-producing CD4$^+$ T cells; suggesting autoreactive Th1 cell-mediated mechanism for their pathogenesis. To further investigate the roles of autoreactive CD4$^+$ T cells in murine lupus, we analyzed disease phenotype of *Irf1*$^{-/-}$ MRL/*lpr* mice in the present study. By 18 weeks of age, unlike wild-type MRL/*lpr* mice, all *Irf1*$^{-/-}$ MRL/*lpr* mice showed minimal to no GN but developed severe diffuse tubulointerstitial nephritis characterized by predominant infiltration of CD4$^+$ T cells. They also developed pulmonary granulomas with severe infiltrations of CD68$^+$ macrophages/epithelioid cells and frequent formation of foreign-body-type MGCs. Intracellular cytokine staining showed significantly increased numbers of IL-4-producing CD4$^+$ T cells in the spleens, peritoneal lymph nodes, and kidneys of 18-week-old *Irf1*$^{-/-}$ MRL/*lpr* compared to wild-type littermates. Age-matched *Irf1*$^{-/-}$ C57BL/6 mice also showed significantly increased numbers of IL-4-producing splenic CD4$^+$ T cells; however none of *Irf1*$^{-/-}$ C57BL/6 mice developed renal or pulmonary disease.
In conclusion, these results indicate that IRF-1 plays a role in the regulation of Th2 polarity in MRL/*lpr* and C57BL/6 mice. Our results suggest that their pathogenesis, in *Irf1*$^{-/-}$ MRL/*lpr* mice, is most likely caused by autoreactive Th2 cell-mediated mechanisms.

Novel anthraquinone derivatives reduce inflammatory cytokines *in vitro* and ameliorate clinical signs of experimental autoimmune encephalomyelitis

***C. Souza Alves**, S. B. R. Castro, C. F. Costa, T. A. Correa, M. V. Almeida, A. Ferreira;*
Universidade Federal de Juiz de Fora, Juiz de Fora, Brazil.

Multiple sclerosis is a non-traumatic demyelinating disease of the central nervous system. Mitoxantrone is an anthraquinone derivative approved for treatment of multiple sclerosis. This study investigated the effect of three classes of anthraquinone derivatives on macrophages and their potential to treat EAE. Macrophages were cultured for 48h with serial dilutions of anthraquinone derivatives. Supernatant were collected to evaluate the NO, TNF-α and IL-1β inhibition. C57BL/6 mice were immunized with MOG35-55 and treated with chosen compounds. The lipophilic compounds **3**, **4**, **5** and **6** (62.4%, 92.6%, 73.4% and 58.4%) and the halogenated compounds **7** and **8** (57.8% and 53.4%) showed reduction in NO production without cytotoxicity. Other compounds with heteroatom's addition were not effective. For the compounds with addition of amino alcohols chains the compounds **4**, **5** and **6** showed inhibition of NO (40.2%, 49.7% and 62.5%) in the 5µg/ml concentration. For the TNF-α production, only the compounds **8** and **9** showed inhibitory effects (62.4% and 52.9%). For the IL-1β production the compounds **4**, **5**, **6**, **8**, and **9** showed inhibitory effects (70.8%, 67.1%, 74.3%, 63.4% and 51.2%). The compounds **3**, **10** and **12** showed properties similar to mitoxantrone with high toxicity on cells. The halogenated compound **8** and the amino chains inserted compound **6** were tested *in vivo* for EAE and showed reduction of the clinical score of disease (1.4±0.9 and 1.2±0.3 vs. 3.6±0.2, respectively). In conclusion, anthraquinone derivatives were prepared in a good yields and showed promissory anti-inflammatory properties.

P5.07.39
The up-regulation of innate immune response can be observed by expression of TLR3, TLR4 and TLR9 by antigen-presenting cells in EAE model

*M. G. Evangelista[1], S. B. R. Castro[1], A. T. Dias[1], **C. Souza Alves**[1], M. A. Juliano[2], A. Ferreira[1];*
[1]Universidade Federal de Juiz de Fora, Juiz de Fora, Brazil,
[2]Universidade Federal de Sao Paulo, Sao Paulo, Brazil.

Multiple sclerosis is a chronic inflammatory demyelinating disorder of the central nervous system. EAE is a model for the study of MS. The objective of this study was evaluating the innate immune response including Toll-like receptors in EAE model development. The EAE mice were immunized with MOG35-55, emulsified v/v in complete Freund's adjuvant (CFA) supplemented with 400µg of attenuated *Mycobacterium tuberculosis* and Pertussis toxin (300ng/animal) was injected intraperitoneally on the day of immunization and 48h later. The MOG negative group only received supplemented CFA and Pertussis toxin. The animals were euthanized at 2nd, 4th and 7th days post-immunization. The spinal cords were removed and analyzed. Only EAE group developed clinical signs. In comparison to the MOG negative group the level of CCL5 and CCL20 in homogenized spinal cord was higher in the EAE group at 4th (1,983.0±237.2 vs. 1,245.0±110.5 and 4,546.0±569.8 vs. 1,992.0±343.0) and 7th (1,459.0±97.3 vs. 717.6±110.0 and 3,262.0±331.4 vs. 1,762.0±259.6) days post-immunization. The levels of IL-10 (8,828.0±1,652.0 vs. 2,063.0±447.4) and TGF-β (128,139.0±55,265.0 vs. 14,311.0±5,461.0) were also higher in EAE group, which showed higher number of antigen-presenting cells expressing TLR3 (34,131.0±3,068.0 vs. 6,620.0±316.8), TLR4 (29,466.0±1,864.0 vs. 6,650.0±589.3) and TLR9 (104,346.0±4,407.0 vs. 21,626.0±1,434.0). The presence of MOG increases the release of chemokine in the spinal cord and up-regulation of TLRs expression by APC. Studies seeking the understanding of EAE may be important for the development of agents that modulate innate immune responses as signaling pathways TLRs may be effective in treating EAE and MS.

P5.07.40
Mouse SCID Models of Systemic Lupus Erythematosus

***A. I. Tchorbanov**, N. Kerekov, N. Mihaylova;*
Institute of Microbiology, Bulgarian Academy of Sciences, Sofia, Bulgaria.

Objectives: Self-specific B cells play a main role in pathogenesis of Systemic lupus erythematosus (SLE) and are a logical target for a selected therapy. SCID mice, which lack both T and B lymphocytes and accept xenogenic cells have been used for cell transfer for evaluating the pathogenesis of SLE.
It has been shown that complement receptor type 1 (CR1) on human and FcγRIIb on mouse B-lymphocytes has suppressive activity. The co-crosslinking of these receptors with BCR inhibits B cell activation and it could be an attractive target for therapeutic intervention.
We hypothesize that it may be possible to establish mouse and humanized models of lupus and to eliminate selectively the pathogenic B cells by protein engineered molecules, which co-crosslink the immunoglobulin receptors and CR1/FcγRIIb delivering a strong suppressive signal.
Methods: The protein chimeric molecules were constructed by coupling an DNA-mimotope peptide to a monoclonal anti-CR1 or anti-CD32 (FcγRIIb) antibodies.
We established autoimmune models by transferring splenocytes from MRL/lpr mice or PBMC from SLE patients to SCID mice and tested the effects of the chimeric molecules.
Results: Reconstituted SCID mice showed presence of auto-antibodies, as well as immunoglobulin deposition in the renal glomeruli. Treatment of the transferred SCID mice with anti-human or anti-mouse DNA-like chimera prevented appearance of anti-DNA antibodies and proteinuria, while the PBS-injected animals had high levels after the transfer.
Conclusions: This study demonstrates the possibility to silence selectively pathogenic B cells in transferred or humanized SCID mice and to delay the progression of autoimmune disease using chimeric molecules.

P5.07.41
Reduced disease severity in an APRIL-deficient lupus mouse model

***N. Tran**, M. Santiago-Raber;*
Medical School of Geneva, Geneva, Switzerland.

Systemic Lupus erythematosus (SLE) pathogenesis is complex, but it is widely accepted that autoantibodies play a key role in the autoimmune process. A proliferation inducing ligand (APRIL), a member of the TNF superfamily, is crucial for the control of plasma-cell survival. We previously showed that *in vivo* APRIL blockade delays the disease in lupus-prone mice. To confirm the role of APRIL in the pathology, we investigated the effect of APRIL-deficiency in our lupus mouse model.
We introduced the *APRIL*-null mutation into C57BL/6-Nba2.*Yaa* (Nba2.*Yaa*) mouse model and followed the development of the disease manifestations such as mortality due to glomerulonephritis (GN), autoantibody production, splenic cells frequencies and Ig producing plasma cells levels in Nba2.APRIL$^{-/-}$.*Yaa* compared to control mice.
Nba2.APRIL$^{-/-}$.*Yaa* developed a reduced mortality due to GN (13% vs. 40% at 11 months of age, p=0.04) compared to Nba2.*Yaa* control mice. APRIL-deficient mice displayed less IgG and IgM deposits in the glomeruli and lower levels of IgG, IgM, anti-dsDNA and anti-chromatin autoantibodies in the sera. Ig-producing cells were decreased in spleen from APRIL-knockout mice whereas no changes in B and T cells frequencies were observed compared to controls.
As observed with the use of an anti-APRIL blocking antibody, our data indicate that APRIL deficiency reduces lupus severity in mice by decreasing the survival of plasma cells leading to lower circulation of immune complexes. APRIL would then become an attractive molecule to target in human SLE since it preserves B-cell homeostasis contrary to other B cell-depleting therapies.

P5.07.42
Effects of Cystamine on CD4+/CD25+ regulatory T cells in lupus-prone mice

***B. Tzang**[1,2], T. Hsu[3], C. Chiu[3], Y. Wang[1];*
[1]Institute of Biochemistry and Biotechnology, Chung Shan Medical University, Taichung, Taiwan, [2]Department of Biochemistry, School of Medicine, Chung Shan Medical University, Taichung, Taiwan,
[3]Institute of Microbiology and Immunology, Chung Shan Medical University, Taichung, Taiwan.

Elevated oxidative stress and attenuated expression of regulatory T cells have been strongly associated with the pathogenesis of systemic lupus erythematosus (SLE). Recently, cystamine is indicated to be beneficial on SLE. To examine the effects of cystamine on anti-oxidant activities and regular T cells in SLE, Western blot, flow cytometry and various assays such as Glutathione (GSH), 1,1-dipheny l-2- picryl-hydrazyl (DPPH) and malondialdehyde thiobarbituric acid (MDA) were performed to investigate the effects of cystamine on NZB/W F1 mice. In the present study, significantly reduced MDA and increased GSH and DPPH were observed in NZB/W F1 mice receiving cystamine compared to those mice receiving PBS. Meanwhile, significantly increased CD4+/CD25+ regulatory T cells were also detected in NZB/W F1 mice receiving cystamine as compare to those mice receiving PBS, accompanying with significantly reduced IL-6/phosphorylated STAT-3 expression. These findings suggested the beneficial effects of cystamine on increasing antioxidant activities and CD4+/CD25+ regulatory T cells in lupus-prone mice via suppressing IL-6/STAT3 signaling.

Autoantibody induction by DNA-containing immune complexes requires HMGB1 with TLR2/miR-155 pathway

S. Xiong[1,2]*, Z. Wen*[2]*, W. Xu*[1]*;*
[1]*Institutes of Biology and Medical Sciences, Soochow University, Suzhou, Jiangsu Province, China,* [2]*Institute for Immunobiology, Fudan University, Shanghai, China.*

Anti-dsDNA autoantibody has been reported as a central pathogenic factor of SLE. However, the mechanisms of anti-dsDNA antibody production still remain unclear. Recent evidence indicates that circulating DNA-containing immune complexes, one of the hallmarks of SLE, might be involved in the autoantibody production. Here we mainly explored the potential role and underlying mechanisms of DNA-containing immune complexes in the anti-dsDNA antibody production. We found that these immune complexes primarily provoked anti-dsDNA antibody production through their HMGB1 component, whose level was highly and positively correlated with the anti-dsDNA antibody level in SLE patients. Furthermore, the HMGB1-mediated autoantibody production was in a TLR2/MyD88 dependent pattern, and modulated by the miR-155 via targeting Ets-1. Our results firstly showed the crucial role of HMGB1 component of DNA-containing immune complexes in the autoantibody production, which was mediated and regulated by TLR2/MyD88/miR-155/Ets-1 pathways. These findings may provide novel mechanistic insight into the persistent anti-dsDNA antibody production and new clues for the development of therapeutic strategies for SLE.

P5.07.44

Differential Modulation of Effector and Regulatory T Cells Leads to Attenuation of Autoimmune Diabetes in Ptpn22 Transgenic Nonobese Diabetic Mice

L. Yeh*;*
Graduate Institute of Medical Sciences, National Defense Medical Center, Taipei, Taiwan.

Ptpn22 encodes PEST domain-enriched tyrosine phosphatase (Pep), which negatively regulates TCR proximal signaling and is strongly associated with a variety of autoimmune diseases in humans. The net effect of Pep on the balance of immunity and tolerance is uncertain because of the simultaneous inhibition of TCR-mediated signaling of counterregulatory effector and regulatory T cells (T_{regs}). In this study, we generated transgenic NOD mice that overexpressed Pep in T cells. The transgenic mice had a significantly lower incidence of spontaneous autoimmune diabetes which was accompanied by fewer IFN-r-producing T cells, and an increased ratio of $CD4^+Foxp3^+$ T_{regs} to $CD4^+IFN\text{-}r^+$ or to $CD8^+IFN\text{-}r^+$ T cells, respectively, in pancreatic islets. Transgenic T cells showed markedly decreased TCR-mediated effector cell responses such as proliferation and Th1 differentiation. By contrast, the inhibitory effect of transgenic Pep on TCR signaling did not affect the differentiation of T_{regs} or their suppressive activity. Adoptive transfer experiments showed that transgenic splenocytes exhibited attenuated diabetogenic ability. To examine further the pathogenic features of transgenic T cells, we generated *Ptpn22*/BDC2.5 doubly transgenic mice and found reduced proliferation and Th1 differentiation in $CD4^+$ T lymphocytes with additional Pep in pancreatic lymph nodes but not in inguinal lymph nodes of NOD/SCID recipients. This finding indicates that transgenic Pep attenuates T cell functions in an islet antigen-driven manner. Taken together, our results demonstrate that Pep overexpression in T cells attenuates autoimmune diabetes in NOD mice by preferentially modulating TCR signaling-mediated functions in diabetogenic T cells but not in T_{regs}.

P5.07.45

Adoptive cell transfer from multiple low dose streptozotocin diabetic donors can induce diabetes in healthy young C57/BL6 mice

N. S. Zdravkovic*, S. Pavlovic, M. L. Lukic;*
Center for Molecular Medicine and Stem Cell Research, Faculty of Medical Sciences, University of Kragujevac, Kragujevac, Serbia.

Multiple low dose of streptozoticin (MLD-STZ) diabetes in C57/BL6 mice is the result of T cell-dependent process directed against the pancreatic beta cells. However, diabetes induction after adoptive transfer of splenocytes and pancreatic lymph node cells (pLNc) has not been established. Therefore, we investigated whether splenocytes (1x108 viable cells) and pLNc (5x106 viable cells) from diabetic donors can induce diabetes in young (6-wk-old) C57/BL6 mice. Our work shows that i.p. transfer of splenocytes and pLNc from MLD-STZ mice altered i.p. glucose tolerance, stimulated the onset of glycosuria and intra-insulitis in young recipients, which was accompanied by the increased levels of TNF-α, IFN-γ, IL-17, and decreased level of IL-10 in the sera. The precise role of different types of mononuclear cells in diabetes induction has been determined by FACS analysis. The number of CD4+TNF-α+, CD4+IFN-γ+, CD4+IL-17+, CD3+CD8+, CD19+, F4/80+IL-12+ cells was significantly increased ($p<0.001$), while the number of CD3-CD8-NK1.1+ cells was decreased ($p<0.05$) in pancreatic lymph nodes and pancreas of recipients in comparison to healthy mice. In contrast with pancreatic lymph nodes, the number of CD19+ B cells in pancreas was similar in the recipients and healthy mice, suggesting that effector Th1, Th17, CD3+CD8+ T cells and M1 macrophages generated infiltrates in the islets of Langerhans in young C57/BL6 recipients. Our study provided the first evidence that splenocytes and pLNc of MLD-STZ diabetic male C57/BL6 mice can transfer diabetes to young syngeneic mice and identifies a new strategy for the examination of autoimmune diabetes.

Downmodulation of peripheral MOG-specific immunity by pVAXhsp65 treatment during EAE do not reach the CNS

S. F. G. Zorzella-Pezavento[1]*, F. Chiuso-Minicucci*[1]*, T. G. D. França*[1]*, L. L. W. Ishikawa*[1]*, L. C. Rosa*[1]*, P. M. Colavite*[1]*, C. Marques*[2]*, M. R. V. Ikoma*[2]*, C. L. Silva*[3]*, A. Sartori*[1]*;*
[1]*Univ. Estadual Paulista (UNESP), Botucatu, Brazil,* [2]*Fundação Dr. Amaral Carvalho, Jau, Brazil,* [3]*University of São Paulo (USP), Ribeirão Preto, Brazil.*

Multiple sclerosis (MS) is the most common inflammatory and demyelinating disease of the central nervous system (CNS). Most of the therapeutic strategies to control this disease are directed to immune modulation and inflammation control. Heat shock proteins, especially hsp65, are described as targets for regulatory T cells due to their enhanced expression in inflamed tissues. In addition, there is strong evidence that they are able to induce anti-inflammatory immunoregulatory T cells. In this context, the objective of this work was to investigate the therapeutic effect of a genetic vaccine containing the mycobacterial hsp65 gene (pVAXhsp65) on EAE development. C57BL/6 mice were submitted to EAE induction by immunization with MOG in Complete Freund's Adjuvant and 5 days later we initiate the treatment with 3 or 4 pVAXhsp65 doses. Although pVAXhsp65 was immunogenic for mice with EAE and was also able to downmodulate the specific induction of cytokines by MOG, this vaccine was not able to decrease the clinical severity. Previously immunized mice presented weight loss and clinical scores comparable to non-immunized animals. Vaccination also did not decrease the intensity of inflammation in the CNS neither the cytokine production by cells isolated from brain and spinal cord in response to *in vitro* stimulation with MOG or hsp65. Immunization with pVAXhsp65 did not increase the frequency of CD4+CD25+Foxp3+ cells in spleen and CNS. These results indicate that hsp65 administered as a genetic vaccine is able to downmodulate immunity against MOG but this effect is not associated with any therapeutic activity against EAE development.

P5.08 Atherosclerosis and cardiovascular diseases

P5.08.01
Elevated vascular adhesion protein-1 (VAP-1) levels in cardiovascular disease events

K. Aalto[1], *M. Maksimow*[1], *S. Jalkanen*[1,2], *V. Salomaa*[3], *M. Salmi*[1,2];
[1]*University of Turku, MediCity, Turku, Finland,* [2]*National Institute for Health and Welfare, Turku, Finland,* [3]*National Institute for Health and Welfare, Helsinki, Finland.*

Inflammation in the vasculature can progress to atherosclerosis, which in turn leads the way to more severe cardiovascular diseases. Normally, the arterial endothelial cells can resist adhesion of passing leukocytes, but any harmful stimulus (e.g. oxidized LDL, modified oligosaccharides, smoking, and diabetes) can activate the endothelial cells, which then start to express different adhesion molecules, enhancing the local inflammation.
One of the adhesion molecules involved in leukocyte migration from the blood into sites of inflammation is vascular adhesion protein-1 (VAP-1). VAP-1's ligands, Siglec-9 and Siglec-10, are found on the surface of monocytes and B-lymphocytes. In addition to its adhesive function, VAP-1 is also a semicarbazide sensitive amine oxidase, an enzyme capable of producing hydrogen peroxide and aldehydes, both of which are damaging for vascular endothelium. Hence, VAP-1 can help the leukocytes to extravasate the vascular wall and aggravate the inflammation by producing harmful agents. As most endothelial adhesion molecules, VAP-1 is also found as a soluble form (sVAP-1) in plasma.
We have shown that in young Finns (n=2200) sVAP-1 correlates with cardiovascular risk factors and early atherosclerotic manifestations. In this study, we have measured the sVAP-1 levels of 2775 Finns aged over 55 years (the Finrisk 2002 -study) with an in-house ELISA assay. The plasma was collected in 2002, and the subjects have been followed up through the national registers thereafter. Since 2002 there has been over 500 cardiovascular disease related events. The correlations and predictive value of sVAP-1 will be shown.

P5.08.02
ROS and RNS signaling in cardiovascular diseases: Could antioxidants be useful?

I. B. Afanas'ev*;*
Vitamin Reseach Institute, Porto, Portugal.

There is not too much success in the antioxidant treatment of heart diseases in humans. However a new approach suggests that depending on their structures and concentrations antioxidants can exhibit a complex activity in many pathological disorders. It is well established that physiological free radicals superoxide and nitric oxide together with their derivatives hydrogen peroxide and peroxynitrite, collectively reactive oxygen species (ROS) and reactive nitrogen species (RNS) play an important role in heart diseases through their signaling functions. This presentation will focus on damaging signaling by ROS and RNS in various heart and vascular disorders: heart failure (congestive heart failure or CHF), left ventricular hypertrophy (LVH), coronary heart disease, cardiac arrhythmias, and so forth. It will be demonstrated that ROS overproduction (oxidative stress) is a main inducer of the transformation of normal physiological signaling processes into the damaging ones. Furthermore, the favorable effects of low/moderate oxidative stress through preconditioning mechanisms in ischemia/reperfusion will be considered. Then we will discuss the possibility of efficient application of antioxidants and enzyme/gene inhibitors for the regulation of damaging ROS signaling in heart disorders.

P5.08.03
Serum amyloid A stimulates macrophage foam cell formation via formyl peptide receptor 2

Y. Bae[1], *H. Lee*[1], *S. Kim*[1], *S. Baek*[2], *J. Choi*[2], *K. Cho*[2], *E. Cho*[1], *B. A. Zabel*[3];
[1]*Sungkyunkwan University, Suwon, Republic of Korea,* [2]*Yeungnam University, Daegu, Republic of Korea,* [3]*Palo Alto Institute for Research and Education, Palo Alto, CA, United States.*

Elevated levels of serum amyloid A (SAA) is a risk factor for cardiovascular diseases, however, the role of SAA in the pathophysiology of atherosclerosis remains unclear. Here we show that SAA induced macrophage foam cell formation. SAA-stimulated foam cell formation was mediated by c-jun N-terminal kinase (JNK) signaling. Moreover, both SAA and SAA-conjugated high density lipoprotein stimulated the expression of the important scavenger receptor lectin-like oxidized low-density lipoprotein receptor 1 (*LOX1*) via nuclear factor-κB (NF-κB). A LOX1 antagonist carrageenan significantly blocked SAA-induced foam cell formation, indicating that SAA promotes foam cell formation via LOX1 expression. We also show that SAA induced-macrophage foam cell formation was inhibited by formyl peptide receptor 2 (FPR2) antagonist WRW^4, as well as by FPR2-targeted siRNA knockdown. In addition, FPR2 is upregulated in peripheral blood mononuclear cells from patients with atherosclerosis. Our findings therefore suggest that SAA stimulates foam cell formation via FPR2 signaling, and thus likely contributes to atherogenesis.

P5.08.04
Association of monoctye expression of Toll-like receptor 4 with coronary luminal stenosis

B. Bagheri[1], *A. Garjani*[2], *B. Sohrabi*[2], *S. Mashayekhi*[2], *B. Taherkhanchi*[3];
[1]*Semnan University of Medical Sciences, Semnan, Iran,* [2]*Tabriz University of Medical Sciences, Tabriz, Iran,* [3]*Shahih Beheshti University of Medical Sciences, Tehran, Iran.*

Background and objectives: Toll-like receptors are well-defined barriers against various infections. Among them hTLR4 on the surface of monocytes, plays a critical role in the formation of atherosclerotic plaques, plaque instability and arterial remodeling. This study was designed to examine the association of hTLR4monocyte expression and response with coronary luminal stenosis in patients with stable angina (SA).
Materials and methods: Blood samples were obtained from 39 patients with SA who were scheduled for a coronary angiography and from 28 healthy volunteers. The samples were collected before the procedure. Expression of hTLR4 on CD14+ monocytes and serum levels of TNF-α and IL-1β were measured using flowcytometry and ELISA techniques respectively. hTLR4 monocyte expression and response were examined with angiographic coronary stenosis. The degree of stenosis was measured by comparing the area of stenosis to an adjacent normal segment of the vessel.
Results: Compared to the control group, patients showed upregulation of hTLR4+/CD14+ monocytes. Furthermore, patients with more severe coronary stenosis exhibited enhanced expression of hTLR4+/CD14+ monocytes ($p<0.01$). This was paralleled by elevation in the serum levels of TNF-α ($p<0.05$) and IL-1β. In addition, the increase in monocyte expression of hTLR4 was positively correlated with the degree of coronary stenosis ($r=0.5$).
Conclusion: Monocyte expression of hTLR4 was positively correlated with the degree of coronary stenosis. Moreover, the serum levels of pro-inflammatory cytokines were associated with hTLR4 expression as well as coronary luminal stenosis. These findings suggest that hTLR4 monocyte expression and sensitization may be involved in progression and deterioration of atherosclerosis.

P5.08.05
Elevated CD14++CD16- monocytes predict cardiovascular events

*K. E. Berg, I. Ljungcrantz, L. Andersson, C. Bryngelsson, B. Hedblad, G. N. Fredrikson, J. Nilsson, **H. Björkbacka**;*
Lund University, Malmö, Sweden.

Background:
Although monocytes in peripheral blood are no longer considered to be a homogeneous population, associations between distinct monocyte subsets and cardiovascular disease have not been highlighted in large epidemiological studies.
Methods and results:
The study included 700 randomly selected subjects from the cardiovascular arm of the Malmö Diet and Cancer study. Among these, 123 subjects experienced ischemic cardiovascular events during the follow-up until December 2008. Mononuclear leukocytes frozen at the baseline investigation in 1991 to 1994 were thawed and analyzed with flow cytometry to enumerate monocyte subsets, based on CD14 and CD16 expression. The percentage and number of classical CD14(++)CD16(-) monocytes were increased in the cardiovascular-event group compared with the event-free subjects (median, 344 [interquartile range 251-419] cells/μL versus 297 [212-384] cells/μL, P=0.003). The hazard ratio was 1.66 for suffering a cardiovascular event in the highest tertile of the number of CD14(++)CD16(-) monocytes compared with the lowest tertile, even after adjustment for common risk factors (HR, 1.66; 95%CI: 1.02-2.72). CD14(++)CD16(-) monocytes did not, however, associate with the extent of atherosclerosis at baseline. In contrast, the percentage of monocytes expressing CD16 was negatively associated to the extent of carotid atherosclerosis measured as intima-media thickness at baseline. The chemokine receptors CCR2, CX3CR1, and CCR5 were not differentially expressed between cases and controls on any of the monocyte subsets, but CCR5 expression on CD14(+)CD16(++) monocytes was negatively associated to carotid intima-media thickness.
Conclusion:
This study shows that classical CD14(++)CD16(-) monocytes can predict future cardiovascular risk independently of other risk factors.

P5.08.06
T-helper 2 immunity is associated with reduced risk of myocardial infarction and stroke

*L. Andersson, D. Engelbertsen, I. Ljungcrantz, M. Wigren, B. Hedblad, J. Nilsson, **H. Björkbacka**;*
Lund University, Malmö, Sweden.

Objective:
Experimental studies in mice have attributed T-helper (Th) 1 and Th2 cells important roles in atherosclerosis, but the clinical importance of these cells in cardiovascular disease (CVD) remains to be clarified. Here, we investigated associations between Th1 and Th2 cells, carotid intima-media thickness, and cardiovascular risk.
Methods and Results:
Blood drawn at baseline and incident cardiovascular events during 15-year follow-up were assessed in 700 participants. Baseline Th1 (CD3(+)CD4(+)IFN-γ(+)) and Th2 (CD3(+)CD4(+)IL-4(+)) cells were analyzed by flow cytometry, and cytokine-release from activated mononuclear leukocytes was measured by multiplex technology. High numbers of Th2 cells were independently associated with decreased mean common carotid intima-media thickness. High numbers of Th2 cells were also independently associated with a reduced risk of acute myocardial infarction in women (hazard ratio, 0.19; 95% confidence interval, 0.06-0.56; P=0.002 for the highest versus the lowest tertile of Th2 cells). Moreover, release of the Th2 cytokine IL-4 from activated mononuclear leukocytes was independently associated with a reduced risk of CVD. No independent associations between Th1 cells and carotid intima-media thickness or CVD risk were found.
Conclusions:
Our observations provide the first clinical evidence for a protective role of Th2 immunity in CVD. They also suggest this protection is more prominent in women than in men. In spite of convincing evidence from experimental studies, we found no support for a role of Th1 immunity in CVD.

P5.08.07
Identification of NOD like receptors (NLRs) in human atheroma lesions

*R. T. D. Oliveira, M. F. Mineiro, R. M. Silva, M. R. Paiao, R. L. Mamoni, F. H. Menezes, **M. H. S. L. Blotta**;*
State University of Campinas, Campinas, Brazil.

Activation of innate immune receptors in atheroma lesions is involved in initiation and disease progression. Recently, a group of innate receptors, Nod Like Receptors (NLRs), was described and associated with recognition of several PAMPs/DAMPs. Members of the NLRs can assemble multimolecular complexes, inflammasomes, promoting activation of inflammatory caspases and maturation of IL-1beta and IL-18. The aim of this study was to investigate whether components of the NLRs family are present in atheroma lesions and involved in the activation of inflammasomes by atheroma related antigens. 44 patients with critical stenosis of carotid submitted to endarterectomy were evaluated. Carotid specimens were analyzed for mRNA and protein expression by real time RT-PCR and immunohistochemistry. Blood monocytes-derived macrophages of 4 healthy donors were cultured in the presence or absence of LPS or cholesterol crystals or both and production of IL-1beta and TNF-alpha was analyzed by ELISA. Our data showed expression of mRNA for NLRP1, NLRP2, NLRP3, NLRC1, NLRC2, NLRC3, NLRC4, NLRC5, Naip, ASC, caspase-1, AIM2 and IL-1beta in all carotid lesions. Immunoreactivity for NLRP1, NLRP3, NLRC2, NLRC3, NLRC5 and caspase-1 in macrophages and foam cells was also detected. Macrophages stimulated with LPS induced small production of IL-1 beta while the LPS + with cholesterol crystals promoted high levels of IL-1beta, while TNF-alpha production was unaffected. Altogether our results showed expression of several components of NLRs family in macrophages and foam cells of human atherosclerotic lesions. In addition, the production of IL-1beta but not TNF-alpha by macrophages after stimulation with cholesterol crystals suggests inflammasome activation.

P5.08.08
Oral anti-CD3 antibody treatment ameliorates mHSP65-induced atherosclerosis

*C. Grundtman[1], **M. A. Buszko**[1], H. Dietrich[2], G. Wick[1];*
[1]Division of Experimental Pathophysiology & Immunology, Innsbruck Medical University, Innsbruck, Austria, [2]Central Laboratory Animal Facility, Innsbruck Medical University, Innsbruck, Austria.

Aim-Accumulating evidence suggests that activated T-cells are the first invaders of the arterial intima in early human atherosclerosis lesions (1). Early atherosclerosis can also be reduced in animal models after T-cell depletion and after oral anti-CD3 antibody feeding. However, no study has shown the effect of oral anti-CD3 antibody treatment after immunizations with potentially atherogenic antigens.
Methods-Mice received 4 immunizations with mycobacterial heat shock protein 65 (mHSP65) (50μg/dose). Non-immunized mice served as controls. To test if we could reduce atherosclerosis in ApoE-/- mice we gave 8 oral feedings with anti-CD3 antibody or with the control IgG (5μg/feeding). The oral feedings were given both to non-immunized and mHSP65-immunized mice. Concomitantly with the first immunization, mice were either kept on normal chow diet (CD) or given high-cholesterol diet (HCD). All animals were sacrificed at week 22 and the aorta was surgically removed for Oil-Red staining to determine total plaque size. Blood was collected for determination of autoantibodies against eukaryotic (human) HSP60 (hHSP60) and prokaryotic mHSP65. Spleen and lymph nodes were collected for CD4+CD25+Foxp3+ T regulatory cell (Treg) determination.
Results-Oral administration of anti-CD3 antibody significantly reduced atherosclerotic lesion formation both in non-immunized and in mHSP65-immunized mice compared with controls. We observed an increase in Tregs in anti-CD3 antibody treated mice. mHSP65-immunized mice showed increased autoantibody titers to hHSP60/mHSP65. These titers were unchanged after oral treatment.
Conclusion-Our findings indicate that oral anti-CD3 antibody treatment has an atheroprotective effects both, in non-immunized and mHSP65-immunized mice. This effect might go via the induction of Tregs.

Study of endothelial progenitor cells as a non-invasive strategy to detect endothelial alterations in patients with idiopathic thromboembolism

F. Calcaterra[1,2], *S. Rambaldini*[2], *C. Lodigiani*[3], *D. Mavilio*[1,2], *S. Della Bella*[1,2];
[1]*Lab of Clinical and Experimental Immunology, Humanitas Clinical and Research Center, Rozzano, Italy,* [2]*Dept of Medical Biotechnologies and Translational Medicine, University of Milan, Milan, Italy,* [3]*Thrombosis Center, Humanitas Clinical Institute, Rozzano, Italy.*

BACKGROUND: Thromboembolism is defined idiopathic (ITE) when occurring without triggering circumstances. Inflamed and dysfunctional endothelium may play a pathogenic role in the disease. Endothelial progenitor cells (EPCs) are newly identified bone-marrow-derived cells crucial to endothelial homeostasis. Yet, their analysis in the blood may represent a novel, non-invasive strategy to study the endothelial compartment. In this study, we investigated possible alterations of circulating EPCs that may reflect endothelial perturbation in ITE patients.
METHODS: EPCs were isolated and expanded ex-vivo as endothelial colony-forming cells (ECFCs), using a method recently optimized in our lab. ECFCs were cultured from peripheral blood mononuclear cells (PBMCs) obtained from 13 ITE patients and 20 matched controls. Cultures were analyzed for efficiency of ECFC colony isolation, cell viability, morphology, immunophenotype, cytokine production, migration, in-vitro vasculogenesis.
RESULTS: ECFC colonies were isolated from ITE patients with the same efficiency as controls, as assessed as number of colonies and time of colony appearance starting from PBMC seeding. ECFC colonies from ITE patients were smaller and characterized by a high rate of early mortality, with cultures undergoing cell senescence within the first passage in a higher proportion of cases in ITE than controls ($p < 0.05$).
CONCLUSIONS: The preliminary results of this study indicate alterations in the growth of EPCs isolated from ITE patients that may indeed contribute to impairment of endothelial integrity in these patients. A full characterization of expanded ECFCs, still in progress, may further reveal functional defects of these cells that may possibly hinder the physiologic antithrombotic function of endothelium.

P5.08.10
A murine model of atherosclerosis, frequency and phenotype of the B cell subsets involved

D. Castaño[1], *H. Rincón-Arévalo*[1], *J. Villa-Pulgarín*[2], *J. R. Ramírez-Pineda*[2], *G. Vásquez*[1], *L. M. Yassín*[1,3];
[1]*Grupo de Inmunología Celular e Inmunogenética. Facultad de Medicina. Universidad de Antioquia, Medellin, Colombia,* [2]*Grupo de Inmunomodulación. Facultad de Medicina. Universidad de Antioquia, Medellin, Colombia,* [3]*Grupo de Ciencias Básicas. Facultad de Medicina. Universidad CES, Medellin, Colombia.*

Atherosclerosis is a chronic inflammatory disease of the artery wall. Several studies have described a role for B cells in atherosclerosis. Adoptive transfer of follicular B cells promoted atheromas, whereas B1a cells protected atherosclerosis onset. Currently, the mechanisms responsible for this modulation are unknown. To characterize the B cell subsets involved in a murine model of atherosclerosis, C57BL/6 wild-type and atherogenic apolipoprotein-E knockout (*Apoe*$^{-/-}$) mice were fed with high fat (HFD) or regular diet for 12 weeks. At that time, *Apoe*$^{-/-}$ mice developed overwhelming lesions in the aortic sinus, compared with wild-type ones. The study of splenic cells according CD19, CD21, CD23, and CD5 expression, showed not differences in the frequency of follicular, marginal zone and transitional 2 (T2) B cells between wild-type and *Apoe*$^{-/-}$ mice, before and after the pro-atherogenic diet. In *Apoe*$^{-/-}$ mice with HFD a significant reduction of CD19 expression was observed in total B cells that was more evident in T2 cells. Also, in this group of mice the percentage of CD5^{+} T2 cells was decreased, and in this subset CD21 expression was decreased while CD40 was increased. There were not differences in IgM, IgD, CD80 and CD86 expression in B subsets among the groups. Since, CD19, CD5 and CD40 are associated with the regulatory function of B cells, the next step in this line of investigation will be the evaluation of the regulatory function of these T2 cells in mice with established atherosclerosis.

Specific oligoclonal T-cell recruitment within epicardial adipose tissue of patients with acute coronary syndrome: evidence for a local, immune-mediated, pathogenetic mechanism

G. Di Sante, *G. Liuzzo, A. Severino, V. Pazzano, D. Pedicino, S. Tziopulos, N. Luciani, F. Glieca, F. Ria, F. Crea;*
Università Cattolica del Sacro Cuore, Rome, Italy.

Immune-driven T-lymphocyte recruitment within epicardial adipose tissue EAT is possibly implicated in acute coronary syndrome (ACS).We examined the T-cell receptor (TCR) repertoire using CDR3 BV-BC spectratyping both in EAT samples (obtained during coronary artery bypass grafting) and in PBMC of patients with either ACS (27) or chronic stable angina (SA; 26). Patients undergoing cardiac surgery for mitral insufficiency, with angiographically normal coronary arteries, served as control group (10). The TCR repertoire enriched in EAT samples of ACS patients was restricted, involving 24% TCR-BV families. In particular, we observed a disproportionately high expression of TCR-BV10 and BV6.2 that were found in 44% and 26% EAT samples, respectively. Intriguingly, TCR-BV10 was strongly associated with the first clinical manifestation of ACS (61% patients at first manifestation vs 11% patients with previous events ($P=0.019$)). Although the size of the repertoire used by SA and control was comparable to that of ACS patients, 62% SA patients expressed preferentially TCR-BV3 in EAT samples, while BV10 and BV6.2 (both 8%) were less frequent ($P<0.01$ vs ACS). Control samples were enriched in BV3 (30%) and BV9 (20%), but none had BV10 or BV6.2 ($P<0.01$ vs ACS). We thus observed that instability of coronary plaque in ACS is associated with specific T-cell recruitment also in the surrounding adipose tissue, indicating that T-cells bearing selected TCRs might be involved in the pathogenesis of ACS.

P5.08.12
Kinins promote aortic aneurysm through stimulation of neutrophil activation via the B2 receptor

T. Dougan, *C. S. Moran, C. Rush, R. Jose, L. Woodward, J. Golledge;*
James Cook University, Townsville, Australia.

Abdominal aortic aneurysm (AAA) is a chronic disease associated with inflammation of the aortic wall involving cells of the innate and acquired immune systems. Aneurysm rupture is responsible for ~1000 deaths annually in Australia. In the absence of effective medication, AAA treatment is restricted to surgical repair. The neutrophil, which plays a central role in inflammation, harbours the complete system for kinin release. This project investigates the effect of kinin receptor agonist (B9972), antagonist (B9430), kinin receptor deficiency and neutrophil depletion on AAA development in a mouse model. Aneurysm formation was monitored by ultrasound at 7-day intervals with aortic diameter determined at day 28 using morphometric analysis. Kinin receptor blockade and activation inhibited and promoted aortic dilatation respectively compared to a saline control ($p<0.0001$). In AngII-infused kinin receptor deficient mice (ApoE-/-B1B2-/-), aortic dilatation was lower compared to ApoE-/- controls ($p=0.0011$). Neutrophil depletion abrogated the ability of the kinin agonist to promote AAA development. Analysis of plasma myeloperoxidase (MPO) levels using ELISA indicated a decrease in MPO in kinin deficient mice compared to ApoE-/- controls ($p=0.0006$). In vitro studies using purified murine neutrophils treated with the kinin receptor agonist or antagonist indicated higher MPO activity with kinin promotion and lower MPO activity with kinin blockade ($p< 0.0001$). In summary, kinin receptor activation promotes AAA development, while kinin receptor blockade, deficiency, or neutrophil depletion, inhibits AAA development. Blocking the kinin pathway could be a novel intervention for treatment of AAA.

P5.08.13
Increased levels of MDA-modified collagen type IV in symptomatic lesions - a possible marker of unstable lesions

***P. Dunér**, H. Grufman, A. Edsfeldt, F. To, J. Nilsson, I. Goncalves, E. Bengtsson;*
Clinical Research Malmö, Malmö, Sweden.

Objective: Subendothelial LDL-aggregation and its subsequent oxidation are considered as key events in the development of atherosclerotic lesions. During oxidation of LDL reactive aldehydes, such as malondialdehyde (MDA) are formed, which modify amino groups of the associated apolipoproteinB100. However, the possibility that these reactive aldehydes also could leak out of the LDL-particle and modify surrounding extracellular matrix proteins has been largely unexplored.
Methods and results: The amount of MDA-modified collagen type IV and native collagen type IV were determined by in-house ELISAs in homogenates from 155 carotid artery lesions, removed by endarterectomy from patients with or without symptoms. Oxidized LDL was determined by ELISA. MDA-collagen type IV, but not native collagen type IV, showed a strongly significant association to oxidized LDL (r=0.31, *P*<0.001) and lipoprotein-associated phospholipase A2 (Lp-PLA2) (r=0.44, *P*<0.001). MDA-collagen type IV was also associated to inflammatory chemokines and cytokines. The amount of MDA-collagen type IV was higher in symptomatic lesions than in asymptomatic lesions. MDA-modification of collagen type IV decreased endothelial cell attachment *in vitro*. In addition, there was an association between autoantibodies against MDA-collagen type IV in plasma and the amount of MDA-collagen type IV in lesions.
Conclusion: Our data supports the hypothesis that LDL-oxidation induces modifications of nearby extracellular matrix proteins, which could contribute to more vulnerable lesions and cardiovascular events.

P5.08.14
Myd88 signalling in CD4+ T cells promotes atherosclerosis and Th17 responses

***D. Engelbertsen**, M. Wigren, H. Björkbacka, J. Nilsson, E. Bengtsson;*
Lund University, Malmö, Sweden.

Background
MyD88 is a transducer of TLRs and IL-1R signalling and crucial for responses against pathogen associated molecular patterns. Myd88 deficiency reduces atherosclerosis, an effect that primarily has been attributed to inhibition of macrophage activation. However, recent studies in autoimmune diseases have highlighted the importance of MyD88 signalling in T-helper cells. Here, we tested whether MyD88-dependent signalling in CD4+ T-cells affects atherosclerosis.
Methods
Apoe-/-Myd88-/- or Apoe-/-Myd88+/+ CD4+ T cells were transferred to lymphocyte deficient Apoe-/-Rag1-/- mice. The mice were fed high-fat diet for 7 weeks and atherosclerosis at the aortic root quantified by Oil Red-O staining and immunohistochemistry. Flow cytometry and multiplex analysis of cytokine-release was done to assess T cell function.
Results
Apoe-/-Rag1-/- mice receiving MyD88-deficient CD4+ T cells developed significantly smaller aortic root lesions than to mice receiving MyD88-competent CD4+ cells (108 000 ± 14 000 µm2 vs 157 000 ± 17 000 µm2, p<0.05). Total plaque area for lipids and collagen were lower mice receiving MyD88-deficient CD4+ T cells and there was also a trend towards less macrophage accumulation. However, the relative amounts of lipids, macrophages and collagen did not differ between the genotypes. Moreover, we observed lower levels of IL-17+ Th17 cells and double-positive IFNγ+-IL-17+ cells in spleens from mice receiving CD4+ T cells lacking MyD88. There were no differences in IL-10+ or IFNγ+ CD4+ T cells comparing genotypes.
Conclusion
This study demonstrates that MyD88 signalling in T cells contributes to development of atherosclerotic plaques and suggests that this involves activation of IL-17.

P5.08.15
Loss of B-cell function in MRas- knock-out mouse and reduced macrophage infiltration in atherosclerotic plaques at the aortic root

***J. Freyer**[1], M. Behrensen[1], Z. Aherrahrou[1], J. F. P. Berbèe[2], H. Schunkert[3], J. Erdmann[1];*
[1]Institut für Integrative und Experimentelle Genomik, Lübeck, Germany, [2]LUMC, Leiden, Netherlands, [3]Deutsches Herzzentrum München, München, Germany.

Recently, we identified by genome-wide association study the MRas gene locus on human chromosome 3q22 to be associated with coronary artery disease. M-Ras is a member of the small GTPases family.
We crossbred the MRas-KO mice onto the ApoE-KO background and fed these mice with western diet. In parallel, we performed adhesion and migration assays with leukocytes to study the influence of MRas on adhesion and migration as a potential pathomechanism of atherosclerosis.
The MRas/ApoE-KO mouse showed no difference in plaque size at the aortic root in comparison to the ApoE-KO mouse after 10 weeks of high fat diet, but there were significant less macrophages in the plaque (n=19/10/15; ~10%; p=0.002). In addition, the ratio between macrophage and collagen in the plaque at the aortic root was significant higher in the MRas/ApoE-KO than in the ApoE-KO under high fat diet (n=19/9/15; p=0.002).
We observed a 15% reduction of CD19+ B-cells in lymphnodes in MRas-KO mice (p<0.05), but not in bone marrow, spleen and blood. Moreover, we noticed a 20% reduction of leukocyte adhesion in in vitro assays with an endothelial cell line (p<0.05). Again, especially B-cell adhesion was reduced in MRas-KO mice in comparison to WT mice. In vitro migration assays show also a reduced migration of B-cells towards the chemokine CxCl12 (p<0.01).
Our data suggests that MRas-KO has no effect on plaque formation at the aortic root but on the plaque stability by less macrophage infiltration. This could be linked to the reduction of adhesion and migration by B-cells.

P5.08.16
Human carotid atherosclerotic plaques with high Interleukin 16 mRNA levels are associated with less clinical symptoms

***C. Grönberg**, M. Nitulescu, L. Hollender, A. Persson, M. Nilsson, G. Nordin Fredrikson, J. Nilsson, H. Björkacka;*
Lund University, Malmö, Sweden.

Background and purpose. Interleukin (IL-16), a proposed ligand of CD4, has previously been attributed a pro-inflammatory role in allergy and rheumatoid arthritis. CD4 expressing T-helper cells are involved in the pathogenesis of atherosclerosis. The aim of this study was to determine whether CD4 and IL-16 mRNA expression measured in human atherosclerotic plaques was associated with symptoms, plaque inflammation and a vulnerable plaque phenotype.
Methods. Carotid plaques surgically removed from 153 patients were analyzed. Plaques obtained from patients that displayed symptoms within one month before removal (n=86) were compared to plaques from patients without symptoms but more than 80% stenosis of the carotid artery (n=67). Natural lipid, collagen, elastin, smooth muscle cell and macrophage content was evaluated histologically. Cytokines were measured in plaque homogenates using multiplex immunoassay and ELISA. IL-16, as well as CD3 and CD4, mRNA expression was analyzed with quantitative real-time PCR.
Results. The IL-16 mRNA expression was significantly higher in asymptomatic plaques compared with symptomatic plaques (p=0.043). The highest tertile of IL-16 mRNA expression was associated with symptoms with an odds ratio of 0.36 (p=0.026 and C.I. 0.15-0.88) compared to the lowest tertile of IL-16 mRNA expression when adjusting for common risk factors as age, gender, hypertension, CRP and statin use. IL-16 mRNA expression correlated to elastin and plasma triglyceride levels. No correlations were detected with pro-inflammatory cytokines in the plaque.
Conclusion. This study shows that high mRNA expression of IL-16 is associated with less clinical symptoms indicating that IL-16 might have a protective role in human atherosclerosis.

P5.08.17
Regulation of endothelial cell survival by the MEKK3-GAPDH axis

C. S. Hii[1,2]*, A. Ferrante*[1,2]*;*
[1]*SA Pathology at the Women's and Children's Hospital, Adelaide, Australia,* [2]*University of Adelaide, Adelaide, Australia.*

Endothelial cell death is key to vascular damage, endothelial dysfunction and atherosclerosis. The molecular pathways that mediate endothelial cell death and survival remain poorly understood. While the MEKK3-MEK5-ERK5 module is critically important to maintaining endothelial cell survival, the mechanisms by which this pathway imparts such action remain poorly understood. We now report, in human endothelial cells, the co-immunoprecipitation of ERK5 with GAPDH, a glycolytic enzyme that also signals for cell death. Serum starvation-induced cell death was associated with decreased binding of GAPDH to the MEKK3-MEK5-ERK5 complex and increased levels of nuclear GAPDH. In contrast, halting cell death by serum readdition was associated with enhanced ERK5 activity, increased amount of GAPDH in the complex and normalisation of nuclear GAPDH. Other inducers of cell death (H_2O_2, tumour necrosis factor α + cycloheximide and 30 mM glucose) also caused an increase in nuclear GAPDH. R-(-)-deprenyl, an inhibitor of the nuclear translocation of GAPDH, inhibited cell death caused by H_2O_2. Interestingly, GAPDH bound directly to MEKK3, and not to ERK5 or MEK5. This GAPDH-MEKK3 interaction was enhanced by serum stimulation. Constitutively active MEKK3 not only exhibited enhanced binding to GAPDH but it also directly phosphorylated GAPDH on 3 sites. The data reveal that nuclear translocation of GAPDH leads to endothelial cell death and this is prevented by growth factors which activate MEKK3 and promote GAPDH binding. Our data suggest that phosphorylation of GAPDH by MEKK3 may play a role in preventing GAPDH-induced death. The MEKK3-GAPDH axis may represent a novel target for atheroprotection.

P5.08.18
IgE and eosinophilia levels in peripheral blood of patients with cardiovascular disease

M. Hosseinzadeh[1]*, A. Khosravi*[2]*, A. Delpisheh*[2]*, S. Safari*[3]*, R. Kafashi*[2]*;*
[1]*Tehran University of Medical Sciences, Tehran, Iran,* [2]*Ilam University of Medical Sciences, Ilam, Iran,* [3]*Ilam University of Medical Sciences, ilam, Iran.*

Background: Recently, several studies have been performed to assess the relationship between the higher eosinophilia and IgE levels with the incidence, progress and severity of cardiovascular disease (CVD) but their exact correlation remains unclear. The current study was designed to measure the levels of IgE and the eosinophilia levels amongst CVD patients .
Materials and Methods: Case group included 59 randomly selected CVD patients and 55 healthy individuals without any history of allergy and parasitic. A questionnaire including age, sex, smoking status was completed by each participant. Subsequently, 7 ml blood was taken from each participant for the CBC measurements and sera were obtained to measure IgE levels by ELISA.
Results: There were significant differences in variables such as family history, diabetes, hyperlipidemia, high blood pressure and physical activity between case and control groups. The mean IgE titers in the case and control group were 95.3 ± 71 and 62.44 ± 49, respectively. The mean eosinophila levels in peripheral blood were 3.95 ± 1.057 in case and 1.53± 0.57 in control group. The differences between the IgE and eosinophilia levels were statistically significant.
Conclusion: We conclude that the higher levels of IgE and the eosinophilia can be considered in the incidence, severity and progression of different types of CVD.

P5.08.19
Immunotherapy with tolerogenic Apolipoprotein B-100-loaded dendritic cells inhibits progression of atherosclerosis in hypercholesterolemic mice

D. K. Johansson*, D. Ketelhuth, A. Hermansson, M. Josefa Forteza de los Reyes, A. Ismail, K. Lindner, G. K. Hansson;*
Karolinska Institute, Stockholm, Sweden.

Objective - Atherosclerosis is a chronic inflammatory disease characterized by a massive intimal accumulation of low-density lipoprotein (LDL) that triggers chronic vascular inflammation with an autoimmune response to LDL components. Treatment of young hypercholesterolemic mice with dendritic cells (DCs) pulsed with the LDL protein apolipoprotein B100 (ApoB100) in combination with the immunosuppressive cytokine interleukin-10 (IL-10) reduces atherosclerotic development.
Methods and Results - To investigate if treatment with DC pulsed with ApoB100 in combination with IL-10 could have an effect on established atherosclerosis, 22 week old huB100tgxLdlr-/- mice (mice transgenic for human apolipoprotein B100 [ApoB100] and deficient for the low-density lipoprotein receptor) fed a high-cholesterol diet were intravenously injected with DC pulsed with ApoB100 in combination IL-10. 8 weeks after treatment atherosclerotic burden in the aorta was measured. Whereas atherosclerotic lesion area showed a 50% increase 8 weeks after treatment with DC only pulsed with ApoB100 and in untreated mice, mice injected with DC pulsed with ApoB100 in combination with IL-10 displayed inhibited progression of atherosclerosis.
Conclusions - Tolerogenic DCs pulsed with ApoB100 inhibits progression of atherosclerosis.

P5.08.20
Apolipoprotein B100 danger-associated signal 1 (ApoBDS-1) is a potent platelet agonist that triggers procoagulant and proinflammatory responses

A. Assinger[1,2]*, Y. Wang*[2]*, L. M. Butler*[2]*, G. K. Hansson*[2]*, Z. Yan*[2]*, C. Söderberg-Naucl*[2]*,* ***D. F. J. Ketelhuth***[2]*;*
[1]*Institute of Physiology, Center for Physiology and Pharmacology, Medical University of Vienna, Viena, Austria,* [2]*Center for Molecular Medicine - Karolinska University Hospital, Stockholm, Sweden.*

Low-density lipoproteins (LDL), occurring in vivo in both their native and oxidative form, modulate platelet function and thereby contribute to atherothrombosis. We recently identified and demonstrated that 'ApoB100 danger-associated signal 1' (ApoBDS-1), a native peptide of Apolipoprotein B-100 (ApoB100), the protein component of LDL, induces inflammatory responses in innate immune cells. Platelets are critically involved in the development as well as in the lethal consequences of atherothrombotic diseases, but whether ApoBDS-1 has also an impact on platelet function is unknown. In this study we examined the impact of ApoBDS-1 on human platelet function and platelet-leukocyte interactions.
By using in vitro models, we observed that ApoBDS-1 is a potent platelet agonist that induced platelet activation, degranulation, adhesion and release of proinflammatory cytokines. ApoBDS-1-stimulated platelets triggered innate immune responses by augmenting leukocyte activation, adhesion and transmigration. The platelet-activating effects were sequence-specific, and stimulation of platelets with ApoBDS-1 activated different intracellular signaling pathways, including PI3K, PLC and MAPK. Moreover, we show that inhibition of the purinergic receptor P2Y1 mitigated ApoBDS-1-induced platelet activation, whereas P2Y12 and COX-1 inhibition had only minimal effects.
ApoBDS-1 is a potent platelet agonist that modulates coagulation and inflammatory processes, and therefore is likely to contribute to the disease-promoting effects of LDL in the pathogenesis of atherothrombosis.

P5.08.21
Study the correlation of haptoglobin phenotypes in acute heart attack patients

***H. A. Khazaei**;*
Zahedan medical sciences university, Zahedan, Iran.

Introduction: AMI is disorders of acute blood and oxygen transfer to the heart cells and part of the heart muscle. Symptoms are differ with pain and burning sensation in the chest and accompanied by nausea and vomiting. Numerous immunological and non immunological factors are involved that can be pointed to the role of inflammatory factors such as haptoglobulin. The aim of this study was to find association of disease with haptoglobulin phenotypes expression and patients demographic factors.
Methodology: 120 patients and healthy control were selected for study. After obtaining serum used for haptoglobulin phenotype distribution by electrophoresis method and results of each phenotype differences in patient and healthy control groups were analysed using the X^2 test and SPSS software.
Results: 50.9% of patients were women and 47.9% men and 47.9% upper 60 years old. High serum haptoglobin Hp2-2 phenotype frequencies were found in 75 patients (62.5%) and in 70 control (58.3%) groups. Comparison of the results between two groups showed no meaningful statistic correlation between these two groups (P Value=0.484) and Hp1-1 phenotype had meaningful statistic correlation with the increased amount of serum acute heart attack indexes, such as hyper lipidemia and Hp2-2 with high blood pressure of patients compared with healthy control (p value =0.01 and 0.04 respectively).
Conclusion; This study revealed that no specific phenotype was related to the disease process whereas some demographic factors were involved in diseases susceptibilities that needs to be investigate more.

P5.08.22
Sublingual vaccination with Porphyromonas gingivalis GroEL elicits protective immunity against atherosclerosis

*M. Hagiwara[1], **T. Kurita-Ochiai**[2], R. Kobayashi[2], T. Hashizume-Takizawa[2], M. Yamamoto[2];*
[1]Oral Surgery, Matsudo, Chiba, Japan, [2]Microbiology and Immunology, Matsudo, Chiba, Japan.

Atherosclerosis has proved to be associated with microbial infection, inflammation, and autoimmunity. Periodontal disease is one of the most prevalent chronic inflammation of oral cavity, and has been reported to be associated with atherosclerosis. Accumulating evidence suggests a positive association of anti-heat shock protein 60 (HSP60) autoantibodies and the presence of atherosclerosis in humans. In this study, we assessed the potential of sublingually administered recombinant HSP60 from Porphyromonas gingivalis (rGroEL) for prevention of atherosclerosis accelerated by P. gingivalis. Apolipoprotein E deficient spontaneously hyperlipidemic (Apoeshl) mice were sublingually immunized with GroEL two times a week for two weeks. P. gingivalis 381 was challenged intravenously three times a week for two weeks and animals were euthanized 16 weeks later. Atherosclerotic lesions in proximal aorta of each animal were analyzed histomorphometrically, and the serum concentration of rGroEL-specific antibodies and cytokines were determined. Sublingual immunization with rGroEL induced significant rGroEL specific serum IgG responses in Apoeshl mice. Antigen-specific mononuclear cells isolated form spleen cells produced significantly high levels of IL-10 and IFN-γ. FACS analysis indicated that IL-10 and IFN-γ production was not derive from the Foxp3+ regulatory T cells. Interestingly, however, mice given rGroEL sublingually possessed significantly reduced atherosclerotic plaque accumulation in aortic sinus and lowered the serum levels of CRP, MCP-1 and ox-LDL compared to nonimmunized mice. These results suggest that sublingual immunization with rGroEL could be an effective vaccine for prevention of atheroscleorosis accelerated by P. gingivalis. Collaborator: Kazuhisa Yamazaki (Niigata University)

P5.08.23
IL-25 treatment inhibits atherosclerosis development in ApoE deficient mice

***P. T. Mantani**, P. Dunér, E. Bengtsson, R. Alm, I. Söderberg, L. Sundius, F. To, J. Nilsson, H. Björkbacka, G. Nordin Fredrikson;*
Department of Clinical Sciences, Skåne University Hospital Malmö, Lund University, Malmö, Sweden.

IL-25 has been implicated in the initiation of type 2 immunity and in controlling the outcome of Th1/Th17 responses suggesting a protective role in autoimmune diseases. The aim of this study was to evaluate the role of IL-25 in the initiation of atherosclerosis development as well as in already established atherosclerosis.
Osmotic pumps containing recombinant mouse IL-25 or control medium (CM) were surgically placed in atherosclerosis prone *apoE*$^{-/-}$ mice either during 10-14 weeks or 20-24 weeks of age, delivering 1µg of IL-25 / day or equal volume of CM. In parallel for the same time periods mice were weekly injected i.p. with 100µg of anti-IL-25 (or control antibody). Upon termination at 25 weeks of age, blood and spleen cells were analyzed with flow cytometry. Oil Red O staining was performed in *en face* preparations of aortas, cytokine levels were determined using Luminex technology and plasma immunoglobulins were assessed with the use of a multi-spot assay and ELISA.
ApoE$^{-/-}$ mice treated with IL-25 during the initiation of atherosclerosis had reduced plaque areas in the aorta while IL-25 blockade led to increased plaque areas in the aortic arch, decreased Th2 cytokines in plasma and increased pro-inflammatory cytokine release from splenocytes. Furthermore, *apoE*$^{-/-}$ mice with established atherosclerosis treated with IL-25 had reduced plaque areas in the aorta while treatment with the IL-25 blocking antibody did not affect plaque development.
In conclusion, IL-25 treatment of atherosclerosis prone mice results in reduced plaque areas indicating a protective role in atherosclerosis.

P5.08.24
Soluble FcγRIIIaMφ levels in plasma correlate with stenosis rate in patients examined with carotid ultrasonography

***M. Masuda**[1], K. Kouno[2], N. Nishimura[1], H. Masaki[1], T. Yokoi[1], Y. Komiyama[1], T. Iwasaka[2], H. Takahashi[1];*
[1]Department of Clinical Sciences and Laboratory Medicine, Kansai Medical University, Osaka, Japan, [2]Department of Medicine II, Kansai Medical University, Osaka, Japan.

Macrophages play a major role in the development of vascular lesions in atherogenesis. The cells express FcγRIIIa (CD16) identical to that in NK cells, but with a cell type-specific glycosylation, and these soluble forms (sFcγRIIIa) are present in plasma. We had measured sFcγRIIIaMφ derived from macrophages in plasma with anti-FcγRIIIaMφ monoclonal antibodies and found that the levels of sFcγRIIIaMφ had been related to the severity of coronary atherosclerosis in patients with coronary artery diseases (CAD). In volunteers, the sFcγRIIIaMφ levels measured at the annual medical chekup had been positively related to both the number of risk factors for atherosclerosis and carotid maximum intima-media thickness (IMT). In the present study, we measured sFcγRIIIaMφ in plasma from patients examined with carotid ultrasonography. The levels of sFcγRIIIaMφ, but not the sFcγRIIIa levels, were significantly increased in those patients compared with age-matched healthy controls. Patients with echogenic/echolucent plaques or mixed with echogenic/echolucent and with calcificated plaques had the highest sFcγRIIIaMφ levels, but patients with only calcificated plaques had levels similar to patients with no plaque or intact carotid artery. The levels of sFcγRIIIaMφ were correlated with the stenosis rates, and the levels of total sFcγRIII were correlated with maximum plaque diameters. Because unstable plaques contain a lot of lipids and macrophages inside, the sFcγRIIIaMφ may serve as a novel risk biomarker for unstable angina or myocardial infarction.

P5.08.25
Atherosclerosis in rats after immunization with human native low-density lipoproteins

***I. Menshikov**, K. Fomina, L. Beduleva;*
Udmurt State University, Izhevsk, Russian Federation.

The principal unsolved question of atherogenesis is why and how lipoprotein metabolism becomes unbalanced. The purpose of this research is to test the hypothesis that autoimmune reaction to native LDL (nLDL) is the cause of dyslipoproteinemia and atherogenesis in the vascular wall. In order to check our hypothesis we made an attempt to induce autoimmune reaction to nLDL in rats. In cases of autoimmune reaction we expected dyslipoproteinemia and development of atherosclerosis features. A single immunization of rats with human nLDL leads to self-maintained, self-reinforced anti-nLDL autoantibodies production in most rats. Anti-nLDL autoantibodies response was accompanied by dyslipoproteinemia and caused increased epicardial and perivascular adipose tissue volume, decrease of cholesterol level in adrenal glands, accumulation of inflammatory cells in aorta wall, together with intima destruction and media disorder. The results obtained favor the hypothesis that autoimmunity to native LDL is the cause of atherosclerosis development.

P5.08.26
Susceptibility to ischemic stroke and HPA4/Annexin5 polymorphisms

***I. Mezni**[1], M. Jeljeli[1], T. Dhaouadi[1], S. Younes[2], N. Benali[1], I. Bannour[3], I. Sfar[1], A. Boughammoura[4], A. Bahloul[1], M. Makhlouf[1];*
[1]hospital Charles Nicolle Tunisia, Tunis, Tunisia, [2]hospital Tahar Sfar Mahdia, Mahdia, Tunisia, [3]Faculty of Medicine of Monastir, Monastir, Tunisia, [4]hospital Fattouma Bourguiba Monastir, Monastir, Tunisia.

Introduction: Some polymorphisms of genes coding for platelet alloantigens systems (HPA:Human Platelet Antigen) or glycoproteins linking membrane phospholipids and feature anti-thrombotic properties, such as annexin5 (AnxA5) can play an important role in ischemic stroke. In this context, polymorphisms (-1C/T) of AnxA5 gene and HPA4a/4b of HPA4 system were determined to find a possible association between these polymorphisms and susceptibility to ischemic stroke in Tunisian patients.
Methods: Case-control study was conducted in 50 patients with ischemic stroke and 249 healthy subjects. (-1C/T) AnxA5 and HPA4 polymorphisms were investigated by PCR-RFLP and PCR-SSP, respectively.
Results: The HPA4b minor allele was significantly higher in patients (0.92) compared to healthy subjects (0.642) (OR: 1.8, 95% CI [1.16-2.78], p=0.007). In contrast, no difference in genotypic and allelic frequencies of C/T mutation of AnxA5 was found between patients and controls (p=0.67). Besides, no significant association was found between studied polymorphisms and age of disease onset, either lesions localization.
Conclusion: If HPA4b allele appears to be a risk factor for ischemic stroke in Tunisian patients, the clinical significance of SNP (-1C/T) AnxA5 is not clearly demonstrated.

P5.08.27
Inhibition of IL-27 attenuates atherosclerosis by inducing regulatory T cells

***O. H. Ramos**, P. J. van Santbrink, I. Bot, M. Bot, R. van der Sluis, M. ter Borg, S. C. de Jager, J. Kuiper;*
Leiden Academic Centre for Drug Research, Leiden, Netherlands.

Interleukin 27 binds to cytokine receptor WSX-1 to activate cells, resulting in both pro- and anti inflammatory responses. In this study IL-27 was blocked in vivo to study the role in atherosclerosis.
LDLR -/- were injected i.m. with a sWSX-1 encoding lentivirus or an empty virus. Two weeks after the injection the mice were put on a high fat diet for 6 weeks to induce atherosclerosis. The experiments were repeated in combination with a regulatory T cell depletion by αCD25 treatment.
Neutralization of IL-27 via the soluble receptor resulted in a 31% reduction in aortic lesion size. The lesion size negatively correlated with the concentration of the soluble receptor in the serum. The collagen content was not affected, while there was a trend toward increased macrophage content. FACS analysis showed that blockade of IL-27 increased the circulating T helper cell population. Furthermore, CCR2 expression on monocytes was reduced while CD163 expression increased. The expansion of regulatory T cells was proven to be crucial for the reduction in lesion size, as no change was observed in combination with the αCD25 treatment. The anti inflammatory monocyte phenotype was not affected by the regulatory T cells depletion.
Taken together these results indicate that blockade of interleukin 27 resulted in an anti-inflammatory immune response by inducing regulatory T cells and anti-inflammatory monocytes . Astonishingly, the regulatory T cells are indispensible for the reduction in lesion size.

P5.08.28
Splenectomy increases atherosclerotic lesions in apolipoprotein E deficient mice

***A. B. Rezende**[1], N. N. Neto[1], L. R. Fernandes[2], A. C. Ribeiro[2], J. I. Alvarez-Leite[2], H. C. Teixeira[1];*
[1]Federal University of Juiz de Fora, Juiz de Fora, Brazil, [2]Federal University of Minas Gerais, Belo Horizonte, Brazil.

Introduction: The spleen plays an important immune function, but its influence in development of atherosclerosis remains unclear. Atherosclerosis is an inflammatory immune disease associated to lipid accumulation in the intima layer of arteries. Evaluation of the role of the spleen in atherosclerosis is justified due to the high incidence of total splenectomies. The objective of this work was to investigate the effect of splenectomy in development of atherosclerosis in apolipoprotein E (ApoE) deficient mice.
Methods and Results: Mice were divided into sham operated control group (CT) and splenectomized group (SP). Thirty days after surgery, animals were fed on the high fat western diet. After 8 weeks, mice were euthanized for blood, heart and aorta analyses. Atherosclerotic lesion areas in the aortic root were stained with hematoxylin-eosin and quantified by morfometry. The atherosclerotic lesions in the thoracic and abdominal portions of aorta were determined by the percentage of the luminal surface area stained by Sudan IV. Total serum cholesterol and anti-oxidized LDL antibodies were measured. Levels of total serum cholesterol did not vary significantly after splenectomy. Anti-oxidized LDL antibodies were also similar between groups. However, compared to control group, lesions in the aortic root were significantly larger in splenectomized mice ($p<0.01$). This data was confirmed by the increase of atherosclerotic area in the thoracic and abdominal portions of aorta in splenectomized mice.
Conclusions: These data indicate that splenectomy increases atherosclerotic lesions in ApoE deficient mice fed an atherogenic diet, suggesting a atheroprotector role of the spleen.

P5.08.29
IL-22 deficiency induces vascular remodeling and alterations in immune cell populations after carotid injury

***R. Sara**[1], G. Roos[2], I. Söderberg[1], H. Björkbacka[1], G. Nordin-Fredrikson[1], A. Hultgårdh-Nilsson[2], J. Nilsson[1];*
[1]Lund University, Malmö, Sweden, [2]Lund University, Lund, Sweden.

IL-22 is a recently discovered cytokine that has anti-inflammatory properties in several inflammatory diseases. IL-22 is produced by e.g. Th17, NKT and innate lymphoid cells and is believed to act on stromal cells as a way for the immune system to control tissue responses. The role of IL-22 in the vascular wall is not widely studied but given the involvement of both immune and tissue responses in atherosclerosis and vascular remodeling we aimed to study the contribution of IL-22 in vascular responses after carotid injury.
In this study, we used a carotid collar model to induce neointima formation in C57Bl6 and IL-22-/- mice. Preliminary results show no significant difference in neointima size but rather a significant increase in media area in IL-22 deficient mice. This might reflect an effect of IL-22 on vascular smooth muscle cell migration or

proliferation, processes which are now under further investigation in the context of IL-22 deficiency. However, the increased media area is not due to any differences in collagen percentage. Furthermore, carotid injury induced substantial alterations in immune cell populations in IL-22-/- mice having larger lymph nodes accompanied with increased amounts of CD4+ and CD8+ T cells, decreased levels of Tregs and IL-17 producing cells as well as more antigen-presenting cells. Taken together, these preliminary results indicate that IL-22 might play a role in the vascular wall by affecting vascular cells as well as inducing a more inflammatory environment in the draining lymph nodes potentially reflecting an overall increased inflammatory status in the vasculature.

P5.08.30
The role of anti-apolipoprotein A1 autoantibodies in cardiovascular risk stratification

P. C. Teixeira[1,2], *P. Ferber*[3], *A. Ducret*[1], *S. Pagano*[2], *H. Gaertner*[4], *O. Hartley*[4], *H. Langen*[1], *N. Vuilleumier*[2], *P. Cutler*[1];

Hoffmann-La Roche, Basel, Switzerland,* [4]*Department of Structural Biology and Bioinformatics, School of Medicine, University of Geneva, Geneva, Switzerland.*

Autoantibodies to apolipoprotein A1 (anti-ApoA1 IgG) have been shown to be both a marker and a mediator of cardiovascular disease, promoting atherogenesis and unstable atherosclerotic plaque. Previous studies have shown that anti-apoA1 IgGs, assessed by ELISA, are independently associated with major cardiovascular events in patients with myocardial infarction. Our investigations have focused on understanding the pathophysiology underlying the ApoA1 autoantibody response. Autoantibody responses can be multifactorial and it is possible that more than one epitope may exist. In order to better characterize the specific epitopes, we have isolated human ApoA1 from plasma utilizing high resolution purification. Since ApoA1 has no cysteines in its sequence, we used thiophilic interaction chromatography to purify ApoA1 monomer from thiol-containing proteins, generating a fraction containing ApoA1 with purity circa 99%. A high level of immunoreactivity to the purified ApoA1 was detected by ELISA, using samples containing high titers of autoantibodies. Moreover, a short synthetic ApoA1 peptide with proper tertiary structure was shown to compete the endogenous epitope. We determined the diagnostic accuracy of patient immunoreactivity to this peptide for non-ST elevation myocardial infarction (NSTEMI) diagnosis on 132 consecutive patients presenting at the emergency room for acute chest pain. ROC curve analyses demonstrated that synthetic peptide was a significant predictor for NSTEMI diagnosis (AUC:0.64; p=0.01), and risk analyses demonstrated that high levels of immunoreactivity to the peptide was associated with a 7-fold risk of NSTEMI (OR:6.98, p=0.001). Taking together, this study may generate innovative prognostic and therapeutic biomarkers, potentially improving the current patient cardiovascular risk stratification.

P5.08.31
Platelet-derived microparticles may contribute to the thrombotic tendency in systemic lupus erythematosus by both procoagulant and immune-mediated mechanisms

K. Tselios[1], *P. Klonizakis*[1], *S. Gerou*[2], *D. Bougiouklis*[2], *A. Sarantopoulos*[1], *I. Gkougkourelas*[1], *P. Boura*[1];
[1]*Clinical Immunology Unit, 2nd Department of Internal Medicine, Hippokration General Hospital, Aristotle University of Thessaloniki, Thessaloniki, Greece,* [2]*ANALYSIS Medical Research Centre, Thessaloniki, Greece.*

Background: Platelet-derived microparticles (PDMPs) represent small vesicles that promote coagulation by exposure of negatively charged phospholipids. Aim of this study was the assessment of PDMPs in systemic lupus erythematosus (SLE) patients and their association with disease activity, presence of antiphospholipid antibodies (aPL) and previous thrombosis.
Patients and Methods: Forty consecutive SLE patients (38 females, 2 males, mean age 50±16.4 years, mean disease duration 110.7±26.4 months) were included. PDMPs were isolated from citrate-treated plasma and characterized by flow cytometry using Annexin-V and CD41 antibodies to platelet surface markers.
Results: SLE patients had significantly increased concentrations of PDMPs (1800±293MP/UI, normal range <1000MP/UI), irrespectively to disease activity, as PDMPs did not differ between active and inactive disease (1879±186 vs. 1805±343MP/UI, p=NS). Interestingly, PDMPs were detected in higher levels (although non significantly) in patients with a previous history of arterial or venous thrombosis (1855±219 vs. 1781±396MP/UI). In accordance, they were marginally elevated in patients with antiphospholipid syndrome (APS) (1892±233 vs. 1776±360MP/UI). Moreover, PDMPs were found in higher levels in patients with positive anti-dsDNA antibodies (1907±317 vs. 1762±303MP/UI) and low levels of C3/C4d complement fragments (1982±334 vs. 1721±256MP/UI, p<0.05).
Conclusions: PDMPs were found in higher levels in lupus patients with a previous history of thrombosis or concomitant APS. Elevated PDMPs in patients with positive anti-dsDNA antibodies and low complement levels suggest that these microparticles may further induce thrombosis via the induction of immune complexes formation. These results warrant further characterization of PDMPs in SLE to elucidate their role in disease pathogenesis.

P5.08.32
GDF-15, ST-2 and Galectin-3 plasma levels and their potential relations in patients with coronary artery disease

E. Vianello[1], *G. Dogliotti*[1], *E. Dozio*[1], *M. M. Corsi Romanelli*[1,2];
[1]*Dipartimento di Scienze Biomediche per la Salute, Università degli Studi di Milano, Milan, Italy,* [2]*Unità Operativa Laboratorio di Patologia Clinica, Dipartimento dei Servizi Sanitari di Diagnosi e Cura – Medicina di Laboratorio, IRCCS Policlinico San Donato, San Donato, Milano, Italy.*

Aim: The key process leading to heart failure is cardiac remodelling in response to chronic disease stresses caused by atherosclerosis and evolved into coronary artery disease (CAD). There is a growing interest in using new circulating biomarkers such as GDF-15, ST-2 and Galectin3 (Gal-3) to obtain pathophysiological insight and improve the management of patients with CAD. Our goal was to investigate these markers of heart disease to better understand involvement of these in different pathology such as coronary artery disease and cardiac valvular replacement (VR). Methods: We have studed 3 groups of subjects: the first consisted of 20 patient affected by CAD undergoing coronary artery bypass grafting (CABG); the second of 20 patient with no signs of CAD undergoing VR and the third group of 20 healthy man without apparent pathologies as controls. Blood samples of patients undergoing elective CABG or VR surgery and of control subjects were collected after an overnight fasting to measure GDF-15, ST-2 and Gal-3 levels by immune-enzymatic assay. Results: Our data show a statistically significant increase of plasma levels of GDF-15, ST-2 and Gal-3 in CABG and VR patients compared to controls (p<0.05), but no difference has been observed between the two groups of CVD patients.
Conclusions: Our results it seems that although these two differentgroups of patients had similar increased circulating levels of GDF-15, ST-2 and Gal-3 none of these resulted mainly associated to coronary artery disease (CAD).

P5.08.33
Aggravation of atherosclerosis by MHC class II antigen deficiency is associated with a loss of regulatory T cells but is independent on IL-10

M. Wigren, *S. Rattik, H. Björkbacka, G. Nordin Fredrikson, J. Nilsson; Lund University, Malmö, Sweden.*

It has been proposed that atherosclerosis involves a loss of tolerance against modified self-antigens generated in response to hypercholesterolemia and that presentation of such antigens on MHC

class II lead to activation of pro-inflammatory Th1 cells. Furthermore, anti-inflammatory Tregs have been shown to reduce atherosclerosis development indicating that both pro- and anti-inflammatory responses exist. To further study the role of adaptive immunity in atherosclerosis we have used hypercholesterolemic mice lacking MHC class II (ApoE-/-MHCII-/-). ApoE-/-MHCII-/-mice had reduced levels of CD4+ T cells as well as Th1, Th2 and Treg cytokines in plasma. Splenic CD115+ monocyte numbers and plasma levels of pro-inflammatory cytokines were reduced indicating reduced systemic inflammation. Despite this, ApoE-/-MHCII-/-mice had significantly more atherosclerosis as assessed both by *en face* lipid staining of the aorta (4.7±2.9% versus 1.9±1.3%; P<0.01) and cross-sectional area of subvalvular lesions (7.7±2.2x105 versus 4.6±2.8x105 µm2; P<0.05). Moreover, macrophage accumulation in lesions was significantly increased (44.8±8.0% versus 24.8±7.8% MOMA-2 stained area; P<0.001). To test the hypothesis that the aggravated atherosclerosis in ApoE-/-MHCII-/- mice was caused by a decreased release of IL-10 from Tregs we gave weekly injections of IL-10 blocking antibodies to inhibit atherosclerosis in ApoE-/- but not in ApoE-/-MHCII-/- mice. Blocking IL-10 significantly reduced the plasma level of IL-10 in ApoE-/- mice but did not promote the development of atherosclerosis. The present observations unexpectedly show that the net effect of MHC class II-dependent antigen presentation in atherosclerosis is athero-protective and that IL-10 does not play a major protective role at this stage of the disease.

Nanotherapy for drug addiction

R. Aalinkeel[1]*, J. Reynolds*[2]*, B. Nair*[1]*, D. Sykes*[1]*, W. Law*[1]*, P. Prasad*[1]*, S. Schwartz*[1]*, S. Mahajan*[1]*;*
[1]State University of New York at Buffalo, Buffalo, NY, United States,
[2]State University of New York at Buffalo, Buffalo, NY, United States.

Substance abuse involves activation of the dopaminergic signaling pathway and a 32kDa dopamine- and cAMP-regulated phosphoprotein (DARPP-32) is a phosphoprotein that is critical to the pathogenesis of drug addiction. Since DARPP-32 plays a central role in regulating the efficacy dopaminergic neurotransmission, we hypothesize that sustained knockdown of DARPP-32 may interfere with conditioned responses and promote brain plasticity in patients who abuse recreational drugs. Our study used a highly innovative nanotechnology-gene therapy approach, using gold nanorods (GNR) conjugated to siRNA to silence DARPP-32 gene expression of a critical molecular target of drug addiction, DARPP-32. We propose that suppression of DARPP-32 expression may help break the cycle of addiction and prevent relapse to drug abuse by reducing the rewarding effects of addictive drugs on the brain. Our results showed significant inhibition of DARPP-32 gene expression both in- vitro primary human dopaminergic cells (85%, p<0.001) and in-vivo by stereotaxic injection to the brain VTA region (68%, p<0.01) in a opiate addicted rat model using GNR-DARPP-32 siRNA nanoplexes up to a period of 4 weeks post transfection when compared to untreated and scrambled controls. Gene silencing was determined by real time QPCR analysis. Further, behavioral outcome was determined in the animal model using condition placed preference (CPP) studies, which showed a significant amelioration of addictive behavior in these opiate addicted rats. This innovative nanotherapy using targeted delivery of DARPP-32 siRNA offers a unique opportunity for pharmacological intervention to treat drug addiction.

P5.09.02
Immunofluorescence patterns in mouse cerebellum and kidney tissues revealed by seric antibodies of patients with various neuroinflammatory diseases

D. L. De la Cruz-Aguilera, J. E. Pablo-Gopar, J. J. Flores-Rivera, T. Corona, A. González-Aguilar, ***M. L. Aguirre-Cruz****;*
Instituto Nacional de Neurología y Neurocirugía, México D. F., Mexico.

Rationale. The autoimmune neurological disorders are severe and disabling conditions. A specific autoantibody associated to Devic's syndrome (or neuromyelitis optica) is NMO-IgG, which recognize acquaporine-4. Routine determination of this Ab by our group has revealed non-classic or nonspecific immunofluorescence patterns (IFP). In this study we analyzed the relation of IFP with the diagnosis of patients with various neuroinflammatory diseases.
Methods. IFP in mouse tissues (cerebellum and kidney), revealed by seric antibodies from 16 patients with: neuromyelitis optica, NMO (n = 1); Devic's syndrome, DS (n = 3); optic neuritis, ON (n = 5); o transverse myelitis, TM (n = 7) were determined. Some of these patients also had diabetes mellitus type 2 (DM2), systemic lupus erythematosus (SLE) or myasthenia gravis (MG).
Results. Three types of IFP were detected: 1) A NMO classic IFP, characterized by staining of blood vases in cerebellum and kidney; 2) An nonspecific IFP, characterized by staining of the nuclei from cerebellum and kidney; and 3) A mixed IFP, in which IFP 1) and 2) coexisted. It is worth to mention that the IFP 2) was found in patients with a neuroinflammatory condition associated to DM2, SLE or MG; and the IFP 3) was seen in a patient with ON and prostate cancer.
Conclusions. Nonspecific IFP in mouse tissues revealed by patients with neuroinflammatory diseases is associated with the presence of an autoimmune disease and the coexistence of NMO-IgG and nonspecific IFP might be a marker of an additional severe disease.

P5.09.03
Importance of the vagus nerve in immunodepression following stroke

L. Akyüz[1,2]*, C. Dames*[1]*, O. Engel*[3]*, K. Winek*[3]*, H. D. Volk*[1,2]*, C. Meisel*[1]*, A. Meisel*[3]*;*
[1]Charité, Institute of Medical Immunology, Berlin, Germany, [2]Charité, Berlin-Brandenburg Center for Regenerative Therapies (BCRT), Berlin, Germany, [3]Charité, Department of Experimental Neurology, Berlin, Germany.

Impaired immunefunction due to overactivation of neuro-humoral stress pathways, in particular of the sympathetic nervous system, has been proposed as risk factor for thehigh incidence of pneumonia after stroke. However, changes in pulmonary immunity and the role of the parasympathetic vagus nerve in stroke-induced suppression of immune responses are poorly understood so far.
We hypothesize that after stroke pulmonary macrophage and epithelial function is impaired due to release of acetylcholine resulting in reduced lung anti-bacterial responses. This anti-inflammatory effect mediated by the vagus nerve is dependent on nicotinergic α7 acytylcholine receptor (α7nAChR).
Inhibition of vagus nerve activity by vagotomy ameliorated development of spontaneous bacterial infections after stroke in wt mice and significantly increased release of pro-inflammatory cytokines upon *ex vivo* stimulation of lung immune cells with TLR-ligands. To determine the role of the α7nAChR onpulmonary immune vs. parenchymal lung cells we used bone marrow chimeras reconstituted with $\alpha7nAChR^{-/-}$ and WT cells. Interestingly, our mixed bone marrow chimera experiments indicate that α7nAChR expression on alveolar epithelial cells is important for impaired pulmonary anti-bacterial responses mediated by increased vagus nerve activity after stroke.
We could show that the vagus nerve and the α7AchR play a crucial role in suppression of lung immunity after stroke. Inhibition of parasympathetic activity by vagotomy or α7AchR deficiency reduces susceptibility to bacterial lung infection after acute CNS damage. Expression of α7AchR on both lung macrophages and alveolar epithelial cells seem to be important to the immunosuppressive effect of increased vagus nerve activity after stroke.

P5.09.04
Expression of cytokines during the innate immune response in a model of hepatic amoebiasis in sympatectomized hamsters

***M. E. Avila-Blanco**, M. Campos-Esparza, M. H. Muñoz-Ortega, A. Quintanar-Stephano, J. Ventura-Juarez;*
Universidad Autonoma de Aguascalientes, Aguascalientes, Mexico.

The sympathetic nervous system (SNS) release noradrenaline that activate the α1 adrenergic receptors expressed on cells of the innate immune response, thus release pro-inflammatory cytokines during an inflammatory process. On the other hand, During the formation of amebic liver abscess (ALA) an inflammatory process occurs. We analyze the role of SNS in modulating the inflammatory process in a ALA model. 3 groups were used: intact, Sham and sympatectomized with 6-OHDA for 15 days hamsters, then were inoculated 300,000 trophozoites via intrahepatic and sacrificed at different times (6, 12, 24h, 2, 4 and 7d) post-inoculation. In the samples of liver ALA were identified tyrosine hydroxylase positive cells, 220+ kDa amebic lectin, IL-1β+, IL-6+, IL-8+, INF-γ+ and IL-10+ cells by immunohistochemistry. The sympatectomized ALA showed no thyroxine hydroxylase + cells in the hepatic portal triad, demonstrating an effective sympathectomy. Were quantified lectin 220 Kda + trophozoites and we found that at 24h was a decrease of trophozoites (3 per field) with respect to control, concurrently with increased IL8+ cells and decline IL1+ and IL10+ cells. On the other hand, during late times of ALA was observed a significant increase of 220 kDa lectin+ trophozoites (5.1 per field) and decreased IL-1β+, IL-6+, IL-8+ cells, and IL-10+ cells increased. These results suggest that increased IL10 and decreased pro-inflammatory cytokines are crucial to the viability of the parasite. The sympatectomy in acute inflammation of ALA induces a variable behavior of anti and pro-inflammatory cytokines, however, it is maintaining an anti-inflammatory profile during chronic inflammation.

P5.09.05
Detection of ANCA (Anti Neutrophil Cytoplasmic Antibodies) by indirect immunofluorescence / ELISA and related neurological diseases: preliminary results on a Moroccan series

***S. Aziz**[1], N. Tahiri Jouti[1], R. Ibn Moufti[2], H. Fellah[3], A. Naya[4], I. Slassi[5], S. Zamiati[1];*
[1]Department of Pathology,Faculty of Medicine and Pharmacy, Casablanca, Morocco, [2]Department of Neurology, CHU Ibn Rochd, Casablanca, Morocco, [3]Laboratory of Immunology, Faculty of Medicine and Pharmacy, Casablanca, Morocco, [4]Laboratory of Molecular Physiology and Genetics, Faculty of Sciences Aïn Chock, Casablanca, Morocco, [5]Department of Neurology, CHU Ibn Rochd., Casablanca, Morocco.

Introduction: ANCA are associated with different pathologies among other vasculitis. Their diagnostic value, prognostic, specificity and their place as a marker of activity deserve to be clarified. Objective: To identify and develop the methodology for the detection of these auto-antibodies through the use of two reference techniques: indirect immunofluorescence (IIF) and ELISA as well as establish possible correlations with neurological diseases. Materials and methods: We tested sera from 47 patients of Neurology Department, Ibn Rochd University Hospital of Casablanca, for whom ANCA were sought in the etiological. The presence of ANCA was investigated by IIF on slides of neutrophils cytocentrifuged and fixed in ethanol and ELISA (anti-proteinase 3 (PR3) and anti-myeloperoxidase (MPO) kits). The fluorescence is split in two aspects: cytoplasmic (c-ANCA) or perinuclear (p-ANCA). The main target of c-ANCA type autoantibodies is PR3, while that of p-ANCA type is MPO. Results: The presence of ANCA by IIF was established in 48.93% cases in two profiles: cytoplasmic fluorescence (c-ANCA) (73.91%) and perinuclear fluorescence (p-ANCA) (26.08%). These autoantibodies with or without PR3 and / or MPO antigenic targets correspond to various neurological diseases: with infectious etiology, associated with vasculitis but also connective tissue disorders (Gougerot Sjogren syndrome) and amyotrophic lateral sclerosis. Conclusion: In case of strong suspicion of vasculitis, it should look for ANCA by IIF and ELISA. In addition to PR3 and MPO, identify other antigenic targets of ANCA. The association of ANCA with amyotrophic lateral sclerosis has never been reported and should be investigated.

P5.09.06
Expression of the galanin system in immune cells: hypothetical key players of the immune response

***R. Bianchini**, A. Koller, A. Lang, B. Brodowicz, E. Müller, B. Kofler; Laura Bassi Centre of Expertise THERAPEP; Research Program for Receptor Biochemistry and Tumor Metabolism, Department of Pediatrics, Paracelsus Medical University, Salzburg, Austria.*

Neuropeptides participate in innate immunity and tolerance. Galanin is a neuropeptide with a widespread distribution in the central and peripheral nervous systems. Several in vivo studies indicate that galanin plays a role in inflammation. The aim of the present study was to identify immune cells expressing components of the galanin system including, not only the peptide but also its three receptors (GalR1-3).
Quantitative RT-PCR analysis was performed on mRNA isolated from different types of human primary immune cells as well as human immune cell lines. We observed the expression of galanin in keratinocytes, endothelial colony-forming cells (ECFC), NK cells, skin mast cells, monocyte and macrophages. Accordingly, galanin expression was detected in the human mast cell line LDA2 and human monocyte cell line THP1.
The analysis of GalR1, GalR2 and GalR3 revealed variable expression, which did not correlate with each other. GalR1 was only expressed by skin mast cells and THP1. GalR2 was detected in keratinocytes, polymorphonuclear cells (PMNs), monocytes, macrophages, skin mast cells, ECFC, LDA2 and THP1. GalR3mRNA expression was observed in ECFC, monocytes, LDA2 and THP1. Moreover, flow cytometric analyses (FACS) revealed expression of GalR3 on T cells, monocytes, B cells and a minority of PMNs.
Our results show the presence of galanin and GalRs in several types of immune cells. Experiments on different types of immune cells are under way to elucidate the functional role of galanin on immune cells expressing GalRs.

Blocking Glutamate Carboxypeptidase II Inhibited Glutamate Excitotoxicity and Regulated Immune Responses in Experimental Autoimmune Encephalomyelitis

***S. Bing**[1], D. Ha[1], G. Ahn[2], J. Kim[1], J. Cho[1], S. Ahn Jo[3], Y. Jee*[1];*
[1]College of Veterinary Medicine, Jeju National University, Jeju, Republic of Korea, [2]Laboratory of Veterinary Molecular Pathology and Therapeutics, Tokyo University of Agriculture and Technology, Fuchu, Japan, [3]College of Pharmacy, Dankook University, Cheonan, Republic of Korea.

Experimental autoimmune encephalomyelitis (EAE) is a demyelinating autoimmune disease murine model which presents clinical similarity to human multiple sclerosis (MS). Although glutamate-induced excitotoxicity has been implicated in the disease progression of MS patient, glutamate carboxipeptidase II (GCPII), an enzyme that produces glutamate and affects the pathogenesis of various neurological disorders, has not received proper attention in MS/EAE.
In this study, we show that GCPII is a potent therapeutic target for MS/EAE. First, the expression of GCPII was significantly elevated on astrocytes of EAE mice proportional to the severity of EAE clinical sign. Furthermore, treatment with a specific GCPII inhibitor, 2-Phosphonomethylpentanedioicacid (2-PMPA), resulted in significantly ameliorated paralysis with ensuing attenuation of EAE-associated neuropathic features. Upon antigen restimulation, lack of GCPII led to marked reduction in myelin-reactive T cell responses and T effector cell polarization in periphery. Moreover, GCPII inhibition favorably altered the expression of inducible metabotropic glutamate receptor 1 (mGluR1) on CD4+ T cells. These data suggest previously unreported interaction between astrocytic GCPII expression and critical EAE-associated features including neuroinflammation and highlight mGluR1 as one of key modulator of glutamate-induced T cell responses during EAE. This work was supported by the National Research Foundation of Korea (NRF) grant funded by the Korea government (MEST) (2012011645)

P5.09.08

A new concept to address inflammatory immune activation in neurological disorders

P. Bolaños[1], *M. Schneider*[2], *K. Bechter*[3], *P. Walther*[4], *H. Raventós*[1,5]; [1]*Cellular and Molecular Biology Research Center, University of Costa Rica, San José, Costa Rica,* [2]*Section Experimental Anaesthesiology, University Hospital Ulm, Ulm, Germany,* [3]*Clinic for Psychiatry and Psychotherapy II, University Hospital Ulm, Ulm, Germany,* [4]*, Section Electron Microscopy, University of Ulm, Ulm, Germany,* [5]*School of Biology, University of Costa Rica, San José, Costa Rica.*

The involvement of immune pathological pathways in the manifestation of complex neuroinflammatory diseases is difficult to address in humans. Schizophrenia is associated with systemic inflammation, trauma, and a higher prevalence of antibody formation. An altered immune response in the central nervous system also plays a role in multiple sclerosis, with evidence for virus infections, and viral reactivation during relapse. Recent evidence from our group supports the concept of altered immune activation in major Depression as well as other psychiatric diseases. These results are based on a newly developed investigative concept: Primary analyses are measurements of inflammatory cytokines, followed by electron microscopy of dendritic cells with phagocytic properties (phDC) in the cerebrospinal fluid (CSF). The third component addresses the contents of miRNA species in fluid as well as membrane particle fractions of the CSF as compared to plasma isolated by ultracentrifugation. We repeatedly found phDC in the CSF of patients with major depression and a high content of microparticles, ectosomes and exosomes. These particles were successfully used to prepare miRNA isolates. Structural analyses suggest that the phDCs with extensive membrane protrusions gave rise to microparticles. Variations in the miRNA species identified, could explain altered gene expression patterns of meningeal cells in the brain. The protocol developed, is feasible to study larger patient populations and compare the miRNA patterns in microparticles, ectosomes and exosomes of CSF as compared to plasma. Results based on this concept may contribute to our understanding the complex etiology underlying these diseases.

P5.09.09

Astrocytes play a key role in EAE pathophysiology by facilitating CNS immune cell infiltration and suppressing remyelination

R. Brambilla[1], *J. Jopek Ashbaugh*[1], *P. Morton*[1], *S. Karmally*[1], *K. L. Lambertsen*[2], *J. R. Bethea*[1]; [1]*University of Miami, Miami, FL, United States,* [2]*University of Southern Denmark, Odense, Denmark.*

Astrocytes respond to insult with a process of cellular activation known as reactive astrogliosis. One of the key signals regulating this phenomenon is the transcription factor NF-kB, which is responsible for modulating inflammation, cell survival and cell death. In astrocytes, following trauma or disease, the expression of NF-kB-dependent genes is highly activated. We previously demonstrated that inactivation of astroglial NF-kB in vivo (GFAP-IkBalpha-dn mice) leads to improved functional outcome in EAE, and this is accompanied by reduction of pro-inflammatory gene expression in the CNS. Here we show that recovery from EAE in GFAP-IkBalpha-dn mice is associated with reduction of peripheral immune cell infiltration into the CNS at chronic EAE. This is not due to an effect on blood-brain barrier permeability, rather to reduced immune cell mobilization from the spleen. Furthermore, the ability of infiltrating T cells to produce pro-inflammatory cytokines is significantly diminished. In parallel, we also show that the number of total and activated microglial cells is reduced, suggesting that functional improvement in GFAP-IkBalpha-dn mice is dependent upon inhibition of the inflammatory response within the CNS sustained by both resident and infiltrating cells. This results in preservation of myelin compaction as well as enhanced remyelination, as shown by electron microscopy analysis of the spinal cord. Collectively our data indicate that astrocytes are key players in driving CNS inflammation and are directly implicated in the pathophysiology of EAE, since blocking their pro-inflammatory capability results in protection from the disease.

P5.09.10

A single dose of Pirfenidone attenuates neuronal cell death after excitotoxic kainic acid-induced in rat hippocampus through inhibition of microglial activation, but not TNF-α and IL-1β production

R. D. Castro Torres[1], *V. Chaparro Huerta*[1], *M. E. Flores Soto*[1], *J. Armendáriz Borunda*[2,3], *C. Beas Zárate*[1,4]; [1]*Laboratory of molecular and cellular neurobiology. Biomedical Research Center of Western. Guadalajara, Jalisco, México, Guadalajara, Mexico,* [2]*Institute for Molecular Biology in Medicine and Gene Therapy. CUCS. University of Guadalajara. Guadalajara Jalisco, México., Guadalajara, Mexico,* [3]*OPD Hospital civil " Dr. Juan I. Menchaca", Guadalajara, Mexico,* [4]*Department of Molecular and Cell Biology. CUCBA. University of Guadalajara., Guadalajara, Mexico.*

Excitotoxicity plays an important role in a variety of neurological diseases such as stroke or Alzheimer's disease. It has been known that pivotal pathways of these neuronal disorders are strongly linked to neuroinflammation. In this sense excitotoxicity KA-induced is a robust model that provides an important tool for pharmacology strategies. The pharmacological inhibition of inflammation in animal model seems to be neuroprotective. In this context, the aim of the current study was to demonstrate whether Pirfenidone (PFD, 5-methyl-1-phenyl-2-(1H)-pyridone) which has a well-known anti-inflammatory properties, protect to the hippocampal neurons from excitotoxic neuronal damage KA-induced in a juvenile 5- to 6-week old rats. We determined the neuroprotective effect of 325 mg/Kg p.g. PFD 90 min after 12 mg/Kg of KA i.p. injection in the rats. Neuronal loss and degenerated cell in CA3c hippocampal areas under Hematoxylin-Eosin and with Fluoro-Jade B stain respectively was reduced at 72 h after treatment($p<0.05$). We demonstrated that the neuroprotective effect was attributed to the inhibition of microglial activation quantifying two markers by tissue immunochemistry of MHCII and Isolectine-B_4 ($p<0.05$). There is no inhibition of mRNA TNF-α and IL-1β measured by real-time PCR in hippocampal brain homogenates 6h after treatment. Further investigations needs to perform in order to elucidate the mechanics of the neuronal damage amelioration, but we infer that neuroprotection observed in our study could be attributed a partial anti-inflammatory effects of PFD. The results support that the uses of PFD in excitotoxic and neuroinflammatory diseases could be explored.

P5.09.11

Increased expression of Toll-like receptors 7 and 9 in Epstein-Barr virus-infected myasthenia gravis thymus

P. Cavalcante[1], *S. Marcuzzo*[1], *S. Franzi*[1], *L. Maggi*[1], *C. Antozzi*[1], *F. Baggi*[1], *S. Berrih-Aknin*[2], *R. Mantegazza*[1], *P. Bernasconi*[1]; [1]*Neurological Institute Foundation "Carlo Besta", Milan, Italy,* [2]*Institute of Myology, UPMC UM76, INSERM U974, Paris, France.*

Considerable data support thymic involvement in myasthenia gravis (MG), an autoimmune disease affecting neuromuscular junction. We recently demonstrated an active Epstein-Barr virus (EBV) infection in the thymus of MG patients, suggesting that EBV might promote onset or maintenance of the autoimmune response within MG thymus, because of its ability to immortalize B-cells. EBV can elicit and modulate Toll-like receptor (TLR) 7 and 9 signalling, known to impair B-cell function and favour autoimmunity.

The aim of this study was to analyse TLR7 and 9 expression in MG thymuses. By real-time PCR, we found that TLR7 and 9 transcripts were significantly up-regulated in EBV-positive MG compared with EBV-negative control thymuses. By confocal microscopy, TLR7 and 9 were detected in B- and plasma cells of MG thymic germinal centers (GCs) and lymphoid infiltrates, where they co-localized with EBV antigens. Proliferating EBV-positive B-cells expressing TLR7 and 9 were detected in MG thymuses, suggesting that TLR7/9 stimulation contributes, along with EBV, to abnormal B-cell activation and proliferation in MG thymus. Both MG GCs and GCs-free thymic sections expressed TLR7 and 9 at higher levels than control thymuses, indicating that, along with GC-cells, other MG thymic populations over-expressed TLR7 and 9. Double immunofluorescence revealed enhanced TLR7 and 9 expression in MG thymic epithelium and plasmacytoid dendritic cells, suggesting TLR7/9 involvement in the inflammatory/interferon signature characterizing MG patients' thymus.

These findings suggest that EBV-driven innate immune responses may contribute to immunological alterations promoting or maintaining autoimmunity in MG thymus.

P5.09.12
Contact Hypersensitivity To Oxazolone Provokes Vulvar Mechanical Hyperalgesia In Mice

***D. Chatterjea**, T. Martinov, R. Glenn-Finer, E. Balsells;*
Macalester College, Saint Paul, MN, United States.

Vulvodynia can affect ~20% of women of child-bearing age. Activities such as contact with tight clothing or sexual intercourse provoke burning pain sensations whose etiology and underlying mechanisms are poorly understood. Epidemiological evidence suggests a link between a history of environmental allergies and the risk of developing vulvodynia. Clinicians find increased mast cell numbers, hyperinnervation and up-regulation of inflammatory cytokines in biopsies from vulvodynia patients vs. controls. An allergy-based mast cell focused mouse model of vulvodynia is needed to elucidate the mechanisms underlying this pathology. We show that challenge with contact hypersensitivity allergen oxazolone produces acute mechanical hyperalgesia in the vulvar region of previously sensitized female mice. Acute pain is localized to the challenge site, lasts up to 24 hours post-challenge and is accompanied by influx of neutrophils into the labiar tissue and up-regulation of several inflammatory cytokine genes including IL-6, Cxcl-1 and Cxcl-2. Pre-challenge administration of H1R-antagonist pyrilamine, tricyclic antidepressant amitryptiline, and sodium cromoglycate all abrogate the hyperalgesic response. Our findings provide the first evidence of the induction of measurable pain following an allergic response in the labiar/vulvar tissue in mice thus establishing a model that can be adapted to chronic challenges and long-term assessment of pain with and without ongoing inflammation.

P5.09.13
Expression of dopamine receptor D3 on CD4$^+$ T-cells favors Th1-mediated immunity

***F. Contreras**[1,2], C. Prado[1,2], H. González[1,2], D. Franz[1], D. Elgueta[1], R. Pacheco[1];*
[1]Fundación Ciencia & Vida, Santiago, Chile, [2]Universidad Andrés Bello, Santiago, Chile.

Inappropriate CD4$^+$ T-cell differentiation may lead to infection susceptibility, tumor development or autoimmunity, thereby this process requires strict regulation. Since T-cells express dopamine receptors (DRs), dopamine may modulate T-cell function. Among five known DRs, D3R displays the highest affinity for dopamine and its stimulation enhances IFN-γ production on human CD4$^+$ T-cells *in vitro*. Thus, the aim of this work was to analyze the role of D3R on effector CD4$^+$ T-cell differentiation and function. Our results show that Th1, but not Th17, -polarizing CD4$^+$ T-cells transiently express D3R transcript and that stimulation of D3R potentiates IFN-γ production by CD4$^+$ T-cells under Th1 conditions. Moreover, whereas D3R-deficient CD4$^+$ T-cells show normal differentiation towards Th17, they display impaired Th1 polarization, which is evidenced by reduced *Tbx21* and *Ifng* transcript expression and limited IFN-γ production. D3R was also shown to be important for Th1 polarization *in vivo*, since D3R-deficient CD4$^+$ T-cells showed attenuated IFN-γ production in response to Th1-immunogen. Importantly, D3R also contributes to CD4$^+$ T-cell activation, as pharmacologic stimulation of D3R potentiates IL-2 secretion and D3R-deficiency on CD4$^+$ T-cells results in reduced IL-2 production and proliferation both *in vitro* and *in vivo.* Furthermore, D3R-deficient CD4$^+$ T-cells were unable to induce weight loss in a colitis model. In line with this, a reduced frequency of IFN-γ-producing CD4$^+$ T-cells was found in colonic lamina propria of mice receiving D3R-deficient CD4$^+$ T-cells. These findings support a relevant regulatory mechanism of CD4$^+$ T-cell function in which D3R expression contributes efficiently to CD4$^+$ T-cell activation and Th1 differentiation.

P5.09.14
Prolactin is dispensable for the development of experimental autoimmune encephalomyelitis

***M. Costanza**[1], S. Musio[1], N. Binart[2], M. Abou-Hamdan[1], R. Pedotti[1];*
[1]Neuroimmunology and Neuromuscular Disorder Unit, Neurological Institute Foundation IRCCS C. Besta, Milano, Italy, [2]INSERM U693, Univ Paris-Sud, Faculté de Médecine Paris-Sud, Le Kremlin-Bicêtre, France.

In recent years several pieces of evidence have suggested that hormones might influence the development of both multiple sclerosis (MS) and the animal model for this disease, experimental autoimmune encephalomyelitis (EAE). In the present work we investigated the role of the hormone prolactin (PRL) in EAE by studying disease expression in PRL receptor (PRLR)- or PRL-deficient mice. *Prlr*$^{-/-}$ and *Prl*$^{-/-}$ mice developed EAE with a slightly delayed onset but with full clinical severity compared to controls. In line with clinical outcome, lymph node cells (LNCs) from *Prlr*$^{-/-}$ mice exhibited reduced proliferation to myelin peptide and decreased production of pro-inflammatory cytokines IFN-, IL-17A and IL-6 during disease priming (7 days p.i.), but not later (day 10 p.i.). Serum titers of anti-MOG$_{35-55}$ IgG antibodies were not affected by PRLR deficiency. Similar findings were obtained in *Prl*$^{-/-}$ mice. LNCs and CD4$^+$ T cells isolated from naïve C57BL/6 mice expressed *Prlr* transcript. Levels of *Prlr* were reduced in LNCs and CD4$^+$ T cells obtained from mice 7 days p.i., as well as in CD4$^+$ T cells stimulated *in vitro* with anti-CD3/CD28 Abs, suggesting that this receptor is down-regulated in stimulated T cells. We did not detect PRL either at transcript level in CD4$^+$ T cells or at protein level in stimulated CD4$^+$ T cell supernatants. These data suggest that PRL plays a redundant role in the development of EAE and of an optimal Th1/Th17 autoreactive T cell response against myelin.

P5.09.15
The immunogenicity of amyloid beta oligomers

***I. Dalgediene**[1], R. Lasickiene[1], R. Budvytyte[2], G. Valincius[2], R. Morkuniene[3], V. Borutaite[3], A. Zvirbliene[1];*
[1]Vilnius University Institute of Biotechnology, Vilnius, Lithuania,
[2]Vilnius University Institute of Biochemistry, Vilnius, Lithuania,
[3]Lithuanian University of Health Sciences Institute of Neurosciences, Kaunas, Lithuania.

Background: The central molecule in the pathogenesis of Alzheimer's disease (AD) is believed to be a small-sized polypeptide – beta amyloid (Aβ) which has an ability to assemble spontaneously into oligomers. Various studies concerning therapeutic and prophylactic approaches for AD are based on the immunotherapy using antibodies against Aβ. However, knowledge on the mechanisms of Aβ-induced immune response is rather limited. Previous research on Aβ1-42 oligomers in rat brain cultures showed that the neurotoxicity of these oligomers considerably depends on their size. In the current study, we evaluated the dependence of immunogenicity of Aβ1-42 oligomers on the size of oligomeric particles and identified the immunodominant epitopes of the oligomers. **Results:** Mice were immunized with various Aβ1-42 oligomers. The analysis of serum antibodies revealed that 1-2 nm Aβ1-42 oligomers are highly immunogenic. They induced predominantly IgG2b and IgG2a responses. In contrast, larger Aβ1-42 oligomers and monomers induced a weak IgG response in immunized mice. Monoclonal antibody against 1-2 nm Aβ1-42 oligomers was generated and used for the antigenic characterization of Aβ1-42 oligomers. Epitope mapping of both monoclonal and polyclonal antibodies demonstrated that the main immunodominant region of the 1-2 nm Aβ1-42 oligomers is located at its amino-terminus, between amino acids 1 and 19. **Conclusions:** Small Aβ1-42 oligomers of size 1-2 nm induce the strongest immune response in mice. The amino-terminus of Aβ1-42 oligomers represents an immunodominant epitope which indicates its surface localization. The results of the current study may be important for further development of Aβ-based vaccination and immunotherapy strategies.

Enhanced susceptibility to pulmonary infections after experimental stroke

C. Dames[1], *L. Akyüz*[1,2], *O. Engel*[3], *K. Winek*[3], *H. Volk*[1,2], *A. Meisel*[3], *C. Meisel*[1];
[1]*Charité, Institute for Medical Immunology, Berlin, Germany,* [2]*Charité, Berlin-Brandenburg Center for Regenerative Therapies, Berlin, Germany,* [3]*Charité, Department of Experimental Neurology, Berlin, Germany.*

Bacterial infection is a relevant complication in patients with acute CNS injury and associated with worse neurological recovery and high mortality. Clinical and experimental evidence indicate that immunodepression is an important factor for the high incidence of pneumonia. Previous studies analysed stroke-induced suppression of immune responses in blood and lymphatic organs. Here, we analyse changes in cellularity and function of lung immune and epithelial cells by FACS and *ex-vivo* stimulation with different TLR-ligands and T-cell mitogens at different time points after cerebral ischemia induced by temporary occlusion of the middle cerebral artery in mice. In addition, we monitored pulmonary host responses *in-vivo* during the course of pneumococcal pneumonia by analyzing cellular changes and cytokine/chemokine levels in lungs of stroke mice and sham controls. Quantitative FACS analysis of cellularity at different time points after stroke shows decreased numbers of lymphocytes, dendritic cells and macrophages in lung. Functional analysis of immune cells indicates an impaired cytokine production in lung cells after *ex-vivo* TLR stimulation. In a model of induced pneumonia we analysed the *in-vivo* host response to *Streptococcus pneumoniae*. Preliminary data paradoxically suggest hyper-inflammatory responses in the early phase with an increase in lung cytokine levels in stroke mice.The correlation between lymphopenia and development of infectious complications is still incompletely understood. It seems that the mechanisms of immunodepression in lung are similar to those in the periphery. Defects in bacterial defences after stroke needs to be further investigated and may lead to new therapeutic strategies to prevent infections and improve outcome.

Alzheimer's Disease (AD) is a neurodegenerative disorder characterized by progressive loss of memory and cognitive functions. Accumulation of Aβ peptide is considered the initiating cause of pathogenic lesions, and immunotherapy strategies targeting Aβ represent promising therapeutic approaches. Vaccination against Aβ provided encouraging results in experimental mouse models and in a clinical trial (AN1792). Although the latter had to be interrupted due to meningoencephalitis attributed to pro-inflammatory T cell responses. Several reports suggest that Aβ-specific $CD4^+$ T cells may be implicated in the course of AD and could have a strong therapeutic potential, pointing out the need for better understanding the role and regulation of T cell responses to Aβ. We previously showed that regulatory T cells control the magnitude of Aβ-specific $CD4^+$ T cell responses in physiological and pathological settings in response to Aβ vaccination. To define the role of Tregs in disease progression, we analyzed the impact of Treg depletion in a mouse model of AD. Depletion of Treg cells accelerated the onset of cognitive deficits in APPPS1 mice. Alteration in spatial memory was detectable in PC61-treated animals, while PBS-treated APPPS1 mice were not yet cognitively impaired as compared to wt. Early cognitive impairment in Treg-depleted APPPS1 mice was associated with alterations in neuropathological features of the disease.
Our data indicate that Treg cells play a beneficial role in the pathophysiology of AD and delay disease progression in APPPS1 mice. These results open new perspectives in the development of tolerogenic Treg-based vaccine immunotherapy strategies for the treatment of AD.

P5.09.18
Possible role of nerve-glial antigen 2(NG2) in the development of experimental autoimmune encephalomyelitis

G. Ferrara[1,2], *S. Morando*[1], *F. Girolamo*[3], *M. Errede*[3], *N. Kerlero de Rosbo*[1], *R. Perris*[4], *R. Furlan*[5], *C. Bendotti*[2], *D. Virgintino*[3], *A. Uccelli*[1];
[1]*Department of Neuroscience, Ophthalmology and Genetics University of Genoa, Genoa, Italy,* [2]*Department of Neurosciences, Mario Negri Institute, Milan, Italy,* [3]*Department of Human Anatomy and Histology, University Medical School, Bari, Italy,* [4]*Centre for Molecular and Translational Oncology, University of Parma, Parma, Italy,* [5]*Neuroimmunology Unit, San Raffaele Hospital, Milan, Italy.*

Nerve/glial antigen 2 (NG2) is expressed by oligodendrocyte progenitor cells (OPCs), essential for remyelination, and pericytes, crucial for blood-brain-barrier (BBB) integrity. We used NG2KO mice to investigate if NG2 is involved in development of experimental autoimmune encephalomyelitis (EAE), animal model for multiple sclerosis associated with remyelination failure and BBB leakage. EAE was less severe in NG2KO mice, with little demyelination and a lower number of macrophages/microglia in CNS, but no difference in infiltrated T-cell numbers. While NG2KO and wild-type (WT) mice not induced for EAE had the same number of OPCs, the sharp decrease in EAE-affected WT mice at late-disease did not occur in EAE-affected NG2KO mice. As the difference in infiltrates between NG2KO and WT mice could be related to differences in BBB integrity, we studied the expression of BBB-relevant proteins, claudin-5 and occludin. In WT mice, the expression pattern of these proteins was altered in EAE as expected, changing from a linear cellular contour to a punctuated one. In NG2KO mice, an opposite pattern was observed, with a punctuated expression in non-EAE mice reverting to a linear one in disease. In WT mice, NG2 was expressed on macrophages, dendritic, and T cells; the lack of NG2 on NG2KO T cells was associated mostly with an increase in IL-4, but also IFNγ, and IL-17a, and with lower proliferation. These results suggest that NG2-bearing cells likely play a relevant role in CNS homeostasis. In addition, NG2 expression on immune cells could impact on effector functions possibly related to CNS autoimmunity.

P5.09.19
Dopamine regulates the induction of Cytotoxic T-Lymphocyte by stimulation of dopamine receptor D3 expressed on CD8+ T-cells and on dendritic cells

C. A. Figueroa[1,2], *F. Contreras*[3], *G. Fuentealba*[3], *C. Prado*[3], *R. Pacheco*[3,4];
[1]*Universidad San Sebastian, santiago, Chile,* [2]*Fundacion Ciencia y Vida, Santiago, Chile,* [3]*Fundacion Ciencia y Vida, santiago, Chile,* [4]*Universidad San Sebastian, Santiago, Chile.*

Dopamine receptor D3 (D3R) is expressed in many cellular components of the immune system, including dendritic cells (DCs) and CD8+ T-cells. Here, we aimed to understand how D3R may regulate the effector function of CD8+ cytotoxic T-lymphocytes (CTLs). Since the relationship between DCs and CD8+ T lymphocyte is pivotal for the efficient induction of cytotoxic response, we study the contribution of D3R expressed on DCs and on CD8+ T-cells in the regulation of CTL response. Results show that loss of D3R in CD8+ T-cells impairs both secretion of cytotoxic vesicles and IFN-γ secretion in vitro. Similarly, lack of D3R in OT-I cells impaired their cytotoxic capability and IFN-γ production in vivo in response to target cells loaded with ovalbumin(OVA)-derived peptide (pOVA), In contrast, when DCs were loaded with OVA and then transferred into wild-type recipients and CTL function was evaluated, D3R-deficiency on DCs resulted in an increased IFN-γ production by CTLs. In agreement with this, both genetic and pharmacologic approaches showed that D3R expressed on DCs attenuates CD8+ T-cell activation without affecting CD4+ T-cell activation and differentiation in vitro. Furthermore, in vitro experiments showed an increased surface expression of class-I MHC loaded with pOVA on DCs when treated with D3R-specific antagonist, an effect lost in D3R-defficient DCs. Thus our findings indicate that D3R expressed in DCs and

CD8+ T-cells may modulate the CTL response in opposite ways. Thereby, depending on the cellular target, the D3R could be considered as a molecular target for the treatment of cancer.

P5.09.20
ATP-mediated interaction between astrocytes and T cells

F. Filipello[1,2];
[1]*University of Milan, Milan, Italy,* [2]*Istituto Clinico Humanitas, Rozzano, Milan, Italy.*

Astrocytes represent a major part of glial cells in CNS and constitute important structural component of the blood brain barrier (BBB). We investigated the biological response evoked in astrocytes and T cells upon their reciprocal interaction, clarifying the role of ATP in the intercellular signaling between these two cell types. T cell costimulation through purinergic P2X receptors, including P2X4 and P2X7 subtype, upon TCR triggering, sustains MAPK pathway activation, whereas blockade of purinergic costimulation results in T cell anergy. Conversely, P2X7 stimulation in the absence of TCR activation determines T cell apoptosis. Thus, extracellular ATP and purinergic signaling play a crucial role in conditioning T cell fate. Real time PCR data revealed that astrocytes inhibit CD4 cells transcriptional program toward effector phenotypes. These results suggest a general anergyzing effect of astrocytes on T cells. We determined extracellular ATP levels by the luciferin/luciferase assay in the supernatants of astrocytes-T cells co-cultures: our data revealed a reduced concentration of extracellular ATP in the presence of T cells, suggesting that T cells may partially inhibit ATP release and/or hydrolyze ATP released from astrocytes. Consistent with the latter possibility, FACS analysis indicated increased expression of the ectonucleotidases CD39 and CD73 in T cells co-cultured with astrocytes. In addition, CD39 knock out T cells did not significantly affect extracellular ATP levels, confirming that ectonucleotidase activity in T cells mediate extracellular ATP hydrolysis. These data suggest that lack of purinergic costimulation in activated T cells upon contact with astrocytes promotes T cell anergy

P5.09.21
Experimental studies of narcolepsy immunopathogenesis in HLA-DQB1*0602 transgenic mice

T. L. Freitag[1], *K. Zitting*[2], *A. Kipar*[3], *I. Julkunen*[4], *T. Hökfelt*[5], *T. Stenberg*[2], *S. Meri*[1];
[1]*Haartman Institute, University of Helsinki, Finland,* [2]*Institute of Biomedicine, University of Helsinki, Finland,* [3]*Finnish Centre for Laboratory Animal Pathology, University of Helsinki, Finland,* [4]*National Institute for Health and Welfare, Helsinki, Finland,* [5]*Karolinska Institutet, Stockholm, Sweden.*

Background: A strong association of narcolepsy/cataplexy (N/C) with the HLA class II allele DQB1*0602 (>90%) suggests that this chronic brain disorder is immune-mediated. The use of AS03-adjuvanted influenza A (H1N1) pandemic vaccine (Pandemrix®) in 2009/2010 was associated with an increased risk of N/C in children and adolescents in several European countries.
Objectives: To understand the mechanisms of N/C immunopathogenesis, and to develop a mouse model of immune-mediated N/C.
Methods: Groups of HLA-DQB1*0602, huCD4 transgenic Ab0 NOD ("HLA-DQ6 mice") or HLA-DQ8 control mice were challenged with Pandemrix® (or PBS control) i.m., mouse hypothalamus homogenate in AS03 i.m., or hypocretin (1+2)-KLH in CFA i.d. One group of HLA-DQ6 mice was injected into the left lateral cerebral ventricle (i.c.v.) with Pandemrix®. Mouse N/C was screened for by videomonitoring of behavior. Mice were sacrificed after 5-12 weeks.
Results: The groups of HLA-DQ6 or HLA-DQ8 mice challenged with Pandemrix® i.m. did not show any changes in body weight, behavior, histology or anti-viral serum antibody titers. No unique serum reactivity was observed with rat brain (immunofluorescence). No differences were noted in hypothalamus sections stained for hypocretin (immunohistochemistry), or in hypocretin precursor mRNA levels (RT-PCR). Mice challenged with hypocretin 1+2, but no other mice, developed serum anti-hypocretin peptide IgG antibodies. Further studies are ongoing.
Conclusions: HLA-DQ6 mice did not develop N/C in response to Pandemrix® i.m. challenge. Serum responses did not differ between HLA-DQ6 mice and HLA-DQ8 controls. In addition, no evidence for crossreactivity between vaccine components and brain antigens could be found to date.

P5.09.22
Schizophrenia is associated with over-expression of the interleukin-2 receptor gamma gene

H. Ghazaryan[1,2], *A. Boyajyan*[1], *R. Zakharyan*[1], *A. Melkonyan*[1], *Z. Navratilaova*[2], *P. Klevcova*[2], *M. Petrek*[2];
[1]*Institute of Molecular Biology NAS RA, Yerevan, Armenia,* [2]*Institute of Molecular and Translational Medicine, Faculty of Medicine and Dentistry, Palacky University, Olomouc, Czech Republic.*

Altered immune response, including low-grade inflammatory processes, are involved in the pathogenesis of schizophrenia - a chronic neuropsychiatric disorder with complex etiology. Distinct gene variants and a number of regulatory, pro-inflammatory and chemotactic cytokines together with their receptors have been implicated in this disorder. Interleukin-2 receptor gamma (IL-2RG) represents a component of several cytokine receptors and so far, no data have been reported about this receptor in schizophrenia, including its functional state. The aim of this study was, therefore, to investigate mRNA expression of the IL2RG gene in schizophrenia patients in comparison with healthy control subjects.
Total RNA was isolated from peripheral blood of 66 schizophrenia patients and 99 healthy subjects from Armenian population. The mRNA expression was determined by quantitative real-time polymerase chain reaction (RT-PCR) using PSMB2 as housekeeping gene.
IL2RG mRNA expression was upregulated in peripheral blood of patients in comparison with controls (patients vs. controls, mean±SEM: 3.06±0.47 vs. 0.52±0.06, $p<0.0001$). In conclusion, our findings suggest that over-expression of the IL2RG gene may be implicated in altered immune response in schizophrenia and thus associated with pathomechanisms of this disorder. Further investigations are required to extend this observation and relate it to disease clinical phenotypes.
We thank the administration and medical staff of the clinics of Psychiatric and Erebouni Medical Centers of the Ministry of Health of the Republic of Armenia for selection of patients and healthy subjects. The study was supported by the International Visegrad fund scholarship (HG_51200594), NAS RA, IGA_PU_LF_2013_009, and CZ.1.05/2.1.00/01.0030 funds.

P5.09.23
Schizophrenia is not associated with changes in blood expression levels of complement factors B, H and I

H. Ghazaryan[1,2], *A. Boyajyan*[1], *R. Zakharyan*[1], *A. Melkonyan*[1], *Z. Navratilaova*[2], *P. Klevcova*[2], *M. Petrek*[2];
[1]*Institute of Molecular Biology NAS RA, Yerevan, Armenia,* [2]*Institute of Molecular and Translational Medicine, Faculty of Medicine and Dentistry, Palacky University, Olomouc, Czech Republic.*

Our previous studies indicated systemic hyperactivation of the alternative complement cascade in schizophrenia. However, molecular pathomechanisms of detected alterations are not clear yet. In the present study we evaluated the expression levels of factor B, H and I in peripheral blood of patients with schizophrenia (n=66) compared to healthy controls (n=99). Factor B is an essential component of the alternative pathway. Factors H and I are negative regulators of this pathway. Methodological design includes quantitative real-time polymerase chain reaction (RT-PCR) of mRNA samples isolated from the peripheral blood cells of the study subjects. Our results showed no significant changes in the selected proteins mRNA expression were detected in patients compared to controls ($p>0.05$). In summary we concluded that hyperactivation of the complement alternative pathway is most probably not conditioned by changes in the expression levels of factor B, factor H and factor I in the peruipheral blood.
We thank the administration and medical staff of the clinics of Psychiatric and Erebouni Medical Centers of the Ministry of Health of

the Republic of Armenia for selection of patients and healthy subjects. This study was supported by the International Visegrad fund scholarship (HG51200594), the National Academy of Sciences of Armenia, IGAPULF2013_009 and CZ.1.05./2.1.00/01.0030 grant funding.

P5.09.24
IL-18 and IL-18BP in Amyotrophic Lateral Sclerosis

*P. Giungato[1], P. Italiani[1], P. Migliorini[2], G. Siciliano[3], B. Borroni[4], P. Bossù[5], **D. Boraschi**[1];*
[1]Institute of Biomedical Technologies (ITB) - National Research Council (CNR), Pisa, Italy, [2]Department of Internal Medicine, University of Pisa, Pisa, Italy, [3]Department of Neuroscience University of Pisa, Pisa, Italy, [4]The Centre for Ageing Brain and Neurodegenerative Disorders, Neurology Unit, University of Brescia, Brescia, Italy, [5]Clinical and Behavioral Neurology, IRCCS Fondazione Santa Lucia, Roma, Italy.

The role of inflammation in neurodegenerative diseases, included ALS, is increasingly recognized. Activation of caspase-1 has been demonstrated in the spinal cord of ALS mice and humans. To investigate if inflammasome hyperactivation is pathogenic, promoting neuroinflammation and contributing to ALS progression, we analyzed the levels of IL-18 and IL-18BP in serum and CSF from ALS patients.
Serum and CSF samples were collected from 103 patients with sALS. A control group consisted of 40 healthy serum donors; a second group included 69 CSF donors, either healthy or with different kinds of non-infectious non-inflammatory diseases. Cytokine levels were measured by ELISA. The levels of free IL-18 were calculated by the law of mass action.
Levels of IL-18 (21.99±14.03 pM), IL-18BP (471.54±230.50 pM) and free IL-18 (9.92±5.21 pM) were significantly higher in ALS serum than in healthy controls (IL-18: 12.12±7.24 pM, $p<0.0001$; IL-18BP: 268.83±165.85 pM, $p<0.0001$; free IL-18: 7.35±4.02 pM, $p=0.0006$). No correlation between cytokine levels and disease stage was found. IL-18 was undetectable in CSF, while IL-18BP was found at significant and comparable levels in both ALS patients and controls.
High circulating IL-18 concentrations may suggest the involvement of inflammasome-dependent inflammation in the disease, but the lack of correlation between IL-18 levels and disease stage suggests that the cytokine is not involved in triggering the disease exacerbation. The abundant presence of IL-18BP in the CSF in the absence of its cytokine target may imply the physiological need of maintaining homeostasis in a fundamental organ like the brain.

P5.09.25
Using the sodium salt of native DNA as an immunomodulator in the treatment of different diseases

***A. P. Godovalov**[1], T. Y. Danielyan[2], N. A. Danielyan[2], A. A. Danielyan[2];*
[1]Acad. E.A. Wagner Perm State Medical Academy, Perm, Russian Federation, [2]Ltd. Medical Studio, Perm, Russian Federation.

We used a solution of the sodium salts of native deoxyribonucleic acid in 0.9% sodium chloride solution (15 mg/ml). Deoxyribonucleinat was obtained from sturgeon milt. It is known that nuclease activates when nucleic acid is injected into a cell; and cytosis, bacteriosis, enzymatic processes of the cell directly depend on the nuclease. During therapy with deoxyribonucleinat we observed an improvement in the elimination of the inflammatory response and menstrual disorders, improvement of the functions of related organs, reduction of psychoemotional disorders at women of reproductive age with chronic salpingo-oophoritis. After treatment with deoxyribonucleinat patients had permanent positive effect, manifested by a significant decrease in pain in the projection of the uterus. We showed that with the inclusion of deoxyribonucleinat in the therapeutic complex there were more rapid relief of inflammation (2-3 days), decrease of gingival hemorrhage, as well as reduction of average treatment duration, significant relief of inflammation in the periodontium, improvement of oral hygiene and the general condition of sick children with functional diseases of the nervous system and musculoskeletal system. The results of investigation indicate significant efficacy of deoxyribonucleinat in the complex therapy of different forms of neurodermatitis. Clinical recovery and significant improvement were observed in 85% of patients. A noticeable improvement of skin status was observed earlier than in the standard therapy.

P5.09.26
Prevalence and evolution of Autoimmune Diseases in patients with Cushing's Syndrome compared to other Pituitary Tumors: a Multicenter Italian Study

***F. Guaraldi**[1], M. De Martin[2], C. Scaroni[3], M. Zilio[3], F. Pecori Giraldi[2], I. Karamouzis[1], S. Grottoli[1], L. Ghizzoni[1], E. Ghigo[1], E. Arvat[1];*
[1]University of Turin, Turin, Italy, [2]University of Milan - Istituto Auxologico Italiano, Milan, Italy, [3]University of Padua, Padua, Italy.

New onset of autoimmune diseases (AID) is reported after remission of Cushing's syndrome (CS), likely due to immune system reactivation after suppression induced by hypercortisolism. We provide results of the largest study comparing prevalence and type of AID in CS during active disease vs remission, and vs other pituitary adenomas (PAs). Methods: 116 patients (F=95) with endogenous CS treated with surgery/drugs/RT, with active disease or after remission; 116 patients with other types of PAs matched for sex and age at diagnosis from 3 Italian Centers. Results: 35 patients (28 F) with CS presented AID, single in 30 cases, multiple in 5. AID appeared before CS in 12 cases: 3 resolved before CS's onset, 5 persisted during active phase and CS' remission, 2 improved during active phase but worsened after CS' remission, 2 resolved after CS' remission. In 10 cases AID appeared in the active phase of CS: 9 persisted, 1 resolved after CS' remission. In 17 cases AID appeared only after CS' remission. 40 patients with PA (26 F) suffered from single AID, whose evolution did not correlate with hormonal status. AID's prevalence was similar in ACTH-dependent and independent (33 vs 30.4%) CS and in pituitary CS vs other type of PA. Relative prevalence was significantly higher in males (21/42 vs 54/190); thyroiditis and psoriasis were the most common diseases. Hypercortisolism, but not the levels of the other pituitary hormones, influenced AID's evolution as the great majority of new cases/exacerbation of AID were registered after CS's remission, confirming previous data.

P5.09.27
Measuring cerebrospinal fluid (CSF) immunoglobulins in neurological conditions

***Y. Hacohen**[1], V. Forsyth[2], G. Swana[3], M. Absoud[2], M. Lim[2];*
[1]Oxford University, Oxford, United Kingdom, [2]Evelina Children's Hospital @ Guy's and St Thomas' NHS Foundation Trust, King's Health Partners Academic Health Science Centre, London, United Kingdom, [3]St Thomas' Hospital NHS foundation Trust, London, United Kingdom.

Background: CSF analysis of immunoglobulins can be done using qualitative [oligoclonal band (OCB) patterns Type 1-5) and quantitative [Albumin quotient (QAlb) and IgG index] techniques to evaluate blood-brain barrier dysfunction and detect either intrathecal synthesis or passive transfer of IgG into the brain.
Method: 189 children who underwent CSF investigation for their neurological condition had CSF and serum testing to i) qualitatively identify oligoclonal patterns Type 1-5 ii) quantitatively measure the IgG index (IgG Index=IgGCSF/IgGSERUM)/(AlbCSF/AlbSERUM) and QAlb (QAlb=AlbCSF/AlbSERUM). Patient case notes were reviewed and patients were grouped to either have an inflammatory (n= 104) or non-inflammatory (n=85) aetiology.
Results: Patients with inflammatory condition were significantly more likely to have abnormal results (PValue = 0.0019). CSF restricted OCB were found in 19% of inflammatory group compared with 5% of non-inflammatory patients (PValue = 0.0036). Mirrored OCB were found in 12.5% of the inflammatory group, compared with 6% of the non-inflammatory group (PValue=0.14)., IgG index and QAlb are significantly higher in patients with an inflammatory aetiology. However, a raised IgG and QAlb were seen in both groups with QAlb abnormalities seen more frequently in the inflammatory group (PValue 0.0028). The qualitative and quantitative evaluation collectively revealed additional positive results than when done in isolation, but did not distinguish between both aetiologies. Overall, the

likelihood ratio of a positive test to help differentiate inflammatory from non-inflammatory causes was 3.1 (95%CI 1.6- 6.0).
Conclusion: Both qualitative and quantitative evaluations of CSF immunoglobulins are useful in identifying inflammatory mechanisms in a range of neurological conditions

P5.09.28
Expression of selected Th1/Th2 transcription factors and immune-response genes in cerebral ischemia and senescence

A. Hakobjanyan[1,2], *A. Boyajyan*[1], *L. Hovsepyan*[1], *Z. Navratilova*[2], *P. Klevcova*[2], *M. Petrek*[2];
[1]*Institute of Molecular Biology, National Academy of Science of Republic of Armenia, Yerevan, Armenia,* [2]*Laboratory of Immunogenomics and Immunoproteomics, Institute of Molecular and Translational Medicine, Faculty of Medicine and Dentistry Palacky University, Olomouc, Czech Republic.*

T helper (Th) subsets have been implicated in ischemic stroke. This study, therefore, aimed to assess functional state of Th1/Th2 cells by measuring expression of genes encoding GATA3 and TBX21, markers of Th2 and Th1, respectively, in stroke-affected and healthy control subjects. 54 patients with ischemic stroke (mean age±SE: 71.91±1.47 years) on 1st day after stroke onset, 28 aged (66.71±1.5) and 46 middle-aged (37.09±1.04) healthy controls of Armenian ancestry were enrolled with ethical clearance. mRNA expression in peripheral blood cells was determined by quantitive real-time polymerase chain reaction (RT-PCR) with PSMB2 as housekeeping gene. There was no difference in GATA3 mRNA expression between the investigated groups ($p>0.05$). However, decreased TBX21 mRNA expression was observed in ischemic stroke patients and in aged controls (3.1 and 2.9-fold, respectively; $p<0.05$) indicating that these changes may be age-dependent. Aging process is a major risk factor for cerebral ischemia and numbers&function of Th1 cells decrease while those of Th2 cells increase during aging. Thus, in further experiments we analysed peripheral blood expression levels of IL2 and IL2RG. Both IL2 and IL2RG mRNA transcripts were downregulated in patients and aged controls compared to middle-aged controls. Moreover, there was a positive correlation between the expression of TBX21, IL2 and IL2RG. In summary, GATA3 expression levels were not altered by ischemic stroke condition or aging processes, whereas TBX21, IL2 and IL2RG were upregulated in ischemic stroke.

P5.09.29
Activation of protease-activated receptor 2-mediated signaling by mast cell tryptase modulates cytokines production in primary cultured astrocytes

X. Zeng[1], *S. Zhang*[1], *L. Xu*[2], *H. Yang*[1], ***S. He***[1];
[1]*the First Affiliated Hospital of Nanjing Medical University, Nanjing, China,* [2]*Nanjing First Hospital Affiliated to Nanjing Medical University, Nanjing, China.*

Background: Since protease-activated receptors-2 (PAR-2), which is abundantly expressed in astrocytes, is known to mediate signaling events in CNS in physiological and pathological processes, the accurate mechanism by which it plays pivotal roles in the astrocytic modulation remains to be elucidated.
Methods: Viability and proliferation of astrocytes was assessed by CCK8 analysis. Intracellular ROS was determined by 2', 7'-dichlorodihydrofluorescein oxidation. IL-6 and TNF-α were measured with commercial ELISA kits. Phosphorylation of MAPKs or AKT and production of TGF-β or CNTF were evaluated by Western blotting.
Results: Tryptase at low concentrations modestly inhibited intracellular ROS levels and proinflammatory TNF-α secretion while significantly increased IL-6 and TNF-α secretion at higher concentrations without affecting astrocytic viability and proliferation, which were both alleviated by specific PAR-2 antagonist FSLLRY-NH2. PI3K/AKT inhibitor LY294002 reversed the effect of tryptase on IL-6 production while inhibitors specific for p38, JNK and ERK1/2 abolished the effect of tryptase on TNF-α production, suggesting distinct pathway responsible for each cytokines production in astrocytes. The enhanced activation of MAPKs and AKT by tryptase administration was eliminated by FSLLRY-NH2, strengthening the evidence of two potential signaling pathways downstream from PAR-2. In addition, the expression of TGF-β and CNTF in astrocytes was as well increased by tryptase treatment.
Conclusions: The present findings first suggest that tryptase is able to regulate cytokines release from astrocytes via PAR-2-MAPK or PAR-2-PI3K/AKT signaling pathway, and reveals a novel profile of PAR-2 as a new target in the regulation of astrocytic function for neuroprotection.

P5.09.30
Detection of novel nitric oxide mediated neuro-inflammatory mechanism against environmental toxins/agents

A. Inamdar, *J. Bennett;*
Rutgers, The State University of NJ, New Brunswick, NJ, United States.

Exposure to environmental toxins/agents is associated with neuroinflammation and oxidative stress which are the primary mechanisms for the pathogenesis of chronic neurodegenerative diseases. Recently, it has been proposed that microglia, the innate immune cells of the mammalian brain, become hyperactivated and deregulated in response to exposure to environmental toxins/agents. The mechanisms for neuroinflammatory responses that exaggerate neurotoxicity are poorly understood. Moreover, the studies to date that investigate neuroinflammatory mechanisms have utilized primarily in vitro approaches. We have established a Drosophila model based on exposure to toxic volatile organic compound (VOC), 1-octen-3-ol which recapitulates most behavioral and pathophysiological features of Parkinson's disease (PD). Using this model, we have discovered that 1-octen-3-ol exposure induces nitric oxide synthase (NOS) and a corresponding elevation of nitric oxide (NO) production in the adult Drosophila brain. NOS is recognized as a major marker for neuroinflammation and shown to be produced by activated microglia in mammalian model. Therefore, the observation of NOS induction during Drosophila neurodegeneration parallels the mammalian process and presents a novel discovery of in vivo model to further dissect the genetic components of neuroinflammatory process which are not possible to perform in mammalian or in vitro models. The discovery of a NOS-dependent inflammatory response in flies provides the foundation for future work to explore cellular and molecular mechanisms associated with neuroinflammatory process in efficient and inexpensive manner.

P5.09.31
Regulation of microglia activation mechanisms following chemical or mechanical stimulation

M. Kalognomou, *C. Simitzi, I. Athanassakis;*
Department of Biology, University of Crete, Heraklion, Greece.

Aim: Deregulation of microglial activation plays a critical role in neurodegeneration, which has been highly correlated with expression of MHC-II molecules. Using BV-2 cells as an experimental model of migroglia, the present study aimed to define the membrane and intracellular expression of H-2A as well as intracellular H-2M, H-2O and CD74 at different activation states, using flat or 3D-micro laser-textured Si scaffolds.
Methods: Flow cytometry and confocal microscopy analysis defined H2-A, -O, and -M expression, while RT-PCR was used to evaluate CD74 in BV-2 cells in the presence or not of LPS, IFN-γ and IL-4. Secretion of H2-A was evaluated by ELISA. Scanning electron microscopy analysis defined the morphological features of BV-2 cells grown on Si scaffolds with gradient 3D micro-geometries.
Results: BV-2 cells expressed all necessary components for post-translational regulation and transport of MHC-II molecules to the cell membrane. Although LPS did not affect MHC-II expression, it induced TNF-a secretion while promoting cytophagy. IFN-γ reduced MHC-II expression but increased secretion of H2-A molecules, whereas IL-4 reduced H2-A while inducing H2-O expression. Roughness of culture substrate was shown to affect BV-2 morphology. At low-roughness scaffolds, BV-2 cells displayed resting microglia morphology showing

elongated bipolar cell bodies with spine-like processes carrying short branches, while at high-roughness cells exhibited an ameboid-like shape with short processes suggesting microglia activation.
Conclusion: Depending on the chemical or mechanical stimulatory signal, BV-2 cells follow different activation pathways, ranging from neuroprotection to neurodegeneration. Understanding the mechanisms governing microglial activation could dictate new therapeutic strategies for neurodegenerative diseases.

P5.09.32
Macrophage migration inhibitory factor has an essential role in age-related hearing loss

***S. Kariya**, M. Okano, Y. Maeda, Y. Noyama, T. Haruna, T. Koyama, K. Nishizaki;*
Okayama University, Okayama, Japan.

Objective: The hearing loss related with aging is the most common sensory disorder among elderly persons. Macrophage migration inhibitory factor is the multi-functional molecule. The aim of this study is to identify the role of macrophage migration inhibitory factor in inner ear.
Study Design: Animal experiment
Methods: The macrophage migration inhibitory factor deficient mice on BALB/c background and wild type mice were used in this study. The expression of macrophage migration inhibitory factor protein in inner ear was examined by immunohistochemistry in wild type mice. The hearing threshold was determined both in macrophage migration inhibitory factor deficient mice and wild type mice by click-evoked auditory brainstem response at the age of 1, 3, 6, 9, 12, and 18 months.
Results: The expression of macrophage migration inhibitory factor was observed in spiral ligament, stria vascularis, Reissner's membrane, spiral ganglion cells, saccular macula, and membranous labyrinth. The macrophage migration inhibitory factor deficient mice had significant hearing loss as compared with wild type mice at the age of 9, 12, and 18 months.
Conclusion: The macrophage migration inhibitory factor was strongly expressed in mouse inner ear. The aged macrophage migration inhibitory factor deficient mice showed the accelerated age-related hearing loss. These findings suggest that macrophage migration inhibitory has an important role in inner ear in mice.

P5.09.33
Evaluation of multiple sclerosis (MS) based on Antibody to Aquaporine-4(AQP-4) in urine and serum compared to total IgG antibody

***A. Khosravi**, M. Mohamad-Rashidi;*
Ilam university of Medical Sciences, Immunology Dep, Ilam, Iran.

Introduction- Multiple sclerosis (MS) is a disease in which the myelin is damaged due to inflammation. As AQP-4 is important water chanel protein expressing in MS the current study aimed to measure the antibody titer against AQP-4 either in urine and the sera of MS patients compared to the total IgG to evaluate the diagnosis of the disease this way.
Materials and Methods- 21 MS patients together with 21 healthy people were included in this study. A urine and blood sample was taken and after RBC and WBC count, Hb measurement, MCV, MCHC and RDW, the total antibody titer (IgG class, IgA and IgM) was measured using Nephlometry. Anti-AQP-4 antibody was measured using ELISA. Data were extracted and analyzed using ANOVA and Pearson correlation test.
Results- The total IgM was similar in both case and control group but there was a higher titer of IgG and IgA in case compared to the control group. The mean anti-AQP-4 IgG antibody was 17.4 and 17.8 in urine and serum respectively while in mild MS was 16.1 and moderate and severe ones it was 19.3.
Conclusion- As the antibody titer to AQP-4 in either serum and urine is similar, but it is higher in urine of severe MS patients, urine levels of this antibody could represent a noninvasive method for diagnosis of the MS with a high reliability. Anti-AQP-4 antibody also can be used a good indicator for analyzing the severity of MS..

P5.09.34
The inner ear findings in macrophage migration inhibitory factor knockout mice

***T. Koyama**, S. Kariya, M. Okano, Y. Maeda, T. Haruna, Y. Noyama, K. Nishizaki;*
Okayama University, Okayama, Japan.

Objective: The hearing loss related with aging is the most common sensory disorder among elderly persons. Macrophage migration inhibitory factor is the multi-functional molecule. We showed that the macrophage migration inhibitory factor deficient mice had significant hearing loss as compared with wild type mice. The aim of this study is to show the inner ear findings in macrophage migration inhibitory factor deficient mice.
Study Design: Animal experiment
Methods: The macrophage migration inhibitory factor deficient mice on BALB/c background and wild type mice were used in this study. We examined the morphological findings of cochlea including cochlear hair cells and spiral ganglion cells both in macrophage migration inhibitory factor deficient mice and wild type mice using scanning electron microscopy and light microscopy.
Results: The scanning electron microscopy showed affected outer cochlear hair cells in macrophage migration inhibitory factor deficient mice. The inner cochlear hair cells were relatively preserved. The number of spiral ganglion cells in inner ear was decreased in macrophage migration inhibitory factor deficient mice. No significant finding was observed in stria vascularis and spiral ligament in the cochlea of macrophage migration inhibitory factor deficient mice.
Conclusion: The cochlear hair cells and spiral ganglion cells are the important components in the auditory system. The macrophage migration inhibitory factor deficient mice had the morphological inner ear abnormalities. These findings suggest that macrophage migration inhibitory has a principal role in neural systems in inner ear.

P5.09.35
Participation of cold sensitive TRPM8 ion channel in modulation of metabolism and immune response

***T. V. Kozyreva**;*
Department of Thermophysiology , Institute of Physiology, Academy of Medical Sciences, Novosibirsk, Russian Federation.

The response of living organism to any stimulus is a combination of the responses of various systems. The combination is determined by the nature of the afferent information providing constant and precise interaction of the systems. Relationship of thermoregulatory and immune systems is an important aspect of unsolved problems, because the widespread influence of temperature on the body. Currently, as the molecular basis of thermoreception discusses TRP ion channels. Cold sensitive TRPM8 ion channel is mostly interesting because it works in the physiological region of temperatures (28-8°C). *In thermoneutral conditions* a preliminary activation of TRPM8 ion channel by its agonist menthol: 1) caused an increase of metabolism due to enhanced fat oxidation; 2) enhanced the antigen binding; 3) inhibited the antibody production in the spleen; 4) significantly reduced the amount of IgG in blood; 5) increased the level of IL-6 and IL-1β in blood that was very close to changes of these cytokines at cooling. *At cooling* additional activation of TRPM8 ion channel by menthol results in initiation of cold defense Thermoregulatory responses at less cooling and leads also to improved maintenance of core temperature in the cold. More over pharmacological activation of TRPM8 attenuated the suppressive effect of deep cooling on immune response. The low expression of *TRPM8* gene in brain structures, and the expression of this ion channel in sensory skin afferents allow us to suggest that the observed effects of TRPM8 activation on thermoregulatory and immune processes are mostly due to its peripheral actions.

P5.09.36
Chronic co-administration of risperidone (RIS) and fluoxetine (FLU) modulates behavior of mice in forced swimming test (FST) and cytokine production by splenocytes

***J. Kusmierczyk**, E. Klimek, A. Roman, Z. Rogoz, I. Nalepa;*
Institute of Pharmacology Polish Academy of Sciences, Krakow, Poland.

Combined treatment with antidepressants and the drugs of different clinical profiles is an option for more efficient therapy. Fluoxetine (FLU) is commonly used as first-line treatment for depression. Risperidone (RIS), an atypical antipsychotic, is being increasingly used for potentiation of therapeutic action of antidepressants. Because antidepressive treatments also regulate immune functions, we investigated whether the chronic combined administration of FLU and RIS to mice subsequently subjected to a forced swimming test (FST) modified the cytokine production by mitogen-stimulated splenocytes. We found that the administration of FLU (10 mg/kg) for 14 consecutive days produced antidepressive-like effects in the FST when assessed 24 h after last dose. Co-administration of RIS (0.1 mg/kg 30 min. prior to FLU) enhanced the antidepressive-like effect of FLU, whereas RIS was ineffective if administered separately. Pro- and anti-inflammatory cytokines were measured in culture supernatants of mitogen-stimulated splenocytes. We found that FLU administered alone or in combination with RIS increased the level of suppressive cytokine IL-10 and decreased the protein p40 level, a common subunit for pro-inflammatory cytokines IL-12 and IL-23. Co-administration of RIS and FLU suppressed IL-4 in comparison to the group treated with FLU alone. Our results showed that chronic administration of FLU inhibited a predisposition for inflammatory processes in the immune system that occurred concomitantly with the FLU antidepressive-like action. Enhanced antidepressive-like effect of combined treatment may be related to suppression of IL-4, a cytokine engaged in amplification of humoral immune response and depressive disorders. Supported by POIG.01.01.02-12-004/09 co-financed by the European Regional Development Fund.

P5.09.37
High prevalence of anti-neuronal antibodies in Tunisian psychiatric inpatients

***L. Laadhar**[1], O. Sidhom[2], M. Zitouni[1], N. Sassi[1], M. Kallel-Sellami[1], Z. El Hechimi[2], S. Makni[1];*
[1]Immunology Department, la Rabta hospital, Tunis, Tunisia,
[2]Psychiatry F department, Razi hospital, Tunis, Tunisia.

Purpose: Antineuronal autoantibodies are associated with paraneoplastic syndrome. They may target nuclear or cytoplasmic antigens. We aimed in this study to determine the prevalence of anti-neuronal antibodies in Tunisian psychiatric inpatients. Subjects and methods: We enrolled in this prospective study, 103 psychiatric inpatients and 41 healthy, age and sex matched blood donors. Patients and controls had no history of malignancies or neurological disorders. For all subjects, we performed indirect imunofluorescence on primate cerebellum sections. Positive sera by immunofluorescence were also tested by an immonoenzymatic test combining a western blot of primate cerebellum extract and recombinant antigens. Results: Using indirect immunofluorescence, antineuronal nuclear autoantibodies were detected in 17 patients and none of controls (p=0.003) and antibodies reacting with cytoplasm of Purkinje cells in 6 patients and 2 controls. There was no difference of the prevalence of autoantibodies across the 4 groups of patients.The immunoblot confirmed well-characterized antineuronal antibodies only in 5 patients: two had anti-Ri (1 man and 1 woman with schizophrenia) and 3 had anti-Yo antibodies (3 men, 2 with bipolar disorder and 1 with schizophrenia). After a mean follow-up of 5 years, none of these patients developed neurological disorder or malignancy. Conclusion: In our knowledge, our study is the first one assessing the prevalence of antineuronal antibodies in psychiatric patients. The high prevalence of these antibodies in our patients may highlight the possible contribution of neuronal autoantigens in the physiopathology of some psychiatric disorders. Further studies on a larger cohort are needed to confirm this hypothesis.

P5.09.38
Usefulness of pituitary antibodies in the management non-tumoral pituitary diseases in Tunisian adults

***L. Laadhar**[1], M. Chihaoui[2], M. Kallel-Sellami[1], N. Sassi[1], B. Ftouhi[2], H. Lahmar[1], F. Kanoun[2], H. Slimane[3], S. Makni[1];*
[1]Immunology Department, La Rabta Hospital, Tunis, Tunisia,
[2]Endocrinology Department, La Rabta Hospital, Tunis, Tunisia,
[3]Endocrinology Department, La Rabta Hospital, Tunis, Tunisia.

Pituitary antibodies (PAs) are directed against cells of the anterior and the posterior lobes of the pituitary gland. The aim of our study was to assess the usefulness of PAs in the management of non-tumoral pituitary diseases in Tunisian adults.In this prospective study, we recruited 43 cases of non-tumoral pituitary pathologies. PAs were detected by indirect immunofluoresence on monkey pituitary gland. Patients were 41 women and 2 men, mean age 43.5 ± 12.8 years. APs were positive in 12 patients (28%), 4 APs were directed against the anterior lobe and 10 against the posterior lobe of pituitary gland (2 patients had APs against anterior and posterior lobe at the same time). Twenty one women had a postpartum hypopituitarism suggestive of a Sheehan syndrome, 7 among them had PAs. Fifteen patients had a hypopituitarism without Sheehan syndrome and without malignancy (according to the MRI of the pituitary gland), 3 of them were APs positive. Seven patients had autoimmune polyendocrinopathy and only 3 of them had hypopituitarism. In this last group APs were positive in 4 cases. APs were more frequently detected in patients with autoimmune polyendocrinopathy than others but the difference was not statistically significant. Despite the low number of our patients, we reported a high prevalence of APs in non-tumoral pituitary diseases even in a context of a non autoimmune hypophysitis confirming the poor specificity of these antibodies. Additional studies are needed to identify more reliable markers for the diagnosis of lymphocytic hypophysitis.

P5.09.39
Idiopathic hypertrophic cranial pachymeningitis: a rare inflammatory cause of chronic daily headache and progressive cranial neuropathies: a case report

***M. B. Laguerta**, E. A. Esposo, B. Mariano, M. Martinez;*
St. Luke's Medical Center, Quezon city, Philippines.

INTRODUCTION: We report a rare case of a 75-year-old male with chronic daily headache for more than one year and later on developed deafness, dysphagia, ophthalmoplegia, and loss of vision. On physical examination, there was ptosis and left gaze palsy, pale optic disc, light perception only on both eyes, weak gag reflex and gross hearing loss. METHODS AND RESULTS: Cranial MRI showed abnormal pachymeningeal enhancement in the posterior fossa, cavernous sinus and orbital apex and bilateral mastoiditis. CSF analyses were normal except for elevated protein, negative results for viral, fungal and bacterial antigen panel and culture, and no malignant cells. ANCA, ANA and RF were negative. Search for occult malignancies was negative. There was elevated ESR consistent with an inflammatory process. Having ruled out infectious and non infectious causes, Idiopathic hypertrophic pachymeningitis was considered, a rare chronic fibrosing inflammatory disease characterized by marked diffuse thickening of the cranial dura causing progressive neurological deficits by compression of anatomic structures by the meninx, thickened by inflammation. After initiation of pulse corticosteroid therapy, methotrexate and maintenance oral prednisone, there was remarkable improvement on hearing, swallowing, and ocular muscle movement, less headaches and marked regression of pachymeningeal enhancement on repeated MRI. However, profound vision loss remained unchanged. CONCLUSION: A high index of suspicion of this rare inflammatory disease is important because early institution and long-term maintenance of steroid may result to complete or partial remission of the neurologic deficits and may help prevent irreversible neurologic sequelae, especially blindness.

P5.09.40
Immune signatures to predict the development and progression of Alzheimer's disease: lymphocyte profiles

***A. Y. Le Page**, E. H. Frost, G. Dupuis, T. Fülöp;*
Université de Sherbrooke, Sherbrooke, QC, Canada.

A large body of evidence links inflammation and immune dysfunctions to Alzheimer's disease (AD). Alterations of the immune system may play a major role during the asymptomatic period of AD. To identify immune parameters that may be used to predict AD initiation and/or progression, we analyzed lymphocyte subsets of amnestic mild cognitive impairment (aMCI) and mild to moderate AD patients. The role of innate and adaptative immunity was addresed by analyzing T, NK, CD4+ helper and CD8+ cytotoxic T cells by cytofluorometry. CD107 degranulation assays were performed on CD8+ and NK cells. We found no differences in total numbers of CD4+, CD8+ and NK lymphocytes among the different groups. Analysis of CD4+ and CD8+ T cells revealed an increase in "terminally differenciated" effector memory T cells CD45RA+ (TEMRA) subset and a decrease of naïve T cell subset in AD patients compared to healthy age-matched controls. Functional CD107 degranulation assays revealed that CD8+ and NK lymphocytes of AD patients did not display basal activity. However, treatment with a combination of PMA and ionomycin induced a higher degranulation activity in AD than controls. There were no major changes in the distribution of classical lymphocyte subsets in AD except for some functional changes. Increases in the number of memory subset TEMRA and low threshold of activation of NK and CD8+ T lymphocytes in AD suggested dysfunctions in the immune system of these patients. Our results are an initial step in a global understanding of the dynamic of the immune responses in AD patients.

Patients with febrile infection-related epilepsy and other syndromes and microtubule-associated tau protein data

***Y. Lekomtseva**[1], G. Gubina-Vakulik[2], T. Gorbach[2];*
[1]State Institute of Neurology, Psychiatry and Narcology, Kharkiv, Ukraine, [2]Kharkiv National Medical University, Kharkiv, Ukraine.

Immune system involvement into epileptogenic process has been postulated in pathogenesis of some partial epilepsies when certain immune-mediated diseases were associated or debuted with seizures. Aim was to evaluate in patients with fever-induced encephalopathy tau which is microtubule-associated phosphor-protein involved in neurotoxic mechanisms found in different neurodegenerative disorders.
Method Controls (n=15; 21-40 years) and patients with febrile infection-related epilepsy (FIRES) and other syndromes (n=8; 18-27 years) were investigated. In anamnesis patients had encephalitis due to immune encephalopathy occurred after onset of acute febrile illness associated with lacking evidence of infectious agent (Mean disease duration 24.7±11.5 years). Tau was measured by immunofluorescent method using monoclonal anti-mouse antitau-2 antibodies also specific for phosho-Tau. Results were expressed as optical density (OD=log10F0/F1) units of FITC-labelled binding sites.
Results Patients had long-standing intractable partial epilepsy, n=6 and primary-generalized epilepsy, n=2, with high seizure frequency and psychiatric complications. Serum tau (Mean±SD) under baseline conditions compare to controls was 0.29±0.412 vs. 0.04±0.016 (P>0.01; t=4.5). Immune status showed presence of serum specific immunoglobulin E in 37.5% patients with a tendency to decreasing of functional T-cells activity. Patients with immunological alterations had chronic drug-resistant course, spike-abnormalities on EEG mainly at occipital, mid temporal lobes, severe cognitive decline; 62.5% had mesial temporal sclerosis identified with MRI; neurological syndromes showed focal symptomatology in 87.5% patients.
Conclusion. FIRES revealed high tau level that could play role in disease progression associated with development of psychiatric complications; changes of humeral immunity may play additional role in pathogenesis of autoimmune-mediated acquired epilepsy.

The neurotransmitter glutamate is a direct and potent activator of very important functions in normal, cancer and autoimmune human T cells

***M. Levite**;*
The Academic College of TLV Yaffo, Tel Aviv Jaffa, Israel.

Glutamate is the most important excitatory neurotransmitter of the nervous system, critically needed for brain development and function, but should be re-named a 'Neuro-Immuno-transmitter', since recent findings reveal functional glutamate receptors and potent effects on most/all immune cells. Regarding human T cells: glutamate by itself, at low physiological ~10^{-6}-10^{-8}M concentration binds ionotropic and metabotropic glutamate receptors in T cells, and activates key functions including: adhesion to extracellular matrix glycoproteins fibronectin and laminin, chemotactic migration, cytokine secretion, proliferation, inward Ca^{2+} fluxes, outward K^{+} currents via Kv1.3 channels, and others. Glutamate also protects activated T cells of antigen-induced-cell-death (AICD). Glutamate-induced effects on T cells depend dramatically on: its concentration (activation at low/physiological levels, but inhibitory at excess/pathological levels); the T cell resting or activated state; and the T cell subtype. Glutamate receptor subunit AMPA/GluR3 is highly expressed only in resting T cells, since granzyme B cleaves membranal GluR3 after TCR activation.
Glutamate also improves the function of human cancerous T-leukemia and T-lymphoma, by enhancing their adhesion, migration, *in vivo* engraftment into solid organs, and production of the cancer-associated-matrix-metalloproteinase MMP-9, and of the MMP-9 inducer: CD147.
Regarding autoimmune T cells: glutamate was reported to enhance proliferation of autoreactive T cells of multiple sclerosis (MS) patients in response to myelin proteins MBP and MOG; AMPA GluR3 is highly expressed in T cells of MS patients and upregulated during relapse; and mouse encephalitogenic MPB-87-99 T cells respond to glutamate. In conclusion: glutamate, via glutamate receptors, triggers/elevates key functions in normal and pathological human T cells.

Activation of exploratory behavior in senescence accelerated OXYS rats by stimulation of cell-mediated immune response with BCG vaccine

***E. V. Markova**[1], N. G. Kolosova[2], V. A. Kozlov[1];*
[1]Federal State Budgetary Institution "Research Institute of Clinical Immunology", Russian Academy o, Novosibirsk, Russian Federation, [2]Institute of Cytology and Genetics, Russian Academy o Sciences, Novosibirsk, Russian Federation.

Changes in cognitive and emotional spheres are typical of aging. Their prevention is an obligatory condition providing active longevity of elderly people. We demonstrated that senescence-accelerated OXYS rats constitute appropriate model for studying ageing processes. Changes in exploratory activity and the degree of anxiety in OXYS rats are significantly related to activity of cellular immune reactions. The present study included 3-month-old male OXYS and Wistar rats. It was shown that stimulation of the cellular component of the immune response by injection of BCG vaccine significantly modified horizontal motor activity of animals. The effect was dose-dependent and peaked after injection of 600 μg/kg vaccine: in this case horizontal motor activity increased 3-fold and did not differ from that of control Wistar rats. Animals receiving the maximum dose of the vaccine did not differ from Wistar rats also by the parameters of vertical motor activity and number of grooming reactions. So, stimulation of cell-mediated immune response caused a dose-dependent activation of exploratory behavior in senescence accelerated OXYS rats. The possibility of correction of behavioral changes associated with early aging of OXYS rats by stimulation of cellular immune reactions is a direct proof of the involvement of neuroimmune relationships in the process of aging.

Effects of transplantation of the immune cells treated with psycho modulators on the nervous system functional activity of recipients

***E. V. Markova**, M. A. Knyazheva, V. A. Kozlov;*
Federal State Budgetary Institution "Research Institute of Clinical Immunology", Russian Academy o, Novosibirsk, Russian Federation.

We first demonstrated the possibility of the exploratory behavior direct regulation by the transplantation of the immune cells with definite functional characteristics. Based on the results of our own previous researches in the present study we demonstrated that immune cells, treated with psycho modulators after the transplantation modulated the nervous system functional activity of syngeneic recipients.
I t was shown that in vitro treatment with caffeine or chlorpromazine of splenocytes from (CBAxC57Bl / 6) F1 mice with depressive-like or aggressive-like behavior consequently modified the functional activity of these cells, manifested in changes in spontaneous and antigen induced cytokines production and cells proliferative activity. The intravenous injection of the cells, treated with caffeine to mice with depressive-like behavior were accompanied by the modulation of the recipient's exploratory behavior parameters, the nature of which depends on the dose of the drug. We also demonstrated the possibility of obtaining a neuroleptic effect in mice with aggressive-like behavior by the transplantation of immune cells, treated with chlorpromazine. The modulation of animals behavior after the transplantation of the immune cells treated with psycho modulators were accompanied with definite changes in the synthesis of TNFα, IL-1β, IL-6, INFγ cytokines in brain of mice-recipients.

Characterization and role of the humoral response after transplantation of porcine neuroblasts in the rat brain

***E. Mathieux**[1], V. Nerriere-Daguin[1], X. Leveque[1], S. Menoret[1], I. Anegon[1], I. Neveu[2], P. Naveilhan[2];*
[1]INSERM UMR 1064, Nantes, France, [2]INSERM UMR 913, Nantes, France.

Cell therapy is a real hope for neurodegenerative diseases. Interesting results were obtained after the transplantation of human fetal neuroblasts into the brain of Parkinsonian patients but tissue availability and ethical concerns limit this approach. Other cellular sources have therefore to be found. Fetal pig neuroblasts are interesting candidates, but intracerebral xenotransplants are systematically rejected, even under systemic immunosuppression. Efforts have been done to inhibit locally the cellular immune reaction but little is known about the necessity of targeting the host humoral response.
We became interested in the humoral response of intracerebral xenograft with porcine neuroblasts in the rat striatum. The antibody production is observed in the sera of rats by immunocytologicals and FACS analysis. We see an increase of IgG production correlated with time post transplant and the stage of rejection. In fact, anti-porcine antibodies appear quite late and maximum of accumulation is observed after the rejection of porcine neurons. Furthermore, a deposit of IgG and complement is found in graft during rejection. Moreover, we demonstrate that IgG recognize neurons, astrocytes and porcine aortic endothelial cells (PAEC).
The question is now to know the balance between humoral response and cellular response in the rejection. For this, the important role of the humoral response in transplant rejection is studied in rats knock-out to immunoglobulin (IgM KO). We observe the presence of a healthy graft at D63 in all IgM KO rats but in WT rats 50% have a graft in rejection or scar and 50% have a healthy graft.

Neuronal toll-like receptor-4 signalling induces brain endothelial cell activation and neutrophil transmigration

***S. Maysami**, S. Leow-Dyke, C. Allen, A. Danes, O. Nilsson, A. Bowie, N. Rothwell, E. Pinteaux;*
University of Manchester, Manchester, United Kingdom.

BACKGROUND: The innate immune response in the brain can be initiated by either pathogen-associated molecular patterns (PAMPS) or danger-associated molecular patterns (DAMPS). These molecules activate members of the Toll-like receptor (TLR) family including TLR4. Although neurons have been reported to express TLR4, the function of TLR4 activation in these cells remains unknown.
METHODS: Using RT-PCR, we assessed the TLR4 mRNA expression in primary mouse glial and neuronal cells. Mouse mixed glial, neuronal or endothelial cell cultures were treated with LPS and the expression of inflammatory mediators was assayed by either cytometric bead array or ELISA. Activation of extracellular-signal regulated kinase 1/2 (ERK1/2), p38, c-Jun-N-terminal kinase (JNK) and c-Jun was assessed by Western blot. The effect of conditioned media of untreated- versus LPS-treated glial or neuronal cultures on endothelial activation was assessed by neutrophil transmigration assay.
RESULTS: LPS induces strong release of the chemokines RANTES and CXCL1 (KC), tumor necrosis factor-α (TNFα) and IL-6 in primary mouse neurons. In contrast, LPS induced release of IL-1α, IL-1β and granulocyte-colony stimulating factor (G-CSF) in mixed glial cells. LPS-mediated neuronal CXCL1 release was completely hampered by VIPER and LPS-mediated activation of JNK in both glial cells and neurons was blocked by SP600125. Moreover, conditioned medium of LPS-treated neuronal cultures induced strong expression of ICAM-1 and VCAM-1 on endothelial cells which induced infiltration of neutrophils across the endothelial monolayer.
CONCLUSION: These data demonstrate for the first time that neurons can play a role as key sensors of inflammation and responder to initiate immune response.

TLR-2 but not TLR-9 is up-regulated in the Central Nervous System and Lymphoid Organs during Canine Visceral Leishmaniasis

***G. D. Melo**, F. G. Grano, J. E. S. Silva, A. Schweigert, J. R. Peiró, V. M. F. Lima, G. F. Machado;*
UNESP - São Paulo State University - College of Veterinary Medicine, Araçatuba, Brazil.

Visceral leishmaniasis (VL) is an anthropozoonosis caused by the parasitic protozoan *Leishmania chagasi* (= *infantum*). The central nervous system (CNS) undergoes inflammatory alterations during the peripheral infection, and we have previously detected high amount of T lymphocytes, matrix metalloproteinases enzymes and pro-inflammatory cytokines such as IL-1β, IFN-γ and TNF-α within the nervous milieu of dogs with VL. Since toll-like receptors (TLRs) are components of the innate immunity which recognize pathogen-associated molecular patterns, such as the major surface molecule of *Leishmania*, lipophosphoglycan (LPG), we aimed to detect and quantify the gene expression of TLR-2 and TLR-9 in the CNS (brain and choroid plexus) and compare with peripheral lymphoid organs (spleen and popliteal lymph node) from 15 dogs naturally infected with VL and from four uninfected control dogs, using RT-qPCR with specific primers and Taqman probes. G3PDH was used as a reference gene. TLR-2 gene expression was up-regulated in the choroid plexus (3.09-fold more; P=0.0475), spleen (2.60-fold more; P=0.0087) and lymph node (3.48-fold more; P=0.0220) of the infected dogs, and there was a trend to be up-regulated also in the brain (2.69-fold more; P=0.0800). The gene expression of TLR-9 presented no differences between infected and control dogs. The up-regulation of TLR-2 in the lymphoid organs is indicative that this receptor takes part in the immune response against the parasite. Further, the increase of TLR-2 in the CNS suggests that in the nervous milieu there is a response to the peripheral infection by *Leishmania*, which associates TLR-2 to the neuropathogenesis of VL.

How asthma should be treated and at what stage anti-inflammatory therapy should be introduced is still debated. Furthermore little is known about the relationship between neurogenic and immune airway inflammation. However recent studies suggest that neurotrophins like nerve growth factor and brain-derived neurotrophic factor participate in the pathogenesis of many features and symptoms of asthma.
By using a C57BL/6 mouse model, we studied the influence of the neurotrophic factor neurturin (NTN) as well as its receptors on acute airway inflammation. The absence of NTN expression in bronchopulmonary cells led to increased airway inflammation and AHR and administration of NTN before challenge with OVA partially rescued the phenotype of NTN-/- mice. These results strongly suggest that NTN decreases the allergen-induced characteristics of asthma. However, the underlying mechanisms remain unclear. To determine which cells are involved in these symptoms, DC-T cell assays were performed, showing higher secretion of Th2 cytokines by CD4+T cells from NTN-/- mice. In order to determine if NTN could directly influence immune cells through its receptors, GDNF family receptor alpha 2 (GFRalpha2) and the proto-oncogene RET mRNA expressions were tested by real-time PCR. These receptors were expressed more after inflammation in NTN-/- lung tissues. Taken together, these results suggest that the absence of NTN in our model induces an over-activation of DC and Th2 cells leading to an increased inflammatory response in NTN-/- mice.

Novel magnetic resonance imaging approaches for monitoring neuroinflammation

***J. M. Millward**[1], M. Taupitz[1], J. Schnorr[1], S. Wagner[1], J. T. Wuerfel[2], K. Riek[1], J. Braun[1], F. Paul[1], I. Sack[1], C. Infante-Duarte[1];*
[1]Charité - Universitätsmedizin Berlin, Berlin, Germany, [2]University Medicine Göttingen, Göttingen, Germany.

Neuroinflammation during multiple sclerosis involves immune cell infiltration and disruption of the blood-brain barrier which can be visualized by magnetic resonance imaging (MRI), in patients and in the animal model experimental autoimmune encephalomyelitis (EAE). However, discrepancies between conventional MRI results and clinical signs underscore the need for new MRI methods to better monitor CNS inflammation. Here we employed two novel MRI approaches to investigate neuroinflammation. Cerebral magnetic resonance elastography (MRE) measures the viscoelastic properties of brain tissues in vivo. To investigate the relationship between inflammation and brain viscoelasticity, we applied MRE to the EAE model. At peak disease we detected a significant decrease in both the storage and loss modului, indicating that the elasticity and viscosity of the brain are reduced during acute inflammation. Interestingly, these parameters normalized at a later time point corresponding to the clinical recovery phase. Additionally, using very small superparamagnetic iron oxide particles (VSOP), we demonstrated that alterations in the choroid plexus represent an early feature in CNS inflammation. After inducing EAE and administering VSOP prior to onset of clinical signs, VSOP accumulated preferentially in the choroid plexus and spinal cord meninges, in the absence of overt inflammation. Moreover, we observed VSOP in lesions with a perivascular accumulation of immune cells but a preserved glia limitans, in endothelial structures, co-localized with phagocytes, and diffusely disseminated in the parenchyma, suggesting multiple entry mechanisms of VSOP into the CNS. Thus these two novel MR-based approaches emerge as effective tools yielding new insights into mechanisms of neuroinflammatory disease.

P5.09.50
A forebrain-immune cell pathway for the maintenance of CNS immune tolerance

***M. G. Mohammad**[1], V. W. W. Tsai[2], H. Li[2], M. G. Hassanpour[2], S. N. Breit[2], P. H. Hart[3], P. E. Sawchenko[4], D. A. Brown[2];*
